Even the development of modules might sound overwhelming. Fortunately, repositories of modules are becoming more available. One example of open educational resources is the *Connexions* project of Rice University. A search of this site returned results for modules with content for teaching biology to computer scientists, for teaching bioinformatics to biologists, and examples of assignments for both. Other universities providing open courseware with resources such as lecture notes, slides, projects and labs include Johns Hopkins Bloomberg School of Public Health, MIT, and the University of Washington. *Math and Bio 2010* includes an essay that supplies profiles of projects merging mathematics, computer science and biology at universities such as Davidson College, Harvey Mudd College, James Madison University, Montana State University, and the University of Redlands. [13] The *Computational Science Educational Resource Desk* provides online resources including applets, links to papers from the new *Journal of Computational Science Education*, and links to a variety of tutorials, courses and workshops related to computational science.

VI. OUR CONCLUSIONS

At PLNU, we decided to begin by building a minor in computational science. Our curriculum has been approved, and our science colleagues are enthusiastically referring students to the minor that begins in the Fall of 2012. The minor is designed to allow MICS students (computer science and mathematics) to gain enough knowledge in one of biology, chemistry or physics to be able to help scientists with the computational needs in their research. In a similar way the minor is also designed to expose biology, chemistry and physics majors to enough computational techniques to help them identify when a Mathematician or Computer Scientist could help with their research.

As a small university with limited resources, we need to use, and re-tool, as many existing courses as possible. We have tried to make sure to cover the most requested hard skills, and explicitly provide opportunities to practice soft skills emphasizing cross-discipline communication and teamwork. We include a track for each of the sciences, so that students can get their science content from biology, chemistry, or physics. Our science counterparts have suggested the sequence of classes that provides the most opportunity for computational content with limited prerequisites. The MICS department will help with the computational modules to be included.

Table 1 shows the courses that have been approved for our minor. The minor assumes a major in one of the disciplines shown, so even though the total number of units is approaching 30, many will overlap with courses already required for the student's major. The numbers in the table indicate the semester units for the course, with a blank cell indicating that that course is already a part of the major. For example, all of these majors require calculus, and none of them currently include the new Python/UNIX Scripting course that will be created. Only the Physics major currently includes a course in MATLAB in their curriculum.

Since courses in scripting and UNIX that are accessible to non-CS majors and meet the specific needs of the scientists do not exist, this course will be created. Its content will include scripting for process automation, data manipulation, visualization, and image processing. In addition, a more accessible database course will be implemented that will look at many of the scientific databases in existence, and the tools used to search them.

At least one section of the existing computational courses in this list will be re-tooled with scientific modules. The statistics course will focus on data analysis, and experimental design. The calculus course will add some modeling content. The MICS department currently has three venues to support student projects: senior honors projects, service learning projects, and supervised internships. Science students can enroll in any of these to join with computational students for an interdisciplinary project.

We anticipate measuring the success of our minor in the following 3 ways:

TABLE 1: MINOR CURRICULUM

| | Math | CS | Bio | Chem | Physics |
|-------------------------------|-------|--------|-----|------|---------|
| Calculus | | | | | |
| Statistics | | 2 | | 2 | 2 |
| Intro Computer Programming | | | 3 | 3 | 3 |
| UNIX/Python Scripting | 2 | 2 | 2 | 2 | 2 |
| MATLAB | 1 | 1 | 1 | 1 | |
| Databases | 2 | | 2 | 2 | 2 |
| Interdisciplinary Project | | | 3 | 3 | 3 |
| Science(7-16) (4 count as GE) | 7-16* | 7-16* | | | |
| Units beyond GE and major | 9-19* | 10-19* | 11 | 13 | 12 |

* Units depend on science option chosen

1. The ability of students to understand a culminating interdisciplinary problem and suggest appropriate tools
2. Continued growth in the program population
3. Feedback from employers and graduate programs

Introducing Parallel Programming to Traditional Undergraduate Courses

Henrique Cota de Freitas

Department of Computer Science

Pontificia Universidade Católica de Minas Gerais (PUC Minas)

Belo Horizonte, Brazil

cota@pucminas.br

Abstract—Parallel programming is an important issue for current multi-core processors and necessary for new generations of many-core architectures. This includes processors, computers, and clusters. However, the introduction of parallel programming in undergraduate courses demands new efforts to prepare students for this new reality. This paper describes an experiment on a traditional Computer Science course during a two-year period. The main focus is the question of when to introduce parallel programming models in order to improve the quality of learning. The goal is to propose a method of introducing parallel programming based on OpenMP (a shared-variable model) and MPI (a message-passing model). Results show that when the OpenMP model is introduced before the MPI model the best results are achieved. The main contribution of this paper is the proposed method that correlates several concepts such as concurrency, parallelism, speedup, and scalability to improve student motivation and learning.

Keywords—Parallel Programming; Computer Science and Engineering; Education; Learning Evaluation

I. INTRODUCTION

Researchers and educators have discussed when parallel programming should be introduced in undergraduate courses (e.g. Computer Science and Engineering) [1][2]. Due to the importance of qualified human resources for the new era of multi/many-core architectures, parallel programming is of great relevance [3][4][5][6]. Personal computers, workstations, and high-performance computer clusters are based on parallel architectures but to exploit them fully it is important to program in parallel. To reduce processing time, the workload needs to be divided into several parts to be executed simultaneously. In this context, we can find issues relating to algorithms (concurrency and granularity), operating systems (process/thread synchronism, scheduling and mapping), memory and networks (architecture and communication overhead), and performance evaluation (speedup, scalability and efficiency).

During the typical four-year Computer Science course, algorithms are discussed in the first two years and all the concepts required to understand the impact of parallel programs are covered by the end of the third year. For this reason, there are two possible methods of introducing parallel programming: i) beginning the concurrency/granularity

discussion during the first algorithm discipline; or ii) beginning all discussion once sequential programming concepts are consolidated. The first method requires a fundamental change in the curriculum and the second method adds one discipline to the beginning of the fourth curriculum year.

This paper describes a two-year experiment on an undergraduate Computer Science course. The discipline called Concurrent and Distributed Programming starts in the 7th semester after concepts relating to sequential Computer Science theory are consolidated. The main challenge is to exploit parallel programming models divided into shared-variable (memory) and message-passing (network). The following problem/question is considered: When can parallel programming models be introduced to improve the quality of student learning?

This paper is based on two hypotheses: i) MPI (Message-Passing Interface) is introduced first since more time is required to learn a new programming paradigm based on network exploitation; and ii) OpenMP (Open MultiProcessor) is introduced first since it is easier to learn programming based on memory. The goal is to evaluate and propose a method of introducing parallel programming to a traditional curriculum.

The results show that when MPI was introduced first, only OpenMP programs were concluded correctly by students. However, when OpenMP was introduced first, 100%, 78% and 22% of student groups developed programs based on OpenMP, MPI, and MPI/OpenMP, respectively. All groups achieved performance speedup. The results can be explained by feedback: i) students find it easier to exploit concurrency in OpenMP and achieve their first speedup results; ii) OpenMP speedup results stimulate new efforts to achieve the same MPI results; iii) MPI is difficult and the time taken to develop a first MPI program reduces the time taken to develop an OpenMP program.

In conclusion, OpenMP should be introduced first in order to create the conditions and foundations on which to program with MPI. The contribution of this paper is the method that shows phases and timeline when both models and all related concepts are introduced.

This paper is organized into the following sections: Section II presents related studies, Section III describes the proposed

method, Section IV shows the evaluation results, and Section V presents the conclusions.

II. RELATED WORK

Parallel computing has been an important issue since the 80's and 90's [7-10]. Educators showed how to introduce parallel computing to improve the quality of human resources by focusing on architectures, algorithms, and processing. An entire curriculum based on parallel computing is proposed by Nevison [11]. Currently, changing an entire curriculum is difficult. However, the popular multi-core processors can help us with this task.

Butler, et al. [7] proposed the use of a set of tools to implement parallel algorithms combined with operating system concepts and artificial intelligence problems in order to obtain performance speedup. Meredith [8] experimented with introducing parallel computing as a natural part of the undergraduate curriculum while Johnson, et al. [9] described parallel computing as the future of computer science. Therefore, the idea is to introduce concepts on data structures for freshmen courses. The proposal is to use laboratories to develop tools and methodologies in order to improve student learning. Kurtz and Alsabbagh [10] proposed a method of introducing parallel computing based on workshops in small universities with no parallel equipment and no research experience in this area. The proposal is based on simulators and web site materials for teaching concurrency, parallel algorithms, architectures, semaphores, and other concepts.

A recent related study discussed the impact of ubiquitous parallel computing hardware on computing curricula. LeBlanc and Wrinn [1] demonstrated the importance of re-examining the sequential programming curricula in order to migrate to parallel programming. Students need to understand the fundamentals of concurrent programming before designing concurrent systems. Thus, they proposed a computing ontology based on concurrent programming.

Brown and Shoop [12] also described the importance of teaching topics related to parallelism and concurrency. For this reason, they proposed a method of flexible modules based on

programming exercises, supplementary materials, and online communities of educators and contributors. The modules can be used for introducing parallelism in several disciplines.

Lammers, Brown [13], and Gross [2] proposed the introduction of parallel programming in the first year. Teaching parallelism for undergraduate students in their first year is a challenge. Gross [2] described a set of concepts that are present in future disciplines in a common computer science curriculum but it is a difficult task to correlate all of them.

This paper evaluates the introduction of parallel programming to traditional undergraduate courses after having consolidated sequential programming, operating systems, computer architecture and networks. The proposal is to exploit several concepts (e.g. concurrency, granularity, performance and process/thread scheduling) and to correlate them when the student has the ability to discuss and understand the impact of a parallel solution (including architecture and software). The main contribution is to demonstrate the greater impact of introducing the shared-variable programming model before the message-passing model.

III. PROPOSED METHOD

This section presents the method which was applied to four classes over the course of two years. The idea behind the method is to achieve the best results with regard to the learning of parallel programming. However, there is an important issue which changes the final learning results: the question of when to introduce the parallel programming model as an experimental activity.

Table I shows the phases and the timeline for introducing each concept related to the discipline. It is important to highlight two phases: i) programming with OpenMP (Open MultiProcessor), and ii) programming with MPI (Message-Passing Interface). The results presented in this paper demonstrate that learning is better when OpenMP is introduced first, compared to introducing MPI first. This section describes the importance of each phase and how they are related to the choice of parallel programming model as an experimental activity.

| 9 | Experimental Work | | | X | X | X |
| 10 | Classroom Activities | | | | X | X |
| 11 | Laboratory Activities | | | | X | X |

The Parallel Architectures phase is introduced to teach students the evolution of parallel computing. This phase is important for demonstrating trends and current parallel architectures that demand parallel programs. Flynn taxonomy, shared and distributed memory models, general-purpose architectures, graphic processing units, multi/many-core processors, hardware multi-threading support, and cluster and grid computing are examples of the subjects presented. Thus, the method begins the explanation of parallel programming by demonstrating where the programs will be executed. Moreover, students are also forced to think about how to program for a distributed architecture, such as a cluster. The moment at which students consider how a sequential program can be executed in a computer cluster or in a multi-core machine is an important opportunity to rethink previous concepts.

The second phase discusses concurrency, synchronism, and barriers. In this phase, it is important to take into account the difference between concurrency and parallelism. There exists a myth that concurrency is bad due to competition for resources. However, concurrency is a good characteristic for programs. Looking for concurrency in a sequential code means identifying the parts of the code that can be executed out of order. These parts are independent and can therefore be executed in parallel (e.g. threads or processes). At this point, it is important to relate parallelism, multi-threading, synchronism and barriers. Operating System (OS) books present us with an important characteristic of OSs known as pseudo parallelism. This is where OSs extract “parallelism” from the speed of a single core for changing threads in execution. However, current machine infrastructures offer us native parallel architecture based on several cores to execute multiple threads or processes. At this point, students can learn the importance of several processes sharing different data. The synchronism obtained from barriers is important for maintaining data integrity while considering data sharing and concurrency. Barriers are strategies in the parallel code to synchronize threads in order to avoid access to shared variables or input buffers. Beginners can develop parallel programs without attention to synchronism. Thus, the program achieves a high speed but the result can be incorrect. The second phase of this method is also about communicating the influence of shared data in the execution and synchronism of threads.

The third phase is based on programming models and is divided into two approaches: shared variable (memory exploitation) and message passing (network exploitation). In this phase, only concepts are presented. The discussion is based on data communication and exploring performance while considering architecture and program scalability. First of all, data communication through shared variable is based on memory. Typical multi-core computers have multiple cores sharing the same memory. However, memory has a scalability problem. It cannot scale while a parallel program increases in complexity, number of operations or data movement. In this scenario, thread concurrency represents negative competition which reduces the efficiency of memory bandwidth. At this point, the computer cluster is presented as an alternative with scalability. Through this architecture, message passing is the model used for data communication using the network. For a large parallel program, a computer cluster can scale thanks to

the network, however, scalability is a compromise of performance. Therefore, students learn that there are two types of scalability: i) architecture, and ii) program. For instance, architecture is related to memory and the network where the network has scalability. Program is related to data movement across the architecture. Although the network has scalability, the message passing can introduce a communication overhead that reduces the computational performance. To complement this phase, some concepts relating to application models based on graphs and machine abstract models are presented.

The fourth phase is designed to appear after programming models. The idea is to ask students: Can this algorithm be parallel (e.g. Fig. 1)? After a discussion, we verify that concurrency is independent of programming models. Next, whether or not an algorithm has concurrent parts and the responsibility of the programmer for adapting memory or network exploitation is discussed. The usage of shared variables or message passing is part of a programmer decision and is related to the available parallel architecture. When the students identify the concurrent parts, it is time to demonstrate the impact of granularity. How can coarse or fine grain be correlated with performance and scalability? Looking for concurrency in a rank sort algorithm (Fig. 1), we can divide the external *for* into *n* parts. Each part is a thread responsible for finding the rank of the value present in vector *a[i]*. The grain of each thread is finer than the process grain that generates each thread. A small grain means a small number of operations to compute. As a consequence, a thread takes less time to finish the computation than the sequential program. However, we have *n* threads in parallel competing for memory (read and write communication). Therefore, there is a memory overhead which increases the final processing time (computation + communication). If there are more threads (finer grain), there is more communication. Computation and communication need to be balanced in order to achieve performance and scalability.

```
for(i=0; i<n; i++){
    rank = 0;
    for(j=0; j<n; j++){
        if((a[i] < a[j]) || (a[i] == a[j] && j < i))
            rank++;
    }
    b[rank] = a[i];
}
```

Figure 1. Rank sort algorithm

Programming with OpenMP is the fifth phase. In this study, the best results were achieved when OpenMP was presented before MPI. The proposal is to exploit the students' ability to program using sequential logic. It is important to take into account that data movement is based on shared variables. This is the difference between parallel and sequential programming. Students learn OpenMP *pragmas* and how to identify concurrency in order to exploit parallelism. The problem is the use of shared and private variables in order to achieve performance with correct results. Laboratories are available for this phase which is characterized as a hands-on approach.

Programming with MPI is not different. For this sixth phase, a hands-on approach is necessary and laboratories are

also available. This phase considers the new programming paradigm based on message passing. The students are presented with a different programming style based on MPI calls to exploit the network. A typical cluster has distributed memories and each computer has a private memory without remote access. This architecture demands programming which involves sending and receiving calls based on network packets. The main problem related to this phase is how to exploit the network without scalability reduction and, consequently, performance reduction. Moreover, the students need to learn how to introduce MPI calls by changing the sequential algorithm at a deeper level than using OpenMP *pragmas*. According to evaluation results, a program based on MPI requires more time to develop and achieve performance. For this reason, it is important to motivate students by first introducing parallel programming based on shared variables, namely through OpenMP. At the end of this phase, hybrid programming based on MPI/OpenMP is presented. Fig. 2 illustrates a cluster composed of seven dual-core machines. This is a good example that demands memory and network exploitation. OpenMP threads communicate by shared variables, while MPI processes establish communication through the network. The hybrid approach attempts to utilize the best aspects of each programming model in order to achieve high performance and scalability.

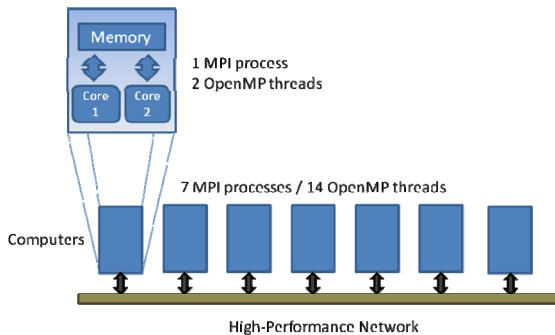

Figure 2. Hybrid Approach (MPI/OpenMP)

The seventh phase is based on performance evaluation and optimization. The students learn about evaluation and code optimization after discussion of the following topics: libraries, algorithms, granularity, concurrency, synchronism, and architectures. Amdahl Law, Efficiency, and Speedup topics are then presented and the students are taught that a high-performance parallel program depends on the programmer using the available materials correctly (e.g. software and hardware). The students learn how to program but also how to evaluate their programs. In addition, several techniques for optimizing code are presented. For instance, loop unrolling, inline functions, efficient compiler usage, and performance monitors are discussed.

When a sequential program is executed in a sequential architecture, the Operating System performs the task of process scheduling. This task is important to ensure high-performance process execution (“pseudo parallelism”). However, when a parallel program is executed in a parallel architecture, in addition to scheduling, there is another important task known as process mapping. When (scheduling) and where (mapping)

to execute a process/thread are now the important factors for achieving high performance. For this reason, processor and memory affinity can be used to reduce the communication overhead through network or cache misses. Fig. 3 illustrates an example of thread mapping. The application graph shows the dependence between threads and a difference number mapped on cores. We can conclude that to achieve high performance, the grain of each thread should be different and the mapping should be balanced. The mapping decision is important because it can reduce the communication overhead and increase the processing time speedup by computation.

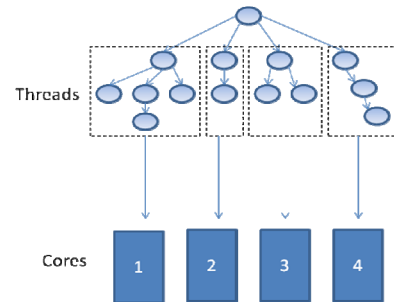

Figure 3. Threads Mapping

Phase 9 consists of discussion of the experimental work. The students form groups and choose a sequential program from previous disciplines that can be exploited in terms of concurrency and parallelism. This is the point at which a professor should prompt the groups to begin with OpenMP (shared variables). Normally, parallel programs based on OpenMP function quickly and this motivates students. After this step, MPI (message passing) is introduced and the desire to see a parallel program functioning helps students to persist with their work. The evaluation results (Section IV) reveal that the best score was achieved by the last class which followed this method fully. To conclude the experimental work, the students write a scientific paper to summarize all the knowledge learned in the discipline.

Phases 10 and 11 are dedicated to discussing experimental work (phase 9) and to conducting student evaluations. The students present their work-in-progress in the classroom and laboratory. The classroom activities are based on typical technical sections of conferences. The laboratory activities are based on experimental work evaluation. These activities occur in two steps to present intermediate and final results. In the laboratory, the students demonstrate the parallel program and execute it for tests. In the classroom, the students show slides that summarize the problems, goals, contributions, proposals, results and conclusions presented in the scientific paper written by them.

IV. EVALUATION RESULTS

This section presents the results of the proposed method based on its evolution. Each result presents a gradual decision from the first class to the fourth class. The fourth class had the full proposed method described in Section III.

Table II shows the results obtained from the first class. The method introduced MPI first and OpenMP afterwards.

Furthermore, the students could decide which programming model to use. Although MPI was introduced first, the expectation of a fast speedup caused a migration of all experimental work to OpenMP. All groups concluded their OpenMP programs but no group concluded the MPI version. The small amount of time taken to finish the work after the change of model reduced the number of groups that achieved speedup (33%). All groups wrote the scientific paper. The students began the work in the 4th month.

TABLE II. FIRST CLASS

| Class 2010-1 (21 students) | | | | | |
|----------------------------|--------|-----|--------|---------|-------|
| Group | OpenMP | MPI | Hybrid | Speedup | Paper |
| G1 | yes | no | no | yes | yes |
| G2 | yes | no | no | no | yes |
| G3 | yes | no | no | no | yes |
| G4 | yes | no | no | no | yes |
| G5 | yes | no | no | no | yes |
| G6 | yes | no | no | yes | yes |
| Total | 6 | 0 | 0 | 2 | 6 |
| % | 100% | 0% | 0% | 33% | 100% |

Table III shows the results for the second class. The method was the same as that applied to the first class apart from the fact that the students began the experimental work in the 3rd month. Although the students had more time to conclude the work, no group used the MPI model. Therefore, MPI as a first model still reduced the students' expectation of producing good work. The positive feedback was that all groups achieved a speedup in their respective parallel programs based on OpenMP. All groups wrote the scientific paper.

TABLE III. SECOND CLASS

| Class 2010-2 (22 students) | | | | | |
|----------------------------|--------|-----|--------|---------|-------|
| Group | OpenMP | MPI | Hybrid | Speedup | Paper |
| G1 | yes | no | no | yes | yes |
| G2 | yes | no | no | yes | yes |
| G3 | yes | no | no | yes | yes |
| G4 | yes | no | no | yes | yes |
| G5 | yes | no | no | yes | yes |
| G6 | yes | no | no | yes | yes |
| Total | 6 | 0 | 0 | 6 | 6 |
| % | 100% | 0% | 0% | 100% | 100% |

Table IV also shows a method where MPI was introduced first. However, all student groups were required to develop parallel programs based on OpenMP and MPI. Although the reason for presenting MPI first is that it takes longer to develop a parallel program, the results continued to be poor. For the

third class, all groups achieved speedup using the OpenMP model but one group did not finish the scientific paper.

The extra time required to develop a parallel program based on MPI is not enough to explain this performance. The reason for it must be in the order in which the parallel programming models are presented. Thus, OpenMP was introduced as the first model since the previous classes obtained good results. It is likely that the subsequently improved results using MPI are the result of improved motivation. Fast performance speedup, in terms of development, could be the answer found in OpenMP programs.

TABLE IV. THIRD CLASS

| Class 2011-1 (19 students) | | | | | |
|----------------------------|--------|-----|--------|---------|-------|
| Group | OpenMP | MPI | Hybrid | Speedup | Paper |
| G1 | yes | no | no | yes | yes |
| G2 | yes | no | no | yes | yes |
| G3 | yes | no | no | yes | yes |
| G4 | yes | no | no | yes | yes |
| G5 | yes | no | no | yes | no |
| Total | 5 | 0 | 0 | 5 | 4 |
| % | 100% | 0% | 0% | 100% | 80% |

Table V shows the results for the fourth class. For this class, the method is the same as that described in Section III. OpenMP was introduced first and all student groups were required to develop parallel programs based on OpenMP and MPI. Moreover, all groups had to evaluate a hybrid approach (MPI/OpenMP) program. The results reveal that this was the best performing class. 100% of groups developed OpenMP programs, 78% of groups develop MPI programs, and 22% of groups developed hybrid programs. All groups achieved speedup but only 89% of groups wrote a scientific paper.

TABLE V. FOURTH CLASS

| Class 2011-2 (41 students) | | | | | |
|----------------------------|--------|-----|--------|---------|-------|
| Group | OpenMP | MPI | Hybrid | Speedup | Paper |
| G1 | yes | no | no | yes | yes |
| G2 | yes | no | no | yes | no |
| G3 | yes | yes | no | yes | yes |
| G4 | yes | yes | no | yes | yes |
| G5 | yes | yes | no | yes | yes |
| G6 | yes | yes | yes | yes | yes |
| G7 | yes | yes | yes | yes | yes |
| G8 | yes | yes | no | yes | yes |
| G9 | yes | yes | no | yes | yes |
| Total | 9 | 7 | 2 | 9 | 8 |
| % | 100% | 78% | 22% | 100% | 89% |

Fig. 4 summarizes the results. It is possible to see that for all metrics the fourth class achieved the best results using the proposed method. The scientific paper is an exception in comparison to the first and second class. However, the experimental work of the fourth class was larger and this could explain the reduction. Some important student feedback relates to OpenMP. This programming model is easier to understand and to program. The motivation to develop an MPI-based program is a consequence of good experiences of OpenMP.

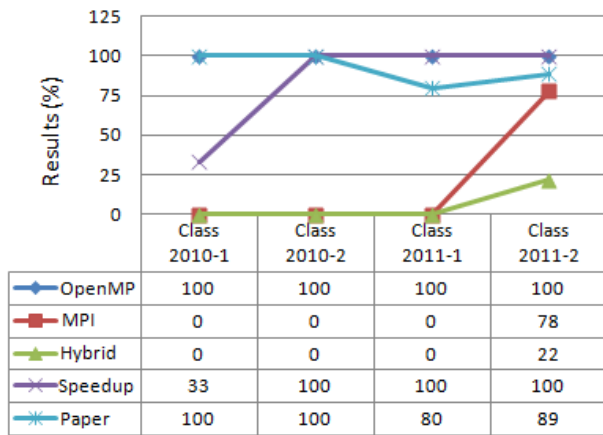

Figure 4. Evaluation Results

V. CONCLUSIONS

The new era of parallel architectures demands the speedy introduction of parallel programming. Multi-core processors, clusters and many-core architectures are available and current professionals need to know how to program them. Parallel programs are the best option for exploiting parallel architectures with efficiency, performance, and scalability. Therefore, traditional undergraduate courses require a discipline that connects several concepts to parallel programs in order to understand the influence, for example, of networks, memory, and operating systems.

The proposed method demonstrates that the shared-variable programming model is easier to understand. Students can quickly learn how to achieve high-performance speedup relative to sequential programs. Based on the motivation generated from the OpenMP model, new programs based on MPI can also achieve performance speedup. The evaluation results present the evolution over a two-year period, as shown by Fig. 4. The proposed method based on phase 5 (OpenMP) and phase 6 (MPI) exploited programming ability and generated the motivation to conclude programs with OpenMP and MPI with efficiency.

Two indirect results were observed in the fourth class, as follows: i) one paper submitted to a conference, and ii) two undergraduate dissertations focused on parallel computing are in development. Therefore, the proposed method achieved its

goal. More students are learning different parallel programming models through experimental activity. For this reason, it is possible to highlight the proposed method as the main contribution of this paper.

Future study will focus on improving the method in order to achieve better results, especially for MPI and hybrid programming approaches. Furthermore, there is currently a discussion taking place, influenced by the results of this paper, with regard to changing the Computer Science curriculum to introduce concurrency and OpenMP in the first year.

Abstract— One of the big challenges that teachers and students face at early stages of CSET (Computer Science, Engineering, and Technology) courses are the difficulties related to teaching and learning algorithms. Usually, such knowledge is presented during introductory programming related disciplines, when students are also presented to some programming language to describe simple algorithms. Therefore, they need to learn not only the new language but also a formal way to describe the solution of problems using that language. This is much different from any formalism they were presented in their previous student's experience. This paper presents iVProg, a system conceived to overcome some of these difficulties by using visual programming. Some experiments were conducted during three years to evaluate students' performance without the system support and with it using different didactic approaches.

Index Terms — *algorithms; visual programming; learning system; introductory programming; free software.*

I. INTRODUCTION

One of the big challenges that teachers and students face at early stages of CSET (Computer Science, Engineering, and Technology) courses are the difficulties related to teaching and learning algorithms [1][2]. Usually, such knowledge is presented during introductory programming related disciplines, when students are also presented to some programming language to describe simple algorithms. Therefore, they need to learn not only the new language but also a formal way to describe the solution of problems using that language. This is much different from any formalism they were presented in their previous student's experience.

Moreover, students are also presented to some programming environment in order to edit, debug, compile and run programs they built and that describe algorithms to solve some proposed problems. Such an overload of new information may decrease student's motivation and compromise their performance, occasionally leading to course abandon.

In order to overcome this problem some attempts of using visual systems to support the learning of introductory programming were proposed [3][4]. Such systems adopt the drag-and-drop approach to guide students on building programs without any concern related to the programming language syntax and semantics. They also offer the possibility of compiling and running programs within them, which avoid the use of programming environments at the initial stage of learning algorithms and programming.

This paper presents a free system called iVProg that offers visual programming features to support both, introduction to algorithms and the principles of programming, considering

teaching and learning aspects. It can run in any desktop, web browser, or integrated to a web-based Learning Management System, such as Moodle. Nevertheless, the paper main contribution is related to the results of some experiments conducted with iVProg, in order to evaluate possible gains while teaching and learning algorithms and programming using it.

II. RELATED WORK

Many researchers dedicated efforts to develop pedagogical methods and educational software to support processes of teaching and learning algorithms and programming. Hazzan et al. [5] made an overview on the main teaching methods based on available educational software, different forms of class organization, and mentoring software development projects.

Existing educational software that support teaching and learning algorithms and programming differ in several ways, e.g. some of them work offline, other work online and a few in both modes [3][4][6][7][8]. Since the number and approaches adopted for educational software is considerable, Rongas et al. [9] proposed four different categories to classify them: (i) integrated development interfaces; (ii) visualizing systems; (iii) virtual learning environments, and (iv) submission systems. Since iVProg is based on the Visual Programming paradigm, our interest relies on visualizing systems. Among them, there are two systems that present many commonalities with iVProg: Alice [3] and Scratch [4]. In fact, both are visual programming software, with open source licenses, that allow online testing as iVProg. However, only iVProg presents the possibility of online edition and integration to Learning Management Systems, such as Moodle.

Scratch was conceived at Massachusetts Institute of Technology and it allows students to learn some important mathematical and computational concepts through an easy and friendly interface [10]. The system use the mouse as interaction instrument where students drag-and-drop some code components to build the algorithm. Students are able to create animations, simple games, musics, interactive histories, and more. It is possible to watch animations and play Scratch games through the Internet, there is also an interesting online repository of Scratch projects, but algorithms edition is only available offline. Furthermore, it is not integrated into a LMS.

Alice was developed at Carnegie Mellon University. The system uses the creation of 3D animation and interactive histories to motivate learners during the processes of developing skills in algorithms design and acquiring computational concepts. Alice also uses drag-and-drop as interaction method, and, such as Scratch, it is not integrated into a LMS.

Initially, Scratch was designed for K12 and high school students and Alice for undergraduate students of introductory courses in Computer Science. Both of them focus the engagement of the students and try to let their first contact with programming easier with a lower cognitive load during the process [11]. In the next session, we are going to explain how iVProg was built and justify our focus on lowering the cognitive load for the student.

III. IVPROG OVERVIEW

iVProg [12] is a system that derives from the Alice system in a way it was built as a simplified version of Alice to run in web browsers and to be used by Brazilian students that, generally, don't speak English. Therefore, it follows Alice license as an open source code and is also coded in Java. It's important to know that iVProg was adapted to teach algorithms using the procedural programming approach while Alice adopts an object-oriented approach. Moreover, in order to make possible the use of iVProg in web browsers it was needed an important reduction of the Alice's original code, which is more than 140Mb heavy. Currently, iVProg code is under 10% of Alice's one. Nevertheless, it was built as an iLM (Interactive Learning Module) [13].

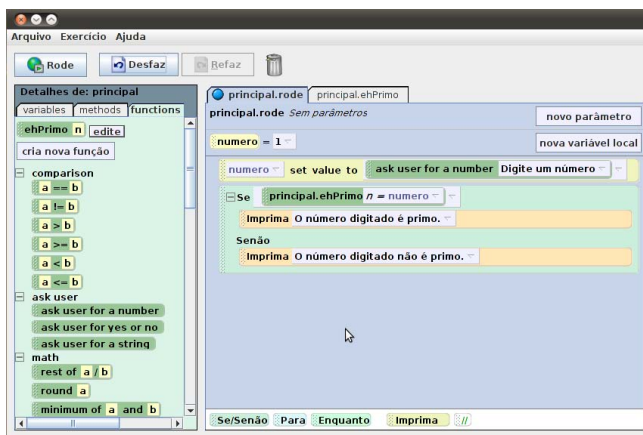

Figure 1 Screenshot of iVProg.

The main functionalities available in iVProg are the ones related to visual programming, such as the possibility of using drag-and-drop to build functions and methods in a program that is built within the system. In fact, there are pre-defined buttons for comparison between variables, for the most used mathematical functions, and for the main programming constructs, such as *if-then-else* and *loops*. Figure 1 shows the screenshot of iVProg. In the left side there are the aforementioned buttons, in the right side is the workspace, where the program is built, the horizontal menu bar presents buttons for running the program, undo/redo functionalities and a wastebasket for discarding program components. Another important functionality that iVProg maintains from Alice is that the system prevents some common mistakes students use to do, such as variable attribution instead of equality between variables content.

Although iVProg is a simple version of Alice, it also presents the additional functionality of communicating with web servers, which allows it to be integrated to Learning

Management Systems (LMS), such as Moodle [14]. By being integrated into LMS, it can foster the development of digital content in a collaborative manner and the use of several LMS resources combined with iVProg in order to visualize the results of activities that were performed by students and sent to the LMS.

iVProg has been used in the last editions of an introductory programming discipline with success, and some experiments were conducted to evaluate how does the system influence the learning of algorithms and programming. Two experiments were described in the next section. Currently the system is being rebuilt in order to be compliant with a framework our research group developed to serve as basis for any iLM and facilitate their maintenance and evolution [15]. The version used in the experiments is available at <http://www.matematica.br/ivprog/iVprog2011.jar>.

IV. EXPERIMENTS

The experiments took place during two semesters of an introductory programming discipline (MAC110), in an undergraduate course of Mathematics. A blended learning approach [16][17] was adopted, since besides being a face-to-face course, there were several assignments to be done at distance weekly.

The idea was to investigate if the use of iVProg could improve the understanding of how to solve problems algorithmically and how visual programming would impact the ability of using an imperative programming language (such as C) in a traditional programming environment.

The first experiment involved students of MAC110, in an undergraduate course of Mathematics during the first semester of 2010. It was a controlled experiment, in a laboratory with observers. The second experiment involved classes T1, T2 and T3 during whole semesters of 2005, 2010 and 2011, respectively. In the following subsections the experiments were described and their results were presented. Discussion about the results is provided in a section dedicated to it.

A. Observed Exercises

The first experiment was conducted with 6 students, volunteered, randomly divided in two groups, G1 and G2. Each one was asked to solve two exercises in a period of one hour. An observer, that would annotate the number of mistakes related to syntax and the number of times the program was run until the student evaluate it as correct, was aside of each student.

Students from group G1 would do the exercises using iVProg at the beginning and using a C traditional programming environment. Students from group G2 would do the same exercises using the C language in a traditional programming environment at the beginning and using iVProg after. In both cases the exercises would be done individually without advice of anyone.

The experiment goal was to analyze the initial hypothesis that the system would simplify the programming task for newcomers in programming.

Participants answered a questionnaire composed of two questions: (Q1) *Do you know the C language? If yes, how experienced are you?* and (Q2) *Did you already attend MAC110? If yes, what was the programming language and*

environment used? and start doing the exercises. After solving each exercise, the student would send it to the LMS.

TABLE I
RESULTS OF OBSERVATION – EXPERIMENT 1 - G1

| | | GROUP 1 | | | |
|--------------|----|-----------|-----------|-----------|---------|
| | | student 1 | student 2 | student 3 | average |
| | Q1 | no | no | no | - |
| | Q2 | yes | yes | no | - |
| E1 iVProg | a) | 2 | 1 | 3 | 2,0 |
| | b) | 1 | 2 | 3 | 2,0 |
| | c) | 0 | 0 | 0 | 0,0 |
| E1 C | A) | 9 | 5 | 15 | 9,7 |
| | B) | 2 | 1 | 5 | 2,7 |
| | C) | 2 | 1 | 2 | 1,7 |
| | D) | 1 | 0 | 1 | 0,7 |
| E2 iVProg | a) | 8 | 2 | 14 | 8,0 |
| | b) | 1 | 1 | 2 | 1,3 |
| | c) | 0 | 0 | 0 | 0,0 |
| E2 C | A) | 16 | 5 | 21 | 14,0 |
| | B) | 4 | 5 | 5 | 4,7 |
| | C) | 4 | 1 | 2 | 2,3 |
| | D) | 4 | 5 | 2 | 3,7 |

The exercises are:

E1- Build a program that has two numbers as input parameters and returning their average.

E2 – Build a program that ask for a natural number N and a sequence of N numbers as input parameters and print the large and the smaller numbers of the sequence in the screen.

Each observer would annotate the following items for exercises done using iVProg:

- a) time in minutes to solve the exercise;
- b) number of times that use the RUN button;
- c) number of times that syntax or logical mistakes were discovered.

Each observer would annotate the following items for exercises done using C:

- A) time in minutes to solve the exercise;
- B) number of times the program was compiled;
- C) number of times the program run;
- D) number of times that syntax or logical mistakes were discovered.

Only one student of Group 2 answered Q1 positively and only one student of each group hadn't attended MAC110 previously. Nevertheless, as we can see in Table I and Table II, it seems that had attended MAC110 before did not influenced in the experiment result.

Table I shows the results of observations with G1. The time spent to solve E1 using C was 5 times longer than using iVProg, even had been solved it immediately before using iVProg. For exercise E2 such a discrepancy was smaller, just 2 times longer, indicating that as students hadn't previous knowledge about the C language (answer Q1) they learned about it while solving exercise E1. This is also visualized in the average column, lines a) and A). Nevertheless, all students did both exercises using iVProg and C, in an interval from 13 minutes (student 2) to 53 minutes (student 3).

Table II shows the results of observations with G2. This group started doing E1 using C and, having solved it, did the same using iVProg. Same steps where followed to exercise E2. As it can be depicted from Table II, only student 4 did both exercises using C and iVProg, spending 68 minutes to finish them, even having previous knowledge about the C language (answer Q1) and had attended MAC110 before (answer Q2).

Students 5 and 6 couldn't finish exercise E2 using both C and iVProg. They had focused on solving debugging problems and forgot the main goal that was to give an algorithm solution to the problem. This was not observed in G1, since an algorithm was defined and tested using iVProg before solving the same problem in C. For E1, the time spent for all students to solve it using C was almost 10 times longer than the used to solve it using iVProg. For exercise E2 we cannot analyze such a discrepancy since only one student did it until the end of the experiment schedule.

TABLE II
RESULTS OF OBSERVATION – EXPERIMENT 1 – G2

| | | GROUP 2 | | | |
|--------------|----|-----------|---------------|---------------|------------|
| | | student 4 | student 5 | student 6 | average |
| | Q1 | yes | no | no | - |
| | Q2 | yes | yes | no | - |
| E1 C | A) | 23 | 50 | 35 | 36 |
| | B) | 4 | 10 | 11 | 8,33333333 |
| | C) | 2 | 1 | 11 | 4,66666667 |
| | D) | 3 | 6 | 10 | 6,33333333 |
| E1 iVProg | a) | 2 | 5,0 | 2,0 | 3,0 |
| | b) | 1 | 1,0 | 1,0 | 1,0 |
| | c) | 0 | 0,0 | 0,0 | 0,0 |
| E2 C | A) | 30 | didn't finish | didn't finish | 30 |
| | B) | 5 | - | - | 5 |
| | C) | 4 | - | - | 4 |
| | D) | 4 | - | - | 4 |
| E2 iVProg | a) | 13 | didn't finish | didn't finish | 13,0 |
| | b) | 5 | - | - | 5,0 |
| | c) | 3 | - | - | 3,0 |

A. Experiment II – using iVProg in formal courses

The main goal was to analyze iVProg influence in the learning process of algorithms and programming in an undergraduate course of Mathematics. It was conducted during 3 years during one academic semester a year (18 weeks) of an introductory programming discipline (MAC110). The experiment involved 3 classes, T1 (without using iVProg), T2 and T3 (using iVProg with different didactic approach), all of them from the same course and discipline, and having the same lecturer.

In T1, algorithms and programming were introduced using a system that simulates a computer (iCG) and adopted an assembly-like programming language during 5 weeks, in a laboratory. High-level commands in C were inferred from the low-level model. This system had a compiler to its machine language and is freely available at <http://www.matematica.br/icg/icg.jar>. From week 6 to 18 only the traditional programming environment was used, but classes took place in classroom. For this reason, only 5 exercises were solved online and other 3 exercises, more complex, involving modeling the problem solution before going to code, were left as homework. Learning assessment was made through the exercises and two theoretical exams, in classroom, at weeks 11 and 18.

In T2, algorithms and programming were introduced using only iVProg during 6 weeks. From week 7 to 11 both, iVProg and a traditional C programming environment were used to solve the proposed exercises. From week 12 to 18 only the traditional C programming environment was used. Classes took place in a laboratory with at most two students by computer. The exercises proposed were related to: average of n numbers; algorithm of Archimedes for GCD; evaluate the n term of Fibonacci's; tests involving types, such as char and int; calculate cos(x) using Taylor's series; vectors: sorting using an

auxiliary function, binary search, representing sets and verifying when a vector is a permutation one. An amount of 33 exercises/programs were done using iVProg and 20 using the C language, most of them solved online. It is important to observe that during the weeks where iVProg and C were used in parallel, exercises were first solved using iVProg and after using C. Learning assessment was made through the exercises and two exams: the first online in the laboratory, one student per computer, at week 11, and the second was theoretical, in classroom, at week 18.

TABLE III EXPERIMENT 2 – T1, T2 AND T3 LEARNING ASSESSMENT

| | T1 - 2005 | | T2 - 2010 | | T3 - 2011 | |
|-------------|-----------|----------|-----------|----------|-----------|----------|
| | Average | variance | Average | variance | Average | variance |
| freq. | 56.48% | 0.109 | 72.92% | 0.0702 | 71.02% | 0.061 |
| exam1 | 3.28 | 8.3 | 5.59 | 8.7 | 5.85 | 5.64 |
| exam2 | 4.33 | 17.02 | 3.47 | 4.92 | 6.36 | 7.29 |
| non-C | 7.0 | 20.5 | 9.26 | 0.35 | 9.59 | 0.65 |
| C | 4.28 | 18.7 | 8.51 | 0.43 | 9.08 | 0.74 |
| final grade | 4.06 | 10.44 | 4.59 | 6.31 | 5.24 | 6.19 |

In T3, algorithms and programming were introduced using the same approach of the one adopted in experiment 1 for G1: the use of iVProg and a traditional C programming environment in parallel. From the very first lecture, students solved proposed problems using iVProg and after that, the same problem was solved using C. Therefore, the idea was using iVProg to find the algorithm that solved the problem and C to learn some programming language. Nevertheless, since some programming concepts such as *file manipulation*, *strings* and *pointers* are not implemented in iVProg, the last 4 weeks of the course were whole made using just C. Thus, 25 problems were solved using both iVProg and C and 04 problems using only C. Learning assessment was made through the exercises and two exams. The first exam occurred at week 11 and was composed of 2 theoretical questions and 3 problems to be solved in the laboratory, individually, using iVProg or C. The second exam occurred at week 18 and was composed exclusively of theoretical questions, to be solved in classroom.

In order to compare the influence of iVProg to support the learning of algorithm and programming, we evaluate the averages of exams 1 and 2, non-C (iCG -T1 or iVProg - T2 and T3) and C exercises and the students' frequency at classes for T1, T2 and T3. Table III shows these results.

Considering the frequency at lectures, T2 and T3 presented higher attendance average than T1. This may represent that T2 and T3 was more motivated than T1, but there is not any conclusion. Concerning the grades students obtained in exam 1, average was increasing from T1 to T3, but from T1 to T2 the growth was bigger. In this case the result was strongly related to the use of iVProg, since students did the exam using it. Nevertheless, average grades of exam 2 indicate that the contact with the C language from the very beginning had influence on it, which is theoretical and C-based. This could be explained by comparing the grades of T2 (where C was introduced after 7 weeks of lectures) with T1 and T3.

Moreover, comparing the performance of students from T2 and T3 with T1 we may infer that the use of iVProg improved understandability related to algorithms. Also, the adoption of iVProg combined to a C programming environment from the

very beginning benefited students understandability about the C language.

V. USABILITY ISSUES

The first time iVProg was used in a formal course was with T2. In order to evaluate some usability issues, the following question was made to students at the very beginning, in order to evaluate their familiarity with computers and its influence on the usability assessment: *Q1) How many hours a day do you spend using a computer?* The results show 3.31 hours/day as average time, and let us considered that they are familiar enough with computers and iVProg usability would not be influenced by difficulties related to computer misuse.

A questionnaire composed of quantitative (*Q2-Q4*) and qualitative questions (*Q5-Q7*) was applied to T2 at the end of semester, in order to assess iVProg usability. For better understanding and organization, we present each question associated with its motivation and results.

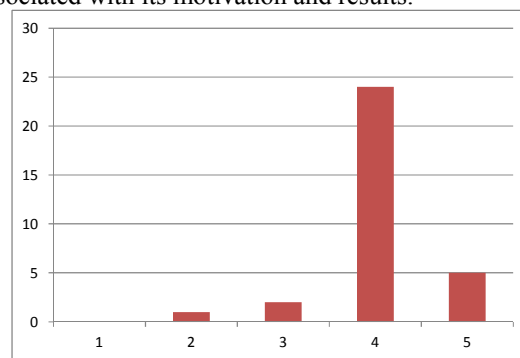

Figure 2 Answers of Q2

Q2) iVProg can be classified as ____, considering its visual aspect.

1. Uncomprehensible;
2. Hard to comprehend;
3. Neutral;
4. Comprehensible;
5. Very Comprehensible.

The goal of this question was verifying if iVProg user interface was comprehensible. Figure 2 shows that 75% answered that iVProg is *comprehensible* or *very comprehensible*.

Q3) In your opinion, iVProg is, in its first use:

1. Very hard;
2. Hard;
3. Neutral;
4. Easy;
5. Very easy.

The goal of this question was discover how comfortable students felt at the first sight with iVProg. Figure 3 shows that 42% answered that iVProg was *neutral* or *easy* to use in their first sight, but a significant number of answers (38%) considered iVProg hard to use at the first sight.

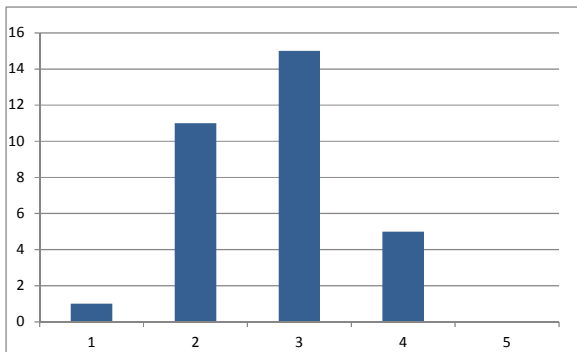

Figure 3 Answers of Q3

Q4) In general, solving exercises using iVProg is:

1. Very unpleasant;
2. Unpleasant;
3. Neutral;
4. Pleasant;
5. Very pleasant.

The goal of this question was discover how comfortable students felt using iVProg while solving exercises. Figure 4 shows that 46.8% answered that iVProg is *neutral, pleasant* or *very pleasant*, but it was classified as *unpleasant* or *very unpleasant* by 53.2%. This was explained in the qualitative part of the questionnaire, where students reported some bugs that occurred while using iVProg.

Qualitative questions are given next, and after some answers will be commented. Q5) *Would you please specify the main advantages of programming using iVProg compared with C?*; Q6) *Would you please specify the main advantages of programming using C compared with iVProg?*; Q7) *Is there any resource you would like to find in iVProg?*.

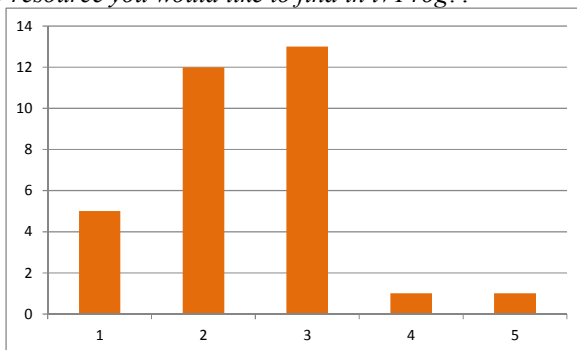

Figure 4 Answers of Q4

In general, advantages of iVProg compared with C are related to the fact that in iVProg the programmer doesn't need to be concerned with the syntax of the language, which is something very important while using C or any other programming language. Also, the use of the drag-and-drop functionality for the main programming commands, instead of typing all of them in C, kept users away of typos. Several answers stated that by using iVProg they could focus on the solution of the problem as an algorithm, instead of issues related to the language.

Concerning the advantages of using C compared with iVProg, answers were related to the time to compile complex

programs, the need of organization and method to comprehend the language syntax in order to use it correctly.

Answers to these questions indicate that iVProg, and visual programming in general, may benefit newcomers in programming.

Nevertheless, answers to the last question give some hints about improving iVProg, since they suggested that iVProg could generate an executable file from an iVProg program; the building of an area for storing programmed functions to be reused, among others.

VI. DISCUSSION

The experiment 1 and the results obtained in 2010 lead us to adopt, in 2011, an approach to smooth the introduction of the C language and its associated programming environment based on the use of both: iVProg and C from the very beginning. iVProg was used to find algorithmic solution to problems and then solve the same problems using C. Comparing the results from 2010 and 2011, we realized that students do improve their understanding about both algorithms and programming.

In general, students had considerable difficulties on dealing with the C language compiler and finding the syntax errors. Therefore, their attention was deviated from the real problem, that is to find an algorithm solution to a problem, to these debugging issues. This fact could significantly decrease their motivation during the course. In the other hand, we believe that iVProg, by reducing the cognitive load during the process, could partially solve the motivational problem.

VII. CONCLUSION AND FUTURE WORK

In this paper we presented iVProg, a visual programming system, as a tool that may enhance the understanding of algorithms and programming during introductory programming disciplines of CSET courses.

Experiments indicated that it does improve understanding about algorithms and may improve the understanding of a programming language such as C when used in combination of it from the very beginning.

The system is being fully redeveloped using a Software Product Line approach [15] in order to simplify its architecture and clean its code with the aim of facilitating its maintenance and evolution. This new development will turn possible the configuration of iVProg as a tool to support the learning of programming for several audiences: from kids to adults.

Also, we intend to implement the automatic assessment support to students' assignments, which will provide immediate feedback for students and reduce teacher's workload. Therefore, teachers may focus their attention to the teaching process and programming techniques. Moreover, since iVProg is an iLM, it can be integrated to Moodle using iAssign [18] and all the functionalities related to assignments reports may be benefited from the automatic assessment feature.

Abstract—Programming can be an important part of a linear systems (a.k.a., signal and systems) course, as programming projects help to solidify mathematical concepts and provide students with a means to visualize and interpret signal and coefficient behavior. However, students often struggle with programming, leading to frustration that minimizes learning and worsens student attitudes toward the material. To address that need, the Kansas State University (KSU) Electrical & Computer Engineering (ECE) Department recently added a required course, *ECE 540 – Applied Scientific Computing*, to the ECE curricula to ensure more overall C programming exposure and to serve as a prerequisite to *ECE 512 – Linear Systems* and other courses that require programming. This paper presents initial assessments of student preparedness for C programming projects in the Fall 2011 and Spring 2012 offerings of *ECE 512* following this course prerequisite change. The primary assessment mechanisms are pre- and post-project surveys that address students' proficiency in C, where the survey results are compared to similar surveys offered in prior semesters unaffected by the new course. These analyses indicate greater overall confidence in C programming, a better understanding of the supporting development environments, and an overall improved attitude toward Linear Systems programming projects.

Keywords—C programming, convolution, Fourier analysis, numerical analysis, scientific computing, signals, systems

I. INTRODUCTION

A. Motivation

A linear systems course that addresses time- and frequency-domain signal concepts is a mainstay in electrical and computer engineering curricula. Experience in teaching this course indicates that students can carry out calculations for Fourier series coefficients and Fourier spectra that help them perform acceptably on handwritten homework and exams. However, these students can have trouble visualizing coefficients graphically or interpreting coefficient behavior outside of recipe-based analyses – they lack the higher-level understanding [1, 2] that aids with long-term retention. Programming projects can help in this regard, since a minimal correct understanding of the mathematical relationships is needed to numerically implement the process. Further, computers allow one to view calculation results in interesting ways, which aids retention. Research

This material is based in part upon work supported by the National Science Foundation under grants DUE-0206943 and DRL-0816207. Opinions, findings, conclusions, or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the NSF.

geared toward computation, hands-on learning, and retention supports these assertions [3-5].

The problem is that many students continue to struggle with programming, and the inability to program sensibly and efficiently leads to frustration that minimizes learning and worsens student attitudes toward the core material. While research has shown that programming efficiency, even with highly trained individuals, can vary dramatically from person to person [6-9], the sensible implication is that the previous KSU Electrical Engineering (EE) and Computer Engineering (CMPEN) curricula were lacking in preparatory programming experience; the traditional introductory programming courses were simply insufficient. This message has been affirmed by the authors based on greater than 10 years of more-than-anecdotal classroom experience with *ECE 512*, supplemented by student comments on end-of-year teacher evaluations and in-class project surveys.

In response, the Kansas State University (KSU) Electrical & Computer Engineering (ECE) Department added a new, required scientific computing course (*ECE 540 – Applied Scientific Computing*) to the ECE curricula (while keeping the overall required hours the same) to ensure more exposure to C programming and to serve as a prerequisite to *ECE 512 – Linear Systems* and other upper-level courses with a programming component. The three-fold goal was to improve students' attitudes towards these courses, to provide these students with a skill set that would increase learning, and to make these students more marketable to potential employers. This new course affirms programming fundamentals introduced in earlier courses and also touches on statistics, linear algebra, and optimization.

This paper presents initial assessments of that curricular change in the context of the aforementioned Linear Systems course, specifically with regard to students' capabilities in (and attitudes toward) C programming as applied to the numerical calculations that support applications such as sliding windows, convolution, trigonometric Fourier series, and discrete Fourier transforms (Fourier spectra). Two forms of assessments were employed: (1) pre- and post-project surveys that address specific C programming concepts in addition to the learning objectives for the core material and (2) end-of-project evaluations based on rubrics that address project sub-areas in support of the stated learning objectives. These assessments occurred over the span of several years, ensuring the inclusion of data acquired before and after the addition of the scientific computing course to the ECE curricula.

B. Course Descriptions

ECE 540 – Applied Scientific Computing (3 credit hours) is a junior-level, single-semester lecture course required of all KSU EE and CMPEN students. The prerequisites for this course are C Programming (CIS 209 || 308) and Introduction to Probability and Statistics (STAT 510). Topics include numerical properties of floating-point numbers, series convergence, transcendental function computation (e.g., $\cos()$, $\sin()$, and $\exp()$), matrix algebra, and statistics. All algorithms are implemented in C or C++. Although C programming is a course prerequisite, students come into the class with a wide range of backgrounds and programming competency. Early assignments focus on basic C programming, whereas later assignments focus more on the numerical and theoretical aspects of the problem domain.

The purpose of the class is to prepare students to program in C so that they may address numerical problems in senior ECE courses. Faculty find that most students retain little of the training from their lower-level programming classes, which are also directed at programming more generic problems. This class was therefore developed to form a bridge between the programming basics and more advanced numerical problems to be solved with C programming. Thus, Applied Scientific Computing (ASC) focuses on the latter, with an emphasis on good fundamental programming and debugging skills.

ECE 512 – Linear Systems (3 credit hours) is a junior-level, single-semester lecture course required for all KSU EE and CMPEN students. The prerequisites for this course are C Programming (CIS 209 || 308), Circuit Theory II (ECE 511), and now Applied Scientific Computing (ECE 540). This course generally provides tools to analyze signals and systems in the time and frequency domains. Topics include categories of signals encountered in system analysis, time- and frequency-domain system response, Fourier series and transforms, filters and signal distortion, discrete (sampled) signals and signal reconstruction, and computational tools for analysis and simulation of linear system behavior.

This course was chosen by the KSU ECE faculty as a venue where (a) programming would supplement the core material as a means to engrain signal analysis concepts in student memory and also allow students to better visualize signal features in the time and frequency domains and (b) students would receive additional exposure to C programming prior to graduation, since C programming is a skill set that continues to be of interest to companies that hire KSU EE and CMPEN graduates.

II. METHODS

The following section presents the approach used by the authors to assess student *preparedness*, meaning their ability to program in C upon entering ECE 512. The intent is to gauge the effect of the new ECE 540 course for its primary intended purpose, which is to provide adequate programming training for follow-on courses, thereby facilitating student learning by removing barriers to programming (whether real or perceived) that the students had faced in the past.

A. Overall Approach

Various computational projects have been assigned to Linear Systems students in the last ten years [10-12]. Pre- and post-project assessment surveys have occasionally been a reasonable means to gather student self-assessment data regarding their comfort level with the facets of those projects, including the project learning objectives and the related areas of programming.

For the work presented here, these surveys provide the initial baseline data against which follow-on data will be compared. More specifically, survey data from semesters prior to Spring 2011 (the first semester where ECE 512 would possibly involve students that had already taken the newly offered ASC course) are compared against more recent survey data, where the majority of the students are expected to have taken ASC. Pre- and post-project data are compared for the two populations, and these results are discussed in more detail in Section III. *RESULTS & DISCUSSION*. While numerous data elements could be compared, the initial focus is on pre-project assessments of the different areas of C programming related to Linear Systems projects – assessments which have the highest likelihood of indicating student *preparedness*, or the level of student comfort and ability relative to the programming tasks required for successful course completion.

B. Computational Projects in Linear Systems

The flow diagram in Fig. 1 illustrates a sequence of broad tasks that would be typical of software projects addressed by students in this Linear Systems course. In these types of projects, students write code that, e.g., extracts data from input text files, processes those data, stores the results in one or more output files, and then creates MATLAB scripts that allow one to plot the results. These projects typically address both the time and frequency domains within the context of topics such as time-domain filtering via convolution, compact Fourier series coefficients computed from signal samples, magnitude/phase spectra from Fast Fourier Transforms (FFTs) applied to discrete data, and frequency-

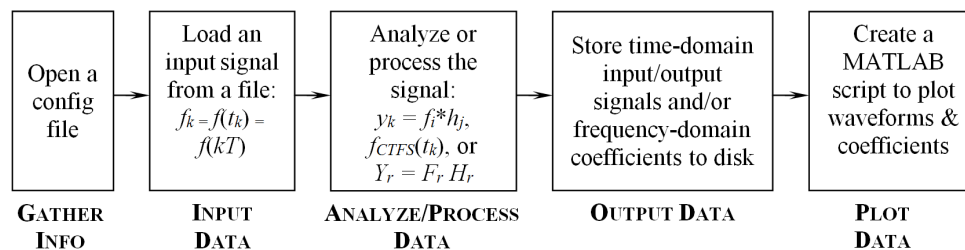

Figure 1. High-level program flow for a typical ECE 512 project.

domain filtering via linear convolution. During this process, students learn to better apply software-development approaches and data structures that promote efficiency and code maintainability. This usually means short C `main()` functions, header/source file pairs, structures that hold object data, functions that pass references to these structures, dynamic memory allocation/deallocation, file input/output, and a reliance on arrays and pointers.

Table I lists the projects that are relevant to this paper. The Spring 2007 and Spring 2009 project were offered prior to the time when the ECE 540 prerequisite was put in place. The Fall 2011 and Spring 2012 projects were offered after the prerequisite requirement became effective. All five project installments rely on a very similar code base that utilizes a predetermined set of header/source files to accomplish the general program flow illustrated in Fig. 1.

TABLE I. LINEAR SYSTEMS PROJECTS AND STUDENT REPRESENTATION

| Semester | Project Areas | Student Population |
|-------------|---|---------------------------------------|
| Spring 2007 | Trigonometric Fourier Series | 29 without ECE 540 |
| Spring 2009 | Sliding Windows; Trigonometric Fourier Series | 30 without ECE 540 |
| Fall 2011 | Trigonometric Fourier Series; Discrete Fourier Transforms | 10 without ECE 540 13 with ECE 540 |
| Spring 2012 | Unit Impulse Response; Discrete Fourier Transforms | 3 without ECE 540 20 with ECE 540 |

C. Pre- and Post-Project Assessment Surveys

Each project is designed to meet specific learning objectives. For example, the following are the learning objectives for a *compact trigonometric Fourier series* project that utilizes the general code base and the flow diagram in Fig. 1. *Upon completion of this project, each student should be able to do the following:*

- **Explain** how a signal can be constructed from sinusoidal building blocks
- **State** the mathematical relationships between trigonometric and compact trigonometric Fourier series coefficients
- Properly **sample** a periodic signal so that numerically determined Fourier series coefficients are equivalent to those calculated by hand
- Numerically **calculate** the Fourier series coefficients for a discrete data set
- Numerically **reconstruct** a data set given its Fourier series coefficients
- **Describe** a signal (its spectrum, bandwidth, primary energy range, etc.) based on Fourier series coefficients that exemplify its frequency domain character
- **Arrange** source code in a manner that promotes reuse and protects proprietary information
- **Organize** information in structures that facilitate bookkeeping and function-level parameter passing.

Prior to beginning each project addressed in Table I, students were asked to fill out a pre-project assessment

survey to gauge their level of starting expertise. For the first part of the survey, they were asked to address the learning objectives:

On a scale of 1 to 5, rate your level of comfort/familiarity with the respective learning objectives. Here, “1” means no comfort and “5” means high confidence.

They were then asked to rate their proficiency relative to the areas of C programming germane to the project:

This project will also address facets of C programming. On a scale of 1 to 5, note your level of proficiency in the following areas, where a “1” denotes no proficiency and a “5” denotes a solid understanding of the concept.

In most of these surveys, students were then asked to respond to open ended questions related to the subject area. Responses to some of these questions are summarized in Section III. *RESULTS & DISCUSSION*. Upon completion of the project, the students were then given an identical survey to gather their post-project viewpoints regarding the learning objectives and the related facets of C programming.

The following data/calculations were tallied/performed for each survey item relative to the projects noted in Table I:

- Pre-project rating
- Post-project rating
- Pre-post difference (post rating minus pre rating)
- Average pre, post, and difference scores for an entire class of students
- Summary metrics for each class
- Side-by-side comparisons of these metrics for the various semesters, with a goal of identifying trends.

C programming areas of interest are listed in Fig. 2 in the next section. Note that survey data are only analyzed for students that passed the class in each respective semester. In semesters where some students had taken the ECE 540 prerequisite and some had not (e.g., Fall 2011), survey responses are tallied for each student subset.

D. Other Assessment Data

While student self-assessment surveys and project rubrics can be useful for gathering quantitative data, anecdotal observations can also provide meaningful insight. Some of these observations are presented in the next section.

III. RESULTS & DISCUSSION

A. Pre- and Post-Project Survey

Representative data from the pre- and post-project survey results are tallied in Fig. 2. These data represent the four separate semesters recorded in Table I (S07 = Spring 07; S09 = Spring 2009; F11 = Fall 2011; S12 = Spring 2012). The first column contains the C programming areas that were addressed in the surveys. (The items in a blue font were not incorporated on the original survey from Spring 2007.) The following three columnar groups represent data for pre-project averages, post-project averages, and pre/post differences. For example, for the category of “Calculation of

| | Pre-Project Averages | | | | | | Post-Project Averages | | | | | | Difference Averages | | | | | |

Figure 2. Results summary for the pre- and post-project student self-assessment surveys.

mathematical expressions,” the average pre-project response from the Spring 2007 class was 4.1 out of 5. For that same class, the post-project response was 4.3 out of 5, on average. On average, the pre/post difference (post response minus pre response) for that category was 0.1 for the S07 semester. Note that post-project averages and difference averages do not exist for Spring 2012 – those surveys have not been completed to date. Underneath the primary tabular layout, one will note the rows that contain the column sums, averages, and standard deviations. These were seen as a way to aggregate numbers for a given semester.

For starters, note that confidence levels of incoming students vary from semester to semester. The time span for this table is relatively broad, and the prerequisite courses that represent early programming instruction in these areas can change quite a lot depending on the assigned instructor and the goals of the departments teaching these service courses. The most interesting set of pre-project data relate to the Fall 2011 semester, where 10 of the 23 students had not taken ECE 540 prior to enrolling in ECE 512. The overall pre-project scores of the class were low in most categories relatively to prior semesters. However, when the data are pulled apart to represent ECE 540 (ASC) participation, the numbers are striking: incoming confidence ratings for the students without ECE 540 experience are lower in every category; the difference is as low as 0.3 and as high as 1.3.

The first question is whether the two columns (F11 w/o 540; F11 w/ 540) represent equivalent student groups. If the students’ final ECE 512 course scores for the respective

groups are averaged, the group w/o 540 has a percentage that is 4% less than the group that had taken 540. This is not a particularly substantive difference (less than half of a letter grade) and may represent the fact that (a) those with ECE 540 experience received higher project scores because they had more familiarity with C or (b) the idea that the students with the ECE 540 prerequisite were more responsible and had therefore managed their curriculum in such a way that their retention was better. Nonetheless, roughly speaking, these students were all at the same point in their curricula, so it is reasonable to compare the two columns of numbers relative to one another.

With that in mind, one first notes that pre-project confidence in some areas of C programming was quite different. Areas with differences greater than 0.5 include standard I/O, array manipulation, pointers, format specifiers, preprocessor directives, dynamic memory allocation, structure references, function prototypes, header/source files, file creation, and .NET usage. All of these areas are emphasized in ECE 540 as the students complete their numerical analysis assignments. These kinds of numbers are mirrored in the ‘Column Sum’ row at the bottom, where scores of 53.8 and 55.7 (for F11 w/ 540 and S12, respectively) are much higher than the number posted by the ‘F11 w/o ECE 540’ group (41.5).

Further, the post-project averages are higher as well for the F11 w/ 540 group, yielding difference averages that are actually *smaller* for the group that had taken ECE 540. This is reasonable when one considers that the group with better

prior C training likely did not have to learn as much new C material in order to perform as desired on the course projects. For the F11 group that did not have prior ECE 540 experience, they would have to work harder on C programming constructs in order to complete the projects to the same level. On the other hand, note that a disparity does still exist in the post-project scores (e.g., a disparity of 4.0 versus 4.8 for file I/O and a disparity of 3.0 versus 3.8 for dynamic memory allocation). This may simply support the assertion that one needs to spend significant time with C programming before it becomes natural. That notion is consistent with studies performed in other areas such as music, where the ability to play at a given level depends mostly on the number of hours invested in the training [13].

B. Rubric-Based Assessments

Early in the assessment process, the author surmised that a correlation would exist between pre/post survey scores, project scores, and overall scores in ECE 512. However, those correlations are not telling. One explanation would be as implied in the previous paragraph, where students will invest more time to receive the desired grade on a project because that grade will provide scaffolding for the overall grade. In these studies, we did not have a mechanism in place to measure overall effort and time invested. Such a metric would provide a good means to answer the question, "Did they feel prepared?" versus "Were they prepared?"

C. Survey Comments

Comments to open-ended survey questions potentially provide the richest source of data for post-processing analyses. Such data were quantifiably important when originally deciding whether to update the curriculum with the ECE 540 course. For example, in the Spring 2007 post-project survey, students were asked, "What was your least favorite part of this project experience?" Of the 36 separate responses, 23 responses were comments that addressed being forced to use C, debugging C code, memory allocation, and other C-like constructs that over time become easier to use and therefore make for a more reasonable programming experience.

In contrast, responses to open-ended questions on the Fall 2011 post-project survey were overall more positive. In that survey, the question was "What thoughts would you be willing to share regarding the C language and its role or placement in our curriculum?" Of the 34 responses, 14 related to the idea that C programming is a useful and important part of the domain. 19 of the remaining responses noted themes such as the idea that C takes a long time to learn and needs to be emphasized in more KSU classes, or that students often lack confidence in C. Only two comments were decidedly negative. In that same survey, 16 of 28 responses noted that C would be an important part of their career employment, whereas only 7 respondents stated that they would not use C after graduating because of their degree area. Overall, these responses are much more positive than responses to surveys from previous years, and it is not unreasonable to attribute that change in attitude, at least partially, to the addition of this new course.

D. Anecdotal Observations

After the realization of the ECE 540 course, the ECE 512 instructor fields relatively few questions about the Microsoft Visual Studio .NET development environment and the C language itself. (For example, most questions in the Spring 2012 semester related to the use of the command line arguments in a console program, a technique that is rapidly becoming outdated due to the proliferation of window-based interfaces. Most college students today have no experience with, or knowledge of, the DOS prompt in Windows. Students that work more with Linux have a better knowledge of such a construct.) The lack of confusion about these items therefore gives the ECE 512 instructor the impression that addressing these items in class is largely a poor use of the students' time. As recently as a year ago, in-class discussions regarding the development environment and the C language were mandatory in order to avoid student onslaughts during office hours.

While the level of "hand holding" has recently decreased for the better, it is clear that students still generally need better training regarding the thought processes required to debug code and to solve algorithmic problems. Arguably a trait of this generation, many students that are faced with a debugging problem that starts to cost them time are more likely to seek help from the Internet or from a group of friends than to logically fight through a problem on their own, which is an excellent learning experience. This issue is exacerbated by many students' preferences to write code in groups, assuming it is even allowed (in ECE 512 and ECE 540, it is not), which (a) muddies the line between group work and outright plagiarism and (b) makes it difficult to surmise which students might be able to write programs independently as a professional engineer.

E. Future Work

The analyses presented in this paper can clearly be supplemented with future endeavors that address further analyses based on the present data as well as new assessments related to programming-centric teaching and learning. The initial update of this material will consist of adding Spring 2012 ECE 512 post-project assessment data (and ideally Fall 2012 ECE 512 data) to the current data set in order to get a more informed picture of the benefits of this new scientific computing class. Given the nature of these data, which are in spirit a comparison of means, this analyses will likely involve paired t tests to ascertain whether these performance data can be reasonably distinguished from one another. Further, the authors are interested in investigating this notion of whether the actual time invested in C programming (as it relates, e.g., to the music illustration earlier) is the driving factor in student proficiency with C. Finally, the authors see value in performing an introspective analysis of the ECE 540 course itself, with the goal of evaluating the effectiveness of different methods for teaching programming-intensive subject areas.

IV. CONCLUSIONS

This paper presented early assessments of student preparedness for C programming projects in *ECE 512 – Linear Systems* following a curricular modification to make *ECE 540 – Applied Scientific Computing* a required prerequisite for ECE 512. Pre- and post-project surveys in ECE 512 from Fall 2001 and Spring 2012 (semesters when the course prerequisite was in place) were compared to similar surveys from Spring 2007 and Spring 2009 (semesters prior to the new mandate). These data indicate greater overall confidence in C programming, a better understanding of the associated development environments, a better attitude toward Linear Systems programming projects, and a better sense of C programming as it relates to follow-on career choices. Efforts are underway to corroborate these initial findings with new offerings of similar programming projects addressed by new groups of students that have met the ECE 540 prerequisite requirement.

Integrating Developmental Instruction in Four Sustainability Contexts into an Undergraduate Engineering Design Curriculum: Level Three

Eric Pappas, Olga Pierrakos, Robert Nagel

James Madison University / PappasEC@jmu.edu, pierraos@jmu.edu, nagelrl@jmu.edu

Abstract - Developmental instruction in four sustainability contexts (*environmental, social, economic, technical*) in an engineering design curriculum offers a strong foundation and framework upon which to build an engineering program that teaches students the necessary methodologies for designing for sustainability. Instruction in sustainability contexts described in the current paper employs a developmental approach using Bloom's *Taxonomy of Educational Objectives*, which is a way to classify instructional activities or questions as they progress in cognitive difficulty. Our objective in this paper and presentation is to detail an instructional methodology (and results of a case study and focused group assessment) that integrates sustainability instruction in four contexts into the fifth and sixth classes in our six-course design curriculum using a developmental approach.

This effort is funded by National Science Foundation IEECI Grant #0933948 and National Science Foundation CCLI Grant #0837465.

Index Terms: Engineering Design, Sustainability, Developmental Instruction

Note: Because of the developmental nature of this three-stage project—this paper describes the third stage—portions of the Introduction and Literature Review are excerpted from our FIE 2011 paper and presentation: Pappas, E. and Pierrakos, O. “Integrating Developmental Instruction in Sustainability Contexts into an Undergraduate Engineering Design Curriculum: Level Two.” *Proceedings of the Frontiers in Education National Conference*, October 2011.

I. INTRODUCTION

Declining environmental, economic, and social conditions world-wide require a response from the engineering community, especially in higher education, since many of the solutions to these problems are related to the discipline, particularly engineering design for

sustainability. We have come to understand well that the greatest and most immediate *sustainability problems* humans face are related to our relationship with the natural world and the populations occupying the planet. This fact places a great deal of responsibility on a discipline that must now move beyond its historical sphere of technical influence and embrace the wide variety of disciplines with which it shares influence. We define sustainability as follows:

A sustainable society possesses the ability to continue to survive and prosper, not just with respect to environmental resources and economic development, but also with respect to quality of life as it pertains to conditions that promote sustainable human prosperity and growth (e.g., opportunity, economy, privacy, community, the arts, education, and health). A sustainable society meets these needs simultaneously, and in the context of human respect and the ability to negotiate differences without violence.

The James Madison University School of Engineering teaches sustainability in the following four contexts:

A) Environmental Sustainability

Briefly stated, designing for environmental sustainability is an approach to the engineering of processes, products, and structures which has, indefinitely, a less negative, a neutral, or a benign effect on all environmental systems. Sustainable engineering design tends to produce products and processes in which nature is not subject to continual 1) increases in the use of natural resources, 2) increases in goods produced by society, and 3) increases in waste products and the effects of their degradation.

B) Economic Sustainability

Beyond the efficiencies of economic policies and manufacturing processes directly related to the efficient, profitable, and sustainable development of a process or product, economic factors in sustainability influence the

economic health and profile of communities, including the standard of living, the existing business climate, employment, and the productive role of the corporation in the life of its employees (e.g., individual well-being, opportunity, productivity).

C) Social Sustainability

Social sustainability includes the role of individuals, relationships among social groups, the family, collective behavior, social class, race and ethnicity, medicine, education, and the role of institutions in society. This includes cultural factors related to the shared values, attitudes, beliefs, behaviors, and social practices that characterize human knowledge and action (e.g., fine arts, humanities, the transmission of knowledge, shared everyday way of life).

D) Technical Sustainability

Technical sustainability addresses a wide variety of factors related to the design and manufacture of products, especially the 1) scientific research and appropriate technology (compared to alternatives) supporting product function and development; 2) ease and efficiency of durable construction and use; 3) maintenance and functioning capabilities that meet the objective for which a product is designed; 4) material selection; and 5) reduction, recovery, reuse, or disposal of parts.

Factors in all sustainability contexts are mutually dependent upon each other in complex ways, and a change in one factor is likely to result in an unpredictable change in the others. *Little work has been done to understand and assess the reciprocal influences (that is, how sustainability in one context influences sustainability in other contexts) this complex system creates.* For example, efforts to promote environmental sustainability have traditionally required trade-offs among resource availability, market forces, and technology—and may include the consideration of *some* human factors—but may ignore or deemphasize issues related to the economic, social, and cultural well-being of a population (community sustainability).

It would appear that determining the sustainability of a product, process, or human community depends upon the careful and complete *assessment and evaluation* [1] of a range of technical and human factors that may (or may not) be influenced by a particular assessment effort, noted in *The Engineer of 2020* as “the core analysis activities of engineering design” [2]. This approach is central to our efforts, but it is a methodology about which little has been written or practiced.

Our overall program objective is to provide a design course sequence that integrates sustainability instruction in four contexts (environmental, social, economic, technical) into our six-course design curriculum using a developmental approach.

Instruction in sustainability contexts described in this paper employs a developmental approach using Bloom’s *Taxonomy of Educational Objectives*, which is a way to classify instructional activities or questions as they progress in cognitive difficulty. Our objective in this paper and presentation is to detail an instructional methodology (and results of a case study) that integrates sustainability instruction in four contexts into the fifth and sixth classes in our six-course design curriculum using a developmental approach.

II. LITERATURE REVIEW

Sustainability in engineering has its roots in two engineering sub-disciplines: green engineering and environmental engineering. In general, green engineering has focused on design that is in greater long-term harmony with the environment while environmental engineering has addressed the deleterious effects engineering design (or, sadly, lack of design) has had on the environment [3]. Sustainable engineering is, in many ways, more related to green engineering as it focuses on design that requires fewer natural resources, produces less (or no) waste, and reduces, reuses, or recycles waste products.

The Brundtland Report of the United Nations World Commission on Environment and Development first expressed concern over sustainable engineering at its 96th plenary meeting (December 11, 1987), noting a concern “about the accelerating deterioration of the human environment and natural resources, and the consequences of that deterioration for economic and social development...” [4]. What is, perhaps, most notable about the Report is a definition of sustainability that includes more than environmental sustainability and the opinion that the environment, the economy, and society compose a *complex system*, and that a change in one factor in sustainability will likely cause change in others.

Other definitions of sustainability often mirror the Commission’s Report. McDonough and Braungart view sustainability from the point of view of balancing environmental, social, and cultural concerns through a “triple bottom line” based on balancing the “tripod” of ecology, economy, and equity [5]. Charles L. Redman, director of Arizona State University’s School of Sustainability defines sustainability as “...an awareness of the connectivity of the world and the implications of our actions” [6]. The University of California Los Angeles Anderson School of Management offers a multidisciplinary approach to sustainability from an economic point of view: “‘Sustainability’ (loosely defined as the simultaneous consideration of economic, environmental, and social factors) has become a key element in decision making in many areas of business and public policy. By definition, sustainability requires a multi-disciplinary perspective” [7]. Roseland focuses on

a variety of issues related to sustainable community development, such as integrating environmental, economic, and social objectives, and concepts of “natural capital and social capital, whether (and if so, how) they are linked, and explores their implications for sustainable development at the community level” [8, p. 89].

Bras-Klapwijk notes the value of integrating instruction in environmental and social sustainability into engineering design curricula using problem solving methodologies. He suggests, as well, that factors related to sustainability have significant influences on each other [9]. Interactions among contexts in environmental and social sustainability can be evaluated, according to Chapin, through a series of “feedback” systems [10]. Expanding the notion of “reciprocal influences” among sustainability contexts, Thom takes a “holistic approach with a clear vision of systems functioning” [11, p. 91]. Crofton developed a curriculum that focuses on the interactions among sustainability contexts she considers central to all engineering instruction [12].

Unfortunately, efforts to integrate sustainability into engineering curricula have met with some resistance, especially problems related to 1) adding courses or integrating instruction in sustainability contexts into already tight engineering curricula, 2) the faculty interdisciplinary expertise necessary to teach new sustainability topics, and 3) the resistance from faculty to revising existing courses [13].

Methodologies for teaching sustainability have taken a largely traditional form, apart from some efforts teaching problem-based learning [14], hands-on approaches [15]-[17] and creativity skills [18]. Teaching critical thinking developmentally, especially using Bloom’s *Taxonomy of Educational Objectives* [19], is well-represented in higher education across the disciplines, and increasing efforts in science and engineering disciplines have met with success [20]-[23] as have methods of teaching creative problem solving in engineering design [24,25].

III. CURRICULUM MODEL

We teach students problem solving in four sustainability contexts (environmental, social, economic, technical) using an integrated and developmental methodology employing Bloom’s *Taxonomy of Educational Objectives* [26], which is a way to classify instructional activities or questions as they progress in cognitive difficulty. The lower two levels of the taxonomy (Knowledge, Comprehension) require basic thinking skills; as one moves from the lowest levels (on the left, below), the activities require higher level thinking skills. As students become adept at analyzing sustainability case studies, developing and building sustainable designs, and assessing products and processes for sustainability at these two levels, they move on to the next Bloom stages. In short:

Knowledge → *Comprehension* → *Application* → *Analysis* → *Synthesis* → *Evaluation*

While stand-alone courses in design are more typical in engineering programs [27], our approach integrates instruction into a six-course, three-year design curriculum which is the “spine” for our instruction in sustainability. Our instructional approach to teaching sustainability is 1) developmental, 2) integrated, 3) interdisciplinary, and 4) hands-on (design-to-build).

Our developmental approach allows students to slowly grasp, understand, and apply increasingly sophisticated thinking and problem solving throughout the conception, design, building, and evaluation of their own designs and redesigns. Students apply the criteria to their own projects *iteratively* to determine how a design can be improved related to sustainability. Our curriculum model provides an effective workplace-modeled approach [28].

Our courses present sustainability problems in the context in which students will encounter them in their professional lives, in the present study, in the form of sustainability case studies. Course instruction and assignments present problems that direct students to confront the *reciprocal influences among sustainability contexts* and design trade-offs necessary to develop workable and creative design solutions.

The effort described in this paper encompasses instruction and assessment of *sustainability case studies* in Stage Three—the third two levels of Bloom’s Taxonomy: *Synthesis* (Descriptors: create, design, integrate, construct) and *Evaluation* (Descriptors: choose, evaluate, prioritize, predict, justify). These final two design courses apply thinking and reasoning challenges for students that fall into the two highest levels of Bloom’s Taxonomy. This is our final of three reports on this project.

IV. ASSESSMENT METHODOLOGY AND RESULTS

In this assessment, the last of three of its kind in our rather extensive mixed-methods assessment of our design sequence, first-semester senior design students (n=44) were given the following sustainability case study at the end of the fall semester. The assessment was a written take-home assignment, limited to two hours, and low stakes (full credit was given for simple completion of the assignment).

Impact of Global Warming in the U.K.

The United Kingdom (U.K.) has recently experienced an upsurge in extreme weather such as storms, floods, heat waves, and droughts. The Climate Change Committee issued a warning

this year of more frequent extreme weather changes throughout the U.K.

The first national assessment of the country's readiness for the impacts of global warming found the UK was very poorly prepared for the changes, with fewer than one in 15 companies, local authorities, and other public bodies taking action to tackle the issue.

A report by the Climate Change Committee calls for speedy action by the government to introduce regulations and funding before it is too late. Recommendations include ensuring new buildings have better insulation and protection against heat waves and flooding, consideration of compulsory water metering to conserve water, "grey" water systems for homes to replace purified tap water with recycled water for gardens and toilets, and better emergency plans to protect vulnerable groups such as the elderly. The report suggests five "priority areas" for action: land-use planning, such as not building homes on flood plains and better surface water drainage; infrastructure, such as building roads to cope with "typical Mediterranean" summers; buildings, including the construction of new homes and retrofitting old housing stock to be better insulated cool in hotter summers; natural resources, such as setting up "wildlife corridors" so species can migrate to more suitable habitats as conditions change and "making space for water" when there is flooding along coasts and rivers; and better emergency planning.

Some changes would mean spending money "smarter" rather than increased funding; others would require up-front spending for longer term savings, reported Lord John Krebs, chairman of the group. Government could also take action by introducing regulations to force higher standards, such as tougher building regulations and more water meters to encourage homeowners to be more careful with their water use, he said. Another potentially controversial suggestion was that industry regulators, such as the water and electricity sectors, should be given powers to make lower bills less of a top priority and more weight to other considerations such as adaptation, said Krebs.

Source: The Guardian, Sept 2010, www.guardian.co.uk

In this third stage, students were instructed to *synthesize* and *evaluate* the sustainability problems at stake in each of the four contexts we have been studying (environmental, social, economic, technical). Each student submitted a maximum one-page written response for each of the sustainability contexts.

Responses were scored as following: a score of 0-3 was given to each of the four written responses submitted by each student and was determined by how many valid issues a student identified, synthesized and evaluated in each of the four contexts, so that synthesizing and evaluating one valid environmental issue in the case study would yield a score of "1" for the environmental sustainability response. In the same manner, if the same student addressed three valid social issues in the case study, she or he would score a "3" for the social sustainability response. Each student, then, received a separate score for each sustainability context. Students were *not* asked to synthesize or evaluate issues in any *other* sustainability contexts, but the figures below show that students are beginning to integrate sustainability issues on their own. The three other bars in the figures below show how often a student *also* mentioned another sustainability context in the particular case study context. For example, Figure 1 below shows that the identification, synthesis, and evaluation of environmental issues in the above case study averages almost three per student. At the same time, the average mention of a social context (in the *environmental* response) was .32. Economic and technical sustainability issues were mentioned with some frequency in the environmental responses.

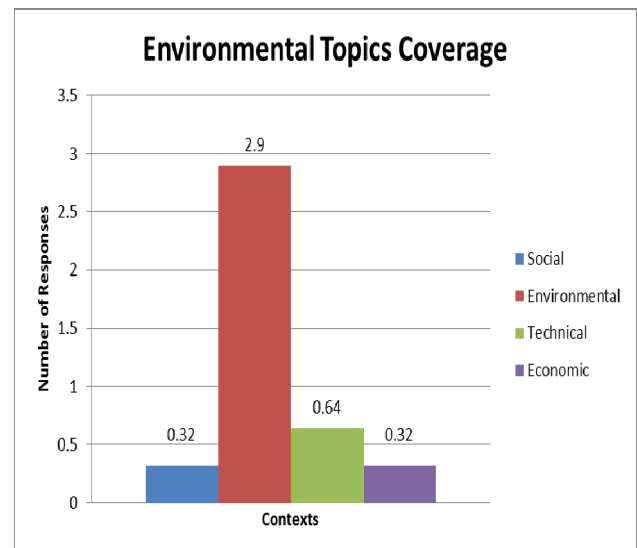

FIGURE 1:
ENVIRONMENTAL TOPICS COVERAGE

In Figure 2, it appears that students were particularly sensitive to social issues (or social justice issues) in the case study. When asked to synthesize and evaluate social

issues in their response, students noted an average of 2.7 issues per response. In this social context response, students averaged .32 environmental issues per response. Averages for technical and economic contexts were a bit stronger.

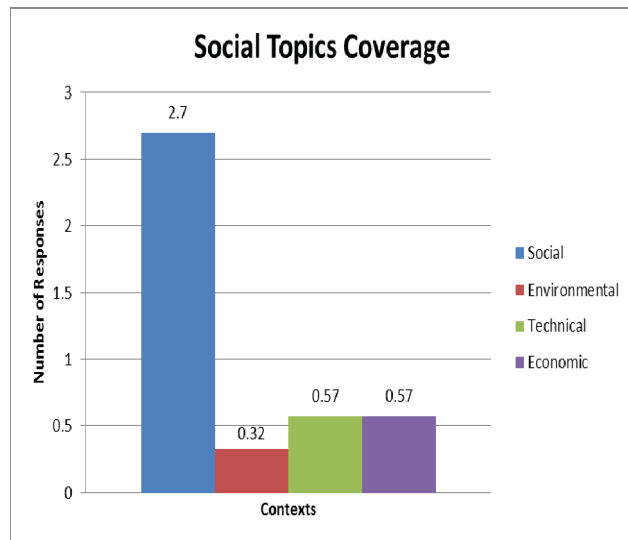

FIGURE 2:
SOCIAL TOPICS COVERAGE

In Figures 3 and 4, students demonstrated a high level of sensitivity to economic (2.7) and technical sustainability issues (2.6). Coverage of other sustainability issues in each major context was rather low but notable (see discussion).

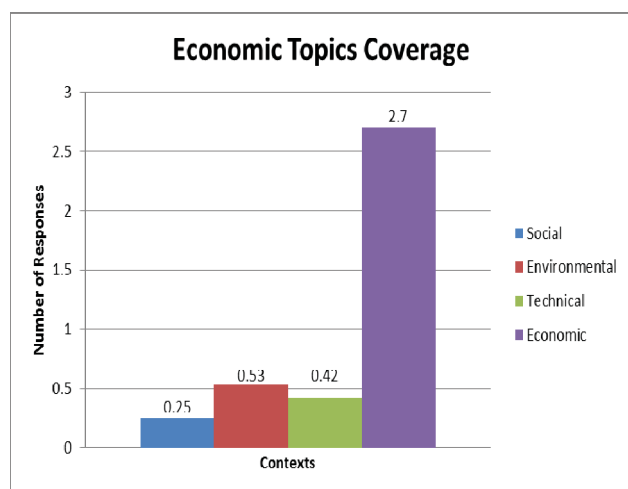

FIGURE 3:
ECONOMIC TOPICS COVERAGE

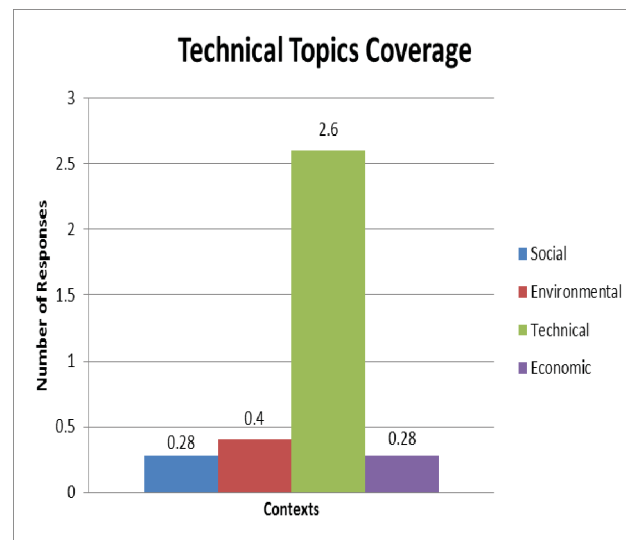

FIGURE 4:
TECHNICAL TOPICS COVERAGE

V. DISCUSSION

It is clear that even with the level of sophistication in thinking required for Stage Three of this project, students are quite easily identifying, synthesizing, and evaluating sustainability problems they found in the case study. We observe, however, that students included other sustainability contexts into their evaluation of each of the main contexts at a *higher rate* than they did for Level One (identify and describe) or Level Two (application and analysis) of Bloom as described in our FIE 2010 and 2011 papers. As noted earlier, students were *not* instructed to include in their response any other context than the main one, so that we could evaluate their “*natural* inclination to think using a systems perspective” to include other related contexts. This is challenging for undergraduate students, and we did not know what to anticipate, considering many academics and professionals in engineering do not exhibit the natural inclination to think in a systems (holistic) perspective.

Our desire here is to change how students think...that they will *naturally* link contexts using a systems perspective. (When directed to address all four contexts in a case study, our students readily do so, and with some skill.)

This effect is natural, perhaps, as the increasing intellectual sophistication required to employ higher levels of Bloom’s Taxonomy makes integrating other sustainability contexts into the main context more challenging.

We consider this NSF-funded effort to be highly successful and have established the approach described in the paper as a permanent component of our design sequence. We will continue to refine our efforts,

especially related to teaching students system theory and holistic thinking. We have recently received another substantial NSF sustainability instructional grant to expand our efforts.

VI. CONCLUSION

The approach to thinking detailed in this (and the two earlier papers) has applications in STEM disciplines as well as across most all academic disciplines. Students need to understand the profound connections and reciprocal influences among the biological, social, and economic factors that determine global sustainability.

We consider social sustainability the central sustainability context because it is the nature of human relations that determine our actions towards the environment. For this reason, we believe many sustainability efforts to be mis-directed in the direction of environmentalism. Social and community sustainability are contexts that need further and serious examination and research.

In particular, we are developing methods for assessing social sustainability especial related to how *individual sustainability* (how well one balances one's intellect, emotions, spirituality, relationships, and physical well-being) influences community well-being. Individual and social sustainability are the likely final determinants in all sustainability efforts. Little serious research has been conducted in these areas.

Abstract—Distributed software system design is by nature an ill-defined or wicked problem. In order to learn to design them, the student must be presented with complex, open-ended problems for which there may be more than one correct solution. The decision-making strategies students acquired in previous courses are not effective when applied to large, complex problems of distributed systems. Students (novice designers) tend to think linearly and focus only on the problem at hand. They also tend to use trial-and-error strategies and they lack confidence in their design decisions. The purpose of the distributed systems' course is to create a learning approach that helps students to adopt and to apply expert design decision-making strategies. We use a case-based learning approach with classroom assessment techniques and rubrics to identify the critical weaknesses in the approaches that novices typically use when attempting to solve difficult design-oriented problems. The novice-oriented knowledge-based learning and application environment is supported by scaffoldings to incorporate expert strategies. In this paper, we describe the experience and the learning environment that provides the opportunities for professional development. We present and analyze our data comparing the students' outcomes over four terms, the time it takes to develop our students' expertise and how time spent with an expert (instructor) is crucial to an overall development.

Keywords—*component: distributed systems, expertise, formative assessment, problem-based learning, scaffoldings.*

I. INTRODUCTION

Distributed systems is concerned with understanding the nature and requirements of pervasive software-based systems of systems that collaborate to provide essential services to society. Software in these systems is often required to (1) operate in distributed and embedded computing environments consisting of diverse devices (personal computers, specialized sensors and actuators), (2) communicate using a variety of interaction paradigms (messaging, media streaming), (3) dynamically adapt to changes in operating environments, and (4) behave in a dependable manner [1, 2]. Understanding and designing are the two key activities of distributed systems development. By design, we mean both the design of specific systems for specific needs, and the design of more generic toolkit environments [3].

A distributed system has design issues that arise specifically from its distributed nature. A distributed software system consists of interacting entities that work together to

perform specific tasks: (1) it provides concurrency by disbursing objects over a network of computing resources. In contrast, centralized systems can only simulate concurrency. (2) An individual computing resources in the network of the distributed system can fail or become unreachable. In centralized systems, failure is usually treated as an all-or-nothing condition. (3) It provides dynamic, incremental change. A distributed system rarely requires a complete shutdown to make changes in the way that it work is performed. Mechanisms for dynamic and incremental change are often built into the infrastructure.

Furthermore, the ideal premise of a minimum conceptual distance between analysis and a corresponding design of a centralized systems design tend to increase and complicate the design process. Some examples are: (1) many software objects distributed across the network can represent a single real-world object; (2) a software object may represent only a portion of the behavior of the entity described in the analysis; (3) the distribution of objects should consider factors like performance, reliability, security, and fault tolerance, and not only locality. Distribution can introduce a significant amount of resource sharing that did not exist in the analysis. [4]

Consequently, the distributed systems design problem can be characterized as a wicked [5] or ill-defined problem [6]. Ill-defined problems refer to the fact that the design problem is incomplete and has no one single solution, while wicked problems are progressively defined during the design process. Wicked problems are essentially unique, and each can be considered to be 'a symptom of another problem' [7]. Wicked problems require an ongoing iterative analysis between problem and solution to begin to understand either [3].

In our Distributed Systems Design course for advanced Informatics Engineering students we have combined a Problem based Learning (PBL) approach with a commitment to developing independent learners with professional (expert) design skills providing guidance through a cognitive support system.

We will describe the experience and the learning environment that provides the opportunities for professional development. We will present and analyze our data comparing the students' outcomes over four terms and the time it takes to develop our students' expertise and how time spent with an expert (instructor) is crucial to an overall development.

II. WICKED PROBLEMS

Rittel and Webber [5] describe two classes of problems: tame problems and wicked problems. A tame problem is one for which the traditional linear process is sufficient to produce a workable solution in an acceptable time frame. Many traditional exercises in Concurrency and Introductory Software Engineering courses fall into the category of tame problems.

Wicked problems are ill-defined problem sets that are too complex to be solved by rational systematic processes. Key properties of wicked problems include the following:

There is no definitive formulation of a wicked problem. Problem definition and solution co-evolve because there is no optimal solution. Solutions to wicked problems are never true or false but instead are qualitatively judged as better or worse. A 'satisficing' (combining satisfy with suffice) [9] or 'good enough' solution is the realistic goal.

The process of solving a wicked problem is inherently non-linear. Progress is defined qualitatively in terms of how much more is understood about the problem rather than distance from the solution.

III. DESIGN EXPERTISE IN WICKED PROBLEMS

The first step in coping with a wicked problem is to recognize its nature and their properties. There is a tendency to treat all problems as tame, perhaps because these problems are easier to solve, reinforced by the lack of understanding about wicked problem dynamics and the tools and approach they require [8]. Rowland [10] found that novices do not see the problem as being ill-structured and thus assume that the information and variables are clearly specified. They do not think beyond the written description of the problem. They shift rapidly from problem analysis to solution generation and failed to elaborate solution alternatives. Therefore, simply engaging students (novice designers) in problem solving does not ensure the development of expertise [11] and get a satisfactory solution for the distributed system.

Experts are able to active mental models that connect relevant previous experiences with domain specific knowledge and skills. They activate a mental framework for representing the problem and seek solutions. Experts integrate given information with prior knowledge and experiences to make inferences that go beyond the state information [10]. Design activities would more or less creative according to conceptual domains evoked sources. Experts can refer to intra-domain or inter-domain sources in order to engage in analogy making for solving the design problem. [12].

Experts delimit the space of research to understand the problem on the basis of different kinds of constraints; in order to quickly reach in depth levels of understanding. Constraints are propagated during design problem solving orienting the designer's reasoning towards the most appropriate decision-making and design choices [12]. Experts usually pursue predominantly breadth-first and top-down strategies.

In contrast, novice designers have only a few reference cases to deal with new design problems, which may restrict their space of research of innovative ideas. The suggestion of sources, whatever they are, either intra- or inter-domain, did

not appear to enhance the production of new creative ideas. Novice designers can often become bogged down in attempts to understand the problem before they start generating solutions. For them, gathering data about the problem is sometimes just a substitute activity for actually doing any design work.

Experts spend more time analyzing the problem and only move to solution generation after ensuring that they have understood the situation completely [10]. Experts usually pursue predominantly breadth-first and top-down strategies.

Novice designers are also frequently found to become fixated on particular solution concepts. Early solution concepts are often found to be less than satisfactory, as problem exploration continues. Instead of searching for a better alternative, novice designers try laboriously to design-out the imperfections in the concept, producing slight improvements until something workable but perhaps far from ideal is attained.[13].

Another difference is that novices will often pursue a depth-first approach to a problem. They sequentially identify and explore sub-solutions in depth, and amass a number of partial sub-solutions that then somehow have to be amalgamated and reconciled, in a bottom-up process.

Researchers [12, 14] suggested that in order to enhance novices' analogical thinking, it appears necessary to go further than simply suggesting intra- or inter-domain sources. Novices would benefit from pedagogical actions during design education in order to show them how and why to use analogies for successful design problem solving [14]. In particular, a specific guidance should lead them to adopt various points of view on the suggested sources, as well as to connect these sources with the object to design. For instance, novices could get specific questions related to aspects that they do not spontaneously consider [12], in order to benefit more from the presentation of inter-domain sources.

Experts make designing seem easy and intuitive. Skilled design in practice therefore often appears to proceed in a rather ad hoc and unsystematic way. However, a study by Radcliffe and Lee [15] did show that a systematic approach could be helpful to students. They found that the use of design processes closer to an ideal sequence correlated positively with both the quantity and the quality of the students' design results. Other studies have tended to confirm this [13].

IV. OUR DESIGN PROCESS

PBL presents a challenge to novice designers. When students explore complex problems in a PBL environment, the problems may generate a heavy load on students' working memory due to their lack of proper schemas to integrate new information with their prior knowledge [16]. Given the complex nature of PBL, it is critical that instructors provide guidance to learners through each of the PBL activities while providing "direct instruction on a just-in-time basis" [17].

Instructors can support students' problem-solving activities with strategies such as providing hints and cues, asking question to direct student's attention, eliciting their causal explanations, and elaborating their thinking [18]. According to

the notion of cognitive apprenticeship [18], while the mentor and novices engage in the same problem-solving experience, the mentor makes his or her thinking visible to novices through social dialogues and scaffolds their problem-solving activities. The literature provides a theoretical framework for designing technology scaffolds to support students' problem-solving processes through the following strategies: question prompting, peer reviewing, expert modeling, and reflective thinking [19].

Our PBL focused on a design project, from the initial statement of the problem to a working prototype. We gave twenty students (our novices) the problem statement and material to work with. Students must follow a systemic approach for solving the problem. To address the demand for providing guidance to support students PBL experience, we designed a cognitive support system or scaffoldings.

V. THE REAL-WORLD CASE STUDY

We match the form and complexity of the problem to a real distributed problem to contribute to the realism of the experience. The problem statement was "Follow a Truck down the assembly line" from GM [20]. It had a decentralized nature to introduce the concepts of decentralized control.

The problem description stated the assembly process through one GM plant, which makes GM's full size pickup trucks. The assembly line had five production stations (Body shop, Paint shop, Trim, Chassis, and Final Assembly). The supplies for the assembly line arrive "Just in Time" (JIT). The JIT logistic is the Toyota Production System using the electronic Pull scheduling (e-Kanban) technique [21]. It is a standard of the Inventory Visibility and Interoperability (IV&V) project of the Automotive Industry Action Group (AIAG) [22].

In addition to the problem statement, we gave students a set of resource material such as videos, pictures and notes describing the different assembly line shops hardware and procedures, standards, papers about e-Kanban specifications, and Internet links. We encouraged students to search for more sources.

VI. SYSTEMATIC APPROACH FOR SOLVING THE PROBLEM

Software design consists of an ongoing series of decisions, from the problem statement and the elicitation of requirements to the initial system architecture sketches to a designer's choices of suitable models, algorithms, data structures, and user interfaces.

The design approach was based on the Rational Unified Process Software Development Process (RUP) [23]. RUP provides an iterative and incremental development process divided in phases. At the end of the design of each phase, students documented the formal solutions using UML (Unified Modeling Language) diagrams. The implemented solutions were tested in the lab. The phases are Requirements Specification, Analysis, Design, Code, Test and Integration.

The project had two RUP iterations. The first iteration was the development of the application's prototype and its API (Application Programming Interface) over raw networking support (TCP connections). Students use an object-oriented

approach and the base constructs of the Integrated Enterprise Modeling method [24].

The second iteration was the development of a middleware for the first iteration's prototype and API. The middleware system was organized into several service layers adapted from Schantz's et al. middleware [25]. The first service layer and API was the domain-specific middleware services layer. The next layers were the common middleware services layer with domain-independent services, the distribution layer providing high-level distribution, and the host infrastructure layer hiding differences between operating systems by providing common abstractions for communication primitives and other resources.

VII. THE COGNITIVE SUPPORT SYSTEM

The cognitive support system consisted of a suite of support mechanism characterized by mentorship and social interactions: question prompt, peer review, expert modeling and self-reflection [19]. Our design process consisted of a real-world case study, an outline of the design process steps using a Software Development Process, CATs (Classroom Assessment Techniques: Assessing skills in Problem Solving) [26], and scaffoldings: questions prompts, peer-review, expert modeling, and self-reflection. Sketches, related information, meeting decisions and formal documentation were shared through a yahoo group.

The Assessing Skill in Problem Solving CATs allow faculty to assess and promote problem-solving skills of various kinds [26]. The assessment techniques in this group are: Problem Recognition Tasks, What's the principle?, and Documented Problem Solution. CATs were mandatory homework for reflective writing activities. Students must write their arguments and the collected evidence for their positions in argumentative essays (reports) for the in-class meetings. The purpose of the reports and collaborative in-class sessions was to create an ongoing process of discovery. The CATs activities were based on Quellmalz's [27] key strategies of critical thinking.

Software design is collaborative. Developers work in face-to-face settings and CATs act as the coordination mechanism to support the design dialogue during the meetings. CATs and rubrics also act as formative assessment tools to give feedback and "just in time" mentoring during the meetings for reflection, in the sense of thinking about something again [28, 29].

Rubrics assessment purposes are to improve the reliability of scoring written assignments and active participation during meetings. Rubrics convey goals and performance expectations of students in an unambiguous way, convey "point values" and relate them to performance goals, and engage students in critical evaluation of their own performance [30]. Rubrics are also a guide of how to do the work.

VIII. SCAFFOLDINGS.

Scaffolds were introduced to support the learning environment. Scaffolds were combination of question prompts, peer-review and expert modeling, to improve novices' problem-solving skills [11, 19].

A. Question prompts.

In addition to the problem-solving outline, the students received prompts consisting of elaboration and metacognitive questions with each problem-solving step [19]. For instance, the following questions were presented among others for the JIT design: How will you manage the concurrent use of the forklifts with the other stations? How will you manage the different types of material (big pieces or parts of the truck, bullets and nuts, raw material, etc.)?

B. Peer review.

The peer review mechanism was designed to enable students to see multiple perspectives from peers' reports and help them notice things they might not have thought about previously. By reviewing their peers' thinking, students were supposedly compelled not only to attend more closely to their peers' ideas, rationales, plans and solutions, but also to their own for self-reflection [19].

C. Expert modeling.

Expert modeling was provided by presenting students with expert's reasoning during in-class meetings. This support mechanism was expected to offer students an opportunity to observe the expert's (instructor) reasoning, which they would compare with their own reasoning. It was assumed that the comparison would result in disequilibrium [19].

When team members are immersed in a design activity, they are often unable (or unwilling) to acquire knowledge that cannot be immediately put to use. If students do not see the need for help, it is unlikely they will ask questions. Experts notice features and meaningful patterns of problem solving that are often not noticed by novices [19]. Walz [31] recommends that formal training activities, when appropriate, be integrated into project activities rather than remain independent. One way to achieve this might be to have an instructor participate in a few design meetings so the training can be custom-tailored to the project.

In the last semester, we included the expert-modeling scaffold and help, as expert designers and mentors, novices to focus on hidden relational properties of the problem during the in-class meetings. We introduced them in practices of reasoning about systematic exploration of possibilities (finding gaps, or finding unexplored relationships between problems and potential approaches) and scenario-based reasoning to explore assumptions and consequences.

D. Self-reflection

A meeting ended with a self-reflection writing activity with a few reflective questions. Self-reflection was an important mechanism to supplement the expert modeling mechanism and allowed students to observe an expert's reasoning facilitating students' reflection on the gaps between student's and the expert's reasoning [19].

E. Agenda and goals

A collaborative design session is more likely to succeed when designers agree on ground rules for conducting the session. By setting time limits and achievement goals, designers can force themselves to focus on the fundamental problems. We scheduled the agenda and goals for the meetings.

For instance, we scheduled three brainstorming meetings for the problem understanding and first design decisions: (1) business process modeling (JIT), (2) production processes and JIT model without faults, and (3) the whole model including faults and defective material handling.

The scaffolds help students to focus on target users, reframing of requirements and sketching before formalizing their notation using UML. Informal diagrams and sketches offer a great way to examine the relationships among objects in the different problem domains, as well as their interactions. Sketches hide students from making premature design decisions because the UML notation pushes them to think of abstractions and focus on understanding the problem space.

IX. A RUP ITERATION

A. Problem Scoping and Information Gathering.

Problem scoping and information gathering are aspects of design activity that involve identifying criteria, constraints, and requirements; framing the problem goals or essential issues; gathering information; and, stating assumptions about information gathered.

A nontrivial portion of a software team's work for the initial stage involves improving their understanding of the problem domain from a succinct problem statement (design brief) and a vague set of requirements to produce a design that addresses users' needs. More than half the cost of the development of complex software systems is attributable to decisions made in this initial phase. [31]

Many students find it difficult to cope with the wicked nature of the problem at the initial stage of the design. Instructor's guidance and scaffolding can facilitate the problem solving process and enables students to bridge the gap between their current abilities and the intended goals of expertise.

Students like to have formal processes or procedures to use for problem solving, but as we have seen and is reported by research [32], the UML formal procedures they learned to use in former subjects do not work well with ill-formed problems. Experts use UML diagrams only after they make the final design decisions for the RUP phase. A flexible and adaptable "design thinking" process for guiding design decision-making would provide an alternative to these formal procedures. This process could explicitly incorporate steps for looking at the big picture of the system, the use of rules, principles, and/or practices for examining the design and generating solution alternatives, selecting and evaluating candidate alternatives, and reflecting on what has been accomplished in an iterative approach.

We supported this design thinking process by "The Problem Recognition Tasks" CAT. The CAT assesses students' skill at determining what kind of problem they are faced with, so they can choose the appropriate solution [26].

Reflective writing and sketching supported the CATs activities.. Student sketched diagrams, and other informal representations of the problem domains and constraints, use UML formal diagrams, annotations (textual and graphical), corrections, alternatives, etc. to communicate ideas.

Cross [13] calls sketching an “intelligence amplifier” and enumerates how sketching helps design thinking. It enables designers to handle different levels of abstraction simultaneously, enables identification and recall of relevant knowledge, assists in problem structuring through solution attempts, and promotes recognition of emergent features and properties.

For the next steps of the iteration, we divided up the class into five groups. Groups were in charge of the design and prototype of the assembly line station (a subsystem) and the exchange of information between stations and other enterprises. We use the same cognitive support system. CATs writing activities and their scaffoldings supported the intra-team problem solving activity and the inter-team decisions to reach consensus on protocols, formats of information exchange, paradigms, models, etc. Inter-team meetings were held in class.

New levels of abstractions and key concepts about distribution’s complexity were introduced after the need to learn them has been established in the context of observed phenomena or unexpected system behaviors.

B. Multiple Solutions Generation

Another aspect of design behavior often thought to be important is the generation and consideration of alternative solutions. However, research results suggest that the role of alternative solutions is not clear. Students tended to focus on one design and tried to make it work.

This activity was supported by the “What’s the Principle?” CAT to assess students’ ability to associate a specific problem with general principles used to solve them [26].

Students’ teams use their CATs to analyze the interrelations and connections of the complex system and generated alternatives for the integration of business processes (e-Kanban cross-enterprise data exchange) with product and service oriented processes of the assembly line.

C. Analysis and Selection of the Solution

Once students have conceived alternative solutions to the design problem, they need to analyze those solutions and then decide which solution is best suited for implementation. Analysis is the evaluation of the proposed designs.

Experiments and programming exercises in the lab were introduced to check and exhibit distributed systems complex behavior against student’s expectations and to show how a population of asynchronously executing processes without central top-down control can exhibit unexpected or “emergent” behavior at the system level.

Students must apply their technical knowledge to the proposed solutions and use the results to decide which solution to carry out. They validated system goals, constraints and connections/interrelations. They documented the solution using a reduced set of the UML diagrams. These are the tasks of the Documented Problem Solutions CAT. This CAT assesses how well students solve problems and how well they understand and can describe their problem-solving methods [26].

D. Prototype Implementation.

A prototype is the first fully operational production of the complete design solution. It is not fully tested and may not work or operate as intended. The purpose of the prototype is to test the design solution under real conditions.

Teams implemented the subsystems. For the individual testing of a subsystem, they programmed simple stubs that emulate the interacting subsystems. For the integration of the prototype, the stubs were replaced by the real subsystems and the whole prototype was tested under normal conditions and in presence of failures.

The next iteration focus was on middleware issues to address “possible repairs” of the unexpected behavior of the prototype in presence of failures of the first prototype.

X. RESULTS AND DISCUSSION

Our course goal is that students master distributed systems design issues. The only way to achieve this goal is that students develop critical thinking and reasoning skills. When we designed our first PBL course, we acknowledged that we would find some hurdles, because students’ interaction with others is not only guided by the learning task, it is also shaped by their emotions, perceptions, and attitudes. Some social-emotional processes are beneficial for learning others are not [19]. Therefore, the relationships between motivation, peer interactions, and wicked problem solving are worth further attention to answer the questions: How much time would it take to develop expertise in our students? How can we improve the process? The successful guidance of PBL is largely dependent on the availability and skills of instructors who can scaffold students’ problem-solving activities. [17].

Having a small number of students in each semester, we had the opportunity to use the PBL processes exhaustively in order to have a close observation of our students’ learning process. We arranged extra out-of-class meeting to help students to develop common positions on relevant issues when they did not meet the in-class meeting goals. We were there for office hours, kept scheduled appointments, and made time for students/teams when they need additional help. We arrived at class early and stayed after class.

After each semester we review literature and transform our cognitive support system for using the in-class time more efficiently. Our support system in 2008 included CATs with report feedback, meetings and peer-review with a facilitator and feedback, in-class experiments. In 2009, we added the self-reflection writing activity and rubrics. In 2010, we included question prompts and in 2011, the expert modeling scaffold.

We use a standards-based grading system where every student, as shown in Table I must meet a determinate level of performance. Each step is evaluated in points from 1 to 10 following a set of rubrics. These are formative assessment earned points; they do not weigh for the final grade but are very useful as feedback.

In the four terms, the points’ statistics are similar, meaning that the performance level from the student remained reasonably high. The difference appears in the Out of Class time and extra meetings we held with the students/teams.

TABLE I. STUDENTS PERFORMANCE AND EXTRA TIME

| ITERATION No. 1 | 2008 Students = 8 | | | | 2009 Students = 6 | | | | 2010 Students = 6 | | | | 2011 Students = 20 | | | |
|-----------------|-------------------|------|--------------------------|----------------|-------------------|------|--------------------------|----------------|-------------------|------|--------------------------|----------------|--------------------|------|--------------------------|----------------|
| | Average | SD | Out-of-class time h/week | Extra Meetings | Average | SD | Out-of-class time h/week | Extra Meetings | Average | SD | Out-of-class time h/week | Extra Meetings | Average | SD | Out-of-class time h/week | Extra Meetings |
| Design | 8.92 | 0.67 | 6 | 4 | 9.62 | 0.32 | 6 | 3 | 9.87 | 0.10 | 3 | 2 | 9.37 | 0.65 | 2 | 1 |
| Implementation | 9.64 | 0.48 | 4 | 2 | 9.86 | 0.21 | 4 | 1 | 9.86 | 0.21 | 3 | 0 | 9.62 | 0.35 | 3 | 0 |
| Total Scores | 9.17 | 0.60 | 10 | 6 | 9.70 | 0.26 | 10 | 4 | 9.87 | 0.12 | 6 | 2 | 9.46 | 0.50 | 6 | 1 |
| ITERATION No. 2 | | | | | | | | | | | | | | | | |
| | Average | SD | Out-of-class time h/week | Extra Meetings | Average | SD | Out-of-class time h/week | Extra Meetings | Average | SD | Out-of-class time h/week | Extra Meetings | Average | SD | Out-of-class time h/week | Extra Meetings |
| Design | 9.91 | 0.18 | 6 | 1 | 9.88 | 0.19 | 4 | 1 | 9.88 | 0.19 | 2 | 0 | 9.88 | 0.11 | 2 | 0 |
| Implementation | 9.89 | 0.19 | 4 | 1 | 9.85 | 0.21 | 4 | 1 | 9.85 | 0.19 | 4 | 1 | 9.83 | 0.17 | 4 | 0 |
| Total Scores | 9.90 | 0.17 | 10 | 2 | 9.87 | 0.19 | 8 | 2 | 9.87 | 0.19 | 6 | 1 | 9.87 | 0.11 | 6 | 0 |

As we included new items in the cognitive support system, fewer meetings and few extra-time were needed to obtain the same result.

As shown in the 2011 cohort with 20 students, an increase in the number of students did not represent an increase in the extra support time. Without the whole scaffolds managing 20 students would have taken all of our office hours and perhaps more.

The use of deliverables in the cognitive support system allowed us to adapt our teaching to the current cohort. These documents also made a good base for reflecting on and pinpointing difficulties.

Work in Progress: Making Room: Creating Design Spaces for Design Practice

Micah Lande

Department of Engineering
College of Technology and Innovation
Arizona State University
Mesa, Arizona, USA
micah.lande@asu.edu

Abstract—This work investigates affordances of co-working, collaboratory spaces in support of engineering design student design teams. A framework for establishing such spaces is presented adapting a set of design axioms: design is a social activity, preserve ambiguity and all design is redesign. Student reflections are used to illustrate these design principles and example spaces are described in brief.

Keywords—engineering design; creativity; workspaces; design thinking; collaboration

I. INTRODUCTION

Design as a driver for project-based learning [1] and capstone engineering experiences is well established in engineering programs [2, 3]. Having dedicated physical space for these design project teams available outside engineering lab and machine space, however, is not. While there are engineering design programs that do make available some shared design co-working space [4, 5], this paper uses an array of design spaces for different engineering design and design programs primarily at a one, single institution, Stanford University, to illustrate what a co-working space can be and what affordances are useful in such a space.

This paper will outline a framework for creating such collaboratory spaces using Leifer's axioms for design [6] that design is a socio-technically mediated activity, designers must preserve ambiguity and all design is re-designing.

These design axioms will be defined in the context of the created design space and the affordances of digital and analog tools available. A set of spaces will be described and reflections and feedback from users and alterations made in response to one particular space will be highlighted.

A brief description of the conceptualization, design and implementation of just such a conceptual design space for teams engaged in design project work at Arizona State University will be shared. The selection and visioning of the space, how it complements existing student fabrication faculties as well as the array of expectations of various stakeholders (students, administrators, faculty) will be mentioned.

A metric for assessing current design spaces will be introduced and presented as basis for future work.

II. AXIOMS FOR DESIGN ACTIVITY

In Reference [6], Leifer captures learnings from decades of teaching engineering design students at Stanford University. Primarily developed from annual cycles of the ME310 Global New Product Development course [7, 8], he highlights for teams of engineering designers design as a socio-technically mediated activity, that designers must preserve ambiguity and all design is re-designing [6].

A. Design is a Socio-Technically Mediated Activity

Engineering design is an activity that often is done in groups or teams of engineers or engineering students. Many interactions among teammates is informal, towards building a high-performing team – a “community of practice” [9] that has shared norms for working in a situated learning environment. The “learning ecology” [10] may extend past the immediate team to include formal and informal advisors [11], in the classroom introducing informal and formal learning loops [12].

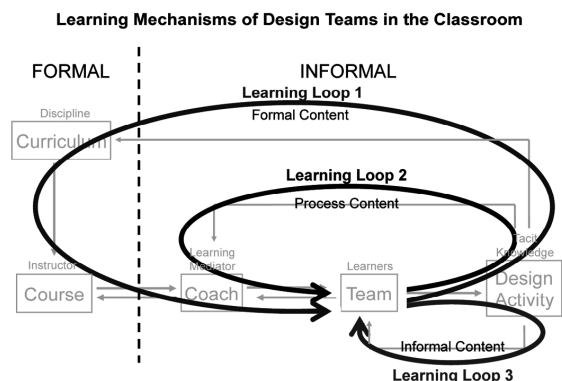

Figure 1. Formal and informal learning loops in the classroom [12]. Learning loop 3 can include the informal, situative learning in a design space. The totality of the 3 learning loops can describe its “learning ecology” [10].

Particularly with a human-centered design process [13, 14, 15, 16, 17], engineering design work increasingly includes a person in the system if not systems of people. At the heart of human-centered design is a motivation to make the resulting design better for those users and stakeholders. Understanding their social and technical needs within their frames of reference also makes it a social endeavor.

B. Designers Must Preserve Ambiguity

Design thinking is a balancing act between divergent and convergent thinking [13, 17]. In the same manner “defer judgment” and “encourage wild ideas” are tenets of the creative brainstorming practice [15], innovative ideas can come from extending the problem and solution area past what is first expected. Reference [17], as seen in Fig. 2, deconstructs the design thinking approach as going from concrete to abstract thinking to be able to break new ground.

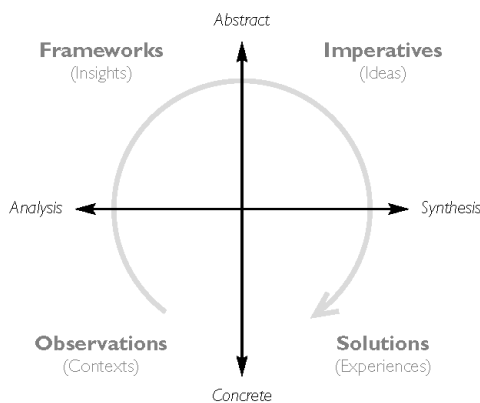

Figure 2. Design thinking approach showing concrete to abstract thinking framework [17].

C. All Design is Re-Designing

Building on these initial axioms, all design activities are acts of re-design. Reference [18], illustrated in Fig. 3, highlights the “comprehensive design engineering approach.” In this model, the fields of engineering approach problem solving through a lens of technical feasibility. Business uses a lens of business viability. Attacking the same problems through the designer’s lens of human values and desirability can result in a much different and differentiated result. It might be that there is not a completely new problem to address but rather a new way to approach solving it.

There are many instances in which previous attempts have been made to create a better artifact, interaction or experience. By acknowledging those and learning from apparent or latent deficiencies, the act of re-design can start from a place further forward than the origin. It’s not reinventing the wheel. Rather by advancing the design is social axiom in concert, one can come to rely on peer designers or users and stakeholders in the value chain to provide insight.

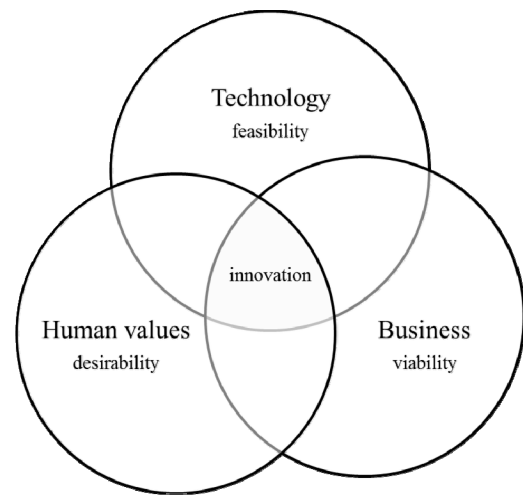

Figure 3. The comprehensive design engineering approach [16].

III. EXAMPLE DESIGN SPACES

A. Global Design and Innovation Studio

The Global Design and Innovation Studio space, shown in Fig. 4, is used as a dedicated workspace assigned to approximately 10 student teams engaged in solving problems posed by industry in the ME310 Global New Product Development class at Stanford University [7]. Each student team is assigned a work table, whiteboard and storage cubby set around a one room studio. There is a small rudimentary shop available to fabricate and tinker.

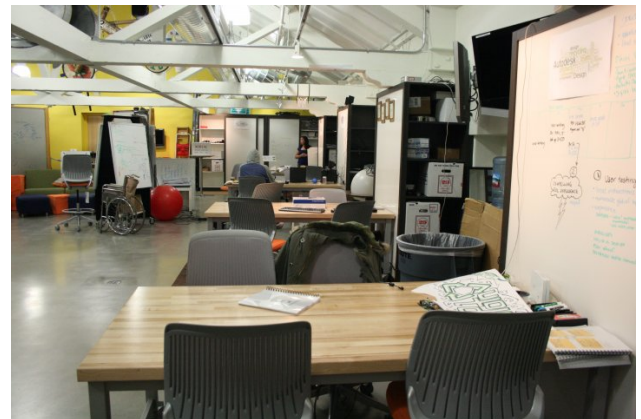

Figure 4. Global Design and Innovation Studio space

B. Mechatronics Technical Lab

The Mechatronics Technical Lab space, shown in Fig. 5, is used by 25-40 students in a 3-quarter ME218 graduate mechatronics course sequence at Stanford University [19, 20, 21]. Students work in teams, are assigned to a computer and technical workbench. Teams share common resources such as soldering stations.

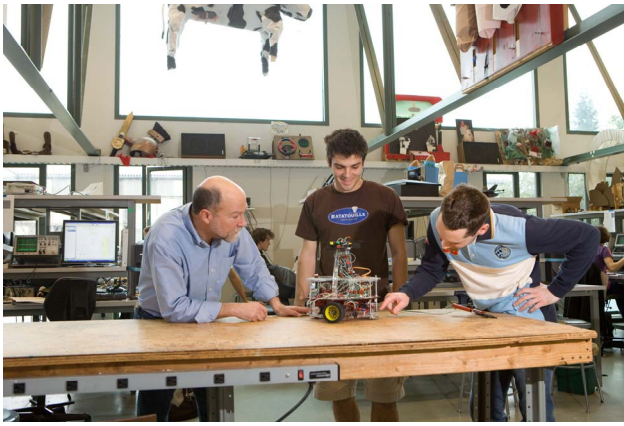

Figure 5. Mechatronics Technical Lab space

C. Design Thinking Studio

The Hasso Plattner Institute of Design at Stanford (the “d.school”) [22] hosts quite a number of hoteling, or temporary spaces, for an array of students teams to use. An example collaborative space in shown in Fig. 6. Reference [23] details the space development and design for furniture and artifacts included therein. There are many student teams from quite an array of classes in the space during any one week so accommodations are always temporary and project boards and technology are employed to help make the use of the collaborative spaces scale. Student teams do belong to classes offered so there is accountability and affinity for those using the space. Reset configurations for each space are posted to aid in managing the use and expectations of returning furniture, tools and materials to a common configuration.

Figure 6. Design Thinking Studio space

IV. IN ACTION REFLECTIONS

A. Reflections on the Global Design and Innovation Studio

The ME310 course resides in a collaborative working loft area that fosters implicit learning in a community of practice [9]. The array of people and affordances in the space allow for close work and peer support in building skills, experiences and developing towards being a future engineer.

As graduate students working on a core class in their design theory and methodology concentration, the loft becomes a popular place to hang out, whether working on their project or other activities. It becomes central to their experience, as one student contributes:

I can't wait to see next year's group of 310er's walk into the loft and have NO idea what lies ahead. They will walk in the door looking at 310 like a regular course, but be confused by the crazy contraptions hanging from the ceiling. In this crazy place called "the loft," they will learn how to really work with other people for the first time. The students will be amazed at how technically involved building a bike out of paper can be [an introductory engineering design activity]. They will read the corporate sponsor prompts, and be both excited and intimidated by the ambiguity of some of the projects. They will form teams, and try to find a balance of both talent and mutual interest with a group of individuals as talented and intelligent as them. They will learn how to rapidly prototype something, and learn that the message conveyed by the prototype is more important than the finished look of the prototype. They will learn how easy it is to become emotionally involved in a project, and will learn how to manage these emotions so that they are always constructive to the project. They will learn how to "embrace ambiguity," and they will learn how some of the best ideas for the project come out with a little (lot) of Jaloviina [brandy] and a late night in Finland. They will learn to leverage the technical skill of each member of the team, and that anything imaginable can be made in the loft. They will spend late nights [there], and come to think of getting to bed by 3am as an early night. They will learn that 501 [a small office] is actually a really nice space to sleep, and that the design group office has some damn good coffee. They will experience the reward and excitement of EXPE [year-end project fair] on no sleep, and be more proud of their project than almost anything else that they have ever been a part of. And, lastly, they will feel a deep nostalgia as the year comes to a close.

Another student quantifies those long hours,

I think success was inevitable, provided most of us put our all in to whatever it is we decided on. And that is exactly what we did. 100hr weeks for a month straight? At least one person in the loft [from our team] from 7:30am till 2am almost every day?

Students in the Mechanical Engineering 310 Global New Product Development course, regardless of their particular project, have some difficulties in approaching and managing their design projects [24]. The constellation of the course affords a strong support structure. Students work in teams of 3-4 students locally at Stanford and are matched up with similar teams of students at globally distributed university partner sites. They are provided with a sizeable project budget and a physical working space in a project loft. Students have regular weekly meetings with the teaching team consisting of Professors, Teaching Assistants and Consulting Professors with technical expertise. Student teams also have a coach from industry to consult on technical and team dynamics issues.

Working together in close collaboration with others is also somewhat of a challenge. Students are in the first year of their graduate program, in their early twenties, without project experience; issues with project management, planning and communication are always learning experiences for student teams. A student reflects on the team experience and lists a few of the bumps along the way:

... We were lucky. The team is effective and our efforts are often well-orchestrated (despite a lack of planning, lapses in communication, and ballooning stress levels)...

Students are introduced to a human centered design process with emphasis given to rapid prototyping and iteration. Moving from planning to doing so rapidly is often a switch in their usual practice for students.

The environment and the people help form strong bonds. The experience has been likened to a start-up environment. A student reflected on that aspect as well:

After completing my undergrad degree I wasn't quite ready to go to the real world. I enjoyed learning, I loved [being here], and I wasn't sure if I was mentally or emotionally ready for a full time job. Well, ME310 fixed all of that in the best ways possible. It perfectly bridges the gap between school and work, functioning as an 8-person startup where you have help and guidance along the way. You make close friends, you stay up late, you wake up early, you work with awesome teammates from around the world, and you solve real problems. I couldn't have asked for a better experience. From the outsourcing to the deadlines to the project management to the travel to the budget to the personalities to the assignment to the pressure to the fun I feel like ME310 did a fantastic job of prepping me for life beyond [here], and I look forward to maintaining many of the friendships I've developed this year.

And another student reiterates the job-like experience,

For me, it has been much like working a full-time job at a typical Silicon Valley startup, sans pay and sans risk of losing your job if you fail miserably. This is the beauty of [class] to me – it allows you to take risks, to really go out on a branch with innovative ideas, without this fear of risking anything more than a hyphen behind your letter grade. It is precisely this type of environment that fosters creative design thinking and innovation that defines [this course].

B. Other Stakeholder Valuation

Design is an active and messy proposition. The workspaces described above all serve as showcases for innovation and innovative work. Potential partners, students and sponsors are regularly toured through all of these spaces to demonstrate the innovative ethos that is inherent in each program. Ironically, with students' schedules, most tours during normal business hours reflect a less than full student engagement. The materials and artifacts left behind, however, demonstrate the type of innovative work they are engaged in. All are useful to instructors, administrators and other visitors to highlight using creative and different working space, whether as a benchmark or the basis on requesting development dollars.

V. MAKING ROOM

A. Developing an Innovation Commons

Another collaborative space is the Startup Labs innovation commons space at Arizona State University's College of Technology and Innovation, pictured in Fig. 7. This space was recently configured based on experiences and applied design axioms previously described. Housed in a converted clean room teaching area, the space is replete with white boards and glass walls for writing as well as flexible and moveable tables, chairs and other furniture. The space is available to engineering students, business students and human factors students throughout the college and space is used in an ad-hoc, as needed basis

The Startup Labs innovation commons adds a co-working space to the resources available to students. It is a collaborative space that is more flexible than the nearby library, allowing for noise and ready reconfiguration of the available furniture to meet immediate student team needs. It augments physical prototyping spaces such as a nearby student machine shop and sophisticated fabrication facilities. The space also serves as an overflow workspace from engineering studio spaces for project work.

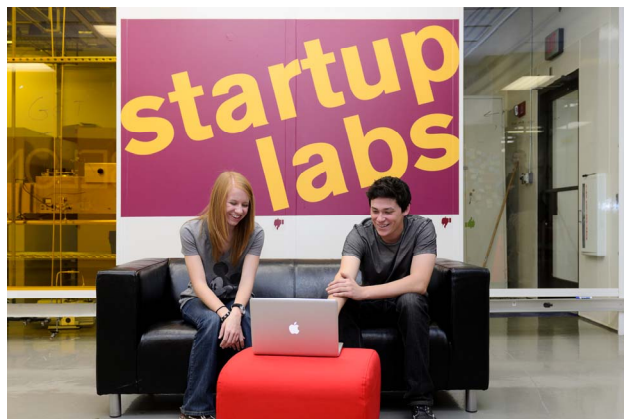

Figure 7. Innovation Commons space

VI. DISCUSSION: METRICS FOR ASSESSING SPACE

The three design axioms introduced above can be the basis for cataloging, comparing and assessing the utility of such collaborative engineering design spaces. In development is a tool specific to highlighting and making visible those distinctions. Already, with brief descriptions and vibrant pictures of a small number of spaces, one can see an array of possible affordances, features and use.

A. Design is a Socio-Technically Mediated Activity

A space can be evaluated based on how well it can accommodate a team of designers as well as the duration of time a team inhabits and owns a space. The array of spaces described above all include meeting space with tables and chairs, whiteboarding areas and storage. Depending on the throughput and number of dedicated users groups or hoteling

teams, the amount of time duration ranges from a whole academic year, quarter to by the day or hour.

B. *Designers Must Preserve Ambiguity*

The simplest means to have a space that affords preserving ambiguity is one that hosts flexible parts that can be easily moved around to suit an immediate need or fashion. Most spaces described have wheeled tables, chairs and carts to do so. Additionally, whiteboarding surfaces in such quantity that most readily available surfaces are writeable allows student teams to create ideas and experiences without bounds, to think and do outside the box. Both the flexibility of the artifacts in the space and the affordances of the room spaces help to create an environment that serves to preserve ambiguity.

C. *All Designing is Re-Designing*

Each space has a means to collect, display and inform of work done previous. It ranges from championed artifacts hung from the ceiling or preserved on shelves to libraries of previous reports and work available for immediate reference. Some are kept as exemplars of project outcomes and some remain as emblematic trophies of particularly wacky or memorable design attempts.

D. *Making Qualitative Measures Quantitative*

The next steps for this work is to codify means to assess design space based on this framework and be able to make qualitative measures quantitative. There is an opportunity to imagine and design work space for design teams and then be able to assess its utility, impact and use to inform redesign and improvement.

ACKNOWLEDGMENTS

The author gratefully acknowledges those in the Stanford Mechanical Engineering Design Group, the Hasso Plattner Institute of Design (the d.school) at Stanford University, and Arizona State University College of Technology and Innovation, past and present, who helped to create the design spaces referred to above.

Integrating International Students' Contests with Computer Science Capstone: Lessons Learned and Best Practices

Amir Zeid

Division of Sciences and Engineering
American University of Kuwait
Kuwait
azeid@auk.edu.kw

Abstract—Microsoft Imagine Cup is the world's premier student technology competition. Every year students from all over the world compete to solve the world toughest problems in different categories. In ten years, the Imagine Cup has grown to be a truly global competition focused on finding solutions to real-world problems. Since 2003, over 1.4 million students have participated in the Imagine Cup with 358,000 students representing 183 countries and regions registering for the Imagine Cup 2011 competition [7].

In this paper, we present our experience in integrating imagine cup (IC) with computer science (CS) capstone courses at the American University of Kuwait (AUK). In the past four years, we coached four different teams in three consecutive years (2009-2012) to win Microsoft Imagine cup in the Gulf region (GCC region includes Bahrain, Kuwait, Oman, Qatar, Saudi Arabia and UAE) and qualify to the world finals. We present our best practices and three case studies of winning projects in the region (one of the three teams was totally formed of girls). We will also present the lessons learned and guidelines on how to integrate such design competitions with computer science capstone.

Keywords- *Software Engineering, Collaborative learning, software engineering education.*

I. INTRODUCTION

A. Education in Kuwait

Kuwait is a small country situated in the Persian Gulf and is part of the Gulf Cooperation Council [GCC] that incorporates: Bahrain, Kuwait, Oman, Qatar, Saudi Arabia and UAE. With crude oil reserves of about 102 billion barrels, oil production represents the main pillar of Kuwait's economy and accounts for nearly half of GDP, 95% of Export revenues, and 95% of government income [3].

Today, Kuwait's education system is larger than ever. There are currently close to 500,000 students enrolled in Kuwaiti schools, constituting approximately 30 percent of the entire population. There are three basic levels of education in Kuwait – elementary, intermediate, and secondary. All stages of state education, including higher education, are free. Students in all Kuwaiti schools study English starting the second grade.

According to the most recent release by the UNESCO Institute for Statistics in 2009, the percentage of female graduates in tertiary education in Kuwait have reached 69% while the female tertiary graduates, as percentage of all graduates in science in Kuwait, has reached 80% [5].

B. Typical problems in traditional capstone class

Traditional teacher-assigned-project capstone classes have many potential problems:

- Maintaining Student Interest

Pre-defined projects by professors may lead to students losing interest in class and project. In this approach, students may be forced to work on a project that does not match their interests and skills. Students mainly focus on obtaining passing grades rather than enjoying the learning process [6]. In other cases, the projects professors assign to students may be too theoretical to be applied out of the classroom, which also affects students' interest in the project in a negative way.

- Interpersonal Skills and Communications

It is widely agreed that most computer science students have problems with interpersonal and communication skills [8]. This is due to the technical nature of the field. Average class size at AUK is 28. Students in capstone class present their projects in front of their class mates only, which may not be challenging enough to prepare them for real life technical presentations and conferences.

- Business and Entrepreneurship Skills

In some technical programs, computer science students do not get enough general education courses in business and entrepreneurship. Adding such dimension to CS students is pretty important; however, it is difficult to incorporate it in the capstone course due to time limitation.

The rest of this paper is organized as follows:

- Section 2 presents an overview of the environment where the research was conducted.

- Section 3 includes how to associate the Microsoft Imagine Cup competition with the capstone course.
- Section 4 includes the hypotheses and findings.
- Section 5 contains main challenges, how to overcome them and how IC addressed some problems.
- Section 6 includes samples of projects.
- Section 7 includes assessments of professors and students.
- Section 8 points to future research directions and concludes the papers.

II. BACKGROUND AND LITERATURE REVIEW

A. Environment

We conducted our research throughout the capstone course offered by the computer science program at the American University of Kuwait (AUK). The American University of Kuwait (AUK) is an independent, private, equal opportunity, and co-educational liberal arts institution of higher education. The educational, cultural, and administrative structure, methods and standards of AUK are based on the American model of higher learning. The language of instruction is English. Established by Amiri Decree 139 in 2003, AUK was accredited in 2006 and re-accredited in 2008, by the Council for Private Universities, Ministry of Higher Education - State of Kuwait. AUK was established by as a Kuwaiti University but with an American name. This necessarily makes it bi-cultural. So while the educational system is American, it exists in a very different cultural environment which provides both challenges and opportunities.

1) Course Description

CSIS-490 (Capstone course) integrates core topics of the computer science body of knowledge, teamwork, and professional practices through the implementation of a large scale project.

2) Intended Learning Outcomes

On completion of Capstone course the student should:

1. Apply the concepts learned in various courses taught in computer science curriculum.
2. Acquire technical information and background on subjects not studied in courses.
3. Develop the ability to work in a team and to give technical presentations.
4. Develop the ability to work under stress and meet deadlines.
5. Develop skills in writing technical reports and manuals.
6. Develop project planning and management skills.

B. About Microsoft Imagine Cup

Microsoft Imagine Cup (software design category) has three main rounds. Round 1 starts by students submitting their proposals using a template provided by Microsoft. The template includes: problem, solution, architecture, business

viability and technologies to be used. Participants have to submit a 15 minute narrated video that includes a demo or a prototype of the proposed solution. Problems have to contribute to solving one of the eight millennium development goals (MDGs) defined by the United Nations Development Program (UNDP). The areas are:

- End poverty and hunger
- Universal education
- Gender equality
- Child health
- Maternal health
- Combat HIV
- Environmental sustainability
- Global partnership

A limited number of proposals advance to round 2: the country's finals. Normally, in Kuwait there are between 2 to 5 teams in the country's final round. The country's final round is a public event where students have to present their projects in front of a panel of 4-5 judges. Each team presents for 15 minutes followed by a 5-minute question session. The winning team advances to the world finals.

The world finals have one team from each country. The world finals are composed of three main rounds:

- Round 1 has around 68 teams and it takes place on day one. Each team presents for 20 minutes, followed by questions from the judges for 15 minutes. Each presentation has to include a live demo for the project. The panel of judges consists of 5 judges. Presentations are not public. Attendance is granted by permission from the team mentor. At the end of the day, the top 12 teams qualify to the second round. The grading criteria for Imagine Cup is included in the following table:

TABLE 1

| |
|---|
| 10% - Problem Definition (How are you making a difference?) |
| 35% - Solution Design & Innovation (What does your solution do?) |
| 30% - Technical Architecture & User Experience (How does your solution work?) |
| 15% - Business Viability (How will your solution become a reality?) |
| 10% - Presentation (How well have you explained your solution?) |

- Round 2 is more technical and it takes place on day 2. More judges sit with the 12 teams and evaluate thoroughly the technical side of their projects. Presentations are not public. Attendance is by permission from the team mentor. At the end of the day, 6 teams qualify to the final round.
- In Round 3 (day 3), the top 6 teams present in public in front of a new panel of judges (mostly judges who have not judged the team in previous rounds). The top 3 teams are awarded [7].

III. HOW TO ASSOCIATE THE MICROSOFT IMAGINE CUP COMPETITION WITH THE CAPSTONE COURSE.

Imagine cup has three main milestones over the duration of a year: The proposal deadline, the country's final and the world finals. Table-2 shows the timeline for the activities

TABLE 2

| Stage | Requirement | Time |
|------------------------|------------------------------|------------|
| Call for participation | Proposal and video | Early Fall |
| Local Finals | Presentation and Demo | April |
| World Finals | Presentation, Demo and Video | July |

CS Capstone is offered twice a year (once in the Fall and once in the Spring semester). Fall semester starts early September and ends mid-January, while Spring semester starts in February and ends around the beginning of June. Table 3 shows the activities of capstone course with the estimated timeline (for both semesters). The percentage of the grade of each activity is shown as well in table-3.

Table-4 shows the timeline of both capstone (CS) and Imagine Cup (IC). We aimed at the following goals:

- We use the same template of Microsoft imagine cup to propose projects in the capstone course. In that case, all of the capstone projects can be eligible and ready to apply for the first round if students are interested.
- Students have to implement a prototype before the country's final. To do so we aligned, the design presentation to be before the country's finals (in

TABLE 3 Timeline for capstone with marking scheme

| Stage | Requirement | Percentage | Time |
|---------------------------|--|------------|--------------------------|
| Finding an idea | Proposal Document and presentation | 5% 5% | October, February |
| Requirements Presentation | Requirements (RS) Document and presentation | 10% 10% | November, March |
| Design Presentation | Design Document (DD) and Presentation, prototype | 15% 10% | Early December, April |
| Final Presentation | Demo and full presentation | 25% | End of December, Mid May |
| Oral Exam | Committee oral exam | 20% | January, End of May |

TABLE 4 Timeline of both Capstone and Imagine Cup.

| | 9 | 10 | 11 | 12 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
|----|------------------------|----------|----|----|------|-----------------|----|--------------|------|---|----|

| IC | Call for Participation | | | | | | | Local Finals | | | WF |

December and in April). The presentation covers solution design and architecture.

- The world finals (WF) are after the end of Spring semester. The practice is that we work to enhance the project after the end of the semester (based on the comments we receive in the country's final and committee exam of the capstone course).

IV. HYPOTHESES AND FINDINGS

A. Hypotheses

The following are the two hypotheses we aimed to verify:

1. Communication skills and performance will improve if students participate in IC
2. The quality of the final products of the capstone course will improve if students participate in IC.

In order to verify hypothesis 1, we mainly collected grades for public presentation before and after participation in IC. Grades of presentations are calculated based on the average of panel of 5 judges. The average GPA of students was the same over the span of the 4 years of the study. Number of students in class ranged from 15 to 23.

In order to verify hypothesis 2, the number of resulted publications out of the capstone class was traced before and after participation in IC as an indicator of quality.

B. Findings

Table-5 shows the results of students' participation in IC and the outcomes. We can notice a steady increase in the number of resulted academic publications after participation in IC. Also, there is increase in course presentation grades.

As shown in Figure-1, the academic publications out of the capstone class increased with the increase of number of participating teams. In addition, the second graph shows how the performance in class presentations improved.

V. MAIN CHALLENGES AND BEST PRACTICES

In this section, we introduce the main challenges we face and how to handle each situation. We also mention how some of these issues fulfill the learning outcomes of the course. As for, learning outcomes 5 and 6 (writing technical reports and planning) participating in Imagine Cup improves both outcomes as participants have to submit reports and videos that are evaluated by external entities.

A. Coaching more than one team in the same year

Aligning IC with the capstone course may result in instructors coaching and mentoring many teams for the same contest. This could be a challenge as classmates compete against each other for the qualifying ticket to the world finals. Confidentiality of ideas, projects, meetings, and rehearsals are

essential in such situations. Other considerations include maintaining an unbiased coaching approach, and equal dedication of time and effort to all competing teams. This builds a trustful relationship between the teams and the coach, essential to keep up the moral. Applying these methods, we could get over the problems arising between the competing groups. In previous years, we managed to coach up to 4 teams simultaneously, all competing against each other in the regional contest. The experience was exhausting for the coach yet very rewarding. In the latest experience in 2012, three teams mentored by the same coach ranked 1, 2, and 3 in the country's finals.

B. Funding

If a team qualifies to the world finals, funds should be obtained for the following items: Publicity material (brochures, posters), Hardware, Software, Video for the demo, Per-diem for team.

In order to produce the best possible product for the world finals, we apply for external grants and sponsorship directly after the country's finals. In the past two years, we managed to get support from Kuwait Foundation for Advancement of Sciences (KFAS). KFAS is the main Public organization funding scientific activities and research in Kuwait.

TABLE 5 Results of Students participation in IC and outcomes.

| Year | Number of teams who submitted proposals | Team formation | Qualified to Kuwait Finals | Kuwait Finals | Regional Finals | Publications | Presentation grades |
|------|---|--------------------------|----------------------------|---------------|-----------------|--------------|---------------------|
| 2008 | 0 | N/A | N/A | N/A | N/A | 0 | 55 |
| 2009 | 1 | All Male | 1 | Ranked 1 | Ranked 1 | 2 | 62 |
| 2010 | 3 | 1 All Female, 2 All Male | 1 (All Female) | Ranked 1 | Ranked 1 | 3 | 68 |
| 2011 | 5 | 4 All Male, 1 All Female | 3 (All Male) | Ranked 1 | Ranked 2 | 4 | 72 |
| 2012 | 4 | 2 All Male 2 Mixed | 4 | Ranked 1,2,3 | N/A | In progress | 76 |

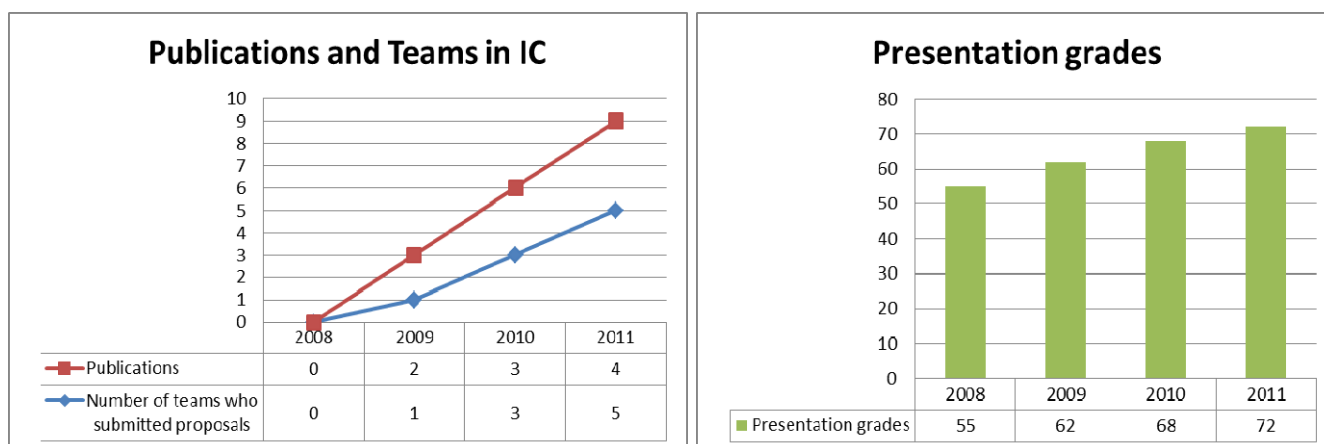

Figure 1 Relation between participation in IC and Presentation grades, Publications

C. Cultural Barriers

Recently, the gender segregation law has been amended to include also private and public higher education institutes, like the American University of Kuwait. By means of Law no. 34 for 2000 for Establishment of Private Universities, Private universities/colleges and branches of foreign universities shall enforce gender segregation [4].

This resulted mostly in single gender grouping in the contest as well as the capstone class. In 2010, we coached an all-female team for the first time. The experience was challenging due to cultural barriers between the male coach and female team. However, the team won on both local and regional levels, advancing to the 2010 world finals. The presence of a female team representing Kuwait in the world finals was a media scoop for the following few weeks. In the current academic year, mixed-gender teams were allowed, so we had two mixed-gender teams for the first time. This issue addresses learning outcomes number 3 and 4.

D. Technology Limitations Using Microsoft Technology

Contestants in Imagine cup have to use Microsoft technology since the competition is a Microsoft initiative. Other tools may be allowed in situations where Microsoft does not have similar tools to support. This limits the technological choices in some projects. It creates a challenge since at AUK we do not use Microsoft technologies throughout our curriculum. We mainly support open source products and languages like Java. In previous years, students had to learn C# and programming for windows phones on their own to be able to compete. This adds an overhead for learning the new tools, yet it is a real life challenge. This also helps to fulfill learning outcomes number 1 and 2.

In order to get over this issue, we organize a set of workshops in collaboration with Microsoft to teach our students how to use Microsoft tools. The workshops are done as an extra-curricular activity where attendance is free for all those who are participating in Imagine cup.

E. Failure to Qualify to Next IC Rounds

In some cases, teams fail to qualify to the next round in Imagine Cup which could be very frustrating for them. Yet, they still have to finish the project for their capstone class. Typically teams exposed to this situation would stop working on the project for one week.

In order to get over this issue and keep students motivated, I created a mini contest in the capstone course where all students in class compete using a more comprehensive criterion than that of Imagine Cup. We have a final public event that is juried and attended by almost 200 people every year [9]. The panel of 5 judges that includes a combination of professors, alumni, and industry experts. The following is the assessment criteria we use: problem definition and innovation, effectiveness and extensibility, functional completeness, Answering questions and creativity.

F. Grading

Students get individual grades in the capstone course depending on their role and the quality of their project. They have to attend an individual oral exam after their final demo and presentation. Imagine Cup does not require all team members to talk during presentations. So, a team may choose to present using two team members only. In class presentations all team members have to present as a requirement for assessment. It is becoming common that students who compete in Imagine Cup present better in class activities since they have better training.

G. Business Case

Imagine Cup assessment criteria includes 15 percent on the business feasibility of the solution. CS students do not necessarily have business background to complete this part of the project successfully. To get over this issue, we integrate the course with other courses offered at AUK. Entrepreneurship courses like ENTR-201 and ENTR-301 are good candidates. The two courses give guidelines on how to operate a business from an entrepreneur's point of view. They

do not have any special emphasis to software projects though. We are currently investigating if this could be added, or if other new courses should be offered. This issue addresses learning outcome number 1.

VI. SAMPLES OF PROJECTS & TEAM STRUCTURES

The following are three samples of projects in different formations:

A. All Male team

ElectReduce is a mobile application that aims at reducing electricity consumption by providing live feedback through mobile phones [1]. ElectReduce was the winner of Gulf-Imagine cup (mobile category) 2009. The product led to a publication in an international conference as well [1]. The team who developed the project went on to start their business and applied for a patent in Kuwait.

B. All Female Team

They Want They Do (TWTD) is multi-touch educational software that aims at teaching physically challenged students basic skills (English, Mathematics, colors, science) using computers. The application uses a combination of technologies in an economically feasible way. TWTD was tested in public schools for the physically challenged students in Kuwait [2]. TWTD is the winner of Gulf-Imagine Cup (software design on 2010). The team went to represent the region in the world finals in Poland (July 2010).

C. Mixed Team

Phyzio is a Kinect-based health software that connects pregnant women with their doctors. The main idea is that pregnant women perform the physical exercises in the form of a computer game using the Kinect sensor. The results are then forwarded to the appropriate doctor who in return advises the patients how to proceed. The project was among the best 5 projects in the Kuwait finals of Imagine cup, April 2012.

VII. ASSESSMENTS

A. Instructors' Assessment

- Culture plays an important role in team management activities. Since Kuwait is a conservative, traditional Muslim country, students tend to pick same gender team members. In a group of 40 students, only two groups had mixed-gender members.
- Competing in Imagine cup raised the quality and motivation level of students. This resulted in raising the average grade in the capstone class. The more teams in the class competing in the Imagine Cup, the higher the average class grade.
- Students definitely learn more and get more experience in handling real time problems as they have to set up their projects in 5 minutes (during presentations). Working under stress is the norm in software industry and competing in Imagine cup definitely prepares students to handle such situations professionally.

B. Students' Assessment

Numerical evaluation was around 4.6 out of 5 (based on anonymous survey that students have to fill around the end of the semester). Students' comments were very encouraging. For most of them, it was a life changing experience. Here are samples of students' evaluations collected anonymously at the end of each semester:

- "This course was the highlight of my senior years. I gained an experience in this course as i am taking whole semesters that i spent together to reach this level"
- "I believe the achievements of Dr. Amir Zeid this semester speaks for his evaluation. Taking 3 teams into the Microsoft Imagine Cup, and at the same time mentoring the rest of the teams in the class. He was able to take his team into the finals of Imagine Cup for the second year in a row"

VIII. CONCLUSION

In this paper, we introduced our experiences about integrating Imagine cup and capstone in Computer Science course. Participation in Imagine Cup has positive impact on capstone course. The contest helps solving typical capstone problems. The nature of the competition raises the level of interest for students in implementing their solutions. Once students start collecting requirements from real stakeholders the understanding of the life cycle process becomes much clearer. Students get trained to present their projects in front of panel of judges in a huge public event. The number of attendees is about 200 compared to the 25-30 normal audience in class room. Students develop the ability to stand, present and answer questions in a more confident manner. We used Imagine Cup as a case study for students design contests.

Work in Progress: The Integration of Human Performance Considerations within Aerospace Engineering Design Education

Alexandra E. Coso and Amy R. Pritchett

Georgia Institute of Technology, Cognitive Engineering Center, acoso@gatech.edu, amy.pritchett@ae.gatech.edu

Abstract—Humans play a vital role in the operation of aerospace engineering systems, whether in the cockpit of a spacecraft or in the control center for unmanned air vehicles. Current research in aerospace engineering design education is limited in defining ways to incorporate the performance considerations of the operator within an undergraduate design experience. In addition, few studies examine the effects of these design experiences on the industry preparedness of aerospace engineering graduates. This research aims to fill this gap by reviewing the design processes, learning outcomes, and pedagogical techniques related to human performance that are currently embedded in aerospace courses and curricula. A brief syllabi review found that aerospace capstone courses are generally comprised of a large-scale design project with requirements dictated by industry, NASA, or a professional society. The students follow a design process commonly defined by a classic aircraft or spacecraft design text. These techniques typically do not address design considerations which affect the operator's performance. This work-in-progress discusses these findings as well as proposed future work regarding (1) how to assess the effectiveness of these different techniques and (2) the development of an appropriate educational intervention to address human performance within capstone courses.

Keywords - Aerospace Engineering, Engineering Design Education, Aircraft Design Curricula, Human Performance

BACKGROUND AND MOTIVATION

Humans play a vital role in the operation of aerospace systems, whether in the cockpit of an aircraft or the control station for unmanned air vehicles. These systems operators interact with on-board automation, monitor system components, and control all or part of the system's dynamics. Due to the context in which aerospace vehicles function, system operators have been labeled as hazards or causes of error and, in some cases, accidents [1]. In addition, the defining characteristics of an aerospace vehicle and its subsystems can affect the operator's ability to complete his or her role effectively [2-4]. Thus, in the design of aerospace systems, it is critical to consider the performance of these human operators and the environmental context in which they operate.

However, current aerospace engineering education curricula emphasize quantitative methods and design processes to assess, for example, aerodynamics, mass sizing, and propulsion concepts. This contrasts with the qualitative

analyses and categorical descriptions used to define estimates of human performance, such as workload [5-7]. While many studies discuss ways to teach aircraft and space system design [7-12], few studies examine the effects of these design experiences on the industry preparedness of aerospace engineering graduates [13, 14]. This research aims to fill this gap by (1) reviewing the design processes, learning outcomes, and pedagogical techniques that are currently embedded in aerospace engineering design curricula and (2) identifying where education regarding human performance considerations could be better integrated into the curricula.

REVIEW OF CURRENT TECHNIQUES

Undergraduate aerospace students typically enroll in a capstone aerospace engineering design course during their final year of study. This course may be focused on aircraft, spacecraft, or another technical component (e.g. engine design). While course outlines vary from program to program, these design experiences generally include a large-scale team project accompanied by course content on the aerospace design process. The most variability among courses and programs comes from the required texts, the instructional approaches, and the requirements of the large-scale project. The subsequent sections describe three trends found in a review of publicly-available aerospace engineering senior design course syllabi from several universities, including MIT, Georgia Tech, Virginia Tech, University of Texas-Austin, Iowa State University, and Purdue University.

A. Human Performance Within Isolated Courses

Both MIT and Georgia Tech offer elective courses which focus on human performance within an aerospace system. These courses introduce students to factors which affect a human's performance, such as perception, attention and decision-making [15, 16]. Students also begin to examine effect of interactions between the human and automation on total system performance [15, 16]. These courses, however, are taught in isolation from the required courses in aerospace engineering fundamentals. By the time of a student's senior capstone design course, he or she may be unaware of the connections between their human performance-related elective and aerospace design.

B. Human Performance Within Design Textbooks

The aircraft design courses mention using one of three classic aircraft design texts [17-19], while space system design courses require *Space Mission Analysis and Design* [20]. In the aircraft design texts, the human component of aerospace systems is emphasized in chapters about sizing the fuselage, estimating the weight of flight deck avionics, and assessing the handling qualities of the aircraft [17-19]. The space systems text goes beyond the discussion of size and weight of the passengers and provides information about the physiological effects of space travel and human safety [20]. While these texts include important components relative to human performance, critical decisions about trade studies involving human performance metrics or where to consider human performance within the design process are not included.

C. Human Performance Within Design Competitions

Each year NASA and the American Institute of Aeronautics and Astronautics, along with industry and other organizations, publish design competitions for undergraduates to design an assortment of aerospace systems. These design tasks range from unmanned aircraft systems to air racers to deep space habitation modules [21, 22]. Each competition provides students with a Request for Proposals that dictates the requirements for the aerospace system they will design. Some past design competitions have focused on an array of human-related design requirements, including cargo handling system with time constraints for loading and unloading and the environmental effect of the reduction of the number of pilots in the cockpit [23, 24]. While this is not the case for all the projects and competitions, the inclusion of human-related requirements may facilitate the focus on human performance considerations within an aerospace design curriculum.

PROPOSED FUTURE WORK

Current aerospace engineering design curricula account for human performance considerations most commonly in the discussion of handling qualities or the size of the fuselage. These approaches forsake discussions about, for example, the implications of a design on the number of pilot training hours and the cost of training. Design curricula could, alternatively, examine the design problem from a holistic systems perspective by integrating the human component.

To further this idea, our future work will begin with a review of the learning outcomes and major concepts in capstone courses from other engineering disciplines and more human-centered design disciplines (e.g. industrial design, human-computer interaction). This will be followed by semi-structured interviews of systems design engineers from a large aerospace engineering company. These interviews will allow the researchers to engage in conversations about the major challenges faced by entry-level engineers on design teams.

The second phase of the research will incorporate an examination of the extent to which aerospace engineering students currently understand how human performance considerations can be integrated into the design process. Small assessments [25] will be used to determine how students' understanding and awareness develop over the course of a capstone design course, based on the current pedagogical

techniques employed (e.g. individual projects versus team projects, simulation-focused versus textbook-focused).

The final phase will be to implement an educational intervention into one section of an aerospace engineering capstone course at a large, research-intensive university and to evaluate its effect on students' understanding of human performance. The researchers will examine learning theories and pedagogies (e.g. situated learning theory and simulation based learning [13], expectancy-value theory [26, 27]) that have been used within the development of other capstone courses [28] to account for the complexities of engineering design education. The results of each phase and the appropriate learning theory will then be used in the design of this intervention which will introduce students to the integration of human performance within the aerospace design process.

EXPECTED OUTCOMES

The future work outlined in this paper will help define human performance-related learning outcomes for senior aerospace design capstone courses. The evaluation instrument will be designed with these learning outcomes in mind to examine students' understanding and perceptions of human performance considerations within the aerospace design process. The development and implementation of an educational intervention will serve as a starting point for future research in pedagogical techniques, integrating human performance considerations into engineering design education. In the design of the evaluation and the intervention, the researchers plan to permit future implementations within any aerospace design capstone course, regardless of the structure.

Over the next few decades, advanced aerospace designs will require engineers to consider critical design issues, such as the implications of fully automated commercial aircraft or long space missions on human performance. By incorporating the human performance component of design into aerospace engineering design education, we hope to assist faculty in preparing their students to respond to these and other future challenges in the aerospace industry.

Abstract— This paper investigates the design collaboration process between the Interaction Design (IXD) program and Engineering Projects in Community Service (EPICS) program at Purdue University. There have been quite a few recent research focused on analyzing the collaboration between Industrial Design students and Engineering students. However, little in the literature has been dedicated to discuss the education of Interaction Design and its collaboration with engineering programs. In this research, we tried to identify characteristics that differentiate IXD and EPICS students by focusing on the experiences of the IXD students. Some characteristics made the collaboration successful, but other created frustrations. In order to understand, explore, and evaluate the collaboration process, we collected the data during and after the collaboration and qualitatively analyzed it using a design collaboration model. This analysis identified several interesting features of this interdisciplinary collaboration. The collaboration between two programs benefited both sides and will be conducted regularly. The understanding gained from this study helps to understand and manage the discourse during the interdisciplinary collaboration, which will benefit our future education and inspire better interdisciplinary education and collaboration.

Keywords - service-learning, community engagement, interaction design, interdisciplinary collaboration

I. INTRODUCTION

The new generation of innovative technologies blurs the boundaries between objects and services causing an increased need of interaction design in engineering projects to improve users' experience. In response to such needs, we created the Interaction Design (IXD) program in Purdue University's Industrial Design (ID) program. Different from traditional Human-computer interaction courses in the computer science, this program tries to weave real-world projects into the courses, study related cognitive and social systems, employ research methodologies to evaluate and improve the industrial design, and adopt innovative technologies to better accommodate human experience [1].

EPICS is a recognized model for service-learning and design education where teams of students design projects serving to meet needs of local and global communities. Started at Purdue University in 1995 as an undergraduate program, it has grown to over 400 students per year [2]. Partnerships with community organizations provide benefits to both the community and to the students. Having real customers is very

motivating for the students and provides a compelling learning environment, while the community organizations benefit from access to knowledge and skills that the students and their team mentors utilize in the projects they deliver.

Professors of IXD and EPICS saw that the collaboration between two programs had great potential to benefit students from both programs and improve the deliverables to the community. In 2011, the IXD and EPICS programs collaborated by linking sixteen IXD students in eight pairs with eight EPICS teams. The collaborative projects range from science installations in Children's museums, iPad applications, interactive recycle devices, to project management systems. Overall, the collaborations were successful and received some positive feedback from the faculty advisors and the participants themselves. However, there were a variety of issues in the process. In order to understand and evaluate the collaboration, and improve the education experience, we collected the data from the IXD students during the design process through weekly progress blogs and end of the semester reflection. The purpose of this paper is to review and analyze the collected data and report this collaboration process from the IXD students' perspective. The sample of data analyzed in this paper represents one set of promising practices for supporting students' engagement around interdisciplinary development in a collaborative design process, while it also affords a glimpse into IXD students' understanding and process of meaning-making at a specific moment in time.

II. THEORETICAL FOUNDATIONS OF THE STUDY

A. Design Collaboration Models

Mattessich and Monsey's survey in collaboration literature [3] has drawn a clear distinction among cooperation, coordination, and collaboration. *Cooperation* is the informal relationship without a commonly defined mission, structure or effort. *Coordination* shares the understanding of compatible missions, but authority still rests with the individual organization. *Collaboration* connotes a more durable and pervasive relationship, and the authority is determined by the collaborative structure. To judge the collaboration type of a design, it is important to identify its mission, authority, and relationship.

Gero and McNeill [4] have shown that design is a process that consists of a series of distinct events that occupy discrete

and measurable periods of time. Most significantly, the temporal span of these design events is remarkably short (15 to 30 seconds). As collaborators come together in design, Kvan [5] suggested that collaboration is also episodic and cyclical. This means that design remains a series of discrete steps. Collaborators work together for moments, then divide up and go their separate ways. Gasson [6] proposed that collaborative design consists of parallel expert actions, each of short duration, bracketed by joint activity of negotiation and evaluation. Thus the design activity itself is discrete, individual and parallel, not intimately linked. This theory strengthened Kvan's model demonstrated by **Error! Reference source not found..**

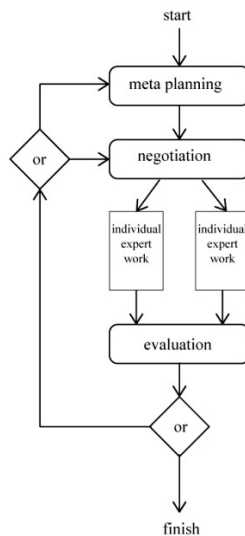

Figure 1. Kvan's model of Design Collaboration [5]

B. Design Collaboration between ID and Engineering

Employing Industrial Design (ID) collaborators to enhance Engineering Education have been studied for more than three decades [7], [8]. There are studies on the educational perspective[9], [10], and design methodology [11]. Esko Kurvinen [12] outlined critical settings and situations that should be taken into account when industrial design is introduced to engineering-oriented product development. In biomedical engineering, Jay Goldberg [13] argued that engineers and industrial designers tend to emphasize different aspects of design. Engineering students tend to focus on the technical aspects of design while industrial design students focus on usability, safety, quality, and the aesthetics of products. Both disciplines place heavy emphasis on identification of customer needs, manufacturing methods, and prototyping. A number of recent research efforts [9], [10], [14] focused on analyzing the collaboration between Industrial Design students and Engineering students in various projects.

C. Design Collaboration between IxD and Engineering

In recent years, researchers interested in studying problems involving complex interactions on human-machine system have risen. Numerous researchers highlighted the importance of user interface features in design as the design will help users

to predict what will happen towards the system [15] [16]. Despite the fact that there are many research studies related to Interaction Design and complex technology products have occurred, still there are limited literature reviews highlight on the emerging themes in Interaction Design, such as the role of methods and theories, interaction design processes and design criteria [17]. Even little in the literature has been dedicated to discussing the education of IxD and its collaboration with engineering programs.

According to the literature review, currently there is no established collaboration framework of Engineering and IxD for us to refer. However, different design collaboration models reviewed are helpful for us to understand and analyze the process. Furthermore, the different aspects of ID designers and engineers are informative to explore the differences between IxD and EPICS students.

III. THE CONTEXT OF THE STUDY

The context for the study was the EPICS Program at Purdue University. EPICS is a multi-disciplinary, engineering-centered design program that teaches human-centered design within a service-learning context. EPICS projects have significant impact on both community and students. Projects can extend to multiple semesters to allow students to see the entire design cycle. The maturity of different projects varies at any point within the semester. Students can enroll in EPICS multiple semesters for one or two credits per semester. While the majority of students are from engineering, the project teams are multi-disciplinary with over 70 majors represented throughout the program last academic year. The teams are also multi-level with first year through senior students. EPICS counts as a technical or lab elective in several engineering departments and as a senior capstone design in Electrical, Computer Multidisciplinary and Environmental Engineering as well as Computer Science. Outside of engineering it counts as various electives, options and selectives. EPICS teams use a human centered design process to address diverse needs within the community through the application of technology [17][18]. Within the teams there are specific roles such as team leader, project leaders, community liaison and financial officer [19]. To collaborate with IxD course, EPICS directors Oakes and Zoltowski selected eleven projects that would benefit from the collaboration with interaction design. Considering the nature of projects and availability of collaborators, we narrowed them down to eight design projects:

- Wireless power (Imagination Station (IS), partner with the Children's Museum in Lafayette)
- Laser harp (IS team)
- Wind tunnel (IS team)
- Cell model (Cellular Engineering Demonstrations (CED), partner with Biotechnology Center in the Children's Museum in Indianapolis)
- Gene Expression (CED team)
- iPad application development for students with special needs (Greater Lafayette Area Special Services/GLASS team)

- myEPICS production system (Information Management System (IMS) team)
- Interaction recycling disposal unit (Boil Green Initiative/BGI team, Purdue EPICS teams [20])

These eight projects range from physical museum installation to digital interface design, from mobile application to strict system development, and their users range from museum visitors, students with special needs, sport fans to EPICS students themselves. These projects are supervised by Supervised by five different EPICS instructors. Professor Qian led sixteen design students in an IxD course. These students range from sophomores to first-year graduate students. Although they have different proficiency in IxD, all of them have received solid design training from industrial design program.

During the first class, EPICS instructors introduced these projects to all the IxD students. Each student was able to rank the projects into his/her own favorite list. After a little bit adjustment, all the students were able to join either the first or the second of their most favorite projects. For each of EPICS projects, there were two IxD students as interface design collaborators. Every week, apart from attending one hour lecture and three hour software workshop in Qian's class, IxD students went to join the EPICS classes to collaborate with their team members.

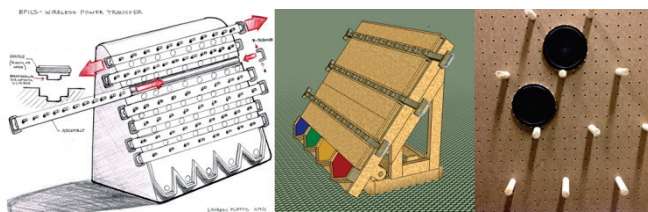

Figure 2. Sketch, digital model, and physical model of Wireless Energy Transfer Project (IS team)

Figure 3. Interactive recycling bin designed for the 2012 Super Bowl in Indianapolis (BGI team)

At the end of 2011 fall semester, eight projects all achieved different stages of success. For example, the interface of wireless power installation was re-modeled and enhanced (Figure 2). The interactive recycling bin (Figure 3) has entered the usability testing stage in the events of Purdue football and basketball games. The iPad application for students with Autism with improved interface and interaction design (Figure 4) has entered the iTunes Apple store.

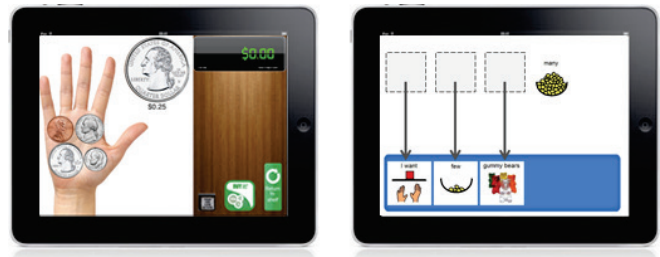

Figure 4. Interface of iPad application for Autism students (GLASS team)

IV. DATA COLLECTION AND ANALYSIS

These design collaborations lasted for a full semester (16 weeks). We received some very positive feedbacks from students, instructors, and external industry reviewers. However, there are a variety of issues existing in different teams. To understand and evaluate the design collaboration process from the IxD student's perspective, we collected the data of their progress through the whole design process, asking each IxD team to blog their weekly progress, and recorded their collaboration reflections at the end of the semester. Apart from this information from IxD students, we also collected external reviewers' notes and reactions from EPICS instructors and team leaders to gain an overview of the whole scope.

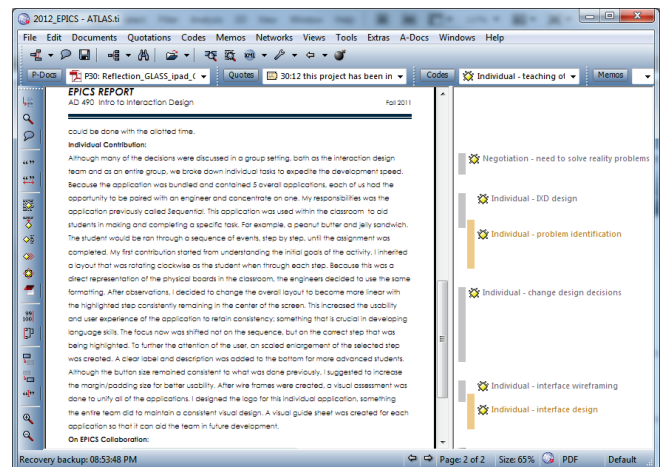

Figure 5. Coding IxD students' blogs and reflection reports in ATLAS.ti

We used ATLAS.ti [20] to analyze IxD students' blogs and reflection notes. In order to code these data, we adopted Kvan's design collaboration model [5] to divide the collaboration process into four stages: meta planning, negotiation, individual expert work and evaluation. After coding 39 documents (Figure 5), we generated 74 codes to identify different issues in the collaborative process. Some sample codes are like: "meta planning – wait for industrial partner's response", "negotiation – narrow down brainstorming ideas", "individual work – interface wire framing", and "evaluation – unsolvable technical problems". Through judging code relationships and connecting them through different logic links (be associated with, be part of, etc.), we created the code networks (Figure 6) to understand the problem scope.

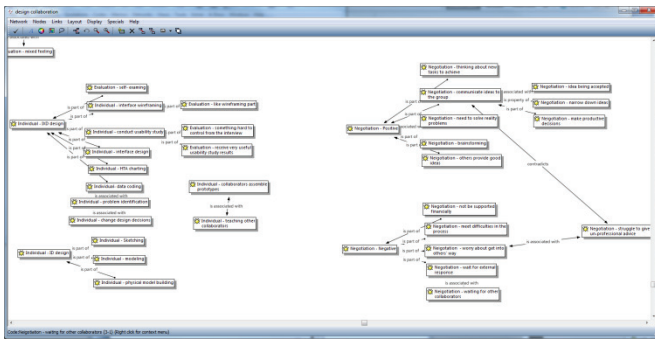

Figure 6. Part of the network view in ATLAS.ti

A. Meta Planning Stage

The stage of meta planning took place after student collaborators have got familiar with each other and started to explore their design problems and assign tasks. Some teams were well-organized, starting from designing the procedure of usability studies and discussing details of interviews. Some team decided to develop a new visual language in order to create continuity between the different games and tie the application together as a logical whole. Some problems started to emerge during this early stage:

- Schedule problem: e.g. Collaborators' course schedules conflicted and hard to find meeting time outside of class. Students were unclear about the project's milestone by the end of semester.
"I had thought at first that this project would be wrapped up by the end of the semester, but it is nowhere near completion."
- Communication problem: e.g. long waiting time for external response from community partners.
- Emotional problem: e.g. there is a tension existed between old participants and new participants.
"Members who were previously on the team seemed to be reluctant to move forward and change some components of the design. The new members would come up with improvements and suggest them, but it seemed as though the older members would disregard them."

Overall, most of the IxD students were "excited" and self-motivated to develop good design since it was their "first time" to collaborate with engineering students and they were going to work on their most favorite projects.

B. Negotiation Stage

The negotiation stage is the period when most main decisions were made. According to the data, the condition split to two parts.

- From the positive aspect, some students were able to communicate their ideas smoothly to the group and got accepted. The whole team brainstormed together in an active way or narrow down to some really cool ideas effectively. From the reflection reports, some students confirmed that other collaborators provided really good

ideas. Some were motivated to propose new design directions:

"I'm feeling the need to regroup myself and create more in terms of output".

- From the negative aspect, different issues showed up such as: the expense of IxD students was not financially supported in some teams, some students felt themselves got into other engineers' way, waited for a long time to get their collaborators' updates, or struggled whether their design would satisfy their collaborators.

"I'm still struggling to have some visual output. So far, all I have are my Persona pages, which really don't have much to do with the operations of the system".

C. Individual Expert Work Stage

Most of the sixteen IxD students have received Industrial Design training since Purdue's IxD program is a branch of its ID Major. While working the EPICS projects, they were able to practice their different design skills:

- IxD design skills: Some students focused on interface design in their teams. They started from drawing the Hierarchical Task Analysis (HTA) charts to understand the current interaction problem, used wire framing to build the interface structure, and then applied graphic design to the interface. Some students adopted user experience study methods to design, implement, code, and analyze usability issues. Though conducting such studies, they were able to receive very useful results.
"As it turned out, we had a good group who not only left good feedback on the paper survey, but were also quite vocal during the focus group."
- ID design skills: In some teams, IxD students were involved in drawing sketches, creating computer models, and building physical models. These students were confident and proud of their quick prototyping skills: "I created the organelles and other CATIA files that are used for 3D printing and cutting out the placement of the organelles in the big Cell."
- Some of them were quite happy that they could teach their engineering partners something – "advising the engineers on options for materials and processes for manufacturing our receiver coil casings, and actually building receiver coils".
- Sometimes, they were also frustrated with their engineering collaborators' productivity: "Even though working on a team was fun, there were times that made things difficult while working with EPICS. At times it seemed like that unless XX and I were there, nothing really got done".

D. Evaluation Stage

As with the other collaboration stages, the IxD students reported having both positive and negative experiences in the design evaluation stage. Shown by Figure 6, the code amounts of two different groups are about the similar size.

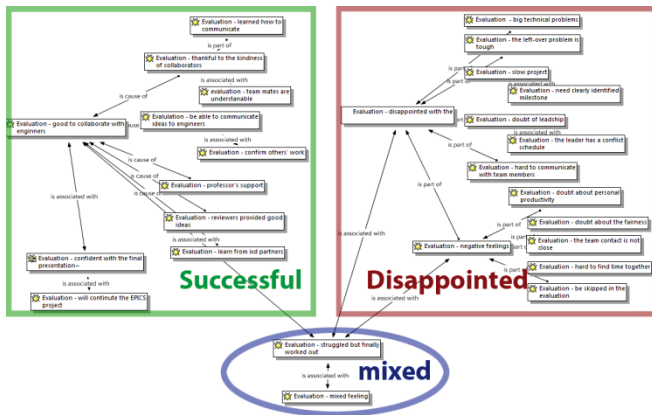

Figure 7. Code network view of Evaluation in ATLAS.ti

From the positive perspective, lots of students were thankful to the kindness of their engineering collaborators.

- They felt they were “welcomed” by the teams, they can communicate ideas with engineers, and their contributions were “confirmed” and “appreciated”. “It was a great pleasure to be welcomed and engaged in a dynamic team of different major, to be able to draw from one another’s skill sets, learn from each other’s experiences, and grow as an individual and as a designer.”
- They confirmed the skills of their collaborators: “My closest project partner (my programmer) XX, was an extremely talented computer science major with a very advanced knowledge of the coding language we were using for the application. This made it easy to refine and implement new changes to our game throughout the semester.”
- They also stated that they learned a lot from their engineering collaborators and the collaborative experience itself: “I learned a lot about collaborating with other groups, especially engineering departments that are really the rhyme and reason to the design groups.”
- They appreciated the good ideas contributed by the external reviewers, and acknowledged some instructors’ kindly support: “I really enjoyed meeting everyone on my team and Professor XX. He was like the second voice for us when we felt like things weren’t getting done. He was able to talk to the other team members and express our frustration without putting us on the spot with the other members of our group.”

These positive attitudes lead to their confidence with the final presentation of project. Four of these sixteen students mentioned that they would take EPICS courses to continue their projects in the future semesters.

However, our coding result also demonstrates a negative aspect. There were mainly two types of problems: the structure of collaborative project and social issues.

- In the collaboration, IXD students were used to defined schedules and wanted clearly identified milestones of the projects. They found the developments of some projects were too “slow”, or the left-over problem of previous semester is so “tough” that their engineering collaborators were not able to solve the technical problems as they expected. Apart from the class time, it was difficult to find time to work together.
- From the social communication aspect, some students did not trust their leaders’ capability or responsibilities. Because of the limited presentation time during the project reviews, lots of their slides were skipped. Without the opportunity to present their contribution, they started to doubt the fairness in the collaboration and suspected their contributions were “ignored”.

In Figure 7, there are two codes, “struggled but finally worked out” and “mixed feelings”, bridging the left “successful” scope and right “disappointed” scope. These two codes were shared by lots of reflections and described a fact in this design collaboration experiment: the interdisciplinary collaboration is challenging and even frustrating, but it is still possible to work out with a successful ending. Students in this category carried on a mixed feeling upon this experience: unsatisfied with some issues but still felt engaged in the teams and expected to see the success of project. This small “mixed” scope is an important and honest portion to present the reality.

E. Feedback from EPICS Instructors and Reviewers

The reaction from the instructors was overall positive. The collaboration provided valuable perspectives on the project with a greater emphasis on the users. EPICS teaches a human-centered design process and the addition of the IXD students brought more students with the user focus into the teams more explicitly. The IXD students not only had a focus on the user, but they had tools to bring to the teams to implement the human-centered design steps. Interestingly, one manifestation of these tools was the increase in prototypes. The IXD students were very comfortable working in the lab making prototypes and often pushed the engineering students to build simple prototypes more quickly. There were tangible benefits to the quality of the end project with the additional features and attention to users from the collaboration. Students on the EPICS teams wanted the collaborations to continue and in a couple of cases talked the IXD students into continuing into the next semester as part of the regular EPICS team.

Some of the challenges included the fact that it was difficult to monitor the collaborations of the teams that did not meet at the same time as the IXD course. These teams often met in the evenings or during the day when the instructor was not present. Some EPICS students were taking it for only one credit hour and the participation in the collaborative sessions left little time to implement suggested solutions. While most teams integrated well, a few struggled to find a complimentary set of roles for their project.

V. DISCUSSION

We employed Kvan’s design collaboration model [5] to catalog the data into four stages, in reality these stages were

implicitly mixed up. In a blog, a student started from evaluating a problem he met, then discussed his work in that week and then described how he negotiated with his collaborators. There was no clear sequence for these events at all. This fact actually matches well with Gasson's theory [6]: the design activity is discrete, individual and parallel, not intimately linked.

Considering Mattessich and Monsey's distinction structure [3], this collaborative experience was actually a mixture of coordination and collaboration. Although students of both sides carried the same mission, they were judged by different instructors in different courses and the duration of collaboration is comparably short. Luckily, students contributed sincerely in the projects and didn't make that issue serious.

According to Jay Goldberg [13], engineering students tend to focus on different aspects of the projects. From the observation, we found that IxD students shared some characteristics with ID students (such as ergonomics and aesthetics), they tended to be more interested in sketching and wire framing user interaction and conducting usability studies to understand the problems. Furthermore, they cared a lot about the milestone of projects and socially they wanted their ideas to be accepted, implemented, and presented. More importantly, since some design decision were implicit in the final outcome; they wanted their contribution to be recognized and confirmed by their engineering collaborators.

For an interaction designer, there is a strict process to go through: identifying the design problems, brainstorming the ideas, selecting the alternatives, and prototyping the solution. EPICS students are taught a similar human-centered design process that involves iteration, prototyping, testing and evaluation and ultimately delivery of a working design to the community. However, since the EPICS projects span multiple semesters and all of the selected projects were in on-going stages, it was impossible to run a complete process of interaction design in one semester. This may model well industrial teams where team members are often brought into on-going projects. Most of students adapted to the context quickly and figured out a way to contribute their design ideas. This collaboration process also demonstrated the flexible potential of interaction design.

VI. CONCLUSION

The collaboration of IxD and EPICS was successful and benefited both sides. Feedback from the instructors and design reviewers were positive and encouraging. We plan to continue the collaboration with the insights gained from this research to help us manage the process. This paper focused on the IxD students' perspective. Unavoidably, some opinions were biased. In the future, we plan to collect more rigorous data from the EPICS students and understand to capture the whole collaborative experience from all perspectives.

Like any collaborations, there were lessons learned and areas to improve. The next iteration will include more preparation before the collaboration starts, set clearer goals motivate and help them throughout the process with more successful outcomes. Scheduling of team meetings will be more explicitly discussed and be a more prominent factor in matching the teams. In the long run, the information gathered

will enrich our understanding of interdisciplinary collaboration format and improve how we implement such experiences to the benefit of the students and the communities we serve.

Abstract—The Collaborative Process to Align Computing Education with Engineering Workforce Needs (CPACE) team developed a partnership among various stakeholders to identify the computational skills that are essential for a globally competitive engineering workforce. Our goal is to redesign the role of computing within the engineering programs at Michigan State University (MSU) and Lansing Community College (LCC) to develop computational competencies – informed by industry needs – by infusing computational learning opportunities into the undergraduate engineering curriculum. In this paper we summarize the process that we used to translate our research findings about the computational competencies needs in the engineering workplace into fundamental computer science (CS) concepts that can be used in curricular implementation. We also discuss the initial phase of our curricular implementation strategy in two disciplinary engineering programs at MSU and transfer programs at LCC.

Keywords—component; Computational thinking in engineering; industry to academia; curricular reform

I. PROJECT IMPLEMENTATION STRATEGY

The CPACE project is divided in two phases: During the initial phase we: a) identified the computational competencies needed in the engineering workplace; b) developed a ‘data-to-computer science (CS)-concept map’ to translate our research findings into CS concepts that can be used in curricular implementation. In the second phase we are using this concept map as a framework to guide the implementation of curricular revisions in Chemical and Civil Engineering at MSU and pre-engineering courses at LCC.

A. Workforce Computing Needs

Based interview and survey analyses, we developed an understanding of industry needs with regard to computational competencies both at the practical-tool level and at the computational problem-solving level. Our findings [1, 2] are consistent with other research on engineering education [3, 4] and indicate that employers: (a) value interpersonal skills, ability to organize and present data, and the ability to function in a team; (b) value critical and innovative thinking, and problem solving; (c) see trends towards computational globalization, which translates to the need for engineers to understand business practices and the importance of integrating engineering data across larger systems; (d) value the ability to

understand both engineering and computational principles that allow them to select and use computational tools to solve engineering problems by moving between physical systems and abstractions in software. Excel, CAD, modeling software, and data and project management software were identified as very important to the engineering practice.

B. A Framework to Align Workforce Computing Needs to Computer Science (CS) Concepts

To translate our interview and survey data into CS concepts that can be integrated in the curricula we evaluated three different frameworks: 1) *Great Principles of Computing* [5]; 2) *Computational Thinking* (CT) [6]; 3) *Being Fluent with Information Technology Report* [7]. The CS concepts enumerated in the latter are instantiated in practical technologies and applications that allowed us to move from the computational competencies identified in our industrial data to CS concepts that can be integrated in the curricula and offered the best framework to complete our alignment. Detailed discussion of the alignment process and findings are presented elsewhere [2].

The chart in Figure 1 shows the distribution of the computational competencies—required in the engineering workplace—mapped to CS concepts. We are using this CS concept distribution as a framework to guide the design and implementation of the curricular reform.

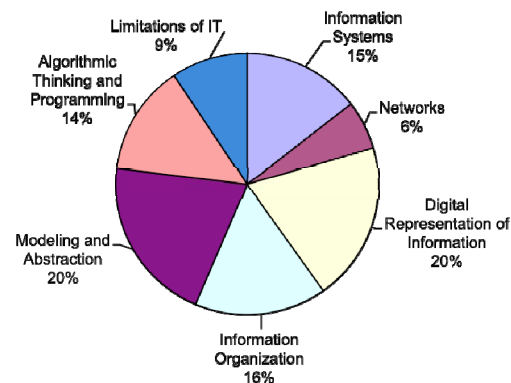

Figure 1. Distribution of engineering workplace computational competencies aligned to computer science concepts.

II. CURRICULAR IMPLEMENTATION

The learning sciences have influenced repeated calls for improving engineering education that focus on providing students with the opportunities to integrate their knowledge across disciplines through authentic problem solving [3].

To accomplish an integrated computing experience our goal is to infuse computational competencies throughout all four years of the engineering curricula [8] and use problems derived from contemporary industrial engineering practice. These problems provide a context where students are required to apply the various computational concepts (Figure 1) for their solution. To collect and develop these problems we have a collaborative team of industrial partners, disciplinary and CS faculty. Key courses are addressed throughout the degree programs on ChE and CE at MSU and pre-engineering transfer courses at LCC.

A. Data Collection and Analyses

Following a mixed methods approach, quantitative and qualitative data are collected through faculty, student, and other stakeholder surveys at the beginning and end of the target courses. The goals of the surveys are: (a) to measure attitudes towards engineering in general and (b) to measure attitudes towards computational problem solving in particular. Other types of data collection include: Systematic observation of selected project and classroom activities; standard class data on learning outcomes and sample course work e.g. final project reports and homework assignments; and faculty and student interviews. We use SPSS V 19 for all analyses.

B. Survey Results

Preliminary results indicate that participation in the course project is helping students feel more confident with respect to their computational skills and competencies. Table I presents a subset of data comparing a freshman course at MSU with the equivalent transfer course at LCC. In the MSU course, the self-reported gains in most computational skills are statistically significant ($p=0.001$). At LCC students report gains in algorithmic thinking and programming skills ($p=0.01$).

TABLE I. COMPUTATIONAL SKILLS RATING: FIRST YEAR (MSU) AND TRANSFER LEVEL (LCC)

| Skill | Transfer LCC* N=11 | | Freshman MSU* N=85 | |
|--|-----------------------|-------------------|-----------------------|-------------------|
| | Before | After | Before | After |
| I can move data from EXCEL into MATLAB. | 4.91 ¹ | 4.91 ¹ | 3.27 ² | 4.61 ² |
| I can check the results of running MATLAB and debug my functions. | 4.36 ¹ | 4.64 ¹ | 3.41 ² | 4.32 ² |
| I can write a correct FOR loop in MATLAB. | 2.55 ³ | 4.45 ³ | 2.08 ² | 4.55 ² |
| I can write a correct nested FOR loop in MATLAB. | 2.09 ³ | 4.36 ³ | 1.99 ² | 4.47 ² |
| I can write MATLAB code that will find the largest number in a 3D numerical array. | 2.82 ³ | 4.27 ³ | 2.78 ² | 4.61 ² |

* Mean; 1. Not significant; 2. Significant $p<0.001$; 3. Significant $p<0.01$; 4. Significant $p<0.05$

Interestingly, data comparisons between the freshman and the sophomore courses at MSU indicate a loss of confidence in the use of some skills from the time students take the freshman course to the time they enter their sophomore year. After our intervention the sophomore students regain confidence in the use of those skills and in some instances return to the initial levels of confidence shown in the freshmen year course.

III. SUMMARY AND FUTURE DIRECTIONS

The CPACE project brings together post secondary educators and industry and community leaders in a collaborative process to transform undergraduate computing education within the engineering and technology fields. Based on interview and survey data analyses we developed an understanding of industry needs with regard to computational competencies. We developed a CS concept distribution framework to guide the design and implementation of a curricular reform (Figure 1). The goal is for engineering graduates to enter the workforce with improved and practice-ready computational competencies that are aligned with industry needs and enable students to integrate conceptual knowledge, technical skills and professional practice. To accomplish this goal we are introducing a series of problems derived from engineering practice in target courses across all four years of the engineering curricula.

The data analyses presented in this paper correspond to the first year of implementation. While encouraging, these are preliminary analyses from self-reported student data and we are in the process of analyzing other data streams including more objective measures such as course and project grade, and other sample course work. Our plans for the second year of the implementation phase include: collection of engineering problems; instructional design and development of course supporting materials, and data collection and analyses.

Uncovering and Repairing Crystal Structure Misconceptions in an Introductory Materials Engineering Class

Abstract – The crystal structure of a metal plays an important role in its relationship to its macroscopic properties as well as atomic mechanisms of structural change. As such, students need to have an ability to visualize planar crystal atomic packing features, but often find it difficult. Thus, the research question here is, "How can a student's baseline knowledge and misconceptions of planar atomic packing features for different metal structures be measured and how well can instruction promote conceptual change and misconception repair." Answering this question will provide insight for developing more effective pedagogy for crystal structures. A multiple-choice survey with six items was developed using misconceptions from students' pencil and paper sketches of face-centered cubic (FCC) and body-centered cubic (BCC) atoms on (100), (110), and (111) planes. Pretests and posttests of the survey were administered to students in a Spring 2012 introductory materials engineering course. Misconceptions that were revealed included: missing atoms, extra atoms, misplaced atoms, "non-touching atoms where they should touch"; and "touching atoms that should not touch". Students' difficulty in solving increased from (100) to (110) to (111) planes for both BCC and FCC structures. Details of the survey instrument and results are described in the paper.

Keywords–*crystal structure; visualization; misconceptions; conceptual change; assessment*

I. INTRODUCTION

The book, *How People Learn* [1] states that, one of the most important principles for more effective teaching and learning is that instructors should be aware of students' prior knowledge as developed from academic courses and personal experience. As such, concept tests, such as the Force Concept Inventory [2], the Statics Concept Inventory [3], and the Materials Concept Inventory [4], can reveal knowledge gaps, skill gaps, and misconceptions. Knowledge of such issues can then inform classroom practice and instructional materials. In introductory materials engineering courses, one of the key topics that students need to understand as part of the underlying microstructural basis for properties of materials, is the topic of crystal structures. An important aspect of instruction on crystal

structures is that students need to develop an ability to visualize two-dimensional projections of atom locations on differently oriented planes for different crystal structures. Such understanding will help students describe relationships between a material's crystal structure and its macroscopic properties, such as elastic modulus, and atomic-level mechanisms that play a role in determining the yield and tensile strength of a material. As such, a method is needed for characterizing a student's misconceptions and baseline knowledge of crystal structures, as well as the effectiveness of instruction designed to promote knowledge and understanding of crystal structures. Thus, the research question for this paper is, "How can a student's baseline knowledge and misconceptions of planar atomic packing features for different metal structures be measured and how well can instruction repair misconceptions and promote conceptual change."

II. BACKGROUND

A. Spatial Visualization

There is a strong relationship between spatial ability and success in science and engineering that is well documented. In engineering, Hsi, Linn, and Bell found that spatial ability predicted course grades and strong spatial skills were necessary for success on course exams [5]. In addition, instruction in spatial strategies improved problem solving and contributed to confidence in engineering, especially for women. Peters, Chisholm, and Laeng also found that initial gender differences favoring males were reduced with practice [6]. No gender differences were found for performance in the associated course. It was found by Piburn, et. al. there was a relationship between visualization skills and success in geology. Moreover, they found that spatial visualization scores were as strong a predictor of success on a geology test as was prior knowledge [7]. They also found that practice on spatial tasks eliminated gender differences. Additionally, Sorby & Baartmans found that a course that was developed specifically to strengthen the visualization skills of engineering students led to greater

The authors of this paper acknowledge support of this research from NSF grants IEECI #0836041 and CCLI #0737146.

persistence in engineering, higher grade point average (GPAs) upon graduation, and better spatial skills for students who took the course than for students who did not take the course [8]. Thus, it can be seen that spatial visualization ability plays an important role in learning engineering, which may be influenced by group dynamics and may also be related to problem solving, retention, and GPAs. The work in this research is intended to contribute to this body of knowledge on the impact of spatial visualization ability on engineering success.

B. Assessment of Knowledge with Pre-Post Topical Quizzes

Constructivist pedagogy is now being applied to teach some introductory materials science and engineering courses [9]. Students' conceptual knowledge baseline and conceptual knowledge gain have been assessed across a semester with the Materials Concept Inventory (MCI). This assessment tool is a 30-item, multiple-choice, pre-post course instrument [4, 10, 11]. This summative instrument measures a student's baseline conceptual knowledge of materials science topics at the beginning of a semester and conceptual knowledge gain for the entire class after it is again administered at the end of the semester. There are two questions on the MCI that are related to crystal structures. In the first question, students are asked to determine how many faces and edges are characteristic of a cube, while the second question queries about how many body diagonals are found in a cube. Surprisingly, for these two questions, students at the beginning of the course only get both items correct about 60% to 70% of the time. By the end of the course, on the exiting MCI, the scores improved to 75% to 85%, but never reached a level of 90% and higher. These results demonstrate the difficulties students have in applying spatial visual thinking skills to relatively straightforward tasks in an introductory materials science course.

In order to determine in more detail the types of misconceptions students hold about crystal structure geometry features, a Pre-Post Topic Quiz was developed for crystal structures. It was administered as a classroom activity before the topic of crystal structures was taught and again after instruction on the topic had been completed. In this test students sketched images of atom projections on different crystal planes as deduced from looking at 3-D images of face-centered cubic (FCC) and body-centered cubic (BCC) crystal structures. The goal of the sketches was to project the atom positions in those two structures onto the crystal's major crystal planes of (100), (110), and (111). The crystal structure sketching activities were used to inform instruction and measure conceptual change. A pre-topic test measures baseline conceptual knowledge and reveals misconceptions and knowledge gaps present. After instruction, the same test measures conceptual gain and remaining misconceptions which are classified as robust misconceptions. These topic pretests and posttests assess with finer granularity and greater depth a student's conceptual understanding of a given topic, as well as revealing students' misconceptions and knowledge gaps for that topic. These are summative across a given topic but, in a sense, they are also formative assessments because they assess a small segment of content within the course. Such formative

assessments can immediately inform the instructor of student understanding of the current content. Formative feedback at this stage of instruction has been shown to be very effective when carried out in real time. This was also true in the materials class when sketched crystal structure atom projection results were given to students.

III. METHODS

A. Development of a Crystal Spatial Visualization Survey

A paper and pencil assessment was created to test students' crystal structure spatial visualization skills and administered before the topic was presented. It was given the past four semesters to 30 to 40 students per class. The types and frequencies of misconceptions were compiled from looking at the frequencies of the misconceptions in the quizzes. The misconceptions from the sketched concept tests were used as the basis for incorrect answers in a multiple choice test, the Crystal Spatial Visualization Survey (CSVS), developed and used for the first time in the Spring 2012 term. A typical sketched pretest is shown in Figure 1 in which a number of misconceptions can be seen. For example, the FCC (110) shows two extra atoms inside the (110) plane. Next, the FCC (111) plane shows two misconceptions; one is the extra atom in the center of the triangular boundary and the other is the fact that atoms should be touching but are not. This is a particularly important misconception because the student does not see that the FCC (111) is a close packed plane on which dislocations would glide. For the BCC (111) there is also a misconception which occurs frequently. There is an extra atom in the center of the plane which represents the body-centered atom. However, for an atom to be on a plane, the atom center must lie on the plane, which students often forget.

Misconceptions like the ones just discussed were used for incorrect answers in multiple choice questions. For any given question, four of five multiple-choice incorrect answers (distractors) were generated from misconceptions from pre- and post topic sketched topic quizzes. Overall, six major types of misconceptions were revealed in the sketched topic quizzes which were incorporated into the multiple choice topic quiz. Figures 2 and 3 show new multiple choice question sets for FCC and BCC crystal structures with the intersecting planes being the (100), (110), and (111) planes. In the next section on results, a comparison of the results of a set of 2009 sketched atom projections are compared to the results of the 2012 multiple choice exam.

IV. RESULTS AND DISCUSSION

The new 2012 multiple choice topic test was compared with the 2009 sketched topic test. The most frequent misconceptions from the 2009 test and the 2012 test are shown in Table I. An overall comparison of those results is found in Tables II and III. Table II summarizes the percentages of pretest answers for all choices for the sketched images in 2009 and, in parentheses, the percentages of pretest answers for the 2012 multiple choice test. Similarly, in Table III there is a corresponding set of results for the posttest results.

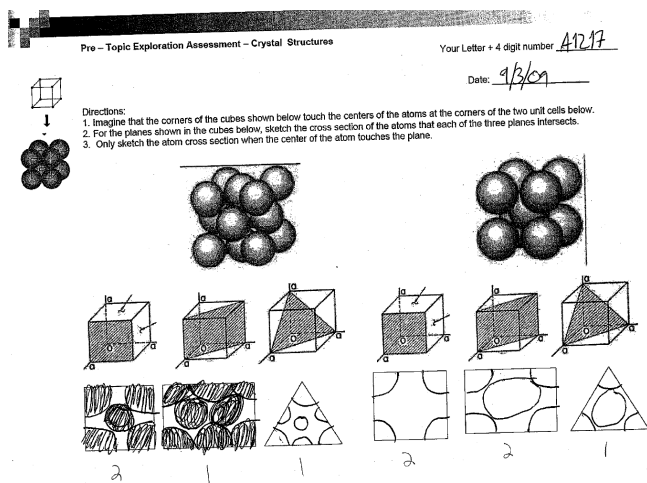

Figure 1. Student Pre-Topic Quiz for FCC and BCC crystal structures for the (100), (110), and (111) planes.

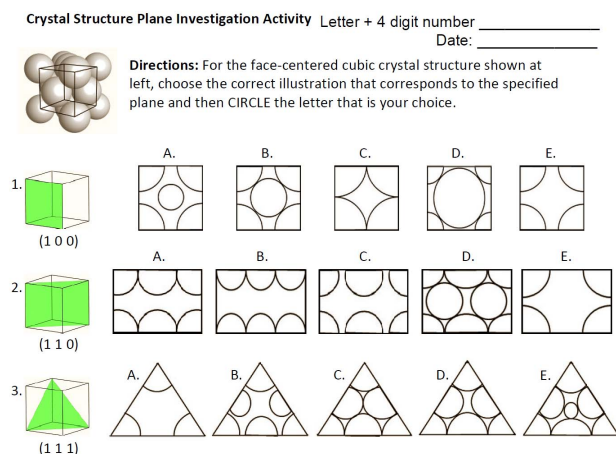

Figure 2. Student Pre-Topic Quiz for an FCC crystal structure for the (100), (110), and (111) planes.

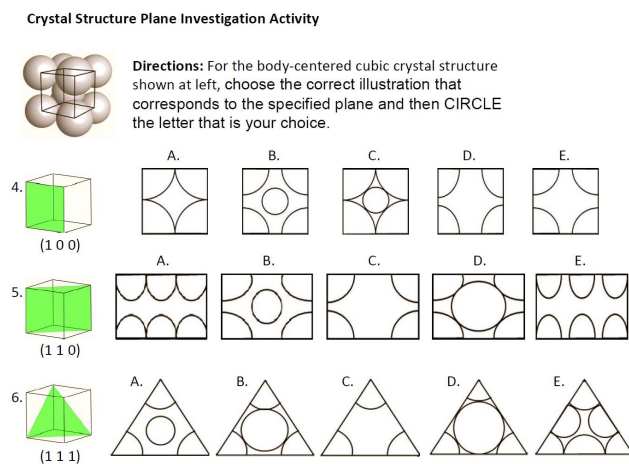

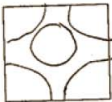

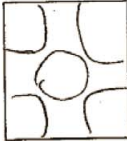

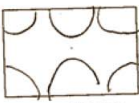

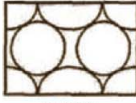

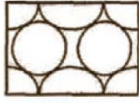

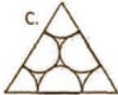

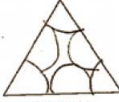

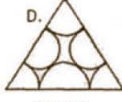

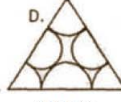

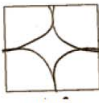

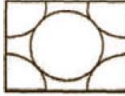

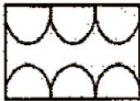

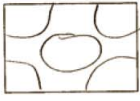

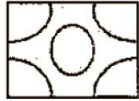

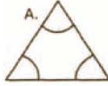

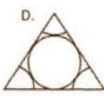

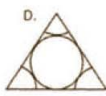

Figure 3. Student Pre-Topic Quiz for a BCC crystal structure for the (100), (110), and (111) planes

In general, it was found that there were six main types of misconceptions that occurred with different frequencies. The most frequent misconceptions are shown in Table I for the 2009 and the 2012 FCC and BCC crystal structures for the (100), (110), and (111) planes. The most frequent misconception was "atoms correctly located, but not touching where they should", with 12 times. This is seen for both the 2009 sketched pretest and also posttest: FCC (100); FCC (110), FCC (111), and BCC (110). It was also seen for the 2012 multiple choice test: pretest FCC (100) ; pretest and posttest FCC (111) ; and posttest BCC (110). The next most common misconception, seven times, was "extra atom(s)" as seen for: pretest and posttest 2012 FCC (110) ; pretest 2012 BCC (100); and all pretest and posttest 2009 and 2012 BCC (111). The next most common misconception is "atoms touching but should not" which occurs for all four pretests and posttests 2009 and 2012 BCC (100). Other less frequently occurring misconceptions included: "missing atom", posttest 2012 FCC (100); "displaced atoms", pretest 2009 BCC (110); and "differently sized atoms", pretest 2012 FCC (100) and pretest 2012 BCC (100).

The summary comparison for percentage of correct pretest and posttest responses for the 2009 sketched test compared to the 2012 multiple choice test is given in Table IV. The average percentage correct for the six items for the pretest in 2009 is 35% and for 2012 is 43%. These values are generally similar for some individual items, but the types of misconceptions sometimes differ. In the posttest there are definitely some anomalies. The average percentage correct for the six items for the posttest in the 2009 sketched test is 37%, a gain of 2%, and for the 2012 multiple choice test result is 72%, a gain of 29%. Additionally, for the 2009 sketched pretest and posttest, some scores actually went down; FCC (100) decreased from 65% to 47% correct and BCC (110) decreased from 41% to 18% correct. In re-examining the data, what had happened was that, in the pretest, many students who had correct answers with atoms touching at correct positions changed to an incorrect answer, atoms at correct positions that *were not touching*. In the 2012 posttest, students after instruction selected the correct answer from five choices and recognized when atoms were touching. In 2009, students did not have a correct answer as a possible choice (while the 2012 students did), but sketched what they thought was the correct answer, but often forgot to show atoms touching, which accounts for lower scores.

In order to see if this hypothesis was true, the answers with the misconception of "atoms not touching" was added to correct answers for both 2009 and 2012 pretests and posttests as shown in Table V. For the 2009 results, the average pretest result (correct + not touching misconception) to posttest result showed a gain from 66% to 79%. The 2012 multiple choice pretest to posttest results showed an average gain from 59% to 78%. The 2009 and 2012 pretest to posttest results for the combined "correct + not-touching misconception" are quite similar. Thus, it seems that one major difference between the 2009 sketched test and the 2012 multiple choice test is that the

TABLE I. CORRECT ANSWER AND MOST FREQUENT MISCONCEPTIONS FOR CRYSTAL STRUCTURE
PRE AND POST TESTS FOR 2009 HAND DRAWN IMAGES AND FOR 2012 MULTIPLE CHOICE SELECTIONS

| Correct Answer | Pre-Tests | | Post-Tests | |
|---|--|--|--|---|
| | 2009 Hand Drawn Sketches | 2012 Multiple Choice Selection | 2009 Hand Drawn Sketches | 2012 Multiple Choice Selection |
|  FCC (1 0 0) |  (35%) Atoms not touching where they should. |  (12%) Atoms not touching where they should |  (47%) Atoms not touching where they should |  (5%) Missing center atom |
|  FCC (1 1 0) |  (29%) Atoms not touching where they should |  (70%) Extra atoms in the center. |  (41%) Atoms not touching where they should |  (15%) Extra atoms in the center. |
|  FCC (1 1 1) |  (41%) Center atoms not touching where they should. |  (37%) Center atoms not touching where they should |  (65%) Center atoms not touching where they should |  (28%) Center atoms not touching where they should |
|  BCC (1 0 0) |  (29%) Atoms touching where they should not |  (26%) Extra atoms and atoms touching where they should not |  (24%) Atoms touching where they should not |  (10%) Atoms touching where they should not |
|  BCC (1 1 0) |  (53%) Atoms not touching where they should |  (14%) Extra atoms and missing center atom |  (65%) Atoms not touching where they should |  (3%) Atoms not touching where they should |
|  BCC (1 1 1) |  (41%) Extra atom |  (47%) Extra atom |  (35%) Extra atom |  (45%) Extra atom |

TABLE V SUMMATION OF PERCENT CORRECT ANSWERS PLUS ATOMS NOT TOUCHING MISCONCEPTION.

| Question's Number | Description | Pretests | | Posttests | |
|-------------------|--------------|----------|------|-----------|------|
| | | 2009 | 2012 | 2009 | 2012 |
| 1 | FCC (1 0 0) | 100% | 82% | 94% | 95% |
| 2 | FCC (1 1 0) | 70% | 52% | 100% | 75% |
| 3 | FCC (1 1 1) | 75% | 81% | 89% | 84% |
| 4 | BCC (1 0 0) | 53% | 40% | 53% | 83% |
| 5 | BCC (1 1 0) | 94% | 76% | 83% | 98% |
| 6 | BCC (1 1 1) | 5% | 9% | 35% | 35% |

presence of the correct answer with "atoms touching" significantly increases performance of students on the posttest. The lack of a correct answer on the 2009 posttest actually created an increase of the "atoms not touching" misconception for the posttest. Although speculative, it is suggested that students may have learned what correct answers look like from the 2012 multiple choice topic test, so the presence of the correct answer in the multiple choice set may have repaired the "atoms not touching" misconception. This is in contrast to 2009 results where the "atoms not touching" misconception actually was more prevalent *after instruction*.

Overall, for the 2012 test, the greatest percent correct after instruction was for the (100) planes, with FCC increasing from 70% to 90% and BCC increasing from 40% to 83%. The second largest percent correct (but the largest gains) were for the (110) planes with FCC at 23% to 75% and BCC at 67% to 95%. The lowest percent correct (and the lowest gains) were for the (111) planes with FCC increasing from 47% to 48% and BCC increasing from 9% to 35%. The reason gains were so low for the BCC (111) was that the students did not adhere to the rule that, for an atom to be considered as on a plane, the atom center must lie on the plane. As such, the majority of students included the body-centered atom on the (111) BCC plane, even though the atom center did not lie on the plane.

V. SUMMARY AND CONCLUSIONS

Overall, for the pretest, there was reasonable registry between the results of the 2009 sketched and 2012 multiple choice images for 2-D representations of atom positions on (100), (110), and (111) planes for FCC and BCC structures. However, for the posttest, a major difference was that the "atoms not touching" misconception decreased significantly on the multiple choice 2012 posttest because the five multiple choice selections for any given question included the correct answer where "atoms should be and are touching". In contrast, the percentage of students creating the "atoms not touching" misconception during their sketching actually increased on the posttest for the 2009 posttests. It then seems likely that, when students see the correct answer on the multiple choice question sets (as in the 2012), or at least see answers that show atoms are touching, they understand which is the correct answer. For instructors, the overall impact of having the CSVS available to identify the major misconceptions for each of the six items could be the potential for encouraging development of more effective teaching strategies for crystal structures.

Thus, a new survey, the CSVS, has been created which can assess students' crystal spatial visualization skills and understanding before and after instruction. It can be used as a topic pretest to uncover student misconceptions about crystal structures and planes and also establish a baseline of conceptual knowledge about crystal structures. Given as a post-topic test it can measure conceptual gain which should reflect the effectiveness of instruction on crystal structures. More effective instructional methods can be devised to improve student visual spatial skills and understanding of crystal

structures. Results from a larger and more varied population of students will be needed to establish the psychometrics of the instrument. It would be interesting to find out what other instructors might find in other settings to see where differences might arise from course prerequisites, gender, or ethnicity. In order to promote broader usage and testing of the survey it has been loaded on to a web enabled testing site AICHE Concept Warehouse, where it can be administered and graded via computer. The results are immediately available for the instructor so that he/she could use them in their classroom in real time. Presently, the Crystal Structure Visualization Survey is a useful tool that has been tested for a limited population, but has the potential to be a catalyst to motivate more development of more effective instructional strategies on the topic of crystal structures. It could be used not only in materials engineering classes, but in any other discipline where crystal structures are studied, such as chemical and electrical engineering, physics, chemistry, geology, and mineralogy. There is the hope that, in a way that the Force Concept Inventory helped transform pedagogy in the teaching of physics, that the CSVS would, in a more focused way, encourage instructors to develop innovative approaches for teaching the topic of crystal structure.

Abstract—This paper presents the results of a pilot study designed to evaluate the effect of attending an intensive remedial course (8 hours worth of work during one week) based on desktop augmented reality exercises to improve the spatial ability of freshman engineering students. Activities based on practice with an augmented reality enhanced exercise book had a positive effect on students' spatial ability, measured by both MRT and DAT:SR tests. To promote students' autonomy, a YouTube tutorial for each type of exercise was developed. This allowed greater freedom for students to advance at their own pace during the training sessions. An evaluation and satisfaction questionnaire based on a five level Likert scale was submitted by participants. The experience was considered very positive by students.

Augmented reality; spatial skills; remedial course (key words)

I. INTRODUCTION

Spatial ability is a key element to students' success in science, technology, engineering, and mathematics (STEM) disciplines [1],[3]. Although some students are better at spatial thinking than others, everyone can improve with appropriate training. Development of students' spatial thinking is currently not widely covered by the educational system, although there are many studies that justify that spatial ability plays a critical role in developing expertise in STEM [2]. Spatial skills are usually developed indirectly. Onyancha & Kinsey report that those students in engineering majors which rely more heavily on these skills (e.g. mechanical engineering) increase them more than other engineering majors [6] from freshman to senior years due to their exposure to an engineering curriculum.

In the context of the Spanish educational system, many students enroll in engineering undergraduate degree programs without proper spatial skills. This paper presents the results of a pilot study designed to evaluate the effect of attending an intensive remedial course based on desktop augmented reality exercises to improve spatial ability of freshman engineering students. Many of these students have problems in managing visual information or in creating mental models of objects represented by their orthographic projections. Due to this fact,

the School of Industrial Engineering at Universitat Politècnica de València (UPV) in Spain provides a series of remedial courses at the beginning of each academic semester to give support to those students that need extra help to follow the regular courses. However, in recent years, some of these remedial courses have been suffering a growing lack of interest and motivation in students. This was the case of the "Introduction to Graphical Expression" remedial course based on classical paper and pencil exercises. The growing gap between the teaching procedures and the technological way of life of students [7] requires bringing new resources to the teaching/learning process. Besides, true learning is experiential. The more senses that are involved (sound, sight, touch, emotions, etc.), the more powerful the learning experience is [8]. In this context, augmented reality (AR) can play an important role supporting experiential learning and giving the students an appealing technological tool to support their learning activity. This has been the approach followed to improve the remedial course "Introduction to Graphical Expression".

In the next section, previous experiences using AR for spatial skills improvement are analyzed. Then the didactic contents used for the development of the remedial course are presented, with all the details about the experimental design. Section IV reflects the results obtained. Discussion and conclusions are presented in the last section of the paper.

II. RELATED WORK

Although spatial ability has been studied using Virtual Reality technology [10],[13] there is a very small number of studies about the application of AR to train spatial ability. In 2006 Dünser et al. [9] presented the first large-scale study (215 students) that analyzed whether spatial ability can be trained using an AR application. They used their collaborative augmented reality system Construct3D. This system employed see-through head-mounted displays (HMD) for the visualization of three dimensional objects that students usually calculate and construct with paper and pen methods. Training groups were composed of two students and a tutor, that attended six 45 minute training sessions (once a week).

The Spanish Ministry of Innovation and Science partially funded this research through project ref. TIN2010-21296-C02-01

Participants worked on the post-test 10 weeks after completing the pre-test. The training was centered on the use of combinations of Boolean operations and transformations in space to model objects. This study could not find a clear advantage for AR-based geometry training in improving spatial ability.

Do & Lee [12] developed a desktop augmented reality 3D LEGO game as a tool to develop spatial ability. The game allows practicing different spatial skills such as analyzing a 3D model's structure, figuring out what to do to make a primitive geometry become a component of a 3D model and assembling components to create a complex model. Physical markers are used by players to control the game. The main limitation of this study is that the authors did not employ any spatial ability test to verify the effect of playing the AR game on players' skills. They concluded that the 3D LEGO game improved players' skills using a questionnaire where users evaluated the game. One of the questions was if the user considered that the game was able to improve spatial abilities. This question received an average score of 6.8 out of 7 from the 67 participants.

Chen et al. [14] developed two teaching aids for the explanation of the relationship between three-dimensional (3D) objects and their projections. These aids were tangible models (physical objects) comprised of a set of differently shaped pieces and augmented reality models. The authors conducted a user test on 35 engineering-major students. However, they did not apply any standardized spatial ability tests to measure the impact of their intervention on participants' skills. They concluded that tangible models significantly increased the learning performance of students in their abilities to transfer 3D objects onto two-dimensional (2D) projections. Students also demonstrated higher engagement with the AR models during the learning process, although the augmented reality model had little effect on the capability for the transformation of 2D images into 3D objects.

III. MATERIALS AND METHODS

The "Introduction to Graphical Expression" remedial course is short and intensive (16 hours of work, during 2 weeks) and it is offered as an elective course to those students enrolled in the first-year "Graphical Expression" course with a poor technical drawing background. Its general learning objectives are to promote the learning of the systems of representation and the knowledge of the common geometric shapes used in engineering. The course is arranged in two blocks.

The first block (four 2-hour sessions in a week) is based on classical paper and pencil exercises where a basic review of metric geometry, the foundations of graphical representation and multiview and axonometric representation systems are provided to participant students. In this part, students are provided with wooden models to support the execution of some exercises.

The second block (four 2-hour sessions in a week) is based on an augmented reality application that uses virtual 3D models to help students to realize a series of activities designed to exercise their spatial skills. Each student is provided with an "augmented book" [17]. There is an exercise in each book's

page that is coded using a couple of small fiducial marks embedded in the book layout. The student uses another fiducial mark (printed on cardboard or loaded in their mobile phone, as seen in Fig. 1) to manipulate and interact with the virtual model linked to that specific exercise.

To promote students' autonomy, a YouTube tutorial [18] for each type of exercise has been developed. This allows greater freedom for each student to advance at their own pace, as to advance, they do not need to wait for the teachers explanation or to adapt to the speed of the rest of the class. This option has been positively valued by the participating students.

A. Description of augmented reality contents

The second block of the remedial course is based on the resolution of a series of exercises organized in level of increasing difficulty.

Level I exercises require the identification on the projected views of the surfaces marked on the AR model (Fig. 1 & 2).

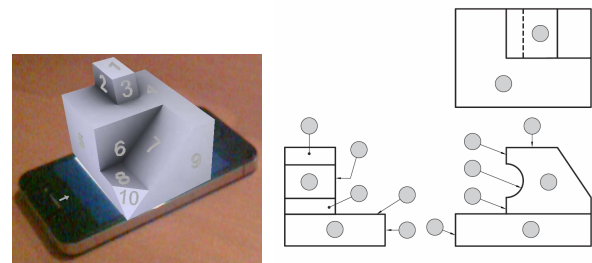

Figure 1. Using a mobile phone to manipulate the fiducial marker.

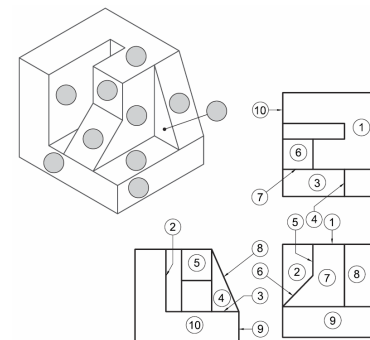

Figure 2. Write in the perspective view the number that corresponds to the surfaces marked on each view

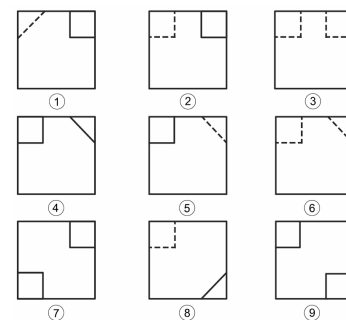

Figure 3. Identify the views that correspond to the virtual object

The second level consists of a series of exercises where students have to select the correct projection view for the representation of a virtual model manipulated through the AR application (See Fig. 3 for an example).

The third level is devoted to prism identification exercises (Fig. 4), and the election of the minimum number of views for the representation of a virtual object (Fig. 5). The fourth level consists of an initial set of exercises where the students have to solve missing view problems (Fig. 6) and draw the normalized views of a virtual object.

The last level does not employ a virtual object. The input for students is a set of views, and they have to sketch a perspective drawing of the corresponding part.

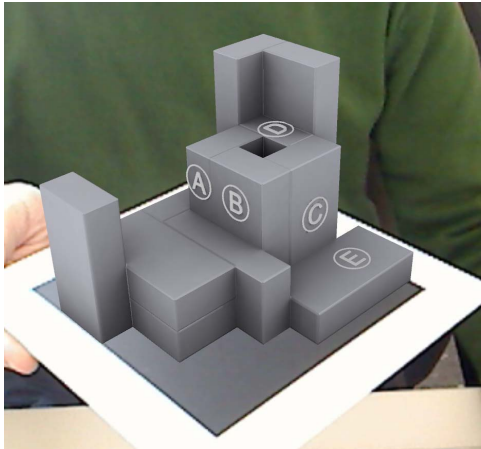

Figure 4. Prism identification exercises.

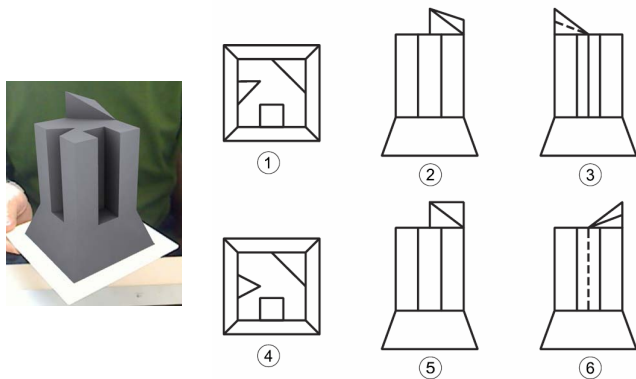

Figure 5. Minimum views exercises

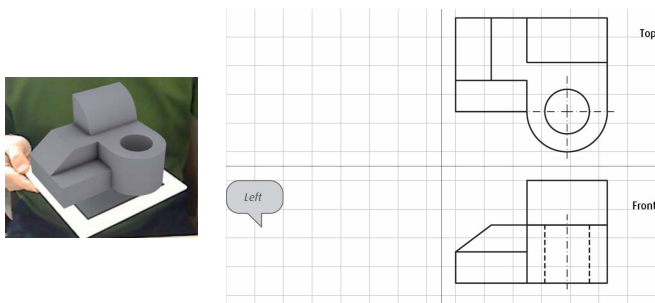

Figure 6. Missing view exercises

B. Participants

This remedial course was offered to freshman engineering students that were enrolled in the “Graphical Expression” course of the Bachelor’s Degree in Industrial Technologies Engineering offered by the School of Industrial Engineering from UPV. 27 students participated in this elective course during the first two weeks of February 2012 and formed the experimental group. A control group of 15 students was selected from one of the regular groups of the “Graphical Expression” course. The control group does not perform any activity related to spatial skills training during the period of realization of the remedial course.

C. Instruments

Although spatial ability is a complex topic, where several subcomponents are identified, for this work only two categories have been considered, firstly “spatial relations” related to tasks that require the mental rotation of simple two-dimensional or three-dimensional objects. Secondly “spatial visualization” that requires the mental manipulation and integration of stimuli consisting of more than one part or movable parts, where usually there is movement among the internal parts of a complex configuration and/or the folding and unfolding of flat patterns. Two tests have been chosen to quantify the values of the spatial ability of participants:

- Mental Rotation Test (MRT) [3] (20 items) for the “spatial relation” subcomponent.
- Differential Aptitude Test (DAT-5:SR level 2) [5] (50 items) for the “spatial visualization” component.

Both experimental and control groups were pre-tested the week before starting the augmented reality based training (second block of the remedial course). Both groups were post-tested the week after they ended the training.

IV. RESULTS

In Table I, MRT (spatial relations) and DAT-5:SR (spatial visualization) values can be found before and after training for both experimental and control groups. As a null hypothesis H_0 , it is considered a fact that there is no statistical difference between average values of both groups. The result of comparing both average values using a “*t*-student in independent series” analysis shows there were no significant differences between groups prior to spatial training, so the null hypothesis H_0 is rejected ($t = -1.557$, p -value = 0.127 on DAT-5:SR and $t = -1.836$, p -value = 0.073 on MRT). In this case p -values are over 5%, so both groups were statistically equivalent in spatial visualization and spatial relation at the outset of this study.

TABLE I. MEAN AND (STD. DEV.) SCORES FOR PRE & POST TESTS

| | Pre- test | | Post- Test | | Gain MRT | Gain DAT |
|----------------------------------|-----------------|-----------------|------------------|-----------------|----------------|----------------|
| | MRT | DAT | MRT | DAT | | |
| Experimental Group n = 27 | 17,04 (6,66) | 34,66 (9,42) | 25,81 (7,83) | 41,11 (7,71) | 8,77 (5,54) | 6,44 (5,44) |
| Control Group n=15 | 21,4 (8,55) | 39,26 (8,68) | 28,26 (10,56) | 41,26 (7,77) | 6,86 (5,75) | 2,00 (5,01) |

In Table II results corresponding to the comparison of the mean scores obtained in pre and post tests using the t-Student paired series test are shown.

TABLE II. RESULTS OF COMPARISON OF AVERAGE SCORES

| | | | |
|----------------|--------------------|------------|-----------------|
| Training Group | PreMRT vs Post MRT | t = -4.435 | p-value = 0.00 |
| | PreDAT vs Post DAT | t = -2.749 | p-value = 0.008 |
| Control Group | PreMRT vs Post MRT | t = -1.957 | p-value = 0.06 |
| | PreDAT vs Post DAT | t = -0.664 | p-value = 0.511 |

The group that underwent training shows a statistical improvement in spatial ability levels, where p -values are below 1% of statistical significance, which indicates that the students have a probability of over 99% of improving their levels of spatial ability by training as proposed by Augmented Reality. Besides this, results show there is no improvement in control group levels.

TABLE III. QUESTIONNAIRE. MEAN SCORE AND (SDT. DEV.)

| | |
|---|------------|
| Q1: The course contents look good. | 4.4 (0.84) |
| Q2: The manipulation of the virtual model with the cardboard marker is adequate. | 4.1 (0.73) |
| Q3: Course levels are well organized and the difficulty and characteristics of exercises are adequate. | 4.1 (0.85) |
| Q4: YouTube videos are a good help to resolve doubts. | 3.3 (1.03) |
| Q5: The augmented reality application worked well. | 4.1 (0.92) |
| Q6: Image quality is good. Virtual objects do not present jittering. | 3.2 (0.95) |
| Q7: The number of exercises to be solved is adequate for the available time. | 4.6 (0.78) |
| Q8: I feel confident to solve all the proposed exercises. | 4.6 (0.90) |
| Q9: The number of exercises of each work session was correct. | 4.7 (0.78) |
| Q10: The manipulation of the virtual object with the cardboard mark is easy to learn | 4.6 (0.59) |
| Q11: The concept of the augmented book is intuitive and easy to understand. | 4.6 (0.66) |
| Q12: I think that the course has improved my spatial skills. | 4.3 (0.88) |
| Q13: I think augmented reality technology is very interesting | 4.7 (0.47) |
| Q14: I think augmented reality technology is very original | 4.5 (0.67) |
| Q14: I think augmented reality technology is very useful | 4.3 (0.83) |
| Q15: I think augmented reality technology is very stimulating | 4.1 (0.87) |
| Q16: I would like to use augmented reality during the regular "Graphic Expression" course. | 4.7 (0.71) |
| Q17: I would prefer to do these kinds of exercises only with paper and pencil | 2.4 (1.38) |
| Q18: I think that the manipulation of the virtual model with the cardboard marker is easier than using the mouse. | 4.1 (1.10) |

V. DISCUSSION AND CONCLUSIONS

The results obtained agree with the previous experience of our research group [15],[16] that augmented reality based training for the development of spatial skills is a feasible approach that provides good results and offers an attractive stimulus to students to enroll in elective activities.

Low cost desktop augmented reality is very easy to implement, adding a webcam and the proper software to a regular CAD computer lab. Although the augmented reality contents presented here are relatively simple, only requiring one mark manipulation, student preferred this physical interaction to the typical mouse interaction (as can be seen in Table III, Q18). This confirms past research into the application of spatial ability in engineering education that suggested that motor activity contributes to the comprehension of the concept of space [19]

The concept of the augmented reality book was very well considered by participant students, as Q11 shows. The book layout has been designed to support a seamless integration of fiducial markers in the page layout, in such a way that they do not distract or break the point of interest centered on each exercise. Students receive the virtual content on a specific cardboard marker that they can manipulate independently of the exercise book. This tangible interaction probably gives the real added value to the experience as Q2, Q5, Q10 reflect.

Perhaps problems will appear when, in the future, students ask for more augmented reality contents to support the regular "Graphic Expression" course. The wide adoption of augmented reality requires authoring environments oriented to provide support to the teacher with a creative and active attitude towards the new technologies. However, current authoring tools are programmer oriented, and require a big effort to create the didactic contents.

Work in Progress: What is Critical Thinking?

Elliot P. Douglas

Department of Materials Science and Engineering
University of Florida
Gainesville, FL
edoug@mse.ufl.edu

Abstract—Critical thinking is generally recognized as an important skill, and one that is a primary goal of higher education. However, there is surprisingly little in the literature regarding critical thinking in engineering. This paper describes two pilot studies. A mixed methods study found that graduate engineering students performed worse than undergraduate students on a standard critical thinking instrument. This difference is explained through the two groups' familiarity with test-taking. In a qualitative study, engineering undergraduates were interviewed about how they use critical thinking. It was found that their descriptions were more complex than typical definitions in the literature. Overall, the results point to a need to further investigate what critical thinking means for engineering.

Keywords—critical thinking

I. INTRODUCTION

Development of critical thinking skills is generally recognized as an important aspect of undergraduate education. As pointed out by Mason much of the rhetoric regarding education and its reform revolves around teaching students to think and question critically [1]. Surveys show that well over 90% of faculty believe critical thinking is one of the primary goals of higher education [2]. Most definitions of critical thinking are based on identifying specific abilities that seem to be associated with critical thinkers and provide general definitions [3-5]. Less work has been done to define critical thinking specifically within the context of engineering. For the most part these studies have considered critical thinking in the context of engineering problem-solving [6, 7]. A comprehensive overview of critical thinking in engineering cannot be obtained from the available literature, which is somewhat surprising given its perceived importance. What is missing from the literature is an understanding of what critical thinking is in engineering and how students use critical thinking. This study begins to address these issues by examining how critical thinking is practiced by engineering students and how it might be measured. The specific research questions that guided this study were: 1) What are the processes students use to solve critical thinking problems? 2) What do students believe that critical thinking is? 3) Is there a difference in critical thinking skills between undergraduate and graduate engineering students? These questions were addressed through two pilot studies, one mixed methods and one qualitative.

II. METHODOLOGY

For the mixed methods study, the CCTST Form 2000 was administered to 12 graduate students in Materials Science and Engineering who had passed the PhD qualifying exam, and 13 undergraduate juniors in Materials Science and Engineering at the same institution. The CCTST is a 34 item multiple choice instrument. Questions on the instrument ask for analysis or interpretation of general topics, such as data on commuting patterns or logic puzzles; there is no specific engineering content. The CCTST was administered several different times and the test manual procedures were followed in all cases. The most important aspect of the procedure for this study is that there was a 45 minute time limit for completing the instrument. Participants were paid \$20 for participating in the study. Statistical analysis was conducted using a two-tailed t-test to compare scores between the undergraduate and graduate students. Subsequent to administering the CCTST, participants were contacted by email and asked to reflect on their experience taking the instrument. A total of 8 undergraduates and 10 graduate students responded. Codes were developed out of the responses by identifying major themes articulated by the students.

The participants in the qualitative study were undergraduate civil engineering students at a large public university. Interviews were conducted in which the students were shown four different problems taken from the California Critical Thinking Skills Test (CCTST), Form 2000. The first two problems were given exactly as on the CCTST. The second two problems were similar in nature to the first two, but they were given without the multiple choice answers. The interviews were semi-structured, with questions focused on the approaches the students used to solve the problems and general questions about how they have used critical thinking, both within and outside of engineering. The interviews lasted 40-60 minutes, and students were compensated \$20 for their participation. The interviews were recorded and transcribed verbatim. Analysis was conducted using thematic analysis. Transcripts were examined for statements that related to the research questions. These statements were then grouped into themes through a constant comparative process.

III. RESULTS

Table I shows the results from the quantitative component of the mixed methods study. As can be seen from this data, the

Financial support was provided by the workshop on Rigorous Research in Engineering Education, National Science Foundation grant number DUE-0341127, at the Colorado School of Mines.

Table I Results from CCTST

| | Undergraduate students | Graduate students |
|--|------------------------|-------------------|
| CCTST index ^a | 24.15 | 21.17 |
| Number of items answered ^a | 33.92 | 30.92 |
| Percentage of items correct ^b | 71.23 | 68.70 |

a: Difference between the two groups is significant at $p < 0.05$.

b: Percentage of correct answers out of the total number answered.

undergraduate students scored higher than the graduate students, which would normally indicate that the undergraduates have better critical thinking skills. However, careful examination of the data showed that the difference in scores is due to the graduate students not being able to complete the instrument in the allotted time. Thus, the qualitative study was conducted to determine the reason for the difference in completion for the two groups. Table II provides a summary of the results from the qualitative component. As can be seen from this table, the responses indicate a difference in familiarity in test-taking, suggesting that the CCTST was actually measuring test-taking ability, not critical thinking skills.

The second qualitative study was used to examine the nature of critical thinking as enacted by students. Five primary themes associated with critical thinking were identified from the qualitative study: identifying the problem and information, organizing information, using prior knowledge, using opinion, and making decisions. All students recognized the need to identify the purpose of the problem and the relevant information needed to solve the problem, develop strategies for organizing the information presented in the problems, and justify their answers. Some students expressed that they did not look solely at the information in the problem, but also looked to prior knowledge that might help them. Opinion was used in different ways, with one student stating that “you have to separate your opinion from what you’re trying to put on the paper.” In contrast, another student accepted the role of opinion in thinking critically, stating, “What’s true to you and what’s not true to you I think you think critically about those issues.”

In addition to these themes, the students discussed what constitutes critical thinking. Here the conceptualizations varied widely. One student believed that critical thinking required you to think in a new way. If you use a known algorithm to solve a problem, for her that is not critical thinking. Another student felt that critical thinking was the development of a process to solve a problem. Thus, even if you use an established algorithm, that is still critical thinking because you are using a process that had to be created. A third student had an

intermediate view, stating that a “plug and chug” problem could contain critical thinking if you thought about what the answer means and did not simply accept the answer as given.

IV. CONCLUSIONS

Taken together, the results from these two studies point to the complexity of critical thinking and the limitations of our current understanding. The mixed methods study shows that critical thinking cannot be operationalized in a simple instrument. There is also the issue of whether critical thinking is more appropriately measured through a recognition task, as in this study, or through a production task. The results from this study suggest that the CCTST, and by extension similar instruments, actually measure test-taking ability and not critical thinking. Contributing to this difficulty in measurement is the complexity of critical thinking as brought out in the qualitative study. It is clear that critical thinking as practiced is much more complex than most conceptualizations imply. Rather than a discrete list of independent skills, critical thinking includes a series of feedback and interactions among the skills. Future work is needed to more clearly understand what constitutes critical thinking in engineering. We are continuing the work described here with a qualitative study that will examine expectations for critical thinking among faculty, how critical thinking is enacted in practice, and how critical thinking in engineering differs from critical thinking in other fields such as humanities. Ultimately, our goal is to create a model for Engineering Critical Thinking.

Abstract — Intelligent Tutoring Systems (ITS) provide many features that improve learning and teaching experiences. ITS are usually interactivity-intense and content-specific. Interactivity-intense assignments are recommended for scaffolding learning, while content-specific systems can offer low flexibility regarding its possible pedagogical approaches and its uses by teachers. In order to overcome this limited flexibility, there are systems which let content-specific interactivity aside to provide authoring tools, with which teachers can author intelligent tutored assignments without programming. The generic model proposed herein intends to address this problem providing flexible authoring tools for interactivity-intense assignments with tutoring features, letting teachers benefit from the flexibility of content authoring tools as well as the interactivity usually restricted to content-specific ITS. We introduce an application framework which implements this model, which is available as free software.

Keywords – *Authoring Systems, Computer Assisted Instruction, Electronic Learning, Intelligent Tutoring Systems.*

I. INTRODUCTION

Intelligent Tutoring Systems (ITS) are educational software that provide intelligent feedback in order to improve learning experiences for students [1]. ITS main benefits are, for instance, recognizing misconceptions, guiding them through the study, enhancing the speed of learning procedures and helping or preventing teachers from repetitive work.

In our point of view, there are two important aspects of educational systems, including ITS: interactivity and flexibility of use. In order to guide the use of interactive mechanisms on user interfaces of software systems, some conceptual frameworks were developed [2]. Using this approach, it is possible to highlight types of interactivity that enhance learning of specific domains, such as sciences and mathematics. We define interactivity-intense assignment as the one in which user interfaces adopt different types of interactivity in order to enhance learning. Flexibility consists of allowing teachers to adapt the system behavior in order to better suit his/ her pedagogical approach [3].

Interactivity is an aspect well explored by ITS, which is not the case for flexibility of use. Most ITS provide assignments for students in a fixed set of problems or they are created automatically using templates. There are authoring tools that intend to facilitate the programming of tutored assignments [4]. Authoring tools for teachers are presented by example-tracing

tutors [6]. By analyzing existing systems, we found no ITS with interactivity-intense assignments and authoring tools for teachers, but systems with one feature or other.

Our goal is to provide means to facilitate the development of ITS that present the two features together. This paper proposes a generic model of ITS in order to develop systems with interactivity-intense assignments and authoring tools, which we call Interactivity-Intense Intelligent Tutor Authoring Tools.

II. A MODEL FOR INTERACTIVITY-INTENSE INTELLIGENT TUTOR AUTHORING TOOLS

In this section, we present the model for developing educational software with functionalities of: (i) intelligent tutoring, (ii) interactive assignments and (iii) authoring tools for teachers. The model is presented as a generic system architecture with its description and the structure for each functionality it provides. By using it, one can develop an ITS with the desired features following a cookbook and reusing the proposed architecture. Fig. 1 presents this model with four components: structural, assignment, domain and tutoring.

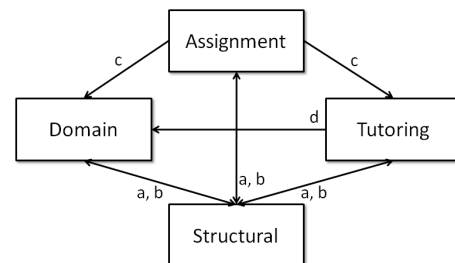

Figure 1. The model components and the communication among them.

The communication flow depicted in Fig. 1 works as follows: (a) structural component initializes other components; (b) use of domain-independent features by them; (c) assignment component integrates domain and tutoring actions to create and manage assignments; and (d) tutoring component reacts to domain actions. A system built with this model can be used in two ways, by teachers that author and edit assignments and students that solve these assignments. We describe the four components of the proposed architecture as follows.

The structural component has three goals: (i) providing basic structure to the system and (ii) to the domain-independent

features; and (iii) initializing and setting communication among other components. Its basic architecture is defined by its conditions of use and its final user, such as Web-based, mobile, or desktop applications. As these specific aspects of the system are essential to designing its architecture, the proposed model is restrained to define this component role.

The assignment component has three main goals: (i) modelling an assignment; (ii) allowing teachers to author assignments; and (iii) allowing students to solve assignments. This modeling must be respected by other components for compatibility. Fig. 2 shows how an assignment is structured: it has a proposition, a configuration, three states (current, initial and expected) composed of domain objects. Domain objects are elements specific to the educational concepts used by the system, such as points in geometry. The student starts an assignment defined by the initial state, interacts with the current state to solve it, and the system compares the solution to the expected state through automatic assessment.

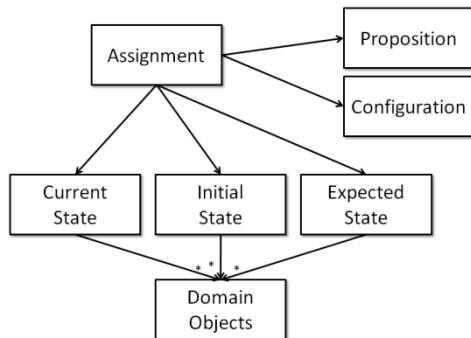

Figure 2. The internal structure of assignment component.

The domain component provides means for the domain-specific features to be compatible with other features. Domain features are functionalities that are specific to the educational domain, such as creating a line in geometry. These features are the essence of the system interactivity-intense assignments. The internal structure of this component is shown in Fig. 3. It uses the *Command* pattern [6]. On the left, the graphical user interface (GUI) has a list of domain actions, which connect an assignment state and a list of domain objects (its parameters) to the domain model, the class responsible for executing the operation.

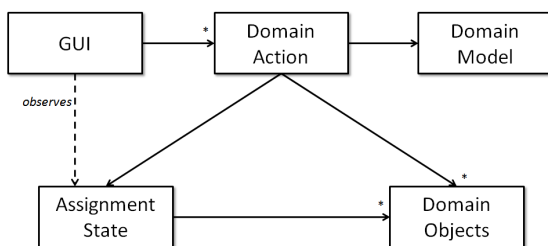

Figure 3. The internal structure for domain component.

The tutoring component provides the intelligent features for the system. Its main goals are: (i) providing intelligent tutoring actions; (ii) managing the way these actions are being accessed; and (iii) allowing the definition of the tutor behavior. Its structure is depicted in Fig. 4. On the left, domain actions are observed by a tutoring sensor, which is associated with the intelligent module, in the same way as the help button. This module has a list of tutoring actions that are selected and

executed depending on the assignment state and its behavior, defined by the authoring user interface on the right.

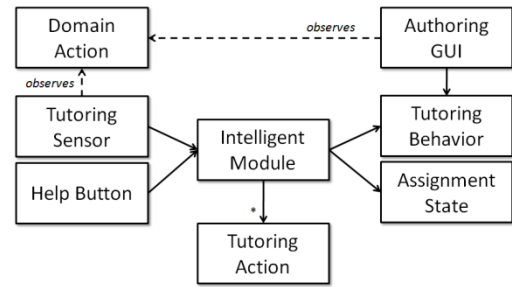

Figure 4. The internal structure of the tutoring component.

III. AN APPLICATION FRAMEWORK IMPLEMENTING THE MODEL AND CONCLUSIONS

After the creation of the model, we developed an application framework for developing Interactive Learning Modules (iLM) [7]. This framework uses a component architecture based on the four components of the proposed model. Currently, the tutoring features are being implemented. The development of iLM using it has resulted in the refactoring process of four existing systems, which facilitated this process. Future work includes adding more features to the framework according to the proposed model and using it to create other systems. This will also serve to evaluate its impact on the development tasks.

The main contribution of this paper is considering the flexibility of use and interactivity features in designing educational systems in general and ITS in particular. Also, by providing abstract reusable concepts and architectures such as the proposed model, the development effort and time of these systems are reduced. The model presented centralizes many concepts and design decisions that serve as a basis for developing educational systems such that the design effort can be focused on the instructional dimension.

Redesign of Senior Capstone Program in Electrical and Computer Engineering and its Assessment

Mark Faust, Andrew Greenberg, and Branimir Pejcinovic
Portland State University, faustm@pdx.edu, adg@ece.pdx.edu, brano@cecs.pdx.edu

Abstract—Our students are required to take part in a year-long capstone program consisting of a one quarter lecture course and a follow-on two-quarter industry-sponsored capstone project. Feedback from students, alumni and capstone sponsors indicated that: a) students needed better preparation before starting their projects, b) we should introduce a realistic mini-project, and c) students should learn and apply project management, time management, teamwork, and communication skills. Our redesigned lecture course has a term-long practicum project that mimics the follow-on project, requiring completion of a project from concept to test. During this practicum project, students apply all the best practices in design and project management that they are learning in lectures. Our program is assessed using multiple methods (focus groups, surveys, evaluation of student work) and multiple sources (students, alumni, sponsors and faculty). This enables triangulation of data and increases our confidence in validity of the results. Data was collected over four years and overall we have found good agreement between different methods and sources. This rich set of data validated our course redesign and provided an insight that students' writing skills and project management need even further improvement.

Index Terms—Capstone program, design, assessment.

INTRODUCTION

Capstone courses are a critical part of engineering education and are also part of ABET requirements. Many approaches exist to implementing them [1] although their overall goals and implementation share many common features. For example, 71% have some form of industry involvement [1-2]. Despite this, there are still many open questions, such as: choice and implementation of assessment tools [3-4], how to integrate project management into capstone design courses [5] and how to use assessment to improve courses and curriculum leading up to them [6-8]. In this paper we will share our experience in redesigning and teaching our latest version of the capstone program, with emphasis on assessment techniques that led to these changes and that we continue to use to monitor the quality of the capstone program.

I. ECE Capstone Program

The Portland State University ECE Capstone Program in its present form was created in 1996. Every ECE student

participates in the program as a requirement for graduation. The overall goals of the program are to:

- Provide students with a realistic design engineering experience, including working in teams,
- Require students to apply fundamental engineering knowledge, and
- Require students to learn and apply project-related skills.

The capstone program consists of two parts: a fall quarter, four credit lecture course entitled “ECE 411 Industry Design Practices,” followed by a two-quarter industry-sponsored project called “ECE 412/413 Senior Project Development I and II.”

II. The Lecture Course: ECE 411 Industry Design Practices

This course prepares students for their upcoming capstone project and for embarking on a career in electrical and computer engineering. The course covers a broad array of topics, such as project requirements specifications, project proposals, test plans and test cases, design reviews, project scheduling, intellectual property (non-disclosure agreements, patents, assignment of rights agreements), communications, and team behavior. In the past, the course was taught in lecture format with homework assignments corresponding to each of the major topics.

III. The Capstone Project: ECE 412 and 413

Following ECE 411, students enroll in ECE 412/3 during which they work on their capstone project. Typically students work in teams of four on an engineering project proposed by an industry or community partner. Over 40 local partners have recently participated in our program. These sponsors include local and internationally recognized technology companies, governmental organizations, and non-profit organizations. More recently, we have included projects from startup companies in order to give students an opportunity to work on projects with smaller, more entrepreneurial partners.

During the fall ECE 411 course, project proposals submitted by sponsors are posted on the capstone program website for students to peruse. In order to accommodate student interests we strive to have a range of project proposals from different disciplines in electrical and computer engineering. This usually requires soliciting many more proposals than there will be teams. Students indicate their preferred choices for projects and the program coordinator assigns them to teams, matching them to

projects and faculty advisors. Students are usually assigned to one of their three preferred projects. From 2004 to 2011, we have a yearly average of 37 proposals, from 20 sponsors, for 70 students, divided in 18 teams.

Teams are created not only on the basis of student preference, but also with an attempt to create a realistic project environment where there is a mix of academic ability (using GPA as a proxy), native English language ability, and cultural background. If students are permitted to self-select their team they tend to choose students of similar background with whom they have worked before in other courses. Although ECE 412 begins in the winter quarter, most teams take advantage of the break between fall and winter quarters to do more extensive background reading, needs assessment, and preliminary requirements definition with the goal of preparing and presenting a project proposal to the sponsor by the end of January. This project proposal includes requirements definition, a preliminary project schedule and a preliminary design strategy.

While project success is obviously stressed, emphasis is placed on teamwork and demonstrating a disciplined design methodology throughout the project. This includes quality design documentation and strong communication processes. Throughout the project students submit weekly progress reports, maintain an engineering logbook, and meet regularly with their faculty advisor and with their industry sponsor as needed. During the project, teams will typically write, review, and present detailed specifications, and test plans. At the conclusion of their projects students make a final project presentation to their sponsors and turn in the project deliverables that include final documentation, prototypes, test results, etc.

The entire department makes a substantial commitment to the capstone program. All full-time faculty participate by advising at least one capstone team each quarter. They meet with the project sponsor and the student team throughout the quarter, review the students' design documentation, and attend and evaluate their project presentations and final report. Further, the capstone program coordinator and other faculty maintain close relationships with sponsors and host an annual event for returning and prospective sponsors. In addition to our surveys of project sponsors these events give us an informal venue for soliciting feedback on the program and on the preparedness of our students.

IV. Assessment and Evaluation Prior to Changes

During a faculty curriculum analysis, we identified ABET student outcomes f, h, i and j as under-represented in our curriculum. Several of these outcomes are natural fits for the ECE capstone program. In addition, review of feedback from capstone program partners, students and alumni showed that:

- ECE 411 should prepare students better for their capstone projects. For example, only 63% of students in 2008 survey strongly agreed or agreed with the statement "ECE 411 adequately prepared me for my senior capstone project."

- Alumni focus group in 2008 suggested that we might:
 - introduce a "mock" project in Capstone program,
 - "teach early and practice often: project management, time management, effective meeting management, teamwork, and communication," and "include more emphasis on applied work."

As a result of this assessment and evaluation, several changes were implemented in 2009-10 academic year.

REDESIGN OF CAPSTONE PROGRAM

The lecture course ECE 411 was the primary target of our redesign. Organization of the two-quarter capstone project, i.e. the second part of the program, was not changed except for the addition of a poster session, poster competition and the addition of several new assessment techniques.

I. ECE 411 Course Changes

Teaching soft skills to engineering students has always been a challenge. To tackle this, we decided to more systematically cover these topics, put them in a proper engineering context and have the students put their newly acquired skills to immediate use. Doubling the number of contact hours and lectures permitted us to add topics and increase time spent on existing topics including: ethics, globalization, contemporary issues, communication, and life-long learning.

In addition, in 2009 we added a "practicum project" consisting of lectures and a term-long project. This team-based practicum project was added to closely mimic the capstone project and gives students a more direct experience with applying the skills and methodology taught in ECE 411, prior to embarking on their capstone project.

The practicum project requires students to form teams and propose a small electronics project. Each project requires one or more sensors, one or more actuators, and a processing section (either analog or digital, with an emphasis on microcontrollers). Students have to develop requirements, write a project proposal, create a project schedule, and develop a test plan. The students must then create schematics, layout a printed circuit board, solder on their components, program their processing sections, and test their design. Benefits of such mini-projects were discussed in [6]. At the end of the term teams must demonstrate their projects in a presentation to their peers, the course instructor, and teaching assistants. Further, each team is required to utilize "best practices" collaboration techniques, such as using collaboration tools like a project wiki and source repository for all design documentation, design files, and code.

Evaluations of the final projects and presentation are modeled on the capstone project and even use the same evaluation forms. This reinforces the parallels between the methodology taught in ECE 411 and expectations for successful capstone projects. Finally, team building and team dynamics have often been cited by students as areas of conflict or difficulty during their capstone project. By giving students a chance to experience these dynamics beforehand

during the practicum they are better able to recognize and address team issues earlier in their projects.

II. Poster Session

To showcase their projects and to give students more experience in communication, a poster session and competition were introduced in 2008. After the conclusion of their two-term capstone projects, each project team creates a poster presentation. Students present their posters during a two-hour session in an event that is open to the campus, our capstone sponsors, and area high school students. A panel of industry and faculty judges selects the best three projects, and winners are given a cash award. The poster session and competition gives students more experience organizing and presenting information graphically and verbally, and has helped them to build confidence in their presentation skills. It also helps to engage the broader community and keep them abreast of our program.

RESULTS AND DISCUSSION

We also implemented new assessments and attempted to triangulate the results by using different techniques [3,4]:

1. surveys of students and capstone sponsors, and
2. direct, rubric-based evaluation of student work by both faculty and sponsors, mostly through evaluations of student presentations and written reports.

Survey results for 2008 are for the program prior to the redesign described here, while those conducted in 2009 and later assess results after the implementation of the redesign. Participation in the surveys is given in Table 1. Note that formal sponsor survey began in 2009, at which time only 3 replies were received. In the last two years we have increased the participation to well over 50% of our capstone project sponsors. Student participation varies, but the sample is big enough to be considered representative and in 2011 it exceeded 50%. The student survey consists of 18 questions which are answered anonymously online while the sponsor survey consists of 11 questions, also answered anonymously online. Survey utilizes Likert-type scale: strongly agree (A), agree (B), neutral (C), disagree (D) and strongly disagree (F).

Three of the statements/questions are common to both student and sponsor surveys:

1. Capstone team met sponsor's goals and expectations.
2. Capstone team was cohesive and worked well together
3. Even though students were not familiar with software and/or hardware tools required, they learned them quickly and became proficient.

This enables us to triangulate student self-assessment with observation and evaluation by their sponsors. Note that sponsors have very detailed and intimate knowledge of students' performance because they work with them directly.

TABLE 1
PARTICIPATION (SAMPLE SIZE) FOR SURVEYS, ORAL PRESENTATION EVALUATIONS AND WRITTEN REPORT EVALUATIONS.

| | Participants | 2008 | 2009 | 2010 | 2011 |
|----------------------|--------------|------|------|------|------|
| Surveys | Students | 22 | 27 | 24 | 47 |
| | Sponsors | N/A | 3 | 10 | 13 |
| Presentation eval. | Faculty | N/A | 8 | 10 | 11 |
| | Sponsors | N/A | 13 | 8 | 15 |
| Written report eval. | Faculty | N/A | 5 | 6 | 9 |
| | Sponsors | N/A | 4 | 5 | 13 |

Figure 1 shows that better than 75% of students and sponsors strongly agree or agree with the statement that the teams met their goals. This seems to be true both pre- and post-changes.

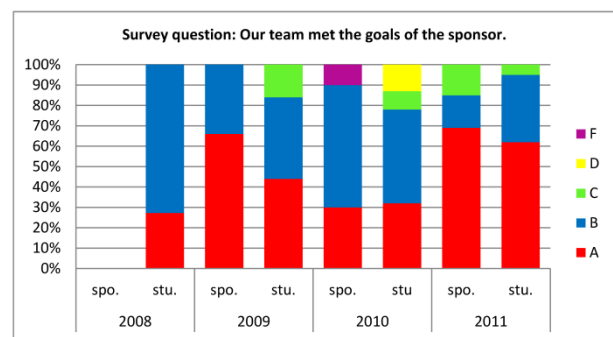

FIGURE 1

COMPARISON OF SPONSOR AND STUDENT RESPONSES TO SURVEY QUESTION: OUR TEAM MET THE GOALS OF THE SPONSOR.

Figure 2 illustrates that in the last two years (2010 and 2011) students and sponsors had very similar evaluation of effectiveness of student teamwork. In 2010 we can observe a brief decline in student performance which bounced back very strongly in 2011. Between 2009 and 2010 the percentage of students agreeing or strongly agreeing dropped by 10%, from 66% to 56%. However, the next year (2011) it bounced back up to 80% which is a 24% increase over 2010. We interpret the 2009 result as a transient and believe that we have turned the corner and now see a significant improvement. We will continue monitoring this result for possible signs of need for improvement in teamwork.

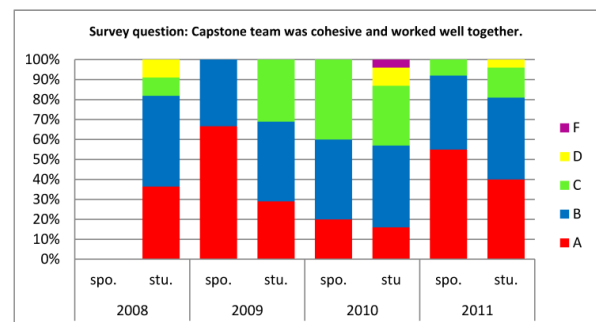

FIGURE 2

COMPARISON OF SPONSOR AND STUDENT RESPONSES TO SURVEY QUESTION: CAPSTONE TEAM WAS COHESIVE AND WORKED WELL TOGETHER.

When it comes to learning new hardware and software tools, Figure 3 shows that students are quick learners. There is a very high degree of agreement between student self-evaluations and sponsor evaluations. Note that the question was asked slightly differently in 2008, and in 2009 only 3 sponsors filled out evaluations. There is a trend of increased percentage of students strongly agreeing with the statement which we interpret as improvement in student abilities and learning over last four years.

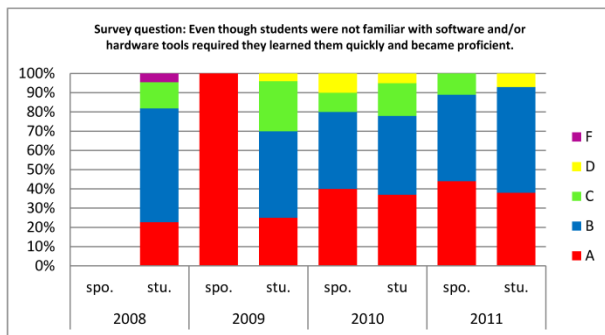

FIGURE 3

COMPARISON OF SPONSOR AND STUDENT RESPONSES TO SURVEY QUESTION: EVEN THOUGH STUDENTS WERE NOT FAMILIAR WITH SOFTWARE AND/OR HARDWARE TOOLS REQUIRED, THEY LEARNED THEM QUICKLY AND BECAME PROFICIENT.

Surveys provide a wealth of additional data that can be used in assessing student learning. One example is shown in Figure 4 which gives students' self-evaluation of their learning regarding ethics. Originally, we intended to triangulate this result with more direct observation and evaluation by capstone sponsors or faculty advisors but few capstone projects have a significant ethical component that can be evaluated directly. Note that the results have steadily improved over the last four years, as measured by those strongly agreeing or agreeing with the statement.

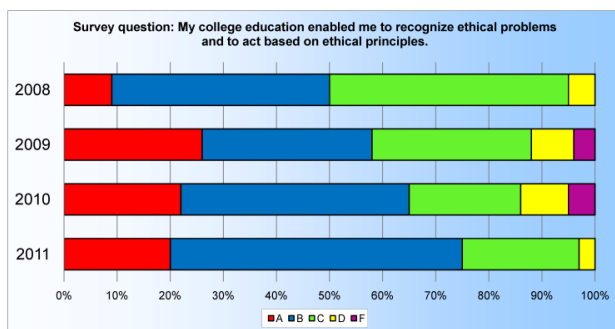

FIGURE 4

STUDENT RESPONSES TO SURVEY QUESTION: MY COLLEGE EDUCATION ENABLED ME TO RECOGNIZED ETHICAL PROBLEMS AND TO ACT BASED ON ETHICAL PRINCIPLES.

Another survey question judges the effectiveness of ECE 411 in preparing students for the capstone project, as shown in Figure 5. The percentage of students who agree or strongly agree that ECE 411 adequately prepared them for

the capstone project was nearly unchanged - around 75% - from 2009 to 2010. In 2011 it rose significantly to almost 90%. Similarly, the percentage of students strongly agreeing rose from under 35% to 45% in 2010 and 44% in 2011. Our 2008 survey had a total of only 63% who agreed or strongly agreed, with only 13% who strongly agreed.

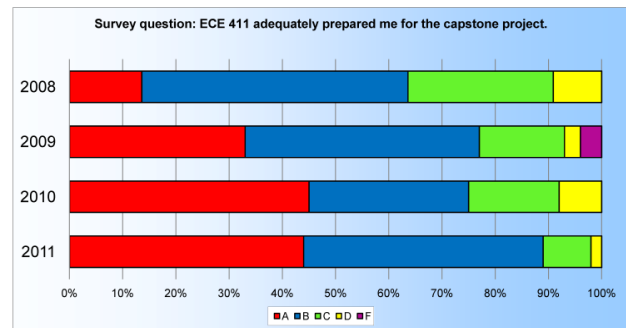

FIGURE 5

STUDENT ANSWERS TO SURVEY QUESTION: ECE 411 ADEQUATELY PREPARED ME FOR THE CAPSTONE PROJECT. NOTE: ECE 411 IS THE LECTURE PORTION OF THE CAPSTONE PROGRAM.

Finally, we also asked students about their preparation for written reports and oral presentations. Survey results are given in Figure 6.

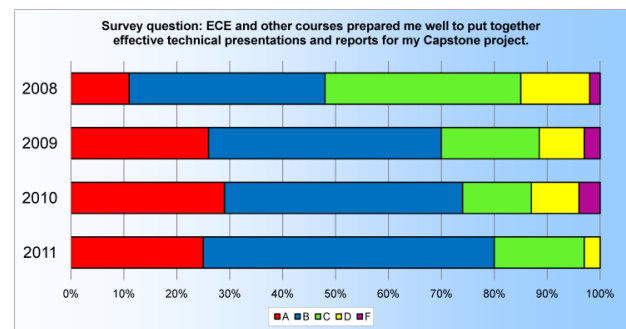

FIGURE 6

STUDENT ANSWERS TO SURVEY QUESTION: ECE AND OTHER COURSES PREPARED ME WELL TO PUT TOGETHER EFFECTIVE TECHNICAL PRESENTATIONS AND REPORTS FOR MY CAPSTONE PROJECT.

The percentage of students who agree or strongly agree that their courses prepared them to put together effective technical presentations and reports for their capstone projects rose from 70% in 2009 to 74% in 2010 to 80% in 2011. The corresponding 2008 figure was 48%. This shows a very encouraging positive trend but these results need to be further evaluated through sponsor and faculty evaluations.

I. Assessment of presentations and reports

Due to the emphasis that employers place on communications skills, we decided to better assess these student outcomes by developing a set of rubrics for oral presentations and written reports. There are seven presentation rubrics: overall organization, preparedness, visual aids quality and effect, technical content, delivery, handling of questions, and effective use of time.

There are two larger areas covered by written report rubrics: overall organization and report mechanics, and technical content. The latter consists of: executive summary, introduction and motivation, problem identification, appropriate analytical method, tools and theory, conclusions, project management, design of experiments, ethical, professional or social issues, and discussion of project weaknesses and strengths. Details on problem identification and conclusions are provided in Table 2.

The rating scale used is: exceeds expectations (4), meets expectations (3), below expectations (2), and unacceptable (1). Note that this is a four point scale whereas our other assessments (surveys) use a five point scale. Participation numbers (sample size) are given in Table 1.

Figure 7 shows the overall assessment by faculty and sponsors of written reports and oral presentations. These plots are obtained from evaluation forms by creating a histogram of how many times each score (1 to 4) was entered. We combined the scores from all of the rubrics and scaled the results to percentage.

Figure 7 shows that the quality of student presentations is exceeding expectations. This assessment is shared by both faculty and sponsors. It is also in agreement with student self-assessment results shown in Figure 6. There were no significant differences from year to year. For written report evaluations in Figure 7 we observe similar results: the number of “4” and “3” scores exceeds 80% indicating that our students are doing very well. Given this level of performance, year-to-year variations are not significant although faculty seem to be a little bit more critical of the written reports than sponsors.

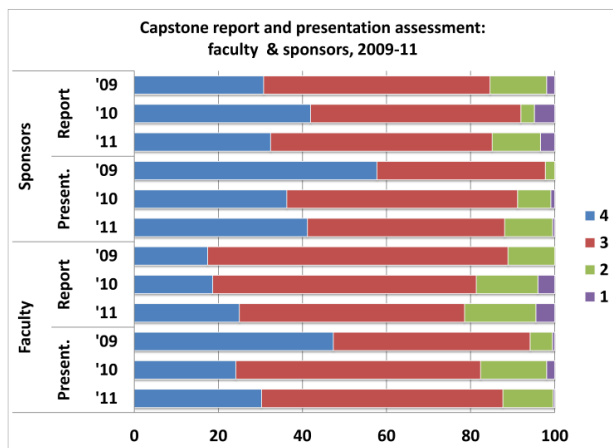

FIGURE 7

OVERALL FACULTY AND INDUSTRY SPONSOR EVALUATION OF REPORTS AND ORAL PRESENTATIONS.

Another way to look at the presentation and written report rubrics data is through average scores, as shown in Figure 8 and Figure 9. For evaluation of attainment we use the following guidelines: average scores in the 1.5 - 2.5 interval are “below expectations,” in the interval 2.5 to 3.5 they “meet the expectations” while those above “exceed

expectations.” For each rubric given in the figures below we also show the ABET student outcome to which it maps.

Rubrics for presentations show little variation between faculty and sponsors, or from year to year. Averages vary from just below 3.0 to over 3.5. Based on this assessment, students meet expectations for their project presentations.

There was a wider variety of rubric scores for the written reports, as shown in Figure 9. Project Management is getting somewhat lower scores, although they are still meeting expectations. Project management is difficult to address through in-class activities due to limited time available. We will be asking sponsors and faculty to pay special attention to this issue in upcoming years, and work more closely with students early on in the project when they are defining and managing the project.

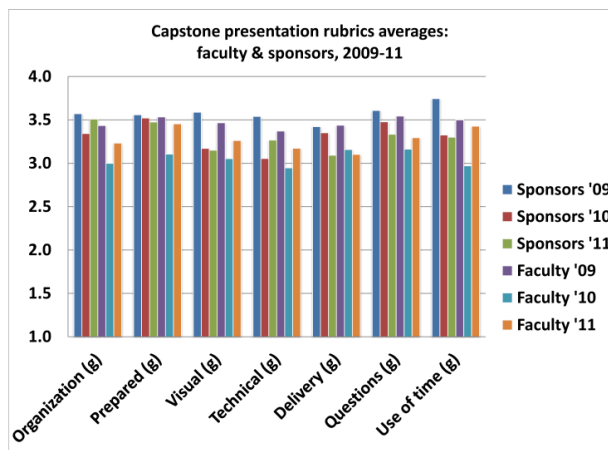

FIGURE 8

FACULTY AND INDUSTRY SPONSOR EVALUATION OF CAPSTONE STUDENT PRESENTATIONS; AVERAGE SCORES FOR A GIVEN YEAR ARE PRESENTED.

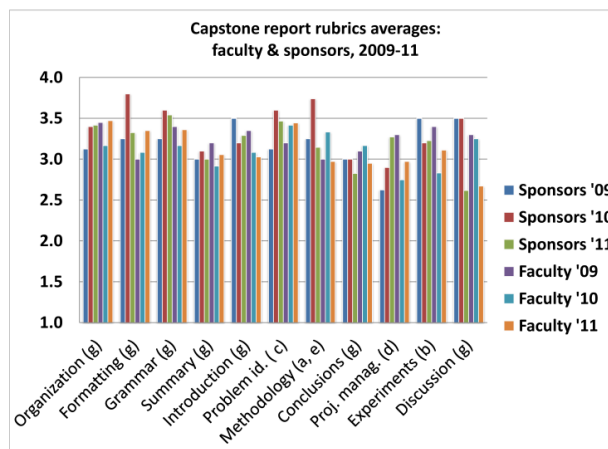

FIGURE 9

FACULTY AND INDUSTRY SPONSOR EVALUATION OF CAPSTONE STUDENT WRITTEN REPORTS; AVERAGE SCORES FOR A GIVEN YEAR ARE PRESENTED.

Overall, our students meet or exceed all of the expectations we had for presentation and written reports outcomes. This is supported by the good agreement between the faculty adviser, sponsor and student assessments.

However, since we started presentation and report evaluations after the capstone program changes, it is not possible to make a pre- and post-change comparisons.

CONCLUSIONS

We redesigned our three quarter long capstone program in two ways. First, we expanded coverage of project management, ethics, globalization, contemporary issues, communication, and life-long learning topics. Second, we provided an experiential component to the project management lecture material by introducing a practicum project that requires completion of a capstone-like project from concept to implementation to test. This approach may appear to be very time consuming but we have found that once we overcame initial hurdles, it was straightforward to implement and it was very well received by students.

Assessment of the program was done over four years and through a variety of techniques: focus groups, student and sponsor surveys and evaluation of presentations, and written reports by sponsors and faculty. We have demonstrated how a combination of all of these assessment methods can be used to effectively improve capstone program design and implementation. We believe that other programs can follow similar approaches. While the assessment process is involved, we did not find it too time consuming. In return we get a rich set of data that enables an in-depth analysis of the program and student learning.

We continue to use the same assessment techniques for quality control and further program improvements. We have documented improvements in several areas and observed consistency between student, sponsor and faculty evaluations. Through faculty and sponsor appraisals we have

observed that students perform very well on their project presentations, but their writing skills and project management need further improvement.

We believe that the new capstone program is a multifaceted, well assessed and novel approach to teaching and organization of capstone courses and projects. Most importantly, it better prepares our students to be successful practicing engineers.

Abstract - One of the challenges in effective software engineering (SE) education is the lack of objective assessment methods of how well student teams learn the critically needed teamwork practices, defined as the ability: (i) to learn and effectively apply *SE processes* in a teamwork setting, and (ii) to work as a team to develop satisfactory software (SW) *products*. In addition, there are no effective methods for *predicting* learning effectiveness in order to enable early intervention in the classroom. Most of the current approaches to assess achievement of SE teamwork skills rely solely on qualitative and subjective data taken as surveys at the end of the class and analyzed only with very rudimentary data analysis. In this paper we present a novel approach to address the assessment and prediction of student learning of teamwork effectiveness in software engineering education based on: a) extracting only objective and quantitative student team activity data during their team class project; b) pairing these data with related independent observations and grading of student team effectiveness in SE process and SE product components in order to create “training database”; and c) applying a machine learning (ML) approach, namely random forest classification (RF), to the above training database in order to create ML models, ranked factors and rules that can both explain (e.g. assess) as well as provide prediction of the student teamwork effectiveness. These student team activity data are being collected in joint and already established (since 2006) SE classes at San Francisco State University (SFSU), Florida Atlantic University (FAU) and Fulda University, Germany (Fulda), from approximately 80 students each year, working in about 15 teams, both local and global (with students from multiple schools).

Keywords-assessment; software engineering teamwork; software engineering education; assessment; machine learning.

I. INTRODUCTION AND BACKGROUND

There is now a consensus across industry and academia that to be successful in today’s workplace, computer science students must learn practical SE teamwork skills defined as the twofold ability (i) to learn and effectively apply SE processes in teamwork setting and (ii) to work as a team to develop satisfactory software (SW) products which have requested

features, and are delivered on budget and on schedule. The need for improved teaching and training in this area is evidenced by statistics on the unacceptably high incidence of failure of industrial SW projects: about ten percent are abandoned, about one third fail, and over half experience cost and schedule overruns [1-5]. The evidence also indicates that these failures stem primarily from failures in communication, organization and teamwork aspects of SE and are not due to the SW technology [1], [4-8].

Most of the current literature on student learning and assessment of SE teamwork skills, while well conceived and developed like CATME [18] and TIDEE [19], or applied on individual instructor basis, relies mostly on qualitative and subjective data from class surveys and instructor observations at the end of the academic term. Due to the subjective and qualitative nature of the collected data, where entries are heavily dependent on the human responder’s judgment, these instruments are difficult to use consistently and repetitively. The use of simplistic data analysis methods fail to address complex interactions among team members and the tools they use (e.g. for communication, code management, issue tracking). The absence of objective, quantitative and comprehensive data on student team activities (e.g. team communication dynamics; usage of software development tools) leaves team communication patterns understudied and poorly understood. The fact that the assessments are performed only at the end of the course also precludes early classroom interventions, which are critically important for improving students’ learning effectiveness. Sophisticated automated machine learning (ML) techniques that are now regularly applied in bioinformatics, medicine, data mining, marketing, analysis of customer behavior, and even in SE for SW quality assessments (e.g. [9-11]) have not been applied to the acquisition and assessment of SE teamwork skills. The work described in this paper aims to discover new factors that can objectively and quantitatively determine, assess and predict SE student learning teamwork outcomes by applying powerful ML

data analysis techniques using only objective and quantitative measures of student team activity.

The authors have been engaged together in joint teaching of SE classes, data collection and some preliminary research since 2006 [12-16]. These SE classes were conducted at SFSU, FAU and Fulda, in a synchronous fashion, using the same team project with the same milestones, with approximately 80 students each year working in about 15 teams. Teams comprised of students only of a particular university (*local teams*) and teams comprised of students from multiple universities (*global teams*).

II. APPROACH

The approach has several distinct steps (see Figure 1).

A. Step 1: Collection of the data on student team activity

A wide range of data (measures) pertinent to student teamwork activity are collected during the joint SE classes from students while they are actively engaged in intensive team projects. All data are: i) quantitative and objective; ii) related to measurable manifestations of teamwork activity; iii) easy to collect; and iv) amenable to analysis by machine learning methods. All student teams are assigned to develop the same project and fulfill the same five synchronized milestones using the same SE tools (e.g. e-mail server, Bugzilla, SVN) during project development. Teams are formed such that the level of combined expertise and gender mix are approximately equal across teams, in order to factor out the students' skill level from this study. Instructors maintain a log of their regular observations about the teams which are later used for assessment and grading. *Student Activity Measures (SAM)* focus on the activity of *each student* and are obtained by weekly online surveys and analysis of usage of SE tools. These are quantitative measures, such as time used for certain activity, counts of e-mail, incidents, etc., which are either measured by automated tools or easily observed by instructors or students. *Team Activity Measures (TAM)* are computed for each team by combining the *SAM* for the team's members. For example, a SAM datum is the number of commits to the team's source code repository; the corresponding TAM is the average and standard deviation of commits for all the team members. We believe that by focusing only on quantitative variables and combining them at the team level we reduce the influence in reporting error and significantly eliminate subjective bias. To examine different patterns of behavior at different stages of project development, a *time variable* related to each of five project milestones is introduced.

B. Step 2: Creation of ML training database

At the end of the semester, independent evaluators (faculty who do not teach the SE classes) evaluate/grade each student team for achievement of SE teamwork outcomes using: a) the class grading rubrics; b) information from the instructor logs; c) manual evaluation of the developed student SW; and d) final team project demonstration. These grades, one for adherence to the SE *process*) and one for the quality of the team's SE *product* , are categorized as "A - above expectations", "C - at expectations", or "F - below expectations". These grades constitute "decision classes" for the ML algorithm, and are

paired with TAM data for each team to construct a *ML training database*.

C. Step3: Applying ML to discover factors that determine and predict student SE teamwork achievement.

The training database will be used as an input to ML training, which will produce a ML classifier that predicts the student team performance based on TAM data, and can assess the effectiveness of TAM measures by evaluating ranked TAM factors. We chose the random forest (RF) [17] ML algorithm for its accuracy, success in many application areas, and its ability to generate simple rules that explain its behavior. We are using open source SW for statistical computing, R [25] for which an easy-to-use RF implementation from [24] is available.

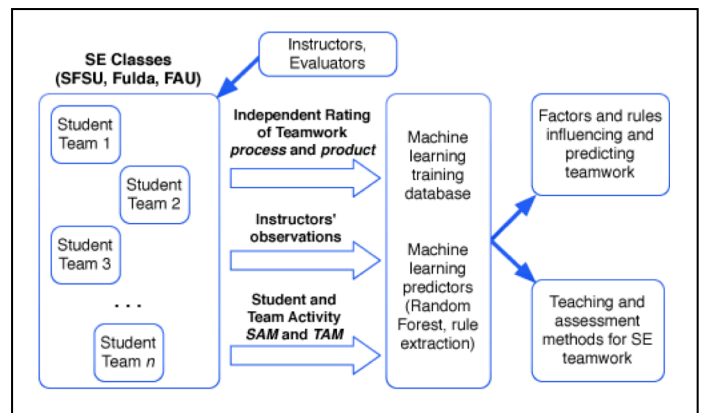

Figure 1. Using ML to assess and predict student teamwork achievement

III. STATUS AND PRELIMINARY RESULTS

We have fully established collaboration, team management and grading methods for the joint SE classes that have been ongoing since 2006 [12-15]. Modified data gathering methods have been in place since Fall 2011 to reflect the new SAM and TAM measurements, when new custom data gathering software started to be used on a new suite of SE tools. These open-source SE tools used by students include: 1) tools for collaboration and communication such as e-mail and wikis; 2) tools for SW development management such as Bugzilla [20] and Subversion [21]; 3) tools for application development such as NetBeans [22]. All team projects are deployed on a server using LAMP (Linux, Apache, MySQL, PHP) stack. Student surveys are administered with LimeSurvey [23]. Tool usage and outcome data is stored in a MySQL database, which is used as training data by the RandomForest package [24] for the SW package R [25]. Data analysis has begun, with first results expected by summer 2012. This work is supported in part by NSF TUES grant 1140172.

Abstract-- This paper presents two related studies; the first explores the typical recurring dysfunction engineering student teams face, and the second evaluates the effectiveness of a virtual facilitator, called the Droid Communication System (DCS), in training such teams to address the dysfunction. Using Patrick Lencioni's Theory of Five Dysfunctions of a Team, this study first measured for the following: absence of trust, fear of conflict, lack of commitment, avoidance of accountability, and inattention to results. Then, a virtual trust-building vignette was developed and loaded onto Droid phones to guide students to potential solutions.

The studies' findings indicate that absence of trust seems to be a significant problem for engineering student teams and that 42% of participants indicate that the DCS process increased their confidence in communicating and interacting with their teams. The development of the vignettes and experimental evaluation can provide a model for future research on engineering education and on student team development.

INTRODUCTION

Engineering students, like the ones enrolled at Missouri University of Science & Technology, are increasingly called upon to work in teams as part of their undergraduate experience. To work effectively in teams, engineering students "must learn not only the technical knowledge of a particular discipline, but also gain the ability to work with and manage team dynamics" [2]. Since they are not yet experienced, they often run into difficulties, but they may be afraid to share these difficulties with their professors, partly due to fear of getting a bad grade [1]. In addition, since many interactions between students occur outside the instructor's view, or may even be purposefully hidden from the instructor, it can be difficult to provide helpful feedback and guidance in a timely fashion. This exploratory investigation attempts to answer the following research questions and hypotheses:

Study One:

Research Question One: What is the most significant problem that collaborative engineering student teams encounter in teamwork?

Study Two:

Research Question Two: How effective is the virtual facilitator (the Droid Communication System) as an intervention in addressing the most recurring problem engineering student teams encounter in teamwork? although the various table text styles are provided. The formatter will need to create these components, incorporating the applicable criteria that follow.

CONTEXTUAL BACKGROUND

A team is a special type of group in which people work interdependently to accomplish a goal. According to Hackman [3], there are three primary factors for team success and these relate to the task, social relations, and the individual. A successful team develops social relations while completing the task, and participation in teamwork is personally rewarding because of the social support, the learning of new skills, and the rewards given for participation. Indeed, motivation, group cohesion, role assignments, and performing both task and social behaviors are the building blocks of successful team performance [6]. According to Levi, teams in any type of collaborative context can face many issues. Levi suggests, "the collaborative dynamic can perpetuate common problems involving conflict, power and social influence, decision-making, emerging leadership, problem solving, and diversity" [6]. Any one or combination of 2

these areas can cause problems within a group. In turn, Johnson and Johnson give special attention to addressing the source of group problems. They explain the interrelated nature of group dysfunctions and how to overcome these “through maturity, practice, and planning” [4]. A study of engineering teams found that more than 90 % of a team’s interactions was task-oriented [7]. When teams are under time pressure as is the case with student teams, they may not have time to devote to group process issues and “may fall back on traditional management methods rather than using teamwork to get the task accomplished” [8].

In an effort to provide aid for educators and to add to the extant literature on teamwork in educational settings, this exploratory study first applied the lens of Lencioni’s theory of Five Dysfunctions of a Team to isolate the recurring problem that engineering students encounter during their work as a team. Then, the researchers considered DCS’s effect on training students in addressing the dysfunction.

For both studies, Institutional Review Board (IRB) approval was obtained before data was collected. Participants were not deceived or misled, and their responses remained anonymous. Participants were volunteers who were recruited as individuals, and they did not receive compensation or payment. No institutional sponsorship was pursued and written consent by human participants was provided. The short informed consent form was administered at the beginning of each survey.

STUDY ONE

The first study explored the following research question and hypothesis:

Research question one:

What is the most significant problem that collaborative engineering student teams encounter in teamwork?

Hypothesis one:

Absence of Trust, the foundational layer in Lencioni’s model, is a highly significant problem that engineering student teams encounter in teamwork.

Method

Quantitative descriptive research was used to identify the recurring problem faced by engineering student teams in the undergraduate program at Missouri University of Science & Technology. This method was selected because it is a means to describe

systematically, factually, and accurately the characteristics of an existing phenomenon.

Participants

A convenience sampling method was used to identify 17 students in the engineering program at Missouri University of Science & Technology. The participants, aged 18 or older, were part of student teams enrolled in undergraduate engineering classes. In addition, the participants were members of student teams composed of 4 members per team.

Measure

Patrick Lencioni’s diagnostic model of Five Dysfunctions of a Team posits that teams fail to achieve teamwork because they unknowingly fall prey to five natural but dangerous pitfalls known as five dysfunctions of a team: absence of trust, fear of conflict, lack of commitment, avoidance of accountability, and inattention to results [5].

Figure 1. Lencioni’s 5 Dysfunction of a Team

These dysfunctions can be mistakenly interpreted as five distinct issues that can be addressed in isolation of the others, but in reality they form an interrelated model so that the susceptibility to even one of these issues is potentially lethal for the success of the team. These dysfunctions build on each other, so having one builds the foundation for the other dysfunctions. An overview of each dysfunction, and the model they comprise, is essential to understanding effective teamwork. Taken individually, each dysfunction means:

Dysfunction #1: Absence of Trust: This occurs when team members are reluctant to be vulnerable with one another and are unwilling to admit their mistakes, weaknesses or needs for help. Without a certain comfort level among team members, a foundation of trust is impossible.

Dysfunction #2: Fear of Conflict: Teams that are lacking on trust are incapable of engaging in unfiltered, passionate debate about key issues, causing situations where team conflict can easily turn into veiled discussions and back channel comments.

Dysfunction #3: Lack of Commitment: Without conflict, it is difficult for team members to commit to decisions, creating an environment where ambiguity prevails.

Dysfunction #4: Avoidance of Accountability: When teams don't commit to a clear plan of action, even the most focused and driven individuals hesitate to call their peers on actions and behaviors that may seem counterproductive to the overall good of the team.

Dysfunction #5: Inattention to Results: Team members naturally tend to put their own needs (ego, career development, recognition, etc.) ahead of the collective goals of the team when individuals aren't held accountable.

According to Lencioni, trust is the first foundation in teamwork and lies at the heart of a functioning and cohesive team. In the context of building a team, trust is "the confidence among members that their peers' intentions are good, and that there is no reason to be protective or careful around the group" [5]. Lencioni further contends that trust in teamwork requires team members to communicate and to make themselves vulnerable to one another. Vulnerabilities in this context include skill deficiencies, interpersonal shortcomings, mistakes, and requests for help. Teammates must become confident that their respective vulnerabilities will not be used against them.

The researchers of this study hypothesized that achieving vulnerability-based trust is challenging because, in the course of education, most students learn to be competitive with their peers and protective of their reputations. It becomes difficult to turn those instincts off for the good of the team. In fact, the researchers agree with Lencioni's assessment that members of teams often have absence of trust as their first and biggest hurdle in teamwork. In fact, if absence of trust is the biggest hurdle for the engineering student teams sampled in this study, then "there should be clear signs that the team members are engaging in the following detrimental behaviors: concealing weaknesses and mistakes from one another, hesitating to ask for help or to offer constructive feedback, holding grudges, dreading

meetings and avoiding spending time together, and jumping to conclusions about the intentions and aptitudes of others without attempting to clarify them" [5]. Of course, our data-gathering instrument should shed further light on our assumption that absence of trust may be the main culprit in undermining student teamwork.

Procedure

During fall 2011, surveys were administered to a sample of engineering student teams to explore typical recurring team difficulties or dysfunctions. Through the lens of Patrick Lencioni's Theory of Five Dysfunctions of a Team, a questionnaire with fifteen questions and a Likert scale measured for the following team dysfunctions: absence of trust, fear of conflict, lack of commitment, avoidance of accountability, and inattention to results (appendix A). For the descriptive question of this study, each item was rated on a scale of 1 (rarely), 2 (sometimes), and 3 (usually). Although not specifically listed in the Lencioni Team Assessment, researchers also included an optional rating in the Likert scale of 0 (no/unknown) for each of the fifteen questions. This allowed for the zero score to be represented in the overall calculation in each statement. A zero rating identified a complete dysfunction of that particular team in the eyes of the sampled student. The placement of the zero score in the Likert scale further argues for (1) allowing a participant in the survey to select a no answer rather than being forced to select a score (i.e., rarely/one point) that may not accurately represent the student team for a particular question, and (2) once a no answer is selected the impact would represent a lower overall score giving a probable indication that the dysfunction needs to be addressed. Each dysfunction comprised of 3 statements. Scores for the statements were summed for each dysfunction and a total score of 3 to 5 indicated a high probability that the dysfunction needs to be addressed.

Results

The analysis of the data collected from the fifteen questions was used to support the researcher's assumptions about the team dysfunction that prevented the student teams' success. Lencioni provided instructions how to calculate an individual sample from the Likert scores of the fifteen questions. The researchers were not necessarily interested with individual scores and the impact these scores would have on an individual member of a student team. Rather, the interest focused on the entire cohort of

engineering students at Missouri University of Science & Technology and how they collectively interact with one another in a team setting. Therefore, taking the 17 individual Likert responses, researchers listed them onto a spreadsheet to determine the frequency in each of the rated areas. Next, the collective scores in each section were calculated taking the number of respondents and multiplying it by the scale score. For example, for question number one, 10 respondents answered Usually which equates to a score of 3. Multiplying 10 and 3 gives a score of 30. Divide 30 by the number of 17 respondents, the average score in this column is 1.76. Researchers continued this calculation to attain the average score for each of the remaining columns as seen in Table 1.

TABLE 1: SCORE CALCULATION

| | Usually =3 | Sometimes = 2 | Rarely = 1 | Unknown/No = 0 |
|-----|---------------|------------------|---------------|-------------------|
| Q1 | 1.76 | 0.59 | 0.12 | |
| Q2 | 0.71 | 0.94 | 0.24 | 1x0=0 |
| Q3 | 1.94 | 0.59 | 0.06 | |
| Q4 | 0.71 | 0.12 | 0.41 | 5x0=0 |
| Q5 | 1.41 | 0.94 | 0.06 | |
| Q6 | 1.06 | 0.82 | 0.18 | 1x0=0 |
| Q7 | 1.41 | 1.06 | 0 | |
| Q8 | 1.59 | 0.59 | 0.06 | 2x0=0 |
| Q9 | 1.59 | 0.59 | 0.12 | 1x0=0 |
| Q10 | 2.29 | 0.35 | 0.06 | |
| Q11 | 1.41 | 0.71 | 0.12 | 1x0=0 |
| Q12 | 0.53 | 0.71 | 0.29 | 3x0=0 |
| Q13 | 2.12 | 0.47 | 0.06 | |
| Q14 | 1.59 | 0.71 | 0.06 | 1x0=0 |
| Q15 | 0.53 | 0.94 | 0.24 | 2x0=0 |

Using the overall respondent average for each statement, the scores were then listed on the scoring sheet as offered in Lencioni (Table 2).

TABLE 2: TOTAL SCORES FOR EACH DYSFUNCTION

| Absence of Trust | Fear of Conflict | Lack of Commitment | Avoidance of Accountability | Inattention to Results |
|-----------------------|----------------------|-----------------------|-----------------------------|------------------------|
| Statement #4 1.24 | Statement #1 2.47 | Statement #3 2.59 | Statement #2 1.89 | Statement #5 2.41 |
| Statement #6 2.06 | Statement #7 2.47 | Statement #8 2.24 | Statement #11 2.24 | Statement #9 2.3 |
| Statement #12 1.53 | Statement #10 2.7 | Statement #13 2.65 | Statement #14 2.36 | Statement #15 1.71 |
| Total: 4.83 | Total: 7.64 | Total 7.48 | Total 6.49 | Total: 6.42 |

A score of 8 or 9 is a probable indication that the dysfunction is not a problem for your team. A score of 6 or 7 indicates that the dysfunction could be a problem. A score of 3 to 5 is probably an indication that the dysfunction needs to be addressed.

The scores on the sheet were added together for an overall average score of 17 responses. The five total scores for each of the five dysfunction statements were compared to the scoring table. The data supported Hypothesis 1 and the literature since Absence of Trust appeared to be the most pressing challenge facing engineering student teams.

STUDY TWO

The second study attempted to answer the following research question and hypothesis:

Research question two:

How effective is the virtual facilitator (the Droid Communication System) as an intervention in addressing the most recurring problem engineering student teams encounter in teamwork?

Hypothesis two:

Student teams who participate in the Droid Communication System intervention will show an improvement in team communication, a meaningful step to building trust.

Method

A descriptive method was used to evaluate the effectiveness of the virtual training intervention or trust-building vignette in helping engineering students address absence of trust in their teams.

Participants

A convenience sampling method was used to identify 55 students in the engineering program at Missouri University of Science & Technology. The participants, aged 18 or older, were part of student teams, enrolled in spring semester undergraduate engineering classes. In addition, the participants were members of student teams composed of 4 members per team. 26 students consented to the post-experiment questionnaire.

Measures

In spring 2012, through a post-survey, the researchers assessed the perceived effect of the vignette on student team communication. The survey was designed to include questions pertaining to the communication aspects of teamwork as guided by the DCS. The premise for the post-survey stems from Lencioni's observation that communication and member interaction, if done within a mode of inquiry and

observation, increases the likelihood of open dialogue and sharing of vulnerabilities [5]. Vulnerabilities at this level include skill deficiencies, interpersonal shortcomings, mistakes, and requests for help. Lencioni contends that teammates must get “comfortable being vulnerable with one another for trust to develop” [5]. Of course, this requires the confidence that members’ vulnerabilities will not be used against them. In effect, an essential component to the sharing of vulnerabilities is non-violent communication and interactions, which, in turn, foster trust-building tendencies.

Procedure

The outcomes of Lencioni’s questionnaire were used to develop a virtual scripted vignette that illustrated absence of trust. The Droid Communication System (DCS) guided students through a trust-building exercise modeled by a team of students from the theater arts department. The scripted vignette was loaded onto wireless Droid phones via an application-based software program designed to mimic approaches similar to expert facilitators. The same students were guided through a trust-building exercise via in-ear Bluetooth devices. The scripted vignette through the DCS modeled specific communication behaviors and guided students through inquiries and observations. Scenarios included instances where group members were troubled with one member of the team. They were prompted in-ear to say a pre-scripted statement as it related to the dysfunction. Fellow team members responded according to the script. The experiment took approximately one and one-half hours to complete. The objective of the vignette was to increase communication and interaction among the team members and to invite inquiry, so some “vulnerability is shown; an essential component for building trust” [5].

Results

After the intervention training concluded, participants were surveyed regarding their impressions of the trust-building vignette and the DCS process. Forty-two percent of participants indicated that the DCS process increased their confidence in communicating with their teams. Similarly, 46% felt that the DCS process helped them become more comfortable in actually communicating with their teams. And just over a third believed that the DCS training would improve their personal interactions with their teams. Furthermore, 44% rated their experience using the DCS process while working with team members as either positive

or somewhat positive. These data suggest that the DCS training was perceived as useful by a substantial proportion of participants. It is unknown exactly why some participants found the DCS process to be useful while others did not. However, these findings are consistent with our hypothesis that participating in a digitally-aided trust-building exercise would improve team communication. However, given the expediency and relatively low expense of this type of team-building intervention, further investigation of the Droid Communication System process is warranted.

RECOMMENDATIONS

This study indicates that absence of trust seems to be a significant problem for engineering student teams; hence, faculty should consider creating opportunities for student teams to engage in trust-building exercises in order to increase communication and interaction among team members. The frequency of communicating and interacting engenders an open environment in which vulnerability is encouraged and trust is built. Furthermore, faculty should consider digitally-aided trust-building exercises in helping address student team dysfunction.

Future research should expand this investigation in three ways: First, it should compare the Droid Communication System process to alternate, more established team-building approaches in order to assess its relative efficacy. Second, future research should utilize standardized, comprehensive assessments of team dynamics in order to capture the nuances of the team structure as it changes over time. Third, it should employ the use of control groups and a pre-test post-test research design in order to allow causal inferences

Work in Progress: Integrating Writing Instruction in Engineering Courses

Tatiana Teslenko, Estella Qi

Centre for Professional Skills Development, University of British Columbia
Vancouver, Canada, teslenko@apsc.ubc.ca; estellqi@apsc.ubc.ca

Abstract— Communication modules were incorporated within engineering projects in an integrated second-year mechanical engineering curriculum. Students learned to identify appropriate communicative strategies and obtained problem-solving experience through design, prototype development, testing, and reporting, with additional activities related to team building and community service learning. The integration process required collaboration among instructors teaching various disciplines and presented challenges that are discussed in the paper. The authors argue that incorporating writing modules with engineering projects adds a substantial emphasis on communication and teamwork and allows students to explore human and social dimensions of engineering. From describing their projects, students move towards the exploration of rhetorical and ethical implications of engineering practice and an understanding of their professional identity. Instructor feedback indicates that students' motivation has improved, their engagement and enthusiasm have increased, and learning outcomes have consistently been achieved. Student feedback has been positive and encouraging; they self-report that they are better prepared for taking upper-level courses. The authors conclude that students are likely enabled to reach higher levels of knowledge in senior courses.

Keywords—communication; teamwork; mechanical engineering; integration; program development; outcomes-based assessment

I. INTRODUCTION

An innovative pedagogical approach was implemented in an integrated second-year mechanical engineering curriculum (Mech 2) at the Faculty of Applied Science at a leading Canadian university. This approach was developed in response to the evolving academic needs of students, the institutional move towards outcomes-based assessment, and the new accreditation criteria. Its purpose is to incorporate communication modules into mechanical engineering courses and to promote rhetorical awareness, teamwork and community service learning. The interdisciplinary context of the project encompasses writing-in-the-disciplines (WID) and engineering education, thus providing an opportunity to bridge the gap between the understanding of writing pedagogy in these two fields. Engineering educators, with their over-arching focus on design skills, view writing skills as fully transferable to the workplace. In contrast, recent writing research and knowledge transfer literature [1, 2] question the notion of transferability and provide a compelling argument that transformation of knowledge, rather than transfer, takes place. Our longitudinal study aims to address this issue.

II. PEDAGOGICAL INNOVATION

A. Integrated Approach

Mech 2, a new fully integrated second-year curriculum, was designed in 2003 and implemented in 2004 to replace the conventional curriculum for 130 second-year mechanical engineering students [3]. The purpose was “to apply a systematic approach for developing analytical, practical and design skills of second-year mechanical engineering students” [3]. Its development required collaboration among seventeen instructors teaching various disciplines [3]. The program has evolved over the years and is now in its 8th year. The engineering component involves design, prototype building and testing, competition, and assessment. Learning activities include elements related to the attending ethical issues, team dynamics and community knowledge-building. The writing component is divided into two parts: 1) integrated assignments linked to Mech 2 projects in content, delivery, and assessment; 2) generic writing assignments (e.g., summary, definition, process description, research report, business correspondence).

Our approach borrows on an established tradition of integrating writing instruction in engineering education [4, 5, 6]. However, this tradition, though long-standing, is not widespread. Only nine US programs use integrated communication instruction, mainly through team-teaching by communication and engineering instructors [7]. Just 15 US and Canadian programs use a combination of required stand-alone communication courses and integrated instruction [7]. Inspired by recent research in engineering education [8], we aimed to develop an approach that would further be applicable in the global context. Topics related to ethics, intellectual property, copyright and global engineering practice were explored through the use of case-studies and research reports. Subsequent to our field observations, we refined our own teaching practices to foreground the global engineering aspect even more, and to help students learn how to use their rhetorical awareness to make sense of new rhetorical environments (see the list of assignments in Table 1 below).

Table 1: Course Assignments

| Integrated assignments | Generic assignments |
|-------------------------------------|---------------------------------|
| Informal memo-report (Project 1) | Research report on ethics |
| Formal report (Project 2) | Process description |
| Oral presentations (Projects 1 & 2) | Summary |
| Mechanism description (Project 2) | Definition |
| Set of instructions (Project 1) | Business letters (case-studies) |

B. New Genres for Mech 2 Design Activity System

The new integrated course could not be a simple adaptation of APSC 201: Technical Communication, our stand-alone course with generic assignments. (It was developed in 1995 for a multidisciplinary context and continues to be a mandatory course for engineering students in other departments at the Faculty.) We modified APSC 201 to suit the needs of Mech 2 and to promote a more inclusive use of writing that would enable engineering students to draw upon their interest in design projects and their own rhetorical resources. Clearly, this integration created an exciting opportunity to compare the standards, disciplinary values and pedagogical practices of writing instruction and mechanical engineering. We used genre theory and activity theory [9] to decide what genres to assign and teach in Mech 2 in order to meet 1) the course requirements of APSC 201; 2) the design requirements of Mech 2; 4) CEAB graduate attributes [10] (i.e., attributes relevant to technical communication, namely criteria 3.1.6-3.1.12 -- communication skills, individual and teamwork skills, professionalism, ethics and equity, life-long learning). We created rhetorical situations that promoted the use of genres related to the activity system of engineering design. Our writing assignments (both individual and collaborative) were linked to projects that students were undertaking concurrently and assessed in terms of both classroom genres and "real-world" genres of engineering communication. Intensive teamwork was introduced to replicate collaboration that is paramount in the engineering workplace. Collaborative writing requires a lot of shared interaction, decision-making and responsibility [11], so it fits the program well. While we accept the view that it is futile to try to import workplace genres wholesale into the academic world [1] and vice versa, we share the belief that transformation of writing skills (if not transfer) will take place in the workplace [2]. Through this transformation students will be equipped with attitudes, competencies and values that will serve them well in the interconnected world of global engineering.

III. CHALLENGES

Whereas our engineering colleagues claim that all Mech 2 components are fully integrated in content and delivery [3], recent evidence suggests that it is not always the case with the writing component. Firstly, design projects received most of the classroom time; therefore, students saw engineering design as the real focus of the course. Integrated writing assignments (see Table 1) are seen as linked to the design activity system; however, generic APSC 201 assignments are seen as irrelevant because they are not specifically linked to Mech 2 projects. Students see them as extra work necessary only for passing the course. We have received feedback from students that demonstrates lack of appreciation for the value of writing instruction, especially towards generic assignments. We agree with [7] that integration of the writing component with the design activity system might have had the effect of diluting or diminishing the value of writing instruction.

Secondly, discipline-specific communication within the Mech 2 cohort becomes somewhat insular. It is permeated with jargon and technical terms that only insiders understand. We have repeatedly expressed a concern that mechanical engineering graduates might then continue this kind of insular communication in the workplace. To increase audience and genre awareness, we have created a lot of meta-documents where we set standards and require performance: guidelines, course notes, assignment specifications and evaluation rubrics. However, requiring performance is not the same thing as providing instruction. Similar to findings reported by [12], we are concerned that Mech 2 students received less writing instruction than they would in a stand-alone course (APSC 201). Whereas all aspects of technical writing are given full attention in APSC 201, Mech 2 students clearly see generic assignments in the integrated course as an additional activity. Therefore, the intensity of the design activity system in Mech 2 tends to de-emphasize the writing component of the course.

IV. OUTCOMES

Overall, the integration of communication modules into a second-year mechanical engineering curriculum helped to increase students' awareness of certain aspects of writing. Appropriate communicative strategies and common knowledge-building activities led to better teamwork and a larger-scale attitudinal change. Such important outcomes as improved motivation, more ambitious projects, inspiration, increased level of enthusiasm and greater student engagement with learning have been reported [3]. Students' in-class engagement and digital discourse on Vista demonstrate the critical role of community in the creation of knowledge; indeed, the creation of a robust learning community is the major outcome of Mech 2. The program won several awards and was recognized by ASME as one of the best curriculum innovations that foster collaboration in university teaching [3]. Mech 2 has recently been recommended to other engineering departments in the Faculty as a model for integrating writing instruction into an engineering program.

Importantly, over the years we have observed a dramatic five-fold reduction in the percentage of students failing the writing component. Another positive outcome is zero plagiarism which is linked to the fact that Mech 2 projects are always new and not recycled from year to year. Moreover, our students do not just need to produce assignments for their instructors' approval; student teams have an investment in the relationships being mediated by their discourse. Students know that the whole Mech 2 learning community is interested in their work. Therefore, plagiarism stops being an issue. Upon completion of the program students self-report better preparedness for taking upper-level courses. As instructors, we believe that they are likely enabled to reach greater levels of knowledge in senior courses; whether this is indeed the case is a question for further research.

Work in Progress: Enhancement of Student Learning via Recorded Worked-out Examples and In-Class Team Based Problem Solving

Asad Azemi, Roxanne Toto
Pennsylvania State University
azemi@psu.edu, rtoto@engr.psu.edu

Abstract—This paper describes our continued work in creating a set of narrated dynamically worked-out problems and the team based in-class problem solving for the Electric Circuits students to improve their problem-solving skills by understanding the key concepts and the way that they should be utilized in solving circuits' problems. The dynamically worked out problems, consists of problem solution annotated with auditory explanations, which students can watch and listen to. The in-class team based problem solving includes students working together, in teams of two, to solve problems that are presented during the lecture and are related to the recorded worked-out problems. The preliminary evaluations of the proposed approach by a group of students and faculty have been very encouraging.

Index Terms—Assessment, Electric Circuits, Multimedia, Problem Solving.

I. INTRODUCTION

In our previous works [1]-[2] we reported that due to the importance of the Electric Circuits course (EE 210) at Penn State's Electrical and Computer Engineering programs, and to address some of the challenges that were reported by students and faculty, we started developing a set of dynamically worked-out problems. We first start with brief background information. Like most other institutions, EE 210 is the first course in electrical engineering and gateway for subsequent EE core courses. Our statistics indicates a direct correlation between strong performance in electric circuits (i.e. B and above) and subsequent success in the follow-up courses in the curriculum. In this regard, our experience with this course, and similar type courses, indicates that the major instructional problem faced by instructors is that students have difficulty knowing where and how to start a given problem as opposed to the mechanics of problem solving. As was reported in [1], in order to address these challenges, we started developing a bank of dynamically worked-out problems, so that students could obtain a greater understanding of the subject matters and increased competency in their ability to analyze basic circuits using the appropriate tools and concepts. The general approach was developed based on step-by-step, expert, think-aloud process to model the details of the problem solving process, and thereby scaffold student problem solving. The worked-out examples focused on:

- Recognizing/identifying the 'type' of problem that is being considered.

- Identifying the tools/laws/concepts that can be used to solve the problem.
- Identifying the most appropriate and efficient approach/tools to solve the problem.
- Setting up the problem given the problem constraints.

While students would obtain the same information through in-class problem solving activities, the intention of this project is to provide the students a supplementary resource that can be used outside of class, while supporting good problem solving skills. Our intention is that students use the supplementary resource either before or following instruction as a way to enhance understanding of the course concepts. In order to reiterate the problem solving approach that was used in worked-out problems, we introduced in-class team based problem solving exercises related to these problems. The presented approach, on one hand, can be considered an enhancement of recorded worked-out problems that can be found on YouTube or publishers' complementary resource sites such as [8]-[9], and on the other hand, a different scaffolding problem solving to achieve deeper learning such as [7].

II. PROPOSED APPROACH

This section briefly describes the approaches that were introduced in [1]-[2] and the modifications that were made or we are planning to make.

In [2], we first tackled the question of number of problems per topic and their relationship. We indicated that depending on the complexity of a subject that is being covered, we designed 1-4 worked-out problems for the topic. A worked-out problem is defined as a detailed solution of a problem, made up of captured annotation with auditory explanation. Next, two other circuits problems along with several multiple-choice questions, related to the worked-out problems were designed. The first circuit problem would be similar to the worked-out problem but with different numerical values. The second circuit problem in the set would again be similar, but more challenging. The multiple-choice questions would correlate to the steps that might be involved in solving the worked-out problem. For example, if a worked-out problem is about maximum power transfer, multiple-choice questions would be related to the relevant power equations/calculations

and Thevenin/Norton equivalent circuits. A more detailed explanation of this structure is provided in the next section.

III. PRODUCTION DETAILS

Production has been done by using Tablet-PC, Microsoft OneNote, and Camtasia [10] for recording the auditory explanation and capturing the annotations. The hypothesized outcome of the narrated engineering problems is the following: Students who listen to and watch the narrated problems will better understand the steps necessary for successful completion. As was reported in our previous work [1], using Tablet-PC in the classroom has provided significant benefits to instructors in the classroom [3]-[6]. While some of the advantages of the Tablet-PC in the lecture format can be duplicated on the chalkboard, students have expressed greater interest and attention in the material when the Tablet-PC is used in the lecture. Production of a worked-out problem takes about 2-4 hours. The process starts with problem selection for a topic, 1-4 problems as stated before. The next step is to solve each problem and identify the key points. The key points will be used for creating multiple-choice questions and identified as points of entry to the video, showing up as links below each video, enabling students to start a video from different scenes. This further emphasizes the key concepts related to a problem, see Table I. At the end of each problem, students are asked to evaluate its usefulness with respect to the intended concepts and problem solving skills. Student feedback will be used to revise the problem solutions as needed to best enhance students' understanding of the material. Each worked-out problem, along with its associated problems, is placed on a separate web page. The aforementioned structure enables students with a wide range of problem solving skills to benefit from our production. Many of the current editions of textbooks come with an accompanying website for students, e.g. [8]-[9]. These websites include recorded worked-out problems for students, which are nicely done, but they lack the flexibility and the emphasis on improving students' problem solving skills. This is the main difference between our approach and the recorded worked-out problems that are available.

IV. A TYPICAL WORKED-OUT PROBLEM

A typical worked-out problem would start by going over the five basic steps of solving a problem, namely, (1) define the problem, (2) present the information related to the problem, (3) discuss the solution steps or alternative solutions, if they exist, and determine the one solution that promises the greatest likelihood of success, (4) work out the problem, and (5) evaluate the solution. The second step would start by identifying the characteristic of the problem that would help students to identify the right tool or approach for solving the problem. The third step will include discussion of alternative approaches, if they exist, and possible pit falls. Students are then encouraged to stop the video and attempt to solve the problem and compare their answer(s) with a provided answer key. Next segment of the video provides a step-by-step solution of the problem. Each video production includes links

to these steps and the main points that are used in solving the problem. As mentioned, Table I illustrates this concept; each description is a link to a specific part of the video that students can go to and start watching the part that they need help with.

V. IN-CLASS TEAM BASED PROBLEM SOLVING

In order to reiterate the key concepts in solving electric circuits problems and encourage students to take advantage of the dynamically worked-out problems, we introduced in-class team based problem solving exercises. These exercises were identical or very similar to the produced recorded solved problems. To motivate students to review the problems before the lecture, bonus points were awarded to the first group that would come up with the right answer during the class. This part is the major addition to our previous works [1]-[2].

VI. MEASURING PROJECT SUCCESS

A set of ten video worked-out problems, along with their associated problems, have been evaluated by a limited number of students, faculty, and teaching assistance. General comments from all three groups have been very positive and encouraging. Summary of these comments will be presented at the conference.

VII. DISSEMINATION PLAN

The dynamically worked-out problems, follow up surveys, and evaluations were made accessible and conducted via ANGEL (A New Global Environment for Learning) [11].

CONCLUSION

Based on our collected data, which will be published in details in near future, we believe that recorded worked-out problems can improve student learning and could be enhanced to promote and achieve deeper learning, by incorporating the approach outlined in this work

ACKNOWLEDGMENT

Abstract—Teachers of STEM students and employers of graduates recognize that success in many professions requires effective multi-disciplinary team performance. While there is abundant evidence that having "diversity" on a team can contribute to greater creativity and innovation, it is not clear how a group of individuals come to function as a team or how they learn from one other [1,2]. To better understand how university students learn in multi-disciplinary teams, 256 undergraduate students participating in teams in the spring of 2010 at a Midwest university were studied. Data collection included self-reported efficacy for cross-disciplinary team learning (CDTL), as well as self-reported attitudes toward team processes and outcomes, and individual characteristics. During the course of the semester, overall self-efficacy for CDTL increased across all respondents. However, a large number of individual students also displayed decreases in self-efficacy from the beginning to the end of the semester. A previously developed framework for CDTL [2] was further tested and modified as part of this study. Individuals with a high "identity" score at the start of the semester tended to report a smaller increase in this score at the end semester, probably for two reasons: they had less room for improvement, and greater likelihood of overestimating their abilities at the start. Several other findings related to team processes and characteristics were identified and will be discussed.

Keywords: *multi-disciplinary teams; cross-disciplinary; self-efficacy*

I. INTRODUCTION

Hundreds of research studies have collectively identified the major dimensions of team functioning and effectiveness and it has been concluded that structural and compositional aspects of teams account for most of the variance in performance. In contrast, research related to team and organizational learning has emphasized how interpersonal and cognitive factors including beliefs about interactions influence effectiveness. These research streams have guided the current cross-disciplinary learning study. The current emphasis on developing a *cross-disciplinary* perspective as one of the desired outcomes of working on a multidisciplinary team presents significant challenges in university project design settings [1]. There is a substantial difference between working on a team where each person "takes on" the expertise related to their discipline, but has minimal interaction with others, and a team where members actually listen and learn from each other, and can appreciate the assumptions and pressures involved within the practice of other disciplines. This shift from multidisciplinary to interdisciplinarity implies that team members really understand enough of the technical terms, models of reality, and constraints to use that knowledge in their

own thinking about complex problems. Furthermore, the communication between team members is thought to be transformative as opposed to transactional, and new ways of learning and knowing are created as part of the process of interacting with others (Pea, 1994). While there is abundant evidence that having “diversity” on a team usually contributes to greater creativity and performance it is not clear how a group of individuals come to function as a team or how they learn from one other. Schaffer, Lei & Reyes (2008) developed a measure of cross-disciplinary team learning, based on the work of Fruchter & Emery (1999), assessing the extent to which team members related to each other as colleagues on a multi-disciplinary team, or felt comfortable with using the vocabulary, conceptual frameworks, and “constraints” embedded in each of the disciplines represented in their team. It was concluded that most of the undergraduate student teams assessed had not evolved from a multidisciplinary to interdisciplinary state during projects.

One effective way to measure students’ psychological perspectives in a team environment is to measure their self-efficacy for performing design tasks (Carberry & Lee, 2010). The theoretical framework for self-efficacy developed by Bandura (1977, 1982, 1986) highlights the role of self-referent thought in guiding human action and change. Students’ self-reported confidence level in working and learning with team members from different disciplines theoretically reflects belief in their ability to engage in such teams. According to Bandura’s model, behavior changes achieved through methods such as guided exposure, modeling, persuasion, and anxiety reduction, are in part the result of creating or strengthening one’s efficacy expectations. Self-efficacy has been hypothesized to influence choice of behavioral activities, effort expenditure, persistence in the face of obstacles, and task performance (Brown & Lent, 1991). It has been measured in many contexts and is typically related to specific skills and abilities related to performance (Eccles & Wigfield, 2002; Schunk, 1994; Stone & Bailey, 2007). Prior research on students’ self-efficacy in project-based learning environment suggests that the quality of project-based learning experiences impacts students’ self-efficacy (Dunlap, 2005). Positive experiences will lead to an increase of self-efficacy, while stress or fearful experiences will lead to a reduction of self-efficacy. However, it is not clear from the literature how project based learning environments impact learner efficacy for cross-disciplinary learning in the undergraduate education context. The current study is intended to address two research questions: 1) Does self-efficacy for CDTL change over the course of a semester? 2) What factors influence this change?

Self-efficacy has been defined in many contexts, and it is often linked to specific skills and abilities (Eccles & Wigfield, 2002; Schunk, 1994; Stone & Bailey, 2007). Existing research suggests that both individual level factors and team context may potentially influence the extent to which individual acquire technical knowledge as well general understanding and skills related to working with people from different disciplinary background. We consider four individual characteristics (gender, GPA, year in college, and prior

experience with teams), four team context variables (team size, task characteristics, team composition including demographic diversity and disciplinary diversity) that may potentially influence learning and self-efficacy, and one team process variable, namely, CDTL behavior.

II. METHODS

Participants were undergraduate students in a service learning program at a Midwestern university. Service-learning is an experiential instructional approach that provides the opportunity to apply knowledge and skills in authentic, real-world environments (Lindsey & Berger, 2009). Purposive sampling (Patton, 1980) was used in this study. Participants were selected on the basis of their commonness (they were typical cases), and convenience (they were students registered in a project-based learning program). Students participated in this program for one or two academic credits, and were assigned to a team based on stated interests or selected by an existing team based on needs. Teams consisted of a mix of freshmen, sophomores, juniors, and seniors, with many majoring in non-engineering fields such as education, technology, liberal arts, science, and consumer and family sciences. In general, students were expected to participate on the team and contribute to one or more projects for at least two consecutive semesters on campus. Three hundred and three students enrolled in the program in the 2010 spring semester on a total of 27 teams.

Questionnaires were administered at two points in time via paper and pencil, and it took about 10 to 15 minutes to complete each. Nearly all 303 students received the surveys and their participation was voluntary. The first efficacy for CDTL questionnaire was administered during week 4 when the project teams were newly formed (T1). This survey included questions regarding students’ educational and demographic background (e.g. gender, age, year in school, major and GPA), prior experience with teams, and efficacy for CDTL. The post-efficacy for CDTL questionnaire was administered at the end of the semester at week 15 (T2). In addition, the post-survey examined characteristics of the task and intra-team learning behaviors. 178 students filled out the pre-survey, while 191 responded to the post-survey. In total, 256 students from 60 teams responded to at least one survey, out of which, 112 from 34 teams responded to both. We also collected information on the college and major of the participants from archival records provided by the service learning program.

III. RESULTS

There are two major findings of this study: first, the change from pre to post survey self-efficacy change is significant; secondly, researchers of this study identified several key team variables that might influence students’ self-efficacy change.

We tested 8 models on the team variables, and we find out that 1) individuals with a high identification score at T1 tend to report a smaller increase (or larger decrease) in their identification score at the end of the project, probably for two

reasons: They have less room for improvement, and greater likelihood of over estimating their ability at the beginning of the project; 2) compared to females, males tend to report a smaller increase in their identification score over the semester. Individuals with higher GPA tend to report a slightly greater increase in their identification score from the beginning to the end of the project; 3) we found that team size have a significant negative impact on change from the beginning to the end of the project. Teams with more members tend to report a smaller increase in the team's average identification score. Tasks that involve more design stages are also associated with a smaller positive change in team average identification score. Both proportion of males and the number of disciplines in the team is significant at 0.1, and both are negatively associated with increases in team's average identification score from the beginning to the end of the project; 4) when we include all team level variables, only the number of design stages involved in team tasks is significant at 0.1, while all other team level variables become insignificant. Students that are more senior tend to report a larger increase in their identification score from T1 to T2. We also found out that gender becomes insignificant when team level variables are controlled.

IV. IMPLICATIONS OF RESEARCH TO PRACTICE

Based on the findings of the study, we were able to better understand how the team environment influences team member levels of self-efficacy for learning in multidisciplinary teams. Some implications that form the basis for recommendations to guide practice include:

- 1) *Organize the teams with male and female students balance*
- 2) *Organize the teams with no more than three disciplines*
- 3) *Organize the teams with mixture of students from different years in college*

4) *Examine methods to formatively assess levels of identification, formation, and integration as defined in the validated CDTL model.*

Work in Progress: Leadership Emergence among Groups in an Online Environment

Dr. Julie M. Little-Wiles, Dr. Stephen P. Hundley

Organizational Leadership and Supervision
Indiana University-Purdue University (IUPUI)
Indianapolis, IN
jlwiles95@gmail.com, shundley@iupui.edu

Abstract - Virtual learning is a growing means of expansion for both courses and programs for numerous colleges. As the popularity of online courses and programs increases, the question of ensuring “excellence” often follows particularly when discussing curriculum concerns. Certifying online instruction presents challenges especially with regard to traditional methods such as that of group work. One factor that assists groups or teams with their work is that of leadership. Often, in more traditional classroom settings, group leaders are selected by the team after several meetings. How then is the selection and the determination of a leader established in online groups? Is the process similar or different? Does an online group share the same experiences in regard to leadership as a face-to-face group? These questions assisted in directing a two year study at the School of Engineering and Technology at Indiana University-Purdue University Indianapolis (IUPUI) that sought to determine how leader emergence is realized in one online course, International Management, in which a group project has been assigned in place of the final exam. The goal of our project is to not only better understand the process of leader selection in group work, but to help guide faculty in developing an online learning that will enhance and promote student engagement. There are several steps to be performed in our project and this work-in-progress paper will outline those steps and our progress to date.

Learning Management System, Online Groups, Leader Emergence

I. INTRODUCTION

With the growth in popularity of both online courses and programs, curriculum issues persist, especially in regard to the integrity comparable to those same courses that are taught face-to-face (F2F). Part of the issue remains about the perceived limitations that online courses may have in a learning management system. A great deal of courses are taught in an asynchronous environment for the convenience of students due to family obligations and work schedules, while still others mix in elements of weekly or bi-weekly real-time chats to help provide the one-on-one interaction students crave.

As instructors try to find the perfect balance to interaction within the courses they teach online, they also deliberate the appropriate assessments for their courses as well. One particular method more often preferred in face-to-face instruction than that of online instruction is that of group work. Group projects present challenges to both students and

instructors in any environment based on one particular factor: leadership. In the more traditional face-to-face setting, students would elect or choose their group leader amongst themselves once they have met together for at least a couple of class sessions. But in an online setting, and in especially an asynchronous environment, this can be difficult. This quandary led researchers to explore this topic with the launch of a two year study at the School of Engineering and Technology at Indiana University-Purdue University Indianapolis (IUPUI) that sought to determine how leader emergence is realized in one online course, International Management, in which a group project has been assigned in place of the final exam. Three main questions guided the research including: (1) How is the selection and the determination of a leader established in online groups? (2) Is the process similar or different than face-to-face courses? (3) And finally does an online group share the same experiences in regard to leadership as a face-to-face group?

II. FRAMEWORK

Researchers focused on several key terms and concepts examining what previous research had already defined to provide a better understanding of the context the study encompassed.

Within a learning management system (LMS), collaboration is an important element that can be very beneficial to students in regards to engagement within the group work. Harasim, Hiltz, Teles, and Turoff define collaboration as "... any activity that in which two or more people work together to create meaning, explore a topic, or improve skills" [1]. Collaboration used in a LMS environment should be viewed as "an essential ingredient in the recipe to create an 'effective learning environment' as it provides learners with the opportunity to discuss, argue, negotiate and reflect upon existing beliefs and knowledge. The learner is "involved in constructing knowledge through a process of discussion and interaction with learning peers and experts" [2]. This is an essential element then in engagement, and more specifically, within a group project used as an assessment in an online course.

Leadership has long been determined to be found in the situation with certain leader behaviors emerging dependent upon the situation [3]. One of the earliest researchers to study

emergent leadership within a group setting was Robert F. Bales. Working with various colleagues on several studies Bales concluded that emergent leaders within a group environment primarily demonstrated two types of behavior: task-focused and socio-emotional [4], [5], [6]. So then we anticipate that an emergent leader within a group will keep their group focused on the goal at hand, while at the same time consciously tending to the social or emotional concerns and needs of the group. Several researchers since Bales have not only confirmed this early discovery [7], but also provided further advancement of the work in the areas of member development, idea cultivation, and support [8], [9], [10].

With this structure in mind, we examine leader emergence as one inclusive to teamwork that is goal driven with the creation of trust amongst members.

III. THE PROJECT

Since our larger goals for this project are to better understand leader emergence in regard to group work within online courses in a learning management system, we must complete several stages in order to reach a final recommendation on elements crucial to the project goals.

Our project is divided into the following four stages:

1. The development of the group project within the selected course, International Management.
2. The launch of the first group project within the International Management online course, fall 2011, with follow-up student survey.
3. The continued assigning of the group project each semester the online course, International Management, is taught between fall 2011 and fall 2013, with follow-up student survey.
4. The final comparison of survey results and student remarks with final recommendations

Stage One was completed last summer 2011 as the class was reassigned to one of the researchers at the School of Engineering and Technology at IUPUI, and the project subsequently planned. For students, the group project consists of the creation of an International Management Business Proposal, consisting of both a written paper and PowerPoint presentation that are turned in at the end of the course. Each student group is assigned their own chat room within the LMS so that they can freely interact whenever most convenient for them. Milestone assignments are set by the instructor to aid the groups in the completion of the task. A "communication" leader is established early in the process as liaison between the group and the instructor; but researchers intend to discover if this same person truly leads the group throughout the entire project or another leader emerges as groups are given the option to change leaders at one point. Finally, a survey is administered at the end of the course with results provided and summarized from all the courses studied in Stage Four of the project.

Fall 2011 observed the completion of Stage Two as the first initial group project within the course was launched. A

total of six groups, each with four student members, occurred. A 10% total response rate to the survey was received from the students as no incentive was given and the approach of the holidays limited response time. Those early results though indicated that a different leader had emerged and that groups experienced similar issues to their F2F counterparts in regards to finding time to meet for the project. Students also expressed that in their opinion, an online group project was more challenging to complete than that of a group project in a traditional F2F course, and as a result they preferred not to have them assigned in online courses.

Stage Three will continue with the scheduled course, International Management, through the end of 2013. The next scheduled sessions will be held in summer and fall 2012.

A final comparison of all results and remarks will conclude during Stage Four, providing researchers with a small-scale example of emergent leadership within online groups to reach a final recommendation.

IV. FINAL REMARKS

As Stages One and Two are now complete, researchers are anxious to continue with the project through the final stages to see if the early results are consistent throughout the project. Researchers are also hopeful that the additional sets of results will continue to reveal details to assist them in answering the research questions posed by the study.

Abstract— At the end of their technical studies, students have to present a final project in order to finish their degree. With this project, students prove that they have got all of the competences they should have acquired. Some competencies, such as the ability to communicate orally or the ability to argue may be evaluated during a face-to-face dissertation defense, but how to translate this evaluation scenario to a virtual environment is a challenge. This paper faces the problem of presenting dissertations in a virtual environment, to evaluate the aforementioned competences. The solution proposed, called Present@, is focused in teaching and technical dimensions, and is complemented with some materials and tutorials that help students to acquire those competences. Therefore, the paper shows Present@ as a solution to the problems that virtual universities have to face when dealing with the evaluation of final degree projects and particularly in their defense. Present@ has been tested over 131 students during six semesters and the results show that it actually helps students to acquire the desired competences in virtual environments. In addition, the analysis about the use of the tool has denoted that videos are an efficient mechanism to evaluate the ability to communicate of students and to work on transversal competencies. Some students also commented that the use of videos make the dissertation defense more natural and closer to face-to-face environments.

Final degree project, virtual dissertation, presentation

I. INTRODUCTION

At the end of their technical studies, students have to present a final project in order to finish their degree. With this project, students prove that they have got all of the competences they should have acquired. Many students are able to develop very good engineering projects, where they show their technical abilities and a dominion of the technical competences acquired during their studies. However, a degree project is not only focused on technical competences, but also

on transversal ones, such as the ability to write and present effectively. These transversal competencies are usually evaluated during the face-to-face dissertation defense of students, but how to translate this evaluation scenario to a virtual environment?

In e-Learning environments multimedia resources are being extensively used to support the student learning, however, the resources students produce during their learning activity are mostly textual. This makes it difficult to assess some transversal competencies that students have to learn; mostly the ones related to oral expression [1] and argumentation [2]. This problem has been addressed by different works to support oral presentations. Some examples are [3][4], which are focused to support oral expression in English for non-English speakers students; [5], on the other hand, shows an environment that is used to teach PhD students to make presentations. It is important to note that actual approaches to that problem are more focused to the methodology than to the technology since, nowadays, the sophistication of learning management systems efficiently supports the use of multimedia resources.

This paper faces the problem of presenting dissertations in a virtual environment, in a way that allows evaluating transversal competences. The solution proposed consists in that students make a video presentation, upload it to a web within the context of the classroom, and answer questions from both the evaluators and their partners, also within this web space. To be successful, the problem is faced from three dimensions: teaching, understood as giving instructions on how to acquire those competences; learning, understood as how students manage to acquire those competences; and technical, understood as offering students the software they need. Thus, some learning resources are given to students explaining how to make effective presentations (teaching dimension); and a tool has been developed, named Present@, that allows students to upload their videos and develop, in the same place, the virtual debate (technical dimension). The proposal has been evaluated by using questionnaires. The paper presents some results about the application of this solution over 100 dissertation defenses in the Computer Engineering grades offered by Universitat Oberta de Catalunya (UOC), a virtual university, during the last three years.

From the analysis of the results it can be concluded that: 1) Students actually face the objective competences, since in the open questions they highlight aspects like making oral and visual presentations, sharing them, and the stress of answering

to partners and members of the tribunal; 2) time dimension should be taken into account, since students complain about the time they have to invest to make the presentations; but also complain about the little time they have to enjoy the virtual debate; and 3) students evaluate positively the changes introduced in the project dissertation. From all these items we conclude that the changes introduced in the final degree project (FDP) actually help students to acquire the competences related with final project dissertation in virtual environments. Nevertheless, some improvements should be made, mainly in the technical and teaching dimension.

The paper is structured as follows. Section two defines the context of the problem to solve (the virtual university where Present@ has been integrated), what a dissertation defense is, the difference between dissertation defenses in virtual and face to face (F2F) universities, and the lack of dissertation defenses in virtual universities. Later, third section deals with Present@, which is the proposed approach to support all the necessary functionalities of the virtual defense. Thereafter, some analysis about the use of Present@ during the last two years and over 100 students is presented in order to evaluate its usefulness. Finally, a brief discussion and conclusions are presented.

II. DISSERTATION DEFENSE: WHAT IS IT AND HOW IT IS CONDUCTED IN VIRTUAL AND FACE TO FACE UNIVERSITIES

A. *The Context: The Virtual Univesrity*

The UOC is the main virtual university in Spain, with over 45,000 students. The UOC corresponds to a 100% online learning university that focuses in the asynchrony in time and space, meaning that teachers and students neither meet in time nor in space. The UOC's Virtual Campus has been the medium through which students and lecturers have communicated ever since the university was founded in 1994. The Virtual Campus has virtual classrooms, where the subjects are taught. Each classroom has a communication facility that enables lecturers to guide learning activities and students to ask questions. The communication facility uses forums and bulletin boards to record the messages that classroom users (lecturers and students) exchange with each other.

The profile of UOC students differs from the profile of F2F university students. UOC students choose this university, among other reasons, because of the virtual environment and the asynchrony, which allow them to combine work, family and studies.

B. *The Problem: Disertation Defense in Virtual Environments*

We are therefore in a context that deviates from traditional patterns [6] and, of course, also affects the completion of FDP. In particular, at UOC various students deal with the same FDP and it has to be delivered at the end of the semester. There are many universities where the project is unique for each student and the student decides when to deliver it. The UOC model leads to a situation where students have passed all other subjects but the FDP, because they are working part or full time and never find time to finish FDP. The fact that different students work on the same project, facilitates the comparison of

results from several students and it even makes possible to suggest bigger collaborative projects where every single student deals with a given part.

It is important also to take into account that the communication between students and teachers is through e-mail within the Virtual Campus context and there is no compulsory personal contact between teachers and students, since they can both live abroad (for example, a teacher can live in Hong Kong and the student in Buenos Aires).

As stated before, in some cases FDP are developed in groups. In these projects a group of students works on different parts of a project under the guidance of the teacher who directs and coordinates the project. Eventually each student submits his/her own deliverables, for the part that he or she is responsible. With this type of project two objectives are accomplished: firstly, to tackle more ambitious goals, and secondly, to learn and practice virtual teamwork techniques within major projects.

At the end, every student has to deliver a report of the personal part of the project as well as a visual presentation. In this scenario virtual students acquire or improve their competences in writing and communicating in virtual environments, in project management, and in some projects, also team work techniques. So, these are some advantages of the FDP at UOC, but there are also some disadvantages, mainly regarding the virtual presentation of the FDP, as we will show in next sections.

C. *Dissertation Defense in Face to Face Universities*

Presentation defense is a usual procedure in most of the universities. Even though there are some differences, there are some common features::

- There is a committee, usually consisting of at least three people. It is advisable that they should be experts on the topic. At some universities, the advisor is also a member of the committee.
- The student writes a report of his/her work, and submits it to the members of the committee.
- The student presents his/her work in an oral presentation during about 30 minutes. Thereafter, the members of the committee make questions in order to clarify some aspects of the work as well as to evaluate the students' knowledge about the topic.
- After the presentation, the committee qualifies the final degree project.

Regarding the oral presentation, the students who pass the final degree project have worked the following competences:

1. Synthesizing their work in a presentation which has time limits.
2. Speaking in public.
3. Making oral and visual presentations.
4. Facing questions about their own work in a stressful situation (argumentation).

All these competencies are really important in a professional environment since a large amount of the work of most of the technical professionals consists in preparing and presenting projects.

D. Dissertation Defense in Virtual Universities: the Case of the UOC

UOC is an on-line asynchronous university and, when dealing with the FDP the question that arises is: how can students at UOC get all the competences regarding the FDP that students in F2F universities develop?

Until the presented work was deployed, the students made a presentation document, with 20 slides maximum, "to be read and not to be presented". Students used to prepare the document using Power Point®, libreOffice[7] or Prezzi [8]. The document should be delivered at the end of the project together with the project report. A few days later, there is a virtual debate in which the members of the committee send their questions to the student by email and the student has to answer in less than 24 hours.

With this method students could address competences 1 (synthesizing) and 4 (argumentation), but not competences 2 (speaking in public) and 3 (presenting). In addition, competencies about synthesizing and argumentation are not fully addressed because it is not the same to synthesize the work in a number of written slides than in an oral presentation, which includes slides as well as a speech. The same happens with fourth competency because answering questions in a face to face presentation with audience increases the stress and is more difficult than doing so from home. Furthermore, students have to deal with a contradiction because "a presentation to be read and not to be presented" is unnatural.

Thus, we faced a situation that started from a contradiction and was not able to deal with all the competences that have to be faced in a final degree project. In the next section it will be shown how to overcome these limitations.

III. A VIRTUAL ENVIRONMENT FOR DISSERTATION DEFENSE

At this point we have already stated the problems faced by FDP presentations in online environments, regarding the main competences the students should address in this exercise. To overcome these problems, a solution has been proposed and tested during several semesters at UOC so that virtual students could acquire the competences related with presentations.

The solution consists on applying several actions, which are grouped in 3 dimensions:

- Teaching dimension: students receive a document explaining how to prepare effective presentations and how to write technical documents correctly [9].
- Learning dimension: students elaborate a video presentation shorter than 20 minutes.
- Technical dimension: a web application integrated in the Virtual Campus has been developed so that students can: 1) upload their presentation file; 2) see and comment about their partners' presentations; and

3) answer the questions from the committee. This web makes the presentation, questions and answers available to other students and teachers.

Regarding the learning dimension, students can use any available software in order to make their presentation, although teachers make some suggestions (see Section IV.B for more information about the tools used by students).

This method could allow virtual students to face all the competences that should have to be acquired in a final degree project. In particular, learning dimension allows addressing competences 1 (ability of synthesizing their work in a presentation which is limited in time) and 3 (ability of making oral and visual presentations), teaching dimensions give the basic knowledge to students to address successfully competencies 1 and 3, and technical dimension allows facing competence 2 (ability of speaking in public), although in a restricted way; and competence 4 (ability of facing questions in an stressful situation). The new proposed system also avoids the contradiction of a "presentation to be read".

Present@ is a tool that has been created to support the participants in the dissertation defense during the dissertation defense. Therefore, it can be seen as an integrated tool that allows:

1. Upload the deliverables of the FDP: including the documentation of the project and the presentation in a video format,
2. Download and visualize the deliverables of the FDP: the access to the documents will be restricted to the students who have made the same (or similar) project and the members of the committee, and
3. Conduct the debate: the system has a communication space where the members of the committee can make questions and students can answer such questions within the time limit.

Sharing the same space with students that have made similar (or the same) projects allow making more interesting and fruitful virtual debates. In some cases teachers may allow that students with similar projects participate in the virtual debate to make questions to their colleagues. We have found that, when allowed, students tend to make questions to other students with similar projects in order to discover alternatives of implementation or how to make something that they have not been able to do.

Present@ has been created by reusing a Wordpress blog with some new developments and pluggins that allow connecting it with a video streaming server and integrate it within the UOC virtual campus using a single sign-on. There are some software systems that could be used instead of Present@, but the necessity to integrate the environment in the Virtual campus of the UOC and the fact that the dissertation defense is asynchronous advised the creation of a new tool.

In Figure 1 the main page of Present@ is shown. It offers the list of videos uploaded, which can be ordered according to author name and surname, title, labels, status, license and comments. It is important to note that the number of comments in red indicates the unread comments. So it is very useful to

committee members in order to see whether there is any new answer of a student, or to students to find out if there are new questions for them. Another useful functionality is to download all the videos in a single zip file, which will facilitate to store and visualize them anywhere and using any kind of device.

Figure 1. Main page of Present@.

When clicking on a video file, the video page is accessed. There, information about the video is presented, the video can be visualized and comments can be added. Since the purpose of this system is to help in the dissertation defense, the comments allowed in this page are only questions of the committee's members (or from other students when allowed) and answers of students to such questions.

It is important to note that this tool is useful for students of any discipline, making it a relevant tool for virtual environments. Also comment that the created tool is fully integrated to the virtual campus, taking profit of the security control of the virtual campus, and has been designed to be used in any platform and web broser.

IV. THE USE OF PRESENT@ IN THE LAST 6 SEMESTERS

The proposed approach has been tested during 6 semesters and 131 students have been questioned about the several items introduced: teaching documentation, preparing a video-presentation and the software tool. In this section results from the questionnaires are presented. Due to space constraints we summarize the results of teaching and learning dimension and give more details about the experiences of the tool created to deal with the technical dimension.

A. Teaching Dimension: The Teaching Material

The students were asked about the usefulness and the completeness of the materials that explain how to write technical deliverables and how to make effective oral presentations. From the answers of students we conclude that the teaching material fits the main aspects expected by students, but actually lack a bit more of information about how to make visual presentations both technically and conceptually.

B. Learning Dimension: Making Visual Presentations

The second item evaluated is the elaboration of visual presentations. The students were asked about the software used

to create presentations and why such software was selected, the experience of creating visual presentations, and what would they improve.

Regarding the software used to create the visual presentations, the most used software was Camtasia Studio [10], which was employed by 80% of the students. Other software used were CamStudio (9%)[11], and, with no more than 1%-2% of users: FireScreen, Quicktime [12], FlexBuilder [13], Windows Movie Maker [14], iMovie [15], PresenterSoftPower VideoMaker [16] and RecordMyDesktop [17]. The main reasons the students give to choose Camtasia Studio were that they find it easy to learn; and find the post-edition capabilities that the software offers both important and time-saving. Students also commented that, even though it is commercial, there is a 30 days trial license, which is time enough for students to elaborate their presentation.

The next set of questions refers to preparing the presentation. It is important to note that 25% of students already created visual presentations before. Most students found easy to make a visual presentation (74%); only 6% of students said that it was difficult.

The 93% of students find the experience of making a visual presentation enriching and 92% of them said that they will create this kind of presentations in the future to transmit their ideas. However, the students were not completely convinced about the necessity of using this kind of presentation in the FDP, in fact only the 51% preferred a visual presentation.

The students were also asked, using open questions, about the best and the worst aspects of making visual presentations. Regarding the best aspects, 57% of the students gave answers regarding their personal enrichment, preparation and experience (even professional experience). 29% emphasize the technical aspect, since they say that the best is learning to use the software, including, edition and post-edition tools. There are a 9% of the students that compare with F2F situations and say that thanks to the video presentations, F2F and virtual experiences are very close. We find also about 4% of the students that highlight the possibilities of webcasting. Finally, we found about 3% of the students that see nothing positive in this kind of presentations.

About the worst aspect of doing visual presentations 30% of the students complained about time: they have to invest extra time to learn new software, as it requires more time to prepare a video-presentation than a "presentation to be read"; also, they would like to have more time in order to get a better result, for instance they would prefer longer presentations (over 20 minutes) and save time in reducing the duration of the presentation. 22% of the students complain about hearing themselves in the video and a 5% complain about scripting capabilities. This item also affects the technical dimension since 17% complains about the software itself, mainly because of the problems with audio level, and the time consumed by testing several software; and 12% complain about the problems to reduce the size of the video file in order to upload it. Only 3% of the students found that nothing has to be improved.

At the end the 90% of students considered that they learnt how to make better presentations.

C. Technical Dimension: Present@

The last two semesters the new tool Present@, version 2 was introduced and 33 students were asked explicitly about this tool. The questions and answers given are:

- *What is the students' opinion about Present@?*
Answers go between 1 (bad) until 5 (very good). 88% of the students answered between 3 and 5 and 55% between 4 and 5. No student marked 1.
 - *What do students liked more?*
 - 48% answered simplicity.
 - 48% answered the possibility of commenting the work from their colleagues and seeing everything at the same place: videos from partners, comments, virtual debate, etc.
- The rest of students highlighted the possibilities offered by the tool.
- *What do students liked less, and what should have to be improved.* In fact, these were two questions but answers were so related that results can be presented together. The answers from students were:
 - 47% complain about technical problems, mainly when uploading the video.
 - 21% criticize about the poor format of the comments, the few flexibility of its editor and the lack of an automatic notification of new comments (similar to a RSS syndication).
 - 16% of the students say that everything is O.K. and would introduce no improvement.
 - 12% complain about usability
 - The rest of students suggest that the tool should have to be more used within UOC.
 - *Do students recommend the tool in future semesters?*
The answer to this question is "yes" from all students but one.

From these results we conclude that students have a good opinion about the tool, although some technical improvements should have to be developed, mainly in the uploading and commenting elements.

V. CONTRIBUTION

From the experience of the Present@ environment during the last 6 semesters, which has been summarized and analyzed in the previous section, we have seen that the new approximation really supports final degree project dissertations, satisfy the students in the process and helps them to address transversal competencies that were not addressed with the former environment.

In the following points we enumerate the competencies that can be evaluated and addressed using Present@. For each competence, we add some complains from students that denote

that they have to excel themselves in such competence in order to achieve the expected results:

- Ability to synthesize the work done in a presentation limited in time: some complains from students about time constraints show that they have to work hard to acquire this competence.
- Ability to speak in public: once again, comments of students about virtual debate, where they emphasize that can comment and receive comments from the rest of the partners, show that they actually work this competence.
- Ability of making oral and visual presentations: complains from students about how to make oral and visual presentations show, once again, that this competence is actually worked.
- Ability of facing questions about their own work in an stress situation: once again, comments from students about the importance of questions from the members of the committee as well as their partners, combined with complains about time, and some comments about stress, show that this competence is also worked.

We believe that the defense process used in Present@ is more natural and closer to the defense process performed in F2F universities. This fact, together with the fact that it allows addressing more transversal competencies, demonstrates that Present@ environment is a useful environment for virtual universities to deal with dissertation defenses. In addition, in the case of the UOC, Present@ clearly improves the former environment.

It is also important to note the good acceptance Present@ had in students, as can be seen in previous section. Unfortunately, no questionnaires have been sent to teachers. But from some private interviews with teachers who have used the environment, it seems that they also find the tool useful. However, as a negative aspect they said that in the new environment they need to spend more time to evaluate each student. This is because with Present@ they have to visualize a video presentation for each student, which takes around 20 minutes, while before they had to read a presentation, which could take less than 5 minutes.

The innovation of the presented approach is not only in the developed environment, but also in the integration of the three dimensions. Therefore, a similar environment may be created and used in other environments using other software able to manage video files, such as Blackboard or eCollege. In fact, regarding the management of video files, the functionalities provided for some other learning management systems may exceed the ones implemented in Present@.

Another contribution of this work is the information that has been extracted from the questionnaires done to students, which has been summarized in the previous section. Such information is being used in order to improve the environment and the related resources. On the one hand, new functionalities are being developed in order to facilitate the upload of videos. Some improvements are also being done to the functionalities related to the debate by both improving the discussion

visualization and allowing to create multimedia comments (audio, video and text). On the other hand, more support have been provided by creating new tutorials that explain how to use the most popular tools and a new book is being created explaining how to make an effective video presentation taking into account the comments of the users.

VI. CONCLUSIONS AND FURTHER WORK

In this paper it is shown a solution to the problems that virtual universities have to face when dealing with final project dissertations. It is especially difficult to face competences regarding speaking in public or making oral and visual presentations.

The solution proposed consists in that students have to make a video presentation, upload it to a public web within the context of the classroom, and answer questions from the committee as well as from fellow students. In order to be successful, the problem is addressed from three dimensions: teaching, understood as giving students instructions on how to acquire those competences; learning, understood as how students manage to acquire those competences; and technical, understood as offering students the software they need.

Thus, some documents are given to students explaining how to make effective and efficient presentations (teaching dimension); and a tool has been developed, named Present@, that allow students to upload their videos and develop, in the same place, the virtual debate (technical dimension).

The proposed approach has been tested during 6 semesters and 131 students have been questioned about the several items introduced by this software: teaching documentation and preparing a video-presentation. From the analysis of the results it can be concluded that:

- Students actually work the desired competences, since in the open questions they highlight aspects like making oral and visual presentations, sharing them, and complain about the stress of answering to partners and members of the tribunal.
- The time dimension should have to be taken into account, since students complain about the amount of time they have to invest to make the presentations; but also complain about the short time they have to enjoy the virtual debate.
- Students evaluate positively the changes introduced in the final degree project dissertation.
- Some technical improvements should have to be introduced in Present@ in the uploading and commenting elements.

From all these items we conclude that the changes introduced in the final degree project actually help students to acquire the competences related with final project dissertation in virtual environments. Nevertheless, some improvements should have to be made, mainly in the technical and teaching dimension.

In addition, Present@ has revealed itself as a very useful tool to communicate and we are starting to use it as a video repository in a similar way to [18]. The repository is located within the classrooms, where teacher makes short explanations and students can ask questions and comment about them.

ACKNOWLEDGMENT

This work has been partially supported by department of Innovation of the Universitat Oberta de Catalunya (APLICA/2010) and by the AGAUR from the Generalitat of Catalonia (2010MQD 00015).

Infusion of ABET–specified Professional and Academic Content into Off-campus Work Experiences via Distance Learning Modules

Chris Plouff and Nael Barakat
School of Engineering
Grand Valley State University
Grand Rapids, Michigan, United States
plouffc@gvsu.edu, barakatn@gvsu.edu

Abstract— Educating engineering students on ABET-required professional and nontechnical skills is usually a challenging task. The related challenges include finding a balance between the content, the delivery format, the time of delivery, and location in the curriculum for this material. This paper presents details on a pilot project to deliver professional and academic content to engineering students via distance learning during required co-op semesters. Assessment of this experience to solve multiple challenges simultaneously is also presented. Students were educated on engineering ethics, engineering economics, and project management, which are readily applied in workplace settings.

This pilot study was conducted during the winter 2011 semester and included six modules, targeting the level of the first co-op course. Twelve co-op students were carefully chosen as a controlled sample to participate in the study. This sample included a horizontal cross section representing all engineering programs, and a vertical cross section including students from each of the three co-op courses. Direct and indirect assessment methods were conducted to assess the project.

Students' perceptions of their knowledge in the targeted topics were greater than their demonstrated knowledge. Direct assessment showed an increase in students' knowledge for all three topic areas.

Keywords – cooperative education; online distance education; professional skills

I. INTRODUCTION

Continuous improvement is a living process that is built into the engineering curricula and emphasized through periodic assessment and evaluation. This project was initiated and conducted as part of this process to assess, evaluate, and improve the academic content and requirements of the co-op sequence of courses at the School of Engineering (SOE) at [the institution]. The sequence includes three co-op courses with a total of nine credit hours that students register for during their co-op experience with an engineering employer.

The goal of this was to identify, deliver, and assess, new content to students via distance learning during co-op

semesters. The new content would focus on educating students on professional and nontechnical skills, such as engineering ethics, engineering economics, and project management, which are not easy to incorporate in classic technical courses, or in an engineering curriculum at content capacity. These skills are emphasized in several ABET program outcomes [1] which are common to all engineering students, and have been difficult to define and assess in traditional education settings [2].

Online education programs in engineering have been around since the early 1990's [3], and internet-based interventions in workplace-based learning date to at least the late 1990's (e.g. [4]). Learning communities for co-op students have been recently studied at the University of Cincinnati [5], with a focus on organizational culture, ethics, social responsibility, and connecting theory to practice. Other studies have looked at the use of online communities during co-op to help with reflective thinking about learning related to the workplace experience [6, 7] and augmenting skills in professionalism [8, 9]. However, none of these studies go to the level of presenting specific academic content, such as engineering economics and project management, and assessing students learning of the presented material from the educational institution.

II. BACKGROUND OF CO-OP PROGRAM

A. Co-op Program Format

The SOE at [Institution] offers a bachelor of science in engineering degree with majors in computer, electrical, interdisciplinary, product design and manufacturing, and mechanical engineering. All programs are accredited as co-op programs through ABET. All admitted undergraduate students participate in a mandatory co-op program, for a total of twelve months of work experience, during the junior and senior year of the academic program. The cooperative education program is an alternating semester program that the student participates in during the last two years of the academic curriculum. Students work with the same company/organization for each of three four-month-long semesters. A typical sequence for a student is shown in Table 1.

B. Existing Processes and Academic Content

Students receive three credits for each semester of co-op, for a total of nine co-op credits applied towards graduation. The student receives a letter grade for each co-op semester which is determined by taking into account the evaluations provided by the work supervisor, and the accuracy and quality of written work. A faculty member monitors and assesses the work of the student in collaboration with the co-op supervisor, including review of weekly student journals and visiting the work site each semester.

Prior to the current study, the requirements for a student when participating in a co-op semester included reading and writing assignments, participation in cultural and/or civic activities, and analyses/discussion of an ethical issue. The content of the readings addressed the relationship between technology and society and, usually, its relationship to ethical decision-making. Students were required to write a summary of the reading material each semester. In addition, students kept a written journal of weekly activities that was submitted and reviewed by the supervising faculty member. The student was encouraged to not only document day-to-day activities but also to reflect on learning and observations of the work environment, including the roles and actions of professionals in their workgroup. Each co-op semester, the entire group of co-op students came together for a meeting to discuss their co-op experiences and reflect on an ethics case study.

III. STUDY RATIONALE

There were two converging events that led to conducting the work described in this paper: 1) continuous improvement instigated by recent self-study reports for ABET reaccreditation, and 2) assessment of the existing academic content of co-op. The following ABET program outcomes are assessed and evaluated through a dual process during the co-op courses:

- 'd': an ability to function on multidisciplinary teams
- 'f': an understanding of professional and ethical responsibility
- 'g': an ability to communicate effectively
- 'h': an understanding of the impact of engineering solutions in a global, economic, environmental, and societal context
- 'j': a knowledge of contemporary issues
- 'k': an ability to use modern engineering tools

At the end of every co-op semester, each student is assessed by the company supervisor using an online data collection tool.

The assessment tool includes questions that are directly mapped to each of the program outcomes. In addition, a faculty member is assigned as an advisor to each student during the co-op semesters. The faculty member corresponds on a regular basis throughout the semester with the student, and visits the worksite to meet with the student and supervisor to review the student's work. This process provides two points for assessing the program outcomes for each student.

Through this on-going process, and in the course of summarizing evaluation of program outcomes for the writing of the Self-Study report for ABET re-accreditation, several themes emerged. It was determined that program outcomes that could use increased and continued attention included: applying economics considerations in engineering design; engineering ethics; professionalism, and professional responsibility.

The co-op courses sequence was reviewed to determine the suitability of current academic content and if there was an opportunity to add value to the co-op course sequence by potentially adding academic content. Two key reasons emerged supporting this approach:

- co-op is a common experience in the upper division for all engineering students, and;
- the workplace environment relates well with the delivery and application of the content and spirit of several program outcomes.

Furthermore, it was determined that potentially adding content to the co-op course sequence could free up time in other courses to either expand or add content. Finally, if academic content was added, review of student's work related to this content would become more robust by adding a level of assessment. In addition to the current assessment practices of obtaining feedback from the workplace supervisor and the faculty advisor, academic content in the co-op course would provide assessment of work product from students as well, essentially resulting in a triangulation of assessment data.

As part of the assessment of the academic content of the co-op semesters, both faculty and students were consulted and provided input on the existing co-op academic content and proposed content through a survey instrument. The results of this survey are provided in Figure 1 through Figure 3. Figure 1 presents faculty and student ratings of the activities required during a co-op semester prior to the pilot work conducted for this project. These activities are referred to as 'existing' to represent academic components that have existed for several years for the co-op course sequence. As seen in Figure 1, both faculty and students rated journaling periodically, analyzing ethics case studies, and reading and reporting on a book related to engineering professionalism the highest of the existing content. Note that there is no student rating for books on professionalism for students as there were no students in the pilot group that had read this book as part of their requirements at this stage of the co-op course, and therefore could not provide an opinion.

Prior to the current study, the requirements for a student when participating in a co-op semester included reading and writing assignments, participation in cultural and/or civic activities, and analyses/discussion of an ethical issue. The

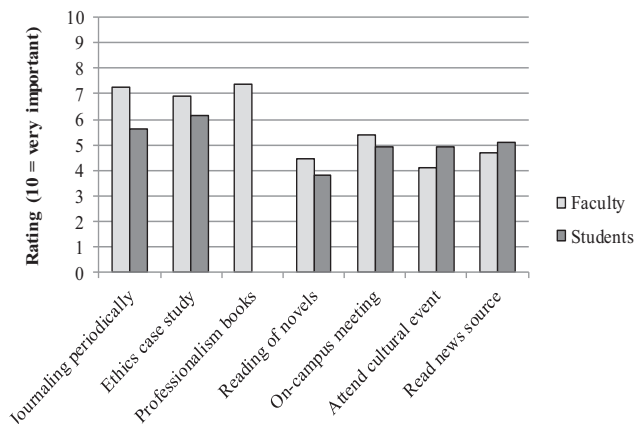

Figure 1. Faculty and student ratings of 'existing' co-op activities.

content of the readings addressed the relationship between technology and society and, usually, its relationship to ethical decision-making. Each co-op semester, the entire group of co-op students came together for a meeting to discuss their co-op experiences and reflect on an ethics case study.

Faculty members were asked whether the 'existing' pedagogical approach was appropriate, and whether there should be any adjustments. Figure 2 shows their responses regarding the pedagogical approach to the co-op course sequence. A small percentage of faculty (8.5%) recommended full replacement of the 'existing' academic content in co-op, while the majority (68%) of faculty recommended partial replacement of the co-op content. Another 20% of faculty believed that the 'existing' academic content of co-op should

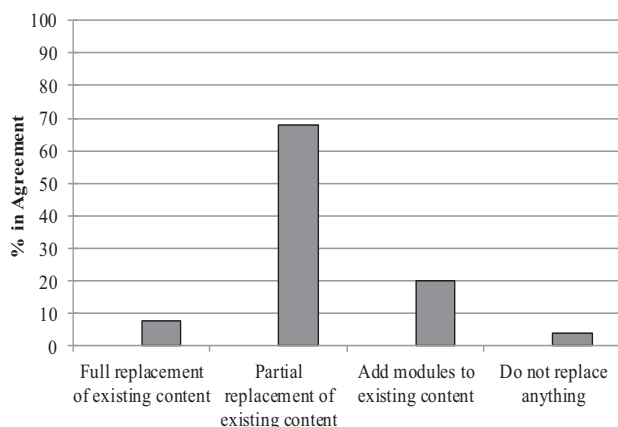

Figure 2. Faculty opinions of pedagogical approach to the co-op course curriculum (25 responses).

be kept and to add academic content to the 'existing' requirements. Finally, 3.5% of faculty recommended not changing the co-op content at all.

Review of assessment results across the greater curriculum, coupled with discussion among the faculty, resulted in strong support (70% of overall faculty respondents or greater in agreement) for added content in the co-op curriculum in the

following areas: professionalism, engineering economics, engineering ethics, communication, and project management. There were also 50% of overall faculty respondents or greater supporting the topics of leadership and team building (see Figure 3).

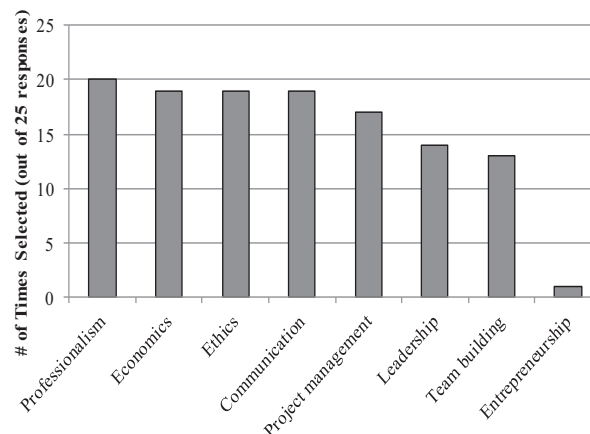

Figure 3. Support for topics to add to the co-op curriculum.

In summary, it was determined that there was support from faculty and students to update and modify the 'existing' curriculum during the co-op course sequence, and that this change in curriculum should replace some of the 'existing' co-op content – namely the reading of novels with technical-ethical themes, on-campus meetings, attending a cultural event, and reading of a news-source. The focus of the additional content should be in the areas of engineering ethics and professionalism, engineering economics, professional communication, and project management.

IV. NEW CO-OP ACADEMIC CONTENT

A. Format

The development of additional academic content for the co-op course sequence received funding through an internal grant for the development of curriculum, in response to a proposal by the authors. The grant supported the proposed production of modules to be used as distance-learning educational material during the co-op education courses by engineering students. These modules targeted the coverage of professional skills that engineering students need but do not easily get from on-campus, traditional technical courses. The content of the modules for the pilot study were geared toward the first co-op semester and included introductory material on engineering ethics and professionalism, engineering economy, and project management. Additional content on professional communication is proposed for the second and third co-op semesters, but was not incorporated into the pilot study.

The complete set of on-line modules would constitute a thread of three full courses that would be divided over the three required co-op courses. Having exposure to these practice-related issues while being in the workplace presents a unique opportunity for the students to apply what is learned. The curriculum was designed with the following characteristics:

- Use of a scaffolded approach to accommodate the logistics of the co-op courses and the maturity level of the students. In every co-op course the students will be exposed to a related set of skills at a gradually advanced level.

- The pedagogical basis provides maximum flexibility for unlimited time and location access. However, the rigor and order of the educational process are maintained by assigning timely periods for the students to provide feedback and responses to the exercises and tests associated with the modules.

Modules were designed to be relatively brief, focused packets of information that could be reviewed within a 30-60 minute timeframe. The modules were delivered via Blackboard, the university-wide, web-based course management software, and consisted of various media including written materials, papers, videos, websites, podcasts, etc. Each module had an associated, short test or quiz that was automatically graded in Blackboard. The objective was to have six to eight modules to complete in a given co-op semester, which is almost equivalent of one lecture-course credit. Modules were 'open' at scheduled times throughout the semester and students were required to complete them during that timeframe. A primary instructor was available for discussion and to answer questions at both regularly scheduled times for phone or video chat, as well as via email, chat or discussion board.

The target was for modules (review and assessment via test or quiz) to take no more than a total of eight (8) hours in a co-op semester. This would not unduly interfere with the primary objective of co-op, which is for students to focus on applying and developing engineering knowledge, skills and abilities through work experience. It also would not preclude the continuation of important pedagogical and developmental activities such as weekly journaling. In addition, there was no anticipated additional work required of the student's co-op faculty advisor each semester, other than incorporating the grading of the tests/quizzes from the modules into the student's final grade.

B. Pilot Study Overview

The pilot study was conducted during the winter 2011 semester, as described above. The content of the modules for the pilot study are presented in Table 2. Twelve co-op students were carefully chosen during the EGR 390 course, as a sample to participate in the study. The student demographics can be seen in Table 3. The sample was selected to include a horizontal cross section representing all engineering programs, and a vertical cross section including one student from the first co-op level and one student from the third co-op level for comparison purposes. A pre-study survey and a post-survey were conducted. The pre-survey included questions about the student's interest in, and the appropriateness of, the past approach and the pilot study approach to delivering academic content during co-op. In between, modules were released, within Blackboard, in a timely fashion and students were given between 7 to 10 days to read each module and answer a companion quiz, which were graded electronically. Finally, the pre- and post-surveys included quiz questions that were used in

TABLE 2. CO-OP COURSE CURRICULUM FOR COURSE I (PILOT STUDY)

Engineering Ethics I & II

- personal vs. professional ethics
- engineering as a profession
- understanding codes of ethics
- connection of ethical problem solving to engineering design
- professional responsibility and legal liability
- legal responsibility of engineering

Engineering Economics I & II

- cost vs. price
- time value of money – cash flow diagrams
- simple and compound interest
- time value of money – uniform series factors, gradient series factors

Project Management I & II

- project life cycle
- types of projects
- project stakeholders
- project planning process – project charter, work breakdown structure

the module quizzes to determine what students knew prior to reviewing the modules, and to assess retention of information after the modules and quizzes were completed.

TABLE 3. DEMOGRAPHICS OF PARTICIPATING STUDENTS

| Category | Number of Students |
|--------------------------------|--------------------|
| <i>Major:</i> | |

| Electrical | 4 |
| Computer and Electrical | 1 |
| Mechanical | 4 |
| Product Design & Manufacturing | 1 |
| <i>Co-op Semester:</i> | |
| EGR 290 | 1 |
| EGR 390 | 10 |
| EGR 490 | 1 |
| <i>Gender:</i> | |
| Female | 1 |
| Male | 11 |

V. RESULTS

The areas targeted by the project were not as familiar as traditional technical areas to students in both content and measurement instruments. Students are usually exposed to some pieces and ideas related to these professional and nontechnical topics in a random fashion that provides them with some impression of being knowledgeable enough in them. That impression results in students' resistance to investing time in these areas and makes their perception of any required effort related to them very negative or indifferent. To investigate this point, students were surveyed on their own perception of how much they know about the different areas targeted by the project, before and after exposure to the proposed modules. Results were collected and compared to an actual test of their knowledge in these areas using both pre- and post-tests. Results are shown in Figure 4.

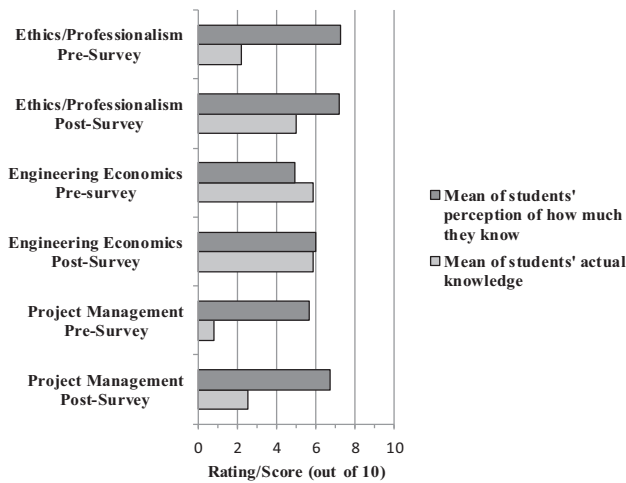

Figure 4. Pre- and post-test results for online co-op modules.

The results displayed in Figure 4 indicate that students' perceptions of their knowledge in the targeted topics by the project were greater than their actual demonstrated knowledge in both the pre-survey and post-survey. For all three topic areas (ethics/professionalism, engineering economics, and project management), scores in the post-survey did increase (if only slightly for engineering economics) from the scores in the pre-survey. In all three topic areas, the actual demonstrated knowledge post-survey was below expected levels, particularly in project management, and will be addressed in future offerings. The content of the modules will be assessed for completeness and appropriateness for the course level, the quiz questions will be reviewed to ensure they are consistent with module content, and additional support will be provided for students including increased instructor contact and access.

Direct assessment was also conducted during this project for performance evaluation and further improvement of the proposed modules. The mean scores on the quizzes associated with each module are shown in Figure 5. The results indicated that students performed at an acceptable level. Mean scores on the quizzes ranged from 61% (ethics/professionalism module 2) to 94% (project management module 1). It is evident that students performed well in general on the quizzes for each module. This was expected since students were encouraged to review their materials as needed when taking the quiz. The one exception was the ethics/professionalism module 2 which was

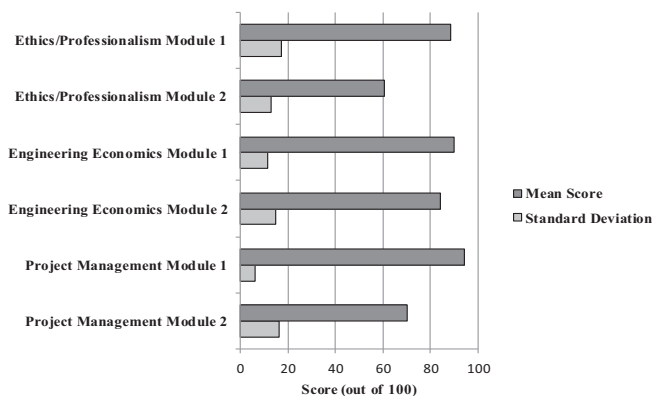

Figure 5. Mean scores on the quizzes for each online co-op module.

written at an advanced level intentionally to act as a check for content appropriateness. As expected, students did not have the knowledge level or professional maturity yet to score at an appropriate level on the quiz for this module. This module will be used in the future during the third co-op semester which is in the students' senior year.

Students were also asked to provide feedback on the experience of participating in this study as part of the post-test. One point of emphasis was how beneficial the students felt the modules were in relation to their educational and professional growth. Figure 6 provides the responses of the students. In total, the students felt that the modules were beneficial, with the project management modules being most beneficial.

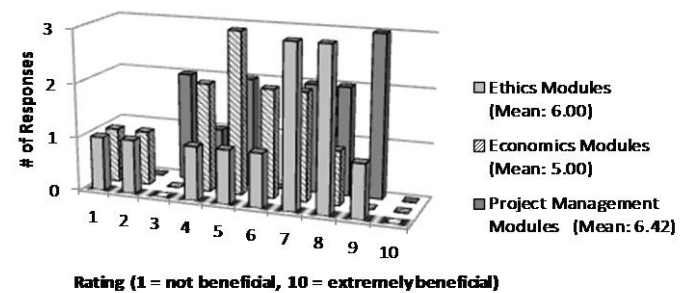

Figure 6. Student ratings of the online co-op modules.

Figure 7 presents the responses of students relative to the overall worthwhileness of having the online modules during the co-op semester. Approximately 60% of students agreed that the modules were worthwhile, while only 8% strongly disagreed with this sentiment.

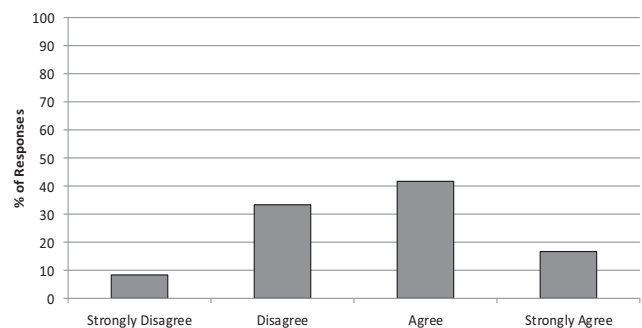

Figure 7. Student agreement of worthwhileness of online co-op modules.

Finally, students were asked to comment on whether the module content was appropriate for a first semester co-op. The majority (approximately 91%) of students indicated that the modules were appropriate for the targeted level of first-semester co-op students (see Figure 8).

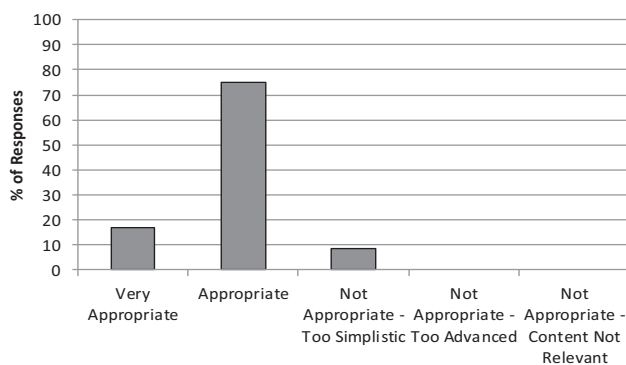

Figure 8. Student perception of appropriateness of online modules for the first co-op semester.

VI. CONCLUSIONS AND RECOMMENDATIONS

This pilot project was conducted to assess the academic side of the co-op course sequence and to develop and test new academic content targeting ABET outcomes which are not easily incorporated in traditional engineering classes. The project aimed at providing this content in an electronic format, as well as its grading process, and with supervision by a specialized instructor to guarantee both flexibility in delivery and reduction of burden for the other co-op instructors, as well as specialized depth in content. The targeted topics for academic content included the following categories:

- Engineering ethics and professionalism
- Effective communication
- Project management
- Engineering economics

Results of the study included:

1. Students falsely perceived their knowledge in the targeted topics. Furthermore, students had a false impression that they already knew enough, based on irregular and unstructured exposure to information and ideas related to these areas. Well-structured academic information with clear purpose would help students realize their knowledge levels in these areas and would motivate them to perform with enthusiasm as the benefits become obvious to them.
2. Students were often incapable of seeing long term benefits or the big picture view, and their maturity level dictated their vision and perception of the importance and relevance of information. The timing of these modules while students are in co-op satisfied that perspective. However, students may not have an appreciation for the content in the modules which does not directly relate to their current context. Therefore the instructor has to convince students of the value and benefits of the content.
3. Students often did not appreciate activities if they were not provided the rationale behind it, and informed about its benefits to their career and education. This was most likely a result of immaturity and compartmentalization of knowledge amongst students as well as a perceived lack of time. Breaking these habits is a significant challenge to engineering instructors. Structured and focused academic

curricula (e.g. scaffolded curriculum) would help alleviate these issues.

For a pilot effort, the academic modules introduced into a co-op course had enough promise to be tried again with modifications and improvements. Because the content of the modules is important to meeting program outcomes requirements in all engineering majors, and the co-op courses provide an efficient means for delivering the content to all students in all programs, the co-op courses are appropriate for this effort. The modules were added to the first co-op class (EGR 290) in the summer semester of 2012 for a larger pilot to collect more data.

It is recommended that the modules and associated quizzes that were pilot tested in winter 2011 be reviewed and modified, then implemented with all EGR 290 students in the summer 2012 co-op course. It is also recommended that changes, elimination, or improvements be introduced to the activities and content of least value, and that some older requirements be removed in favor of new content that is academically focused and covered by the modules.

ACKNOWLEDGMENTS

This study was supported through a grant provided by the Faculty Teaching and Learning Center at [institution] to the authors during 2010. Graduate assistant Jennifer Edwards is also thanked for helping to implement the online modules.

Abstract—Merging a Learning Management System (LMS) and a social network has social advantages for students. Among others, students can show off their achievements among their acquaintances, which in turn improves their social leadership and self-esteem. This is specially true in the case of distance learning, where there are no physical interactions between students, so their student life is totally isolated from their everyday life (e.g. students do not go out together, since they may live in different cities or even countries although they study the same subjects). All these points suggest that the use of social networks for distance teaching has clear advantages that can be harnessed.

In order to achieve the aforementioned benefits, we are working on integrating a commonly used LMS, Moodle, into one of the most widely-used social network, Facebook. This integration allows students and faculty to use Facebook as a communication tool that improves the learning process and social life of students in the ways presented before.

I. INTRODUCTION AND MOTIVATIONS

With the recent development and wide-spread use of Web 2.0 [1] concepts, such as social networks [2] and cloud computing [3], an interesting guideline for research is how these new technologies can be applied to education. These technologies have a number of interesting features, and some of them can be of real interest for educational purposes. Among others, the easy ways of sharing information and interacting between users in social networks (users can write in walls, define their status, like and dislike learning resources, send messages, chat, share applications, etc). We are working on the implementation of a full-featured system that uses the aforementioned Web 2.0 concepts for e-learning purposes. Authors have worked on harnessing another main technology among the Web 2.0 realm, which is cloud computing [4], and in this work we propose how to harness social networks for e-learning purposes.

Social networks can be of real interest because they allow the creation of virtual classroom spaces outside the Learning Management Systems (LMS) of the University. Thus, these tools can increase the interoperability of students and faculty and improve the quality of the learning process of students. For example, students can be hanging around in their favorite

social network and get instant updates on the status of the courses or evaluation feedback from their activities (e.g., the practical exercise 5 has come out, it must be presented by 1st of February).

Social networks are a very important communication media in Spain. According to [5], 50,9% of Spaniards use a social network (which rises to 80.3% for young people between 16 and 24 years old), and 35,3% of Spanish people use social networks as the main tool to communicate with each other, which increases to 54.1% of Spanish youth (a 19% increase compared with the previous year). Also, more than 79,2% of young users connect to a social network at least once a day (60,4% considering all the ages).

Among all the Web 2.0 tools available at the moment, Facebook (www.facebook.com) stands up in the crowd of the social networks. According to [5], Facebook is the leader in Spain in terms of the generated web traffic (e.g. users visit web sites recommended via Facebook), since 63.9% of this traffic is generated by Facebook, distantly followed by YouTube (13.8%). Moreover, more than 40% users choose Facebook as their favourite social network, followed by Tuenti with 14.4%.

All these figures highlight the wide-spread use of Facebook in Spain and identify it as a very interesting tool to improve the learning mechanisms of a University. This is specially true for totally distant universities, such as the National University for Distance Education of Spain (Universidad Nacional de Educación a Distancia, UNED, www.uned.es) which depend on technological infrastructures (such as LMS, videoconferencing, etc) to make the learning processes feasible in the absence of face-to-face classes.

Furthermore, integrating a LMS into a social network has social advantages for students. Among others, students can show off their achievements among their acquaintances, which in turn improves their social leadership and self-esteem. This is specially true in the case of distance learning, where there is no physical interactions between students, so their student life is totally isolated from their everyday life (e.g. students do not go out together, since they may live in different cities or even

Fig. 1. Searching the application using Facebook search engine.

countries although they study the same subjects). All these points suggest that the use of social networks for teaching has clear advantages that can be harnessed.

In order to achieve the aforementioned benefits of social networks, we are working on integrating a commonly used LMS, Moodle, into Facebook. This integration allows students and faculty to use Facebook as a communication tool that improves the learning process and social life of students in the ways presented before. For this integration, several tasks have been performed. First, an in-depth study of the Application Programming Interface (API) of Facebook has been conducted. After that, the integration of the log-in facilities of Facebook and Moodle has been performed, which allows participants in the learning process log-in into Moodle using Facebook credentials.

The next step is the development of web services in Moodle to be accessed by Facebook. Moodle supports several types of web services, and for this work, services using Representational State Transfer (REST) will be used for their ease of implementation. A web service showing the course information has been developed in this work, which allows participants see the contents of the course.

Finally, Facebook applications have been developed to access the aforementioned web services. The application that performs the integration between Moodle and Facebook is called PFC UNED Mdl-Fbk and can be found using Facebook search engine as can be seen in Figure 1. Once it is installed, it allows us to connect to our Moodle LMS and offers the possibility of logging in to it and see our courses.

II. FUTURE WORK

Regarding future work, a more detailed integration is being implemented. Among the points being treated, the publication of messages from the LMS forums or assessments results in the wall of Facebook are two of the first ideas. For this, the Spanish Organic Law for Data Protection (*Ley Orgánica de Protección de Datos*, LOPD [6]) must be taken into account since no private data can be published. Facebook privacy settings can be of real interest to decide what students/faculty want to publish/hide from public view.

ACKNOWLEDGMENT

Olaf.Hallan.Graven@hibu.no and Dag.Samuelsen@hibu.no

Abstract— The work presented here has a focus on the software controlling the remote laboratory in the context of pedagogy. This in contrast to the traditional focus when developing remote laboratories, which has been on functional performance as seen from an engineers' perspective: number of functions to perform, similarity to the physical laboratory it should imitate, scheduling of experiment, etc. As the supervisor is removed from the scene in the transition from physical to remote laboratories, the remote laboratory environment must facilitate the student-teacher interaction in a more or less automated manner. A list of requirement for the software controlling the remote laboratory environment has been developed where focus is set on ease of setup, access and readability, integrity of the hardware, protection from misuse, and support for learning. We here present a preliminary report on the implementation of such a system.

Remote laboratory; Automated pedagogical support

I. INTRODUCTION

Laboratory exercises are an important part of engineering education, and should aid the theoretical understanding, as well as give hands-on experience for the students. Running laboratories requires significant resources from the institution and is time consuming for the students. Therefore, it is a current trend in engineering education to transfer these laboratories into remote controlled laboratories that can coexist with the vast developments of online learning offerings. A number of examples of remote labs using premade software environments exists, many of which use LabView[1,2] other use different development tools and platforms, like[3] with Matlab.

The authors have over a number of years worked on implementation and use of remote laboratories for learning and support for learning at university level. Most work in the area of developing remote laboratories has focused on functional performance as seen from an engineers' perspective: number of functions to perform, similarity to the physical laboratory it should imitate, scheduling of experiment, development of portals or creating of metadata for learning objects for these remote labs, iLab[4], Lab2Go[5]. A significant difference between the systems presented in the above referenced publications and the system presented in this article is the software controlling the hardware and the web server, or the environment that the students should benefit from. The focus

for the development is the constructs needed to support pedagogical aspects like adaptive individual feedback.

A student doing a laboratory exercise in a traditional setting, i.e. physical laboratory, will typically have immediate access to a supervisor in the laboratory, giving feedback according to the progress of that particular student or group of students. A remote laboratory is an installation that in most cases will be available for the students 24/7, anywhere in the world, and a user of the remote laboratory will probably not have access to a supervisor should they run into problems. This means that the software must facilitate transfer of information on each user's usage of the remote laboratory and the results obtained from the laboratory experiment for later supervisions, alternatively a system with automatically generated adaptive feedback can be envisioned.

A survey was carried out on a group of students that had utilized remote labs for a set of experiments in two different modules in an electrical engineering course. The feedback from this survey identified that the main challenge with the current remote labs that is based on a LabView setup, is mostly connected to access and setup of the software. Once the setup was sorted out, the use of the lab itself was straight forward, enjoyable and was reported to give a good learning effect. Another main point for the students is that the lab is available 24/7.

II. NEW DIRECTION IN REMOTE LAB

The work in the community on remote labs is shifting toward a focus on how to integrate remote labs into learning. Our work is focused on the next step in this evolution: How to support learning and utilize pedagogical and games based techniques in remote labs. The key to achieve this is to look at the software controlling the remote laboratory in the context of pedagogy. As the supervisor is removed from the scene in the transition from physical to remote laboratories, the remote laboratory environment must facilitate the student-teacher interaction in a more or less automated manner.

A list of requirement for the software controlling the remote laboratory environment is created and serves as the basis for the implementation. The focus for these requirements are set on ease of setup, access and readability of the environment, points for integrity of the hardware and protection from misuse are also included. A significant effort is

also committed to describe the system requirements for learning support.

The authors has identified that the main shortcoming of most of today's remote labs are a lack for support for learning. Software like LabView and Matlab are tools built for a specific purpose. The configuration options for these tools are limited, particularly when it comes to adding in pedagogical support, a necessity in a learning situation where the tool is used without any other support.

III. FOCUS FOR WORK

The process of creating a remote lab environment with learning support is complex and requires several steps. First the system is designed to allow capture of information on who performed the experiment, what functions were utilized, how the setup looked like and what the results are. Information about what strategy individuals are using, and how different users are progressing with the experiment can then be generated from these captured data by comparing different experimental runs by a single user over time. A user attempting multiple different setups in quick succession may indicate that a trial and error approach is being used, or multiple attempts at longer time intervals may indicate a struggling user, attempting to calculate or use other sources to arrive at a more correct setup.

The project described here does include the setup of a framework for implementing remote labs. An outline for the requirement for such a framework for remote laboratories have previously been published [6]. A test implementation of a remote laboratory is set up. This test implementation embodies the basic requirements set out for the framework: Simple setup and support for multiple browsers i.e. use of a web page that does not require external installed components, graphical display, and setup of experiment on client without the control of the experiment whenever possible. The implementation utilizes a structure shown in figure 1.

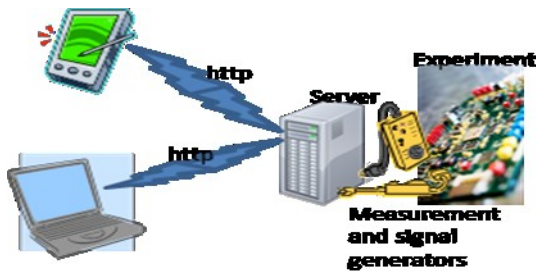

Figure 1: Structure of a remote laboratory setup.

The remote laboratory setup utilizes a standard web server with a webpage based on java script to setup the experiment. The experiment is then submitted to the server by the user via the web client. The server maintains a queue of experiments that needs to run. In the current set of implemented experiments the runtime for a single experiment is 0.5 to 1 second so this queue is mostly short or even empty and the wait time for running is equally short. Once the experiment is admitted to the queue the web client is updated with an estimated waiting time. Once the experiment is complete the data obtained is temporary stored in a database and then

transmitted to the web client, on a web page utilizing java script and if necessary an AJAX setup where data is loaded as it is required.

Multiple implementations of remote laboratories are planned that will serve as test cases for the developed framework. The reasoning behind these implementations is that in addition to serve as a test case for the framework, an implementation of a remote laboratory is used to capture information and serve as a basis for the desired user support described above.

IV. FURTHER WORK

A substantial further effort is required to indentify behavior, scenarios and a set of rules that can be included in the remote lab environment, giving the environment the ability to detect these predetermined behaviors, notifying the instructor or take automated action. The information captured about the users will also be used for further identification of behavior, for development of a more complete and complex rule-set. These rules will give the system the ability to detect predetermined behaviors and take automated actions. These automated actions will be determined by the rules and can be to offer assistance, hints or to simply notify the instructor. The development of a more complete and complex rule-set will be of primary importance to a remote learning environment.

It is also necessary to ensure that captured information about the users is not made available to the wrong persons. The information captured will not be of a highly sensitive nature, but any information relating to individual students must be kept secure and only be made available to the identified persons, like a lecturer/instructor in a module.

The Role of Social Networking Sites in E-learning

Xiaosong Li, Kathiravelu Ganesan, Guorong Xu

Department of Computing
Unitec Institute of Technology
Auckland, New Zealand

xli, kganesan@unitec.ac.nz, topcpu2003@hotmail.com

Abstract—This paper explores the role of Social Networking Sites (SNS) in e-learning by investigating the attitudes, behaviors, knowledge and views of computing students towards the use of SNS in e-learning. Data was collected from an online survey and interviews, and analyzed to discover the practices, tendencies and the current status of the use of SNS in e-learning as well as how these can be improved.

Major factors that facilitate the usage of SNS in e-learning were identified as collaboration, communication, resource sharing, social influence, usefulness and ease of use. Facebook was identified as the most popular SNS.

The role of SNS in e-learning is supportive and important. Although the participants were computing students with a high level of IT literacy, and were interested in using SNS for e-learning, only a few were frequently using SNS for e-learning.

Reasons for this minimal utilization of SNS for e-learning were identified as security and privacy concerns, reliability and currency of content and network issues such as speed of access, real time synchronization and efficiency.

We believe that SNS can play a major supporting role in e-learning and that the potential for using SNS in e-learning is not fully reached. The situation may be improved by providing increased guidance and training to students. Learning activities using SNS should be planned and organized.

Brief guidelines on using SNS in e-learning are also included in this paper. These guidelines may be further refined and adapted for use in other institutions.

Keywords—component; teaching and learning; social networking sites, facebook, collaboration, interaction, personalised environment.

I. INTRODUCTION

Modern educational theorists argue that knowledge transmission depends on the individual's participation and reconstruction and that learning can be considered as a kind of social process and that it happens by sharing information and interactions in each individual [1]. Social interactions, communications or collaboration with more capable peers during problem solving will enhance the learner's understanding [2, 3].

Conventional learning management systems (LMS) such as Moodle and Blackboard, are commonly adopted as formal teaching and learning environments by tertiary institutions. While these systems provide valuable services to the teaching and learning process, some issues were identified. These LMS lack social connectivity tools and personal profile spaces that can be used by the students involved [4].

On the other hand, Social Networking Sites (SNS) can help people find connections that may be hidden in the real world. Creating an account on a social networking site such as FaceBook means that individuals can share and communicate with others in their personalized environment, which facilitates spiral building of personal understanding and interest toward learning. Therefore, SNS have the potential to be online platforms for e-learning. This has drawn the attention of certain researchers in higher education. Research studies on how to successfully include SNS in the process of teaching and learning are being conducted in recent years.

The faculty's views regarding the use of SNS in education were compared with students' views in [5]. Using SNS for learning from the Vygotskian perspective was reviewed in [3]. An Education Usage Model of FaceBook was proposed in [4]. Integrating SNS with other systems was reported in [6, 7]. Valuable experiences of medical students using FaceBook to support their learning were described in [8]. An algorithm which automatically groups distributed e-learners with similar interests and make proper recommendations was proposed in [9]. Research in this area is still continuing.

This paper is based on a study conducted to explore the role of SNS in e-learning by investigating the attitudes, behaviors, knowledge and views of computing students towards the use of SNS in e-learning.

Data was collected from an online survey and interviews [10] and analyzed to discover the current status, practices and tendencies of using SNS in e-learning as well as how these practices can be improved. Out of a total population of around 300 computing students from a tertiary institution in New Zealand, 60 took part in the survey. From these 60 participants, 9 were interviewed to gather additional data.

In the following sections, the research method is described first, followed by the presentation of the results, discussion of the findings and conclusion.

II. METHOD

A. Data Collection

Both quantitative data (via an online survey) and qualitative data (via interviews) were collected [10]. The sample population chosen was the students in the Computing Department of a New Zealand tertiary institution. Out of a total population of around 300 computing students (approximately 250 undergraduates and 50 postgraduates), 60 responded to the invitation and took part in the survey. Among these, 9 interviews were also conducted. The survey and interview questions were designed based on the researchers' experiences and relevant literature review.

The online survey questions were designed to find out the attitudes, behaviors, knowledge and views of the respondents towards the use of SNS in e-learning. There were 25 questions, most of which were multiple choice questions with three exceptions: two asked the participants to rank all the possible answers; another asked if the participants were willing to be interviewed [10, Appendix C].

Face-to-face interviews were used whenever possible and e-mail communication was used to bridge the geographical distance when appropriate. Eight open-ended interview questions were designed to explore in detail the participants' attitudes, perception and behaviors towards the use of SNS in e-learning [10, Appendix D]. There were nine interviewees (four undergraduates and five postgraduates) who agreed to be interviewed. Four participants were interviewed face-to-face, and five participants, via email communication.

B. Data Analysis

All the survey data was cleaned to eliminate invalid information and then summarized to generate categories or themes. This data was then analyzed and studied to generate possible answers to the research questions. Simple statistical information such as percentages was calculated for comparison purposes. Related and similar results gathered from the online survey and published literature were compared and analyzed. While convenience samples could provide useful information, they would differ from an ideal sample that was randomly selected. The small sample size added further limitation to the data. These limitations were taken into consideration in the data analysis and interpretation.

The researchers carefully examined all the data gathered from the interviews, and made sense as a whole, and then the data was categorized into two categories: answers from undergraduates and answers from postgraduates. In the meantime, the researchers used the method of coding to generate categories or themes according to the key points from the answers. Each individual was anonymously identified by a code. Due to the page limitation, only a summary of the interview results is reported in this paper.

III. THE RESULTS AND ANALYSIS

The survey and interview results are presented and interpreted respectively. Each set of data is analyzed and interpreted.

A. Survey Data

The demographic information of the respondents was gathered first. The majority of the survey respondents were male (83.3%) and most of them are undergraduates (68.33%). As they were all from the Computing Department, it's reasonable to assume that they all have adequate computing skills to make use of SNS.

More than half of the respondents (54%) had more than three years experience using SNS. In total, 92% of the respondents had at least one year experience using SNS. This may not be necessarily true for non-computing students.

Although the respondents have a reasonable level of experience with SNS, they do not have the same level of experience using SNS for e-learning as shown by the data in Table I, with only 56% of the respondents using SNS as a tool to discuss course related topics.

TABLE I. FREQUENCY OF THE USE SOCIAL NETWORKING SITES TO DISCUSS COURSE RELATED TOPICS WITH CLASSMATES

| Frequency | Number | Percentage |
|-----------|--------|------------|
| Always | 4 | 8% |
| Often | 7 | 14% |
| Sometimes | 17 | 34% |
| Seldom | 10 | 20% |
| Never | 12 | 24% |

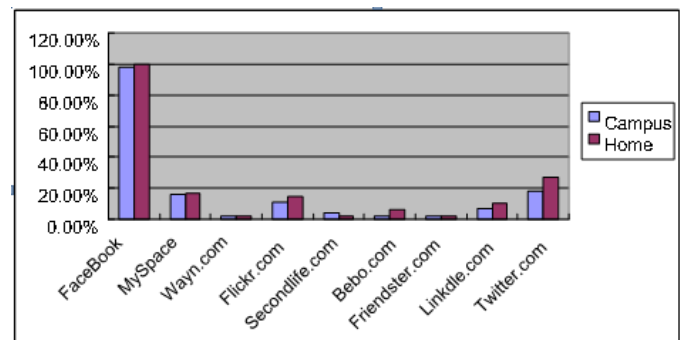

Figure 1. Social networking sites computing students like to use

Figure 1 shows the preferred SNS among the students. Nine SNS were presented. Regardless of whether they used the SNS on campus or at home, FaceBook was the overwhelmingly favored site, followed by Twitter, MySpace and Flickr. This result is consistent with the findings of similar research studies [3, 4, 5 and 11]. This is likely true in New Zealand and other similar countries. However, it may not be necessarily true for all the countries, for example, China.

Table II compares the different ways used by the students to discuss course related topics, where SNS is much less preferred than email and obviously in a less supportive role.

Table III shows that more than half (51%) of the respondents had never used SNS to find other students to collaboratively study with. Only about 15% (7) respondents

frequently used SNS to find their peers to build their knowledge in a collaborative manner.

TABLE II. WAYS OF DISCUSSING COURSE RELATED TOPICS WITH OTHERS

| <i>Ways</i> | <i>Number</i> | <i>Percentage</i> |
|-------------------------|---------------|-------------------|
| Face to Face | 43 | 87.8% |
| Social Networking Sites | 22 | 44.9% |
| Phone | 24 | 49.0% |
| Email | 42 | 85.7% |
| Other | 7 | 14.3% |

TABLE III. FREQUENCY OF THE USE OF SOCIAL NETWORKING SITES TO FIND STUDENTS TO STUDY WITH

| <i>Frequency</i> | <i>Number</i> | <i>Percentage</i> |
|------------------|---------------|-------------------|
| Always | 3 | 6.1% |
| Often | 4 | 8.2% |
| Sometimes | 14 | 28.6% |
| Seldom | 3 | 6.1% |
| Never | 25 | 51.0% |

About 61.9% respondents believed that the most important factor affecting the students' use of SNS in e-learning on campus is network speed. Approximately 35.7% respondents believed that network access is the second most important factor. 31% respondents believed that network security and privacy is also an important factor. Network was identified as a key factor in the use of SNS.

In Table IV, the majority of the respondents (66.7%) thought uploading and watching videos and photos is a feature that facilitated their learning, followed by electronic mail (64.6%).

TABLE IV. FEATURES OF WEBSITES (INCLUDING SOCIAL NETWORKING WEBSITES) THAT FACILITATE E-LEARNING

| <i>Features</i> | <i>Number</i> | <i>Percentage</i> |
|----------------------------|---------------|-------------------|
| Upload/Watch Video & Photo | 32 | 66.7% |
| Chat Room | 25 | 52.1% |
| Games | 7 | 14.6% |
| Forum | 26 | 54.2% |
| Mail | 31 | 64.6% |
| Blog | 28 | 58.3% |
| Event | 10 | 20.8% |
| Other | 5 | 10.4% |

The attitudes of the respondents in relation to the use of SNS in e-learning are optimistic and encouraging. More than half of the respondents (61%) said that SNS were helpful in e-

learning in one or more courses. On the other hand, there were 39% computing students who did not find SNS helpful in e-learning.

About half of the respondents (50.9%) were willing to use SNS for e-learning and further 40.4% respondents were sure that they would use it in the near future. In total, over 90% of the respondents accepted the use of SNS in e-learning.

What features of social networking websites facilitate your e-learning? (You can choose more than one option)

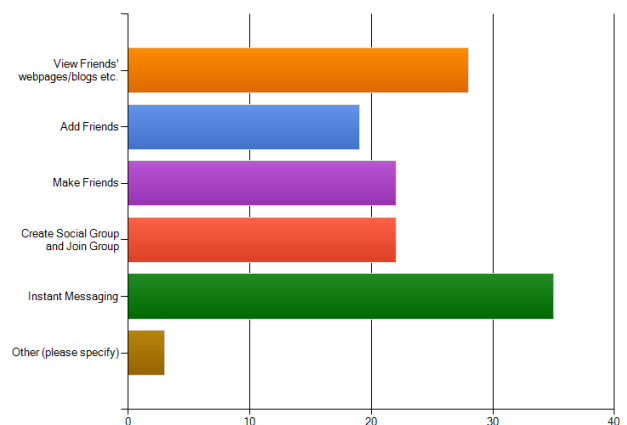

Figure 2. Features of social networking websites that facilitate learning

Figure 2 demonstrates that most computing students (35 participants = 74.5%) believed that Instant Messaging of SNS can facilitate their e-learning.

When you need to find the answer to a question related to your course, where do you go to find the answer? (You can choose more than one option)

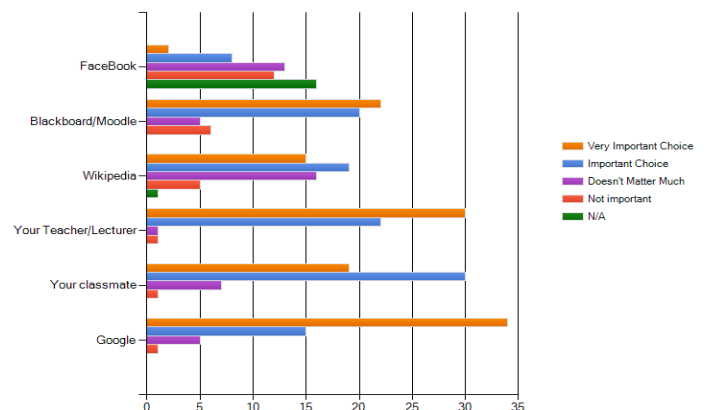

Figure 3. Ways of finding the answers when students need to answer a question related to their course

Figure 3 clearly shows a comparison of the methods the respondents used to find answers when they needed assistance with a course they are doing. Options included FaceBook, Blackboard/Moodle, Wikipedia, lecturers, classmates and Google search. These results reveal that the three most popular ways used by these students to find answers were, Google search, classmates and teacher/lecturer. About 61.8% respondents considered Google search to be very important

and another 27.3% believed Google to be important, followed by teacher with 55.6% responses as very important and 40.7% responses as important, and 'ask classmate for help' was at 33.3% very important and 52.6% important. Facebook was the least favored in this case. There was no indication that SNS could replace a teacher. In terms of e-learning, SNS could be considered as a supplement to conventional LMS like Moodle and online search engines. This reinforces the interpretation of Table II that the role of SNS is supportive.

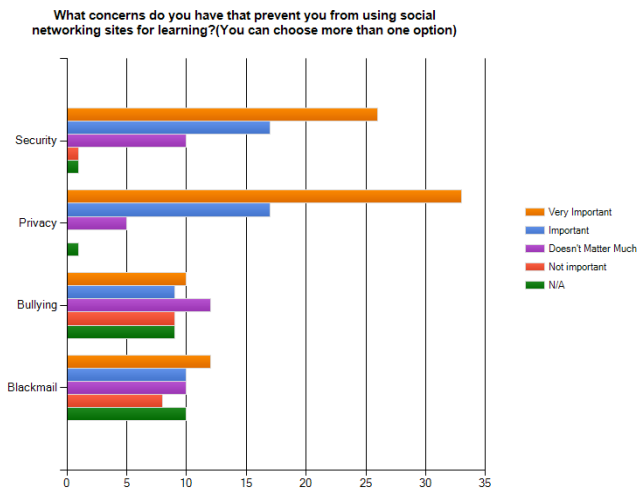

Figure 4. Factors preventing students from using SNS for e-learning

Figure 4 shows the distribution of the factors preventing students from using SNS for e-learning. Most of these computing students thought privacy was a major concern, with 58.9% considering it very important and another 30.4% considering it important. This was followed by security with 47.3% considering it a very important concern and another 30.9%, an important concern. In contrast, bullying and blackmail were two factors with only 20.4% and 24.4% concern.

Figure 5 shows that one third (38.8%) of respondents agreed that the use of SNS in e-learning will play an important role in the tertiary education sector in the future, with 14.3% in strong agreement.

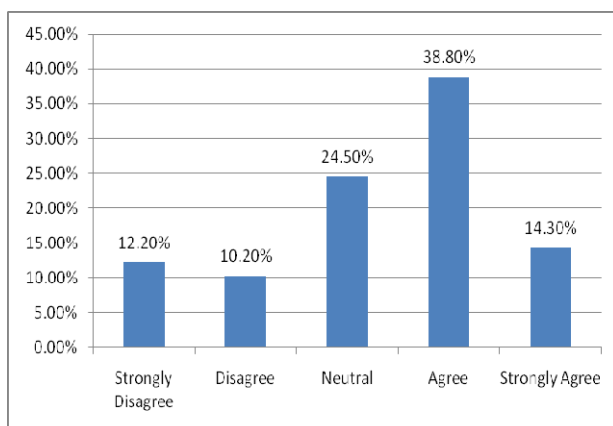

Figure 5. Opinions of the use of social network tools in e-learning playing an important part in studying at tertiary level in the future

The participants considered SNS as a supplementary tool to normal learning methods such as face-to-face discussion as well as to e-learning tools such as LMS and search engines. In terms of e-learning, search engines and email were considered more useful than SNS. This may be due to the amount of learning related information held in SNS being limited. This highlights that SNS are currently not a main stream tool in learning for these students but obviously play a supportive role.

Of the factors that had negative impact on using SNS for e-learning, security and privacy were found to be the most significant. Amongst the SNS features that facilitate learning, instant messaging and video/photo were the two most useful. Blog is a personalized environment and forum is a shared environment, however, there was no significant difference in the participants' preferences in the use of these in e-learning.

Attitudes towards using SNS for e-learning now and in the future were clearly positive. Although they did not use SNS much for their learning, the participants were very confident about the future of SNS in e-learning.

B. Interview Results

Nine interviews were conducted. Eight questions were asked, the results from undergraduates and postgraduates were studied respectively, and the key points regarding each question in the discussion were identified [10]. Due to the page limitation, only a summary of the results is reported below.

Questions:

1. What are the advantages of using social networking sites for e-learning?
2. What are the disadvantages of using social networking sites for e-learning? Why?
3. What experiences do you have using social networking sites and/or Web2.0 technologies in e-learning?
4. In your opinion, do social networking sites help in your e-learning now and future? If yes, how? If no, why?
5. How many people you know are using social networking sites? How many of them use these sites for e-learning? What are their attitudes towards this?
6. Are there any features of social networking sites that affect your decision to use social networking sites in your e-learning?
7. In your opinion, do the factors (such as network access, speed, security and privacy) impact your using social networking sites in e-learning on campus? Why?
8. Do you have any suggestions about the use of social networking sites for e-learning at present or future?

In summary, the views held by the undergraduates and the postgraduates were very similar. The following points are worth noting.

Responses to Question 1, indicate that *Communication* (Sharing opinion and other Communication), *Collaboration* (Collaborative studying), *Resource Sharing* (Useful e-learning resource), *Usefulness* (Studying efficiently, Meeting new

people) and *Ease of Use* (Convenient and comfortable) were clearly identified as SNS features that could facilitate e-learning. These findings are consistent with the research results published in [4], that *Communication*, *Collaboration* and *Resource Sharing* will have a significant influence on the educational usage of FaceBook; *Usefulness* and *Ease of Use* will have a significant influence on FaceBook adoption and will in turn have a contribution to the educational usage of FaceBook.

Issues that form barriers to using SNS in e-learning were identified by the responses to Question 2. These include *Synchronization* (Hard to get answers immediately), *Security and Privacy*, *Currency* (Online resource not up to date), *Efficiency* (Wasted time), *Authority* and *Network* (Access, Speed and Policy). Some of these issues, such as *Security and Privacy* and *Network* also featured heavily in the survey results. The *Synchronization* issue may explain why instant messaging was identified as the most important feature of SNS to facilitate e-learning in the survey results.

Responses to Question 3 reveal the participants' experiences with SNS. Most of the students have used FaceBook for *Resource Sharing* and *Communication*. Postgraduates used SNS more than undergraduate students, however, they used SNS less for e-learning than the undergraduates. During the interviews this was explored further and led to the finding that the postgraduates had higher standards regarding the quality and reliability of the resources.

The participants' attitudes towards using SNS for e-learning, explored using Question 4, were certainly positive. The factors that contribute to these positive attitudes included *Collaboration* (Collaborative studying) and *Communication* (Discussing with other students, Keep in touch anywhere, Sharing different opinions). These findings are in agreement with the Education Usage Model of FaceBook [4].

Question 5 was used to explore the experiences and attitudes of the participants' social community in relation to SNS and the use of SNS in e-learning. Some interviewees said they joined a SNS on the invitation of a friend. This conformed to the argument that *Social Influence* will have a significant influence on FaceBook adoption [4]. Obviously SNS were very popular in their social community. This should have a positive impact on the participants' SNS adoption and educational usage. It is worth noting that the undergraduates and the postgraduates had differing views on using SNS for e-learning. The undergraduates thought many of their fellow students made use of SNS to aid their learning while the postgraduates thought not many of their peers used SNS to aid their learning. This may be due to issues relating to currency and reliability and how these are viewed, as discussed under Question 3.

Features that might impact the participants' adoption and educational usage of SNS were explored using Question 6. These features included *Communication* (Online forum, Blogging, Chatting room, Bulletins), *Collaboration* (Group) and *Resource Sharing* (E-book collections, Sharing resources). It is worth noting that there was no special preference of blogging over online forum. This led to the question: Are personalized learning environments important to these computing students?

Question 7 investigated the factors that may have a negative impact on the participants using SNS in e-learning. These factors included *Security and Privacy* as well as *Efficiency*. Some of the undergraduates believed that these issues won't prevent them from using SNS for learning.

Responding to Question 8, the participants made suggestions for the improvement for the future usage of SNS in e-learning. It was observed that the postgraduates had better understanding of SNS than the undergraduates. The suggestions included the following.

- The concerns such as security, privacy and reliability of information and issues such as network bandwidth should be addressed.
- Provide training and guidance (training and education for web2.0).
- Provide more powerful features (virtual tutor, 3G mobile technologies support, LMS integration with SNS).
- Organized learning activities on SNS such as study groups on SNS.

IV. DISCUSSION

All the participants, being students in a computing department had at least a reasonable understanding of computing and communication technologies. Most of them had been using SNS for more than one year. Although they were using SNS for e-learning now or willing to use in the future, only a few were frequently using SNS for e-learning. These few students not only had a high level of comfort and satisfaction, but also their perceptions of advantages of the use of SNS in e-learning considerably exceeded the perceived disadvantages.

Most of the students thought SNS have good potential for e-learning. They identified the factors that could facilitate the usage of SNS in e-learning as *Collaboration*, *Communication*, *Resource Sharing*, *Social Influence*, *Usefulness* and *Ease of Use*. It's interesting to see that all these were included in the Education Usage Model of FaceBook proposed by [4]. As FaceBook was identified as the most popular SNS in this study as well, it can be said that the participants' view of this research partially verified the Model of [4] from New Zealand.

The main issues that might create hurdles for the students using SNS in e-learning were identified as *Security and Privacy*, *Content Authority*, *Content Currency*, *Network Issues*, *Real Time Synchronization* and *Efficiency*. Some of the participants mentioned problems such as the inability to type a mathematical equation or a chemical symbol as barriers to using SNS for learning.

Judging from the overall results it can be said that the use of SNS for e-learning is another way to help achieve study goals complementing other e-learning tools such as LMS and search engines and traditional learning methods such as face-to-face lectures and discussion. SNS, as a supportive environment, allows communication and collaboration during learning, which positively influences learner development [3].

However, the full potential of using SNS in e-learning has not yet been realized and there are a number of reasons for this. Some current features of SNS were not fully utilized. For example, there was no obvious evidence showing that the students were using SNS to build study relationships with more capable peers from different locations remotely.

How SNS can be effectively used in e-learning deserves further study [12]. For improvement, the students need to be guided and trained in using SNS for e-learning. The perception (and, perhaps the intention of SNS developers) that the main purpose of SNS is for social activities and not for learning activities [5] may hinder the use of SNS in learning.

Resolving some of the issues raised by the participants of this study may make SNS more valuable and effective in e-learning. We could either integrate SNS with appropriate LMS and other systems [6, 7] or find out what types of learning are suitable to use SNS.

The case studies in [8] provide valuable experiences. In the four cases presented, the first case (to facilitate exam revision) and the last case (to keep in touch while studying in different locations) were more successful, which suggested that SNS are more suitable for broader topic and remote learning. In addition, the learning activities on SNS should be planned and organized. For example, [9] proposed an idea of grouping distributed e-learners with similar interests.

The following is a proposed set of guidelines for using SNS in e-learning:

- Select a suitable SNS.
- Select suitable learning contents.
- Train the students to become both technique competent and pedagogy competent.
- Group the students in an appropriate manner.
- Design learning tasks carefully, which should include task description, learning objectives, milestones, member roles and implement steps.
- Provide authoritative and current learning materials.
- Check progress regularly.

V. CONCLUSION

The findings of this study, although limited to computing students in one institution in a small country, are significant. Further studies are needed to explore how students of engineering, other sciences and disciplines use or plan to use SNS in their e-learning, by investigating their attitudes, behaviors, knowledge and views of the use of SNS in e-learning.

Noting that the role of SNS in e-learning is supportive and important, SNS are underutilized in e-learning, even computing students need guidance and training to make better use of the many features of SNS, learning activities on SNS need careful planning and organization, there is much work to be done.

Collaboration, communication, resource sharing, social influence, usefulness and ease of use, the desired features identified in this study, and supported by other related studies, can all be built into a new SNS/LMS combining the best features of, YouTube, Twitter, FaceBook and Moodle, taking care to eliminate or minimize the barriers to the use of SNS in e-learning, such as security, privacy, content authority and currency, real time synchronization and inefficiency.

We believe that the use of SNS to support e-learning can and will increase as network bandwidths increase, reliability and currency of content improve and security and privacy issues are sorted out with better legislation. We also believe that some major integration of SNS and LMS will soon happen as identified by some of the participants of this study. ATutor is an example of a LMS that has a social networking module which can be used to create a social learning environment.

The proposed guidelines for using SNS in e-learning may be further refined in practice and adapted for use in schools, tertiary institutions and adult education in the future. We are working on refining and putting these guidelines into practice as well as planning further studies with larger numbers of students and from other disciplines.

What are the Implications for Teaching?

An Analysis of How Educational Implications are Represented in Engineering Education

Jennifer Turns, Drew Paine, Brook Sattler, Diana Muñoz
jturns@uw.edu, pained@uw.edu, brooks2@uw.edu, munozd@uw.edu

Abstract – The objective of this work is to explore how implications for educational practice are represented in the scholarly literature of engineering education. This work is motivated by the increasing urgency to understand how research can be used to transform educational practice. Because scholarly writing (such as conference papers and journal articles) represents one place where researchers articulate ideas about how their research can be used (i.e., educational implications), an analysis of how such implications are represented can provide insight into ideas about the uses we imagine for our research. Once we have characterized the vision of use, we can step back and think about whether the collective vision we present may provide clues to the more general issue of transforming education.

Index Terms – Educational implications, Rhetoric of science

I. INTRODUCTION

In recent years, the engineering education community has invested significant energy and resources on the creation of a rigorous empirical knowledge base to support the transformation of engineering education practice. The idea is that this research will contribute to the transformation of engineering education; however, there is evidence of impatience with the speed by which such transformation is happening.

In this exploratory project, we are seeking to add to the conversation by applying the Rhetoric of Science [1] to the analysis of journal articles that present research. Because scholarly writing (such as conference papers and journal articles) represents one place where researchers articulate ideas about how their research can be used (i.e., educational implications), an analysis of how such implications are represented can provide insight into ideas about the uses we imagine for our research. The specific questions addressed in this paper are (1) To what extent are implications for educational practice emphasized in the most recent year of the *Journal of Engineering Education*? and (2) When implications for educational practice are present, who is implicated?

Answers to these questions can create a base for pragmatic suggestions for writing journal articles. The answers to these questions can also provide opportunities for reflection, even critical reflection, on the concept,

politics, and other forces that frame research-to-practice efforts in engineering education.

II. BACKGROUND

In this section, we explore two questions related to the issue of research informing practice: (1) what can research offer practice and (2) what does practice need from research. In addition, we motivate the idea of journal articles as a place to explore the connection of research and practice. In this section, we draw on ideas from engineering education but also from the field of human-computer interaction (HCI).

What can research offer practice?

In 2005 Dourish, an ethnographer who works in the field of HCI, stirred up that community with a paper entitled "Implications for Design" [2]. This paper explored the types of implications for design that ethnography can offer HCI, such as inspiration for new products. The work was motivated by a sense that members (reviewers) of the HCI community had narrow and strong expectations for what ethnography should offer design—specifically expectations that ethnographers should be able to provide design requirements.

The idea that different research methodologies have potentially different implications for practice raises at least two questions for the field of engineering education: What types of research are being done in the engineering education community and what types of implications for practice stem from these different types of research? While these are clearly large questions, one thing we do know is that the field of engineering education has become increasingly pluralistic in terms of research methods. A ramification of these observations is that we need a way to study the research-to-practice issue that is capable of connecting to the breadth of research being done in the community.

What does practice need from research?

In 2008, a designer involved in the HCI community again drew attention to the research-to-practice issue but this time by looking at it from the perspective of design [3]. In his paper entitled "The Nature of Design Practice and Implications for Interaction Design Research," Stolterman [3] explored the challenges of design as the creation of a "particular," and posited that designers are best helped by

research that offers concepts and new ways to think about things rather than prescriptions about exactly how to go about doing design. Connected to the realm of engineering education, such an analysis raises questions about the nature of teaching. What kind of thing is teaching?

Debates about the nature of teaching are actually at the heart of critiques of the evidence-based practice movement as it has been brought into education. The general idea of the evidence-based practice movement, which originated in medicine [4], is that research provides evidence that practitioners can use in order to make their decisions. In some instances of this ideal, evidence is loosely constructed and the decisions of practitioners are represented broadly. In other instances of this idea, however, evidence is understood to be experimental studies (ideally randomized controlled trials) and the evidence from such studies will indicate to practitioners what they should do. In critiquing this ideal, Biesta [5] focuses on a mismatch between assumptions about teaching and the reality of teaching. Interestingly, though, many publications on evidence-based practice in education focus on the use of evidence-based practice by leaders (i.e. principals) rather than classroom teachers.

Collectively, these ideas suggest that we need a way to study the research-to-practice issue that permits us to think about what we mean by practice such as what aspects of practice are supported and which practitioners we are talking about.

The role of journal articles

In this work, we have chosen to analyze articles in the Journal of Engineering Education [6]. This choice reflects the themes introduced in the previous two sections. First, by focusing on the research published in the journal we will ensure our analysis reflects the type of research being published in field. Second, because of the nature of the mission of the journal, a requirement of the journal is that authors make connections to practice. By analyzing these connections to practice, we can then look to see what aspects of practice are implicated, such as who is implicated.

Studying research papers is admittedly only a small window into the research to practice issue, and also a problematic window for a variety of reasons. For example, journal articles are not necessarily widely read and they are only one place where research is connected to practice. At the same time, journals are a foundational part of the scientific enterprise. The recognition that journals are foundational has led to their study in the realm of Rhetoric of Science [1], a field that we draw on in this work. Drawing on the Rhetoric of Science, our analysis below contains a quantitative component as well as a qualitative component.

III. METHODS

In this exploratory work, we examined the ways in which implications for education are represented in one year

of the Journal of Engineering Education (JEE). Our methodological choices aimed for a certain degree of rigor balanced by the goal of creating information to guide the next iteration of the method.

The sample

In this analysis, we focus on the April 2011, July 2011, October 2011, and January 2012 issues of JEE —the four most recent issues as of the writing of this paper. As shown in Table 1, the resulting set of thirty-one papers covers a diversity of topics and methods.

In order to focus our analysis, we decided to code the sections of the articles most likely to contain implications for educational practice: the abstract, the discussion, and any sections in the paper following the discussion. This approach reflected an idea that if implications for education were to be present, they would likely be in these sections, and further, if implications for education were present in other sections, they would likely be overlooked by most readers. With this approach, we coded a total of 2464 sentences. The number of sentences coded per article was variable, not only because the articles differed in length but also because some papers had combined their discussion with their results (via sections entitled "Results and Discussion"). As will be discussed further below, a small number of papers had sections specifically devoted to educational implications.

The coding approach

The coding process involved two major steps: determining if a sentence could be read as an implication for educational practice and, if so, determining who was implicated. Generally speaking, a sentence was considered to represent an implication for educational practice if it could be read as encouraging or even pushing an actor to engage in an action related to education. From an analytic standpoint, such an implication for educational practice could be represented in a sentence of the following form: *Because of finding x, actor with some degree of certainty should engage in action.* From preliminary explorations of the data, we knew that such sentences were present in the dataset. We also knew, however, that sentences were often experienced by the coders as implications for educational practice even when they did not follow this formula. For example, sentences might indicate that an action needs to be taken but not identify the actor who needs to take such an action. Because of the exploratory nature of this work, we took a liberal approach to coding. Below are examples of sentences representing implications for educational practice. These examples and others later are cross-referenced with the notation x(y)-z where x represent the volume, y represents the issue, and z represents the position of the specific paper within its issue. We selected this cross -referencing approach in order to focus attention on patterns in the results rather than the identity of the authors

- "At the university level, in assessing students' readiness, educators must go beyond standardized placement tests and subsequent placement in "remedial" courses and provide opportunities to develop

other academic success skills, and help students to be aware of and take advantage of the institutional resources in place designed to help them succeed." (101(1)-1)

- "We recognize that these types of academic support systems exist in many engineering colleges, however, our data point to the importance of continuing to allocate resources and promoting such programs in order to improve retention." (101(1)-1)
- "A recommendation from the study here, which showed that there are critical processes, is to couple a structured teaching approach, like Gray et al., with an assessment rubric, in order to document and dynamically respond to the changes in thinking and reasoning that result from pedagogical interventions." (100(3)-4)
- "Software could be created to guide the student, but also to record and analyze the path the student follows in reaching a solution."
- "DAA activities may offer a potential solution to the challenge of poor instruction, a cited cause of discontentment among undergraduates in STEM." (100(3)-4)
- "Including humanities courses across the freshman through senior years, particularly courses that include materials besides textbooks, may help students retain and develop a transactional and constructivist orientation to information and knowledge to a larger extent than is currently occurring." (100(2)-8)
- "Depending on the results of these studies, changes to the typical engineering curriculum may be required to nurture and strengthen students' innovation abilities throughout their undergraduate education." (101(1)-3)
- "In other words, the time has come to thoroughly examine and deconstruct how cultures of engineering education both reinforce masculine biases and (re)produce gendered identities." (100(2)-3)

In the second part of the coding, we analyzed each "implication for educational practice" sentence to determine who was implicated. If the sentence involved explicit identification of an actor, then we recorded the identity of the actor. If the sentence did not involve explicit identification of an actor (e.g., because the sentence was written in passive voice), then we noted the actor as implicit. For example, "faculty interested in implementing problem based learning" (100(2)-2) is an example of an explicitly identified actor while "students should be given feedback and opportunities to reflect on and evaluate their own team processes" (100(4)-2) represents an implication for educational practice in which the actor is implicit.

The coding procedure

Four coders (the four authors of this paper) were involved in the coding of the data. Each coder was responsible for coding all of the articles in one of the journal issues being studied. Several procedures were used in order to contribute to the rigor of the study at a level appropriate to this exploratory analysis. First, the coding approach was developed using an iterative process and refined based on issues raised by the group. Second, we maintained a detailed audit trail of our process. Third, our analysis of the coded data provided many opportunities for the coders to inspect and question aspects of the data coded by other coders—a form of a skeptical peer review. While no formal double coding was used in this process, three of the researchers read and reviewed articles beyond the ones to which they had been assigned. This helped in the review of the coding. In future stages of this research, we plan to use a double-coding procedure to contribute to rigor [7].

Analysis and interpretation

All of the coding was aggregated into a single Excel spreadsheet containing a row for each sentence in the coding sample. In addition, for each sentence that had been identified as an "implication for educational practice" sentence, our spreadsheet also contained notes about the identity of the agent who was implicated. We addressed the emphasis question quantitatively, by counting the number of sentences coded in each article, and qualitatively, by looking at the patterns created by the number of sentences coded and also the location of the sentences that were coded. We addressed the "who is implicated" question qualitatively, by looking across the recorded results to identify themes.

IV. RESULTS

In our analysis of how implications for educational practice are represented in the most recent issue of JEE, we noted variation in (a) the extent to which educational implications were emphasized by the authors, and (b) the identification of who is implicated.

Emphasis on Educational Implications?

The papers varied in the extent to which they emphasized educational implications. Table 1 presents the results of this analysis. The table consists of a row for each paper that was analyzed (each paper is identified by the issue and the paper number within the issue). For each paper, the table indicates the number of sentences that were analyzed, the number of sentences that were coded as an educational implication ("absolute emphasis"), and the percent of coded sentences that were educational implications ("relative emphasis"). The table is sorted in terms of the results for absolute emphasis.

As the table shows, absolute emphasis ranged from zero sentences to sixteen sentences, and relative emphasis ranged from zero percent to eighteen percent. In other words, some papers had a high level of emphasis on implications for educational practice while at least one paper did not address educational implications.

On the high end of emphasis, four papers were identified as having ten or more sentences devoted to educational implications, representing 10% or more of the sentences that were coded. The titles of these four papers suggest that these four papers were varied in terms of topic and methodology: (1) Using paper-and-pencil solutions to assess problem solving skill, (2) Leaving engineering: A multi-year single institution study, (3) The relationship between team discourse, self-efficacy, and individual achievement: A sequential mixed-methods study, and (4) Problem-based learning: Influence on students' learning in an electrical engineering course.

At the other end of the spectrum, seven papers had one or zero sentences devoted to educational implications, representing one to three percent of the sentences that were coded. This is not to say that these papers did not have any implications for future activity (e.g., these papers did have

implications for future research). Rather, the finding is that these papers placed low emphasis on implications for educational practice. The titles of these seven papers suggest that they were varied in terms of topic and methodology: (1) The motivational and transfer potential of disassemble/analyze/assemble activities, (2) Information fluency growth through engineering curricula: Analysis of students' text-processing skills and beliefs, (3) An experimental investigation of the innovation capabilities of undergraduate engineering students, (4) Feminist theory in three engineering education journals: 1995–2008, (5) A psychometric re-evaluation of the design, engineering and technology (DET) survey, (6) The socially responsible engineer: Assessing student attitudes of roles and responsibilities, and (7) Nonparametric survival analysis of the loss rate of undergraduate engineering students.

Table 1. Emphasis on Educational Implications

| Issue | Article | Coded | Absolute Emphasis | Relative Emphasis |
|-------------|---------|-------|-------------------|-------------------|
| 2011-3July | 4 | 93 | 16 | 0.17 |
| 2012-1Jan | 1 | 122 | 16 | 0.13 |
| 2011-4Oct | 2 | 82 | 10 | 0.12 |
| 2011-2April | 2 | 92 | 10 | 0.11 |
| 2011-4Oct | 4 | 123 | 9 | 0.07 |
| 2011-2April | 4 | 45 | 8 | 0.18 |
| 2011-3July | 8 | 59 | 7 | 0.12 |
| 2011-3July | 1 | 44 | 6 | 0.14 |
| 2012-1Jan | 7 | 83 | 6 | 0.07 |
| 2011-4Oct | 7 | 77 | 5 | 0.06 |
| 2011-2April | 5 | 80 | 5 | 0.06 |
| 2011-3July | 5 | 82 | 5 | 0.06 |
| 2012-1Jan | 5 | 120 | 5 | 0.04 |
| 2011-3July | 3 | 75 | 4 | 0.05 |
| 2011-2April | 1 | 92 | 4 | 0.04 |
| 2012-1Jan | 2 | 110 | 4 | 0.04 |
| 2012-1Jan | 6 | 123 | 4 | 0.03 |
| 2011-3July | 7 | 50 | 3 | 0.06 |
| 2011-2April | 7 | 63 | 3 | 0.05 |
| 2011-3July | 6 | 186 | 3 | 0.02 |
| 2012-1Jan | 4 | 40 | 2 | 0.05 |
| 2011-4Oct | 1 | 46 | 2 | 0.04 |
| 2011-4Oct | 3 | 67 | 2 | 0.03 |
| 2011-4Oct | 6 | 73 | 2 | 0.03 |
| 2012-1Jan | 3 | 36 | 1 | 0.03 |
| 2011-4Oct | 5 | 49 | 1 | 0.02 |
| 2011-2April | 3 | 61 | 1 | 0.02 |
| 2011-4Oct | 8 | 73 | 1 | 0.01 |
| 2011-3July | 2 | 84 | 1 | 0.01 |
| 2011-2April | 8 | 105 | 1 | 0.01 |
| 2011-2April | 6 | 26 | 0 | 0.00 |
| Min | | 26 | 0 | 0.00 |
| Max | | 186 | 16 | 0.18 |
| Median | | 77 | 4 | 0.05 |
| Average | | 79 | 5 | 0.06 |

Looking a bit beyond the quantitative emphasis measurements, it is interesting to note that five of the papers emphasized implications for educational practice by creating a section dedicated to this issue. For example, one

paper has a section entitled, “The ‘How’ – Implications for Curriculum Design and Teaching Practice” (100(4)-4), while another had a section entitled “Recommendations for Practice” (100(3)-8). The use of explicit sections or subsections makes it easy for a reader to readily see how the work presented in the paper may be applied to educational practice. In the other papers, the implications for educational practice were often interwoven with other discussion or conclusion points.

Who is Implicated?

The implications for educational practice sentences were almost evenly divided between those in which the actor was explicit (~47%) and those in which the actor was implicit (~53%). To better understand the nature of the explicitly identified actors, we tabulated the number of times different explicitly identified actors were referenced.

The following actors were implicated more than once. It is not surprising that the more frequently mentioned actors represent relatively generic terms. It is also interesting to see the relatively equal use of the generic terms educators, faculty, instructors, and practitioners. It is also interesting to note the appearance of the first persona plural (e.g., “We need to provide students with opportunities to engage the internal frame of reference with which our participants were particularly concerned”).

- educators (6)
- faculty (6)
- instructors (4)
- we (4)
- practitioners (3)
- researchers and practitioners (3)
- students (3)
- engineering education (2)
- engineering programs (2)
- institutions (2)

In our analysis, we also looked into the actors which were used more than once in the sample. Below is an alphabetical list of actors that were mentioned only once. It is interesting to note that some of the actors on this list are distinct from the actors listed above (e.g., ABET, educational practice, advisors), some are elaborations of the generic actors above (e.g., faculty implementing inductive teaching approaches), and some are compound actors (e.g., engineering professors and educational practitioners). It is also interesting to note that the categories vary in terms of how many people are being implicated (e.g., “educators at the university level” is a broader category than “high school summer camp”). The breadth of this list reminds us of the breadth of the engineering education system.

- an educator
- ABET
- advisors of teams in project-based learning programs
- college professors
- educational practice
- educational programs
- educators at the university level

- engineering colleges interested in increasing the level of preparation of students
- engineering colleges with the goal of increasing the self-efficacy of engineering students
- engineering educators
- engineering faculty
- engineering professors and educational practitioners
- engineering professors, educational practitioners and students
- engineering programs seeking to encourage program completion
- entire college or school
- faculty adopting instructional approaches, such as PBL, with expectations of seeing results similar to this study...
- faculty implementing inductive teaching approaches
- faculty implementing the PBL approach
- faculty who work with advisory boards and employers on the development of curriculum
- faculty interested in implementing problem based learning
- high school summer camp
- instructors and the students, and especially those just starting out or disappointed with their groups
- Instructors interested in scrutinizing homework quality
- K-12 and university educators
- K-12 practitioners who incorporate engineering education ideas in their classrooms
- outreach programs
- outreach programs focused on preparing students to study engineering in college
- outreach programs intended to prepare students to study engineering
- pre-engineering programs
- schools who graduate a large percentage of students who are underrepresented in engineering
- teachers
- the instructor
- the teacher
- those first starting out with the cooperative learning methodology, or disappointed with its initial results
- university researchers and K-12 practitioners alike

As noted above, in over half of the implications for educational practice sentences, the actor was implicit. In other words, the author is identifying an implication for educational practice but not specifically identifying who is expected to enact the practice. In some of these cases, the implications for educational practice were written in passive voice (e.g., "Vicarious experiences can be used to scaffold students' development of self-efficacy and effective teaming skills", 100(4)-2). Other sentence structures were also used. Analyzing the range of the sentence structures associated with implicit actors was beyond the scope of this paper.

V. DISCUSSION

Our goal in this paper has been to explore two questions related to implications for educational practice in the *Journal of Engineering Education*: the emphasis on this issue and the nature of who is implicated. In our analysis, we found variation to be a key feature of the answer to each question: variation in the level of emphasis on implications for education practice across the articles and variation in who is implicated. This suggests, in turn, that the discourse around educational implications is not a unified discourse.

It is interesting to think about how to interpret the varied *emphasis* on educational implications. In fact, the variation

raises more questions than it answers. For example, is one approach (e.g., low emphasis or high emphasis) more appropriate? Also, what might explain the variation that was observed? Is the variation the result of author preference, editor preference, or genre conventions? Or perhaps it is less about choice and more about the type of research. Perhaps different types of research and/or different research methods have different connections to practice? Another possibility is that different researchers have different capacities to imagine, identify, and articulate potential implications for practice. It is useful to note that the type of thinking associated with rigorous research is not the same as the type of thinking required to connect research to practice.

It is also interesting to think about the ramifications of different patterns of emphasis. For example, a consequence of having few or no clearly stated implications for educational practice is that this might cause readers to question the usability or relevance of the study. Further, when implications for educational practice are present but not in a dedicated section, they become harder to find and may simply be overlooked. As a result, if a reader does not have the imagination to make connections to practice, such connections might not be made regardless of whether such connections are possible. On the other hand, there are clearly challenges associated with including implications for educational practice, such as determining the best way to frame such implications (i.e., how assertive and specific should such implications be) and determining how much emphasis to place on such implications. While having explicitly articulated educational implications can be valuable, there could be negative ramifications to having too much focus on implications for educational practice. For example, a journal article (as an archival reference for the research) needs to fully address the relevant research issues and high emphasis on implications for educational practice could compete with emphasis being placed on the research.

The "who is implicated" analysis highlighted a split between explicitly and implicitly identified actors, and also a range of explicitly identified actors. Similar to above, it is possible that the split between explicitly and implicitly identified actors is related to author preferences, editor preferences, or genre conventions. It is also possible that deciding who is implicated by the research is simply challenging, since the system itself is composed of many people with multiple roles. Indeed, the range of explicitly identified actors in the "who is implicated" results remind us that engineering education is a large system. This breadth raises a question—how does an author know whom to focus on when there are potentially many agents who could do many things with the results of the research? Because such a question might be difficult to resolve, authors might respond by articulating implications for educational practice that do not implicate specific actors. However, such choices might decrease accountability felt by the reader.

This work is limited by its emphasis on only one year of articles in the *Journal of Engineering Education* and a coding approach that did not yet feature double coding and inter-rater reliability. Future research can address these issues and determine if the patterns identified by this analysis remain. Such future research can also explore additional issues in the data such as (a) what actions are highlighted in implications for educational practice, and (b) the extent to which implications for educational practice are connected to research findings.

V. THE IMPLICATIONS OF IMPLICATIONS

This work provides a basis for practical, scholarly, and even pedagogical implications. At a practical level, the findings suggest that there may be room to improve the writing of implications for educational practice so that, when they are present, they can be found and effectively understood by readers. For example, authors could consider adding explicit implications for practice sections to their articles, and editors of journals could consider providing guidelines about this issue. It is also possible that there could be a community solution that involves creating a space where additional "implications for educational practice" could be located. Of course such implications assume that it is appropriate or even desirable that implications for educational practice be explicitly articulated in journal articles and/or in another location.

This issue gives rise to the scholarly implication—that there may be value in exploring the cultural context that gives rise to different levels of emphasis and different levels of explicitness in the articulation of implications for educational practice. Our conversations among ourselves and with others around these findings suggest that the variability that we noticed in the data is related to important backstories concerning preferences, politics and power. In addition, as we have thought about this issue, we wonder about an assumption that researchers can always be expected to be able to identify the kinds of educational implications that their findings may have for educational practice and whether educational practitioners are prepared to read original research and identify educational implications of research findings. Complicating this issue further is the inherent complexity of education. Perhaps the variation in educational implications reflects variations in underlying ideas about the nature of educational practice.

Finally, our experience of doing this research has led us to believe that this research process has pedagogical value. In other words, when people analyze existing literature to understand the way implications for educational practice are handled in that literature, they learn a great deal. This idea deserves future investigation.

VI. CONCLUSION

This paper addressed the ways in which implications for educational practice are represented in scholarly work in engineering education. Contributions of this work include the findings concerning variation in emphasis and who is implicated, the coding approach that will make it possible to extend this work, and the ideas represented in our own implications section. In addition, a key contribution of this work is to draw attention to the issue of "implications for educational practice" as a topic that warrants further study if we are to succeed in using research to inform the transformation of engineering education.

Abstract —The purpose of this investigation was to develop the STEM Active Listening Skills Assessment (STEM-ALSA), a conceptually grounded instrument designed to measure four components of active listening, a key element of communication in an academic setting. The STEM-ALSA is comprised of three unique scales that measure a person's knowledge (12 items), ability to apply (25 items), and self-efficacy (5 items) with respect to active listening. Two pilot studies were conducted with N = 99 upper level undergraduate students enrolled in STEM disciplines to develop and evaluate the instrument. Results of an exploratory factor analysis identified both a unidimensional factor structure for each of the three scales and total scores with adequate internal consistency reliability estimates. The STEM-ALSA provides a mechanism for measuring active listening skills among students in STEM.

Keywords—Assessment; communication; graduate students in STEM

I. INTRODUCTION

Effective communication skills are an essential commodity in today's workplace. In engineering, technology, and the sciences, communicating disciplinary knowledge to the public is considered critical. Interpersonal communication skills (ICS) are also recognized as key transdisciplinary capabilities necessary for career success [1]. For example, an estimated 50-75% of scientists' work involves communicating with others individually, in small groups, and in teams [2]. The *Engineer of 2020* report [3] and other researchers [4], [5], [6] have also highlighted the fact that communication skills will become increasingly important as engineers are required to communicate in globally diverse and interdisciplinary teams. However, despite the expressed importance of these communication skills, numerous research studies, reports from industrial recruiters, and anecdotal evidence by educators have indicated that graduates of science, technology, engineering, and mathematics (STEM) disciplines are inadequately equipped to communicate effectively in the workplace [7]. This leads organizations such as The Society for Manufacturing Engineers to list "lack of communication skills" among the top "competency gaps" in engineers' education [8].

In addition to plaguing recent graduates of STEM disciplines who work in industry, inadequate training in ICS at

the undergraduate level has implications for graduate studies in STEM. It has been stated that "science these days...increasingly draws on skills in written and oral communication with scientists and non-scientists alike" [9]. For the most part, however, the oral communications that are central in students' daily practices are conversational and informal. Additionally, students who are able to communicate their needs to their graduate program are more likely to complete their degrees [10]. In fact, recent research suggests that graduate students who take a more active role in developing ICS are more successful in graduate school [11], [12].

An ICS identified as a particularly important element for communicating across disciplines is "active listening" [13]. Active, or empathic, listening can be traced to Carl Rogers [14] and is a cornerstone of his humanistic psychology [15]. Since its introduction, active listening skills have been found to play an important role in effective communication and have now become a mainstay of communication training programs across a variety of fields [16].

In addition to being widely recognized as an important interpersonal communication skill, active listening has also been shown to be a teachable skill. For example, research has shown that the listening skills of counseling students [17] and helpline volunteers [18] improved with active listening training. Moreover, the effects of such training continued for at least nine months in the case of the helpline volunteers [19]. Yet, despite the importance of the skill and the fact that it has been shown to be something that can be learned, there are few empirically validated instruments available to measure active listening skills.

This paper discusses the development of the STEM Communication Skills Assessment (STEM-ALSA), which is comprised of three unique measures: knowledge of, self efficacy in the domain of, and skill in the application of active listening. The context of all the items in the instrument is the advisor-advisee relationship. Advising is at the heart of the institutional and interpersonal structures that make up graduate education [20]. Consequently, it is imperative that the advisor-advisee relationship takes on a supportive stance. This is especially the case for female doctoral students, for whom the graduate program milieu is often described as a "chilly

42nd ASEE/IEEE Frontiers in Education Conference

climate” [21], [22]. The STEM-ALSA was developed for a specific study within the *CareerWISE* research program. In the following sections, we provide a brief description of *CareerWISE* to help situate the motivation for the instrument development, outline the process of instrument development, and describe the scales within the instrument in more detail.

II. CareerWISE RESEARCH PROGRAM

The *CareerWISE* research program is a large, NSF-funded, multidisciplinary research program housed at Arizona State University. The program strives to both understand the reasons that women in STEM doctoral programs drop out and to develop and disseminate a resource to strengthen key personal and interpersonal skills so that women will be better equipped to persist in their doctoral degree programs. Built on an extensive foundation of theory and research, the *CareerWISE* resource (<http://careerwise.asu.edu>) is an online resilience training program designed to address the personal and interpersonal challenges of women in science and engineering fields by strengthening their personal assets and supports [23]. Key objectives of the resilience training program are to enhance the communication skills of doctoral women and to improve interpersonal problem solving skills. The *CareerWISE* resource is unique in that it is an individualized program that pairs empirically based pedagogical materials with an interactive simulation environment designed to hone users’ ICS skills. It is the first program of its kind to provide systematic training in ICS customized for female students in STEM. Consequently, instruction in active listening skills is an essential building block in the ICS within the *CareerWISE* program.

III. OVERVIEW OF THE THE INSTRUMENT

The development of the STEM-ALSA was underscored by the following definition of active listening: “active listening requires that the listener try to understand the speaker’s own understanding of an experience without the listener’s own interpretive structures intruding on his or her understanding of the other person” [13, p. 35]. The goal in active listening is to develop a clear understanding of the speaker’s concern and also to clearly communicate the listener’s interest in the speaker’s message [18]. The *CareerWISE* team specified the following four sub skills for active listening and defined them as indicated in Table I: asking open ended questions, listening for critical information, communicating via nonverbal cues, and perception checking. Items in the instrument were specifically included to assess each of these four elements.

The STEM-ALSA is comprised of three unique scales. The Knowledge Assessment scale measures the respondent’s self-reported current knowledge of active listening. The following are two sample items from this scale: “I know how to restate a speaker’s message to verify my understanding” and “I know how to convey nonverbally that I am interested in what the other person is saying.” Response options for this scale are arrayed on a 5-point Likert scale ranging from 1 (*strongly disagree*) to 5 (*strongly agree*).

The Self Efficacy Assessment scale is designed to measure an individual’s confidence in her own ability to use active listening skills in an academic setting. Two sample items from

this scale are: “I can detect the important messages in a conversation with professors,” and “I can ensure that I have understood the speaker’s message.” Response options for this scale are also arrayed on a 5-point Likert scale, ranging from 1 (*strongly disagree*) to 5 (*strongly agree*).

TABLE I. DESCRIPTION OF ACTIVE LISTENING SUB-SKILLS

| | |
|------------------------------------|---|
| Asking open-ended questions | Questions that are broadly framed to encourage elaboration and allow for responses other than yes or no. |
| Attending to nonverbal cues | Observing the speaker’s nonverbal cues (e.g., facial expressions, hand gestures, posture, etc.) for information about the meaning of the speaker’s message. |
| Listening for critical information | Identifying the main points of a speaker’s message. |
| Perception checking | Ensuring that the listener understands the speaker’s message by paraphrasing the listener’s interpretation of the speaker’s feelings and message content. |

The third scale, Skills Assessment, measures the participant’s ability to actually apply her active listening skills. Skills are often measured using an observation rating approach [24]. However, actual observation can be costly and time intensive. To get around this issue, the STEM-ALSA uses a self-report format to measure skill application. In this section of the instrument, a series of scenarios is presented, modeling situations that could realistically occur for a female doctoral student in STEM. Each scenario includes a stated goal for the student. Following each scenario are four responses, each corresponding to a particular course of action that could assist or hinder the student in achieving her desired outcome. Participants are asked to rate the likelihood of achieving the desired goal for each action on a five-point Likert scale with response options ranging from 1 (*very unlikely*) to 5 (*very likely*). Figure I gives a sample scenario and its corresponding items.

A month ago, Dr. Simpson asked Sarah to organize an informal bi-weekly meeting at which graduate students from the department would present their research to each other. Today is the first of those meetings, and Sarah is presenting her own research to kick things off. During her presentation, she notices that Dr. Simpson appears to be falling asleep and is not paying attention to what she is saying. For each of the following actions, indicate how likely it is to assist Sarah in getting his attention.

1. Pause for a moment to convey nonverbally that she is waiting for his attention.
2. Talk as usual while ignoring his lack of interest.
3. Catch Dr. Simpson’s gaze when he looks up.
4. Speak with more animation and address him by name.

Figure I: Sample item from the Skill Assessment scale

IV. INSTRUMENT DEVELOPMENT METHOD AND RESULTS

The STEM-ALSA instrument was developed in three phases. The first phase consisted of initial item development and expert feedback, the second phase involved piloting and then modifying the instrument based on expert feedback (pilot study #1), and the third phase included a second pilot and associated modifications (pilot study #2).

A. Phase 1 – Initial Item Development

Initially, 16 items were written for the Knowledge Assessment scale, 32 items for the Skills Assessment scale, and 8 items for the Self Efficacy Assessment scale. Items were developed using the literature on active listening and were examined by an interdisciplinary research team consisting of students and faculty from the disciplines of counseling psychology, engineering, and educational technology. To assess content validity, three experts in psychological measurement and interpersonal communication provided open-ended comments on the original items in each of the three scales. The experts rated each item on content appropriateness and clarity/readability using a 5-point scale that ranged from 1 (*not at all appropriate or clear*) to 5 (*very appropriate or clear*). Based on their feedback, several items were revised for clarification. Two of the original content experts then re-evaluated the three revised measures for appropriateness and clarity.

B. Phase 2 – Pilot Study #1 Methods

The purpose of pilot study #1 was to examine the initial factor structures of the items in each of the three scales in the STEM-ALSA instrument. During the pilot, undergraduate women majoring in mathematics, sciences, and engineering at a large southwestern public university were recruited through university organizations and contacts within the departments. Participants in the study were given a short online introduction to communication skills and then were presented with the instrument so that their active listening skills could be assessed. Demographic information was also collected from participants.

A total of 72 participants (primarily juniors and seniors with an average age of 21.6) completed the anonymous online pilot study. The majority of participants reported that they were US citizens with English as their primary language, and over 90% of those who responded stated they had an advisor with whom they interacted. Participants who completed the study were given a \$25 gift card redeemable at the university bookstore.

Using the participant responses, a principal-components analysis was performed on the items in the STEM-ALSA instrument. A separate analysis was performed for each of the three scales. Of note is that the responses in the Skills Section were scored in a unique way. First, three experts were asked to score each item for how likely it would be to produce the desired outcome. The mean of those values was recorded as the final “best answer.” Participant scores, then, were recoded based on this best answer. Participant responses that were in the same direction as the best answer (i.e., above or below the score of “3”, the midpoint of the scale) were scored as “1,” and those that were not in the direction of the best answer were scored as “0.” For example, if the best answer based on for an item based on expert scoring was 4.33, and a participant’s score was 5 (also above a score of “3”), then the participant’s score was recoded to be a “1.” On the other hand, if the participant’s score was “2”, which is in opposite direction of the best answer, the participant score was recoded to be a “0.”

C. Phase 2 – Pilot Study #1 Results

Analyses of each of the three scales in the STEM-ALSA indicated that a one-factor solution was most interpretable. In the Knowledge Assessment scale, the factor structure accounted for 33.31% of the variance. All 16 items loaded at or above 0.40, and the internal consistency of the scale was good, with a Cronbach’s alpha [25], of 0.84. In the Self-Efficacy scale, three of the eight items were deleted, as the factor only accounted for a small amount of their unique variance. After excluding these three variables, the structure of this scale was reanalyzed. The revised structure accounted for 62% of the total variance and was comprised of five items that loaded above 0.70. Cronbach’s alpha [25] for the total score of the one factor solution in the Self Efficacy scale was found to be 0.85. The results were not quite as good for the Skills Assessment scale. The one-factor solution in that scale, while most interpretable, only accounted for 14 % of the total variance. The Cronbach’s alpha coefficient [25] for the total score of the one factor solution in the Skills Assessment scale was also only 0.38.

D. Phase 3 – Pilot Study #2 Methods

After completing pilot study #1, the three experts in the areas of interpersonal communications and psychometrics were again consulted to examine the items of the three scales, paying particular attention to the Skills Assessment scale. Based on their analysis, items in the Skills Assessment scale for which the experts disagreed on the general direction of the best response were dropped (e.g., when two of the three experts thought it was generally a good course of action, and one didn’t).

Following the expert input, a second pilot study was conducted to further examine the factor structure of the revised STEM-CSA. For this pilot, undergraduate students in an introductory computer informatics course at a large southwestern public university were recruited. As in the first pilot study, participants in this pilot were given a short online introduction to communication skills and then were presented with the instrument so that their active listening skills could be assessed. Demographic information was also collected. Students’ majors included liberal arts and communication, as well as computing. A total of 27 participants (primarily sophomores and juniors, with an average age of 21.3) completed the second pilot study. The majority of participants reported that they were US citizens with English as their primary language, and over 76% of those who responded stated they had an advisor with whom they interacted. Participants who completed the study received course credit for their participation.

E. Phase 2 – Pilot Study #2 Results

Analysis of the Knowledge Assessment scale in pilot study #2 supported the one-factor solution. However, the factor solution accounted for less than 50% of the individual variance for four of the 16 items. Consequently, these four items were excluded from the instrument. The revised structure accounted for 56% of the total variance and included 12 items that loaded above 0.50 (See Table II.). Cronbach’s alpha for the total score of the one factor solution was found to be 0.93.

A one-factor solution in the second analysis of the Self Efficacy Assessment was also robust and conceptually sound. The measure accounted for 69% of the total variance, and included 5 items that loaded above 0.70 (See Table III.). The alpha coefficient for the total score of the one factor solution was found to be 0.88.

Based on expert suggestion and the statistical results of pilot study #1, a number of items were deleted and/or revised in the skills-assessment section. Analysis of the revised, 25 item STEM- Skills Assessment indicated that a one-factor solution again yielded the most interpretable solution. This factor structure accounted for 16% of the variance. The alpha coefficient for the total score of the one factor solution was found to be 0.52. Factor loadings ranged from 0.04 to 0.72. Therefore no support was found for this scale. As such, further revision is necessary.

V. CONCLUSION

The development and initial validation of the STEM-ALSA is an important preliminary step in filling the gap of empirically-validated instruments for measuring active listening. The scales, Knowledge Assessment, Self Efficacy Assessment, and Skills Assessment were designed to measure a respondent's perceived knowledge, self efficacy, and ability to apply active listening skills respectively.

The results indicated that two of the three scales in the instrument, Knowledge and Self Efficacy, demonstrated high internal consistency and fit a unidimensional factor solution. STEM-ALSA also contained a unique section for measuring the application of active listening skills. In this section, a scenario based approach was used, representing a novel approach for measuring the ability to apply active listening skills. However, the analyses suggest that this section of the instrument needs further validation and examination of the factor structure. In future work, we plan to further assess the scenario based approach of the Skills Assessment scale and examine the construct validity of the STEM-ALSA scales.

Finally, of note is that although the STEM-ALSA was developed for use in the context of a specific study, further studies can evaluate the usefulness of the instrument for measuring academic communication skills in other populations (e.g., STEM undergraduate students) as well as within other professions.

TABLE II. STEM-KNOWLEDGE ASSESSMENT ITEMS, FACTOR LOADINGS, MEANS, AND STANDARD DEVIATIONS FOR STUDY 2

| Items | Factor 1 loadings | M | SD |
|--|-------------------|------|------|
| 1. I know how to quiet my own thoughts in order to listen carefully. | 0.57 | 3.93 | .96 |
| 2. I know how to listen and watch for the main points of a speaker's message. | 0.71 | 4.37 | .69 |
| 3. I know how to identify the overarching message even when other topics come up. | 0.81 | 3.63 | 1.08 |
| 4. I know how to ask a question that doesn't give away the answer I'm hoping to receive. | 0.70 | 3.96 | .90 |

| | | | |
|---|-------------|------|------|
| 5. I know how to ask questions that will encourage the other person to elaborate. | 0.76 | 3.85 | 1.20 |
| 6. I know how to find out more about the other person's perspective. | 0.75 | 4.19 | .79 |
| 7. I know how to ensure that I have understood someone's point of view. | 0.78 | 3.96 | 1.09 |
| 8. I know how to restate a speaker's message to verify my understanding. | 0.82 | 4.19 | .92 |
| 9. I know how to check whether what I heard is what the speaker meant. | 0.87 | 3.81 | 1.04 |
| 10. I know how to convey nonverbally that I am interested in what the other person is saying. | 0.73 | 4.11 | 1.05 |
| 11. I know how to recognize when someone I am conversing with is distracted. | 0.72 | 4.26 | .984 |
| 12. I know how to be consistent in what I'm saying and how I'm saying it. | 0.71 | 3.70 | 1.10 |

Note.. Scores on individual items in the STEM- CSA Knowledge Assessment scale ranged from 1-5. Total scores ranged from 5-60.

TABLE III. SELF EFFICACY ASSESSMENT ITEMS, FACTOR LOADINGS, MEANS, AND STANDARD DEVIATIONS FOR STUDY 1

| Items | Factor 1 loadings | M | SD |
|---|-------------------|------|------|
| 1. I can detect the important messages in a conversation with professors. | 0.86 | 3.93 | 0.92 |
| 2. I can identify the intended meaning of a verbal message even when it is phrased ambiguously. | 0.88 | 4.04 | 0.85 |
| 3. I can behave in a manner that is consistent with how I am feeling. | 0.72 | 3.78 | 0.97 |
| 4. I can verify my perceptions of what the other person is telling me. | 0.90 | 3.81 | 0.88 |
| 5. I can ensure that I have understood the speakers' message. | 0.77 | 3.78 | 0.85 |

Note.. Scores on individual items in the STEM- CSA Self Efficacy Assessment scale ranged from 1-5. Total scores ranged from 5-25.

ACKNOWLEDGMENT

We would like to thank the experts who reviewed the STEM-ALSA instrument for their valuable input and suggestions.

Implementing an Outcome-Based Assessment Technique in Applied and Theoretical Courses

Keith Garfield

Electrical, Computer, Software, and Systems Engineering
Embry-Riddle Aeronautical University
Daytona Beach, FL
garfielk@erau.edu

Abstract— This paper presents experiences with implementing a grading technique to closely couple student performance on specific course outcomes with student grades. The course selected for this technique is an undergraduate computer modeling and simulation course, which required an individual research component in addition to assignments and in-class tests. This class tested a technique whereby assignment of aggregated numerical scores for homework or tests was replaced by pass/fail feedback on individual course outcomes. Each assignment or test enumerated which specific course outcomes potentially satisfied within the assignment. Outcomes loosely correlate to Bloom's taxonomy levels of recognition, understanding, application, and creation. Student feedback reported that the technique enhanced learning, though an increased tendency towards procrastination was also reported. Instructor experiences were positive, with the assessment technique integrating easily with course design and delivery.

Keywords—Assessment, Criteria Based Assessment, Outcomes Based Assessment, Learning Outcomes

I. INTRODUCTION

This paper presents experiences with implementing a grading technique that closely coupled student performance on specific course outcomes with student grades. While instructors have access to a wide range of assessment techniques, effective techniques should strive to be formative, learner centered, ongoing, and align closely with course syllabus [1][2][3]. Additionally, the technique should measurably support an institution's goals and be an integral part of the planning and teaching processes [4][5][3]. This class tested a technique whereby student performance was assessed using pass/fail feedback on individual course outcomes.

Two courses were selected for this technique. The first is an undergraduate computer modeling and simulation (M&S) survey course. Course material covered a wide range of M&S concepts, followed by in-depth presentation of the critical challenges currently confronting the M&S community. In addition to assignments and in-class tests, students were required to design, implement, and document a unique simulation experiment that investigated a topic of their choice.

The project provides students with opportunities to display mastery of course topics, and affords an opportunity to reinforce technical writing skills ancillary to the core course topics. The second course is a computer science organization of programming languages course. This course provides a comparative study of programming paradigms, and the content has more emphasis on theoretical concepts than the modeling and simulation course. Formal language concepts are introduced, related to real world programming paradigms, and reinforced through language design and programming assignments.

Traditional assessment techniques do not necessarily tie mastery of course topics to a final grade. A typical process may loosely be described as identifying a desired skill, creating an activity to demonstrate the skill, assign a numeric value to the demonstration, and assign a letter grade based on numeric totals. This process potentially encourages students to focus on numeric scores or letter grades while losing sight of course learning objectives.

Some educators advocate techniques that employ criteria based assessment of outcomes as indicators of learning [2]. Learning outcomes are a set of distinct and well defined set of skills or knowledge that students should be able to demonstrate as a result of the course [6][7]. Measurement of outcomes must be based on some observable event [7], so the measurement criteria provided to students contains actions words such as "define," "distinguish," "solve," or "design." Instructors implementing an outcomes based assessment technique should use the outcomes as a focus during course preparation. The instructor must shape course content and assessment opportunities such that students understand what they are to learn, and understand how they are to demonstrate their knowledge. A focus on the outcomes during the planning period facilitates this goal [8]. Introduction of outcomes alone does not modify the assessment process described above. The technique described in this paper was to express desired skills as learning outcomes, develop activities in which students may demonstrate those skills, and assess each outcome on a pass/fail basis. Course letter grades were assigned based on the number and complexity of the outcomes demonstrated as described in Section III.

The outcomes utilized in this study loosely correlate to Bloom's taxonomy levels of knowledge/recognition, understanding, application, and analysis/creation [7]. The highest level of mastery assessed was the ability of students to create and analyze their own working examples. The inclusion of higher levels, such as synthesis, was not deemed appropriate for this undergraduate survey course. The Bloom taxonomy levels as presented to the students are:

- Level 1 (Recognition): Students demonstrate recognition by simply providing a working definition of a glossary term.
- Level 2 (Understanding): Understanding is demonstrated through correct usage of a term, or identification of the principle, while providing feedback on reading material. The student must justify the usage by referencing the key attributes that make the reference appropriate.
- Level 3 (Application): Application level outcomes were satisfied by using a concept or analytical technique to solve a problem provided on test or assignments.
- Level 4 (Analysis): Students demonstrate the ability to create new material for outcomes through completion and documentation of a large or small project.

For example, the term *dynamic verification* refers to any technique in which the correctness of a simulation model is assessed by running the simulation. The student demonstrates completion of the outcomes for *dynamic verification* by supplying a definition for the term (Level 1, Recognition), justifying why a described verification technique is or is not dynamic (Level 2, Understanding), describing how a dynamic verification technique could be applied to an example problem (Level 3, Application), and creating a dynamic verification plan for their course project (Level 4, Analysis).

II. IMPLEMENTATION

A detailed list of course outcomes was drawn up by the instructor as part of course preparation. This list was provided to students as part of the introductory course materials (Table 1). Explanatory material as to how each outcome level may be satisfied was also provided. Each assignment, test, and project deliverable enumerated which specific course outcomes were potentially satisfied within the assignment. The instructor found it most useful to explicitly tie an outcome to a test or assignment question. For example, one exam assessed a portion of the outcomes listed in Table 1. A short functional description of a notional simulation named "The Altruism Game" was presented to the students with the following questions.

1. Sketch out how this simulation could be created using a CFD model. (Level 2 CFD, Level 3 CFD)
2. Sketch out how the Altruism game could be created using Agent Based techniques. (Level 2 Agent Based, Level 3 Agent Based)
3. Sketch out how the Altruism game could be created using a Discrete Event Model. (Level 2 Discrete Event, Level 3 Discrete Event)

Each question requires that the student demonstrate that they know **why** their solution was of the requested simulation type, (Level 2 outcome), and then **create** a high level design description of a simulation. Students received feedback via a tracking sheet noting all outcomes demonstrated thus far. This feedback acted as a formative assessment, as students were allowed to re-visit missed outcomes during future assignments in order to gain credit for them later in the semester. The ability to repeatedly attempt the same outcome was viewed by the author as in keeping with the goal of outcomes being an ongoing part of learning [1][5].

Each course assessed students via homework assignments, tests, and projects. Level 1, 2, and 3 outcomes were assessed primarily via homework and test questions. Level 4 outcomes required the students to display a capability to deeply analyze an aspect of the topic. This was accomplished in the modeling and simulation course via the course project, which required that the student design, implement, and report on a relatively sophisticated and in the programming languages course through course assignments where the class wrote language requirements documents, and designed small programming languages.

Table 1: Partial List of course Outcomes

| | Level 1 | Level 2 | Level 3 | Level 4 |
|----------------------------------|---------|---------|---------|---------|
| Model (1) | 1 | 1 | | |
| Simulation (1) | 1 | 1 | | |
| Finite Element Modeling (2) | 1 | 1 | | |
| Computational Fluid Dynamics (2) | 1 | 1 | 1 | |
| Discrete Event Simulation (2) | 1 | 1 | 1 | |
| Agent Based Simulation (2) | 1 | 1 | 1 | |

III. IMPACT ON COURSE PREPARATION AND PRESENTATION

The use of this grading scheme presented several benefits and challenges. The presence of clearly defined learning objectives or outcomes is believed to assist in course organization, lecture presentation, and creation of assignments [7]. Overall course preparation time was not significantly affected from previous semesters offering the same course. The organization of topics, lecture schedule, and lecture content were assisted by the unity of the process. The instructor was cognizant of the need to provide opportunities to obtain credit for specific outcomes, which drove the design of assignments and tests. Since outcomes were equally weighted, the issues of how much weight to assign to a specific skill, or aspect of problem solution, were avoided. Grading student work on a pass/fail criterion resulted in a reduction in time to grade student work. The percentage of course outcomes achieved in each of the outcome levels was used as the basis for computing overall course letter grades (Table 2). Thus, the goal of removing the potentially arbitrary assignment of traditional 0 – 100% grading schemes was not fully achieved. However, the

grading scheme did result in a concise record of attainment of specific outcomes at all levels to serve as grade justification if needed. Therefore, student performance was tied to course grade in this fashion.

TABLE2 – COURSE GRADE BASED ON ACHEIVEMENT OF OUTCOMES

| Level | 1 | 2 | 3 | 4 |
|-----------|----|----|----|----|
| Available | 84 | 59 | 38 | 24 |
| A | 76 | 36 | 32 | 16 |
| B | 76 | 32 | 28 | 8 |
| C | 68 | 28 | 24 | 4 |
| D | 64 | 24 | 16 | 0 |

IV. IMPACT ON STUDENT EXPERIENCES

Boud proposes seven principles to keep in mind when designing and performing effective assessments [3]. Among these are that assessment and feedback should actively improve learning, engage students in learning that is productive, and allows students and teachers become partners in learning [3]. The focus on demonstrating skills based on a specific outcome, and the existence of multiple opportunities to demonstrate those skills appears to contribute to those results.

Students reported less test anxiety, citing two reasons. First, students knew that outcomes not achieved on a specific test may be achieved later. This contrasts with a traditional setting where each test serves as the only opportunity to capture a fixed percentage of total points available in a course. Second, since students were made aware of what outcomes they had not yet achieved in the course, they were able to target parts of the test that would potentially yield the highest results.

The most prominent negative aspect of this grading scheme during the initial trial was that students demonstrated an increased tendency to procrastinate. This trial occurred during the modeling and simulation course, and affected student completion of the course project. Two mechanisms were identified to encourage students to perform timely work in the future. The first is to enforce due dates after which certain outcomes would no longer be accepted. This technique was implemented in the programming languages course and eliminated the tendency to procrastinate. The second technique is specific to courses having a lengthy course project experience. This technique would require students to obtain permission from the course instructor to proceed from one project phase to the next. Since the project should provide a significant opportunity to obtain level 4 outcomes, this would encourage timely completion of project goals.

Students participate in an online course evaluation survey at the end of each semester. Students were encouraged to provide feedback on the use of outcomes in the course assessment. Positive responses were as follows:

“Providing us with learning outcomes to complete is a lot less stressful than raw grades. We have multiple opportunities to complete these outcomes so it's a very fair class setting.”

“Learning [sic] outcome style of assesment [sic] made it easy to identify what needed to be learned & eliminated the pressure of tests by not emphasising [sic] a time coonstraint [sic] on knowing the material.”

“No stress tests due to the grading system”

“The grading system really requires the students to know and understand the course material to succeed in the course. It doesn't [sic] require memorization and promotes learning.”

“A decrease in pressure due to the grading system allowed for flexibility in time management. “

“The outcomes were clearly addressed during class and gave multiple ways to achieve those outcomes. Many other classes try to implement this method but fail because the outcomes were not clearly addressed. In this class the professor made the material understandable. He made sure that we achieved the outcomes.”

Negative responses focused on the need for timely feedback on their progress in completing outcomes. For the programming languages course, instructor feedback was not as timely as the system required, resulting in the following negative student feedback responses:

“The grading system was difficult in determining were [sic] you stood during the semester but I still like the grading system.”

“Not enough assessment. I liked the new grading scheme but it would have been nice to get opportunities to get points.”

“no feed back on our work”

“The lack of feedback for the entire course made many of us uneasy.”

These responses highlight the need for timely and continuous feedback from the instructor in order for students to self-assess their progress and manage their time effectively.

V. SUMMARY AND FUTURE WORK

The author tested a technique whereby student performance was assessed using pass/fail feedback on individual course outcomes. This technique was attempted in two courses having a mixture of theoretical and applied course material. This technique was seen as consistent with current trends in assessment techniques [1][2][4][5], and arguably tied student performance more directly to assignment of course letter grades. The instructor viewed the experience favorably, and experienced no additional workload while reporting a deeper alignment of assessment with other course activities. Student

feedback was positive for the most part. Student's identified the focus on outcomes as an enhancement to the learning process, while reporting an increased tendency to procrastinate. Offering multiple opportunities to demonstrate achievement for a single objective must therefore be coupled with a firm "last chance" date in order to reduce the tendency to procrastinate. Student feedback made it clear that timely feedback is an essential part of this process. Feedback allows the students to self-assess and manage their time effectively.

The author intends to continue to utilize and refine this assessment technique for future courses. Students identified the focus on outcomes as an enhancement to learning. Since learning objectives were clearly identified, effort applied to learning was consistent with effort applied to obtain a grade. This was consistent with assessment intent and good practices [1][2][5].

Abstract— Assessment process in one of the most important issues in the learning process and in many cases it is the process that define the sequence of the instruction because it measures the performance of the student in the educational process. In last decades the inclusion of TICs in teaching-learning process has facilitated to address the diversity of students and teachers features. Learning technologies enhance have permitted to adapt the different ways of learning and teaching that coexist in the educational context through the generation of adaptations process as well as user modeling process. This paper describes the item response theory and how it can be applied in a test scenario of an online course for the generation of adaptive assessments within a course of introduction to Object Oriented Programming from items (assessment questions), which are available in online repositories. Being a probabilistic theory the article describes the variables to consider and how to calculate the probability that a student answers correctly a specific item, which is known as the student proficiency level or theta, based on a skill test and their previous answers. In other papers write for the authors it is described the experience of working with fedora commons repositories, which are distributed across a network, in order to have enough questions to be applied properly normalized in the adaptation process. These questions are described under the Dublin Core standard.

The main contributions of this project are the implementation of a probabilistic theory in the generation of adaptive assessment and use of distributed repositories that allow the reusability of items properly parameterized. A second phase of the research includes the implementation of the project (APIP) Accessible Profile Portable Item, allowing standardization of assessment items in a suitable format in the LOM. (*Abstract*)

Keywords—component; IRT (Item Response Theory), Adaptive Assessment, Items and Items Repositories.

I. INTRODUCTION

Information and communication technologies (ICT) have allowed the work done within the classroom can be complemented by using virtual learning environments that

involve a number of tools to enhance teaching and learning in extracurricular work. However, it should be a work of the academic community aim at improving the services provided by information technology, to enhance the services of teaching-learning that provides students and teachers, who are the end users of tools of this type.

For that reason and with the intention of making a contribution to improving the tools used in the field of teaching, this paper presents an research work into the process of adaptation assessments in a course of OOP in the university “Universidad Distrital Francisco José de Caldas” by using the item response theory (IRT). The article presents the main statements of the IRT and how it was applied to an online course for the generation of adaptive assessments, based on the student proficiency level.

Additionally, the last section of this paper presents an explanation of the use of learning repositories and how they enhance the generation of an adaptive assessment and in a general way on learning management systems.

II. BACKGROUND

Previous works [1] [2] [3] deal with the problem to measure student competence level based on the Classical Test Theory (CTT). Assessment Structures in the IMS Learning Design (IMS LD) [2] have been automatically generated using planning techniques [3]. These structures are organized in different level of competences according to a particular scale of measure based in the Bloom’s taxonomy [4]. The structures also define the course sequence, i.e. the student growth in his/her competence level through the different Bloom knowledge levels.

In this paper, we are focusing on the automatic generation of Item Response Theory (IRT) based adaptive tests in the contexts of a Unit of Learning (UoL). ITR offers us the opportunity to alleviate the workload for designers of adaptive courses on the complexity task of authoring adaptive test that

takes into account the demonstrated performance of student in the virtual environment.

Despite the fact that there are many works related to IRT the present research has decided to work with distributed repositories, which are going to be discussed in other paper, because these one is focused on the application of IRT.

The items retrieval system is supported by distributed items repositories of which the most suitable items are selected according to the temporal student model. Student temporal user model is based on competence level and it is update each time that the student response an item in the system.

As long as this project was developed within a research group, the IRT selected methods were choose at random, so that other research teams in the group had the opportunity to taste other methods. Then, as future work it is quite necessary to compare the efficiency of each method.

III. ITEM RESPONSE THEORY (IRT)

Test theories offer validated frameworks to conceptually link unobservable variables with observable variables.

Item response theory is a general statistical theory about examinee item and test performance and how performance relates to the abilities or traits (in our case, competence levels) that are measured by the item in the test. Within the general IRT framework, many models have been formulated and applied to real test data [5]. This article will be considered the models that apply dichotomously scored data.

The most general and accepted IRT model is shown in (1):

$$Probability(\theta) = c + \frac{1}{1 + e^{-a(\theta - b)}} \quad (1)$$

This model defines the probability a particular Item has to be correctly answered given a proficiency level (θ) using the logistic function $Probability(\theta)$. The model assumes the relation between item performance and the competence is given by a logistic function described by one-, two-, or three parameters. Parameter a , tells us how the item can discriminate between highly proficient students and less proficient students; parameter b , indicates the difficulty level of the item; and parameter C indicates how likely the examinees are to obtain the correct answer by guessing [6].

In our case, the unobservable variable (θ) is referred to the competence level of student. Some important formulas associated to the model are:

A. Item Characteristic Function

Birnbaum's three-parameter model states that the probability of a correct answer to an item, given a value q of the knowledge level, is defined by (2) [2].

$$P_i(\theta) = c_i + (1 - c_i) \frac{1}{1 + e^{-1.7a_i(\theta - b_i)}} \quad (2)$$

B. Calculate student proficiency level

Maximum likelihood method (Lord, 1980): This consists of finding the value of θ that maximizes the likelihood function, as it is show in (3).

$$L(u|\theta) = \prod_{i=1}^n P_i(\theta)^{u_i} (1 - P_i(\theta))^{(1-u_i)} \quad (3)$$

In equation (3) $u = (u_1, \dots, u_n)$ is the vector of the examinee's answers, that is, for $i = 1, \dots, n$, u_i is 1 if the answer to the item is right and 0 otherwise.

Bayesian methods, (Owen 1975): which compute the ability level for which the posterior distribution is maximum. This posterior distribution is proportional to the product of the likelihood function and the a priori density function.

Neural Networks Methods. (Benitez,2000): Alternatively to the classical methods it have been proposed using competitive neural networks and Kohonen neural networks for sorting, since theoretically, it has been shown, in general terms the results obtained by competitive neural networks similar to those obtained with Bayesian classification [7].

C. Item Selection Methods

Test Information Function: Consists of selecting the item that maximizes the item information for the provisional estimate skill level so far (θ). Is given by the following function (4) [2]:

$$I_i(\theta) = \frac{2.89a_i^2(1-c_i)}{\left[c_i + e^{1.7a_i(\theta - b_i)}\right] \left[1 + e^{-1.7a_i(\theta - b_i)}\right]^2} \quad (4)$$

Bayesian methods: Select the question that minimizes the expected posterior variance of ability distribution.

Method based on the level of difficulty: Selecting the question of which level of difficulty is close to the current estimate of the student's skill level.

IV. DESCRIPTION OF IRT FUNCTIONALITY

This section describes the functionality of IRT in the development of a tool that presents to the students items based on their proficiency level, taking into account the theory explained before.

A. General Description

As was mentioned before, .IRTT was thought as a tool to support teachers in the difficult task to deliver adaptive test to students. In this order of ideas, the role of the teacher is, actually, control the definition of assessment process. In particular Teacher: 1) provide to system an initial sample of items for the item difficulty definition; 3) define the parameters for the initial sample and 3) provide new items and its initial parameters. Teacher also provides and initial level of competences of her ser of students.

The students are the object of assessment. They login into dotLRN learning management system to present the adaptive test. They are interested in verify their performance in the system and the system offers they the possibility to follow their advances through an open learner model.

Figure 1, shows a general vision of IRTT.

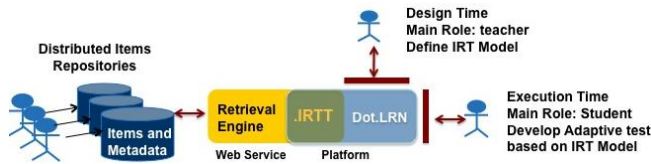

Figure 1 General Framework of IRT in adaptive assessments

IRT consists in two important components. The first component .IRR Retrieval Engine offer a web service client to connect with some based web service items repositories and also an intelligent mechanism to select the most suitable items according to the student model. The second component .IRT package upon .LRN integrates in the learning platform, the necessities users interfaces to support the teachers and student actions.

At the execution time, when a student request for a particular test, .IRT package verify the achieved and desired level of competence of this particular student and then, recovery system of items, select the most adequate repository of items (according with the available number of items) and look there an appropriate item and returns it to the interface of the student to begin your test.

According to her response, IRT infer the new competence level of student and taking into account the desired competence level and the finalization criteria will consider for delivering a new item. This process is repeated until the application decides to terminate the test.

Teachers could define how many times the student could present the test and the finalization criteria.

While items are stored in a Distributed Repositories its necessary a traffic analysis in order to optimize the process of selection the most suitable items. This process includes the study of the busiest times and the number of service requests, it means the number of users attempting to access the system simultaneously.

B. First Parameter estimation

As was mentioned in the first section the .IRT model assumes the relation between item performance and the student competence is given by a logistic function described by one-, two-, or three parameters.

In order to define the estimation of the, a student sample and a sample of the items were defined.

The test scenario was created in the context of an object-oriented programming course, where the students resolved a test in a traditional manner. In this way the Difficulty (b), considering an average value of the results of all students to an item.

Considering the experience of different teachers we asked, Discrimination parameter (a) was defined depending of the type of question:

| Classification of item | Value |
|------------------------|-------|
| Definition Questions | 0,2 |
| Intermediate Questions | 1,2 |
| Application Questions | 2 |

Table 1 Discrimination

Finally and taking into account [2] Guess (c) was defined. c was based on the number of alternatives available to the question as follow:

| Classification of item | Value |
|---|-------|
| 2 alternatives | 0,50 |
| 3 alternatives considering the options yes / no | 0,33 |
| 3 alternatives | 0,33 |
| 4 alternatives | 0,25 |
| 5 alternatives | 0,20 |
| 6 alternatives | 0,16 |

Table 2 Guessing parameter

C. How the items are selected and how the competence student level is update?

From the results of this initial test, we identified the probability of a correct answer to an each item in the sample, it means we generate each Item characteristic curve using the equation 01. The a, b, c parameter values correspond to the parameters of item i and the value of θ is equal to an estimated average of all responses of a particular student and then taking these results on a scale between -3 and 3.

Based on the probability value of each item for each student, he obtained a student's competence level more optimal (θ), for which use the maximum likelihood method according to (2), where u is the result of each item ($1 = \text{success}$, $0 = \text{failure}$) and $P =$ probability of success of each item (estimated above).

For selecting the next question, we used the method of maximum information in (3), where all values are defined as explained above parameters.

V. METHODOLOGY IMPLEMENTED

In order to construct .IRT we identify some necessary steps to follow:

- 1) Conduct an assessment test to a group of students as statistical sample for the b parameter inference.
- 2) Identifies a level of proficiency for each student, based on his or her correct answers.
- 3) Identifies a level of difficulty for each item.
- 4) Perform a calibration of the items from an iterative process involving the student attempted competition and the difficulty of the item.
- 5) After having the item parameters estimated, they are used to model the response pattern of an item, with the mathematical function CCI (Item Characteristic Curve).
- 6) To implement adaptive testing, initially you must select a method of estimating the level of competence (θ), which is not directly observable and must be estimated for each student from her response to items.
- 7) You should choose a method of items selection.

- 8) From her response, the system calculates a new level of competences, which takes into account to apply again the method of selection of items.
- 9) Carried out this last step until the stopping criterion implemented to establish the final competence level.

In table (3) is presented the methodologies to frame the development of this research project:

| Methodology | Description | Systems/modules |
|--|---|--|
| IRT (Item Response Theory) | Allows calibration of the data, identify the ranges of the parameters a, b and c and thus make the selection of items. | Items Recovery System |
| RUP (Rational Unified Process) | So that this project is a software development, selected the RUP development methodology. | Items Recovery System Web Service Integration |
| MEC (computerized educational materials) | Moreover, the methodology for the development of computerized educational materials (MEC) developed by Alvaro GalvisPanqueva [8], the project relates to computer material that is available to perform an online course. | Repository Development |
| METHADIS | Methodology METHADIS (Prieto, 2006), defines the activities to be performed when we implemented adaptive learning systems in the table presented below specifies the activities to be undertaken during the project. [9] | Web service to automatically generate Items. |

Table 3 Methodology

VI. DISTRIBUTED REPOSITORIES

Virtual repositories of learning objects are used to store Learning Management Objects and then be sought by different people all over the world. Some of the learning repositories are MERLOT, CARE, CLOE, these repositories are software systems that have the functionality to store educational resources and their metadata, a search interface, either manually or automatically [10].

In this project it was used geographically distributed repositories of items and IRT provided the steps to select the appropriate item to be presented to the student.

CONCLUSIONS

In this paper we deal with the problem to relieve teachers' design work when they have to create adaptive test in the context of a virtual learning environment using 3 parameter model of item response theory as a strong and highly utilized tool for adaptive testing.

At the design time, teachers need to provide only few amount of information while the system provides a transparent interface with items distributed repositories to reuse.

At the execution time, adaptive tasks are delivered to users in the context of a virtual learning environment using an .IRTT based.

Although the production of items repositories and their semantic characterization require an initial extra effort for the teachers, this effort decreases as the possibility of reutilization grows. One of main issues of our proposal is the integration task. Actually, the integration task is progressing and a layered evaluation has been defined for the validation process of the proposal. This validation includes real-time courses development with more than 500 students. Future works also are oriented to take into account other types of questions to construct more performance-oriented tests.

Abstract— This paper presents pedagogical architectures designed specially to support the process of teaching and learning of programming in engineering and computer science courses. A pedagogical architecture is a pedagogical approach and the technological resources required to implement it, i.e., it is defined in two levels: the level of educational strategy and the technological level that establishes the set of technological resources used.

The professional programmer needs to have special skills. Based on the human learning theory of Piaget and on the researches in computers in education, this paper presents the research results on the development of these skills in students of undergraduate courses in Computer Science and in Computer Engineering, during the first programming course.

This paper presents pedagogical architectures (pedagogical approaches + technological resources) specially designed to develop these skills in students and the evaluations of these architectures made by students of programming, in undergraduate courses in Computer Science and in Computer Engineering, in the second semester of 2011.

Keywords- *pedagogical architecture, problem solving, learning of computer programming, cooperative authoring, CSCL*

I. INTRODUCTION

The difficulties encountered in the teaching-learning of the initial programming disciplines are related to the development of various skills needed to program computers, which generally are not treated before students enroll in the University. Among these skills are:

- domain of a methodology for problem solving, specific, focused on the construction of the artifacts that satisfy a set of requirements;
- domain of a methodology for assessing the quality of programs produced;
- skill to solve problems cooperatively;
- using the syntax, semantics and pragmatics of a programming language;
- domains of different computational tools to support the development and evaluation of programs.

In the current pedagogical practices, the teacher presents the methods, elements of the programming language and submits lists of exercises to be solved individually or in groups. Subsequently, the lists are delivered and corrected with respect to the operation of the programs produced. In this approach there are no major concerns regarding the use of strategies to

support the development of the skills mentioned above, which implies the inadequate training of programmers.

From the context presented, were investigated pedagogical approaches and technological resources that can effectively support the teaching and learning of programming to make good programmers. So, we started to use the concept of architecture pedagogical.

A pedagogical architecture is a pedagogical approach and the technological resources required to implement it, i.e., it is defined in two levels: the level of educational strategy and the technological level that establishes the set of technological resources used.

A good programmer needs to have professional especially developed skills. Based on the human learning theory of Piaget and on the researches in computers in education, this paper presents pedagogical architectures specially designed to develop these skills in students to enhance and facilitate learning of computer programming, with the aim of graduating good computer programmers. The use of digital resources to support the teaching and learning of engineering in technology courses is defended by several authors [7,11]. Now it is necessary to emphasize the importance of using more constructivist pedagogical approaches. Therefore, in this research is used the concept of pedagogical architectures.

II. THE CONSTRUCTION OF KNOWLEDGE ACCORDING TO GENETIC EPISTEMOLOGY

To understand the learning process of the freshmen in computer courses, we use Piaget's theory on learning as a reference. According to this theory, reported by Ramozzi-Chiarottino [2], the individual undergoes a process of cognitive development which begins with the manipulation of concrete objects, includes the use of mental operations (reversible actions) applicable to the objects until you can develop the ability to formalize, allowing you to ignore unimportant details in order to generalize the characteristics of the objects, etc. Finally, the formalization allows you to construct hypotheses about the world and infer results (knowledge items) based on such assumptions. This evolution involves the discovery of the laws governing the observed world, ie, the laws needed (needs) to the organization and operation of this world. The possibilities of organization and operation of this world, ie, the "possible solutions" to a problem are inferences made from the "needs".

In the model of cognitive development proposed by Piaget [2], students (teenagers) from introduction to programming may not yet have fully developed the cognitive capacity of formalization, which could cause difficulties for the student to solve programming problems, either in analysis of errors, either in creating / proposing new programs.

The development of these formalizations can be favored by interactions and challenges posed to students. These challenges are not just to achieve a goal, or to succeed in terms of practical actions, but must reach the understanding, the reasons for things, meanings, the whys. The understanding is not limited to the here and now, she coordinates what is general (constructive generalization) and that applies to a range of situations. In this sense, the error corresponds to a gap in knowledge or failure in the hypothesis of the subject that seeks to explain some phenomenon or situation [1].

As in many situations, the student has no awareness of the means employed to achieve an end and thus can not be anticipated errors (he does not realize the errors, the errors are not observable to the subject). From the undesirable results, it initiates the resumption of his actions and he reaches back to discover the causes of this result and seek corrections.

In order to construct knowledge, an error corrected is more important than a success, since it requires the intervention of self-regulatory mechanisms that are responsible for reconstructions. These self-regulations allow individuals to achieve the ability to solve problems in a formal level [2].

The resolution of challenges can contribute more effectively to student learning, if it occurs in groups. The system of cooperative work (in teams) contributes to the development of the formalism since it encourages awareness of the student's own thinking, so he can get arguments to express it and defend it, as well as enhances learning by allowing exchanges of views on the object of learning [6]. Still on the cooperative work, Piaget [6] states that "... cooperation is essential for the development of reason. The method of teamwork seems to be based on the essential mechanisms of child psychology."

To accompany the student and understand the level of his development, we can use, as strategy, monitor him closely while he solves problems, seeking to record the process of resolution used by him [3]. This record provides the basis for a detailed analysis of the cognitive process used by the individual during the construction of the proposed solution. We are referring to Piaget's clinical method, which involves the recording, analysis and understanding of how an individual learns [3].

Piaget [5] noted that in the period of 11 or 12 years until he was 14 or 15 years, the individual, positively stimulated, develop formal thinking which allows you to "think hypothetically and deduce the consequences that are implications of the assumptions (independent of the intrinsic truth or falsity of the premises)". In some individuals who live in cognitively unfavorable contexts, the development of formal thinking can be completed only at age 20.

III. THE USE OF DIGITAL RESOURCES IN TEACHING - LEARNING OF PROGRAMMING

There is a growing amount of experience with the use of digital resources to support the teaching-learning programming. Some of these experiments use digital resources to facilitate access to educational material from initial programming disciplines (videos, manuals, texts, exercises, programs, etc.). Others report the use of digital resources (forums, FAQs, etc.) to access information that will help resolve doubts [7]. Many works investigate the influence of cooperative/collaborative work on learning [8].

There are researches that emphasize that the computer programming requires the use of problem-solving techniques [7] [9] [10]. The lack of mastery of these techniques makes it difficult to learn programming.

More recent studies propose digital resources to inform the learner about the program code built by him, ie, an automatic feedback on the program code built by the student [11], [12]. This feedback is being called, in many studies of automatic regulation [11] [13] [12].

Researches strongly supported in learning theory of Piaget, as is the case of the research reported in this article, use digital resources to socialize the programs developed by students [7]. Thus, they encourage learning through observation and comparison of several possible solutions [7] [11].

More recent research [7] [4] have sought to emphasize the importance of the pedagogical approach when using digital resources to support learning through the application of the concept of architecture pedagogical. Thus, the use of any digital resource needs to be backed by an appropriate pedagogical approach, since architecture pedagogical = pedagogical approach + technological resources.

IV. CURRENT PRACTICES IN THE PROGRAMMING DISCIPLINES

Tavares et alli [4] reported problems in current practices of pedagogical approaches used in introductory programming disciplines, where:

- The teacher presents the methods and elements of the programming language and model programs fully ready;
- Submit to class lists of exercises to be solved individually or in groups;
- The lists are delivered and corrected with respect to the operation of the program code produced.

In this approach there are no major concerns regarding the use of strategies to support the development of skills of the programmer, such as:

1. domain of a method for solving problems especially directed to the construction of artifacts satisfying a set of requirements;
2. domain of a methodology for assessing the quality of programs produced;
3. easy to solve problems cooperatively;
4. use of syntax, semantics and pragmatics of a programming language;

5. domain of different computing resources to support the development and evaluation of programs.

This implies an incomplete formation of the graduates of the discipline.

Aiming at the development of these skills, needed for the programming, in the freshmen of the undergraduate courses in computing, Tavares et al (2010) conducted a research on pedagogical architectures that can minimize these problems. The design of an overall pedagogical architecture for this purpose is presented below.

V. TEACHING-LEARNING PROCESS OF PROGRAMMING (TLPP)

From our previous experiences, we structured the TLPP with the following steps:

- 1) understanding the problem;
- 2) planning of the test of the solution;
- 3) specification of a solution;
- 4) manual testing of the solution;
- 5) encoding the solution;
- 6) automatic test of the code;
- 7) analysis of the solution;
- 8) publication of the solution to the class;
- 9) visit to the solutions of colleagues;
- 10) contributions and comments from colleagues about solutions;
- 11) reanalysis of the own solution and
- 12) construction of other possible solutions.

For each of these steps can conceive pedagogical architectures that can help the learner acquire the skills necessary to carry out activities related to the step.

VI. PEDAGOGICAL ARCHITECTURE PA1

This section details the pedagogical architecture PA1, designed to support the development of programming projects by students of a discipline of programming.

A. Principles

The pedagogical approach adopted in this initial class schedule was based on the following principles:

1. Authoring of solution: encourage students to develop solutions, reflect on the results and on the process of development of the solutions and create a custom method of building the programs;
2. Cooperation: cooperating with classmates to enhance learning and motivate students to participate more actively in the learning process;
3. Critical thinking: build many possible solutions for each proposed problem and compare them with each other and with the solutions built by other students.

B. Objectives of the PA1

We seek to build architectures to support the educational training of students to:

- solve problems - to challenge students to solve problems and reflect on the process used to resolve them, through the exploration of all possible solutions in order to build their own method to solve problems;

- assess the quality of programs produced - to motivate the student to build multiple solutions to each problem and compare these solutions in order to reflect on metrics for comparing the quality of the programs produced;

- handle errors - instigating the student to resolve the errors detected in the process of building solutions, with proactive actions that may involve individual reflections, consulting of manuals or texts, exploratory interactions with colleagues, tutors and teacher, but never with the expectation of receiving the solution of the error;

- solve problems cooperatively - to exercise cooperation in solving problems;

- know the computer model programming - developing the student theoretical and practical knowledge about computer model programming (syntax, semantics and pragmatics of programming, performance and program implementation);

- use computational tools for the development and the evaluation of programs – to create conditions for students to learn how to use a programming environment with editor, interpreter, code debugger, web spaces to access information of the discipline and of the programs produced by the student individually and by groups, web resources to interact with colleagues, tutors and teachers.

C. Indicators of learning

With respect to verification of student learning, we sought to evaluate the individual development of each student through the course, with respect to learning indicators used especially for that purpose. The learning of each student has been checked in each classroom, in each session of interaction in each laboratory practice, each exercise solved at each presentation of resolutions made by the student on each question raised. We tried to record as much information as possible through records on the web made by each student and each group of programming project. These records were made on the web by the student or group, but were visited and commented on by peers and teachers in the classroom.

Other learning checkpoints were questionnaires applied to each student, student interviews with the teacher, individual and group presentations made to socialize the problem solving and individual and group reports on the development of programs (model presented by teachers).

The teachers of the discipline elaborated, during the execution of the research project, the learning indicators used here.

Following, skills needed to program computers are presented as indicators of student learning, in addition to pedagogical activities used to increase students' skill with respect to each indicator:

1) the skill to solve problems indicates the effectiveness of the methods used by the student to solve problems. The lists of problems to be solved by the students are proposed to encourage the development of this skill;

2) the skill to handle errors is related to the effectiveness of the method used by the student to resolve errors that occur during the development of the program. As an error may have different causes (understanding the problem, test plan, the logical solution, encryption etc.), the heuristics used by the student to identify the cause of the error are related to maturity, security, independence and pro-activity of the student in developing a program. Specially designed exercises should be proposed to allow the student to develop this skill. A model of exercise that can be used is to challenge students to identify types of error that may arise during the development of the program;

3) the skill to solve problems cooperatively indicates the student's skill to work in groups, interacting with colleagues, finally, to learn and teach. The programming project developed within group allows the development of the skill to develop programs cooperatively. The report's analysis of group programming project and a personal interview between students and teachers allow the identification of how cooperation has occurred in the group;

4) the skill to use the syntax, semantics and pragmatics of a programming language is related to the student's knowledge about this language. The coding of the programs developed by students during the resolution of the proposed lists of problems, among other objectives, increases the knowledge (knowledge = information + experience) of each student of using the programming language;

5) The skill to use computational tools for development and program evaluation indicates the student practical experience in developing these programs with computational resources. This practical experience is developed during the preparation of programs to compose the lists of exercises proposed by the teachers and monitors;

6) the skill to understand problems is related to the student experience in addressing the problem properly in order to understand it correctly. This skill increases with special exercises of interpretation of problems descriptions. And it also increases when the student represents the problem in a high level language.

7) the skill to plan the test for each solution is related with the understanding that the student has of the problem domain. This skill is developed with exercises in which the student must test programs of various authors, apparently correct, but fail to deal with data from all relevant subdomains;

8) the skill to specify a solution allows the student to make the description and composition of the transformations provided in

the test plan on the input data. Exercises about description of transformations of input data on expected outcomes help develop this skill;

9) the skill to manually test the specified solution allows students to simulate the mapping done by the program between each data of the domain of the function and its image. The type of exercises to develop this skill is one that presents the specification of the program (in a high-level representation. Eg.: Mathematics, logic, English text, flowchart etc..), and the domain of the function represented in the program. So, it is asked the student what is the image set of the function and also to relate possible errors in the treatment of domain data;

10) the skill to code a solution: it is not just enough the student to know the programming language. He/she must learn to use it in order to encode the specification of each solution, ie, to represent in the appropriate programming language the same function described in the specification of each solution. The coding, in the target programming language, of functions, represented in high level language, serves to increase this skill;

11) the skill to automatically test the code allows the student to use the features of the programming environment for test codes. To exercise this skill you can ask the student to test code, previously prepared, in the programming environment used in the discipline. Optionally, it can be delivered to him data of the coded function to be used in the test. The student may be encouraged to prepare a report with the results of each test;

12) the skill to correct errors reflects the knowledge of the student to correct errors that exist in the program code. Exercises specially prepared with program code including different types of error, are recommended to enhance this skill in the student;

13) the skill to evaluate a program is important for a programmer and can be developed in the apprentice through the comparison of different programs that solve the same problem. As the student performs these comparisons, it develops criteria of comparison that will serve as criteria for evaluating programs. The skill produced to evaluate the quality of programs is related to the efficiency of the heuristics used by the student to assess the quality of programs. Exercises for the comparison of equivalent programs (representing the same function), prepared by different authors, allow the student to develop criteria for comparison and evaluation of program quality.

14) the skill to publish the solution to the classroom causes the student to appropriate technological resources for publication and presentation of programs and interaction with his/her classmates. This skill reflects on the importance of presenting the results of the solution constructed by him/her;

15) the skill to review the colleagues solutions indicates the easeness of the student visit, suggest contributions, and comments on the solutions of the colleagues. With these activities, students develop criteria for comparing the solutions developed by them and the solutions of other classmates;

16) the skill to build other possible solutions allows the student to seek alternative ways to construct solutions to each problem. This quest leads him/her to solve the problem in different ways and to a deeper understanding of the process of building program;

17) the skill to cooperate with the project group allows students to exchange ideas with partners in their group, to understand and evaluate other ways of addressing the problem and to explain, defend, and evaluate their own ideas. The students are encouraged to participate effectively in the construction of the solution prepared by the group in order to get full benefit from the opportunities that arise in this activity.

D. Pedagogical approach of the PAI

We present the following conditions created to allow the student to achieve the goals of the pedagogical architecture. We will focus on the conditions created for the implementation of pedagogical architecture AP1 designed to support programming projects in a classroom of programming, of the semester 2011/2, consisting of 16 students beginning courses in Computer Science or Engineering.

This group was organized in groups of two or three members. Each group chose a problem to which the project should develop a program that solves the problem.

Each group created a web space, shared it with the classroom, which included the description of the problem and reports on the solutions produced, according to the following model:

- 1) problem description (caption on the context of the problem and a precise identification of the passage chosen to tackle the project);
- 2) proposed solution (including data organization, the main algorithms used and how is the interaction between user and program);
- 3) evidence of correction:
 - a) explanation of the conviction that the critical parts of the program works;
 - b) planning and carrying out the tests (with which data the program has been tested? what was expected, was it obtained?)
- 4) program performance (brief consideration of the memory consumption and computational effort);
- 5) evaluation of the project by the group (managed to achieve the desired goals with the solution: What are the main difficulties? What were unable to be achieved and what were the reasons?)
- 6) source code (with comments).

The web spaces of each group were visited by classmates and received comments.

Each group has prepared a presentation of the results achieved, has published in the web, and presented it to the classroom.

The comments posted on the classroom web space and those received during the presentation were used to produce new versions of the solution constructed by the group.

Doubts could be raised in the classroom or shared with peers and teachers via digital resources.

E. Digital resources PAI

We used the following digital resources to implement the pedagogical approach described: wikis, emails, forums, chats and videos.

On the home page of the wiki of the course there is a list of programming project of the groups. The themes of the projects were proposed by the groups and approved by teachers. Each group built a wiki with: a group presentation, a description of the problem, the final solution, the peer review, the assessment made by the group on the solution, the alternatives produced by the group, the presentation (ppt) of the project made by the group and the presentation to the classroom on video.

VII. ASSESSMENT OF EDUCATIONAL ARCHITECTURE

To raise the students' opinions about the pedagogical architecture adopted, at the end of the semester (2011/2), to each student, was asked a report covering topics related to: individual work, group work, the use of technology, the learning achieved versus his expectations.

Analyzes made by the researchers on the students' responses are presented below:

1. to challenge the student to learn how to build solutions is a good way to help him/her to achieve autonomy in learning;
2. the need to present the results of the programming project for the classroom requires an additional effort to articulate the program code in order to make easier the presentation of the solution;
3. autonomously after constructing solutions to the problems posed, all students testify in favor of the pedagogical approach adopted in the discipline;
4. the majority of students reported on the importance of considering several possible solutions, in order to gain familiarity with the problem and its solutions;
5. students realized the importance of developing programming projects for learning in the class;
6. some students emphasize the importance of understanding the problem before seeking to resolve it;
7. the students testify in favor of group work, emphasizing the acquisition of much knowledge and experience, during the programming project (developed in pairs) and the skill to work together, "essential skill in today's job market."
8. group work significantly increases students' interest in solving the problem;
9. group work is a way to expedite solutions and enhance creativity and performance;
10. difficulties of group work are related to reconciliation of spaces and times to schedule meetings;
11. the student becomes more involved with activities in the classroom when he/her is called constantly to expose his/her ideas, make suggestions and raise questions during classroom;

12. there were reports of increased learning due to the procedure of making the student independently seek to solve their own doubts;

13. problem solving and collective reflections on the solutions developed by students were considered as potential factors of learning.

14. some students are motivated to continue the programming project even after completion of the semester;

15. One of the difficulties highlighted "the need to pay attention to several disciplines simultaneously, which hinders their dedication to the discipline of programming";

16. all reports considered appropriate and sufficient the digital resources used in the pedagogical architectures adopted in the discipline.

VIII. FINAL CONSIDERATIONS

This article presented the results of research on pedagogical architectures to support the teaching-learning process in initial programming disciplines.

The pedagogical architecture studied shows a constructivist pedagogical approach, emphasizing the learning to learn, the autonomy of students, the student as the author of the programs (solutions to problems), the doing as the predecessor of understanding, cooperative work, socialization of the results (programs), the search for generating several possible solutions, all of this, seeking greater awareness of problems and their solutions.

The digital resources of the pedagogical architecture allowed the proper implementation of the pedagogical approach and were well accepted by students.

The pedagogical architecture presented in this paper allowed the following gains:

a) students are involved in the choice of a problem which leads them to think of real-world problems, rather than being focused on solving problems lists;

b) there is an intellectual effort to specify, design, implement and present a problem that makes the student more familiar with the activities of a "programmer";

c) living with a significant amount of problems raised by the group enriches the experience;

d) socializing in small groups and the exchanges that they do go beyond what they may experience in conventional classes, since they are engaged in seeking information;

e) the socialization of issues through a workshop in which students present their solutions, with recordings and support for the continuation of discussions, puts them in a position of problem solvers, similar to what is expected of them when formed, rather than mere solvers of artificial problems.

We expect to have produced results that collaborate with the adoption of pedagogical practices in early programming courses, which promote greater motivation among students in learning to program machines.

Abstract— This paper describes the first-year progress of a TUES Type 2 project funded by the National Science Foundation (NSF) that supports scholarly innovation in engineering education. The project, known as the Appraisal System for Superior Engineering Education Evaluation-instrument Sharing and Scholarship (ASSESS), builds on a precursor NSF CCLI Type 1 project, the Inventory of Evaluation Tools for Engineering Education Projects. The paper reports on the process and framework for developing ASSESS as a sustainable library of superior evaluation instruments that promote scholarly innovation in engineering education. The online database supports information storage, retrieval, and input as well as expert review and user feedback. Adoption research currently being conducted will determine factors that influence broad utilization of the database. Feedback is invited from the community to produce a user-friendly website that enables engineering educators to locate and implement tools that can be used to credibly evaluate the impacts of engineering education innovations.

Keywords—evaluation, engineering education, evaluation capacity building

I. INTRODUCTION

Growth and improvement in the field of engineering education depends on effective evaluation of impacts of innovations designed to enhance student achievement. While several engineering educators utilize innovative methods of student assessment [1-3], identifying instruments and evaluation processes to determine the impact of such innovations for adoption by others is challenging.

The purpose of this paper is to document the processes used to develop an online repository of engineering education evaluation tools known as the Appraisal System for Superior Engineering Education Evaluation-instrument Sharing and Scholarship (ASSESS). ASSESS was created in response to a call from a national panel of 30 engineering education and evaluation professionals for a resource that would enable effective project evaluation and that would help build the evaluation capacity of engineering educators.

The online database supports information storage, retrieval, and input. Users can search for instruments of interest using keyword searches and selected item characteristics based on their evaluation needs (e.g., content, instrument type, technical specifications). The web interface will also support expert review and user feedback. Because the project is designed to build the evaluation capacity of engineering educators [4],

adoption research is currently underway to determine factors that influence broad utilization of the database. User needs and adoption preferences will then be used to guide the final deployment of the ASSESS system.

As the database becomes fully operational by the end of 2012, it will undergo extensive review by members of the user community. Feedback is invited from the community on the usability of the database, which will positively impact the adoption of best practices for improving student achievement and will, ultimately, advance the field of engineering education.

II. PROJECT GOALS AND OBJECTIVES

The ASSESS project is a TUES type 2 project funded by the National Science Foundation (NSF), DUE 1065486. The project builds upon previous proof-of-concept work conducted through a precursor NSF CCLI type 1 project: Inventory of Evaluation Tools for Engineering Education Projects [5]. The overall goals of the present project are to create, thoroughly test, and strategically communicate the ASSESS system to engineering educators and to encourage future adoption of ASSESS by the engineering education community.

Two sub-goals guide project development, including:

- 1) **Instrument utilization.** Enable engineering educators to locate and effectively deploy superior evaluation instruments to enhance engineering education project discoveries and successes.
- 2) **Instrument development.** Support the engineering education evaluation community in the identification and refinement of evaluation instruments with potential to become major assets to the profession.

In addition, four objectives are vital to achieving the project goals. These objectives include: (1) Developing an evaluation instrument database and user interface that support users in accessing desired instrument information and in providing feedback on instrument and system features; (2) Establishing an appraisal process that identifies, reviews, certifies, and supports refinement of superior evaluation instruments for engineering education; (3) Documenting the performance of the integrated software system and instrument appraisal process to ensure desired value added to the

engineering education and evaluation community; and, (4) Conducting communication, vetting, and adoption research of the ASSESS system needed to establish its value and to define steps essential for broad adoption by the engineering education community.

III. FIRST-YEAR ACTIVITIES

The core ASSESS project activities began with a meeting of project consultants to review and revise the project team's understandings of the requirements for an evaluation tools database that can best support the engineering education community in building its evaluation capacity. Project consultants reviewed the team's proposed set of parameters for characterizing the instrument, reviewed prototyped web interfaces for the evaluation instrument database, provided exemplar evaluation instruments and critiques of instrument characterizations, and suggested additional resources to support the work. The consultants also helped refine software and database requirements.

IV. SOFTWARE DEVELOPMENT AND INSTRUMENT IDENTIFICATION

The software development process included three phases:

- 1) Needs analysis produced software specifications to guide programming
- 2) Integration and coding of database and user interface to define and demonstrate desired functionality
- 3) User testing (by project team) to test the software and associated evaluation instrument data.

Suitable evaluation instruments were defined for inclusion in the ASSESS database using a three-pronged search strategy, which included: searching peer-reviewed journal articles, using branching techniques from reference sections of papers and reports, and identifying innovative projects that may have developed and employed evaluation instruments. In addition, certain tools identified in the type 1 project, such as the Thermal and Transport Concept Inventory, were incorporated into the ASSESS database. Instrument quality was rated based on a team-defined appraisal process that evaluated the available psychometric evidence for each instrument as non-existent or limited, emerging, or strong.

V. STAKEHOLDER NEEDS AND ADOPTION

A variety of individuals with multiple backgrounds and perspectives is expected to utilize the ASSESS database. To better guide development of the database and interface and to get a clearer picture of prospective users, project leaders developed a survey that was administered to thirty workshop participants who attended the precursor Inventory project's national workshop. The survey was followed up by interviews with prospective users using a combined 'push' and 'pull' approach to obtain a richer data set based on user needs and to make the ASSESS system more adoptable and broadly used. More specifically, the pull questions focused on users' current approaches to gathering instruments as well as users' visions on how to better acquire information. The push questions, on the other hand, focused on feedback regarding the database.

VI. DATABASE STRUCTURE

The Engineering Work Group developed a series of prototype templates for characterizing evaluation instruments based on recommendations from the consultants and from the Measurement Work Group. Five different templates were prepared over the course of the year as trial mock-ups. Each template was reviewed and refined by the leadership team. At the end of the first project year, the template presents instrument data in the form of: summary, technical description, technical specifications, reviews, and links.

VII. NEXT STEPS

To date, the ASSESS project website prototype includes information for viewing details of different instruments and a search page for locating the instruments within the database. These functions are not only critical for the usability and adoption of the website but also drive the structure of the database.

The next steps in the development of the ASSESS online database will be to:

- Add other prototypical instruments to the database to span the types of instruments that are of interest to our customers and to exercise the full range of the database structure.
- Refine the instrument data model based on experience with more data.
- Build administrative pages to support instrument entry, review and editing functions.
- Add home page and other informative pages to guide users.
- Build a system for registering with the site, logging in and out, and managing user roles.

Work in Progress: First Year Engineering Women:

A Qualitative Investigation of Retention Factors

Jordan Hornback, Daniel Knight and Beverly Louie

University of Colorado at Boulder
Boulder, United States of America

Abstract— Many universities face disturbing trends in the retention, underrepresentation and socialization of women students in engineering. The focus of this present study is the retention of first-year women students currently enrolled in a large state college of engineering in the Rocky Mountain region. Eight hour-long focus groups were conducted consisting of four to ten first-year women in a first-year engineering design projects course. Participants were asked a structured set of questions to investigate several topics. These focus groups were video-taped and later transcribed for analysis.

Six research questions were posed for the current study:

- Do women express a loss of interest during the first year of the program?
- Is there a chilly climate for first-year women in the college?
- Do women's self-efficacy levels change during the first year of the program?
- Do academic performance levels play a role in women's retention in engineering during the first year?
- Do women have adequate support structures in the college during the first year?
- Does the structure of the academic program instill career awareness in the first year?

Implications for strategies to boost retention and an explication of the themes from the qualitative analysis will be discussed in the paper.

Keywords: Gender, Retention, First-year programs

I. BACKGROUND

Across the nation, and in our own university, disturbing trends have been observed in the retention, underrepresentation, and socialization of women in undergraduate engineering programs. Among first-year undergraduate students, women are much less likely than men to enter the field of engineering, and only 20% of the Bachelor's degrees earned in engineering are held by women. The presence of women continues to decline in the STEM work place [1]. Women are often socialized to enter other more "feminine" fields as many are often stigmatized for strong abilities in engineering and other STEM fields, causing doubts about entering a STEM field in the future [2]. Anderson-Rowland acknowledges that many women are raised to believe it is not "cool" to succeed in STEM fields,

and many women are not aware that they can help others by following an engineering career, causing them to select other career choices [3].

While the recruitment of women into colleges of engineering is increasing by about 1% per year in most universities, the retention of women is still below that of men [2]. This trend of decreased retention of women was observed at our own university. Figure 1 below illustrates the six-year graduation rate of men versus women in our college.

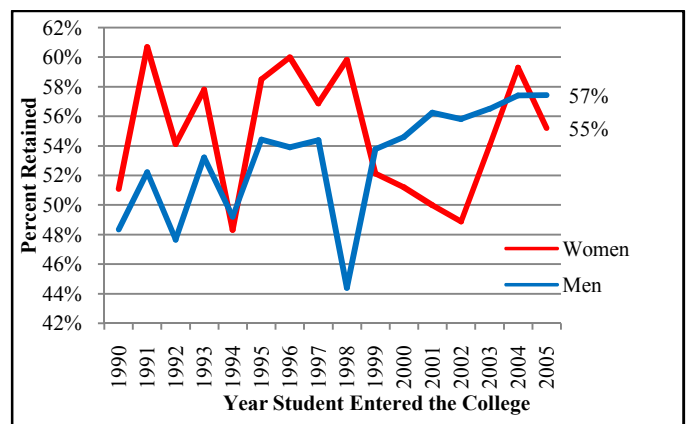

Figure 1: Six-year graduation rate of men compared to women in our college

To investigate this drop in retention, six research questions were formed for the current study:

- Do women express a loss of interest during the first year of the program?
- Is there a chilly climate for first-year women in the college?
- Do women's self-efficacy levels change during the first year of the program?
- Do academic performance levels play a role in women's retention in engineering during the first year?
- Do women have adequate support structures in the college during the first year?
- Does the structure of the academic program instill career awareness in the first year?

II. LITERATURE REVIEW

Investigation of the literature revealed self-efficacy as a significant factor in the retention of first-year engineering women [4]. According to Anderson-Rowland, self-efficacy is built through past performance, accomplishments, learning through female role models, encouragement, support, and lowered anxiety. She reports that there is a lack of information and female role models for women to build this self-efficacy causing a dramatic separation between men and women in their self-confidence. She also noted that while men blame the teacher or test for poor performance, women tend to blame their abilities, further decreasing self-efficacy [3]. Despite the pre-qualifications of women entering the college, many tend to enter with higher anxiety and lower confidence than their male peers [5]. Hutchison reported that women also tend to have lower confidence in their overall engineering skills after their first-year than male students as well and found this change in efficacy to be related to understanding of the material, students' motivation and team experiences [6].

Several other factors have been reported by the literature to affect the retention and enrollment of first-year women in the engineering program [2, 7]. Many women are discouraged by male students and faculty members who truly believe engineering is a male field, creating a chilly climate for the students. Similarly, international students can create this discouragement for women due to the presence of a patriarchal society in other countries and different rights and social roles for women [3].

Besides the presence of a chilly climate, the lack of support structures has been shown to have an effect on the retention of women in engineering. Findings by Groll reported that persistence in engineering for women in their senior year had a positive correlation with strong advisors and positive interactions with said advisors [8]. It has also been shown that women who are retained tend to take better advantage of these support groups, indicating their importance in retention [3].

III. METHOD

Eight hour-long focus groups were conducted for this study with a range of four to ten students resulting in a total of 55 participants. Participants consisted of first-year women enrolled in an engineering design projects course. Each focus group was video-taped and transcribed to ensure quotations were captured properly and no information was missed. Students were asked six questions with various probes for each question. At the end of the discussion, participants were also asked an open-ended question to see if there was anything else they wished to discuss. A detailed list of these questions and probes can be seen in the Appendix.

Analysis of the data was done using Krueger and Casey's "long table method" [9]. In this method, quotes from each focus group were coded into various themes under each

question [9]. These themes were then compared to our research questions.

IV. RESULTS AND DISCUSSION

Results will be discussed in order of the six research questions.

A. Research Question 1: Interest

In the second focus group question (see Appendix), women were asked how they defined success. One of the three major themes that arose during this discussion was enjoyment of the subject. Participants who defined success in this manner were adamant that "if you don't enjoy it and you are just trying to get by... you are not going to survive." This definition of success implies that women who are encountering a loss of interest in the curriculum may feel they are not successful in the college of engineering, and thus select a new major or college.

The fifth focus group question dealt with specific courses and professors that have had an impact on the women's decisions to stay in the college of engineering. Many students stated that the professor can greatly impact their interest in class as well as their interest in engineering. Students had positive reactions to professors who were passionate and involved in the class and felt like they retained more information. Students also felt like they had more support and were encouraged by the professor's involvement with the students. One student stated regarding her Physics professor: "He keeps me coming back to class every single day and he makes me want to like Physics... it gives you a purpose to going." These results acknowledge the importance of a professor in keeping women interested in their course material and indicate that professors of first-year courses should be engaging and able to capture the attention of students during lecture to increase the retention of women.

B. Research Question 2: Chilly Climate

The third focus group question asked women how welcoming the college of engineering has been to them as women. When asked if they had ever felt treated differently due to their gender, most students stated they did not. One woman commented "I knew going into it that it was supposedly supposed to be less girls, and you always hear how it's a male dominant field... But I can honestly say that since I've been here I have not been reminded of that... I can't think of a time where I've been reminded that I'm a minority in this specific college." However, one theme that arose indicated some women felt they were treated differently not by their professors, but by their male peers. In the engineering projects course, some of the women felt they were placed into stereotypical female roles in their teams such as developing presentations or writing reports. One woman also felt she was underestimated, saying "people ask me excessively if I understand stuff that is fairly simple, which is frustrating."

Overall, this discussion showed a generally warm climate for most women in the college. Women who reported a chilly climate were more likely to acknowledge its presence among teams. These results imply special attention needs to be placed on team experiences to ensure women are being given the same opportunities as their male teammates and enjoying their team experiences.

C. Research Question 3: Self-Efficacy

While first-year women in the engineering program may have a high self-efficacy regarding their school work, their self-efficacy for succeeding in engineering decreases when extracurricular activities are considered. Extracurricular activities emerged as a theme in the first focus group question. While all students showed a strong desire to participate in more their outside interests than they were currently, most women agreed that the engineering curriculum and work load were preventing them from joining the extracurricular activities they desired to participate in. One student stated “I am scared to do something else... they give a lot of pressure like you have tons of things to do.” However, most understood it as the “price” of being an engineer. These results imply the need for a mentor program that can assist women with balancing their outside interests with school and keep women thinking positively about their ability to succeed in engineering and still participate in extracurricular activities.

A second theme that emerged during the discussion regarding success was the understanding of concepts taught to students in class. Many women stated that they wanted to apply the knowledge gained in the college of engineering to their degrees in the future so they wouldn’t have “a degree that doesn’t mean anything.” One student commented on this definition of success, stating “if you don’t comprehend it then you don’t know what’s going on after college.” This definition of success may reflect the lower self-efficacy of women who may not feel successful if they do not fully comprehend everything they learn in class, leading to a decreased retention.

During the discussion of courses and professors, most core classes were shown to have little impact on the students’ self-efficacy and resulting desire to stay in engineering. However, one course, general chemistry, had a negative impact for a large majority of students due to the large lecture size. Many students did not feel like they were learning the necessary concepts. One woman spoke regarding chemistry, saying “you could give me a chemistry problem and I could spit it back out to you and give you the calculated answer which is all the midterms are, but I feel like I don’t necessarily understand the concepts.” This lack of understanding in such classes as chemistry could lead to a decrease in self-efficacy large enough to cause students to leave the college of engineering. These results imply women need to understand the concepts being taught in first-year classes to obtain the confidence to succeed.

D. Research Question 4: Academic Performance

A third theme that emerged during the discussion of success was academic performance. Many of the freshman women defined their success in the college of engineering by their academic performance, whether by beating the average, obtaining a high GPA, or improvement in their grades. This definition of success indicates the large stress many women place on their academic performance and the effect a lower GPA may have on the retention of women who hold themselves to high standards. Regarding her goals for academic performance, one woman stated “I want to get a 4.0, even though I probably won’t but I just want to do really well”. In other words, our women students might fail *themselves* out by holding themselves to higher GPA standards than the college. This is due to the fact that many of these high performing women view a B as unsuccessful, and in turn may select another major in which a 4.0 GPA is more obtainable.

E. Research Question 5: Support Structures

The third focus group question also explored the participation in women-supportive groups available on campus. While some of the women had attended meetings once or twice, most were not very involved in these support structures. Those who participated more actively found it beneficial and a great networking opportunity. One theme that arose was that many women did not feel these support groups were necessary, and further singled out women in the engineering field. One woman stated “I don’t need a support group as a woman, more a support group as an engineer in general.” This discussion implied that while women do need and appreciate the presence of support structures, gender-specific support structures may be further emphasizing women as the minority and reflecting the stigmatization that many women wish to avoid.

The fourth focus group question focused on the participants’ experiences with mentors both before and during college. Some students had experiences with mentors in high school through peer mentoring programs, teachers and their parents. Many students also had similar experiences in the college of engineering using advisors and mentoring programs. However, some students shared their struggle to find a mentor in college due to the large amount of students in classes or assigned to each advisor. One such student described her struggle, saying “I was trying to develop that relationship with my advisor (name deleted) but she quit I guess recently... we were both kind of left out there trying to fend for ourselves. Like who do we talk to? What do we do?” Some women also described the awkward interactions with their assigned faculty mentors, leading them to question their value. These comments brought to light the fact that some women are not receiving the support they need from their advisors and that women desire a more personal advising experience.

The concept of a new mentoring program was also discussed. Many of the women acknowledged that mentors participating in this program would need to have experience in the college of engineering and would like the mentors to have similar majors and interests. The gender of the mentor, however, was not important to the majority of the women. Many students also shared that they found the presence of a mentoring program to be important and beneficial. Some women stated that they would not find the program beneficial because they desired to be independent and solve their problems on their own. However, this discussion revealed the importance of a personalized mentoring program to many women as a support structure.

The final focus group question asked women how supportive their current living situation was to their studies. Many women lived in the honors engineering dorm, and reported it as a very supportive environment due to the various study locations, the large engineering community, and the presence of older engineering students. One resident spoke regarding the honors dorm, stating "There are always people I'm studying with and we can always find somewhere eventually to study because there are just a million classrooms there. And then if I always have questions on my homework and people I'm with aren't in the same classes as me I can walk around and find somebody." Many women living in the honors dorm desired to live there again in succeeding years. Similarly, students living in other engineering dorms found them to be very supportive due to the presence of an engineering community. However, these women felt like it was socially unacceptable to live in the dorms in succeeding years since residents were primarily freshman.

While many women found their living environment to be supportive, those who lived in non-engineering dorms found the opposite to be true due to the lack of fellow engineering students and the noise levels. One student stated "I requested to live in [a non-engineering dorm] for a healthy balance... I made the worst choice by not being in the engineering quad where it's like, not only do I not have people on my floor I can go to for help for say like a problem... but also what I'm surrounded by instead is detrimental to what I'm doing." Clearly, the engineering residence halls serve as an important support structure for first-year women, and an unsupportive environment is creating additional stress for these women.

F. Research Question 6: Career Awareness

While many of the core classes in the first-year did not seem to promote career awareness due to the technical nature of the curriculum, the introduction to engineering courses taught students how they could apply their knowledge to their future careers and gave them an opportunity to see what they could do in the future with their degrees. Participants stated these introduction courses were helpful in defining their majors and helping them decide if it was an appropriate choice for their interests. The guest speakers were said to be the most beneficial aspect of the course. The first-year engineering

design projects course was also enjoyed by all students because it opened their eyes to what they would be doing after graduation and gave them the opportunity to experience it beforehand. One woman spoke regarding the course, stating "you know if I just had calculus and chemistry I'd really be questioning, but we get a taste of what we are going to be doing, like after we learn all that stuff, and that's really encouraging." These results suggest the need for more classes that promote career awareness in the first-year to give women the desire to push through the core classes and increase retention.

V. SUMMARY

The underrepresentation, socialization and retention of women in undergraduate engineering colleges have been issues nationally [2, 7]. In a large state college of engineering in the Rocky Mountain area, the retention of women has dropped below that of men. This drop in retention was investigated through the conductance of eight hour-long focus groups with four to ten participants (n=55). Participants consisted of first-year women enrolled in a first-year engineering design project course.

Overall, the interest of first-year women was demonstrated to be greatly affected by the professors of first-year courses. Engaging professors were stated to have a positive impact on the interest of students, indicating the importance of having such professors to keep first-year women interested in the course material. Most women reported a warm climate in the college of engineering. However, women who reported a chilly climate indicated that male peers in project teams were the source, implying the need for special attention on project teams to ensure a positive environment for female members. The self-efficacy of women in the college was found to be relatively high. However, many women expressed doubts about being able to perform well in school while maintaining outside interests. These results imply the need for a mentoring program to help women understand how to balance their extracurricular activities with school work. Academic performance was demonstrated to have a large impact on how women defined their success in the college and, with the high standards women set for themselves, illustrates the potential for women to fail themselves out of the college due to personal standards higher than those imposed by the college. Support structures in the college were found to be very important to the women of the college. However, many women reported they felt uncomfortable that gender-specific support programs tended to emphasize women as the minority and singled them out. While career awareness was not instilled in most core classes, the introduction classes and first-year engineering projects course were reported to help students understand what they would be doing in the future and give them something to look forward to while taking "weed out" classes. These results indicate a need for more courses that promote career awareness in the first-year curriculum.

This study demonstrated that all six of the posed research questions can have an impact on the retention of first-year women. To further investigate these research questions, the focus group questions will be revised to further focus on the research topics, and more focus groups will be conducted.

APPENDIX

Focus Group Questions:

1. Warm-up Question (~5 min): How have you found friends so far in the college of engineering?
 - *Probe:* Do you do extra-curricular activities with your friends? If you had infinite time on your hands, what sorts of things would you do? What is preventing you from doing these things now? What about a job during school?
2. Defining "Success" Question (~10 min): What does "success" look like in engineering to you or your friends?
 - *Probe:* How do you feel about that definition of success? Do you think your definition of success is different from other people's
3. Climate Question (~10 min): How welcoming has the college and/or your department been to you as a woman?
 - *Probe:* What kinds of groups are you involved in which are supportive of you as a woman? How important is it for you to have groups which support you as a woman? Have you ever felt treated differently because you are a woman?
4. Mentor Question (~10 min): What is a mentor to you as an engineering student?
 - *Probe:* Describe mentoring experiences you have had since entering college or before college? What do you talk about with them? How did you find them (e.g. university, family, industry)? If the university were to initiate a mentorship program for women in the college, what kinds of qualities would be important to you for matching you with a mentor (is gender an important quality)? How important or not important is it for you to have a mentor?
5. Course-Specific Question (~10 min): Are there any courses or professors that are currently impacting your decision to continue in your program.
 - *Probe:* What aspects of the course or professor were most impactful? What about the intro to engineering courses, (GEEN 1400, Departmental intro courses, math, science, computing)? In particular, what are your opinions about the Calculus courses? What about the women's manufacturing/skills workshop? Discuss any impact of your courses on the development of your knowledge of the engineering profession?
6. Supportive Housing Question: Tell us about your current housing situation.
 - *Probe:* How would you compare yourself to your roommates? Where, in terms of location, do you like doing your school work?
7. Open-Ended Question (~10 min): Is there anything we did not cover that would you like to talk about?

definitions in the college? What do you think success looks like for students in other fields or colleges?

Perceptions of Engineering Identity: Diversity and EWB-USA

Kaitlin Litchfield, Amy Javernick-Will

University of Colorado at Boulder, Department of Civil, Environmental and Architectural Engineering
Kaitlin.Litchfield@colorado.edu, Amy.Javernick@colorado.edu

Abstract - Currently, the engineering community faces shortages. These shortages can be conceptualized as both literal shortages of numbers, particularly females, and a more conceptual shortage of engineers who are trained and qualified to handle the transitioning global context of the profession. With its rapid growth, high female involvement, and global vision, Engineers Without Borders-USA (EWB-USA) stands as a prime research model for the larger engineering field. During a series of five regional EWB-USA workshops, participants were asked to respond to six open-ended questions dealing with identity and gains from their involvement. Thousands of unique responses were coded into emergent themes to identify the most common responses and to compare response themes across questions. Results suggest that EWB-USA members identify strongly with the organization, which may increase their identity with and motivation to remain in the profession. Results also show that EWB-USA members are filling significant education gaps from their organizational involvement and are gaining the desirable global engineering qualities required within the field. These results help unpack the motivations driving EWB-USA members and gains from their membership that may help, through future curriculum development, attract and retain a diverse engineering population able to handle future challenges required by the profession.

Keywords: *Engineering Identity, Motivations, EWB-USA*

I. INTRODUCTION

Today, the engineering field faces significant challenges. Recognizable shortages of young professionals have been reported by the National Academy of Engineers [1] and female engineers are drastically underrepresented in both universities and the workplace [2]. Current numbers state that 20% of the engineers in the university and 11% of the engineers in the workplace are female [3]. To combat this shortage against the rising demand for engineers, recruitment and retention efforts are prevalent topics in engineering practice and research.

In addition to the shortage of engineers, the engineering profession must also confront demands for new skills and attributes of future engineers. In particular, NAE identified a need for globally aware and prepared engineers ready to navigate the world of 2020; the identified qualities of these future engineers are often not taught inside the typical engineering curriculum [4]. Engineers are now being asked to obtain these attributes while the universities and workplaces adapt their educational goals.

In the midst of these challenges, the engineering organization Engineers Without Borders-USA (EWB-USA) has witnessed rapid membership growth since its origin ten years ago. It currently has over 12,000 members, which includes both student and professional membership. These members have worked on over 350 community-driven engineering projects in over 45 developing countries [5]. Additionally, this organization reports that roughly 40% of its members are female, which provides a much more gender-balanced ratio than the typical engineering setting [6]. Due to the success of EWB-USA, this research aims to unpack its success to better understand the motivations attracting its volunteers to join and remain in the organization. With its rapid growth, high female involvement, and mission of global service projects, EWB-USA may serve as an ideal model for the challenges facing the larger engineering profession.

II. LITERATURE REVIEW

Current literature regarding the shortage of engineers, particularly female engineers, offers many factors impacting retention. Social cognitive theory proposes that behavioral, cognitive, and environmental factors simultaneously influence an individual's actions [7,8]. In applying this theory to vocations, social cognitive career theory suggests that expected outcomes and self-efficacy, or the belief in one's own ability, are the foundations for professional interests and goals [9,10]. Because of its extensive application to education and career choice, this theory provides the framework used for this research. Examining the interests, identities, goals and motivations of EWB-USA members, can help us determine the expected outcomes and self-efficacy these members hold. Appreciating all four key theoretical components for EWB-USA involvement will aid our understanding of the organization as a model for recruitment and retention. Although the literature assessing involvement in professional organizations is scarce, one study found that undergraduate women involved in professional organizations (such as ASME, IEEE, ASCE, SWE etc.) had higher academic achievement and commitment to engineering when compared to women without professional organization involvement [11]. To further unpack these trends using the lens of social cognitive theory, this phase of the research focuses primarily on the identity and motivations of EWB-USA members as retention factors.

A. Identity

Work by Matusovich et al. shows that aligning engineering with one's sense of self is an important factor for persistence in the field [12]. Additional research confirms that a sense of inclusion and finding "people like me" assists female engineers in identifying with and persisting in STEM disciplines [13,14]. Formal and informal mentoring serves as a way for female engineers to find role-models to identify with and learn from; however, with limited resources of similar mentors, female retention may be hindered [15,16,17]. Other research shows that most engineers are assumed to be Caucasian men [18], which restricts the identity of the overall engineering profession. In contrast, EWB-USA may provide supportive career scaffolding in transition from university to workplace because of its formal and informal mentoring opportunities, which may lead to an improved and diversified engineering identity and may encourage female retention.

B. Motivations

Motivation is another important factor for retaining engineers. In a survey of over 3,600 individuals, students reported that "making a difference" was a significant motivation for joining the profession [1]. Seymour and Hewitt (1997) found similar results in their study of gendered STEM data. They found that over 90% of students reporting altruism as a reason for majoring in a STEM field were female [19]. The mission and vision of EWB-USA aligns with these findings: "*Our passion is to make a difference*" [5]. If EWB-USA helps its members connect engineering and their motivations, including a place where they can help others to feel their altruistic intentions, the organization may help retain both male and female engineers in the profession.

Understanding motivations may also help give insight to areas in which educational gaps can be filled. A diversified engineering profession may be achievable by attraction to both male and female motivations. Some research suggests that men prefer to work with things while women prefer to work with people [20]. As Schreuders et al. conclude in their study of women in engineering, "An emphasis should be placed on the direct human benefits of engineering practice..." (p. 16). If engineering curriculum can be transitioned to include more humanitarian or societal emphasis, which is naturally present in the field, female retention may improve. With the natural humanitarian component of EWB-USA projects, this educational gap, along with other recognizable gaps, may be fulfilled through organizational involvement.

The current research aims to build on these two retention factors, identity and motivations, to unpack the success of EWB-USA. This research is part of the first phase of a three-year, multi-method NSF funded project that seeks to understand why the organization enjoys a balanced gender membership. Answering this larger question requires that the research question is broken into smaller, more manageable, and, as a result, more thorough parts. At this initial phase of research, the questions of interest ask how involvement with

EWB-USA affects a sense of identity, and how participation in EWB-USA supports, sustains, or diminishes motivation to enter and stay in engineering.

III. RESEARCH METHOD

This research aims to unpack the success of the EWB-USA organization by using a multi-method approach. This larger approach begins with a qualitative portion of open-ended responses, focus groups and interviews followed by a quantitative questionnaire. At this phase of the project, the initial qualitative portion is underway. Eventually, quantitative surveys will be delivered to memberships of a number of engineering organizations, including EWB-USA, the American Society of Civil Engineers (ASCE), the American Society of Mechanical Engineers (ASME), and the Society of Women Engineers (SWE). For this paper, we report results from one phase of the qualitative portion of the research. We refer to this phase as the "Sticky" notes.

During the fall of 2011, seven regional EWB-USA workshops were held for student and professional members across the country. In total these conferences brought together 1,005 engaged EWB-USA members, which represented 8.4% of the organization's total reported membership. At each of these workshops, members were asked to answer six open-ended response questions. These questions were delivered via a sheet of paper that contained 6 blank colorful boxes that resembled "Post-its"® with demographic data, including gender, professional status, professional training, organizational membership, and year of birth at the bottom of the paper. During the workshop, the workshop facilitator asked willing participants to answer a question in a colored box, rotating through the questions during the talk. Five of the conferences asked the same six questions and have been analyzed together, while the other two conferences asked unique questions that will be used in future research. The five conferences with identical questions will be analyzed for this research, resulting in 505 respondents.

The six questions for this phase of research asked:

1. How do you describe yourself?
2. How do you describe a typical engineer?
3. How do you describe a typical EWB-USA member?
4. What do you think an engineer needs to know?
5. What, if any, are the gaps in your engineering education?
6. What are your biggest gains from your experience with EWB-USA?

These six questions were chosen to gain preliminary insight into the identity and motivations of EWB-USA members. The first three questions aim to answer identity questions while the last three intend to unpack the motivations driving EWB-USA members. Instead of asking for motivations outright, these three questions looked at the gains experienced by members from their involvement and whether

or not those gains were beneficial for their expected outcomes of being an engineer (i.e. needed for engineering or to fill an educational gap). In order to distinguish these questions from explicit motivations questions posed during interviews and focus groups, these were deemed ‘*awareness*’ questions as they referred to the respondents’ awareness of their engineering needs, educational gaps, and EWB-USA gains.

Collecting such large quantities of data allowed for greater breadth of data than interviews, and the open-ended format permitted unrestricted responses. Because of the nature of open-ended questions, participants had freedom to write any format of response, which generated a range of response types including paragraphs, sentences, and bullet points. This format often led to multiple unique answers per question per person and gave a total of 7,661 unique responses to analyze. Each response was transcribed and imported into the program QSR NVivo. This software package allows researchers to manage and analyze qualitative data by grouping responses into emergent themes and comparing and contrasting trends.

Throughout the process of coding responses, we kept a descriptive coding dictionary for each emergent theme in order to maintain consistency between responses and between periods of analysis. For example, the word *motivated* was a common descriptor of self and therefore became its own theme. In the dictionary, this theme also included words such as *driven*, *focused*, *hardworking*, etc. The dictionary was shared with the research team to check for validity and to ensure inter-coder reliability. Responses to each of the six questions were initially coded separately for their unique trends, and once patterns were found, themes between questions were aligned to allow for cross-question comparisons. In general, themes for questions one, two, and three—the identity questions—were matched, while themes for questions four, five, and six—the awareness questions—were matched. Each question primarily generated responses in the main, matched themes; however, each question also generated a few unique themed responses. Once the themes and definitions were established, the relative frequencies of each response were compared and analyzed.

IV. RESULTS

Responses to open-ended questions were analyzed from the following five regional EWB-USA conferences: Great Lakes (n=118), Midwest (n=71), Mountain (n=62), Northeast (n=188), and Southeast (n=66). These 505 responses represented 68% of total conference attendance. For those respondents who reported their gender, 41.5% were female and 53.3% were male. These statistics follow the gender-balanced trend that EWB-USA claims. Additional demographics showed that 74.4% of respondents reported being student members, while 16.2% reported being professional members.

Analyses of the coding results were based upon relative frequencies of responses to the open-ended questions. We calculated relative frequencies based on the number of responses coded to a theme in comparison to the total number of responses for each question. This allowed us to compare the relative frequency of unique themes for each question and the relative frequency of equivalent themes between questions.

Because the questions were open-ended, many unique themes emerged, which resulted in themes with relative frequencies under roughly 25%. In order to reduce the results to a manageable amount, only the top twenty themes for each set of questions are reported and compared. For all six questions, the top twenty themes hold at least 80% of the responses. A category labeled *other* collected themes with low relative frequencies or unique responses for each question. The *other* category differed by question but generally contained between five and ten unique or smaller frequency themes. For instance, the *other* category in the identity questions includes themes such as *traveler* and *nature lover*, while the awareness questions included *humility* and *professional development* in the *other* category.

A. Identity

Results for the relative frequencies of responses to the first three questions of the study are shown in Table 1, which lists the themes ranked in descending order based on responses to question 1, the description of self. The top five most common descriptors of self were *motivated*, *humanitarian*, *passionate*, *creative*, and *goal-oriented*. These top results are highlighted in Table 1 in bold along with the top five results for the other two questions. *Motivated* is the only theme that appeared in the top five categories for all three descriptive questions, while four of the five top responses between the descriptions of self and the descriptions of the typical EWB-USA member matched.

Table 1 holds two dominant responses: an EWB-USA member is typically *humanitarian* (19.2%) and an engineer is typically *analytical* (24.2%). The table also indicates that there was not one single dominant trait for the descriptions of self—where the relative frequency was significantly higher than the other two questions. Interestingly, for twelve of the top twenty themes, the relative frequencies of the response themes for describing self are in-between those of the engineer and an EWB-USA member. These results suggest an emerging trend that EWB members often identify themselves as someone with combined traits of an engineer and an EWB-USA member.

This trend was also noted in reading responses to all three identity questions from individual participants. For example, one participant described herself as, “*analytical, driven to serve others and make a difference.*” She then described a typical engineer as, “*educated, problem solvers, strategic, analytical, innovative,*” and a typical EWB-USA member as, “*wants to make a difference, thinks of others, wants to use own knowledge to help others.*” This response is illustrative of

TABLE I. IDENTITY RESULTS

| Relative Frequencies of Response Themes (%) Ranked by <i>Self</i> | | | |
|---|-------------|-----------------|----------------|
| | <i>Self</i> | <i>Engineer</i> | <i>EWB-USA</i> |
| Motivated | 15.4 | 9.6 | 13.8 |
| Humanitarian | 12.3 | 3 | 24.2 |
| Passionate | 6.2 | 1.3 | 9.4 |
| Creative | 5.8 | 9.1 | 4.2 |
| Goal-oriented | 5.7 | 4.7 | 4.3 |
| Analytical | 5.3 | 19.2 | 1.6 |
| Curious | 5.2 | 3.1 | 2.7 |
| Outgoing | 5 | 0.3 | 3.5 |
| Smart | 4.6 | 10.8 | 3.7 |
| Organized | 3.3 | 4.1 | 1 |
| Adventurous | 3.1 | 1 | 2.6 |
| Global Perspective | 2.4 | 1.3 | 8.3 |
| Problem Solver | 2.2 | 8.7 | 1.1 |
| Respectable | 2.2 | 1.1 | 1.5 |
| Well-rounded | 2 | 0.5 | 2.5 |
| Confident | 1.9 | 1.3 | 2.2 |
| Optimistic | 1.9 | 0.1 | 1.4 |
| Narrow | 1.5 | 9.5 | 0.8 |
| Introvert | 1 | 3.3 | 0.1 |
| Adaptable | 0.9 | 0.6 | 0.5 |
| Other | 12.1 | 7.5 | 10.6 |
| n | 1467 | 1431 | 1550 |

typical responses where the participant's description of self consists of traits included in her descriptions of both the engineer and the EWB-USA member. Looking at the results in this way—based on the individual—further supported the results based upon relative frequency alone, suggesting the individual often identifies as both an engineer and an EWB-USA member.

Additional results from the identity questions showed that three quarters of the top themes for the descriptors of self are found in frequencies closer to the EWB-USA member than to the engineer. Although members often describe themselves with traits of an engineer and an EWB-USA member, the descriptive responses for self tended to lean closer to the identity of an EWB-USA member than that of an engineer. This further suggests that EWB-USA members commonly identify with this engineering organization. Since the literature states that better aligning personal identity and engineering increases retention, the data provides strong

evidence to the claim that EWB-USA is supporting its members to persist in the engineering field.

B. Awareness

Results for the relative response frequencies of the last three questions of the study are shown in Table 2 and are ranked in descending order based on responses for question 4, what an engineer needs to know. The top five most common themes identified included *technical skills*, *interpersonal skills*, *problem solving*, *societal awareness*, and *awareness of engineering impact*. These top results are highlighted in Table 2 in bold along with the top five results for the remaining two questions. None of the top five themes match across the three questions; however, three of the top five themes match across the responses for gaps in education and gains from EWB-USA.

Two prominent responses are seen in Table 2: an engineer needs to know *technical skills* (25.2%), and a major gap in engineering education is *experience and application* (25.9%). As with the dominant identity responses, these results are somewhat natural or expected, although in this case the extreme response rate to *experience and application* as an education gap is noteworthy.

Six of the top twenty response themes reported for these questions are responses limited to one question. These responses were given with high enough frequency to merit consideration. *Problem identification* and *ability to learn* were highlighted as unique responses for question 4, what an engineer needs to know, and *personal awareness*, *sense of fulfillment*, *confidence*, and *enjoyment* were frequent response themes for question 6, gains from EWB-USA. These last four unique responses to question six illustrate that EWB-USA members are gaining much more than standard curriculum from their membership. For example, two members wrote about their personal gain from their involvement that, “*It has helped me define what I want in my career*,” and “*I learned where I fit, and figured out why I get out of bed every morning*.” Clearly some of these personal gains are very significant and impact motivations.

The most interesting response themes for the awareness questions were those where the trait or skill was needed for an engineer. Some responses may be interesting, such as finding *relationships* as a top gain from EWB-USA involvement; however, without a present engineering need for this theme or additional knowledge of how this leads to a specific gain, the gain might not have much application. The themes that we focus on here are those with an existing need, a present education gap, and a comparable gain from EWB-USA involvement. Several themes fall into this pattern, specifically *global perspective*, *project management*, *teamwork*, *experience and application*, and *humanitarian emphasis*. Based on the recognized need, tangible gap, and significant EWB-USA gain, these five themes stand out as significant progress made by the organization. If students and professionals are aware of their needs and their knowledge

TABLE II. AWARENESS RESULTS

| Relative Frequencies of Response Themes (%) Ranked by <i>Gains</i> | | | |
|--|--------------|-------------|--------------|
| | <i>Needs</i> | <i>Gaps</i> | <i>Gains</i> |
| Technical Skills | 25.2 | 4.4 | 3.3 |

* limited to Question 4; ** limited to Question 6

gaps, and then are able to fill them through involvement with EWB-USA, the organization is benefitting the profession.

Additionally, based on the agreed upon theme definitions, EWB-USA members report *global perspective* as their highest gain from EWB-USA involvement. These members also report *global perspective* at the third largest gap in their education. Because this theme is among the top responses, the results suggest that the organization is having a strong impact on the global awareness of its members. EWB-USA is creating more globally aware engineers and extending the typical engineering skill set further than the traditional curriculum.

In its report *The Engineer of 2020*, the National Academy of Engineers highlights nine unique attributes that the engineer of 2020 should have: strong analytical skills, practical ingenuity, creativity, good communication, business and

management skills, leadership, high ethical standards or professionalism, resiliency and flexibility, and a desire for lifelong learning [1]. Based on this research, EWB-USA members are explicitly gaining at least seven of these attributes from their experience with the organization. *Technical skills, problem solving, creativity, interpersonal skills, project management* (which includes *leadership*), and *humanitarian focus* are comparable emergent themes that EWB-USA members report to be gaining and match with the engineer of 2020 attributes. With these seven gained attributes and the additional gains of *global awareness, personal awareness, teamwork, and experience and application*, EWB-USA members are becoming well-equipped current and future engineers.

With such significant gains experienced by the members of EWB-USA, the larger engineering profession can benefit by applying the EWB-USA model in the classroom. As Schreuders et al. suggest, educational institutions can help engineering retention by incorporating more of the motivational factors driving diverse engineers, such as making a difference [20]. With EWB-USA reporting a population with atypical engineering demographics, the top gains found in this research would be valuable to incorporate into engineering curriculum as they may lead to similar trends found within the EWB-USA membership: fast growth, diversified population, and increased global awareness.

V. CONCLUSION

Based on these initial results, EWB-USA members identify themselves with characteristics consistent with their descriptions of both other engineers and other EWB-USA members, suggesting that their identity is complete through the combination. As the literature states, identity as an engineer and with the engineering profession is a key factor in recruitment and retention of engineers. As EWB-USA members are identifying strongly with this engineering organization, their identity alignment to the profession are likely increasing, which other research would suggest improves their likelihood of persisting in engineering. Results also show that these members gain valuable engineering and personal attributes desirable for the engineer of 2020. Further research will help us determine if these gains are the underlying motivations of organizational involvement; however, if these gains are allowing EWB-USA members to connect engineering to their motivations, literature says that the desire to remain in engineering should increase. Based on the literature and these two primary findings, EWB-USA appears to have significant impact on engineering retention.

Some limitations of this study stem from the data collection methods. With such large amounts of data collected from volunteers, the depths of responses were significantly limited and gave primarily only a few words for each response. This limits understanding the identities and motivations of EWB-USA members to phrases rather than richer, deeper explanations. The research team is expanding these findings

through interviews and focus groups, with students and professionals to gain richer insight to the organization. This depth of data will also allow us to better understand how a member's level of EWB-USA involvement changes their responses. Another limitation of the data collection method was that the data was gathered at EWB-USA conferences, which limited the respondent population to only EWB-USA members. Ideally, equivalent amounts of data could be collected from engineers not involved with EWB-USA for comparisons. As part of the future focus groups and interviews, engineers not involved with EWB-USA will be included. Comparative analysis between members and non-members will allow us to better determine differences between identities, motivations and gains. After we feel theoretical saturation has been reached, a survey is planned for the memberships of EWB-USA, ASCE, ASME, AGC, and SWE to validate the findings across multiple students and professionals and compare EWB-USA with other professional organizations. These future steps will continue to support the aim of the research to understand why EWB-USA is enjoying gender-balanced ratios and determine how these results can be extended to engineering curriculum and workplaces to recruit and retain a larger, more diverse, and more globally prepared engineering population.

ACKNOWLEDGMENT

We gratefully acknowledge EWB-USA Executive Director, Cathy Leslie, for her input and assistance with data collection. Additionally, we extend our gratitude to Jessica Kaminsky for her preliminary work on this project and to Casey Casias for transcribing the responses to excel spreadsheets.

Work in Progress: Understanding the Experiences of Women of Color in Engineering

Renata Revelo Alonso
University of Illinois at Urbana-Champaign
revelo@illinois.edu

Abstract— This qualitative study aims to understand the experiences of undergraduate women of color in engineering; specifically how their gender, race, and ethnicity shape their construct of an engineering identity. For many of the students, engineering identity was only understood along with gender and race/ethnic identities.

Keywords—identity, women of color, diversity

I. INTRODUCTION

In 2008, the percentage of women who graduated with an engineering bachelor's degree in the United States was 18.5% [1]. In other traditionally male-dominated fields such as business the percentage of women awarded degrees in 2006 was 49.2% nationwide [2]. In a population where the percentage of women is 50.7% [3], gender disparity in engineering is intolerable. These disparities are similar, if not worse, for women from racial and ethnic minorities in engineering.

In a changing U.S. population, it is critical to understand the experiences of women of color in science, technology, engineering, and mathematics fields in order to improve the campus climate and curriculum in higher education. This study builds on previous literature about undergraduate student identity development by looking at women of color and their engineering identities. As [4] suggests, studies of women in engineering through a feminist theory lens can be enriched by the parallel studies of identity formation. In previous literature, researchers have studied professional engineering identity [5,6] science identity [7], student social and academic engineering identity [8,9] and engineering identity of students working in a research environment [10]. As emphasized in [11], there is a great need to expand on qualitative studies of underrepresented people in the field of engineering. The focus of this study is on the intersection of racial, ethnic, gender identities and engineering identity.

II. RESEARCH METHODS

The research questions posed in this study were (a) How do the race or ethnic identities, gender identity, and engineering identity play a role in the experiences of undergraduate female students studying engineering? (b) How does engineering identity intersect with other identities, specifically racial, ethnic, or gender identity?

After receiving Institutional Review Board approval, I conducted 35-50 minute, semi-structured interviews with nine undergraduate female students at a large, public, predominantly white university. All of the participants were majoring in an engineering field and self-described as African-American, Black, Hispanic, or Latina. The students were recruited via a mass mailing list and through snowball-sampling. The interviews were audio recorded, transcribed, and coded using induction [12] and iterative methods [13].

After several iterations of data analysis, the themes presented below were constructed. Next, specific occurrences of identity understanding and/or construction as it related to the model of multiple identities presented by Abes et al. [14] were coded. Finally, occurrences of "engineering identity" – that is anything related to how students understood themselves as engineers were also coded across all interviews. All of the names presented are pseudonyms.

III. PRELIMINARY FINDINGS

Using the research questions as guides, the following three prevalent themes were found.

A. Being Recognized as an Engineer

The idea of being recognized in a positive way as an engineer was a key element in the students' experiences on campus. The students discussed instances of recognition from staff, faculty, family, and friends. Ana described the warm welcome from staff in her department as a positive experience that reinforced her goal of attaining the engineering degree.

I remember going to the head of the department for funding for a [National Conference], and we got into the topic...[The staff said] "Hey you should come around more often, we do recruiting, we would love to see more female Hispanics here." They're very excited about having females in [Engineering Major] especially Hispanics because I think I'm the only one. I like it. They embrace it and I appreciate the way that they treat me in the department. (Ana, 3rd year)

B. Feeling like a "Minority"

Even though the word minority was not used in any of the communication with the participants, it was voiced by all of

the students in different ways. Some discussed the idea of being the only one, with respect to their gender or race/ethnicity on campus, others discussed seeing more opportunities because they are a minority, and experiencing stereotypes.

Kiara talked about seeing more opportunities because of her race and gender. Her representative quotation below illuminates the idea of how being a minority had positive and negative consequences.

I've been getting a lot of opportunities just because of my gender and race. I get the double shot. It's like they're both working against me and for me at the same time, so it kind of breaks even... I was discussing with the [administrative staff] about reapplying, he's like Kiara, you have three things going for you right now...you're Black, you're female, and you're transferring from out of state. Use it, use it, use it! That really broke my heart. (Kiara, 2nd year)

C. Perceptions

The students discussed situations where others' perceptions of them as engineers mattered or had a role in their experiences. In a lot of ways, "perceptions" is opposite to positive recognition – when talking about perceptions students referred to negative experiences they encountered at the university. Jessica shares her encounter with fellow engineering students in the beginning of the semester when student organizations set up booths to recruit other students. This story was in response to my question about what kind of a role her ethnicity plays in her experiences as an engineering student.

I got completely ignored by engineering societies I walked up to them and asked a question and they said "hmmm, this is for engineering students" and I looked at them and said "I'm an [Engineering Major]" (Jessica, 3rd year)

Ana shares a similar story with regards to how she might be treated in the classroom, a story I have heard from other women I interviewed as well.

You see it in your classes, when you ask a question and [male classmates] kind of role their eyes like "How could you not know that? It's probably because she's a girl" Or when I'm trying to explain something and they don't listen. (Ana, 3rd year)

IV. CONCLUSIONS

For many of the students, engineering identity was only understood along with gender and race/ethnic identities. In other words, students' identity as a woman of color was crucial to their construct of an engineering identity.

Participants' engineering identity was understood through

contextual influences in the student's lives such as family and climate. Abes, Jones, and McEwen's [14] dynamic and fluid model of multiple identities helps illuminate the experiences of women of color in engineering. Contextual instances play a major role in understanding the experiences the women talked about especially with regards to gender and race/ethnicity. The next step in this study is to conduct follow up interviews with the nine students. The follow up interviews will focus more transparently on a discussion of engineering identity.

ACKNOWLEDGMENT

Thank you to Professors Lorenzo Baber, Timothy Cain, and Michael C. Loui and their continuous advice in the development of this project. Their support and guidance have been instrumental.

Critical Questions of Engineering Students by Gender and Ethnicity

Dr. Armando A. Rodriguez
Dr. Mary R. Anderson-Rowland
Arizona State University
aar@asu.edu/mary.anderson@asu.edu

Abstract— Engineering and computer science careers are not well known to the general public. Most students studying these majors also have limited knowledge and information about their chosen area of study. In working with students over many years, the authors have experienced many questions from these students. As part of the evaluations for Academic Success Meetings, the students have been encouraged to ask questions about areas that they need to know more about. The questions tend to repeat themselves and fall into general categories. Not all students have mentors to answer these questions. Starting with the most important, the answers to all of these questions will go on a website that has been developed especially for transfer students under a National Science Foundation Step Award # 0836050.

An initial 136 questions were presented to over 100 students. The students were asked to choose the 20 most critical questions to them. From this data, in an earlier paper, the top five questions were determined for students over 21 and the top five for students 21 and under, as well as by academic level.

In this paper the similarities and differences in these critical questions by gender and by race/ethnicity are considered. The males and females in this study had two questions in common for their top five: “Why should I consider getting a PhD degree in engineering?” and “How do I choose a job?” The three race/Ethnicity groups of White, Hispanic/Latino, and Other/Unknown had only one question in common: “Will there be a job for me when I graduate?” Each of the three two-pair combinations had one question in common. The differences in critical questions by gender and ethnicity will also be discussed.

The information determined here will help educators and advisors encourage potential and actual students in engineering and computer science. With this information they can focus their message by honing in on the critical questions of their particular audience. These questions and their answers can also be used for intentional advising.

Keywords— *critical engineering questions; ethnicity, gender, intentional advising, recruitment, retention, survey.*

I. INTRODUCTION

Women and minority students have always been underrepresented in engineering. Even now, after years of attention on the matter of recruitment and retention and the establishment of women in engineering and minorities in engineering programs, although the percentages are better, the

number of women and minorities are still far too low as “Engineering by the Numbers” shows in Table 1. The 17.8% for women Bachelor’s degrees is the lowest since 1995. This may mean a decrease in the percentage of women’s graduate degrees in the following years. Henceforth in this paper, the term “engineering” shall include computer science.

Table I. Degrees in Engineering and Computer Science 2009. Source: Engineering by the Numbers by Michael T. Gibbons.

| Degrees in Engineering and Computer Science 2009 | | | |
|--|-------|-----------|-------------------|
| Degree | Women | Hispanics | African-Americans |
| Bachelor’s | 17.8% | 6.6% | 4.6% |
| Master’s | 23.0% | 5.3% | 4.7% |
| Doctorate | 21.3% | 3.8% | 3.8% |

Much attention has been paid to the retention of women in engineering; however, recent studies have shown that women are retained as well as or better in engineering than men [1, 2]. The first study also concluded that engineering students are very much like other students, but more of them need to be attracted to engineering [1]. Although retention rates certainly are not ideal, with less than half of all students who begin engineering graduating in engineering, the major problem with the scarcity of women in engineering is that not enough of them begin engineering in the first place. The percentage of both women and men who expect to have their career in engineering is low (less than 12%) [3]. In addition, few students switch into engineering often because the student would need to do catch up work in mathematics. Therefore, one way to have more students switch into engineering is to have more students well-prepared in mathematics and science in high school or during the first years at a community college. A major conclusion from this research is that most young girls do not know about or learn about engineering in their early years. Cosentino de Cohen urges “School teachers – and in later years career counselors – need to encourage girls to become engineers by exposing them to engineering professions [2].” Another action urged by this study is to provide women with a better understanding of different ways to get an engineering degree. This action fits in well with our research

that shows many community college students do not know what they want to major in [4] and need someone to spark in them an understanding of and interest in engineering.

The reasons that more women do not choose engineering have been much debated. There are no easy answers, but there are several plausible theories. Eccles believes "There are two key factors women face in their decision-making process: how much they believe in the ultimate utility of mathematics and how much they value working with and for people [5]." This leads us back to the facts that if you do not take very many mathematics classes you do not realize the ultimate value of mathematics and if you know nothing about engineering, you will not know that engineering is really about working with and for people.

A second cause for few women in engineering proposed by research is that their self-efficacy, the fundamental perception of one's ability to succeed at a task or in an environment, is often low without cause. For example an internship or co-op can change the self-efficacy of students about their ability to perform well in an industry environment [2]. Women often feel that they are not "good" at math when they do just as well as the boys and often have a higher GPA and retention rate.

Not much has changed in the past 18 years. In 1975 only 3 percent of engineering graduates were women. This was increased to over 10% in the 1980s. By 1994, over 17% of engineering graduates were women; however, in 2009 the percentage of engineering degrees earned by women was 17.8%, a 15-year low [6]. So what is the answer?

Tietjin asked this question in 2004 [7]. She wondered why, after 50 years of working on this issue, it had not been solved. Her conclusion was that "If we really knew the answer, we would have solved it already." Her conclusion is that "Engineering in the United States suffers from a huge image problem [7]." Until it is "cool" for girls to like and do well in mathematics and science, we will struggle as a nation to have a good representation of women in engineering [8]. A 1998 Harris Poll revealed that most Americans do not understand what engineering is and what engineers do: "The Harris Poll survey revealed that 45 percent of Americans feel that they are 'not very well informed about engineering and engineers' while another 16 percent stated that they are 'not at all well informed about engineering and engineers.'" Among women, however, the percentages increased to 55 percent and 23 percent, respectively. While education level correlated positively to the respondents' level of informedness, the majority of college graduates (53 percent) still reported that they are "not very well informed or not at all well informed" about engineering and engineers [9].

It seems clear that young women do not know about engineering in general and what they do hear is not very inviting. Phrases such as "math is hard" are commonplace. Women often want to interact with others, to help others, to make things better: however, this is not the usual engineering message. Change was called for. In 2007, the Committee on the Public Understanding of Engineering Messages was tasked by the National Academy of Engineering to do something about this. The result was the publication, "Changing the Conversation: Messages for Improving Public Understanding

of Engineering [9]." This committee talked to people and ran studies to determine messages that could make a difference. A few of these messages are: Engineers are Creative Problem Solvers, Engineers Help Shape the Future, Engineers Make a World of Difference, Engineering is Essential to our Health, Happiness and Safety, and Because Dreams Need Doing. This new style of conversation is already having results. The National Academy of Engineering website [10] has case studies of how using these messages have increased enrollment by women and underrepresented minority students, with the University of Colorado as a prime example.

II. THE SURVEY

The authors are the PI and co-PI on four National Science Foundation (NSF) grants which are leveraged to increase the recruitment and retention of engineering students in order to produce more engineers. An emphasis of the programs is to recruit and to retain women and underrepresented minority students and also to have students go right on to graduate school full-time after receiving their Bachelor's degree. These programs have been described elsewhere [11-14]. As a part of the work the authors are doing under their National Science Foundation (NSF) STEP grant which targets five non-metropolitan community colleges (CCs), they are concerned with the conversations that they have with potential engineering transfer CC students, as well as with some 160 engineering students each semester in Academic Success Classes sponsored by three NSF S-STEM grants (# 0728695, 0807134, 1060226), and additional engineering students who use their Motivated Engineering Transfer Students (METS) Center. Since many of these students know little about engineering even if they have chosen it for their major, the authors receive many questions. Of great concern is the lack of women engineering students coming from rural CCs.

A website has been developed as part of the STEP grant activities. Included on this website are 136 common questions that students ask. The list is being expanded and answers are being added to the questions [15]; however, 136 questions are a lot of questions and the authors wanted to know which questions were the most important to the students. Knowing which questions were the most important, it would make sense to answer those questions first and to emphasize this material to the students. To determine this, the authors surveyed the students in their academic success classes with 103 respondents to select their top 20 questions. At the same time the students were asked to note the questions and to let the authors know of additional questions that should be added.

After receiving the survey results, the authors noted the top 5 questions selected by various groupings: gender, ethnicity, over 21 or 21 years of age and under, academic class standing, and others. The number of students in each category who had selected a particular question was noted. In a previous paper [11] the authors reported and analyzed the results for the students divided by age (over 21 and 21 years of age and under). The only common "top five question" between these groups was "How do I choose a job?"

The top five questions were also analyzed by academic class. Freshmen and sophomores shared two questions in their top five: "Will there be a job for me when I graduate? Will it

pay well? Will it be challenging/boring? Will it require travel?" and "How is my engineering school viewed by industry?" Juniors shared two questions with sophomores: the question on the industry view and "What is the engineering work environment like?" Juniors also shared two questions with seniors: "How do I pay for graduate school?" and "How do I choose a job?" Seniors and graduate students shared two questions: "Why should I consider getting a PhD degree in engineering?" and "How do I weigh the factors that go into choosing a job?" Interestingly, freshmen also chose this last question on weighing job factors as one of their top five.

The 13 major categories of questions, with the number in parentheses identifying how many questions were in that category, were as follows:

- BS in Engineering (5)
- Why Engineering? (8)
- Choosing an Engineering Discipline (13)
- Financing My BS in Engineering (8)
- Why Pursue a BS in Engineering at ASU? (27)
- Importance of a Mentor (6)
- Importance of Research: Figuring Out What I Want to Do (14)
- Important Skills (24)
- Importance of Graduate School (9)
- The MS Thesis (6)
- Getting a PhD (8)
- Starting a Company (6)
- Choosing a Job (2)

The survey results for gender and ethnicity are given and analyzed in the next section.

III. SURVEY RESULTS AND ANALYSIS

Seventy men and 33 women selected and ranked their top 20 questions from the Critical Engineering Questions list. The two groups had two questions in common in their top 5. The women were more united as group on their choices. The most important question for women was "Will there be a job for me when I graduate? Will it pay well? Will it be challenging/boring? Will it require traveling?" Of the 33 women, 60.6% of them chose this as one of their top 20 questions. Their fifth most popular question (selected by 42.4%) was "How do I choose a job?" On the other hand, the most popular (42.9%) question in the men's top 20 was "How do I pay for graduate school?" The men's fifth most selected question was "How is the ASU Ira A. Fulton Schools of Engineering viewed by industry?" This question was in the top 20 for 38.6% of the men. The two questions that were shared by the men and the women in the five questions most often selected were: "How do I choose a job?" and "Why should I consider getting a PhD degree in engineering? What will it offer me over an MS in engineering? Advancement opportunities? Flexibility? Responsibilities? Salary?" See Table II for the top five questions by gender.

Since these students are all in Academic Success Classes where going to graduate school is emphasized, it is not surprising that both the men and the women had questions about getting a Ph.D. Since the Ira A. Fulton Schools of Engineering has a 4 + 1 program allowing students to double-count three courses for the BSE and the MSE, many students come to the conclusion that getting a Master's degree, if at all possible, is a "no-brainer". The question that remains then is

Table II. Top Five Questions by Gender

| Gender | Category | Question | Sample Size |
|--------|--|--|-------------|
| Women | Why Engineering | Will there be a job for me when I graduate? Will it pay well? Will it be challenging or boring? Will it require traveling? | 20 (60.6%) |
| | Getting a PhD | Why should I consider getting a PhD degree in engineering? What will it offer me over an MS in engineering? Advancement opportunities? Flexibility? Responsibilities? Salary? | 16 (48.5%) |
| | Important Skills | What professional organizations should I join? What do they offer? | 15 (45.5%) |
| | Importance of Graduate School | What is a fellowship? | 14 (42.4%) |
| | Choosing a Job | How do I choose a job? | 14 (42.4%) |
| Men | Importance of Graduate School | How do I pay for graduate school? | 30 (42.9%) |
| | Choosing a Job | How do I choose a job? | 29 (41.4%) |
| | Getting a PhD | Why should I consider getting a PhD degree in engineering? What will it offer me over an MS in engineering? Advancement opportunities? Flexibility? Responsibilities? Salary? | 28 (40.0%) |
| | Choosing a Job | How should I weigh each of the following: engineering/technical responsibilities? Flexibility? Choosing what you work on? Flexible work hours? Working from home? Day Care? Work conditions? Work group dynamics? Opportunities for advancement? Location? Traveling? Benefits? Retirement plans? Bonuses? Salary? | 28 (40.0%) |
| | Why Pursue a BS in Engineering at ASU? | How is my Engineering School viewed by industry? | 27 (38.6%) |

if they should go for a PhD. For those who aspire to go into academia the answer is easy, but for those who plan to go into industry, the answer is not as transparent.

Both women and men are concerned with how to choose a job. The students are urged to do internships with different companies to see how they fit with that company. An internship experience can give the student good feedback on what type of job they want. The students are also urged to look around during an internship and to note what engineers with a Bachelor's, Master's, or PhD degree are doing. This information can then help them decide what type of work they want to do and what final degree they should obtain.

The women were concerned with being able to get a job as one of their top five questions, while the men were not. The reason for this is an area that needs more research. Related to this question, however, is the men's concern about how ASU is perceived by industry. This last topic is discussed in the Success Class, but obviously needs to be talked about further. ASU has been ranked by recruiters as the fifth best school in the nation for recruiting [16]. Since many women want to know more about fellowships, this is an area that needs to be clarified and emphasized more.

Paying for graduate school is a concern for the men. This is a topic that is often discussed in the class. The students are urged to become involved in leadership and volunteerism, and especially to participate in research. Most students do not know what research is and are quite sure that they do not want to do it. The students are told that if they can begin research as an undergraduate and find a good mentor, this research can carry into graduate school and they will be paid to go to graduate school and continue the research. Students are also told that not having money is not a good excuse for not going to graduate school. Students have proved that taking out an extra loan to get a Master's degree is a good investment both in terms of job opportunities and in terms of pay. The payback on this investment is usually only a year or two and at that point the person has a higher salary that is compounding. The authors emphasize with the students that choosing a major and a job are not commitments for life. As engineers they are being taught to solve problems and that process applies to all fields. The authors have brought in speakers from industry who have changed their job situations several times to accommodate family constraints or other interests at the time.

Since the ASU programs have an emphasis on both women and underrepresented minority students, the authors are also concerned that the needs of underrepresented minority students are being met. Typically, 60% of the scholarship students attending the Academic Success Classes are women and/or underrepresented minority students. In Arizona, the largest minority group is Hispanic/Latino. In 2010 nearly 30% (29.6%) of the population was of Hispanic or Latino origin compared with 16.3% in the nation [17]. This percentage is likely to increase given that since 2000, the Arizona population has increased 24.6%, the second highest increase in the nation [18]. At the same time, the percentages of Blacks (4.1%, USA 12.6%) and American Indians (4.6%, USA 0.9%) are very

small. The "Other" category" for this study includes Blacks, unknown, and foreign national students who are not scholarship holders, but who do attend the Success Class

Table III shows the top five question choices of the major ethnic groups at ASU. As can be seen from the table, there is one question that was common to all three groups: "Is there a job for me when I graduate? Will it pay well? Will it be challenging or boring? Will it require traveling?" This question was the most popular or tied for top spot for both the Hispanic/Latino and Other groups. It ranked fourth for the Whites. It is possible that the groups other than the Whites feel that they may have more trouble finding a job than Whites. Interestingly, each set of two groups had one question in common in their top five. Both Whites and Hispanics/Latinos are concerned with getting a PhD, with a rank of third for Whites and tied for first for Hispanics/Latinos. Again, this is good news for the authors who are encouraging the students to consider both a Master's degree and a PhD. It is possible that since some of the students in the Other group, which did not rank this question in their top five, know that they will return to their country with a BSE or MS and are not concerned with a PhD. This topic warrants further investigation. The Hispanic/Latino and Other groups shared the question, "How is my engineering school viewed by industry?" As mentioned earlier, although the authors have discussed this point in the past, it is a topic that apparently needs more explanation. This question ranked tied for fourth for the Hispanic group and was ranked third by the Other group. Lastly, the Whites and Other groups shared the question, "What professional organizations should I join? What do they offer?" This question was tied for fourth with the Whites and in fifth place for the Other group. A possible explanation why more Hispanics may not have chosen this as an important question is that the student organization of the Society of Hispanic Professional Engineers as well as the Society of Mexican American Engineers and Scientists, are quite prominent on the ASU campus and so Hispanic/Latino students know that they will continue with these organizations.

Each ethnic group chose two questions in their top five that were not chosen by the other two groups. The Whites were alone with their top two questions: "How do I pay for graduate school?" and "How do I choose a job?" Further study is needed to understand if Whites feel there is less money for them to attend graduate school than for the other ethnic groups. The questions tied for first and fourth for Hispanic/Latinos were unique to their top five: "How do I weigh the factors in a job?" and "What is a fellowship?" The weighing of factors in a job choice is similar to one of the top questions asked by Whites, "How do I choose a job?" These questions will be revised in the future. It is interesting to note that more information on fellowships was on the top five lists for both women and Hispanics. The Other group's unique questions were: "What is the engineering work environment like?" and "How do I pick a research topic?" These questions may have been more important to this group because they had less internship experience among them. The research topic question will be investigated further. This question may have

Table III. Top Five Questions by Ethnicity

| Ethnicity | Category | Question | Sample Size |
|---|--|--|-------------|
| White | Importance of Graduate School | How do I pay for graduate school? | 20 (44.4%) |
| | Choosing a Job | How do I choose a job? | 20 (44.4%) |
| | Getting a PhD | Why should I consider getting a PhD degree in engineering? What will it offer me over an MS in engineering? Advancement opportunities? Flexibility? Responsibilities? Salary? | 18 (40.0%) |
| | Why Engineering | Will there be a job for me when I graduate? Will it pay well? Will it be challenging or boring? Will it require traveling? | 17 (37.8%) |
| | Important Skills | What professional organizations should I join? What do they offer? | 17 (37.8%) |
| Hispanic/Latino | Why Engineering | Will there be a job for me when I graduate? Will it pay well? Will it be challenging or boring? Will it require traveling? | 17 (44.7%) |
| | Getting a PhD | Why should I consider getting a PhD degree in engineering? What will it offer me over an MS in engineering? Advancement opportunities? Flexibility? Responsibilities? Salary? | 17 (44.7%) |
| | Choosing a Job | How should I weigh each of the following: engineering/technical responsibilities? Flexibility? Choosing what you work on? Flexible work hours? Working from home? Day Care? Work conditions? Work group dynamics? Opportunities for advancement? Location? Traveling? Benefits? Retirement plans? Bonuses? Salary? | 17 (44.7%) |
| | Why Pursue a BS in Engineering at ASU? | How is my Engineering School viewed by industry? | 15 (39.5%) |
| | Importance of Graduate School | What is a fellowship? | 15 (39.5%) |
| Other/Unknown (than White or Hispanic/Latino) | Why Engineering | Will there be a job for me when I graduate? Will it pay well? Will it be challenging or boring? Will it require traveling? | 12 (60.0%) |
| | Why Engineering? | What is the engineering work environment like? | 12 (60.0%) |
| | Why Pursue a BS in Engineering at ASU? | How is my Engineering School viewed by industry? | 11 (55.0%) |
| | The Importance of Research: Figuring Out What I Want to Do | How do I pick a research topic? | 10 (50.0%) |
| | Important Skills | What professional organizations should I join? What do they offer? | 9 (45.0%) |

been important to this group because they are concerned about graduate school or want to get into research as a way of getting support for graduate school.

IV. SURVEY DISCUSSION AND SUMMARY

The top questions chosen by the various groups seem reasonable. The women and men had two questions in common and then each had questions which seemed reasonable to be of importance to that group. The three ethnic groups had one question in common and then each of the three pairs had two questions in common. Similar results were found when comparing the 21 years of age and under with those students over 21: these groups had one question in common, “How do I chose a job?” [11]. Freshmen and sophomore students shared two questions: “Will there be a job for me when I graduate?” and “How is my engineering school viewed by industry.” Juniors also were concerned enough about industry’s view of ASU engineering to have it in their top five. The question, “How should I weigh each of the following engineering/ technical responsibilities (relative to choosing a job)?” is shared by freshmen, seniors, and graduate students. Juniors share “What is the engineering work

environment like?” with sophomores. Junior share just two questions with seniors, “How do I pay for graduate school?” and “How do I choose a job?” Seniors and graduate students shared two questions exclusively for these two groups, “Why should I consider getting a PhD degree in engineering?” and “How do I weigh the factors that go into choosing a job? [11]”

An addition interesting view of these results is to note that by selecting the top five choices by the two age groups and by the seven student academic standings, the list of 136 questions is narrowed down to 17 questions. Nine questions were determined by age and an additional 8 questions were determined by academic class. Eight top five questions were determined by gender and ethnicity added only two additional questions to that set for a total of 10. Further we note that 7 of the 8 questions noted in the top five due to gender are included in the top 9 questions defined by the age comparison. The one question that is not is included is, “What is a fellowship?” which was identified by women and Hispanic students. Eight of the 10 top five questions defined by gender and ethnicity are included in the 9 top five questions defined by age. The other question gender/ethnicity question that is not included in age is, “How do I pick a research topic?” selected by the Other

ethnicity group. The two age questions that are not included in gender are: “What is the engineering work environment like?” (included in ethnicity) and “How do I find a mentor?” The eight questions in academic class in addition to age do not include any of the gender and ethnicity questions. If we combine the gender, ethnicity, and age categories, we have reduced the list of 136 questions to 11 questions. If we include the academic standing category, then the list of 136 questions is reduced to 19. This summary can be seen in Table IV.

Table IV. Top 22 Questions

| Category | Question |
|-------------|---|
| Gender | 1. Why should I consider a PhD in engineering? |
| | 2. How do I choose a job? |
| | 3. How do I pay for graduate school? |
| | 4. How do I weigh engineering responsibilities? |
| | 5. How is my engr school viewed by industry? |
| | 6. Will there be a job for me when I graduate? |
| | 7. What professional orgs should I join? |
| | 8. What is a fellowship? |
| Ethnicity | 9. What is the engineering work environment? |
| | 10. How do I pick a research topic? |
| Age | 11. How do I find a mentor? |
| Acad. Class | 12. What are typical salaries for engineers? |
| | 13. What are the scholarship opportunities? |
| | 14. What exciting research is at my school? |
| | 15. What is a research proposal? |
| | 16. Master's thesis or comprehensives? |
| | 17. Unique support programs at my school? |
| | 18. How does one develop leadership skills? |
| | 19. What is a PhD qualifying exam? |
| | 20. What are exciting engineering problems? |
| Targ Trans* | 21. What should I do during summers? |
| | 22. I prefer to build stuff. Must I love math? |

- TARGETTED TRANSFER STUDENTS FROM NON-METROPOLITAN COMMUNITY COLLEGES

If we consider the categories for transfer status among the students who took the survey, only one group, 5 students from the targeted non-metropolitan community colleges, had top five questions in addition to the first 19 questions listed. Their questions have been added to Table IV as 20-22. It is good to note that the 23 non-transfer or graduate students in the class had no additional questions in their top 5, neither did the 31 transfer scholarship students from metropolitan community

colleges nor the 14 transfer students in the class who did not have scholarships

V. CONCLUSIONS

This survey identified 22 primary questions out of 136 that are of interest and judged “critical” to the students that we are serving through an Academic Success Class. The authors will first provide answers to these questions on the Motivated Engineering Transfer Students website. The identification of these 22 questions also gives guidance to the topics that should be covered in the Academic Success Classes, if they are not already and to the topics of interest for outreach. Additional research will be done.

A Program to Increase Female Engineering and Science Enrollments Through NSF STEM Scholarships

Ralph Ford, Jane Brady, Michael Campbell, Barbara Gunnison, Oladipo Onipede, Jr., Ruth Pflueger and Andrew Watters
School of Engineering and School of Science
Penn State Erie, The Behrend College
Erie, PA 16563
rmf7@psu.edu

Abstract—This paper describes a scholarship and student mentoring program created to increase female enrollment and graduates in our Schools of Engineering and Science. This program was developed and administered jointly by both of the schools, and the admissions, financial aid, student life, career development, and learning resource departments. Scholarship recipients were required to participate in a mentoring program in which they met regularly with an upper-division peer mentor. Student participants also engaged in academic preparation activities to help develop study, organization, and test-taking skills for academic success. Further, social activities, such as field trips and dinners, were included to build camaraderie. A team of faculty was highly involved as academic advisors to all students in the program and as an advisory board for the grant overall. The program has been effective in increasing female enrollments and improving retention in both schools, particularly in engineering.

Keywords—female; engineering; science; enrollments, scholarships; mentoring

I. INTRODUCTION

The trends of STEM degree enrollments in the U.S. are well known and have been the subject of a number of NSF and National Academy of Engineering reports. The National Science Board of the NSF issued a 2003 report, The Science and Engineering Workforce: Realizing America's Potential [1], that addresses the need to increase STEM graduates. The report showed that the total number of engineering baccalaureate degrees in the U.S. has steadily declined since 1985, whereas the total number of baccalaureate degrees granted has increased. Today, engineering represents less than 5% of all baccalaureate degrees. The percentage of foreign-born baccalaureate scientists and engineers increased from 11% to 17% from 1990 to 2000. This represents a risk because the U.S.'s ability to attract foreign-born scientists and engineers is diminishing. The percentage of traditionally under-represented minorities in the U.S. is increasing, and the percentage of degrees awarded to women across all fields exceeds that of men and continues to grow, yet minorities and women have the lowest participation rates in pursuing STEM degrees. The report notes flat or reduced domestic student interest in critical areas, including the physical and mathematical sciences. It is

important to both attract and retain students in STEM fields, but less than half of the students intending to major in them currently complete a degree in these areas. Furthermore, underrepresented minorities drop out of these majors at a higher rate than other groups, and female college students in computer science are far more likely (69% in the late 1980s) to switch to another major than males (46%) [2].

Penn State Erie, The Behrend College is primarily a four-year and graduate college within a large land-grant and research university. The College enrolls approximately 4,700 students and has four schools: the Sam and Irene Black School of Business, the School of Engineering, the School of Humanities and Social Sciences, and the School of Science. The School of Engineering enrolls 1,300 undergraduates in nine degree programs, and the School of Science enrolls over 600 students in eight degree programs. Many of our students are of the first generations to attend college in their families, and many of them work while attending college to meet their financial needs.

In western Pennsylvania and our institution, female enrollment in engineering and science fields is lower than the national average. This has motivated us to develop a program, with an NSF S-STEM grant, to attract and retain female students in STEM fields. The NSF S-STEM grant program helps institutions provide scholarships for academically talented students with financial need to enable them to enter STEM careers. Furthermore, the grants provide support for curricular development, training, and retention. Many studies have demonstrated that building strong cohort groups is an effective way to retain female students. Other studies have shown that peer mentoring and use of role models does increase confidence level in lower division female STEM students [3]. Several studies have shown that this approach of using peer mentors can significantly benefit female STEM students [4]. Thus, retention was selected as an overriding theme in implementation of this program. The grant period ran from 2006-2011 and the results presented in this paper reflect that period of implementation.

This program has had a significant impact on increasing female enrollments in our STEM majors and our renewal application was funded by the NSF. Our purpose in presenting this work is to demonstrate exemplary NSF S-STEM program implementation and assessment processes for others to follow as they see fit. Furthermore, this article discusses the impact of the grant on our institution.

II. OBJECTIVES

The primary objectives established for this program were:

1. To provide scholarships to approximately 50 new STEM students in engineering and science who are academically-qualified members of underrepresented groups and who demonstrate financial need as per NSF guidelines.
2. To increase the female/underrepresented student enrollment in our engineering and science disciplines, putting us on a path to meet national averages.
3. To enhance the support structure for the scholarship recipients and increase their success rate in our engineering and science programs.
4. To improve the in- and out-of-class environments for females and underrepresented groups in STEM majors and to provide support for students' academic and social integration with a particular emphasis on interpersonal skills, leadership development, and other forms of student engagement.

III. PROGRAM IMPLEMENTATION

The cornerstone of this grant is the mentoring program, which was developed to retain STEM scholars, optimize their academic performance, and expose them to a wide range of opportunities. The program accomplishes these goals through a comprehensive system of academic support that begins prior to the College's student orientation program in the fall and continues through the fall and spring semesters.

The mentoring program focuses on students' academic and social integration. Each fall semester begins with an orientation meeting for the freshmen, followed by a meet-and-greet event for all STEM scholars. Throughout the fall semester, first year scholars meet in small groups or individually with peer mentors weekly to discuss, for example, time management, test taking skills, how to work with academic advisors, course scheduling, test anxiety, study sessions, and stress management. Some sessions are led by peer mentors and students, while others are led by staff from support offices such as the Academic and Career Planning Center and Personal Counseling or a faculty member. Group meetings addressed topics of interest to all participants and created an atmosphere of camaraderie and mutual support. Individual meetings enabled the mentors to provide targeted assistance on an individual basis and develop rapport with their mentees. During the first weeks of the spring semester, the first year students participate in a resume building program that also begins exploration of academic planning and career development topics. Program topics for the remainder

of the semester are driven by the interests and challenges that the students identify.

Second year scholars have a more individualized program. They are required to create an Individual Activity that is monitored by the supervisor of the mentoring program through meetings several times during the semester. They select from a variety of activities that include identifying topics for honors theses (for students who are also in the university-wide honors program), researching minors, graduate schools, internships, co-ops, and options for on-campus research. All scholars are encouraged to attend our undergraduate research and engineering design conferences.

There are annual field trips for all STEM scholars that foster interactions between scholars and build a stronger community. Trips have an academic focus and have included the Tom Ridge Environmental Center, the Erie Maritime Museum, the Carnegie Museums in Pittsburgh, the Cleveland Science Museum and Frank Lloyd Wright architecture in Buffalo.

Peer mentors are upper-division students in science and engineering and have all been female so far. They are selected based on strong academic records, interpersonal skills and demonstrated leadership skills. We wanted peer mentors who were examples of the kind of students we hoped our scholars would be in two years—with a good GPA, involved in academic activities, and with well-developed academic goals and career plans.

The mentors complete an application and are screened, interviewed and selected by the program faculty advisors, administrative coordinator and, in later years of the grant, current peer mentors. The first mentors were recruited from students who were recommended by faculty and then contacted by the committee. As the scholars became upperclassmen, they were encouraged to apply and were eager to be involved in the program from the "other side of the fence." For the last year of the grant the mentors were scholarship recipients, and this will continue into the renewal grant. They bring a unique viewpoint to the position, since they have experienced the program and are now helping to direct it. Each year brings a unique group of scholars with slightly different needs, so the creativeness and thoughtfulness of mentors in ongoing program development is very important to the program's success.

Peer mentors have also benefitted from participation in the program and have developed personally, academically, and professionally. They participate in a training program at the beginning of the academic year. Group meetings with their supervisor are held every third week during the semester to provide ongoing guidance. Discussions include the progress of their mentees, program planning, and address any immediate concerns. Support from faculty members is readily available as needed.

A Faculty Advisory Committee consisting of two faculty members each from the Schools of Engineering and Science,

the peer mentor supervisor, a staff member from the office of Student Activities and the director of the Learning Resource Center meets monthly, providing feedback on the progress of students and the program. Faculty members on the committee also serve as academic advisors to the students. Peer mentors often attend the meetings to provide information, participate in program activity development, and bring any immediate needs to the attention of the committee.

A. Student Recruitment and Selection

Penn State Behrend embarked on extensive outreach and publicity initiatives upon being approved for the original grant. A National Science Foundation STEM Scholarship brochure and Web site were developed that specified the scholarship and support program details. Targeted mailings were sent to prospective students who indicated an interest in STEM fields, encouraging them to look at Penn State Behrend and this unique opportunity. We also host numerous K-12 STEM outreach events on campus designed to attract students into STEM fields – over 2,000 K-12 students attend activities hosted through our K-12 Engineering Outreach Center annually. During these activities, we distributed information on the NSF STEM scholarship program. As students were offered admission, they were sent letters from the directors of our Schools of Science and Engineering, detailing the benefits of our STEM majors, faculty, facilities, and commitment to the STEM Scholarship Program. Lastly, potential STEM students were invited to a special on-campus breakfast with their parents where they learned about the program, opportunities in STEM careers, how to apply and personally met our STEM Team. Scholarship recipients and peer mentors also speak about their experiences and meet prospective students. They really provide the “peer to peer” touch that we hope will convey the uniqueness and benefits of pursuing a STEM major at Penn State Behrend. In our opinion, these outreach efforts had a significant impact on STEM enrollment.

Upon grant renewal, we were able to incorporate student testimonials in our recruitment activities. “Graduates” of our STEM Scholarship Program have been featured in our newest brochure. Interestingly, several STEM students who were offered admission for Fall 2012, but did not receive the scholarship, still chose to enroll at Behrend because we welcomed them into the mentoring/experiential learning

component of the program.

Scholarship recipients were chosen from women and minority STEM applicants demonstrating financial need. Secondary data used in selection were SAT scores, high school GPA and ranking, and predicted GPA. As our awarding process matured, we determined that we lacked a piece of valuable information from the applicants – their knowledge of and commitment to a STEM major. With the renewal grant, students are required to write an essay as part of their application that describes what they have done to prepare themselves personally and academically for a career in a STEM field. This additional information was extremely beneficial as we reviewed applications for the Fall 2012 class..

Independent sample T-tests found that STEM Scholars had significantly stronger entering academic qualifications and a higher first-year predicted cumulative GPA. Because Penn State uses a validated multiple regression model for science/engineering students’ predicted cumulative GPA that accounts for differing academic qualifications, one might expect scholars and non-scholars to achieve approximately their predicted GPA values. However the last variable in Table 1 shows Scholars’ mean first-year cumulative GPA significantly exceeded their mean predicted cumulative GPA (+.19), while non-scholars performed below their predicted GPA (-.03, not significant). This suggests that the STEM program positively influenced scholars and contributed to their first-year academic performance exceeding the expected level.

B. Student Monitoring

Academic progress is monitored regularly during the semester. Feedback is solicited from instructors, peer mentors and the students themselves. Students are evaluated at the end of each semester to ensure that they are making sufficient academic progress toward completion of a STEM degree; they must maintain a GPA ≥ 3.0 and complete courses for their stated major. Students who do not meet these criteria are sent a warning letter and are required to prepare an academic plan for the next semester that is monitored by the peer mentor supervisor. They are encouraged to consult with the Learning Resource Center to address academic problems and to meet with personnel in the Academic and Career Planning Center and Personal Counseling as appropriate. Students will have their scholarships renewed if they continue to participate in the mentoring program and make adequate academic progress.

TABLE 1. MEAN COMPARISONS: STEM SCHOLARS VS. STEM-ELIGIBLE NON-SCHOLARS

| | Variable | Group | Total Students | Mean | Standard Deviation |
|----------------------------------|---|--------------|----------------|-------|--------------------|
| Secondary Selection Criteria | SAT verbal score | Scholars | 61 | 561 | 90.00 |
| | | Non-Scholars | 397 | 502 | 95.92 |
| | SAT math score | Scholars | 61 | 593 | 73.32 |
| | | Non-Scholars | 397 | 533 | 97.58 |
| | High School GPA | Scholars | 61 | 3.78 | 0.33 |
| | | Non-Scholars | 398 | 3.47 | 0.54 |
| | Predicted Cumulative GPA | Scholars | 61 | 2.98 | 0.25 |
| | | Non-Scholars | 397 | 2.71 | 0.38 |
| Performance Evaluation Criterion | First year Cumulative GPA | Scholars | 60 | 3.17 | 0.55 |
| | | Non-Scholars | 387 | 2.68 | 0.71 |
| | Difference between first-year cumulative and predicted GPAs | Scholars | 60 | 0.19 | 0.49 |
| | | Non-Scholars | 386 | -0.03 | 0.67 |

Students will have their scholarships rescinded if their GPA is < 2.7 for two consecutive semesters.

IV. RESULTS

A. Objectives

The primary purpose of the grant was to provide scholarships and a mentoring program to support student recipients. A total of 61 students were awarded NSF S-STEM scholarships over the grant period: 57 students were female and 4 were male. Ten of the students were minorities.

The second objective was to increase female student enrollment in our engineering and science disciplines. Throughout the grant period, female student enrollment has increased steadily to over 60% (66 to 110 female students) in the School of Engineering and 10% (98 to 109) in the School of Science. Overall, enrollment in STEM majors in the Schools of Engineering and Science increased by 16%. Not all of these increases can be directly attributed to the STEM program. For example, other programs were put in place to increase female enrollment at the same time, and the female student increase exceeds that of the scholarships awarded. However, it is clear that the grant had a significant impact on the academic environment.

B. Student Retention

In terms of student retention in college and STEM fields, students in the NSF STEM Scholarship program have done well, greatly exceeding our institutional averages, which include all majors (STEM and non-STEM) as indicated by the following:

- The first-to-second-year retention rate in college for NSF STEM scholars is 96% vs. the institutional rate of 86%.
- The first-to-second-year retention rate in STEM majors for NSF STEM scholars is 93% vs. the institutional rate of 81%.
- The first-to-third-year retention rate in STEM majors for NSF STEM scholars is 83% vs. the institutional rate of 62%.

Beyond the quantitative results above, the grant has had a number of other impacts. The mentoring program has continually evolved (the types of activities and the ways in which they are delivered), based on survey feedback, to address the changing needs of the cohorts. In terms of impact on our students' careers, upper division STEM scholars are obtaining internships in their fields. The peer mentors hired to support the program have also been successful in obtaining STEM degrees and have obtained full-time employment or gone on to graduate studies in engineering and science.

C. Program Assessment and Evaluation

A series of assessment surveys were administered to measure student success and the effectiveness of mentoring activities. The surveys are summarized in Table II in the Appendix. Both the mentees (student scholar participants) and

peer mentors were surveyed. We used instruments from the AWE project (Assessing Women and Men in STEM fields, www.aweonline.org) beginning in the spring semester of the third year of the grant, when they became available. These assessment tools are validated and allow comparison to a national norm. AWE provides a comprehensive range of surveys. Prior to that time, we administered surveys we created for the purpose of guiding the development of the mentoring program into a support system that would be responsive to students' needs. AWE surveys were administered on-line via a class management system. Previous surveys were administered in paper format during meetings.

Mentees and mentors assessed the program in both pre- and post-participation surveys that included multiple choice and open-ended questions. Scholars indicated that the program helped their academic achievement in STEM majors. This is evident in the change in freshman response rate to the same question on pre- and post-participation surveys. The question asked scholars to indicate their goals for the program from among a list of eight options, with the opportunity to add additional items. 26.7% of scholars listed as one of their goals: *"Assist in doing well in my major"* in the pre-participation survey. In the post-participation survey, that response increased to 85.7%. A similar trend was found among sophomores, juniors, and seniors with a pre-response rate of 34.5% increasing to post-response rate of 75%. Thus, the program has had an impact on academic achievement for students enrolled in STEM fields, as exemplified by this scholar's comment about her mentor's effectiveness on an AWE post-participation survey: *"She [mentor] gave us her phone number the first day and told her (sic) to contact her with any questions. I did this on a regular basis. She helped with anything from school to how (sic) where things were on campus. She was a very reliable resource. Also when it came to scheduling she made sure that I as a freshman knew how to schedule properly. She was very enthusiastic about her schoolwork and this motivated me to do well like her."*

Additionally, based on responses to AWE pre and post participation surveys, the program has had an impact on student awareness of the importance of career and job search skills. On the pre-participation survey only 6.7% of freshman selected *"Help me with career and job search skills"* as one of their goals for the program. That percentage increased to 71.4% on the post-test survey. For sophomores through seniors, that percentage increased from 31.3% pre- to 85.2% post-participation. One scholar noted on an AWE post-participation survey question regarding whether or not she would recommend the program to a friend: *"I would recommend it because I already feel that I am ahead of my friends that did not participate when it comes to career choices and major decisions. For example even though it may not have been comfortable for me to attend a career fair as a freshman and talk to employers, being required to do so got me out there and I gained valuable experience from it."* Another commented, *"It is helpful for deciding if your major is right for you and how to find internships."*

First-year scholars were nearly unanimous in their opinion of the overall effectiveness of their mentors and program effectiveness. Ratings of effective/very effective were 85.7%

for mentor and 92.9% for the program overall. Satisfied/very satisfied was the same, 85.7% for mentor and 92.9% for the program overall.

The vast majority of scholars noted that the program met their goals for participating, with 85.7% of first-year and 82.1% of sophomore through seniors agreeing/strongly agreeing. Furthermore, 100% of mentors said their expectations were met. This suggests that the stated program objectives are being accurately communicated to participants, and also being achieved through the program's activities.

Finally, all scholars, freshman through senior, and all mentors, unanimously agreed/strongly agreed that the program should continue. All scholars would recommend participating in the mentor program to a friend starting college. One scholar said on an AWE post-participation survey *"It is very helpful because you get to know other students from your major and all the programs are very helpful also. The resume and interview programs and the research activities we did were very important in my success thus far in school and in my internship."*

D. Areas for Improvement

The program can benefit from additional programming for sophomore through senior scholars. Only 21.4% of these students noted being active/very active in the program, compared to 100% of first-year scholars. Several scholars noted more activities for upper-level students were needed, and one suggested on an AWE post-participation survey: *"I think it's good for underclassman (sic) to have mentors. Juniors and senior (sic) still need support I believe so I think there should be workshops to get them thinking about professional exams like GRE MCAT (sic)."* This confirmed the opinion of our faculty committee that the original grant was more relevant to first-year students, and upper-division students had fewer opportunities. This has been addressed in the renewal grant with the introduction of new experiential learning components to be completed during sophomore through senior years, with more faculty involvement.

In addition, 57.1% of sophomores, juniors, and seniors rated their mentors as effective or very effective, compared to the 85.7% rating by freshmen. Of the non-freshmen, 64.3% were satisfied or strongly satisfied with their mentors, compared to the 85.7% freshman rating.

Mentor responses were generally positive across the board, which makes it difficult to identify areas for improvement. Two that might bear reviewing are mentor training and mentor perceptions of scholar satisfaction with mentor performance. Both items received unanimous agree ratings, which is good, but no strongly agree ratings. Almost all other fields on the mentor surveys received some strongly agree responses, which

suggest that these two are "low" in a relative sense, even though their rating is still positive.

V. SUMMARY

This paper presented an implementation of an NSF S-STEM Scholarship program. The focus of this program was to increase female participation in our STEM majors, notably in our Schools of Engineering and Science. To achieve this, scholarships were awarded to students for up to four years for each student, and a mentoring program was developed for all participants. The mentoring program was intended to help students acclimate to the academic environment, improve study skills, explore career choices, and most importantly to develop student cohort groups. The program was assessed using nationally-normed instruments from AWE that allow for comparison to other program implementations.

The results of the program and grant are promising. Female participation increased in both of our schools, and the results in engineering were quite dramatic, with a 60% increase. Furthermore, the retention rates for students who participated in the program greatly exceeded our institutional norms. The overall assessment of the effectiveness of the program was quite high, with over 82% of all participants agreeing/strongly agreeing that the program met their goals for participation.

VI. APPENDIX

TABLE II. OVERVIEW OF THE ASSESSMENT PLAN.

| Surveys | What it Measures | Time of Administration |
|---|--|--|
| AWE Mentor Pre-Participation | Ability to lead other students; ability to communicate effectively; ability to solve problems that arise during mentoring activities; ability to provide direction and offer productive suggestions | Annual Before mentoring program activities begin |
| AWE Mentor Post-Participation | Adequacy of support received to accomplish responsibilities; adequacy of training received; satisfaction with supervision; respondent's suggestions for improving the activity | Annual At the end of participating in the mentoring program |
| AWE Mentee Pre-Participation | Collects baseline data on each participant on students' preparation for a STEM study, confidence in preparation, and sense of inclusion in their academic environment, | Annual Before mentoring program activities begin. |
| AWE Mentee Post-Participation | Feelings of isolation/inclusion; impact of role models, influence on academic/social behaviors; satisfaction with the activities; extent that the respondent participated in the activities; overall satisfaction with the program; perceptions of the mentor; extent of contact with the mentor; suggestions for improving the activities | Annual At the conclusion of mentoring activities each semester. |
| AWE Student Persisting Survey | Reasons for deciding to persist in engineering/science, specifically: initial commitment to and preparation for studying engineering/science; impact of course workload, climate, advising, teaching, etc.; other factors /events that contributed to decision to persist; participation in academic and in extra-curricular activities; confidence in completing an engineering degree; post-graduation plans | Annual At the end of the second and fourth years. |
| AWE Student Leaving Survey | Reasons for deciding to transfer out of engineering/science, specifically: initial commitment to and preparation for studying engineering/science; impact of course workload, climate, advising, teaching, etc. ; other factors /events that contributed to decision to leave; participation in academic and in extra-curricular activities; retrospective confidence in finishing a degree in engineering/science; confidence in completing (another) degree; post-graduation plans | As soon as students leave the NSF STEM program or a STEM field. |
| In-House Freshman Self-Evaluation Survey | Self-evaluation of academic, math and writing abilities as well as self-confidence in academic and social situations. Expectations of a variety of aspects of college career including changes in major or career choice, activities, communicating with professors, etc. | Annual During Orientation and at end of freshman year |
| In House Program & Peer Mentor Evaluation Surveys | Feedback on programs, activities and mentors. Request ideas for activities for the coming semester. | End of each semester |

Science Bound: A Success Story for STEM Education

Abstract—At the 2005 Frontiers in Education Conference, members of Purdue University and Indiana University Purdue University Indianapolis (IUPUI) presented the results of the first year of the Purdue Science Bound program. Science Bound was created to give young people from minority and low SES households an opportunity to pursue STEM careers in college. In cooperation with the urban Indianapolis Public School (IPS) system, candidate students with aptitude in math and science were selected and given the opportunity to participate in summer camps, enrichment activities, after school projects, and mentoring programs aimed at increasing their likelihood of acceptance to, and success in, collegiate STEM programs.

Analysis of summer camp results has shown that introduction of pre-engineering concepts, and exposing technology and scientific method to secondary school students can significantly enhance problem solving skills and prepare them for collegiate STEM careers. Researchers were also pleased to see that the pre-engineering curriculum modules help participating students improve understanding of associated mathematical concepts. The Science Bound program is now ten years old, and the original cohort of high school freshmen are graduating from college. This paper will examine the success of the program and provide insights into successful elements for STEM enrichment programs and approaches for engaging under-represented students in STEM careers.

I. INTRODUCTION

The projected job growth for STEM graduates is expected to be 22 percent while the National Science Foundation, predicts that only about 17 percent of US college graduates will earn a degree in subjects related to STEM. [1] That not only predicts a shortfall in college graduates prepared for STEM related careers, but it also falls well below the world average of 26 percent of college graduates earning STEM related degrees. [2] America is becoming more diverse at an unprecedented rate as shown by US Census Bureau projections that indicate underrepresented students will make up more than half the national collegiate population by 2050. Yet these students are significantly underrepresented in STEM fields. [3]

It is therefore imperative that colleges and universities find ways to increase the success rate of underrepresented students in STEM if America is to maintain a competitive edge in the global marketplace. [3] Chubin, May and Babco have pointed out that if American colleges and universities cannot meet the required demand for the quantity and quality of Engineering and Technology (E&T) graduates, then industry will be forced to increase the trend of outsourcing its engineering needs to countries outside the U.S., which may mean moving entire operations overseas. [4] One of the major ways that institutions of higher education can work to reverse this trend is to increase the number of minority students who pursue E&T educations that lead to these careers. Currently only about 10% [5] of students enrolled in E&T collegiate programs are from underrepresented households.

Regarding the shortage of women studying engineering, Cavanaugh indicates that girls have less confidence in their abilities in math and science and they also enjoy those subjects less than their male peers. [6] There are varying theories why young females are not pursuing engineering and technology plans of study. One theory is that they are put-off by engineering, which is stereotypically seen as a “guy” career. [7] Another theory is that young women lack self-confidence in their math and science abilities. Regardless of which is the cause, researchers say that if girls lose interest in STEM topics while in middle school, when social pressures and gender differences become more pronounced, they typically will not find their way back to those subjects. [8] A study of women in university engineering programs shows that this shortage of self-confidence is a major issue which follows them from their high school careers. [9] The Center for Pre-College Programs states that young women still avoid advanced mathematics and science related courses and careers because they underestimate their capability rather than because they lack competence or skill. [10] University outreach programs in conjunction with public school systems, similar to Science Bound, are intended to attack the issue by creating pre-engineering programs in middle school and high school. [11]

A second major shortage is African-American males in STEM. Ways need to be found to improve the yield and

retention rate of this tremendous resource. The Quality Education for Minorities Network's Final Report on African American Males in STEM documents that 67.9% of all STEM bachelor's degrees awarded by Historically Black Colleges and Universities in 2007 were female, but only 32.1% male. [12] The old adage that there are more African-American males in prison than college still rings true today. At the 2012 Best Practices for Students of Color Conference, Dr. James H. Johnson, Jr. presented a logic model for early intervention for boys of color that is consistent with the Science Bound program. Johnson stresses that boys of color are more likely to experience trauma/violence, less likely to have nurturing caregivers/parents, less prepared for school and more likely to receive inadequate/inappropriate educational services. [13] In numerous ways, Science Bound strongly parallels four of Johnson's suggested improved coping mechanisms: (1) parent focus (2) engaging students in high interest activities (3) using evaluation data to assess and improve future programming, and (4) leveraging corporate, community and university partnerships.

II. PURDUE'S SCIENCE BOUND INITIATIVE

Grose states that US engineering and technology schools are struggling to recruit, maintain, and graduate students from minority families. However, despite their best efforts, low income minority students can present a special set of challenges in STEM programs. They may have raw talent, but underrepresented students often suffer from inadequate academic preparation, particularly in math and science, which are two key requirements for engineering and technology students. Unfortunately, those who do make it to the university often are forced to drop out due to economic pressures and the need to begin earning a living early in life so as to help support their family. [14] Based on the data relative to females in STEM programs, there is a compounded issue for young ladies caught in this situation.

However, in Indiana, Purdue University partnered with the 40,000 student IPS public school system to form Science Bound, a program aimed at guiding urban students into STEM careers. The objective of Science Bound has been to locate IPS students who exhibit both an interest and aptitude for success in such careers. If located while they are still in middle school, then Science Bound can assist them, utilizing a program of science oriented classroom mentors, special activities, and enrichment programs. These all help to cultivate the student's STEM interests through the high school years, thus helping to prepare them for entry into the Purdue University program of their interest. These participants selected for the program are roughly evenly divided by gender, making Science Bound an excellent tool for evaluating both racial and gender minority issues.

In order to keep these students on track through their four year high school career, there needed to be a certain amount of incentive. Purdue President Martin Jischke established the objective that each student who completed the Science Bound program in high school and who was admitted to any Purdue degree program in one of the STEM related fields, would be

offered a full four year tuition scholarship plus additional support services such as tutoring, mentors, and professional development to help them succeed. This is an opportunity that few inner city students ever see as a possibility. So Science Bound opens new horizons for them.

In order to achieve this, a strong corps of local mentors, and a range of educational activities, summer camps and assistance programs were instituted during the high school years. Chubin, Babco and May have concluded that an effective pre-engineering program must (1) promote awareness of the engineering profession, (2) provide academic enrichment, (3) have trained and competent instructors, and (4) be supported by the educational system of the student participants." [4]

III. CORPORATE PARTNERS

There is a growing trend wherein both industry and academia have increased efforts to direct students into the pipeline leading for STEM programs. This requires reaching out to K-12 students in local school systems. Purdue's Director of Science Bound, Wesley Campbell, has had the task of recruiting corporate partners from the central Indiana area. Many businesses have become involved by contributing in a number of different ways. These businesses have supported the program financially, providing the funds for the scholarship offers made to students when they complete the high school program. The corporate partners have also provided the financing to provide the summer camps free to students, and to even offer small stipends to the mentors at various IPS high schools who volunteer to stay after hours and work with the Science Bound students on various after-school projects and investigations. However, corporate sponsor participation goes beyond the purely financial aspects of the program. They participate in career days, plant visits, and perhaps most importantly, they provided some of their employees for one-on-one mentoring and counseling.

One of the first companies to sign on as a corporate partner with Science Bound was Bowen Engineering, an Indianapolis based full service contractor that specializes in site-work, underground utilities, concrete, mechanical and process equipment installation, with over a million dollars in business annually. Company founder and president, Bob Bowen is a Purdue Civil Engineering graduate. Despite still being actively involved in the running of his company, Bowen himself is an active participant in the Science Bound program, often volunteering his time as a tutor to students at one of the local high schools. "You spend a lifetime building a corporation, an organization, and work hard to make it a success," says Bowen. "But when all is said and done, you consider it a privilege to give something back."

IV. APPROACHES

The Science Bound Office at Purdue has the responsibility for bringing together all the pieces necessary for the success of the program, coordinating with the IPS high schools to make sure that each school has at least one mentor working with the Science Bound students at that school. They arrange monthly

meetings for both students and parents, so that the entire family remains aware of the progress of the program, and both excited and supportive of their student's efforts in the program. This helps to keep the students focused on the goal.

A number of summer enrichment programs have been offered, and the Science Bound Office works to ensure that students get exposure to their specific areas of interest. Some of these summer programs serve a dual purpose of helping students improve the basic skills necessary for STEM careers and also exposing them to engineering type challenges that stretch their boundaries and help them learn to problem solve. One particular example of a successful enrichment program was a month long summer activity in which the students met in a modified classroom environment for four hours each day where they were exposed to simple engineering concepts. Examination of these concepts and solution of related problems required an understanding of math skills necessary to understand those concepts. None of the math skills were beyond the level that the students had already seen in high school. Nevertheless, when given a skills test at the beginning of the summer program, a majority of the students showed a definite shortfall in comprehension of some of the necessary algebra and geometry concepts.

Approaches used in this summer activity involved showing the students that the math skills they sometimes avoid in school have applications in the real world that do interest them. One example was showing students how mechanical advantage can be used to make their life easier, utilizing a number of common devices that students have seen in use in their everyday lives, such as pliers, wrenches, pulleys, or jacks. Means of determining and maximizing the mechanical advantage were discussed. However, in order to effectively use these new found skills to make their lives easier, the students had to know how to apply concepts of ratios and algebra. Similarly, one class involved a discussion of driving a car, and determining how fast the car could take a corner without sliding into the ditch. The analysis of this situation involved use of vectors and geometry. These two concepts were areas that the students were obviously struggling with, but applying them to real world situations increased their comfort level with the concepts.

The students were also involved in inquiry based learning. The final project of the summer session was to build a structure of balsa wood, capable of supporting a load using the least structural weight. The load which was successfully supported, and the weight of the structure, factored into a scoring rubric that also included appearance and sound use of engineering concepts. But before they began any construction, students were allowed to use different shapes and dimensions of balsa wood materials and a load application mechanism to determine what types of beams held the most load. Some teams even constructed composite beams of their own design to further analyze this relationship. Students and instructors then worked together to plot and analyze the data, extrapolating relationships that helped the students understand the optimum use of the available materials.

The construction of the final projects showed that it was obvious that the students had gained insight into how to choose their materials and how to optimize their structures. On the final day, some of them held impressive loads. Some of the Science Bound corporate sponsors sent representatives to the final day of the summer session, when structures were tested. An aerospace representative from Rolls-Royce Corporation had the following reaction, "The camp appeared to be received by the students with enthusiasm. This, despite their "giving" of a month of their summer to it. They definitely showed that they had learned a lot and were able to apply that learning and talk about it."

It has been suggested that females, more so than males, tend to seek careers where they can make a difference in society and apply less traditional solutions. Too often, engineering is not seen as one of those careers. To address this issue, one of the modules constructed for the summer enrichment camp focused on sustainable engineering and environmental impact, thus tying readily to current societal concerns. The students conducted a study of the environmental footprint created by one of their favorite devices: the cell phone. After learning the process by which cell phone circuit boards are manufactured, they examined the toxic waste byproducts that come from that process. They conducted chemical experiments on dilution, metal extraction from waste water and evaporative processes and even built and tested their own miniature version of a landfill, examining how dangerous chemicals leach into groundwater aquifers. These topics were always tied closely to the necessary mathematics, whether in calculating dilution concentrations, balancing chemical equations, or extrapolating laboratory sized experiments to the size necessary for an entire city.

V. RESULTS

By the end of the month long class, significant improvements in student performance were obvious. Not unexpectedly, there was an increase in comprehension of the engineering concepts, but there was also a surprising increase in accompanying math scores. The full data from the pre- and post-course assessments of one of the classes is shown in Table I.

Table I Results of Pre-Class and Post-Class Assessment Test Averages

| Subject Area | Pre-Class | | Post-Class | |
|----------------------|-----------|------|------------|------|
| | Female | Male | Female | Male |
| Mechanical Advantage | 30% | 16% | 63% | 94% |
| Friction | 50% | 33% | 57% | 83% |
| Structural Mechanics | 17% | 6% | 27% | 18% |
| Algebra | 80% | 60% | 83% | 74% |
| Ratios | 80% | 80% | 83% | 87% |
| Geometry | 70% | 16% | 90% | 73% |
| Chemistry | 20% | 16% | 30% | 26% |
| Problem Solving | 37% | 31% | 48% | 45% |

The instructors believe that this gain in math scores resulted from students overcoming the all-too-frequently encountered mindset of “I will never use this math.” Once they were shown simple engineering concepts that they could easily relate to, and which required the use of the math concepts, then there was a positive gain in math comprehension.

Perhaps the most promising aspect of the summer program was the qualitative gain that the instructors saw in student self-confidence. Several students who initially showed doubts in their own math and science abilities, were leading their teams by the end of the month, as well as speaking encouragingly about their fall math and science classes back at the high school. Data from that subsequent semester showed that 67% of the students from this summer program had improved grade point averages over the semesters prior to the summer camp.

The Purdue Science Bound program is currently in its tenth year of operation. Of the eighth grade students who were the initially selected for the first year of the program, seven have graduated from Purdue University and nine are in their fifth year of study, still on track for graduation. Participating students have been tracked since the summer of 2009 and the data reflect that a remarkable 98% of all program participants went on to college. Of these, 47% attended Purdue; 51% went to other institutions of higher learning, 1% enlisted in the military and 1% were unable to be reached. These results are summarized in Table II. The high school graduation statistics for the participating students are shown in Table III, indicating completion of high school and solid ACT and SAT scores.

TABLE II Where Science Bound Students Are Now

| Graduation Year | # of SB Seniors | Purdue | Other College | Military Or Unknown |
|-----------------|-----------------|------------|---------------|---------------------|
| 2007 | 41 | 28 | * | * |
| 2008 | 52 | 36 | * | * |
| 2009 | 27 | 11 | 15 | 1 |
| 2010 | 30 | 13 | 17 | 0 |
| 2011 | 32 | 18 | 13 | 1 |
| Totals | 182 | 106 | 45 | 2 |
| Percent | | 47% | 51% | 2% |

I. CONCLUSIONS

A number of things have brought about the success of the Science Bound program. These are not things that are unique to IPS or to Purdue. They, therefore, could be implemented anywhere. These key factors are:

1. Select students with both the aptitude **AND** the interest that is necessary for a career in STEM related fields. It is not enough to simply select students with strong test scores on math and science aptitude tests. If their desire is to be a musician or an artist, no amount of science aptitude will see them successfully

through the program. The selection process must find those students who *want* to succeed in STEM careers.

TABLE III Test and GPA Statistics

| Academic Year | High School GPA | SAT | ACT | Cohort Size | One Year Retention | | |
|---------------|-----------------|------|-----|-------------|--------------------|-----|------|
| | | | | N | N | % | GPA |
| 2007-08 | 3.35 | 1541 | 21 | 28 | 21 | 75 | 2.45 |
| 2008-09 | 3.42 | 1525 | 22 | 37 | 33 | 83 | 2.51 |
| 2009-10 | 3.40 | 1602 | 23 | 11 | 10 | 90 | 3.07 |
| 2010-11 | 3.38 | 1569 | 22 | 12 | 12 | 100 | |
| 2011-12 | 3.40 | 1589 | 23 | 17 | | | |

2. Provide mentors in the school system who are both active and involved. There needs to be someone active in each school who is working with the students participating in the program, meeting with them regularly and developing after-school activities that will develop their interest in pursuing STEM careers. These mentors, by virtue of their position in the student's school, will also serve as an early warning system to detect when one of the students is struggling.
3. Supply a support system that students and parents can fall back upon when the going gets tough. High school students experience a tremendous number of life changes. It is not surprising that a great many of them struggle at some point during their secondary school years. This problem is only exacerbated when dealing with minority students from urban. Low SES neighborhoods. For the program to be successful, there must be a safety net mechanism that the students can call upon when they feel themselves falling behind in a subject. The support system also should be one that the parents can access when they see their students struggling, or when they, themselves, do not know how to deal with a situation.
4. Offer interesting enrichment programs. These programs should provide the students a taste of what it would be like to be an engineer or scientist. This strengthens their interest in staying the course with the program, and also helps them refine their ideas of exactly which career path interests them.
5. Provide positive role models who are accessible to the students. Students need people in the industry that they can relate to, learn from, and call upon when they need help or advice. This also gives them a solid vision of what their life could be like if they

complete the program and reach their ultimate career goal.

The fields of Engineering, Science and Technology can only benefit from an increase in the diversity of students who chose STEM career paths. Programs such as Purdue's Science Bound that tie together university resources, corporate support, public school system participation, and parental involvement with the common goal of bringing more urban high school graduates into STEM related careers may present the best means of achieving the required numbers and balance of Engineering and Technology graduates in the coming decades.

Abstract—In this paper we propose a new multi-strategy model for immersing students in STEM. Rooted in the current research and experiences, the new practices are being developed and implemented in a college-based hybrid STEM learning center that is geared to serve as a hub connecting high schools, higher education institutions, and industries bringing new and existing strategies together into one integral system with unique online features. The Hub model would serve as an educational research laboratory contributing to the knowledge base about STEM by investigating what strategies (or combination of what strategies) will best support student development for the STEM workforce. In addition, the model would illustrate the importance of interconnection between engineering education research and engineering education practice.

Keywords – *Multi-Strategy, Hybrid Learning, Hybrid LaGuardia Youth Center for Engineering Excellence (H-LYCEE), Online Learning Component, Research, Practice, STEM*

I. INTRODUCTION

The U.S. economy is currently experiencing a crisis in STEM education that can potentially cost the United States its leading position in most areas of engineering and affect our scientific and engineering workforce in the 21st century [1-3]. In order to address this issue, numerous research ideas on various strategies to stimulate STEM education are being generated and implemented [4-7]. Nevertheless, the STEM pipeline, especially in engineering, is deteriorating at significant rates over the last decade [2, 3], and the quest for new strategies promoting students' interest in STEM related careers continues.

The current educational research shows that attracting and retaining students in STEM fields is most effective when it is done in early stages of their educational path [2, 3, 8]. Moreover, research on learning in STEM disciplines suggests that students' problem solving ability comes from the creation of increasingly complex connections among diverse learning sources [12, 13]. Similarly, it is possible that various methodologies and approaches working together would better promote students' interest in STEM and help them in learning STEM disciplines. This paper discusses a novel idea of creating a college-based center that would serve as a hub connecting high schools (HS), higher

education institutions, and industries; the center, unlike most of the existing programs for HS students, would be an educational research laboratory where new and existing strategies for immersing students in STEM are interconnected into one integral system with unique online component. The center will design, implement, and evaluate new ways to promote students' interest in STEM careers and facilitate their readiness for it.

II. THE CENTER/HUB MODEL AND ITS IMPLEMENTATION

The HYBRID-LYCEE (H-LYCEE) center implementing the proposed multi-strategy model is currently being built on the basis of successes and experiences of LaGuardia Youth Center for Engineering Excellence (LYCEE) that was established in LaGuardia Community College of the City University of New York in 2009 to offer HS students various after-school and summer learning programs/activities (e.g., robotics, mechatronics, CAD/CAM design projects, math tutoring) designed to promote their interest in STEM-related careers [14]. The significance of the new model lies in the authors' effort to intertwine a wide scope of various approaches to the existing problem of attracting students in STEM and preparing future professional workforce in U.S. through the extension of LYCEE into H-LYCEE Center/Hub and to make different learning models work together as one in promoting the STEM-related careers.

The new and existing strategies for immersing students in STEM that can interlock and work together are as follows: (a) hybrid learning with face-to-face and online components; (b) learning through hands-on experience; (c) multidisciplinary learning; (d) teamwork; (e) contextualized learning; (f) professional development workshops for HS teachers; (g) college admission counseling; (h) talks by professional speakers; (i) creation of an Advisory Board, whose members are faculty, teachers, industry professionals, educational researchers, and parents, that will advise, guide, and help evaluate the center's work. Some particular activities towards the multi-strategy model implementation would include: creating a Robotics Academy; conducting robotics competitions for student teams from the NYC area; conducting professional development workshops for HS teachers on incorporation of H-LYCEE activities in high school curriculum; creating a new after-school program (H-

LYCEE Math Academy) where students will learn how math can be used to solve various engineering/science problems; and conducting information sessions on admission policies in STEM-related academic programs at the colleges and universities in the NYC area.

An innovative curriculum with an online component as well as an online chat platform would be key components of the proposed multi-strategy model which will provide the opportunity for any HS student from local area to join the center and get easy access to its resources. This will create a virtual world for HSs and colleges: students would be able to meet and interact with college professors and staff, while HS teachers and college professors would communicate via webinars around issues that affect STEM education.

The hub's specific feature would include a novel curriculum with an extensive online component, including online technical training on the Intelitek's LearnMate e-learning platform. The design of the new curriculum, both adapting existing hands-on projects and developing new projects, is currently being led jointly by LYCEE faculty and Intelitek. Some of these projects are as follows: the existing *Robotics Projects* will be completed using LearnMate and VEX components; the existing *CAD/CAM Design Projects* will be completed using LearnMate, CATIA, and AUTOCAD software; the *Electrical and Electronic Projects* use the Electrical Systems (Lab) module, that is already LearnMate-based; the *Biology Projects* will be offered in order to diversify the STEM areas covered in the Center.

H-LYCEE with its online component would make it possible to extend the participation of students from NYC area, especially from low-income and underrepresented groups, via newly created network/hub and, thus, will enhance and further promote STEM education.

III. EXISTING RESULTS. EVALUATION.

During the period of its existence as LYCEE, the Center has served 9-12 grade students from twelve high schools located in Queens. By the end of Summer 2011, 239 students had successfully completed the program which has shown a steady increase in the participation of minorities with Hispanic students constituting an average of 40% of all students each academic term. LYCEE was also successful in attracting female students (comprising 31% of all participants) to the program in a relatively short period of time. The Center is fostering an atmosphere promoting the development of mentoring relationships between high-school students, faculty, and current undergraduate engineering students. As follows from students' testimonials and reports, they are very appreciative of such learning environment [11]. College major choices of LYCEE participants were evaluated using a sample of 44 students who had made a college decision and had chosen a major (see Table 3). Out of 44 students, 36 (81.8%) had chosen a STEM major. Many students who attended LYCEE since Spring 2009 are still high school students and are not in the position where they can make a college major choice.

The evaluation of existing practices is not complete. In the future, in the process of implementing H-LYCEE and as more quantitative and qualitative data is acquired, we will be able to further analyze the Center's impact on college/major

choice of its participants while working on developing an efficient tracking system that will enable us to track H-LYCEE HS participants all the way to college. The project evaluation (internal and external) will employ a mixed methods approach to examine its implementation, effectiveness, and impacts. The formative and summative evaluations will capture participants' interest, engagement, and motivation.

TABLE I. MAJOR CHOICES OF LYCEE PARTICIPANTS

| Major | Number of Students |
|--------------|--------------------|
| Business | 5 |
| Engineering | 26 |
| Liberal Arts | 2 |
| Math | 1 |
| Nursing | 1 |
| Science | 9 |
| TOTAL | 44 |

IV. IMPACTS. BENEFITS.

The broader impacts of the project are multi-faceted. The proposed multi-strategy model can be duplicated for any higher education institution to facilitate STEM in general and, in particular, make engineering education accessible to as many HS students as possible. Thus, the audience that would be interested in the model is broad. The H-LYCEE will maintain, operate, and modernize shared education infrastructure and ensure that multi-user facilities serve as sites of mentoring for large numbers of underrepresented students from different racial, ethnic, and educational backgrounds. The online component would make it possible to extend the students' participation via newly created network and, thus, will enhance and further promote STEM education. The project's broader impact does not only involve immediate impact on participants but also leads to long-term outcomes. The strategy, by its design, advances discovery and understanding while promoting teaching, training, and learning. H-LYCEE can be seen as a learning/educational research laboratory contributing to the knowledge base about STEM by investigating what strategies (or combination of what strategies) will best support student development for the STEM workforce of the future. It would provide the research foundation that would feed inventive practices and, simultaneously evaluate new practices supporting the research. The results and outcomes of all activities will be disseminated broadly to enhance scientific and technological understanding. The current research and practices are in progress and have not been widely tested.

The proposed multi-strategy model is addressing a problem of growing demand for STEM professionals in the United States. The potential national benefits of the model can be found on a variety of levels; namely they can be seen through the chain starting from individual, going through the community, and expanding to the whole society.

Work in Progress: Incorporating an Open-ended Systems Engineering Project in a Minority Middle School Outreach Program

Dr. Carl White
School of Engineering
Morgan State University
Baltimore, United States

Clifton Martin, Givon Forbes
Innovative STEM Foundation (ISF)
Baltimore, United States

Abstract--Cultivating Adolescents in Systems engineering Habits (CASH) is an innovative STEM (science, technology, engineering, and mathematics) summer experience designed for middle school students (Grades 6-8). CASH participants are composed primarily of students from minority groups historically underrepresented in STEM fields. The main program goal is to stimulate and sustain interest in STEM majors and careers for these students. In CASH, participants are placed in a student-centered learning environment where they are given course instruction in several subject areas, such as math, engineering, financial literacy, in an effort to enrich them mainly with systems engineering basics and other concepts like research fundamentals, critical thinking principles, and team working skills.

For the program's first three years, projects given were devised to illustrate the fundamental concepts that were being imparted on students. This paper will examine the efforts being made to develop and incorporate an effective open-ended systems engineering-based project into CASH. The decision to do so was based on several reasons, such as the results of several studies that show that hands-on projects may be the best way to teach engineering concepts. In addition, the program's core subject of systems engineering is an interdisciplinary field that lends itself to a project that will incorporate the assorted topics that the students are taught in the program. Creating a culminating program project that is open-ended will allow participants to explore their imagination, utilize critical thinking principles and team working skills to creatively problem solve and present solutions for a challenge that require them to use the concepts they have learned during the program. This paper will explore CASH's history, its effectiveness, and its current status and development in constructing this new project for the program.

STEM industry is facing a diversity issue. Professionals in the STEM fields do not fully represent the variety of minority groups that exist in America. The CASH program was created in an effort to address these two challenges.

During the program, participants are placed in a student-centered learning environment and are given course instruction in math, financial literacy and the program's core area of systems engineering. Each day in the program is split into two sections-**Instruction** and **Lab**. The Instruction portion is delivered in a traditional classroom-setting and is the time period when the participants take the previously mentioned courses. Lab follows the Instruction portion, and begins after lunch. During this time, students work on hands-on projects in an out of the classroom learning environment. Since the summer of 2010, several of the projects featured have been based on NASA's Juno mission.

Juno is a five year cruise to the planet Jupiter, which was launched in August 2011. The mission is operated by NASA's Jet Propulsion Laboratory (NASA-JPL) in Pasadena, California. NASA-JPL has partnered with the CASH program for the past two years. They have provided CASH with solar-based and telecommunication-based projects centered on the Juno mission. This has given the program activities relevancy as they allow students to apply the lessons they are taught to real life experiences. The open-ended systems engineering project that will be developed and incorporated in the CASH program will also be based on the Juno mission.

I. INTRODUCTION

Cultivating Adolescents in Systems engineering Habits (CASH) is a summer program for middle school students (Grades 6-8). For the past three years, the program has been based in Baltimore City, Maryland and 100% of the participants to date have come from racial minority groups. The main program goal is to stimulate and sustain interest in STEM majors and careers, in hopes that these students will eventually join the nation's STEM pipeline and help to address the shortage that the country is currently facing. Additionally, the

II. CONTRIBUTION

CASH has proven to be highly effective in exposing and exciting participants about the world of STEM. However, each year the program is assessed and evaluated to identify which practices, projects, and methods can be improved or added. It has been decided that one of the more promising additions that can be made to the program would be to develop and incorporate a project that is open-ended and allow the participants to apply the system engineering concepts they learn throughout the program. In the development of this project, it was resolved that based on the research available a project would be compelling if it accomplished and contained the following objectives.

A. Open-Ended

An open-ended project will require students to explore their imagination, utilize critical thinking principles, and team working skills to creatively problem-solve. Projects and activities with pre-determined answers may serve to be more effective when dealing with a classful of students at different developmental levels and deadlines for class learning objectives. But a summer program that isn't constrained by those same requirements can be more conducive for projects that are open-ended, and as such the new project developed will feature this.

B. Authentic Learning

Authentic learning aligns with research into the way the human mind turns information into useful, transferable knowledge [1]. Tying the course lessons in CASH to projects that are based on the real life Juno mission allows participants to see the relevance of the activities they are completing. George Siemens suggested that learning to be a STEM professional is helpful when forging concrete connections [2]. By giving students an authentic learning experience in the program, it will serve to be more effective in helping them to see themselves as potential STEM professionals and members of the country's STEM pipeline.

C. Hands-On

Hands-on projects are useful when attempting to retain students' interest in a subject. The project developed will be one that is heavily hands-on and will allow the students to have fun while completing the objective. There may be a need for students to complete research, in order to successfully devise solutions for the project. But it will primarily be hands-on, as research has shown it is more effective when trying to teach engineering.

III. PROJECT DESCRIPTION

Systems engineering is an interdisciplinary that lends itself extremely well to an open-ended project that incorporates all of the assorted lessons and topics that students learn in the program. When students engage in complex, multidisciplinary projects, they learn how to ask other experts for assistance and how to manage collaborative relationships [3]. The main systems engineering concepts stressed to participants in the program include the importance of working in teams, understanding external and internal effects of decisions, and the engineering design-making process.

The project implemented will be a culminating one as students will have been given the opportunity to gain enough knowledge to competently complete the project objective. The project will be centered on NASA's Juno mission and will be based on one major challenge that may occur in the duration of the mission. The program will work with NASA-JPL scientists and engineers to identify a real-life challenge that the mission is facing and develop a program project based on this information. This major challenge will be broken into smaller segments and will be assigned to the students who will be broken up into groups. Each group will have to accomplish their mini-objectives, while remaining cognizant of the major challenge, as they will all be required to integrate into one central project at the conclusion of the program.

Initial methods of assessment will include pre- and post-surveys and compared to previous year's results to identify the effect, if any project may have had in accomplishing the program's main objective of stimulating participant's interest in STEM. As there are not pre-determined answers to the project, evaluations will be based on the extent to which the solutions and projects submitted by the students accomplish the main objective, individual team objectives, and integrate with other groups.

Work in Progress: Developing Engineering Systems Thinking through the Modeling of a Complex Bioengineering System

Christina Foster, Monica Crowder, Katherine Nelson, Tirupalavanam Ganesh

Arizona State University, cnhobson@asu.edu, mcrowd@kyrene.org, kmuto@asu.edu, tganesh@innovatek12.org

Abstract— Systems thinking is an important habit of mind that should be promoted in K-12 engineering education. This work in progress paper describes how systems thinking was introduced in middle school grades through the modeling of a biological system: the artificial heart. Preliminary qualitative results show that introducing systems thinking through modeling is both feasible and useful. Students demonstrated their knowledge of the heart as a system through the structural, functional, and behavioral components of their models.

Index Terms—K-12 engineering education, systems thinking

I. INTRODUCTION

The National Academy of Engineering [1] called for engineering education to promote the engineering habits of mind as essential skills needed for the 21st century. Systems thinking is an important habit of mind that enables students to recognize and think about the interconnectedness between parts of a system [1]. Most engineering design work represents a system or is part of a larger system, and as such, engineers must effectively be able to understand how systems work, how the parts are related, and what factors influence them. Thus, it is important that K-12 engineering education support students in developing systems thinking. The purpose of this effort is to determine ways to introduce systems thinking and effectively teach the content in a middle-school engineering curriculum. Modeling is one type of method used to understand a system and demonstrate systems thinking. Bioengineering provides useful inspiration for teaching modeling through systems thinking due to the complexity of the human body and designed engineering products that interact with it. Using the lens of design-based research methods and drawing upon the work of Hmelo-Silver and Kolodner [2,3], a systems thinking learning experience was developed to teach middle school students how to use engineering systems thinking by modeling a bioengineering complex system: the artificial heart. We describe the methods, outcomes, and challenges of the first design iteration of a design research methodology, in which a learning trajectory towards systems thinking and the support curriculum will be documented and analyzed. In subsequent design iterations we will revise, test, analyze, and modify our curricula based on data collected from multiple perspectives, that of the researchers, teachers, and students. The ultimate goal is to have a domain-specific, instructional theory for teaching systems thinking in a middle school classroom.

II. METHOD

22 (grades 6, 7, & 8) students applied and were accepted to participate in the systems thinking learning experience, entitled *Bioengineering: Design an Artificial Heart*. Arizona State University's Citizen Scientist-Engineering project listed this learning experience under their after-school course offerings, selected a local school from one of their partner school districts, and managed all student applications. Students were encouraged to come explore the complexity of a biological system, the human heart, by designing and building a model of an important bioengineering technology: the artificial heart. The program met once a week after school for 90 minutes for 10 sessions, with 2 additional optional sessions. The program was structured under the context of a design challenge that communicated the need for socially conscious entrepreneurial biomedical engineers (i.e. the students) to design a practical artificial heart and build a model of some piece of the design. Session 1 was designed to introduce students to each other through an activity where each student had a different part of a biological system taped to their back and other students gave the student hints until she/he ascertained the biological part labeled on her/his back. Session 1 also introduced students to the process of documentation in an engineering notebook and using personal sized whiteboards with markers/dry erasers to present their daily progress on the design challenge. During session 2, the design challenge was announced. The design challenge approach is beneficial to systems thinking because it plunges students into thinking about the system of the heart, as they are required to not only construct the structural components of the heart but also implement the more complex functional and behavioral aspects of the heart. The inherent iterative nature of engineering design also encourages students to reflect upon the heart as a system and then revise their models accordingly. Throughout the process, students were asked to use their engineering notebooks to describe and predict their models' structures, functions, and behaviors. At the end of each session, students were also asked to present their daily progress to the class on whiteboards. The researcher served as the classroom teacher and served as a facilitator of learning. The researcher/ teacher aided the students in identifying the problem through the design challenge, gathering information on the heart through books, hands-on heart models, and internet resources, guiding the students through imagining solutions and selecting a feasible solution, and managing the

students' progress in planning, building, and testing their models. Students worked in groups of two to three. The class was provided with an assorted mix of recyclables, such as bottles and containers, and materials from the home improvement store, including paint sticks, plastic tubing, and syringes, to design and construct the designs of their models. In session 3, students modeled the pumping action of a heart using siphon pumps and containers of "blood" and, in session 4, students modeled the one-way valve function of the heart using plastic gloves and tubing. These activities were used to demonstrate modeling techniques and provide tangible experiences with the functions and behaviors of the heart. This experience was used to demonstrate how students' increasing knowledge of the heart's structures, functions, and behaviors can be transferred to inspire design ideas for an artificial heart. In session 5, students continued to imagine solutions for their artificial heart and select a feasible solution. Over sessions 6-10, students planned, constructed, tested, and revised their models.

III. OUTCOMES AND FUTURE STEPS

Student groups had various foci in their approaches to designing and constructing an artificial heart. Some student groups focused on the valve function of the heart, while others focused on the pumping action. Of the nine student groups, six groups primarily focused on the structural components of the heart. These groups planned and constructed appearance-based models that had four chambers and other structural elements similar to the heart. The groups constructed components that represented the one-way valves and double pump of the heart, but these components did not necessarily function or behave as they were intended. Students in these groups gave consideration to the heart as a system with integrated parts, but only at a high level. During the design sessions, Jackie (grade 6) and Evan (grade 7), brainstormed how they would design the four chambers of the heart with the materials on hand. Jackie and Evan focused their discussions on selecting the materials that would help them simulate the ventricles and atria to hold and release blood and also to compress and expand. The one-way valves were a later consideration for Jackie and Evan, and were added in the passage ways between the atria and ventricles with little flaps made of duct tape. During the last design session, Jackie and Evan began to discuss the functionality of their design and how they would achieve the behaviors of the heart. Jackie proposed a question: how would they propel the blood from the left and right atria to the corresponding left and right ventricles to simulate how the right and left sides of the heart work in series. Jackie and Evan decided quickly that each of them would manually be in charge of a side of the heart and would forcefully compress the atria in sequence. The other five groups that created appearance-based models of an artificial heart were also primarily grade 6 and 7 students. The three groups of grade 8 students created more complex designs, including a design made by two male students that used basic circuits knowledge

to construct an operable motor-driven rotary pump. Another student group of three female grade 8 students designed an inertia-driven pump with an accordion-style pipe that functioned as a single pump. Grade 8 students gave more focus to one specific part of the system, such as a mechanism for moving blood through the heart. Their conversations early on in the design sessions focused on the behaviors of the heart, such as circulating blood through parts of the heart. These groups did not give consideration to the materials available until after their first design plan was completed. The three grade 8 groups revised their designs after seeing what materials were available. Two of the three groups sacrificed their original plan to have a motor-driven function and replaced this with materials that required transfer of energy by human force. Throughout the systems thinking learning experience, all class sessions were tape-recorded and, as preliminary assessment, students were qualitatively assessed through observation and interviews. With the exception of three students, the class began the program with limited knowledge of pumps and valves, and of the heart. Even though the human body is part of middle school science curriculum, these students did not learn about the heart in their science classes due to time constraints in their classrooms.

For the next design iteration of this systems thinking learning experience, ways to guide students to consider the structural, functional, and behavioral aspects of the heart will be modified. Students should be guided to integrate their growing knowledge of the heart as a system into their models, which includes the multiple parts of the heart and its interactions. Further, requirements for the models will need to be of appropriate complexity for the student's knowledge. Students will need to be given the opportunity for multiple iterations to design and re-design their models and to reflect on the parts and interconnectedness of the heart system. In the first design iteration, ten sessions led to a packed curriculum. For this reason, two additional, optional sessions were added. In the future, time constraints will have to be more carefully considered. Finally, even though the hands-on nature of the design process as well as the context of the design challenge was motivating to the students, the scope and broadness of the project was large. The learning experience will need to balance the opportunity for creativity and systematic exploration of the heart as a system.

Abstract—This paper presents preliminary results of implementing the *Grand Challenges for Engineering* (GCE) modules in math and science courses in 6 Wisconsin middle schools. Sponsored by the National Science Foundation (NSF), this project was designed to increase students' understanding of engineering careers and their appreciation for the societal impact that engineering can have. Preliminary results suggest gender differences in whether math and science are seen as male domains and in the types of work values endorsed.

Keywords—middle school; STEM; Grand Challenges; engineering education; program evaluation

I. INTRODUCTION

Fourteen *Grand Challenges for Engineering* (GCE) were identified by the National Academy of Engineering (NAE) [1]. These grand challenges highlight the needs of both local and global societies for which engineering will need to furnish answers. Themes include topics such as energy, health care, infrastructure, and safe food and water supplies.

Middle school is a critical juncture during which many students begin to seriously consider career options. Attitudes about self and the world of work that are held during this middle school period form the foundational belief system from which students draw to set career goals for themselves and to choose high school courses and activities. Evidence suggests that an emphasis on STEM activities with middle school students can have a profound impact on students' motivation and interest to pursue careers in STEM related fields later in life [2, 3]. However, a survey from the American Council of Engineering (ACE) [1] indicated that an emphasis on "math and science" can be perceived by middle school students as intimidating and may discourage students from pursuing engineering as their future career. An emphasis on the societal impact that engineers can have may interest a more diverse group of students, especially women, to pursue career in STEM related fields.

The NSF's Innovative Technology Experiences for Students and Teachers (ITEST) program provided the opportunity to implement innovative curricular modules in middle schools to support students' development in STEM and to promote students' self-efficacy and interests in engineering related fields [4]. The preliminary results presented in this paper are based on the baseline data collected prior to the

implementation of two GCE instructional modules for middle school math and science classes.

This paper has three broad foci: 1) to describe the research methods used to examine the impact that inclusion of the GCE content into math and science courses has on student outcomes, 2) to describe the research methods used to examine the impact that using the GCE curricula has on teachers' practices and attitudes, and 3) to report results of the baseline data collection completed with middle school youth.

II. STUDENT MEASURES

A pre/post, comparison group design is being used to examine student level data. We are examining whether students in the GCE curriculum infused math and science courses: 1) report higher levels of STEM interests, 2) report higher math and science self-efficacy and outcomes expectations, 3) report higher beliefs in the egalitarian nature and utility of engineering careers, and 4) endorse different occupational values. Gender, race/ethnicity, and socioeconomic status will be considered as we examine our student data.

Student participants will be asked to complete 4 surveys that measure experiences in school, and opinions and attitudes toward math, science, and engineering. Students will be asked to complete the 1) Middle School Self-Efficacy Scale [3], 2) the Modified Fennema-Sherman Attitude Scale for Math and Science [5], 3) the Occupational Values Scale [6], and 4) the Personal Globe Inventory [7].

The Middle School Self-Efficacy Scale assesses a student's self-efficacy, outcome expectancies, intentions, and goals in the areas of career-decision making and math and science. The Modified Fennema-Sherman Attitude Scale assesses student's attitudes about egalitarianism, self-efficacy, utility of math and science, and perceptions of teacher support. The Occupational Values Scale assesses a student's preferences for occupational values, such as power, money, family, and altruism. The Personal Globe Inventory assesses students' interests in different careers and types of work.

III. SCHOOL STAFF MEASURES

The impact of participation with the GCE curricula on educators and schools will be measured by the school team members' perceptions of: 1) school-wide middle school innovative practices, 2) beliefs about STEM, 3) instructional and counseling practices in STEM, and 4) self-efficacy and

outcomes expectations among school team members for STEM instruction and counseling. School staff data is being collected in a pre/post-intervention, comparison group design.

Teachers will be asked to complete 1) a modified version of the Science Teaching Efficacy Beliefs Instrument [8], 2) the Engineering Education Beliefs and Expectations Instrument [9], and 3) the Teaching Design, Engineering, and Technology survey [10]. School counselors will be asked to complete 1) the Engineering Education Beliefs and Expectations Instrument - Counseling, and 2) the Teaching Design, Engineering, and Technology survey [10]. School administrators will complete 1) the School-Wide Middle School Innovative Practices Survey [11] and 2) the Teaching Design, Engineering, and Technology survey [10]. These measures are being collected before and after training and implementation of the GCE curriculum modules.

Six middle schools (4 urban, 2 rural) in the Midwest are currently implementing our GCE modules in math and/or science classes. Student data has been collected from both student groups (GCE participating and non-participating students) prior to the GCE module implementation. Post GCE curriculum implementation data will be collected in late spring 2012. Similarly, school staff pre-test data was collected in late summer/early fall 2011 and post school staff testing will be done in June 2012. Normative group data collection for the school staff measures is ongoing and will be completed by the end of summer 2012.

IV. PRELIMINARY RESULTS

In spring 2011, initial baseline data were collected and preliminary analyses have since been completed. Two hundred and seventy-six eighth grade middle school students provided baseline data for this project. Students' responses on the Middle School Self-Efficacy Scale were ranked on a Likert-type scale, ranging from 1 (*strongly disagree*) to 5 (*strongly agree*) and resulted in average scores of 4.02 ($SD = .46$) for the Career Decision Making Self-Efficacy, 3.90 ($SD = .56$) for the Career Decision Making Outcome Expectance/Intentions and Goals, 3.72 ($SD = .59$) for the Math and Science Self-Efficacy, and 4.37 ($SD = .59$) for the Math and Science Expectancy/Intentions and Goals subscales..

Students' responses on the Modified Fennema-Sherman Attitude Scale were ranked on a Likert-type scale ranging from 1 (*strongly disagree*) to 5 (*strongly agree*) and resulted in average scores of 3.92 ($SD = .73$) for the Confidence in learning mathematics, 4.10 ($SD = .61$) for the Mathematics usefulness, 3.76 ($SD = .61$) for the Mathematics as a male domain, 3.64 ($SD = .55$) for the Perceptions of teachers with math, 3.74 ($SD = .62$) for Confidence in learning science, 3.59 ($SD = .59$) for the Science usefulness, 3.79 ($SD = .60$) for the Science as a male domain, 3.83 ($SD = .59$) for the Perceptions of teachers with science subscales.

Students' responses on the Occupational Values Scale were ranked on a Likert-type scale with responses ranging from 1 (not at all) to 4 (very much) and resulted in average scores of 3.08 ($SD = .64$) for the Male-typed/Power, 3.38 ($SD = .69$) for the Male-typed/Money, 3.14 ($SD = .71$) for the

Female-typed/Family, and 3.14 ($SD = .74$) for the Female-typed/Altruism subscales.

These analyses indicate that there are no gender differences in students' perceptions of teachers' attitudes and support, in their math/science self-efficacy, or in their math/science outcome expectations. They do, however, suggest that there are gender differences regarding students' perception of seeing math and science as a male domain ($t = 4.53, p < .05$), and students' occupational values of family ($t = 2.68, p < .05$) and altruism ($t = 3.32, p < .05$). These results suggest that girls hold stronger beliefs that math and science are male career domains and hold stronger occupational values that allow for cultivation of family and altruism in their future career compared to their male counterparts.

Post module implementation data will be collected in spring 2012. Two new modules will be implemented during the 2012-2013 academic year.

V. ACKNOWLEDGEMENTS

The authors thank Allen Phelps for his input during the early stages of project development.

Abstract—The National Academy of Engineering “Grand Challenges for Engineering” (GCE) initiative has inspired the introduction of humanitarian applications of engineering into middle school science and math classrooms. Two GCE case study instructional modules have been developed by an interdisciplinary research team and piloted at six participating middle schools during the 2011-12 school year. Each module employs realistic fictional scenarios to engage a broad spectrum of students through role-play as engineers. Students develop engineering skills by tackling specific problems inspired by societal needs. Relevant science and math content, based on state and national middle school standards, are embedded within the modules. Integration of engineering with science and math instruction is aligned with recommendations in the *Framework for National K-12 Science Standards*, recently published by the National Research Council. The pilot modules, “Improving Aging Infrastructure” and “Solar Energy,” were introduced to teachers at participating schools at a professional development workshop during Summer 2011. The success of this approach as a strategy to increase interest in STEM (science, technology, engineering and math) fields among all students, especially women and under-represented groups, is being evaluated through measurement of participating students’ attitudes toward math, science and STEM-related occupations.

Keywords—middle school; STEM; Grand Challenges; engineering education; national K-12 science standards; diversity

I. INTRODUCTION

The “Grand Challenges for Engineering” (GCE) effort at UW-Madison is a pilot project supported by the National Science Foundation (NSF) ITEST program, with the ultimate goal of increasing the representation of women and other

under-represented groups in college-level science, technology, engineering and math (STEM) programs. The innovative practices piloted in this project are two-fold: a) following the recommendations of the *Framework for National K-12 Science Standards* [1], engineering is integrated into core middle school science and math instruction, and b) the societal context of STEM fields is embedded into instructional case study modules through story lines inspired by the National Academy of Engineering (NAE) “*Grand Challenges for Engineering*” initiative [2].

By introducing engineering through the GCE modules in middle school science and math courses, we aim to increase student interest in subsequent high school courses in science, math and engineering design. We also seek to influence the perceptions of not only potential future engineers, but also their peers, teachers and counselors, all of whom influence career choice. In this way, successful implementation will strengthen support for consideration of STEM-related careers at participating schools, through an enhanced appreciation for the value of STEM skills in making a difference in a wide spectrum of societal challenges.

The GCE strategy is motivated in part by National Science Foundation (NSF) sponsored research showing that messaging about engineering, which often emphasizes a passion for math and science and the notion of a “challenge,” is not well aligned with key motivators for high school girls [3]. The data suggests that a focus on features of the engineering profession not widely emphasized, such as “making a difference in the world” and “creativity,” hold stronger appeal.

The research basis of this project lies in Social Cognitive Career Theory (SCCT) [4]. This theory provides the context

Supported by the National Science Foundation (award #DRL-1020126), the Young Scientists of America, and the Plexus Charitable Foundation.

for evaluating the impact of the GCE modules on participating students' sense of math/science self-efficacy and outcomes expectations, their attitudes towards math and science, and their interest in STEM-related occupations. Further, it explores the impact of teacher training in and use of the GCE modules on their teaching practices and their self-efficacy for teaching engineering content.

II. MODULE OVERVIEW

Two instructional modules have been developed to date, *Solar Energy* and *Improving Aging Infrastructure*, based on two of the fourteen "Grand Challenges for Engineering" topics identified by the NAE. Each two- to three-week-long module includes a fictional story line that builds on the GCE themes to illustrate humanitarian applications of engineering. Hands-on activities integrate engineering with underlying middle school science and math instructional standards in a logical way that highlights the connections between the disciplines, as illustrated by examples described below. The centerpieces of both modules are activities designed to build self-efficacy in engineering, science and math [5].

The *Solar Energy* module consists of two units on solar cooking and photovoltaics for lighting. In the solar cooking unit, students construct and test solar cookers built from cardboard boxes and aluminum foil. They next consider design modifications to optimize performance given operating constraints provided by pen pals who have requested their help in designing the cookers. The pen pals live in the fictional country of Aridia, in which cooking fuel is scarce due to a recent influx of refugees from a neighboring country.

Science and math concepts in the solar cooking module relate to properties of light and transfer of energy. Students consider the concentration of solar power as it relates to heating food in designing the reflective panels in the cookers, with activities including a hands-on demonstration of specular reflection. They also use published graphs of solar spectral intensity to estimate the power converted to heat by the cooker, and compare this to their own estimates of energy required to heat the food.

The *Infrastructure* module also consists of two units, which respectively address restoration of aging bridges and retrofitting buildings to withstand natural disasters. In the bridge restoration unit, students role-play as engineers, construct bridge models from blueprints and subsequently inspect the models for damage and repair as needed.

Many of the math and science concepts in this unit relate to the truss design of the model bridge. Mathematical concepts include geometric analysis of triangular substructures, such as the application of the Pythagorean theorem to determine lengths of elements in the model. Students also develop skill in proportional reasoning and unit conversions as they use the blueprints to accurately construct their model to the specified

dimensions. With its focus on load-bearing structures, mechanical forces, static equilibrium and strength of materials dominate the science content of this module.

In the capstone activity, community input from a diverse set of stakeholders is considered along side of technical constraints, highlighting trade-offs between repairing an existing bridge and rebuilding from scratch. This activity culminates with the composition of a recommendation written by student teams in the form of a letter to the fictional city council.

III. IMPLEMENTATION AND EXPECTED OUTCOMES

Six Wisconsin middle schools, with student populations representing a spectrum of ethnicities and income backgrounds, are implementing the first two GCE modules during the 2011-12 school year. A critical element of the curriculum development is the involvement of teachers at the partner schools. Participating teachers evaluated and tested draft curriculum materials at a four-day summer institute held on the UW campus in July 2011. Teacher professional development also included guidance in developing implementation plans, discussion of the upcoming national science standards, and an introduction to the NAE Grand Challenges initiative.

Following classroom implementation of the instructional modules, data collection at the end of the 2011-12 school year will be conducted to assess the impact of the GCE modules on student outcomes as well as teacher experience in implementing the modules. In addition, the feedback will form the basis for revisions to improve the modules in advance of a second round pilot during the 2012-13 school year.

ACKNOWLEDGMENT

The authors thank Kevin Anderson for his input during the early stages of module development.

Work in Progress: A comprehensive approach for mapping student's progress: Assessing student progress in freshman engineering

John W. Pritchard, Mani Mina, Anthony Moore
Iowa State University, johnp@iastate.edu, mmina@iastate.edu, awmoore@iastate.edu

Abstract – A new method of assessment is developed that comprehensively maps students' progress in a course. The technique involves the use of two grading rubrics measuring performance in technical and conceptual proficiency, respectively. With these rubrics, one can identify students' progress and learning more effectively and future activities can be adapted accordingly. This paper discusses the development of these rubrics, how to use them, how to interpret their results, and describes an experiment showing their effectiveness in a freshman engineering classroom.

Keywords – assessment, evaluation, learning verbalization, reflection, engineering education, mental representation.

I. INTRODUCTION

As educators, we strive to inspire and motivate students to be at their best. This is an ongoing challenge as each generation has brought different perspectives, and new sets of educational tools. It is our duty to facilitate a learning experience that promotes knowledge transfer, defined as “the ability to extend what has been learned in one context to new contexts” [1]. Such transfer of knowledge in problem solving is known as productive thinking [2]. In contrast, students who use reproductive thinking may be simply finding a solution through rote memorization, and trial and error. Good thinkers practice productive thinking and monitor their progress through metacognition. “Metacognitive approaches to instruction,” such as concept mapping as an assessment technique, “have been shown to increase the degree to which students will transfer knowledge to new situations without the need for explicit prompting.” [1]. Current assessment methods may not capture the desired deeper level (analysis, synthesis) thinking that happens through metacognition. Educators have put great effort in addressing these issues with combinations of related technical and conceptual questions [3]-[6]. However, there is still a need for a continuous, systematic mapping of student progress throughout the entirety of the course (especially for a technical course). In this paper, a method for providing this mapping is proposed.

Traditionally, educators assess student activities based on their correctness of the solutions and methodology. In some cases, problems that are both technical and conceptual are provided such that the educator can know if the student understands the theory and also apply it in a useful way. However, a single grade is given in the end, leaving no separation of technical and conceptual understanding from a grading perspective. It would be useful to provide a more comprehensive recording mechanism that can be applied to any engineering classroom and still achieve a more

TABLE I. TECHNICAL PROFICIENCY RUBRIC

| Technical | Rating | | |
|---|---|---|---|
| | <i>Competent (3)</i> | <i>Developing (2)</i> | <i>Unsatisfactory (1)</i> |
| Appropriate Use of Equations | Clear identification of correct equations | Some equations correct, but makes some mistakes | No idea of what equations to use, writes unrelated things |
| Correct application of the equations to the problem | Clearly puts the right numbers in the right places achieving the right answer | Some numbers put in the correct places, some are not, but may still get the right answer in the end | Majority of numbers are in the wrong places |
| Awareness of the validity of the solution | Clear, correct discussion of the answer | Discussion of the answer is present, but unclear | Lost, or intentionally provides no discussion |

TABLE II. CONCEPTUAL PROFICIENCY RUBRIC

| Conceptual | Rating | | |
|---|---|---|--|
| | <i>Competent (3)</i> | <i>Developing (2)</i> | <i>Unsatisfactory (1)</i> |
| Concept is clearly understood | Use of graphs, equations, process, etc. are sufficient, understandable, and correct | Correct graphs, equations, process, etc. are present but are not used correctly, coherently, etc. | No equations given, or incorrect graphs, equations, process, etc. They are also not used correctly, coherently, etc. |
| Connections between concepts and ideas are made | Demonstrates a valid connection between ideas and concepts | Understands connection with invalid argument, process, etc. | No connection between any concepts is made |
| The student communicates these ideas | Student communicates ideas effectively in sentence form | Communicates ideas but there are inconsistencies or are incorrect | No attempt or communication is incoherent or unrelated |

comprehensive understanding of the class' performance in both technical and conceptual problems.

II. RUBRICS

In order to demonstrate the idea, two rubrics are proposed (Table I and Table II) that are each applied to technical and conceptual problems. The rubrics consist of questions that help assess the student's performance in the problem and, based on their answer and approach, a rating is assigned. The sum of the technical rubric ratings for the technical problem and the sum of the conceptual rubric ratings for the conceptual problem will provide educators a good idea where the student may or may not need help.

These rubrics are most useful in informing instruction. The idea of measuring the technical and conceptual proficiencies

separately is not necessarily different or new. It is the use of these rubrics to accurately map the interconnection of information in a student's mind that give them their novelty. Rubrics commonly used in problem-based learning (PBL) are similar to that which we propose in this work. However, to accurately map a student's progress in an engineering environment, specificity is required. The rubrics proposed are tailored to engineering-type problems assuming a technical and conceptual component exist in the problem. Commonly used PBL rubrics do not separate these components with the intention of mapping cognition.

In addition, if used consistently throughout the student's college career, this rubric could be used in conjunction with the graduate attributes similar to those outlined in the Washington Accord to provide a full student profile showing term-by-term progression, providing a more complete portfolio of the student's work for optimum assessment.

III. EXPERIMENTATION

A. Test Setting

The proposed rubrics were used in an engineering classroom at Iowa State University. A quiz was given to about 130 students, 24 of which were chosen for grading at random. Each quiz consisted of two problems relating to complex numbers. The first question was a technical problem, asking students to determine polar coordinates in the complex plane from a set of rectangular coordinates. The second problem was conceptual, asking students to discuss what the relationship was between a polar coordinate and the complex exponential format, $e^{j\theta}$. An evaluator was then asked to use the rubrics in order to quickly assess the performance of the class from a technical and conceptual perspective. The technical rubric was used to evaluate the technical quiz question, and the conceptual rubric for the conceptual question.

A rating of 3 indicated the student was competent in that aspect of the rubric, a rating of 2 meant the student was developing, and 1 unsatisfactory. So, for the proposed rubrics, a score of 9 was possible for each quiz question, totaling in 18 possible for each quiz. The class technical and conceptual scores were averaged, and then represented as a percentage. In addition, the 9-point technical and 9-point conceptual scores were broken down into three sub-scores which could total in 3-points each. The class sub-score was then averaged, and the scores were represented as a percentage.

B. Results

With this particular problem and classroom, the rubric showed that the overall average score out of 18 points for the class was 87%. This is shown on the left of Figure 1. It was also found that students scored, on average, 94% on the technical question and 81% on the conceptual discussion. Therefore, it can be concluded at the very least that students in this class are generally able to obtain correct numerical results but are having difficulty discussing, recognizing, and justifying them.

Breaking the graded data down even further for the technical question, it was found that students were able, on average, to score a 97% on using equations appropriately, 96% on applying the equations correctly, and 88% on having an awareness of the validity of the solution. For the conceptual question, it was found, on average, that students were able to score a 94% on understanding the concept, 78% on being able to make connections between different concepts and ideas related to the problem, and 72% on being able to communicate these ideas. This is shown in the graph on the right of Figure 1. This information is interesting, but not particularly instrumental in the immediate future. However, it can facilitate finding the next steps to take to address learning issues or shortcomings.

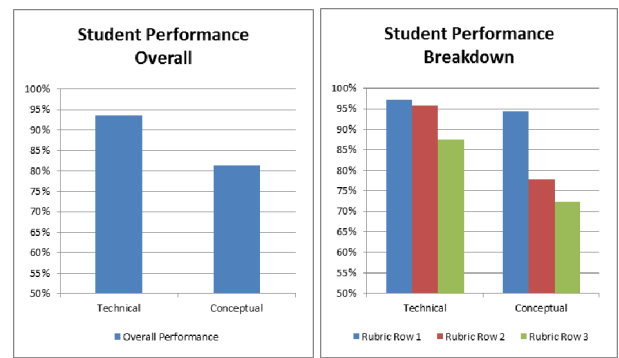

Figure 1: Graded results using rubric

C. Interpretation of Results

Based on the results discussed, it can be concluded that, when given a technical problem, the students in the classroom evaluated are able to recognize problems and solutions in numerical form but have difficulty validating their solution, connecting it to reality. Therefore, it may be useful in future activities to focus on the concepts and ideas and being able to communicate them.

It should be noted that the percent ratings are indeed used for tabulated grading purposes; however, to the ambitious educator these scores are simply indicators of what topics need to be stressed more or less in following assignments or lectures. Such results from these rubrics allow educators of any engineering course to quickly take the next steps to enhance and facilitate student learning. These rubrics together with more frequent small assessment strategies offer a continuum of evaluation and assessment, providing sufficient data that allows educators to adjust the course "live." In addition, the rubrics also provide thorough, detailed data that can be used for the mid- or end-course evaluations.

IV. CONCLUSION

A set of rubrics with new approach to evaluation were developed that enable educators to more effectively map student progress. It was shown the idea provides a valuable set of evaluating questions that accurately assesses how a student understands concepts. Also, the resulting data provides the necessary information for taking the next steps in the course. Preliminary experiments suggest that these rubrics are effective and useful in the engineering classroom.

This research was supported partially by National Science Foundation DUE0837314.

Abstract— In 2010 the Australian government commissioned the Australian Learning and Teaching Council (ALTC) to undertake a national project to facilitate disciplinary development of threshold learning standards. The aim was to lay the foundation for all higher education providers to demonstrate to the new national higher education regulator, the Tertiary Education Quality and Standards Agency (TEQSA), that graduates achieved or exceeded minimum academic standards. Through a yearlong consultative process, representatives of employers, professional bodies, academics and students, developed learning standards applying to any Australian higher education provider.

Willey and Gardner reported using a software tool, SPARK^{PLUS}, in calibrating academic standards amongst teaching staff in large classes. In this paper, we investigate the effectiveness of this technology to promote calibrated understandings with the national accounting learning standards.

We found that integrating the software with a purposely designed activity provided significant efficiencies in calibrating understandings about learning standards, developed expertise and a better understanding of what is required to meet these standards and how best to demonstrate them. The software and supporting calibration and assessment process can be adopted by other disciplines, including engineering, seeking to provide direct evidence about performance against learning standards.

Keywords- academic standards; benchmarking; peer review; self and peer assessment

I. INTRODUCTION

This paper aims to describe the potential benefits of calibrating understandings about academic standards using collaborative conversations around assessment artefacts and supported by online self and peer assessment technology. The motivation for this research is the international trends for greater provider accountability to funders, accrediting authorities and agencies at state, professional and international

levels as custodians of standards, and employers and graduates as consumers. Without appropriate consensus and calibration around the meaning of minimum standards of graduates' learning, it will be difficult to assure these stakeholders that assessment has been valid and reliable.

II. LITERATURE REVIEW

The academic assessment community has been concerned about practice for some time. Recently forty academic experts proposed six tenets for change in the *Assessment Manifesto* [1]. Tenet 2 urged a move towards the valid assessment of the achievement of intended program learning outcomes because of the problems that arise from the current focus on marks and grades and outcomes at the individual unit of study level [2]. Another set of concerns arises from the local and disciplinary focus on standards [3],[4]: that standards are imprecise and rely on individual professional judgments [5], resulting in variability across regions, subjects and even types of assessment leading to reduced credibility in standards [6],[7],[8],[9],[10],[11],[12],[13],[14],[15]. Tenet 6 of *Assessment Manifesto* [1] advocates the establishment of appropriate forums for the development and sharing of standards across multiple communities.

Assessment is largely dependent upon professional judgement and confidence in such judgement requires the establishment of appropriate forums for the development and sharing of standards within and between disciplinary and professional communities.

Such an approach stands in stark contrast to existing national approaches. The most notable example is in the UK where over 70 disciplinary benchmark statements exist under the auspices of the Quality Assurance Agency (QAA) each containing a list of typical and threshold learning outcomes graduates might achieve. In that approach an external examiner reviews disciplinary intended syllabi, learning

outcomes and assessments at the unit of study level. In theory external examiners review outcomes against QAA benchmark statements and professional body requirements. The QAA found however most examiners assumed that their use was in curriculum planning “and merited little further attention”. Importantly an external examiner is not randomly selected and the scope of their review is limited to an individual provider. Given the latter, it is no surprise that following a major review by Burgess [16], the QAA admitted that despite all of its efforts:

it cannot be assumed students graduating with the same classified degree from different institutions, having studied different subjects, will have achieved similar standards; ... and it cannot be assumed students graduating with the same classified degree from different institutions, having studied the same subject, will have achieved similar standards [17].

Vygotsky [18] and Nonaka [19] found that shared experiences with observation, imitation and practice induce tacit knowledge to be made explicit. Deep shared understandings of assessment standards applied to high-level complex learning requires active engagement of members of the disciplinary community in the assessment of artifacts to identify those standards. Price *et al.* note that cultivating a community where dialogue, trust and participatory relationships can occur should result in more consistent judgements and a restoration of confidence [1].

Emulating trends in primary and secondary education with the PISA project [20], some are calling for standardized tests as an alternative option for tracking and benchmarking higher education learning standards. The *Collegiate Learning Assessment* (CLA), which purports to measure generic graduate outcomes, is gaining traction in the USA’s Voluntary System of Accountability. It is also being used in the OECD’s *Assessment of Higher Education Learning Outcomes* international benchmarking project and will be one performance indicator in Australia’s publically funded university agreements with the Australian government. However, standardized tests have their own perverse problems as evidenced in the Australian primary and secondary school systems; for example, teaching to the test and gaming strategies [21].

III. CONTEXT

Concerns about academic standards of graduates are not new amongst employers. For example in engineering a number of researchers and government-sponsored reports [22],[23],[24],[25] discuss a gap between the skills typically developed in engineering education and a range of skills required for professional practice. Similarly, in accounting, employers have expressed concerns about the standards of accounting graduates, particularly in relation to their employability skills [26],[27].

Recently the Australian government has made changes to the higher education sector to improve national productivity from 2012. An expanded, more inclusive and demand-driven higher education system has been complemented by the establishment of TEQSA, a stronger centralized outcomes-

based regulator. Of the five standards domains, namely Provider, Qualifications, Teaching and Learning, Research and Information, the first two have mandatory or threshold status TEQSA [28]. Provider accountability for academic standards is specifically mentioned in the new system:

The academic standards intended to be achieved by students and the standards actually achieved by students in the course of study are benchmarked against similar accredited courses of study offered by other higher education providers.

In preparation for TEQSA’s role of assuring the quality of academic standards at the discipline level, the ALTC led a project over 2010-2011 where 9 disciplinary groups including engineering established threshold learning standards. As the demonstration discipline for business, management and economics, stakeholders in accounting higher education collaboratively agreed a set of five learning outcomes considered thresholds for Australian graduates of accounting bachelor degrees and another set for coursework master degrees. Some 2,100 people were engaged representing 38 Australian universities, 21 private and other providers, and 20 other key stakeholders including professional and peak bodies. Following endorsement by the Accounting Expert Advisory Group and the Australian Business Deans Council (ABDC), *Learning and Teaching Academic Standards for Accounting* was published by the ALTC in March 2011. In addition the ABDC decided to sponsor a pilot project to obtain external blind peer review evidence of achievement benchmarked against the learning standards. The two major Australian professional accounting bodies subsequently agreed to jointly fund the project and the peak academic association agreed to play a key support role in the external peer review process. Further funding was subsequently obtained from the ALTC to allow the project to expand to all other public and private providers of accounting coursework degrees.

IV. PROJECT

The project compares and evaluates assessment outputs for students in their final year and also the validity of the related assessment inputs (i.e. assessment requirements) and outputs. Each of the accounting departments in ten universities provides two senior academics as external peer reviewers. In addition, professional bodies sourced a range of practising professional accountants.

Underpinning the project methodology is the concept of a ‘cultivated community of practice’ model, put forward by O’Donovan et al. [29] for managing change in assessment in higher education following the 2008 *Assessment Manifesto*. It builds on the communities of practice approach to change [30] and the social constructivism approach to developing students’ understandings about assessment standards [31]. The underlying imperative is that participating professional and academic reviewers need to have collaborative conversations both pre-review (e.g., for training and moderation) and post-review (e.g., for clarifying assessment variances and identifying improvements) to ensure that reviewers are grading to the same standard.

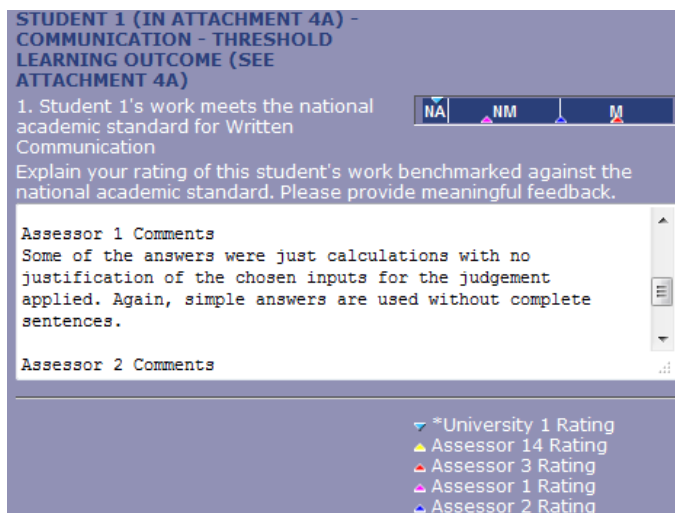

Figure 1: SPARK^{PLUS} results screen showing ratings and explanations of an example student's work.

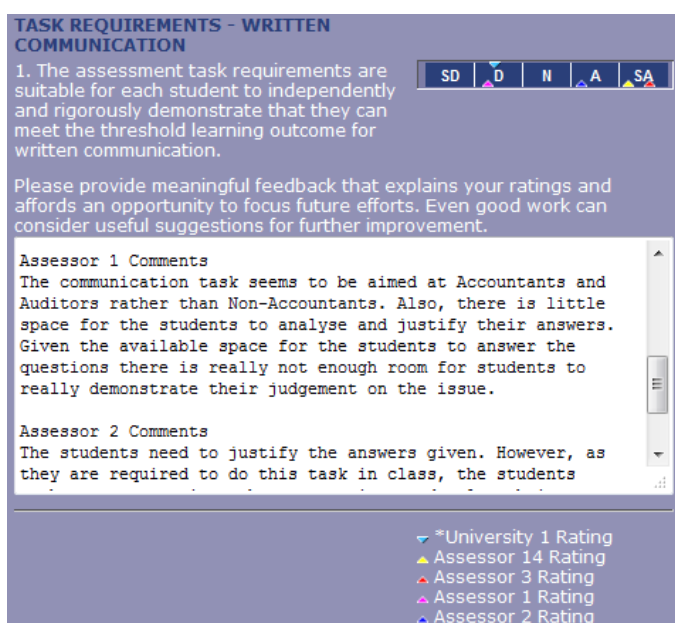

Figure 2: SPARK^{PLUS} results screen showing assessment task validity ratings and explanations.

The calibration process contains two phases. The first phase comprises remote peer assessment where each reviewer independently assesses the sample student work as meeting or not meeting the national standard (see Figure 1), and also assesses whether the task is valid (strongly disagree, disagree, neutral, agree, agree) for students to demonstrate achievement of the standard (see Figure 2). In a process similar to that reported by Willey and Gardner [32-34] reviewers use SPARK^{PLUS} (Self and Peer Assessment Resource Kit), an online tool to submit before the workshop (individual pre-work) both the ratings for the sample work and assessment task (e.g., meeting or not meeting) and importantly the rationale for the rating. Consistent with Dahlgren [35], there are two broad categories (met or not met), but reviewers can actually grade along a continuum within the two categories. The software features can be set to require reviewers to submit a minimum

explanation (e.g. 10 words) to explain their rating – this feature has been utilized as it was found to improve the quality of assessors' feedback. The second phase is a face-to-face workshop where conveners facilitate participants to reach consensus on the standard. The independent peer reviews published on SPARK^{PLUS} are made available to enable reviewers to anonymously compare and interrogate ratings and related reasons. Participants work in small groups discussing each sample sequentially against the reviewing criteria. This allows individuals the opportunity to learn from their peers' justifications before reaching consensus with the whole group of academic and professional reviewers. Near the end of the workshop new samples are introduced and considered in order to confirm that understandings have been calibrated.

This paper focuses on the effectiveness of the technology in improving peer review and collaborative conversations to benchmark academic standards.

V. RESEARCH METHOD

Two survey instruments and convener observations from the workshop were used to collect research data from participants. The first survey was conducted online at the end of phase 1 prior to the calibration workshop (n=20) focusing on the standard or threshold learning outcome (TLO) for written communication where bachelor level graduates are required to "justify and communicate accounting advice and ideas in straightforward collaborative contexts involving both accountants and non-accountants".

The second survey was conducted on paper at the completion of the face-to-face workshop. Twenty senior experienced academic reviewers participated in the activity. Participants were asked a range of questions about their experience of engaging with and interpreting the national learning standards. Eight statements were rated using a continuous scale categorized under five headings (i.e., strongly disagree, disagree, neutral, agree and strongly agree). Participants were also invited to provide free-response comments for a further three questions. However, in this paper we report the research directly associated with the use of technology in the process.

VI. RESULTS / DISCUSSION

The advantage of using an online tool for the pre-work activity (phase 1) is that it required participants to commit their judgement and not be influenced by others. It allowed reviewers to easily readjust their ratings if required at any time during the assessment pre-work period. In addition, the availability of the continuous scale on which sliders could be adjusted and the requirement to provide explanations provided peer reviewers with the opportunity to make fine distinctions. This allowed them to reflect on their initial judgment and assisted them to turn their tacit understanding into explicit descriptions. Consequently, phase 2 workshop discussions were both fruitful, efficient, informed, targeted and covered a range of views. The pre-work activity alone resulted in approximately a third of participants agreeing that it changed their understanding of the two academic standards considered; namely, judgment (30%, Figure 3) and written communication (35%, Figure 4). It is of note that 35% and 45% for judgment

and written communication respectively provided a neutral response in relation to a changed understanding of the two academic standards. This may reflect the challenges associated with the project in working towards a shared understanding of academic standards. However, the vast majority of participants agreed that having to enter their pre-workshop ratings into SPARK^{PLUS} required them to both formalize (90%) and reflect (95%) on their reasons for their judgments (Figures 5 and 6). This finding provides evidence of the value of the technology in improving the quality of academic conversations to benchmark academic standards.

In addition, participants reported that *“the use of spark and subsequent moderation is an excellent learning experience (sic)”* and *“having to use spark made me reflect on my own judgement as well as articulate my reasoning”*.

Furthermore, participants reported that the pre-workshop activity *“provided a valuable opportunity to reflect upon one’s own criteria for assessing students’ work relative to the national thresholds”* and *“forced me to really reflect on what the learning standards mean. It also showed how much professional judgment is needed to assess these key areas and why we as a discipline need to desperately reach a shared understanding of what these standards mean”*.

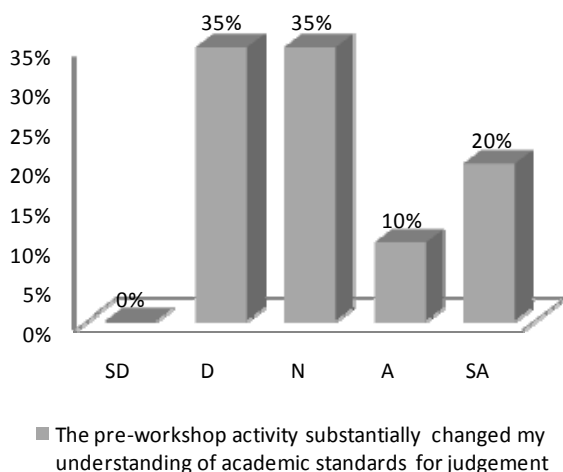

Figure 3: Peer assessors’ ratings of impact of pre-workshop activities on their understanding of the judgment learning threshold.

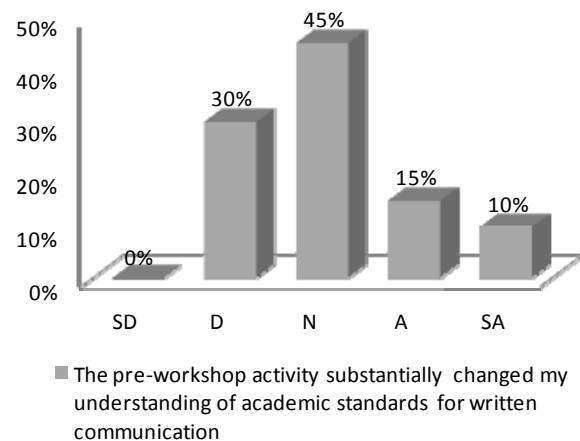

Figure 4: Peer assessors’ ratings of impact of pre-workshop activities on their understanding of the written communication learning threshold.

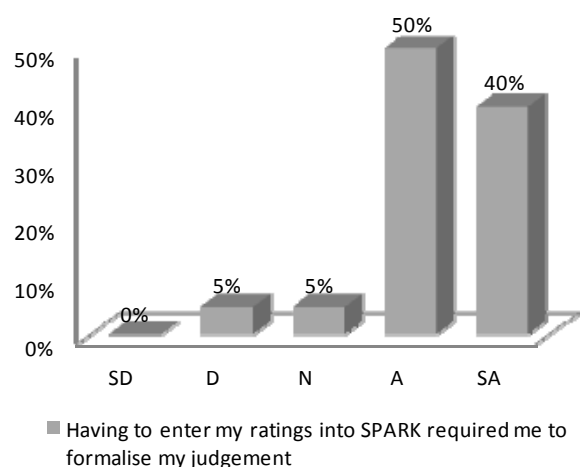

Figure 5: Peer assessors’ perceptions of the impact of SPARK^{PLUS} as a mechanism for formalizing their judgments.

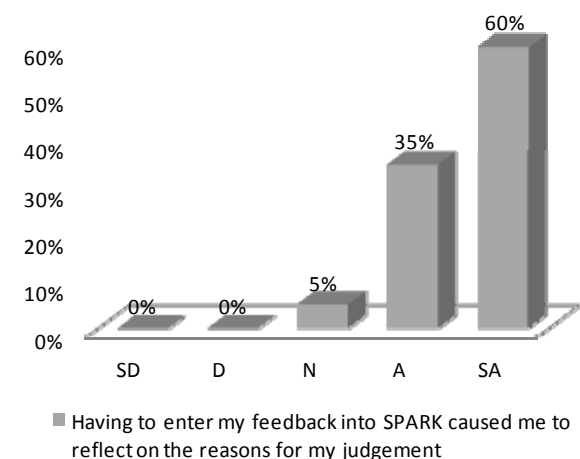

Figure 6: Peer assessors’ perceptions of the impact of SPARK^{PLUS} as a mechanism for forcing reflection about the reasons for their judgments.

A. Impact on activity conveners

Compared to a paper-based approach the conveners found that the automated data collation and ability of the software to present results to participants in an easily accessible form while maintaining their confidentiality provided considerable time efficiencies. Other software features could be leveraged because of this confidentiality: examples of pre-workshop systematic bias by individual reviewers could be easily identified by the software and used as the basis for workshop discussion to distinguish between local and national standards; pre-workshop examples showing considerable inconsistency between ratings and explanations could be easily identified and highlighted for whole group discussion. The software enabled the conveners to identify where there was greater diversity of views of peer reviewers and this information was valuable in planning the workshop activities. The conveners allowed more time for such areas such as assessment design in recognition that this was likely to be required to achieve a shared understanding by reviewers. Furthermore, the software's capacity to enable tasks to be easily cloned, manage groups and add or delete participants reduced the time to organize the initial and subsequent activities.

VII. REFLECTIONS / OBSERVATIONS

Participants indicated that the pre-work activity and workshop had initiated some change to their assessment practice as typified by the following free response comments:

The best aspects of the activity was ... in terms of coming to grips with what was actually in the TLO - much broader than I might have expected. Also there is a difference with what is required to meet assignment outcomes and what is required to meet the TLOs. This means that TLOs need to be given consideration in designing assessment items and in establishing marking criteria.*

The project offers an opportunity for quality enhancement in the setting of assessment tasks via reflecting on the purpose of the task and the design of the task.

[It forced me to] *"reconsider the basis for assessing student work"*.

Throughout the workshop the participants noticed that access to the range of opinions reported by SPARK^{PLUS} enabled areas of agreement and disagreement during group discussions to be quickly identified and understood. This in turn led to well-focused and better informed discussions and promoted consideration of all points of view, discouraging the group from being overtaken by groupthink or a dominant participant.

Conveners identified several improvements for future activities including:

- replacing the 5 category scale for judging assessment task validity with a 2-category scale (acceptable and not acceptable)
- more time was required to enable reviewers to articulate diverse tacit perspectives to adapt pre-existing, institutionally-centric views and calibrate to a national standard

- reviewing new samples was critical to confirming calibrated views
- workshop participation of two professionals was crucial to resolving expectations of standards
- allocating more time to participants identifying improvements in assessment task design would pay considerable dividends in validly and reliably evidencing standards
- While the first workshop was one half-day, subsequent workshops should be a full day and focus only on one standard instead of two and Masters level achievement of the same standard should be resolved before moving to the next learning standard.

The requirement for individuals to provide clearly articulate explanations for their ratings was crucial to the calibration process. It encouraged participants to view and interrogate others views prior to the workshop, allowing reflected perspectives to be voiced during the workshop, first in small groups and subsequently to reach a consensus prior to inter group consensus discussion.

VIII. CONCLUSION

Accounting is the first discipline in Australia seeking to collaboratively develop and implement a national model of expert peer review for benchmarking learning outcomes against nationally-agreed threshold learning standards. It aims to refine a model for assessing learning outcomes based on double-blind external peer review using experienced academics and practitioners as reviewers. Using online self and peer assessment software to complement face-to-face workshops, a process for calibrating reviewers' judgments ensures a process of assessment that is inclusive, efficient, and supports rich, reliable, and valid information. We report how the online self and peer assessment software assisted collaborative conversations and therefore calibrating judgments about standards. The software also facilitated collaborative conversation about assessment design thus promoting quality enhancements in assessment and therefore in curriculum renewal assessment.

SUMMARISE THE RESULTS AND WHAT WE FOUND

The use of SPARK^{PLUS} has been extremely valuable in the process of establishing a shared understanding and application of the accounting learning standards in Australia. The software allowed reviewers to complete the pre-workshop activities remotely and then to view the assessments and comments of others with anonymity. The use of the software provided results of the pre-workshop activity which allowed the conveners to structure the workshop to facilitate an efficient process for calibration of reviewers. The process was effective and efficient in promoting informed conversations between academics from 10 universities that resulted in an increased level of understanding about the two academic standards being assessed. This represents a substantial achievement.

There are several limitations in this paper. First, it involves a limited sample and reports only one instance of the pre-work and workshop activity. Second, it does not provide substantial confirmatory data following the calibration process to

demonstrate that the changed understandings are lasting. Third, while the free-response items asked respondents to describe changes arising from the project, it is an untested assumption that these arose from participating in workshops. However, it would be difficult to imagine how participants would otherwise have heard about them.

Notwithstanding these limitations, the entire process, incorporating sophisticated use of the software pre-workshop facilitated extensive face-to-face dialogue around specific assessment artifacts and greatly limited the potential hazard of groupthink. As other disciplines, including engineering set learning standards at either the national and increasingly international level, the use of SPARK^{PLUS} technology with the supported model process adopted in this project is ideal to sustain these activities.

Work in Progress: Engaging Faculty for Program Improvement via EvalTools®: a New Software Model

Mohammed Eltayeb¹, Mak Fong², Oguz Soysal³

^{1,3} Department of Physics and Engineering Frostburg State University,
Frostburg, MD, USA

²Electrical and Computer Engineering Department, Gannon University,
Erie, PA, USA

Abstract— In this paper we present our experiences with a new software-tool model for program assessment and evaluation, and engineering programs improvement in assessing learning effectiveness. In the past, the assessment plan was based on the typical practice of assigning a person in the department for overseeing the whole process. The non-collaborative evaluation that is managed by a single program leader is not effective and problematic. To involve more faculty and in an effort to prepare for the most recent ABET visit, we decided to adopt EvalTools® in fall of 2010. EvalTools® is designed and developed according to ABET standards to provide a mechanism for collecting and analyzing data about the program, students' performance and their learning achievements. In addition, EvalTools® is instrumental in providing a mechanism to simplify the process of inspecting the assessment results as well as identifies strengths and shortcomings of the program before ABET review. More importantly getting faculty members excited about results and involved in the process of program improvement is a major accomplishment. Our experience via first-time implementation of EvalTools® shows very useful results for this model that can be easily disseminated for various programs in various disciplines. In this paper we will show: process of best use of relevant features in aid of streamlining faculty's time in data collection as well as evaluation was achieved; our results and how we succeeded in improving our program quality in an effective, efficient and systematic way; that simple curriculum revisions for multiple programs as a result of using EvalTools® for programs under going ABET is possible; that capturing the process of effective trainings needed for faculty and staff in a simple manner; faculty's experience in a constructive and engaging manner.

Keywords- *Quality Assurance, ABET, Program Evaluation, EvalTools, Faculty Engagement*

I. INTRODUCTION

Engaging faculty in program improvement process is proven to be critical in reaching programs objectives more effectively. It holds the promise for overcoming many of the challenges relevant to the improvement process. Faculty engagement in the process helps keep attention focused on the ultimate purpose. It also results in outcomes that are directly connected to the daily activities of teaching by the faculty members and learning by the students. It is clear that programs improvement is “continuous efforts” that are most effective if

embedded in these daily activities. Majority of faculty members, if not all, would conceivably agree that “*there is always room for improvement*” at various levels. In fact, program improvement is usually attained naturally as faculty exercise simple routine and intuitive measures in their courses overtime. The problem lies in attempting to reach better qualities most effectively and to reach program objectives/goals most efficiently. Structured objective-driven program assessment lies in the heart of these challenges and endeavors. Assessment is, by far, considered by many faculty members as the least interesting of all activities despite the fact that its importance is well acknowledged. Multiple reasons contribute to this sentiment as pointed by the assessment professionals [1]. One main reason is that, assessment essentially is a lengthy process of data collection, organization, sorting, and filtering. The lack of faculty time in most cases constitutes a major hurdle in the instrumentation of a rigorous and detailed assessment method. The lack of expertise in assessment planning and execution is also pointed out by many as another reason. However, the main contribution to problem from the side of many faculty members is the isolation between data collection and the immediate benefit of that on class improvement and student learning. It is clear that engaging in activities of planning, data collection and data analysis is time consuming for the faculty member as well as department assessment leader. It is also argued that the usual assessment process is a “gamble” as it is not clear how to relate or pinpoint the effect of the gathered evidence on a specific learning outcome. In [1] the authors reached a conclusion that the best result in assessment is achieved by implementing a department-level process. They created a model by which responsibility of assessment is assigned to faculty members with encouraging factors.

In this paper we show that simple and clear model based on a simplified software-assisted process can yield better result for program improvement in general. It can also excite faculty members to engage in decision-making at various levels in the process. The software tool, EvalTools® [2], is a comprehensive software tool that allows for many functionalities ranging from course development and management to various assessment and evaluation practices. It symmetrically streamlines the process of data collection process and presents the results readily for assessing teaching effectiveness in meeting course outcomes as well as student outcomes. EvalTools® is designed based on ABET accreditation standards [3] for engineering programs which makes it easy to deal with for that purpose. Aside from ABET

injunction, we saw great improvement in our faculty perceptions towards program assessment when we applied EvalTools®. The software alleviated the burden of planning and provided a clear process that can be geared towards program specific structure and needs.

The paper is organized as follows: at first we present a brief background about our program and our department. Then we provide a general description of EvalTools® outlining its main features that we used in preparation for our accreditation visit in 2011 for the Mechanical Engineering program. We then explain our assessment plan and how EvalTools® was instrumental in capturing our students learning attainment addressed by ABET. It is imperative to mention that the faculty engagement was also quite instrumental not only in executing the assessment plan but also in improving the program. The tool made it easy, in a relatively short term, to see the benefits of the old assessment data which kept faculty excited and awaiting the new set of data.

II. BACKGROUND OF FSU PROGRAMS

Frostburg State University (FSU) has been providing higher education opportunity to Western Maryland since 1898. In spring 1994, FSU and University of Maryland at College Park (UMCP) began planning collaborative programs in Electrical Engineering (EE) and Mechanical Engineering (ME) on the FSU campus. The programs are provided in the department of Physics and Engineering at FSU. The goal of the project was to establish a national model by offering engineering education in a rural area, with access to the resources of a large metropolitan university over distance. The first students were admitted to the program in fall 1997, and the first group of students graduated from EE and ME programs in spring 2001.

The department of Physics and Engineering also offers a BS degree awarding program in General Engineering from FSU with four concentrations: Electrical Engineering, Material Engineering, Engineering Management and Industrial Chemistry. This program started in fall 2008 as a replacement for the collaborative EE major. While the collaborative EE program experienced enrolment decline following the national trends, the collaborative ME program was steadily on the rise. Our focus in this paper is on the experience acquired during the ABET accreditation efforts for the collaborative ME program. This collaboration model developed by FSU and UMCP is a unique one that showed great success in meeting its objectives. Advantages and limitations of the developed collaborative engineering programs based on the structure of the curriculum, available facilities, assessment results, and alumni feedback in their initial phase were reported at the American Society for Engineering Education Zone I Conference [4-5].

Faculty Involvement:

In the past one faculty member was in charge of the activities of implementing the assessment. A plan for assessment was created to meet ABET accreditation criterion. The plan was based on the typical practice of assigning a person (faculty member or staff) in the department for

overseeing the whole process. Although the plan was greatly simplified to take advantage of data related to students' performance (exams, assignments, etc) and graduates attainment of program objectives, the plan did not succeed in identifying and executing particular action-items related to the findings of the assessment process. Perhaps because these typical methods are, often unclear, cumbersome, un-scalable, seasonal (whenever ABET review date is approaching), highly contingent (if ABET department coordinator disappears, the plan stops), or most importantly, perceived as non-beneficent. We researched the aforementioned problem and reached the following two conclusions: 1) faculty members committed to quality education would individually or collectively adopt and apply any method if it shows clear direct impact on students' performance in their class. Two, those faculty members will embrace such a method if it was simple, non-time consuming and sufficient training is provided.

The software tool described below satisfies these aforementioned conditions.

III. EVALTOOLS® SOFTWARE

EvalTools® – an online program assessment toolset – that replaces the functionality of Blackboard® for daily classroom lesson and assignment activities; additionally, it tracks key assignments which are automatically ported into the appropriate Faculty Course Assessment Report (FCAR) [6] document for evaluation purposes. EvalTools® integrates best assessment practices into its features. In particular, EvalTools® uses a performance vector that classifies student learning performance into four categories: Excellent (E), Adequate (A), Minimal (M), and Unsatisfactory (U), which form the EAMU performance vector [6-7]. The results are flagged with different colors according to heuristic rules which indicate academic status. The performance vectors are collected from a matrix of selected courses for particular student outcomes; the resulting performance vector table illustrates the areas of strength, weakness, and concern. The computation and tabulation of EAMU performance vectors are embedded in EvalTools®. Once a key assignment is graded, the scores are submitted to EvalTools®. EvalTools® then produces the necessary EAMU vectors for each key assignment and their mapping to either the course outcome or the student outcome in the relevant FCAR. EvalTools® also provides the necessary objective evidence folders electronically at the end of the semester. As a result, the faculty workload is lessened, allowing faculty members to focus on teaching and their usual daily activities.

The following are highlights of essential features of EvalTools® pertaining to outcomes assessment:

- Lessons – a depository for lessons and lectures
- Assignments – tracking of assignments in meeting course objectives
- Grade book – maintaining course grades
- FCAR – Faculty Course Assessment Report
- Course syllabus – systematically documenting learning activities
- Rubric – easy creation of rubric for consistent gauging of meeting outcomes

- Objective evidence folder – a centralized depository for all artifacts collected in class
- Course exit survey – tracking end-of-semester course survey in meeting course outcomes
- Senior-exit survey, alumni survey, employer survey – customizable surveys to suit this university's needs
- Curriculum outcomes matrix – facilitating easy review of program strengths and weaknesses
- Trend-analysis course matrix – giving longitudinal perspective on course performance
- Action items matrix – systematically documenting action items for closure and improvement
- Student outcomes evaluation – tracking and reporting the review and results on PVT
- Executive summary on Student outcomes – tracking and reporting the review and results on evaluation

IV. FACULTY ENGAGEMENT IN PRPGRAM EVALUATION

Our faculty engagement started early in the process of developing a plan for program assessment and continuous improvement. In the spring semester of 2010 the Physics and Engineering department chair met individually with the department faculty members whom are involved the mechanical engineering program. These are faculty members teaching or supervising students' projects, research, and/or other activities. The department chair discussed ABET's program review process in general and many specific items related to the individual faculty. These individual meetings helped prepare the faculty members to take part in the process as issues and concerns related to time budgets were discussed at this stage. The following was the outcome of these individual faculty meetings:

- Create individualized consultation for program assessment/evaluation and assessment evidence gathering.
- Prepare faculty members to become part in the program evaluation and continuous improvement process by mapping the program outcomes and objectives to the instructor courses.
- Incite the faculty member to use new software tool (EvalTools®) by highlighting the software features relevant to the faculty member's course delivery, course assessment and improvements.
- Emphasize course learning outcomes related to program learning outcomes required by ABET in courses.
- Construct the *Curriculum-Student Outcome Matrix* in a way that supports program efficient assessment.
- Discuss with faculty their time limitations and the challenges that may occur as a result of the process and review alternative solutions like student help and staff assistant.
- Improve course syllabi in general and the syllabi for the courses included in the Student-outcome course assessment matrix in particular.

Developing Curriculum-Student Outcome Matrix

Constructing Curriculum-Student Outcome matrix was accomplished by involving faculty members in multiple one-

to-one meetings with chair in spring of 2010 as well as meetings in, a newly established committee for program assessment and improvement (PAC). The chair of the department of Physics and Engineering who is, also, leading the program review initiative worked with faculty members in the department in identifying key courses in the ME curriculum to set one aspect of the program assessment as the heart of the program continuous improvement. Bloom's Taxonomy [8] for learning pattern was used where learning pattern suggests that a learner goes through the cycle of *knowledge, comprehension, application, analysis, evaluation and synthesis*. Even though this cycle of learning pattern takes place in many courses at various levels, our curriculum focuses mainly on a specific pattern of learning which is presented in Table 1. Similarly, one can also use Biggs constructive alignment principles [9] for this stage of evaluation instead of Bloom's taxonomy.

Table 1: Bloom taxonomy applied to evaluation

| Level of Courses | Focus of Learning |
|------------------|--------------------------|
| first year | Knowledge/ Comprehension |
| second-year | Knowledge/ Comprehension |
| third-year | Application and Analysis |
| final-year | Evaluation and Synthesis |

The Curriculum-Student Outcome matrix lists the courses which are used in assessing our student outcomes. Table 2 bellow represents this matrix. Once this matrix is established, the designated courses are considered key or "core" courses in the assessment process. A faculty who teaches a core course becomes an owner in the program assessment and improvement process.

Table 2: Curriculum-Student Outcome Matrix (generated by EvalTools® representing a-k coverage)

| Spring 2010 - Fall 2010 | | Student Learning Outcomes | | | | | | | | | |
|-------------------------|--|---|--|-------------------------------|--|--|------------------------------------|--|---|----------------------------------|---|
| Course ID | Ability to apply mathematics, science, and engineering knowledge to solve problems | Ability to design and conduct experiment, and to analyze and interpret data | Ability to design a system, component or process to meet desired needs | Ability to function on a team | Ability to identify, analyze, and solve problems | Understanding of professional and ethical responsibility | Ability to communicate effectively | Ability to understand the impact of engineering on the environment | Recognition of the need for, and an ability to engage in life-long learning | Knowledge of contemporary issues | Ability to use the techniques, skills, and engineering tools necessary for the solution of engineering problems |
| Total Courses: 13 | 7 | 4 | 3 | 4 | 5 | 1 | 5 | 3 | 2 | 3 | 4 |
| Spring 2010 | | | | | | | | | | | |
| ENES100001 | x | | | | | | | | | | |
| ENME232001 | x | | | | | | | x | | | |
| ENME271001 | | | | | | | | | | x | |
| ENME332001 | x | | | | x | | | | | | x |
| ENME362001 | | x | x | | | | | | | | |
| ENME472001 | | x | x | x | | x | x | x | x | x | x |
| ENME480001 | | | | | | | x | | x | | |
| Fall 2010 | | | | | | | | | | | |
| ENES220001 | | | | | x | | | | | | |
| ENES221001 | x | | | | x | | | | | | |
| ENME231001 | x | x | | | x | | x | | | | |
| ENME250001 | x | x | | | x | | | | | | |
| ENME271001 | | | x | | | | | | | x | x |
| PHYS311001 | x | | | | | | | x | | x | |

As can be seen from the matrix above, the courses selected for the assessment of the program provides complete coverage for ABET Student Outcomes. Late on we will be able to see that the required student outcomes map into our program educational objectives and hence the educational objectives (PEO) are linked to several courses in the curriculum. Our assessment for the PEO was attained by obtaining data about our graduates. We were able to learn about our curriculum from this data. It can be easily demonstrated that adjustments in our curriculum, course offering, pedagogy, course content (and generally any activity at this level) would have an effect

on the program attainment of Student Outcomes and general PEO.

A course owner is required to map the Student Outcomes in the matrix to the specific course learning outcomes. These course outcomes are typically identified by the instructor and reviewed by the PAC and department chair. A course owner develops the assessment tools for these course learning outcomes. The assessment tools are referred to as *Key Assignments*. We required that the course owner maps the course learning outcomes to the Student Outcomes. It is of the essence to mention here that the selection of courses in the matrix is based on multiple factors:

- Focus of learning according to the Bloom's taxonomy
- Level of course and depth of material covered and skills developed
- Coverage of the program Students Outcomes
- Relevancy of the course outcomes to the overall PEO
- Level of interest in the process as identified by the faculty
- Simplicity of the assessment instrument developed to measure the outcome attainment

Strategies for Faculty Engagement

Designing course assessment instruments for courses in the matrix based on simplicity was clearly outlined to faculty members who are participating in the accreditation process and the program improvement process in general. It is essential to be able to bring concerned faculty members on board, and to stress on the simplicity and efficiency of the process. Our strategy to reach this goal was based on two **main** factors: First, highlighting and stressing on the direct and immediate benefit of this (program improvement) process on the faculty's course performance. The second factor is stressing on the simplicity of using the software tool and the added value of utilizing the tool for improving their course performance and the program in general. The software tool, as was described earlier, alleviates the burden of organizing, saving, presenting assessment data in a form easy to study and contemplate. Its features allow for other class management activities that are also quite useful. When this fact was made clear to our involved faculty member they felt more encouraged. One faculty member (also member of PAC) commented "...I was able to easily discover how my course and others impact future engineers. I was also able to adjust my teaching to have better impact". Another PAC member commented "I am happy to join this project. I was skeptic at first that I would not have time... Through this software (EvalTool®) we can easily identify where in the curriculum students have problems and help select the action-items". Hence, involving faculty members as owners of the process and the careful strategizing prepares faculty members to embrace and interact with the process as part of their own teaching goals rather than dealing with it as part of a mandated project.

Building Course Assessment Instruments

Building the assessment tools for courses in the Curriculum-Student Outcome matrix is in the core of this

project. For each course the "course owner" (or instructor) developed appropriate assessment tool for the various course learning outcomes. We focus on including only those course outcomes which are related to our general Student Outcomes. As can be seen in the matrix above, courses may map to one or more Student Outcome. EvalTools® presents also the mapping between the Program Educational Objectives and the Student Outcomes.

The appropriate assessment instruments developed by the course owner vary based on the learning outcome. Currently we use the following instruments referred to as *Key Assignments*: homework problems to address concepts and principles, exam problems, project assignments with specific outcomes, design projects, lab experiments, project presentations, surveys of team collaboration, rubrics for various observations addressing soft skills, targeted assignments and other graded work.

In EvalTools®, the course portfolios include, course syllabi, Key Assignments, grade book to store results, etc. EvalTools® automatically calculates the attainment of the Student Outcomes based on a rigorous and adjustable formula that takes into account the data collected from all various courses which are related to the specific Student Outcome. For example, in Table 1 if we take the Student Outcome C: "*The ability to design system, or process to meet a designed need*", we find three courses that map into this outcome: ENME 371, ENME 472 and ENME 488. Key assignments are developed in these courses to address this ability at junior and senior level. PAC will be able to review the result and identify problems in the respective outcomes. Then PAC is able to delve into the courses where these outcomes map. Section 5 gives details of EvalTools® output.

PAC review includes data from the previous evaluation cycle as old action items are reviewed. Based on the review results, new action items are developed at the level of Students Outcomes attainment. This allows for closing of the loop on the program Students Outcomes. In addition, on the level of course learning outcomes, EvalTools® allows for closing a smaller loop by allowing the instructor identify action-items related to the course. These course specific action-items are reviewed by the instructor at the end of the semester to develop new ones. The third loop is due to the general PEO review which takes place every two to four years.

Training Faculty for Effective Use

To achieve effective and efficient use of this process of program continuous improvement and the use of EvalTools® we provided a number of training sessions. Two of these sessions were provided by EvalTools® as part of their support. The sessions involved designated course owners and PAC members. Each one of the two main sessions was provided as one full-day workshop held in the department. EvalTools® training was very instrumental in emphasizing the importance on the procedure adopted. The workshop covered essential topics for program assessment and continues improvement. It also helped identify our departmental priorities related to this process. It brought faculty members involved in the process to a better understanding of the process in general and EvalTools® as a software package. After the training sessions,

our faculty members were ready to apply the process immediately.

V. RESULTS FOR PROGRAM ASSESSMENT AND REVIEW

We will now discuss the results of the application of our new assessment and improvement plan in conjunction with EvalTools® for the cycle of 2010-2011. The data collection started in the spring of 2010. Assessment data from spring 2010 were compared to data collected in spring 2011 by individual faculty members to close the small cycle on a portion of the programs **key courses**. Data from fall 2010 were compared to fall 2011 data. Hence, the small cycle for improving these key courses which insure targeted Student Outcomes is completely closed by the end of fall 2011. It is essential to observe that it required two full years’ data to close the smaller loop. However, one full year data is sufficient to identify ABET’s program outcomes attainment and identify improvement actions. The closing of the loop takes another year to reflect on the actions provided for improvement. Also the two year period provides complete data on the workability of process itself. We will discuss bellow our review data from two spring semesters and one fall semester. From this data we can prove that the process works and that improvement items were identified and reflected upon by our faculty. Obviously, the improvement in the program is attained only if the correct action is applied. EvalTools® provides the way of identifying, applying and reflecting on action items.

Student Outcome Assessment and Review

Figure 1 shows the process utilized for Students Outcomes assessment. We will provide the results of the assessment as presented by EvalTools® for one ABET outcome bellow.

Performance Vector Table (EAMU Table)

To measure the performance of students in the designated key assignments we adopted the EAMU performance vector approach come with EvalTools®. The results from a graded Key Assignment are converted into the EAMU vector which simply carries the number of students in the Excellent, Adequate, Minimal and unsatisfactory categories in that particular Key Assignment. One or more Key Assignments will be used to identify the students’ performance in a course-outcome. Consequently, that course-outcome is used to indicate the students’ performance in a Student Outcome which is mapped to that course. The EAMU vectors are flagged with different colors according to heuristic rules which indicate academic status. The efficiency of this rules-based approach during program evaluation relies on well-justified Key Assignments that address the course-outcomes and form the performance vectors. Table 3 shows the explanation of the codes for the EAMU vector. Bellow, in Figure 2, we see a page generated by EvalTools® showing the result of evaluating one Student Outcome. EvalTools® captured the PAC member discussion and actions.

The review shows data for one year when completing the cycle this page will be utilized by course instructors to implement the actions on specific courses.

Course Outcome Assessment and Review

The course assessment and review takes place by the individual faculty to ensure the course quality. EvalTools® captures the outcomes related to the specific course, allowing the instructor to see the performance and performance criterions. By seeing this color-coded section the instructor is

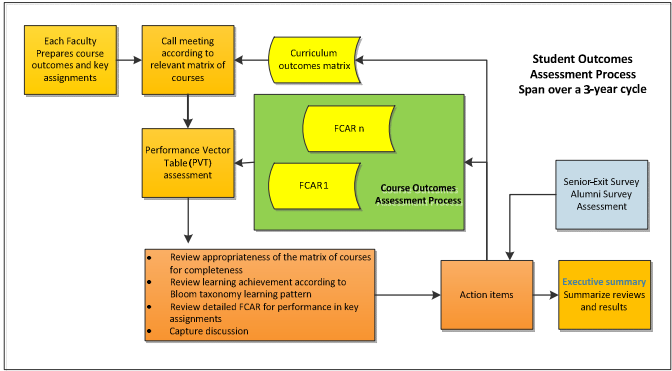

Figure 1: Student Outcomes assessment process

Table 3: Criteria category

| Category | Criteria Description |
|-------------|---|
| Red flag | Any performance vector with an average below 3.3 and a level of unsatisfactory performance that exceeds 10% in the U column |
| Yellow flag | Any performance vector with an average below 3.3 or a level of unsatisfactory performance (U) that exceeds 10%, but not both |
| Green flag | Any performance vector with an average that is at least greater than the 4.6 and no indication of unsatisfactory performance (U) |
| No flag | Any performance vector that does not fall into one of the above categories |

able to identify leaning outcomes that need improvement in the course. EvalTools® reports provides a way to reflect on the action-items identified by the instructor the next time the course is reviewed. We currently review these courses by PAC to ensure the quality of the evaluation process. [6-7] reported examples on course assessment matrix generated by EvalTools®.

VI. LESSONS LEARNED AND CONCLUSIONS

Engaging faculty members in program improvement via use of software is considered an innovative practice which was quite successful because of the following reasons: 1) Engineering faculty members, are generally well acquainted with the use of online software tools, like Blackboard, for classroom and general educational activities. Such tools provide access from remote locations and can be utilized in flexible times. 2) The direct relationship between program improvement (as required by ABET) and specific course improvement (as strived for, naturally, by instructors) was clearly highlighted by EvalTools. This enticed faculty members to embracing the process from the beginning. 3) Creating a sense of ownership of courses for involved instructors helped enhance faculty engagement. Performance improvement became a clear goal and the new process provided a clever way to gauge individual course improvement and general program improvement.

Spring2010: Ability to apply knowledge of mathematics, science, and engineering

Fall2010: Ability to apply knowledge of mathematics, science, and engineering

Metric: FCAR reports from the following courses will summarize the necessary evidence in meeting this specific outcome.

| Term | Course | Name | E | A | M | U | Average |
|------------|------------|---------------------------------|-----|-----|-----|-----|---------|
| Spring2010 | ENES102001 | Statics | 6 | 2.5 | 0.8 | 3.8 | 3.03 |
| Spring2010 | ENME232001 | Thermodynamics | 0 | 8 | 7 | 5 | 1.92 |
| Spring2010 | ENME332001 | Transfer Processes | 5 | 2 | 0 | 1 | 3.96 |
| Fall2010 | ENES221001 | Dynamics | 5.5 | 4.5 | 0 | 1 | 3.86 |
| Fall2010 | ENME331001 | Fluid Mechanics | 12 | 4.5 | 3 | 1.5 | 3.81 |
| Fall2010 | ENME350001 | Electronics and Instrumentation | 9.5 | 3.5 | 7 | 7 | 2.62 |

Classification: Below Expectations (1.5 barely meeting)

Discussion:

- Students' math abilities need improvement at lower levels.
- Improvement is seen at upper levels.
- Many students were Excellent and Adequate and some are Minimal.
- Result is alarming but can be rated 1.5 with immediate strong actions to be taken in all of the courses.
- ENES102 Statics: Weakness in application of cross product moment of force.
- ENME232 Thermo: Application of calculus to fluids, physics, chemistry. They can't finish the math operations to the end. Instructor needs to set up the title of the key assignment and the description and justifications for the key assignments.
- ENME350 Electronics & Instrumentation: Solving differential equations was not satisfactory or was minimal for many students because they don't have adequate the background or the training for that. The solution is in the form of gaining more diff. eq problems to work on.
- PYHS311 Thermo: Same as above
- List of courses is okay for this outcome. We need to challenge the students with their math abilities, make them do the work.

Action:

- Give more math problems in the above listed courses.
- Seek resources to hire math graders to help in grading the extra problems needed to strengthen the math abilities.

Reviewers:

- Eltayeb, Teker, Soysal, Budzien, Wang, Moore, Mak.

Review Date: 2011-04-08

Figure 2: EvalTools® review Student Outcome page

4) Highlighting the simplicity of software use and simplifying the whole process, removing unneeded efforts was instrumental in the success of the process. 5) Providing essential training for involved faculty members helped reduce learning time. 6) Finally, it is worthwhile mentioning that faculty collaboration and teamwork spirit was a valuable asset in the process. The key, always, was to develop and maintain this spirit.

In conclusion, our experience with EvalTools® as a software tool to help improve faculty interaction with program improvement is summarized as follows: First, we were successful in meeting ABET accreditation criterion relevant to program assessment and continuous improvement applying this process to our program. The program reviewers commented "...EvalTools is a 'great tool' to apply because it provided a thorough and solid assessment mechanism for improving the program...". Second, we were successful in developing an assessment and evaluation process that is quite sustainable. Third, with the use of EvalTools, we were able to focus more on data evaluation than on data collection and compilation. Faculty members are less burdened on evaluation data and more focus on their teaching and hence, yield a better result in the use of faculty time and effort in program improvement.

Work in Progress: Building Information Literacy Assessment

J.A. Rozzi-Ochs, C.J. Egelhoff, H.V. Jackson, S. Zelmanowitz

Department of Mechanical and Civil Engineering

U.S. Coast Guard Academy, New London, USA

Abstract— In today's electronic age, information literacy skills are more important than ever. It has been challenging for most engineering faculty to find a place to infuse and integrate information literacy into already demanding curricula. However, engineering faculty need to address the topic of information literacy in order to support achievement of ABET student outcomes related to communication, contemporary issues, and lifelong learning. This paper presents the steps taken to assess and evaluate information literacy skills through the development of specific performance indicators related to ABET student outcomes g, i, and j. Using existing assignments, assessment data were captured and preliminary results are presented.

Keywords—Assessment, Information Literacy, Outcome, ABET

I. INTRODUCTION

According to the Final Report of the American Library Association Presidential Committee on Information Literacy [1], Information Literacy (IL) is defined as “an individual's ability to know when there is a need for information, to be able to identify, locate, synthesize, evaluate, and effectively use that information for the issue or problem at hand.” IL knowledge and skill have been identified as critical components to gathering and using information. With the tremendous amount of information available at the click of a mouse, knowing how to find, organize, and evaluate this information is the challenge [2-3]. Despite the amount of information that is available, students are still not information literate and are struggling to retrieve and evaluate information that is required for problem solving and decision making in the workplace and society [4]. Engineering students must be encouraged to develop these skills to be successful. It has been challenging for most engineering faculty to find a place to infuse and integrate IL into already demanding curricula [5]. Research has shown that IL is most successful when it is associated with an existing assignment within a course [2, 6]. The authors believe that the best way to ensure that teaching faculty provide students with opportunities to develop IL skills and the most effective way to assess and improve the curriculum in support of IL development is to incorporate IL into existing assessment processes. For engineering programs this means incorporating IL into assessment of student outcomes known as ABET a-k [7].

II. PROGRAM OUTCOMES AND INFORMATION LITERACY

The curricular ABET outcomes for the ME department are generic to the four engineering majors at the U.S. Coast

Guard Academy (USCGA) and correspond to ABET-student outcomes a-k. During the development of the three student outcomes under consideration herein, the ME faculty noted that the USCGA Civil Engineering (CE) program evaluation provided a model from which ME could launch its own assessment [8]. The ME faculty observed that IL was not specifically addressed in the current curriculum, which sparked the ME faculty to reevaluate the current program outcomes and make several modifications. The process developed by the CE faculty was used to identify IL-related student outcomes, link them to current courses and develop assessment tools. This process is shown in Figure 1.

FIGURE 1. PROCESS TO IDENTIFY IL LINK TO COURSES

It was identified that IL was captured in the following ABET-student outcomes: g (the ability to communicate effectively, i (ability to engage in life-long learning), and j (knowledge of contemporary issues). Once this was established, performance indicators were developed to capture IL skills, knowledge, and ability. The performance indicators related to student outcomes were then mapped to current courses in the ME curriculum as shown in Table 1.

TABLE I.
PERFORMANCE INDICATORS RELATED TO IL ASSESSMENT MAP

| ABET-Student Outcome | Related Performance Indicator | Courses that Contribute |
|--|--|--|
| g: an ability to communicate effectively | Research information from a variety of sources, use information to make engineering decisions/ judgment and produce a technically sound report | Mechanics of Materials, Mechanisms, Engineering Experimentation, Mechanical Engineering Design, Design Project Management |
| i: a recognition of the need for, and an ability to engage in life-long learning | Use a variety of tools such as professional journals, books, codes, and standards as sources of industry information | Engineering Experimentation, Mechanisms, Machine Design, Mechanical Engineering Design, Design Project Management |
| j: a knowledge of contemporary issues | Investigate, gather and analyze information related to contemporary issues | Intro to Mechanical Engineering Design, Mechanisms, Thermal Systems Design, Mechanical Engineering Design, Design Project Management |

The performance indicators developed in Table 1 were further examined and an evaluation process and plan was constructed. This included identifying which classes would be the primary source of assessment data, the assessment tools to be used, the collection cycle, the assessment coordinator, and the evaluation of results.

III. ASSESSMENT TOOLS

A variety of tools can be used to assess student performance, to include research papers, technical papers, journals, capstone project reports, laboratory reports and oral presentations. Graded performance criteria were developed to ensure IL components were consistently assessed and evaluated. The IL components of the graded performance criteria (PC) evaluated students' ability to: (1) write a well organized paper, (2) develop a clear and concise theme, (3) identify the type and importance of information related to theme, (4) use of good technical writing skills and (5) incorporate a variety of high quality references. The student performance results were divided into three performance categories: (1) exceed, (2) meet, and (3) below expectations.

IV. RESULTS

Examples of student performance in two courses, *Mechanisms* and *Machine Design*, are presented in this section. In *Mechanisms*, a junior level spring semester course, students were required to write a paper on contemporary issues including engineering failure cases.

In *Machine Design*, a senior level fall semester course, students were required to write a technical research paper that would contribute to their capstone senior design project. The objective of the paper was to research a specific component, problem, or technology related to that topic. Although each senior capstone design project consisted of four to five students, each individual student was required to submit a separate research paper. As part of the assignment, IL guidelines were provided and discussed.

The students assessed in the *Mechanisms* course and *Machine Design* course were not the same group of students, nor was the assessment completed in chronological order. The results of the student performance assessment, based on the IL-related components of the writing assignment, are shown in Figures 2 and 3.

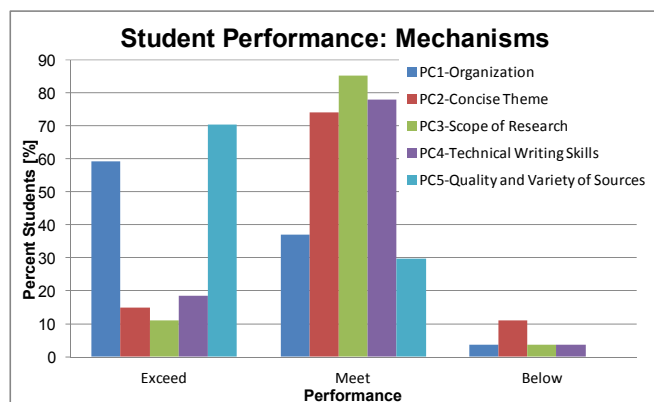

FIGURE 2. IL COMPONENT IN MECHANISMS PAPER.

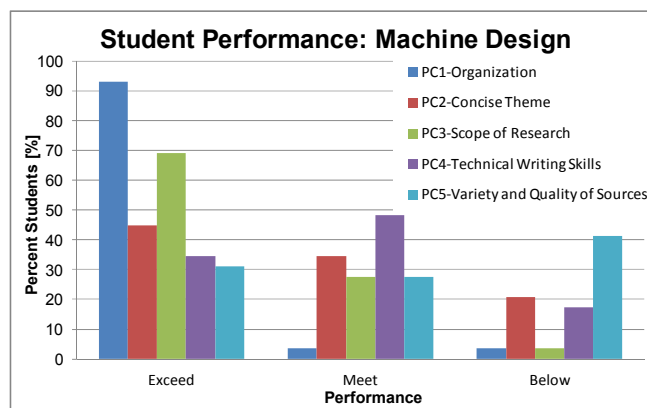

FIGURE 3. IL COMPONENT OF MACHINE DESIGN PAPER

In both figures, “exceed” corresponds to a score of 90-100%, “meet” corresponds to a score of 70-89%, and “below” corresponds to a score less than 70%. Figure 3 shows us that overall student performance met or exceeded expectations. One might expect a higher level of performance in *Machine Design*, but over 40% of the senior level students fell below minimum (70%) in PC5 (variety and quality of sources), while 100% of the students in the junior level class met or exceeded in the same category.

These results indicate that more work is required in the area of assessing and evaluating IL. One area of improvement is to provide students with the grading rubric along with the assignment to ensure that expectations of the instructors are known. Assessment and evaluation of IL skills should be expanded to additional classes within or outside the ME program of study and should continue to be assessed annually or bi-annually. The progression of student performance should also be evaluated to include assessment at the sophomore, junior, and senior level. Results of assessment need to be documented and changes will be incorporated into the holistic assessment process used by the ME program. Indirect assessments from the operational Coast Guard should be used to gauge the IL skills of ME graduates. Finally, Engineering and English faculty should collaborate to strengthen assessment standards and practices and improve student technical writing skills.

V. CONCLUSION

It is essential that educators help undergraduate engineering students develop and improve their information literacy (IL) skills in the context of the current and emerging information infrastructure. As a result of applying the continuous-improvement program assessment cycle, the Mechanical Engineering faculty at USCGA has developed performance indicators and assessment tools under existing ABET outcomes to investigate the current state of engineering student IL skills. This was achieved by utilizing existing grading rubrics for classroom assignments that students are already doing. Preliminary results indicate that embedding IL into the existing assessment model will inspire greater development and improvement of student IL skills in a sustainable and effective manner.

Managing Student Outcomes in a Totally Asynchronous Learning Environment: Lessons Learned

Larry G. Richards and Susan K. Donohue
University of Virginia, lgr, susand@virginia.edu

Abstract – A graduate course, APMA 6430 *Probability and Statistics for Engineers and Scientists*, has been offered by the University of Virginia's School of Engineering and Applied Science since 1985 in both traditional and synchronous distance learning modes. The decision to move to a totally asynchronous delivery mode was made in 2009 and fully implemented in Spring, 2010, based in part on the desire to support student achievement given the many – but different – challenges faced by both on-grounds and off-grounds students. The shift in delivery method brought its own set of challenges along with its inherent flexibility in student engagement with the course. In this paper, we review the lessons learned and how we met various administrative, support, and instructional challenges from the first three offerings of this course in a totally asynchronous on-line mode.

Index Terms – Asynchronous learning, on-line learning, graduate engineering education, statistics education.

INTRODUCTION

The question is not whether asynchronous learning will be a major instructional delivery method, but when it will be the method of choice, and under what circumstances. Distance and on-line learning have a long history in Virginia and at many other schools (Illinois, Florida, Georgia Tech, and Southern California). The Sloan Consortium has focused on on-line and asynchronous learning for several years. These efforts have existed within established educational institutions

Now several new educational initiatives are challenging traditional educational institutions and their practices. Massive open on-line courses are now offered by edX and UDACITY. These offer free on-line courses to anyone who decides to enroll. They provide instruction, assess student progress and award certificates, but not course credit or degrees. Massachusetts Institute of Technology's OpenCourseWare program has been available for several years; it also allows anyone who wishes to sit in on an MIT class. The Khan Academy has over 2700 lessons mostly on basic math available for free. [1] – [3] David Brooks warned of a “campus tsunami” based on his interpretation of comments by Stanford president David Hennessy. [4] These experiments are exciting and informative, but they have not yet established a business model that challenges that of the

traditional model of the mortar-and-brick colleges and universities.

The support infrastructure for asynchronous learning allows for the capture and retention of lectures, discussions, and labs from leaders in academe and industry. The implications of having this archival material are many, and we have yet to work through them to a coherent vision of education in the Internet age. For example, the upfront investment in time and equipment in recording lecture modules may be recouped in succeeding semesters, allowing professors more time for teaching another course, conducting research, working in an administrative role, or providing community outreach. Guest lecturers can be easily accommodated. Or, it could be decided that a faculty member leaving, for whatever reason, does not have to be (fully) replaced since his/her class(es) can be covered using the archived material. However, these benefits may be more apparent than real given the need to material up to date, factoring in advances in the area or changes in texts and other supporting material.

The delivery method for APMA 6430, *Probability and Statistics for Engineers and Scientists*, a graduate course offered by the School of Engineering and Applied Science, University of Virginia (SEAS UVa), switched from mostly real time to totally asynchronous in the spring of 2010. What happens to student attitudes, learning, and achievement when a course's delivery method changes? We explore the impact that offering this course in asynchronous mode has on student perceptions and attitudes, learning outcomes and on course management in this paper.

BACKGROUND

APMA 6430¹ has been delivered in several modes since 1985: in a traditional classroom setting to resident students; as distance learning with resident students on-site and non-residential students participating at local viewing sites, first through satellite transmissions and then via Internet streaming; and now as distance learning through pre-recorded lesson units downloadable from the course site. Asynchronous learning opportunities were available when the course was taught through a distance learning program, the Commonwealth Graduate Engineering Program (CGEP)

¹ Formerly APMA 643; a university-wide change in the course numbering system was necessitated by a switch to a new student information system in Fall, 2009.

[5], via videotapes and archived streams; however, these asynchronous learning opportunities could occur only after a given class had been delivered. In addition, students who wanted to make up a missed class or review material in the videotape era could also encounter logistical challenges in obtaining, viewing, and/or returning a tape. The move to internet streaming removed many of those challenges but again, asynchronous learning opportunities could occur only after the fact. Creating a pre-recorded version of the course meant that learning could occur at the student's convenience, following his/her schedule, not an institutional timetable.

The decision to go to a totally asynchronous delivery mode was made in 2009, based in part on the desire to support student achievement given the many – but different – challenges faced by both on-grounds and off-grounds students. Challenges faced by on-grounds, or residential, students are reported in [6] and [7]. Students are typically in their first or second year of graduate study, and therefore are dealing with various challenges that may include balancing classroom and research loads, taking qualifying exams, and adjusting to a new environment. In the case of 13% of students in 2010, 21% in 2011, and 34% in 2012, this challenge also included adjusting to a new country. We've noted in [6] and [7] that international students would review materials in informal study groups held right after a lecture or by reviewing course modules recorded during previous CGEP offerings in order to overcome cultural and linguistic barriers to comprehension. Off-grounds students must balance class attendance and work with full-time employment, which may include travel, and family obligations. These students have, in the past, reported difficulty in accessing viewing sites in Northern Virginia and Tidewater/Hampton Roads due to traffic volume and class times that conflicted with work. For example, the first UVa time slot for a CGEP class time is 3:30 pm ET, and the first Virginia Tech time slot is 4 pm ET [5]: the mid-end of a typical workday and beginning of the afternoon rush hour in both regions.

Richards has been the primary instructor of APMA 643/6430 since 1985; his historical perspective has been invaluable in the analyses presented here and in [6] and [7]. Additionally, all SEAS graduate students, whether master's or doctoral, regardless of department, must complete at least one course in (applied) mathematics as part of their graduation requirements. This requirement is one explanation for the enrollment figures presented later in this paper and for some of the unique challenges encountered in delivering and administering this course no matter the mode chosen.

ASYNCHRONOUS CLASS STRUCTURE AND DEVELOPMENT

Delivering a course in the asynchronous mode allows us to realize the best pedagogical practices that we frequently ignore in traditional lecture based classes: present the material in manageable chunks, make sure the student learns the material before moving on, perform formative assessments on a regular basis and provide immediate

feedback, personalize the learning experience, pace the presentation to the individual learner, address common misconceptions and misunderstandings, and provide help and assistance as needed.

In the asynchronous version, the lecture material was previously delivered twice a week in 75 minute class periods. Now the material has been segmented into a series of 20 - 30 minute modules, which better suits student attention spans. The modules are clustered into units. Each unit focuses on a coherent set of topics such as data analysis and display, basic probability and random variables, estimation, hypothesis testing, analysis of variance, correlation and regression, quality control, and categorical data analysis. Supplementary modules review prerequisite knowledge, such as set theory and basic probability concepts; the use of the course's software application, Minitab; course logistics; and test reviews.

The modules were initially recorded over six months in mid-to-late 2009 using Camtasia [8]. Existing course notes were elaborated and adapted to the new delivery mode. A number of course delivery systems were explored and evaluated and we experimented with several formats and approaches. Each had advantages and drawbacks. Faced with a deadline (the start of classes), we had to just select a system and start recording. We decided that seeing the instructor was not necessary, and that voice over slides was sufficient. Initially we tried editing the videos to improve their quality and eliminate verbal distractions. After the fifth class, we tried just recording and eliminated all editing. The students did not seem to notice.

Links to the modules, which reside at screencast.com, are available on the course's UVa Collab site [9]. Collab is UVa's course management system, based on open-source code from Sakai (current version 2.8.1). The ability to download the modules was enabled after the first offering in response to student requests to be able to view them when internet access was not available or allowed. Modules are periodically re-recorded to update the content based on student feedback; advances in pedagogy, asynchronous or otherwise; and current examples related to the covered topic(s). The welcome and course logistics module is re-recorded for each semester. A list of modules is provided in Table V, presented at the end of this paper.

MANAGING STUDENT OUTCOMES

The initial plan was to grant students access to a unit for a given amount of time, with the students deciding when and where to review the material. Each unit has embedded assignments to facilitate active learning. Graded homework is also assigned. Answer keys are provided for both the embedded assignments and graded homework: concurrently with the embedded assignments and consecutive with the graded homework. Tests and quizzes are assigned at defined times throughout the semester to insure steady progress by the students. Learning is self-directed but ideally done at a pace that allows a student to cover the materials throughout the provided time. The goal is to provide a personalized path

through the material relevant to the students' interests and needs.

However, we found that some students in the initial offering had delayed longer than they should have in viewing modules and completing assignments when they requested an extension for the first test. Providing a suggested viewing schedule was not sufficient to keep some students on track; additional graded homework turned out to be the most helpful means to ensure steady and consistent progress.

Based on student feedback concerning having only a few modules available at a time, we now post all modules before the class' official start. A map of the readings and modules to cover each week (again, please see Table V) is available to help students pace themselves, but individual students are free to move ahead as they wish. This change has given the students a greater sense of control over their learning: a good thing.

Communication, monitoring student use of course materials, and keeping students to the schedule by numerous and carefully spaced graded assignments and exams are vital to managing student outcomes. Managing the email traffic is also extremely important, especially in the immediate period before and then during the administration of graded assignments and exams. The class email listserv is an efficient method of communicating to all students. We assume that if we get similar questions from several students that it is likely that others will have it as well, so the answer goes out to the listserv. Students are also notified by email when class materials are (re)posted, which also serves as a means of reminding them about class responsibilities and requirements. However, we have learned to respond to each student individually even when his/her question have been answered in a mass e-mail. That personal attention has increased the perceived level of connection and engagement between the instructor and student.

ASSESSMENTS

At the end of every test, students are asked to complete a short survey and provide comments on the progress of the course. A survey on class logistics is given midway through the semester, and three end-of-course surveys are available, but not required, for students to complete. We always use our own survey tailored to the needs and format class. The other two surveys, administered by SEAS and CGEP, are standard surveys. These surveys gather some useful information, but our main data comes from the class survey. The other advantage of having our own survey is that we obtain responses from almost all of the students.

Table I present shows on- and off-grounds enrollments for the three semesters in which APMA 6430 was delivered in total asynchronous mode, and Table II presents the gender breakdown of those enrollments. It is interesting to note the 50% increase of on-grounds enrollment relative to the more stable percentage of off-grounds students between Spring 2010 and Spring 2012, presumably due to students disseminating the benefits of taking at least one required

course asynchronously given the "busyness" of their previously discussed schedules. The increase in the percent of females enrolled (55%) is comparable to the percent increase of males enrolled (50%), so a gender balance of sorts has been preserved. Additional time and research will be needed to determine the worth of this finding.

TABLE I
APMA 6430 ENROLLMENT – SPRING 2010 - 2012

| Spring | On Grounds | Off Grounds | Total |
|--------|------------|-------------|-------|
| 2010 | 19 | 26 | 45 |
| 2011 | 31 | 25 | 56 |
| 2012 | 47 | 21 | 68 |

TABLE II
APMA 6430 ENROLLMENT BY GENDER – SPRING 2010 - 2012

| Spring | Females | Males |
|--------|---------|-------|
| 2010 | 9 | 36 |
| 2011 | 14 | 42 |
| 2012 | 14 | 54 |

The comments reported here are from the CGEP survey for all three offerings of APMA 6430 from 2010 - 2012. The CGEP survey, since it asks the same questions from year to year, is the best source of comments that can be compared over time. The presented comments are selected but representative.

2010: Selected Comments

The convenience of online modules makes it possible for me to learn on my own time. This is extremely valuable since I'm on the road 80 percent of the time for work and this venue enables me to pursue an advance degree while working.

Completely recommending UVA progress with this pilot project and offer more courses through the methodology that was deployed for this course.

Great format adopted by Prof Larry. He actually worked hard and I think this format should be extended to other classes.

I felt that the online environment offered a relaxed and flexible environment for learning the course material. Initially, it was a bit tricky to set a pace for the material, but once the course was underway, this was less of an issue.

Inadequate turnaround time for graded materials

I liked most everything about the class, but I was generally a bit confused about the pace through different parts of the class. There were some very slow periods when no lectures or homework were due. Then the gates would open up and lectures and homework would be assigned.

2011: Selected Comments

I enjoyed having all the lectures at once and then a practically at your own pace course with specific deadlines.

I thought the idea of breaking the material into modules was very helpful and made the course more manageable. Also, being able to access the course lectures on my own schedule was beneficial.

My previous experiences showed serious deficiencies in both material preparation, as well as online access to materials, whereas this course (MAE 6430) was well prepared, and all materials were easily accessed from all the locations I used.

There was a set your own pace element to this class which was nice for a working/traveling professional. Also you could download the lectures to put on tablets so you can view them offline during plane rides and hotel rooms.

The only thing missing as opposed to in-class courses is that there was no peer-to-peer interaction or group projects. I tend to prefer these since, as a student, you tend to learn more when you participate in these types of projects. As I found out on the 3rd homework and 2nd test, I was unaware of several of the flaws in my understanding until seeing the results of my missed problems on a graded assignment.

2012: Selected Comments

This course was meticulously structured and very simple to follow from one module to the next.

30 minute asynchronous classes are much much MUCH easier to focus on and comprehend than 90 minute lectures.

The asynchronous delivery of this class was much preferred over live delivery of other classes

Comparing my previous on-ground course work, I haven't seen any downside of taking a course online. I even got the chance to pause and play any section of the lecture at any time.

The challenge is to stay engaged and the on-line format can be difficult if a student doesn't make a conscious effort to do this.

Most pleasant: Ability to take lectures whenever. (Ability to digest information in small chunks comes in a close second). Unpleasant: None.

Most pleasant aspect of this course is the flexibility in time management, which enables the student to spread learning out over day-to-day, or take large chunks of the class in a single setting. It was particularly helpful that all the classes were pre-loaded onto the COLLAB site, allowing maximum flexibility.

The CGEP surveys also contained several questions about the instructor's performance and student reactions to this course. The most relevant are summarized in Table III, following.

TABLE III
APMA 6430 STUDENT EVALUATIONS (SELECTED QUESTIONS), 2010 – 2012

| | 2010 | 2011 | 2012 |
|---|------|------|------|
| 11. Apparent knowledge of the subject matter | | | |
| Poor | -- | -- | -- |
| Fair | 1 | 2 | -- |
| Good | 2 | 12 | 7 |
| Excellent | 15 | 27 | 33 |
| 12. Success in communicating or explaining subject matter | | | |
| Poor | -- | -- | -- |
| Fair | 4 | 4 | 1 |
| Good | 5 | 20 | 19 |
| Excellent | 9 | 17 | 20 |
| 13. Degree to which subject matter was made stimulating or relevant | | | |
| Poor | 1 | 2 | -- |
| Fair | 5 | 7 | 5 |
| Good | 5 | 22 | 15 |
| Excellent | 7 | 10 | 20 |
| 15. Concern and respect for individuals as students | | | |
| Poor | 1 | 1 | -- |
| Fair | 2 | 3 | -- |
| Good | 5 | 16 | 10 |
| Excellent | 10 | 21 | 30 |
| 16. Administration of class and organization of materials | | | |
| Poor | 3 | 2 | -- |
| Fair | 3 | 7 | 3 |
| Good | 8 | 22 | 19 |
| Excellent | 4 | 10 | 18 |
| 17. Encouragement and management of class interaction | | | |
| Poor | 2 | 5 | 1 |
| Fair | 3 | 8 | 4 |
| Good | 11 | 23 | 19 |
| Excellent | 2 | 5 | 15 |
| 18. Responsiveness to inquiries outside of class | | | |
| Poor | 5 | -- | -- |
| Fair | 3 | 7 | 2 |
| Good | 4 | 19 | 17 |
| Excellent | 6 | 15 | 20 |
| 19. Overall rating of this instructor | | | |
| Poor | -- | -- | -- |
| Fair | 5 | 4 | -- |
| Good | 4 | 22 | 13 |
| Excellent | 9 | 15 | 27 |

The important conclusions to draw from the data in Table III are that both the course and instructor show improvement over the three iterations of the course to date. The content has remained unchanged, but we have learned to manage the environment, logistics, and relations with the students.

The change in responses to one question from the last two CGEP surveys is especially relevant: Based on the quality of your on-line experience this semester, would you recommend courses in this format to fellow engineering school students in the future? The responses are reported in Table IV, below.

TABLE IV
APMA 6430: WOULD YOU RECOMMEND THIS COURSE?

| | 2011 | 2012 |
|--------------|------|------|
| Definitely | 8 | 14 |
| Probably | 15 | 9 |
| Maybe | 4 | 1 |
| Probably not | 1 | 1 |
| Never! | 0 | 0 |

We clearly made real progress in the latest iterations of the course. There were fewer problems each year. In 2010, we attempted to grade the homework on-line with a tablet p.c.; we quickly fell behind and received complaints about the slow return of assignments. In the last two years, all homework is graded by hand; this traditional, “old-school” method is much quicker and more accurate. This change has been valuable as we have been able to add much more graded homework at the request of the students, and to provide feedback in a more timely manner.

MAIN BENEFITS AND CHALLENGES

Using total asynchronous delivery for a course can confer many benefits. For example, we receive emails from students viewing a particular lesson while waiting for a flight or between meetings. The ability of students to view class material at times that fit into their schedule and demands is a strong selling point. Total asynchronous delivery can also benefit non-native English speaking students; a certain topic can be replayed until understanding is achieved. Another potential benefit is that students can take the course outside of traditional offering times, such as over the summer. The logistics of such offerings are still being worked out.

Total asynchronous delivery can also be frustrating for both students and instructors. An on-grounds student can attend office hours and receive immediate feedback or pick up graded assignments and exam as soon as they’re ready; feedback for off-grounds students is typically delayed and delivered through impersonal methods such as email.

The shift to total asynchronous learning brought its own set of challenges along with the flexibility. Making connections among class members in the virtual community was a particular challenge. Keeping students on pace is

another. More detailed schedules and additional graded homework helped students plan their studies better.

STUDENTS’ REACTIONS TO THE CLASS AND ITS FORMAT

The level of acceptance of the on-line, on-demand lectures was surprising. On-grounds students, some of whom initially had misgivings about the change in format, are as happy with this format as off-grounds students. Referring to Table I, the increase in enrollment is driven by on-grounds students because the flexible schedule helps them meet other commitments. All students report high levels of satisfaction with the quality of the material, mode of dissemination, flexibility, and convenience. Student performance is comparable to that in previous semesters. Therefore, the switch to a totally asynchronous delivery method has not compromised student learning and accomplishment.

Providing a course in asynchronous mode does not remove the need for instructional support. In fact, instructional support is critical to positive student outcomes. Interaction tends to be more electronically-based than in person, with emails the predominant method. It is critical that the instructor is free to respond to student questions, develop assessments, and manage class progress. A teaching assistant / grader is essential to grade the homework and exams, and support is needed to coordinate the reception and shipping of materials to off-grounds students. The assistance of an education technology specialist was invaluable in the design and initial phase of module production. Therefore, personnel staffing needs are not diminished or removed because the classroom is now virtual; in fact, more personnel hours are likely necessary if course enrollment increases as per our experience.

CONCLUSIONS

This course is a work in progress. For the next offering, we will revise and update all the recordings and alter the pacing of the materials. By student demand we will condense the material at the beginning of the course, expand the coverage in the middle part and include greater coverage of the advanced material

For example, we participated in an e-text experiment with McGraw Hill this year. The textbook was available in electronic form and it could be annotated and highlighted by both students and the instructor. We are continuing the experiment this year and plan to make greater use of the features of the electronic book.

We would also like to develop asynchronous courses on multivariate statistics and quality control as funding permits. These topics were requested by students and industry contacts.

Finally, we would be remiss if we neglected to mention the degree to which the issue of online learning played in recent events at UVa; see, for example, [12]. It is critical that this debate be conducted from a solid base of evidence.

ACKNOWLEDGMENT

We thank the students from the first three asynchronous offerings of this course; they were part of an educational experiment and their input has helped shape the coverage and organization of the course. We also thank MICRON for funding for the transition to asynchronous mode, and the reviewers for their constructive comments.

Abstract— This paper describes practices of the Supplementary Instruction (SI) Problem-Solving Workshop in helping entering engineering students develop the concept of problem solving and obtain the necessary knowledge and skills required to succeed in their courses.

Keywords—problem solving; content-based; peer-led; outside classrooms

I. INTRODUCTION

In an increasingly globalized and technology-driven world, engineers need excellent problem solving abilities more than ever. But reasons exist to doubt that many of today's engineering students are obtaining such abilities. Because students who enter an engineering school in a big research university such as the University of Wisconsin-Madison (UW-Madison) have passed through a very selective process requiring proficient knowledge and skills in mathematics and science, they are usually considered "high achievers." However, many studies find that some entering engineering students lack confidence when encountering new academic challenges [1]. These students often possess ineffective habits and skills, which hinder their learning. Researchers have identified deficiencies in problem solving skills as one significant learning obstacle college students face, leading to calls for instructional innovations to increase college students' practical problem solving ability [2]. The recently released DBER (discipline-based education research) report summarizes key findings on problem solving and includes an excellent literature review in the area [3]. The research examines how students use conceptual understanding to solve problems and investigates how spatial thinking and the use of representation facilitate or impede students' problem solving. Even though there is a large volume of research focusing on students' problem solving with well-defined problems, only a few studies took a deeper look at why beginning students get stuck in solving such problems [4]. There are some

observations of students' inability in problem recognition, yet in depth discussions concerning students' struggles when attempting to start the process of problem solving are still lacking.

Our current study uses results from student surveys to identify student learning needs and to discuss Supplemental Instruction (i.e. SI: Problem-Solving Workshop), specifically SI's outside-the-classroom strategy to facilitate learning problem solving skills within the course content. The survey results reveal that many students lack an intuitive concept of problem solving and that the SI program effectively helps them develop the concept. This study will argue that it is important for beginning engineering students to obtain an intuitive concept of problem solving and that engineering curricula thus need to provide well-structured activities to facilitate students' acquisition of the concept. To help students develop the concept, it is important for instruction to emphasize the role of domain-specific and metacognitive knowledge [5]. Failure to develop curricula that help students attain such a concept in their early learning stage will delay students' learning in problem solving, and will prevent students from reaching their full potential as engineers.

II. BACKGROUND OF THE STUDY

A. General information

The Supplementary Instruction Program (SI) in the College of Engineering at UW-Madison has a strong focus on the development of problem solving skills within the course content and shares some common practices established for SI at various institutions for different disciplines [6]. SI programs are designed to target traditionally challenging, so-called "at risk" courses. Currently, SI at UW-Madison is listed as a course in the timetable, InterEGR150-SI Problem-Solving Workshop, for zero credits. The college's Undergraduate Learning Center manages the program. SI supports a statics course, two calculus-based intro-level physics courses, and two dynamics courses; it is open to all students enrolled in these

courses. The SI session for each course consists of a small study group of 20 students that offers a peer-instructional, cooperative problem solving environment. The group meets for an hour session twice a week under the direction of the SI facilitator, an undergraduate engineering student who has completed and excelled in the course. Students spend the majority of a session's time working on problems within a smaller group of three or four students. SI facilitators provide worksheets with problems that highlight the important concepts. Most worksheet problems are well structured with course content constraints. SI facilitators assist with problem solving, lead group discussions, and also give a mini lecture at the beginning of each session [7].

B. Setting and methodology

(i) Post-midterm surveys to identify learning challenges

Periodically during the semester, SI encourages students to think retrospectively about their learning progress. Starting in fall of 2007, the SI workshop has routinely asked students to review their learning experiences after every midterm exam. Physics and statics courses have three midterms. One dynamics course has two midterms while the other has one. SI uses surveys to understand students' learning difficulties and to find better ways to help students. The survey questions regarding learning challenges are listed in Table (I). Responses were on a scale of 1-5 where "1" was defined as "a little bit difficult", "2" as "somewhat difficult", "3" as "difficult", "4" as "very difficult", and "5" as "the most difficult". Empty entries were considered as "not applicable". The analysis consisted of frequencies for each question and ratings of "4" and "5" were characterized as "very and most difficult" in this study. From fall 2007 to fall 2010, between 400 to 500 students responded to survey questions after the first midterm examination, 250-300 responded after the second exam, and about 90 after the third. In spring 2011, modifications for some of the survey questions were made. See Table II.

TABLE I. POST-EXAM SURVEY QUESTIONS (FALL 2007-FALL 2010)

| Label | Questions |
|-------|--|
| Q1 | Cannot figure out what concepts are relevant. |
| Q2 | Don't understand what the question is about (wording). |
| Q3 | Get stuck with computation. |
| Q4 | Difficult to identify equation. |
| Q5 | Don't know how to get started. |

(ii) End of semester surveys to assess learning progress

Surveys conducted at the end of each semester include three questions designed to assess SI students' learning gains in conceptual understanding of the course material and problem solving. A scale of 1-3 was applied to measure the degree of helpfulness of SI in these areas. "1" is defined as "least helpful" and "3" as "most helpful". Students were also asked to provide explanations about if and how SI workshops help them improve their problem solving skills.

(iii) SI facilitators' professional development and workshop teaching

All SI facilitators receive ongoing professional development and are required to attend class lectures as well as weekly training meetings for session planning. In the weekly meetings, peer instructors describe the main concepts covered in lectures, identify students' learning challenges, and present session plans and worksheet problems. SI facilitators typically receive constructive criticism from their peers and from the program director, who leads these meetings. Weekly training meetings have led to the production of a series of online teaching modules. In this study, we utilize a representative module to illustrate teaching in the SI workshop. The module captures crucial elements of SI facilitators' professional development as well.

TABLE II. REVISED POST-EXAM SURVEY QUESTIONS (SPRING 2011)

| Label* | Questions |
|--------|---|
| Q1 | Couldn't figure out what concepts are relevant. |
| Q2 | Didn't understand what the question was asking (wording of the problems). |
| Q3* | Didn't know how to interpret the diagram. |
| Q4 | Got stuck with computation (not proficient in math skills). |
| Q5 | Didn't know which equation(s) should be applied. |
| Q6* | Didn't know how to get started to solve the problem even though I knew which equations should be applied. |

Q* referrers to modified questions

III. RESULTS

A. Post-midterm surveys

Fig. 1 shows students' responses to the 5 questions about their learning difficulties (questions shown in Table I). The questions are intended to help students uncover areas that challenge them the most. Figure 1 displays the three main learning obstacles identified by students: (i) "Don't know how to get started", (ii) "Difficult to identify equation", and (iii) "Cannot figure out what concepts are relevant". Most students reported "Don't know how to get started" as a major challenge in all three midterms. The percentages of students who used "very difficult" and "most difficult" in responding to this question are shown in Fig. 1(e): 51% of the 425 for the first exam, 38% of the 217 for the second, and 40% of the 90 for the third. Figure 1(d) shows "difficult to identify equation" as another hurdle: 35% out of 476 for the first, 29% of the 294 for the second, and 51% of the 82 for the third one. Fig. 1(a) illustrates students' struggles with concepts: 32% of the 401 for the first exam, 39% of the 265 for the second, and 25% of the 72 for the third. In the end of the semester, students significantly improved their conceptual understanding of the course content and confidence in starting the problem solving process. However, no measurable gains in their ability to identify equations in the process have been observed.

Fig. 2 displays the spring 2011 survey results of three of the six questions listed in Table II. The rating for the survey used a

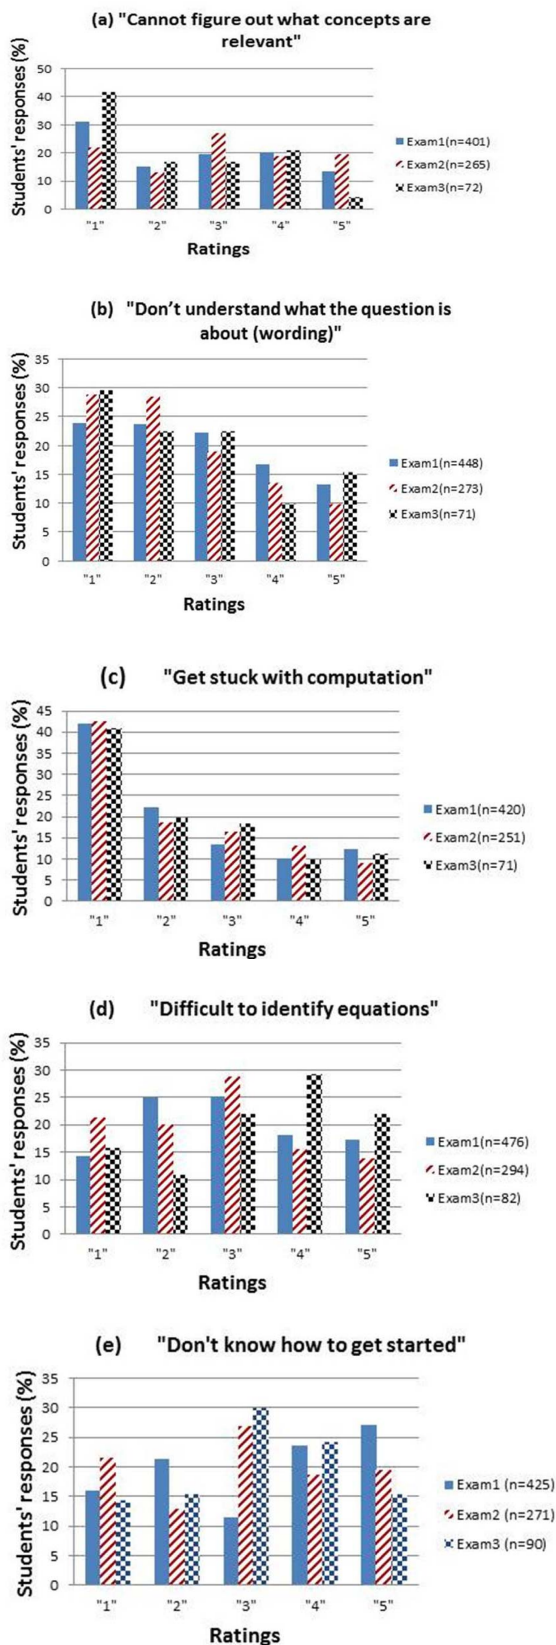

Figure 1. Survey results (Fall 2007-Fall 2010)

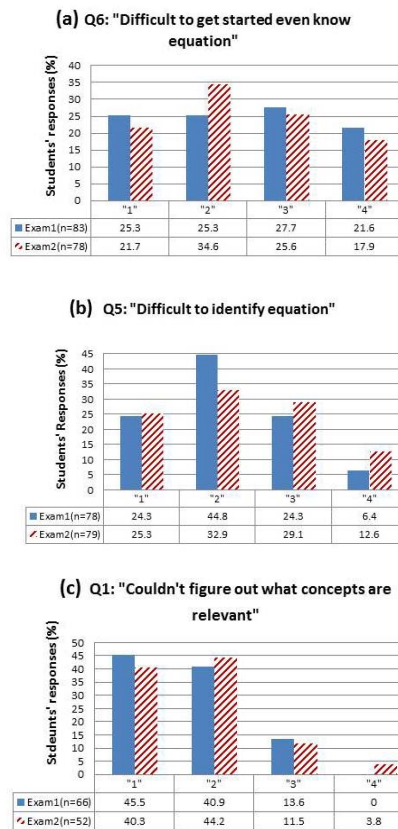

Figure 2. Selected survey results for Spring 2011

scale of 1-4 where "1" is defined as "a little bit difficult", and "4" is "the most difficult".

To gain greater specificity in the survey questions, some statements were revised in spring 2011. For example, because many students consider problem solving merely a process of "matching equation with the problem," we speculated it was likely that a number of students who indicated they did not know "how to get started" really struggled to "identify which equation to use" [8]. We also wanted to know whether some students answered that they "did not know how to get started" because of their inability to interpret a diagram. In the revised survey conducted in spring 2011, "Didn't know how to get started even though I knew which equations should be applied" got half of the 83 responses with ratings of both "very difficult" and "most difficult" for the first exam, and 31% of the 78 for the second exam, and the ability to interpret a diagram was not the cause. These results are consistent with what is shown in Fig. 1(e). Students continued to indicate that "identify equation" is "very" and "most" difficult.

B. End-of-semester surveys

Table (III) shows students' ratings of three questions about their learning gains in conceptual understanding and problem solving skills after attending SI workshops. Average ratings, used

in this table, are converted to a percentage for the purpose of display. That is, a score of “1” is equivalent to “33%”, and “3” is “100%”. All three questions drew ratings of 87% or higher. Students’ answers to the free response question regarding their views of why and how SI is helpful in fostering true learning are generally encouraging. While almost all reported positive learning gains, some indicated that SI had helped them master problem solving in an organized and systematic way as we hoped. These results will be discussed in the concluding section.

TABLE III. IMPROVED LEARNING IN SI WORKSHOPS (SURVEY RESULTS, 2001- 2010)

| Survey questions | n | Percentage |
|---|------|------------|
| Instructions from the facilitator are helpful. | 667 | 93% |
| Facilitated discussions in SI help me learn how to solve problems | 667 | 92% |
| Discussions in SI help learn course material | 1074 | 87% |

IV. INTERPRETING RESULTS

A. Students lack an intuitive concept of problem solving

More and more instructors are aware that students rely on memorization when faced with learning challenges, but only a few instructors are aware of why it is happening in students’ learning [8]. In the survey results, students particularly expressed concern regarding their learning difficulties in three areas. The survey results shown in Figures 1 and 2 indicate that students need help in (i) learning basic skills of problem solving, i.e. skills to start a process, (ii) gaining conceptual understanding of the subject matter, and (iii) understanding how and why equations they study in class can be applied to solve problems. It is not surprising that students who struggle to grasp conceptual understanding in physics and engineering physics courses have difficulties identifying the appropriate equation to apply. However, it is alarming that more than half of the 425 students indicated that “don’t know how to get started” was the main problem during their first exam. Some may argue these three items are connected and influence one another. So, if our teaching focuses on learning concepts, students should be able to overcome hurdles and learn how to apply equations to solve problems. Nonetheless, students continued to report challenges with “problem solving” even though they indicate that they know the equation (see Figure 2). In fact, research in physics education provides evidence that vindicate students’ concerns. Researchers have found significant improvement in conceptual understanding in studio style classrooms, but no observable gain in problem solving skills. It suggests that if we want students to be proficient, we must teach concepts and problem solving skills together [9]. Why do students struggle with basic “problem solving” skills? Our observations suggest two explanations: (i) misconceptions of “problem solving”; (ii) students’ prior learning experiences in “problem solving”. Quite often, the terms “solving a problem” and “problem solving” are used interchangeably, leading to misconceptions about learning. Essentially, solving a problem refers to the conclusion stage of a larger process of “problem solving” that includes the procedures of defining and

framing a problem [10]. Problem solving requires higher levels of cognitive thinking and skills. Unfortunately, many students consider problem solving as nothing more than finding a solution. When they fail to reach a conclusion using for example, “matching equation and problem” approaches, they are left no choice [8]. The students’ sentiment that they “don’t know how to get started” indicates that a very important component in problem solving is missing: an intuitive component. In other words, students who actually possess a good deal of knowledge often seem clueless when encountering a new and unfamiliar problem because they have not had enough exposure to situations in which they are encouraged to use logic and analytical methods to find answers or explanations. Students need to uncover their spontaneous analytical ability while developing the concept of problem solving. The first step in teaching problem solving is to help students understand that problem solving requires more than finding a solution.

B. Integrate instruction- and problem-based approach

How do we teach problem solving? SI, a peer-led workshop to teach problem solving, is an effective strategy to help engage students in a life-long learning process. First, SI helps take away stigmas some struggling students may possess. Many students are less intimidated seeking assistance from a peer to whom they relate easily than from an instructor in a big lecture hall. Second, problems which integrate course content in the workshop add incentives, keeping students motivated and interested in learning. Problem solving requires students to integrate factual, conceptual and procedural knowledge within the content, and helps students gain necessary skills to succeed in the course. Third, using well-structured problems allows SI workshops to direct students’ attention to the concept of problem solving. SI helps students become familiar with the procedures of defining and framing problems. Students have to build a strong belief in “problem solving” and understand that solutions draw on logic and analyses to solidify the concept.

SI workshops align teaching and learning goals by using a teaching method that combines instruction- and problem-based approaches. Guided by an understanding of students’ learning difficulties, each SI session reinforces important concepts to help students harness various topics taught in the class. Illustrations of how to break down a problem step by step show students ways to define and frame a problem. SI instructors work very hard to balance the need for instruction and hands-on practice to facilitate true learning. SI workshops introduce a problem solving framework, shown in Figure 3, which helps novices break the barrier of “don’t know how to get started” [2, 11,]. Applying the framework properly can keep students on track by showing them how to analyze problems instead of rushing to reach a numerical solution. To many beginners, the framework is a useful reference when they come across different aspects of problem solving: the meaning, the nature, and the solution of a problem. Instructional strategies applied in SI are based on a systematic approach of cognitive apprenticeship developed by Collins, Brown, and Newman [12]. This model has been effectively applied to teaching complex tasks in physics and other

disciplines [13]. Even though some of the problems used in the workshop ask for one solution, there are multiple ways of defining, rephrasing and representing these problems. Exercises like these allow students to establish and test various strategies for problem solving. Teaching and learning that focus on developing an intuitive concept at an early stage of engineering education will have a lasting impact on students' skills. For one, it will help students avoid, or at least minimize, adoption of the default "trial-and-error" approach when confronting real-world situations. Sometimes the "trial-and-error" approach is necessary. Yet, as engineering educators

C. A concrete example in SI workshop teaching

The SI program's online teaching module, "the framework of problem solving", highlights important strategies of SI instruction [15]. Like other aspects of engineering learning, developing problem solving skills requires students to comprehend knowledge in a constructive and organized way. Students need to integrate conceptual and procedural knowledge, and constantly assess and reflect on their learning progress. This module provides one concrete example of how SI students are taught to apply the framework.

Although facilitators typically introduce the problem solving framework in the SI workshop at the beginning of the semester, the online module is a representative illustration made available to students to reinforce their exposure to this important topic [15]. The "three-legged race" problem used in the module (Fig. 3) highlights logic and an organizational matrix, which can be generalized and applied to more sophisticated situations. The way the material is organized and delivered, as displayed in the module, provides the students with a framework that the facilitator will refer to throughout the semester using examples based on course content. By encouraging students to approach problems using the problem solving framework, SI helps them make connections to applications outside the classroom.

SI facilitators created other online-teaching modules for subject matter students typically found difficult to learn. These "difficult" topics are also important for subsequent engineering courses for example, mechanical properties of material as well as other courses [15].

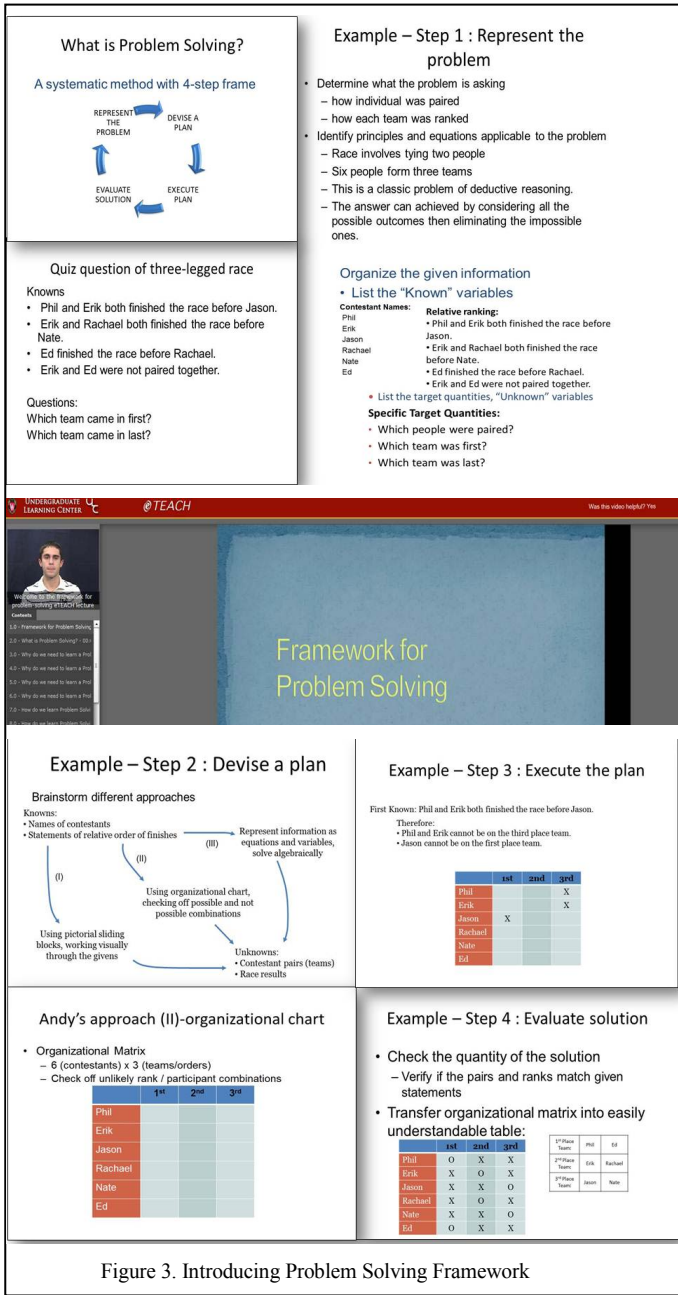

Figure 3. Introducing Problem Solving Framework

observe, it is not productive if used frequently [14].

V. CONCLUSIONS AND FUTURE PLAN

Due to space limitations, we present here just a few SI students' comments that are representative of those collected in the end-of-semester surveys. These comments provide insights into why SI is helpful and highlight core education values that SI has embraced since it started more than 10 years ago.

- During SI sessions, I learn how to, in an organized and logical way, approach the highly complicated problems in this class.
- In SI, my facilitator does an excellent job explaining how to set up a problem from the beginning in order to reach the correct solution within a short amount of time.
- SI helped me thoroughly learn concepts instead of just going through the motions of doing the homework.
- SI made me much more confident in my ability to do the problems and more confident in what I knew going into exams.

The positive learning outcome is also confirmed by the shrinking number of students who struggled with challenges of "did not know how to get started" in problem solving by the third exam, from 50% to 38%-40% as shown in Fig.1(e), and from 50% to 31% in Fig.2(a). Students' comments also highlight several contributing factors to the success of SI workshops, including students' engagement, a supportive

learning community, aligned teaching and learning goals, effective pedagogies and teaching techniques, and critical roles that facilitators play [7].

With an improved understanding of what underlies students' learning challenges in problem solving, the SI workshop applies content-based problems to align teaching and learning goals for entering engineering students. Without a strong foundation of intuition about problem solving, teaching and learning will be difficult and unproductive. The intuitive concept of problem solving developed in students' early learning is effective not only in engaging students in learning, but also in facilitating skill transfer. The effectiveness of instructional approaches applied in the SI workshop is due in part to the concept of metacognition while focusing on mastering content knowledge [5, 16]. The SI workshop contextualizes instruction to help students develop problem solving concepts and skills.

The current study also indicates several areas in which SI can improve. When asked in our surveys if they feel comfortable learning concepts on their own, only 65% of the 445 participants responded positively. In addition, as displayed in Fig.1(d), students continue to report difficulty finding and applying relevant equations even when they are equipped with the framework for problem solving. Research indicates that students' struggle in this area is caused by their misconceptions about the nature of the solution process [3]. SI plans to help students to improve skills in problem representations and gain deep understandings in concepts and principles, including more activities to help students confront their habits of "selecting and sequencing equations" during the process. These skills are important for a creative learner, and will help students make transitions from encountering content-based problems to real-world problems. Students need to learn how to solve open-ended and ill-structured problems [17, 18]. Problems that simulate and represent real-world situations are critical to help advance their knowledge and skills, and help them become innovative problem solvers. Engineering curricula need to provide learning activities that are tailored to meet students' learning challenges at every stage of their learning.

ACKNOWLEDGMENT

The Undergraduate Learning Center was partially funded by NSF Grant No 0402549, Wisconsin Alliance for Minority Participation (2004-2009) and more recently fully-funded by generous gift from the Grainger Foundation.

Abstract—In our Operating Systems course we make available in advance the lecture slides and lab sessions material. The slides are built paying attention to present the key ideas and with embedded links to sites in the Web where the topic is covered in greater detail. We also provide the corresponding excerpts of selected textbooks. Following the download activity and paying attention on what our students are doing during the lectures, we are able to collect some data on notes usage. By carefully selecting some questions in the test we can distinguish which student used the material available in links and excerpts. In this paper we present some patterns of use of the lecture notes. est

Student Notes; Hypertext; Student Attendance; Operating Systems

I. INTRODUCTION

In a classical work [1] a description of the potential benefits of note taking and reviewing is presented. Note taking and reviewing are labeled in the literature as *encoding* and *external storage* respectively. *Encoding* is described as generating a personalized written record of the lecture or the class activity. *Storage* is keeping this written record during the gap between presentation and evaluation and use the record for review or study guide.

There are several studies on the benefits of both functions [2] [3] with the storage function having an apparent greater impact. However these researches are related to the humanities. In Science, Technology, Engineering, and Mathematics (STEM) the storage function appears more standardized and is supplemented by other course materials, mainly books and Internet available information.

The potential productivity of reviewing notes is limited by the encoding function of the note taker. If key ideas are missed or misinterpreted, students start at a disadvantage when reviewing the material. In addition, students are notoriously incomplete note-takers, generally recording less than 50% of the critical ideas [2] [3]. These facts are addressed by providing students with instructor's notes.

Providing that notes are to be made available to students, there is a question concerning the detail of the material. Some teachers use skeletal notes in the form of slides, supporting a further development of the subject. This detailed development can be made in the lecture. If the

student does not attend to the lecture, she/he is supposed to search more information in order to force a personal encoding of the provided key ideas. This approach can lead to a surface learning-strategy where students tend to rote-learn by heart repeating only the provided key phrases with no further elaboration. The opposite approach is to provide detailed notes which are close to textbook detail.

II. INSTRUCTOR'S NOTES FOR STUDENTS

We decided to make available to students the slides we use to develop our lectures in the basic theory track. There are skeletal notes with the key ideas hoping to complement the coding function of note taking. As for helping with the storage function two levels of details are added to this first skeleton: embedded links in the slides to selected web pages and excerpts of the course recommended books. As a final information source, course main and consulting books are available at the institution's library.

The slides notes follow the same pattern we do when we explain the subject in class. The hypertext links are real world examples or more detailed explanations of these key concepts. Slides are projected during the lectures and selected hyperlinks were explored and augmented with searches leading to videos, animations, and other material. When real world examples are wanted, product logos are inserted in the slides and links to product descriptions are used. After some time the linked pages migrate and finally we decided to link Wikipedia pages as an intermediate step.

III. HOW STUDENTS USE THE MATERIAL

Mean enrollment in the course is around 80 students. There are very few drop-outs. Attendance to lectures is not mandatory and when students get the idea that the whole subject is covered by the material with no "hidden surprises" they begin to skip classes. In end of course surveys, other courses pressure and homework are blamed for this desertion. Usually we move after midterm to a lesser Lab with a capacity for 30 stations. We call this use of notes as substitutional use because students believe that a careful study of the material can substitute classroom attendance. By the end of the term, attendance was reduced to a 30% of the enrolled students.

This study was supported with the grants I333 and I226 from the University of Buenos Aires, Argentina

Figure 1 shows attendance rates in the two 2011 terms. The very low rates at weeks 9 in the first and week 10 in the second term reflect other subject's homework deadlines. In average we have half of the enrollment attending lectures. We consider high attendance students to those who attended at least to six out of twelve classes.

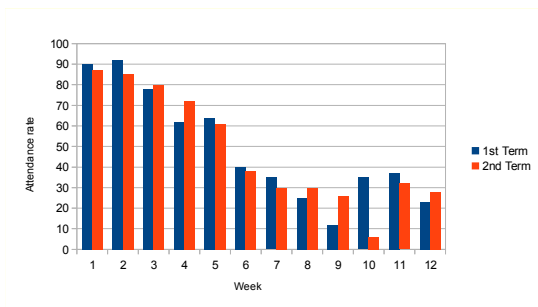

Figure 1. Week attendance rate

Other students use the material as a supplement or a guide for their study, according to their learning style. In spite of our use of annotation tools, and specifically addressing these kind of tools in our lectures, very few students made use of electronic annotations, most of them after our presentations. Not even do they use text editors on the provided computers.

We do not tape the lectures or the lab sessions. Students are very concerned about their privacy and recording the session is seen as intimidating. However we observed that many students brought printed copies of the slides. It seems that a printed copy defeats the whole purpose of the hypertext.

Some of the students annotate the slides explaining in their own words the meaning of the key ideas. Other highlight when we followed some links and in some cases the URL are copied. All of these activities can be made automatic using tools like the ones we use in our presentations. We expected students to annotate their pdf version of the slides and to use some cloud storage system like Dropbox to made them available later at home but this behavior was seldom observed.

IV. GRADES

In the following sections we use a three pass grades scale. These are not the final grades the students got because the final grades are obtained using a mix of the test, the team work performance and scripting midterm examination.

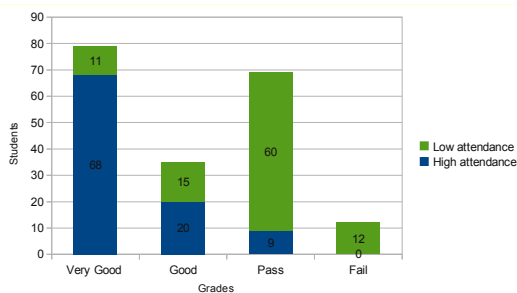

Figure 2. Attendance and grades in 2011

Very few students fail the test. Actually the number has been steadily increasing in the last years. Operating systems

is a subject at junior level and students are well trained to know when they are to ready to pass the test.

In Figure 2 we plot the attendance and the earned grades. The figure shows clearly that the substitutional use of the provided material is not a good strategy if a student wants to earn a good grade. In our country motivations for a good grade are more intrinsic to the student than institutional. There is no honor program or GPA.

In surveys completed online after they approve the subjects, students acknowledge the importance of class attendance. They find a greater engagement with the subject in the face to face interaction. However working only with the material pays for students who actually are not able to assist to the lectures and have a real interest in the subject.

In order to know if the links embedded in the slides have some effects, some questions ask for material addressed in the first order links. Figure 3 relates the reading with the grades.

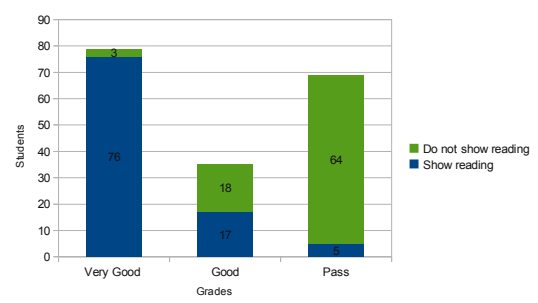

Figure 3. Reading the material of the embedded links and/or books

Answers that show the use of links also show the use of textbooks. It is clear from the style the answer is written and the precision the used technical jargon. Interesting enough, we found no mention of the commercial products we refer to in slides using logos and links

V. CONCLUDING REMARKS

There is little doubt that the coverage of the material is useful for the students at least in two ways; students are able to pass the course without attending to the lectures and students who really are engaged get the supplemental material they want.

Students do not show advanced technology uses in our lectures. This is opposed to the idea of the 'digital natives', a generation of tech-savvy young people immersed in digital technologies for which current education systems cannot cater. Further research is needed but some confirmation of this trend is beginning to show up in the literature [4] [5]. Students seem to look to their lecturers for clues as to how to use technology tools for learning.

Abstract - Great emphasis has been given to the cognitive and methodological aspects of learning and teaching programming. Nevertheless, research shows a significant correlation between student self-regulation and academic achievement in higher education. The Attitudes and Study Behaviors Inventory (IACHE) is a multidimensional inventory that integrates in its design behavioral, affective-motivational and cognitive aspects of learning. This paper presents the results obtained from the application of the IACHE inventory to 190 introductory programming students from Brazil and Portugal. Data suggests that Brazilian and Portuguese students have very similar attitudes and behaviors regarding learning strategy, self-efficacy perception and study activities' organization, which seems to suggest that the same type of students choose undergraduate computing programs in both countries.

Keywords – *Self-regulation; Behavior; Motivation; Cognition; Achievement; Programming, IACHE.*

I. INTRODUCTION

Teaching basic programming in higher education is one of the greatest challenges of computing. Many students entering computing degree programs have their first contact with programming in their first semester, and are faced with the need to develop a logical/algorithmic reasoning, to learn about a new technology and acquire knowledge about a new language's syntax and semantics, in addition to dealing with their transition from high school to university. Given this scenario, it is not a complete surprise that these courses have been globally responsible for large failure and dropout rates in undergraduate computing programs [1].

Although great emphasis has been given to the cognitive and methodological aspects of learning and teaching programming, research shows a significant correlation between students' self-regulation and academic achievement in higher education. According to Zimmerman [2], self-regulation

implies personal knowledge and motivation to make deliberate use of skills to act. In school, self-regulated learning involves the regulation of three main aspects of academic learning: *behavior*, which involves the active control of the many resources that students have available to them, such as their time and study environment; *motivation*, responsible for controlling and changing motivational beliefs such as self-efficacy and goal orientation, so that students can adapt personal resources to their school settings' demands; and *cognition*, which involves the control of several cognitive strategies implied in the learning process, such as the use of deep processing strategies [3]. In the following, we will focus on how each one of these regulatory dimensions of academic learning is related to students' academic achievement.

(i) *Behavior*. Starting in elementary school and throughout schooling, students face several tasks, contexts and learning methodologies that help them develop their study behavior, helping them find a learning approach that best fits their personality, beliefs and values. They set goals to be achieved, select resources, and implement strategies to tackle specific learning tasks [2]. In this context, study skills and academic learning approaches include, for example, time management, use of information resources, taking notes in class, communicating with teachers, or even, preparing for and taking examinations. In their meta-analysis, Hattie, Biggs and Purdie [4] conclude that if we aim to improve academic achievement and increase academic success in higher education, institutions must foster interventions directed at students' learning strategies.

(ii) *Motivation*. Understanding motivation to learn requires a deep analysis of the socio-cognitive components associated to personality (identification with the institution, chosen program, vocational project and career, accessibility to teaching, analysis of school success) and the quality of relationships in life environments (social identification and learning approaches) [5]. The motivational dimension has a great impact on the individual's cognitive development and is a determinant factor

for success in the learning process [6]. It is motivation that fosters in the student the disposition to want to progress and reach the goals that were set, maintaining an adequate level of volition to overcome the demands that are being dealt with [2].

(iii) *Cognition*. The interaction between motivation and cognition positively impacts students' academic performance [7]. Furthermore, students who have a more adequate approach to learning and who are more motivated, elaborate more positive cognitions regarding themselves in the long term, increasing their chances of academic success [2]. In other words, such students build self-efficacy beliefs, which are influenced by their motivation and affect their judgment about personal ability to perform a task in a specific domain. In learning situations, self-efficacy influences the use of efficient cognitive strategies while solving problems, the amount of effort expended, the type of coping strategies adopted, the level of persistence in the face of failure, and the performance outcomes [8].

Based on these research findings, the "Attitudes and Study Behaviors Inventory" – *IACHE* (in Portuguese, *Inventário de Atitudes e Comportamentos Habituais de Estudo*) [9; 10], a self-report questionnaire, was developed by a Portuguese research group to assess behavioral, motivational and cognitive factors related to students' study habits and learning approaches in higher education.

Considering the difficulties, failure and dropout rates experienced by introductory programming students, and having in mind the impact of self-regulated attitudes and behaviors in academic achievement, we have used *IACHE* to assess Brazilian and Portuguese university students. Despite the clear differences between both countries, the programming learning-teaching scenario has some aspects in common, namely high failure and dropout rates, hence the interest in analyzing what students from Brazil and Portugal share in common and what sets them apart, in order to identify possible clues to successfully intervene on these issues.

II. BRAZIL AND PORTUGAL, TWO REALITIES

Content delivered in introductory programming courses is very similar in Brazil and Portugal, despite the realities inside the classroom in both countries being very distinct. In the last few years, the Federal University of Goiás, in Brazil, and the University of Coimbra, in Portugal, changed the way introductory programming courses had been historically taught in their institutions. The reasons that have led to such changes varied, as well as the new chosen approaches, as presented in the following.

A. Federal University of Goiás (Brazil)

In 2008, Problem-Based Learning (PBL) with tablet PC support was introduced in the Computer Programming 1 course of the Bachelor in Computer Science's program of the Computer Science Institute of the Federal University of Goiás (UFG), in Brazil, to minimize the recurring problems of students' low achievement, high dropout rates and lack of motivation [11].

The forty students that enter the program are divided in two groups of twenty, so that each student can have his/her own tablet PC. The laboratory used to teach the course is composed of four trapezoid-shaped tables with up to six students each. Each student is provided with a tablet PC with the necessary environments installed. Besides the professors, one for each class, there is a teaching assistant for each class, usually an undergraduate student, to help during class and in specified hours after class, with a weekly workload of 12 hours.

In the classroom, the PBL method [12] is used to introduce the concepts in the course syllabus as a series of open-ended problems, using a method adapted from Nuutila, Torma and Malmi [13], according to which groups of four to five students work collaboratively to reach a solution to the proposed problems. The description of a problem is given to each group; students are given approximately 40 minutes to discuss among themselves possible ways to solve the problem, relating it with the knowledge they already possess and identifying topics for which they need more information or with which they are not yet familiar. After this "brainstorming stage", students filter their ideas and the group identifies learning objectives that represent knowledge they must have to solve the problem and that must be researched/studied. Outside the classroom, students work individually each of the learning objectives, and are not allowed to divide their task. Having obtained the necessary knowledge to solve the problem, students gather again to propose a joint solution, obtained from suggestions and individual solutions from each one of the members of the group. The resulting algorithm is then implemented. This process can take a week or more, depending on the complexity of the problem. Eventually the teacher can give a lecture addressing issues that were misunderstood by the students or to complement the learning objectives proposed by the groups.

The course is divided in two parts: the first using only the SICAS environment [14] for flowchart diagramming, and the second using the DevC++ environment. The SICAS environment allows students to draw flowcharts that are then automatically translated to C or Java. The system offers a drag and drop environment with constraints that guide the students in the algorithmic definition of the problem, contributing to the learning process. All basic programming concepts are discussed in the first phase, and again in the second phase. The first part extends for about a month and a half, while the second part lasts 3 ½ months. In each stage, several distinct problems are proposed. Examples of these problems include defining a calculator or implementing games such as Battleship and Pac Man.

This course is offered in the first semester of the program, with a total of 64 hours in the classroom (32 encounters of 2 hours, twice a week). Attendance is mandatory. Students that are absent in more than 25% of the classes fail the course. To be approved, the students must achieve a minimum of 5 points, in a 0-10 scale; these points are distributed by the activities of the course, and the teacher has autonomy to define the distribution. In the last few years, the distribution that is being used is: 20% for individual participation in class and exercises, 20% for group solution of problems, 30% for the mid-term exam, and 30% for the end-term exam.

B. University of Coimbra (Portugal)

In Europe, one of the most important recent events in the educational sphere has been the evolution and adaptation of universities to the Bologna Process, which led to the creation of a European Higher Education Area (EHEA) with unified strategies and development goals [15]. Within this new reality, the University of Coimbra (UC) has adapted its programs to conform to Bologna Declaration since 2005 [16]. In some cases, this means classes with a greater number of students and the standardization of some courses so they can be attended by students from several programs, which accounts for an expressive heterogeneity of student profiles in some of them. This is the case for the introductory programming disciplines. Students from the Bachelor's Degree in "Engineering and Information Technology" – LEI, in the Faculty of Science and Technology of the University of Coimbra (FCTUC), attend classes where the number of enrolled students is usually very high: between 200 to 300 candidates, who come from several programs such as "Industrial Engineering and Management" and "Communication and Multimedia".

In the new curriculum, introductory programming was divided in two courses: "Introduction to Programming and Problem-Solving" and "Principles of Procedural Programming" – PPP. The first was proposed as a transition programming course designed to present the first programming concepts to the students in a problem solving context using Python. This course is followed by "Principles of Procedural Programming" – PPP, the second programming course of the LEI program, aiming to support the basic problem solving knowledge acquired in the first semester which is taught using ANSI-C. There is no pre-requisite, which explains the high number of students enrolled in these courses.

Although the PPP course accepts students from several programs, the whole course was designed to fit the LEI students' profile. The program includes basic programming knowledge for understanding the ANSI-C programming language (1999 standard), memory management, pointers and algorithms for fundamental data structures. The course is based on content presentation lectures and more applied classes, where students can practice what they have learnt from lectures, with evaluation points done using small practical programming challenges done in pairs. Classes in the UC are usually organized into:

- (i) Lectures (2 hours). All students enrolled in PPP have class with a coordinating professor responsible for the subject;
- (ii) Practical sessions (2 hours). The class is divided in smaller groups in order to do hands-on lab exercises under the supervision of a teacher, who may or may not be the lecturer, depending on the total number of enrolled students and the capacity of the laboratories. These groups have usually 20 to 30 students, with a total of 10 to 14 groups for each course, and involve 3 to 4 teachers, in addition to the coordinating professor;
- (iii) Practice-Lab Sessions (2 hours). These are not classes *per se*, but support sessions in which the students have study guides, reinforcements and clarification of doubts, with the aid of a tutor, usually a graduate student.

With the exception of practice-lab sessions, which are not mandatory, all classes require advance registration and attendance, except from working students. Besides classes, the activities developed during the course included: 10 exercise lists to be implemented in the practical sessions (with the designation of some exercises to be presented orally), a theoretical evaluation, a mini-project and a final exam taken at the end of the course. All activities are scored, and students must achieve a minimum of 10 points in a 0-20 scale, in order to be approved in that subject. To qualify for the final exam, each student must obtain a minimum frequency and grade that is equivalent to 35% of the points attributed to the activities. For those that do not succeed in the final exam, there is a second chance with a "special season exam". However, even amongst those who have the right to take the final exam, there are approximately 40% that choose not to take the exam because almost all exams occur in the same period and the students choose to study for those that they believe they have a better chance of success in. Furthermore, many students who failed "Introduction to Programming and Problem-Solving" enroll for PPP, as there is no pre-requisite and enrolment is done once a year. However, most of these students dropout in the first month, or right after the first exam is taken.

III. GOALS OF OUR STUDY

With our study, we aimed to use IACHE to assess Brazilian and Portuguese university students. We believe that the analysis of data obtained from IACHE can provide some important information about the attitudes and behavior of students, individually and in groups, and shed some light on cognitive and motivational aspects of programming students' profile.

Our main research goals were to:

- (i) Apply IACHE to introductory programming students in Brazil and Portugal and estimate the psychometric proprieties of this instrument;
- (ii) Identify possible differences between the profile of introductory programming students in Brazil and Portugal;

IV. METHOD

A. Participants

A total of 190 students – 72 from UFG (in Brazil) and 118 from UC (in Portugal) – participated in our study. To have a more homogeneous profile of our sample, we chose only UC students enrolled in PPP that come from the LEI program, as this program has a similar objective and structure as the Computer Science program of UFG. Furthermore, we chose to evaluate students from the PPP course that occurs in the second semester, as the course uses an imperative language, similar to the one used by the UFG students.

In UFG, testing was done in 2009-2, 2010-1 and 2010-2, always at the end of the course. In the Brazilian sample, 23 students were assessed in 2009-2, 31 in 2010-1 and 18 in 2010-2. On the whole, 63 were male and 3 were female (6 did not identify their sex). The sample ranged in age from 16 to 26 years ($M = 18.5$; $SD = 1.68$). IACHE was administered to

students who had just completed or were completing the first semester of introductory programming.

In UC, testing was done in the beginning of the second semester of the 2008/2009 school year. From a total of 320 enrolled students in the PPP course, 244 were from the LEI program of which 118 answered the inventory. Of these, 109 were male and 9 were female. The sample ranged in age from 18 to 31 years ($M = 20.0$; $SD = 2.73$).

B. Procedures

IACHE was applied collectively, in a classroom environment. Students were informed about the study purposes and assured about the confidentiality of their results. Participation was voluntary and there was no financial compensation.

C. Instrument

The instrument used in our study, IACHE – “Attitudes and Study Behaviors Inventory” –, was administered to assess behavioral, motivational and cognitive aspects of students’ study habits and learning approaches. This multidimensional inventory integrates in its design three main factors: *behavior* (concerning actions, daily routines, time management and study materials), *motivation* (concerning commitment, interest, involvement and progress in the study) and *cognition* (concerning personal perceptions, strategies or approaches to learning). Regarding the learning approach, IACHE allows to contrast between a superficial and a comprehensive approach to learning: the first focuses on the memorization of information; the latter emphasizes a more significant learning and understanding of learned contents. According to these factors, IACHE is divided in five sub-scales:

- **Comprehensive Learning** - using reflection and analysis in depth of content, which means more effort and time spent by the student in learning, who is focused on understanding (10 items, $\alpha = .86$);
- **Surface Learning** - tendency to spend a minimal effort to learn. Learning is superficial, based on memorization and reproduction of contents (8 items, $\alpha = .81$);
- **Intrinsic Motivation/Involvement** - the availability for study activities, primarily related to requirements of intrinsic motivation (8 items, $\alpha = .83$);
- **Study Activities Organization** - examines the evidence of structured activities and study. Focus on how students organize and manage their study (time, materials, etc.) (10 items, $\alpha = .83$);
- **Self-efficacy Perception** - personal perceptions about capacity to succeed in the academic tasks, self-concept, expectations, etc. (8 items, $\alpha = .80$).

IACHE is composed of 44 items, distributed in the five dimensions previously described. Items are presented in a six-point Likert scale, according to the degree of agreement (1 = “never” and 6 = “always”). In the parenthesis associated to each dimension description above, the distribution of these items can be found, along with the value of Cronbach's alpha,

used as a measure of the internal consistency or reliability of a psychometric test score for a sample of examinees, associated to each dimension. Values above .80 indicate good reliability. According to preliminary studies (see [10]), the factorial analysis and internal consistency of the items of IACHE have shown satisfactory results (Cronbach's alpha coefficient ranging between .80 and .86).

V. RESULTS

Before comparing the results obtained in the sample from Brazil and Portugal using IACHE, it was necessary to test the validity of the scale. This was undertaken through a factor analysis of the internal structure, in order to see if the items grouped alike in the two countries. Even though theoretical background, as well as preliminary studies of IACHE, assumed the existence of five dimensions, the factor analysis of our data captured three dimensions that can be interpreted with a minimum of coherence. Each one of the factors attained the 5% minimum variance criteria (Kaiser criteria), explaining together a total of 45.7% of the variance. Thus, there were identified three dimensions explaining what is common to both countries, which was used to test the hypothesis of the existence of differences between Brazilian and Portuguese students.

The items that did not meet a minimum of 0.5 factor loading criteria were eliminated. A closer analysis of the items associated to the three identified factors revealed that they correspond to the items originally associated to the *Study Activities Organization*, *Comprehensive Learning* and *Self-efficacy Perception* sub-scales proposed by the theory underlying IACHE. Hence, although the original factor analysis did not replicate the theory, some level of validity may be given to these three factors.

Following, a score per subject was calculated for each one of the three dimensions. This was done using a regression factor analysis. An original Z score was obtained and transformed to a T score, to avoid working with negative values. No correlation between the three dimensions was found according to the Varimax rotation factor that was implemented. A UNIANOVA was calculated for each dimension, separating the groups (Brazil and Portugal), with sex and age as covariates. Significant variance was found for the *Study Activities Organization* dimension ($F(1,188) = 4.64$, $p < .05$).

To better understand the variance encountered in *Study Activities Organization*, an analysis of the items associated to this dimension was undertaken using an Independent t-Test. Significant variance was found in item 17 ($t(93.35) = 5.49$, $p < .001$). This item asked if the student went regularly to the library to read or browse for books and documents. Brazilian students ($M = 3.0$; $SD = 1.66$) presented a higher mean than Portuguese students ($M = 1.9$; $SD = 0.84$), suggesting that Brazilian students go more often to the library to read or browse for books and documents, even though their mean was positioned in an intermediate level of the scale ranging from 1 to 6, corresponding 6 to maximum agreement. For the remaining items, no significant variance was found, with means ranging from 2.6 to 3.7 for both Brazilian and Portuguese samples, indicating that students rate themselves in an intermediate level of the scale.

VI. OTHER CONSIDERATIONS

In addition to the analysis of the IACHE results, we have undertaken an analysis of the academic grades obtained by both samples. Table I compares Brazilian and Portuguese realities, presenting the total number of enrolled students in the cohorts where IACHE was administered, the number of dropouts, as well as the number of students who failed even though attending classes (were not dropouts), and finally, those who succeeded. A mean grade was calculated for those who succeeded. A general mean grade was not available because in UC failure grades are not recorded. As the grade range in UC varies from 0 to 20, we have divided the mean grade of approved students ($M = 14.12$) by two, so that it can be compared to the Brazilian sample. Furthermore, we calculated the total percentage of approved and retained students considering only those who did not abandon the course.

TABLE I

CHARACTERIZATION OF PROGRAMMING COURSE STUDENTS IN THE BRAZILIAN AND PORTUGUESE SAMPLES

| | Course-Program-University | |
|-----------------------------------|---------------------------|-----------------|
| | PC1-INF-UFG | PPP-LEI-UC |
| Enrolled students | $n = 110$ | $n = 244$ |
| Dropout | $n = 15$ (14%) | $n = 126$ (52%) |
| Failed | $n = 20$ (18%) | $n = 37$ (15%) |
| Approved | $n = 75$ (68%) | $n = 81$ (33%) |
| Mean Grade of approved students | 6.54 | 7.06 |
| Not considering dropout students: | | |
| Percentage of approved | 79% | 69% |
| Percentage of retained | 21% | 31% |

According to the information presented in Table I, the teaching methodology appears to have a relevant impact on the dropout rate. However, it does not seem to have the same impact on the students' grade nor in the percentage of retained students (only 10 % difference). This may suggest that the methodology, by itself, is not decisive to reduce the percentage of failure. This may lead us to question the validity of the investment made by INF-UFG, where the number of students in each cohort was drastically reduced, given the expectation that a more personalized methodology would foster higher success rates.

This information, along with the results of our study, lead us to wonder if the high failure rates found in Introductory Programming courses may be mainly due to internal factors associated to the cognitive and motivational processes of the students. In fact, authors have suggested that the difficulties experienced by novice students who are learning to program are related to the lack of fitter mental models [17, 18, 19, 20, 21, 22]. For several reasons, including the difficulty of first year students, several researchers propose the development of Computational Thinking skills, i.e., thought processes involved in formulating problems and their solutions so that the solutions are represented in a form that can be effectively carried out by an information-processing agent [23], as early as elementary school [24, 25]. However, these are hypothesis that would need to be tested in future studies.

VII. CONCLUSIONS

In the traditional method of teaching programming, students hardly feel excited because they have to concentrate on coding and compiling problems generated by the rigidity of professional programming languages, in addition to solving the algorithmic problem. In the aim of tackling such challenges, different approaches have been defined, mostly through the use of new classroom methodologies and the use of different programming languages and tools.

At UFG (in Brazil), the Computer Science program adopted, in 2008, the PBL method for teaching their CS1 course, along with the use of tablets PC and flowcharts. The results obtained were quite satisfactory. Although there had been no significant increase in average scores, compared to classes in previous years, there was a significant decrease in the number of failures and dropouts rates. However, there is still a 25% failure rate in this course.

The adaptation to the Bologna process undertaken in UC (in Portugal) aimed to make students more independent and proactive in building their own knowledge, returning teachers to their role of guides of the students' learning journey. Even though the idea is interesting, its implementation still has some issues to overcome, given the large classes and the heterogeneity of students' profile, and also the expressive dropout and failure rates.

To improve the CS1 outcomes, new solutions must be thought of, taking into account the students' profile, their attitudes towards learning and their method and strategies to acquire knowledge. In this sense, a first step is to better understand the students and their profile. To do so, we have applied the IACHE questionnaire to Brazilian and Portuguese university students, aiming to identify their attitudes and behavior towards study and academic learning. Data obtained from our application allowed us to observe that there are no major differences between Brazilian and Portuguese students concerning their attitudes and behaviors, despite the fact that they belong to two very idiosyncratic realities, where two very distinctive teaching approaches are being implemented.

An analysis of the academic outcomes of Brazilian and Portuguese students seems to indicate that the teaching methodology has an impact on the dropout rate, but not so much in the grades or in the number of retained students. This raises the hypothesis that the problems faced by students may be related to internal factors associated to their cognitive processes. Further investigation is needed to test such possibility, as well as to better comprehend and intervene on difficulties experienced in introductory programming courses, as well as to verify if a specific student profile can be expected when we consider students who chose Computer Science programs.

Abstract— In this research the motivational levels of the students in a social welfare department while learning computer programming were analyzed relative to the contents that were taught in each lesson. The introductory programming course was game-based, and Java language was used with Eclipse as the Integrated Development Environment (IDE). The lessons were designed in such a way that as the students finished more and more assignments they were nearing completion of the Tetris game. The motivation levels were measured using a questionnaire based on the ARCS motivation model, which has four factors: Attention, Relevance, Confidence, and Satisfaction. As a result, it was found that the motivation of the students changes according to the lesson content.

Keywords—introductory programming; motivation; analysis; ARCS model

I. INTRODUCTION

It is often said that being fluent in information technology is important not only for computing majors but also for non-computing majors [1], and many universities offer programming modules in their CS/IT courses [2]. However, teaching programming is not an easy task especially when teaching to non-computing majors because their motivation to learn programming is not as strong as computing majors. Therefore many researchers have been concerned with the motivation of students studying programming. T. Jenkins assessed the motivation of students at the beginning of a computing course [3]. He defined four types of motivation: extrinsic, intrinsic, social, and achievement. He obtained a somewhat disappointing result that there was little evidence that any significant number of students were motivated by an intrinsic interest in the subject itself.

In this research, the ARCS motivation model introduced by J. M. Keller [4] was used as the background theory. This model assumes that motivation has four factors: *Attention*, *Relevance*, *Confidence*, and *Satisfaction*. In the context of the ARCS model, using games in programming courses can be considered

as a mean to raise *Attention*. M. Feldgen and O. Clúa introduced what students regard as their ‘real world’: games and Web-programming, to motivate their freshman students to learn programming [5]. They used University statistics such as rate of attendance in class or rate of drop out from the institution to prove the effectiveness of their approach. Some researchers also used robots [6], narrative media [7], artwork [8], and media computation [9] for the same reason. Using graphical programming languages such as Scratch can be considered as a mean to raise *Confidence* and *Satisfaction*. S. Uludag et al. used the Scratch programming language in order to achieve constructionist learning and contextualized computing education in their CS0/IT0 course for majors and non-majors [10].

In this research, an introductory programming course was offered to the students in the department of social welfare, and the motivation of the students was regularly assessed using the questionnaire based on the ARCS model. The programming course was game-based because games played on mobile phones are very popular in Japan and the authors thought that games would attract the students’ attention. The game chosen to be used in the course was Tetris. Though there are several programming languages/environments that are said to be suitable for novices such as Scratch, Java language was used with Eclipse as the IDE in the course so that the students could prepare for the programming environments at the work places.

II. THE PROGRAMMING COURSE

The programming course was offered to the sophomore students in the Social Welfare Department, Niigata Seiryō University from April to early August 2010. There were 51 students enrolled in the course, and 48 students remained at end of the course. None of the students had previous programming experience. The students were supposed to complete the programming of the Tetris game at end of the course of 15 lessons. Since the students were not expected to do this by themselves, most of the Classes were prepared by

the instructors, and the students were supposed to work only on the program in Tetris Class which controlled the behavior of the game. The assignments given to the students in the late stage of the course were designed in such a way that as the students were nearing completion of the Tetris game as they finished more assignments. After finishing the assignment given in Lesson 14, the students could play Tetris. The last assignment given in Lesson 15 was to display the score of the game. The syllabus for the course is shown in TABLE I.

III. PRELIMINARY EXPERIMENTAL RESULTS

The motivation of the students in the programming courses was analyzed using the authors' original questionnaire based on the ARCS model. Each of the 12 question item in the questionnaire was presented using a five-point Likert scale where answer 5 always corresponded to "agree" and answer 1 to "disagree".

Among the 48 students who finished the course, 24 students attended all the 15 lessons and filled out the questionnaire 15 times. The data of those students were used for the analysis. The change of the average scores for all the 12 question items from Lesson 1 to Lesson 15 is shown in Fig. 1. As can be seen in the graph, the motivation score at Lesson 14 was highest. Toward the end of the course, the Tetris game is near completion, and it could be played by the students after they finished the assignment in Lesson 14, and that is considered to be the reason of the high score. The motivation scores dropped drastically from Lesson 14 to Lesson 15. The authors presume this is mainly because the assignment given to the students brought their motivation down. The students worked on the final assignment in the class and none of them could finish the assignment by end of the lesson. Most students needed one more week to finish the assignment. In other lessons, if the assignments looked too difficult to the students, the instructor gave some hints to the students.

In any introductory programming course, new concepts are being introduced and the degree of difficulty should increase as lessons progress. But, if the increase in difficulty and the learning of the students are balanced, the motivation would not drop. Therefore, when new concepts are introduced in a lesson, care should be taken not to increase the difficulty too rapidly.

TABLE I. SYLLABUS FOR THE PROGRAMMING COURSE

| Lessons | Title | Contents |
|---------|--------------------|--|
| 1 | Eclipse (1) | Installation of Eclipse |
| 2 | Eclipse (2) | How to use Eclipse |
| 3 | Java basic (1) | main() method, Import statement |
| 4 | Java basic (2) | variables, data types |
| 5 | Loops (1) | for statement |
| 6 | Loops (2) | while statement, Random() method |
| 7 | Event handling | Event, Listener, Mouse event |
| 8 | Conditional branch | if statement, if-else statement, nesting |
| 9 | Arrays | Array initialization, 2D arrays |
| 10 | Animation | Thread, moving ball, moving balls |
| 11 | Classes | Fundamental programming structures |
| 12 | Inheritance (1) | Circle Class |
| 13 | Inheritance (2) | Ellipse Class, Inheritance and Override |
| 14 | Tetris (1) | Making Tetris playable |
| 15 | Tetris (2) | Displaying scores |

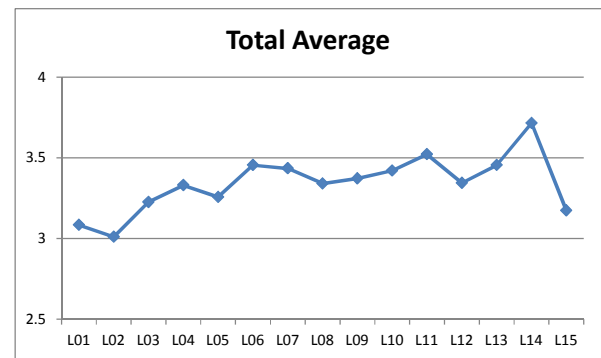

Figure 1. The Change of Total Average

Also, when giving assignments to the students, they should not be too challenging.

IV. CONCLUSION

In this research, the motivational levels of the non-computing major students while learning introductory programming were monitored and analyzed.

Work in Progress: What Calculus Do Students Learn After Calculus?

Andrew Bennett and Todd Moore

Department of Mathematics
Kansas State University
Manhattan, KS, USA
bennett@math.ksu.edu

Abstract— Clinical interviews were held with students in senior level electrical engineering and methods of teaching secondary mathematics classes. These students had all completed a 4-semester calculus sequence including differential equations. Engineering students had then taken advanced classes applying mathematical ideas in real-world contexts while mathematics education students had taken a similar amount of coursework in advanced mathematics courses. Students were interviewed to determine how their conceptual understanding of function and accumulation (integration) had grown or regressed during work after calculus. Back-transfer, where later learning improves conceptual understanding of earlier material, was observed.

Keywords—component; back transfer; APOS; function; accumulation; understanding

I. INTRODUCTION

There have been numerous studies looking at the concept of transfer, where material learned in one course is available (or not) for application in later courses (for a variety of examples of such studies, see chapter 3 of [1]). The idea of transfer underlies much of the structure of the modern engineering curriculum, where students begin in calculus and physics and then apply that knowledge in later work. Much less studied is back-transfer, where seeing material in a later course deepens understandings of concepts that could have been developed in an earlier course [2]. A proper understanding of how engineers' conceptual understanding develops throughout their training requires an understanding of how both transfer and back-transfer work. The research questions addressed in this study are:

- Does back transfer occur?
- If so, does the application of math in different contexts lead to different levels of back transfer?

This study focuses on the concepts of function and accumulation (integration) as developed in calculus. However, a better understanding of back transfer in mathematics should provide a guide to the study of transfer and back-transfer in other aspects of the engineering curriculum.

II. METHODOLOGY

A. Subjects

This study builds on earlier research about the level of conceptual understanding exhibited by students at the end of a 4-semester math sequence, Calculus 1, 2, 3, and Differential Equations [3]. The participants consisted of 20 senior-level engineering majors and nine senior-level mathematics education majors. Each group was selected from their classes in the Spring semester of 2011. The engineering majors were recruited from ECE 512: Linear Systems in the College of Engineering. The mathematics education majors were recruited from MATH 570: History of Mathematics in the Mathematics Department. These groups were selected because students in both groups had completed the same 4-course sequence, typically during their first two years of college, and had both taken additional courses which used that material afterward. However, the engineering students had seen the calculus ideas applied in more real-world settings than the education majors, few of whom took any additional science courses and instead primarily looked at more abstract applications in advanced math courses. By comparing the conceptual understanding displayed by the seniors to that displayed by sophomores, back transfer could be assessed. By comparing engineering and education majors, the role of different contexts of application could also be assessed.

B. Interviews

Each student participated in a (roughly) 60 minute clinical interview. Interviews were conversation-style following a protocol with predetermined questions along with spontaneous, related follow-up questions determined by the course of the interview to get at understanding. Questions were taken mostly from the level of Calculus I and II with two questions coming from Differential Equations. The questions were chosen based on whether each would demonstrate a student's understanding of various calculus concepts including function, differentiation, and integration. For example, the interview questions included:

Graph $x(t) = \cos t$, $y(t) = \sin t$, $0 \leq t \leq 2\pi$

Graph $x(t) = \cos 2t$, $y(t) = \sin 2t$, $0 \leq t \leq \pi$

Are these the same functions?

The researchers were not specifically interested in the “correctness” of the student responses. However these questions lead easily to a discussion of ideas about what it means to be a function, from which the students’ understanding of the concept could be assessed.

C. Analysis

Interviews were transcribed and analyzed using both qualitative and quantitative techniques.

1) First pass (qualitative)

After each interview, students were rated on their level of conceptual understanding of function and accumulation. These ratings were based on a modified Action-Process-Object-Schema (APOS) scale that was refined to admit intermediate levels between each of the normal Action, Process, Object and Schema levels (see [4] for details about the APOS scale). A student was rated by the researchers by analyzing how they answered the series of questions in the interview and deciding to what level a student could think about a particular topic. A student would be rated at a particular level if the researchers felt that the student could think about a topic and operate within a problem at that level. The rating was not an indication to which level a student would naturally operate when answering a question but rather an indication of the highest level a student could reasonably operate when answering a question.

The overall rating for each student was assigned based on a composite of the student’s individual ratings on each question. Once all students had been rated, the percent of engineering majors and the percent of mathematics education majors at each level were compared to results after Differential Equations to see if seniors demonstrated deeper understanding (showing back transfer) or lesser understanding (demonstrating forgetting of basic concepts).

2) Second pass (quantitative)

As a check to prevent the preconceptions of the researchers from blinding them to ideas expressed by the students, we also used a quantitative data-mining approach to analyzing the interview data. The transcriptions were used to create a matrix where each entry was the total number of times each student said each word. So the sixth entry in the eighth row would be the number of times the eighth student said the sixth most commonly used word from the interviews. A non-negative matrix factorization was then used on the resulting “word bags” to identify different vocabularies used by different students. The researchers were somewhat surprised when the vocabularies did not indicate differences between different majors, but did identify groups based on words linked to confidence or willingness to participate in answering questions when they weren’t sure of the answer such as “don’t” and “know”, “understand”, etc.

3) Third pass (qualitative)

Once the quantitative analysis suggested student confidence in dealing with questions where they were unsure of the answer was important, the interviews were divided into segments of information (sentences or phrases as appropriate) and coded for topic, level of understanding, current representation, confidence, and willingness to participate.

These codes were then used by the researchers to rate each interview with an average level of confidence and willingness from 1 to 3 using half steps so that they would be more comparable to the rating of the student’s level of understanding on the modified APOS scale.

III. PRELIMINARY RESULTS

Senior students had, on average, progressed along the APOS scale farther than students at the end of the calculus sequence. However, not all students exhibited growth. Indeed, some students never advanced past the initial Action level during their entire college career. So in answer to research question 1, back transfer can occur, but is not guaranteed.

While engineers overall displayed higher levels of conceptual understanding than education majors, we are unable to conclude that exposure to more concrete applications was better at supporting back transfer than the more abstract applications of advanced mathematics classes. Variations within the majors were larger than variations between the majors, which suggests that the nature of the student rather than the application is the most important variable in supporting back transfer. Of course, self-selection of students into majors complicates this analysis.

Finally, the coding for confidence demonstrated that engineering majors were in general more willing to try problems when they didn’t know how to work them. Again, self-selection is an issue here. But it appears that in comparing practical vs. abstract extensions of mathematical ideas, the difference lies less in terms of supporting back transfer and more in terms of developing confidence to persist in problem solving in the face of uncertainty.

IV. FUTURE WORK

Additional research will need to be done to identify what conditions support development of conceptual understanding in general, and back transfer in particular. It seems clear from the preliminary results that these conditions depend not just on the type of application but also on the student. This involves not just their academic abilities, but also their attitudes, especially toward working with problems where the solution technique is not immediately obvious. The connections between transfer, back transfer, self-efficacy, and conceptual understanding are not currently well understood.

Work in Progress: Video Tutorials that Enhance Laboratory Learning

Veronica Fortino and Weizhao Zhao

Dept. of Biomedical Engineering, College of Engineering, University of Miami, Coral Gables, FL 33146.
v.fortino@umiami.edu, w.zhao1@miami.edu

Abstract—Laboratories are a means by which students take a hands-on approach and practice concepts learned in class lectures under real or close-to-real world settings. This provides a kinesthetic method of learning which rounds out the auditory methods typical of a lecture course. Unfortunately, many students spend most of the lab time troubleshooting their experiment instead of deepening their understanding of the concepts taught in class. This causes frustration and anxiety amongst students. In our opinion, this is due to a lack of knowledge of equipment used in the lab as well as training on different equipment in previous classes. We have developed a video tutorial series for our Biomedical Measurements class that teaches basic circuit building, equipment set-up, and equipment use – students may watch these videos before the lab and at any moment during the lab. Thus far, post-semester surveys have indicated that all respondents, whether bio-electrical, pre-medical, or bio-mechanical concentration in biomedical engineering, find the video tutorials helpful in the lab. The incorporation of technology in the lab session ensures that the lab time is spent deepening conceptual knowledge instead of troubleshooting circuits.

Keywords: *laboratory, videos, tutorials, YouTube, circuits*

SITUATION AND MOTIVATION

Laboratory components (whether large or small) are required in all engineering curriculums. In our experience teaching a Biomedical Measurements Class and Lab, we noticed that troubleshooting usually took up most of the laboratory time, taking the emphasis away from deepening the knowledge of the concepts taught in the lecture. Sadly, out of a 2 hour lab session, students would spend over three-quarters of it fixing basic mistakes and the last 30 minutes rushing to get data because the lab was going to close. The only “understanding” that they would leave the lab with was: “Circuits is hard”, and/or “I hate circuits”. Such impressions were particularly stated from biomedical engineering students who were not bio-electrical concentration.

Psychologically, most of the students entering our lab for the first time expressed how extremely anxious and nervous they were because they were afraid that they would not be able to finish in time. They were going in “blind” without understanding exactly what they were doing; additionally, they were not confident in their skill level to complete the tasks. As educators, we know that the more nervous and/or anxious a student is, the worse they will perform and the longer it takes for them to perform a task [1].

Observing the students semester after semester led to the realization that the students (especially those that were not bio-electrical concentration) had a gap in their knowledge base. Although many of the students had taken a circuits-building lab and class before, they didn’t use the same equipment in their prior circuits classes and/or had taken the class at least 2 years earlier and were no longer proficient in their ability to build and troubleshoot circuits. We envisioned that tutorial material designed specifically to describe equipment use, techniques of building circuits, and the laboratory setting would be an efficient tool to assist students and increase their probability of success in the lab. The objectives of the tutorial tools would be to: i) promote efficient use of lab time, ii) reduce anxiety in the lab, and iii) help students focus on the important part of the lab; namely, reinforcing important concepts being taught in the lecture course.

OUR CONCEPT AND APPROACH

Visualization is the concept that communicates abstract and concrete ideas using images, and stemming from the adage “a picture is worth a thousand words”, we believe that a video is better than a static picture at conveying ideas [2,3]. It is our opinion that incorporating video tutorials as part of the pre-lab work (in addition to reading/reviewing the assigned handouts) will enhance the ability of students to deepen their knowledge and understanding of the lecture concepts instead of troubleshooting a circuit for the most part of a lab. It is widely known that visual learners represent approximately 65% of people while auditory learners represent 30% and kinesthetic learners represent 5%. Video tutorials take full advantage of the 95% of learning styles (both visual and auditory) present in the classroom [4].

Additionally, we wanted to take advantage of the fact that 49% of college age students own smartphones [5], and that 54% of smartphone users watch videos on their smartphones [6]. The use of tablets and other devices makes it even easier for students to access videos or video websites such as YouTube. In fact, most phones and tablets have a YouTube “app” where they can directly stream videos from this extremely popular site. YouTube has emerged as a new technology to assist in the facilitation of deep learning in fields such as nursing [7] and chemistry [8]. Our approach therefore was to create a library of tutorial videos for our Biomedical Measurements laboratory that involved basic circuit building, equipment set-up, and equipment use and upload these videos as a channel on YouTube – students would have the ability to watch these videos before the lab and at any moment during the lab.

In the beginning of the semester, we recruited students who were taking the Biomedical Measurements Class to create the tutorial videos. Students volunteered to create the videos. Our expertise in being a teaching assistant for 5 semesters for this laboratory course allowed us to set-up requirements based on the needs and mistakes we saw in the laboratory semester after semester. The students were required to learn about the equipment (set-up, use, etc), capture and edit the video, and present a 10 minute long final product that was interesting and informative to assist future students. Here is where a huge benefit of today's "technological revolution" took place – many students did the recordings on their iPhones and were very quickly able to edit their videos using pre-installed software on their Mac and/or PC computers. The students were encouraged to enhance their videos with music, titles, and captions in order to maximize the attention-grabbing power of their tutorial. Following completion of the videos, a majority of which were less than 10 minutes, the students turned them in for approval prior to receiving credit. The videos were evaluated by the TA's for video and content quality and accuracy of content. Comments were given to the students and once the final version was submitted they received the extra credit.

SURVEY SAYS...

After completion of the first set of 7 videos (Breadboards 1 and 2, The Power Supply and DMM, The Oscilloscope, Powerlab, The Thermistor, and The Function Generator), students who took the Biomedical Measurements Class were asked to watch the tutorial videos and answer a survey. The post-semester surveys indicated that all respondents, whether bio-electrical, pre-medical, or bio-mechanical concentration in biomedical engineering, found the video tutorials helpful in the lab. Survey results indicated that 52% of respondents believe that watching the videos makes understanding the concepts easier. Also, 36% and 29% said that building the circuit would have been faster and easier, respectively. Finally, 76% said that watching the video before the lab would have made it easier to use the lab equipment.

BETTER OR NOT?

While our survey results indicated very positive feedback, we performed a very small study (5 students in total) to determine if there was a positive effect of watching the videos before building a basic circuit. In our preliminary study there was no statistical difference in terms of time spent in an introductory laboratory experiment among students who had watched the videos beforehand versus those that only heard the pre-lab lecture. We strongly believe that this was due to the small number of students that volunteered for the study. What was obviously different however, was the level of nervousness prior to completing the circuits. Compared to students that had taken the class before and never watched the videos, our test takers were much more at ease once they were told they would get to watch a video before starting to construct their circuit that would explain all of the required steps.

SUMMARY AND FUTURE PLANS

Biomedical Measurements and Bio-instrumentation are two important and mandatory training courses for most Biomedical Engineering programs/curricula. In our department we have a unique situation which results from three different concentrations (Pre-medical, Bio-Mechanical, and Bio-Electrical) of Biomedical Engineering. Students that are pre-medical and bio-mechanical concentrations do not have a lot of previous training on circuits. As this is the majority of the students in the department, our present situation provided for students not being able to maximize their lab time to strengthen and further their understanding of the concepts taught in class.

Tutorial videos may be applied to most engineering courses to enhance the quantity and quality of learning. This method may also be beneficial in training and preparing students to work in other lab-based settings such as research labs – they will have an understanding of the concepts before they go to work. The wonderful aspect of tutorial videos is that they need not be created/compiled by the professor – students created our tutorial videos with specific requirements and were given extra credit for their work.

Our future work will include increasing the number of tutorial videos to cover all of the lab topics. We also want to perform a more robust study on the benefits of watching the tutorial videos before arriving to class. Not only the physical aspect of building the circuit but also on the level of anxiety and nervousness that the students experience in the lab.

Abstract—Possibilities for collaboration in globally distributed projects have radically changed with the introduction of new Collaborative Technologies (CTs) in the Web 2.0 era. The use of such technologies in the context of students collaborating in a globally distributed project is little explored in research. A better understanding would provide opportunities for improving the collaboration, and more importantly is that a better understanding would improve the possibility of scaffolding, and student learning in general. In this paper we present results from a study of students' use of CTs in a globally distributed project with a focus on the challenges encountered in trying to collaborate using this technology. The study is focused on a few aspects of how a combination of CTs could be utilized and issues associated with their set up and adaption for use. We discuss potential reasons for the observed patterns of technology use and how they influenced the collaboration environment around a globally distributed student project.

Keywords—component; survey; reflections; Open-Ended Group Projects; global collaboration; collaborative technologies

I. INTRODUCTION

Use of Collaborative Technologies (CTs) in globally distributed projects is the theme of this paper and we look at it from an instance of student collaboration. The educational setting is a semester long collaboration between Computer Science students at Rose-Hulman Institute of Technology in USA and IT engineering students at Uppsala University in Sweden. The learning environment is based on the Open-Ended Group Project (OEGP) concept [1, 2] in which the students gather and expand knowledge about a complex real-world issue in the health care area on behalf of an external client. Close and genuine collaboration is essential for the success of this project and use of CTs is a necessary component in achieving this due to the geographical distance between the two cohorts. One of the students depicts the importance of CT in this colorful quotation:

"I don't think this project would exist without the communication tools available to us"

Use of CTs has become an everyday activity and is today more or less taken for granted in the workplace and in education. It has certainly made communication both easier and richer since we first started our student collaboration in 2005. The students' collaboration has nevertheless not been without problems and difficulties, and an attempt to improve

communication by giving the Swedish students access to a high tech laboratory classroom was made during the 2011 instance. This attempt has been studied and some observations from this study are reported in this paper and in companion paper [3] looking into how the students reflected on CT.

A result of our study is an increased understanding of the challenges students encounter in trying to collaborate with the use of CTs. This is done with the broader aim to improve scaffolding and learning with regards to collaboration and communication in globally distributed projects. Data in the study was gathered using two surveys and two written reflection assignments during one semester in a course with computer science and IT students from two countries six time zones apart. The study also included direct observations of the collaboration made by the teaching faculty and staff at a collaboration room at one of the Universities. Results show that students use numerous technologies in their collaboration, and that their perception of the usefulness of the different technologies depended on factors such as the possibility of using the technology on a smart phone, their previous experience with using the technology, and the possibility of combining asynchronous and synchronous communication. Surprising results revealed that email was much less frequently used than expected and had to a large extent been replaced by asynchronous use of chat through Skype. Moreover, many students considered the collaborative project platform useless despite its advanced technology, which included possibilities for different forums, milestones and shared folders. It appears that the demands of technology use mediation imposed by collaborative technologies were not appreciated by students with prior experience of more personalized technology use.

We will first present the local setting in some detail in order to provide the reader with an understanding of the context of the study. This is followed by giving a general theoretical framework for the study and presenting the data collection methods used. Some results of the study are then presented and discussed.

II. BACKGROUND

A. The Student Collaboration

The local context for this study is a globally collaboration between students at the Swedish university taking the IT in Society course and students at the American university taking

the Computing in a Global Society course, where the two cohorts are almost 7.000km and six time zones apart. This setting and different aspects of it have been described elsewhere [4 - 8], but a short summary is given here to provide the reader with a quick update.

The educational setting is aimed at developing professional competencies that are essential in relation to working in a global collaboration setting. This setting is based on the Open-Ended Group Project (OEGP) concept, where complexity and many options for how to approach a problem are central issues. OEGP is a suitable concept for preparing our students for working on a global arena. An important aspect of the educational setting is that the project is placed in a real environment with a real client, which adds to the complexity and also is shown to increase motivation for the students [9]. An issue with real clients is that they also have other obligations and can be hard to get reasonable access to, which we have addressed by only using one reliable client and putting all students into one project. This solution has, as seen from an OEGP perspective, the added benefit that it adds to complexity. Another issue with a real client might be that some students feel ethically constrained to help certain clients, e.g. for political, religious, or competition reasons. We have for that reason chosen to work with in the public health sector, i.e. the Uppsala County Council and the associated academic hospital.

Also of relevance to this paper is that the students have more or less total freedom in choosing CTs. Examples of constraints set up by the staff are that some form of collaboration platform should be used and that there should be weekly synchronous meetings that preferably should include video. The choice of CTs and how to use them is up to the students and varies over the years, e.g. this year the team leaders required the members to keep track of the time they spent on the project. The CTs used this year are presented below.

The students participating in the course this year were all men of age between 20 and 37; the American cohort was between 20 and 22, and the Swedish cohort had all but one member in the range of 21 to 24. The majority of students had their major in computer science or IT, but some students had other majors such as mechanical engineering. This year there were ten Swedish students and eight American students taking the course. Most students had studied for three or four years at the university.

B. Uppsala Learning Lab and the Laboratory Classroom

Uppsala Learning Lab (ULL) was created in 2000 as a part of an effort to raise the level of IT use in education, research and especially international collaboration. It is now an administrative unit at the Swedish university with the task of spreading knowledge on how IT can be used in teaching and in research projects. ULL experts actively collaborates with faculty in order to develop their use of IT and an essential part of this effort is to maintain, to develop, and to evaluate the use of a high tech classroom, called the laboratory classroom. The laboratory classroom is open and free of charge to all teachers at the Swedish university for education and seminars. The classroom seats up to 80 persons and has four interactive whiteboards and four large screens that can be used for video

conferencing facilities, and the opportunity to lend laptops to students. The room can be subdivided into smaller sections and all furniture is on wheels and can thus easily be adapted to different needs. ULL's staff provide technical support for users, but above all help faculty to test and evaluate the possibilities offered by CTs in a classroom setting from a pedagogical perspective.

When using the laboratory classroom in the project course, the students were in charge of the contact with faculty at ULL, and they made arrangements regarding furniture, the use of different rooms and technology.

III. RELATED RESEARCH

A. The Digital Generation

The students have grown up in a world of CTs, and they have other ways of thinking, interacting, working and socializing that revolve to a much higher degree on CTs. This is seen as fundamental difference as expressed by Prensky [10] on what he denoted the Digital natives and the Digital immigrants and by Tapscott [11] on what he called the Net generation. Similar ideas are expressed by Veen and Vrakking [12] in what they describe as the Zapping generation. Selg [13] did a study of students and faculty in Sweden where he classified use behavior into Web 1.0 and Web 2.0 categories, where the latter is roughly the same as Digital natives, the Net generation, and the Zapping generation. He concluded that Web 2.0 behavior is predominant in the age group 25 years and younger to a much higher rate than for older age groups. Notwithstanding this observation, he points out that there are substantial differences within the different age groups that indicate that it rather is a question of culture than generation. That is, having the competencies to use CTs in a Web 2.0 manner can be seen as being in a culture, e.g. a Digital native, and is not a definition of a whole generation. It might thus not be appropriate to describe our students as digital natives just because they are young, but Selg observes that CS and IT students to a high degree belong in the Web 2.0 culture. The behaviors and views of this culture are thus relevant for our study.

B. Communication and Globally Distributed Projects

Technology plays a crucial role in supporting communication in globally distributed projects, and an increasing range of collaborative technologies are available for use, ranging from the ubiquitous email through wikis, blogs, text chat systems, version control systems, video-conferencing systems from desk-top applications such as Skype to dedicated rooms and services, cloud based file sharing services such as Dropbox, and virtual learning environments (often incorporating a range of features). Personalized social networking services such as Facebook, Youtube, Twitter are also complementing the more group focused collaborative technologies. However, this plethora of choice does not necessarily contribute to effective communication in a global team context. Many challenges remain to be surmounted, as noted by Olson and Olson [14] and elaborated in [15], where "common ground" needed to be established with respect to "collaboration readiness" and "technology readiness" in order to engage in "tightly coupled" work activities.

Central to the functioning of geographically distributed collaboration is the creation of “common ground”, i.e. establishing “mutual knowledge”, which is addressed in a paper by Cramton [16]. Mutual knowledge can be established through 1) Direct knowledge created in first hand experiences with individuals, 2) Interactional dynamics, where it is created through any kind of interaction (although it should be remembered that uniquely held information, as opposed to commonly held information, is much less likely to surface in interactions [17], and 3) Category membership, where assumptions on another’s knowledge is based on social categorization [18], (e.g. a cabdriver is assumed to know how to get to the airport). Establishing such mutual knowledge in a distributed collaboration in which only the last two are available, is not an easy task. There are difficulties in conveying nuances when compared to face-to-face meetings [19] and these are exacerbated by the fact that CT communication is slower [20]. Cramton identifies a number of problems that contribute to difficulties in establishing this mutual knowledge: failure to communicate and retain contextual information, unevenly distributed information, communicating and understanding the salience of information, differences in speed of access to information, and difficulty interpreting the meaning of silence. She also points out that the difficulties are accentuated by the fact that the collaborators often are unaware of these problems.

IV. METHOD

In this study, data was generated during four months through observations, two surveys and two written reflection assignments. Faculty made observations throughout the course on the use of technology when participating in meetings, and in the university’s laboratory classroom. Faculty consisted of three people who were the main teachers responsible for the courses, and during meetings in the university’s laboratory classroom studies were made by people responsible for the high tech collaboration room. The first survey was sent to all eighteen students in the middle of the project. Thirteen students answered the survey. It consisted of 21 questions regarding CTs in the project course. Most questions were multiple choice, but there were also open-ended questions. The first reflection was a compulsory written exercise answered by all students in the course. The task was to reflect on the positive and negative aspects of the different communication technologies used in the project. The last reflection was also a written compulsory reflection sent to all students in the course, and it contained general questions regarding the work and learning in the project as well as some specific questions regarding their use of CTs.

Data was thematically analyzed [21] and reviewed, organized and read through to identify themes. At this stage a mind map was used, and data was then reviewed again to iteratively refine the themes and to categorize the findings in a data analysis software program. Finally the different themes were exported from the software tool in order to get an overview. This overview constitutes the basis for the written text presented in this article in the following section. When writing the quotations from the different data sources, language errors have been corrected in order to make them easier to read.

V. THE STUDENT’S DESCRIPTION OF COLLABORATIVE TECHNOLOGIES USED

The following is a description of how the students reported CTs in their project, categorized by the different technologies that were identified. In some cases, short descriptions of the technologies are provided, based on information from www.wikipedia.com.

Adobe Connect is software used to create information and general presentations, online training materials, web conferencing, learning modules, and user desktop sharing. It was used in the very beginning of the project and most students described that they used it once or twice during the project. The students’ ranking of the value of Adobe Connect was 2.46 on a scale from 1 to 5, and due to technical problems it was soon replaced by Skype during meetings: “We started out trying to use Adobe Connect for communication, but after a while we moved over to mainly using Skype”. It seems that the features in Adobe Connect were not appreciated by the students, and problems with sound and video made them abandon it. Moreover, the students found that it was easier to communicate with a technology that they were already using, such as Skype, and that the possibility to use Skype with their cell phones made a difference.

Email was frequently used in the project, and most students used it on a daily basis. However, compared to previous instances of the course, the use was less frequent, and much communication was directed through Skype instead. It was ranked as very useful in the survey (4.08 out of 5), and gave rise to comments such as “E-mail is the best way to spread information because everybody check their mail everyday” and “best way to get hold of people”. Some students stated that other means of communication such as Skype had been preferred and that email had also been an option when other ways of communicating failed. It is also interesting to note that many students did not answer emails, even though they frequently read them. This might be due to the students being “flooded with irrelevant information and therefore [didn’t] pay attention to broadcasted emails”.

Github is a web-based hosting service for software development projects that uses a revision control system while *LaTeX* is a document markup language and document preparation system. They were both used when writing up the final report, and many students described them as easy to use and without any problems. However, a few students not experienced in using Github and LaTeX stated that they were “tedious to learn” and at the same time as writing the report. Others stated that LaTeX can be “tricky” to use, but that the design of the report became very nice and professional. The technical matters when making LaTeX and Github work together on all computers were time consuming and frustrating. It is noticeable that the expectations on the usability of LaTeX was quite different the other forms of CTs mentioned, and that “this is to be expected if someone has not used it before”. Several of the students perceived Github and LaTeX as more similar to programming languages, and explain this difference in usability requirements as a consequence of this.

Google Docs is a web-based office suite and data storage service. It allows users to create and edit documents online

while collaborating in real-time with other users. It was used in the project to collaboratively write reports and for making presentations. Many of the students have used Google Docs extensively: "Google Docs is a well used tool in my small team. We have used it for drafts of what we gather now doing research. We also did write conclusions of what we found in a shared document. It is really good and you can get a direct look at each others work as they progress".

Microsoft Word was mentioned by very few students, but was presented as a "very simple tool" that fulfilled the basic needs during the course.

Phone. Some students reported that calling people when asking for interview times was one good way of getting a contact, which could then be followed up by emailing the person regarding questions etc. Most students did not use phone calls in the collaboration as their use was too expensive compared to Skype, for example. However, despite the description that phones were not very much used, faculty observed that most students used their smart phones for communication on a regular basis. This discrepancy might be due to the fact that many students had traditional models of phone usage in mind when answering questions about their use. One student reflection reveals this usage of phones in the project: "I often used my phone to check my mail and login on Skype to see messages and calls. I even had a Skype conference call from my phone once. ". Moreover, the example of phone use illustrates quite well that there are several grey zones to consider when talking about CTs, e.g. has the phone evolved into essentially being in the same category as a computer. We could perhaps choose to talk about voice calls instead of phone use, but what would then be the difference with using Skype for a voice call?

Skype is a service that allows users to communicate with peers by voice, video, and instant messaging over the Internet. The students described that they used Skype daily or several times a day in the project and its usefulness was rated very good with an average of 4.31 (out of 5) in the mid-term survey about collaboration. Skype was used in the project for chat conversations between two or several students as well as voice and video call. The reflections about Skype described a simple and useful tool that was easy to use, and with which the students think that they have had very few problems. For example, in this quote: "No problem, works great for team meetings". However, many students point to the fact that they would have appreciated the group video functionality in the project and that this would have improved communication.

There were several "permanent discussion groups in Skype", i.e. group chats where group members add a constant flow of comments from different areas, both personal and professional. These "permanent discussion groups" occurred within the whole project group with faculty as members, in subgroups, and within the writing team and the presentation team. Many of the conversations in these groups were informal, such as a virtual coffee room, and students posted items from YouTube or links to both unrelated and related websites. One feature of Skype mentioned several times in the reflections on communication was the delivery of messages

even when the recipient is off-line. This was perceived to have a positive impact on communication.

Some of the students reported that one advantage with Skype is that they used it in their day to day work. Moreover, it was seen as an advantage that you could chat in Skype at any time without risking disturbance to anyone: "We are able to communicate any time, any place and free of charge".

An example of a reflection regarding the use of CTs in the project, and how it affected the discussion was the following: "One interesting drawback of using Skype is that it is harder to discuss freely. A good [Skype] meeting is usually one where someone takes charge and decides who should speak when, but this means that opinions and thoughts that would've been shared if the meeting was on location in the project room might get missed. Having frequent Skype meetings means that you are less likely to meet the people you're working with in person so in that sense the technology actually separates us when the spatial distance is small (but connects us when the distance is big, as it is with the Americans)"

Another interesting reflection about using this technology for meetings is that many students did things other than participating in the meetings during the time allocated. This was perceived by many as very disrespectful, and some students reported that they explicitly asked people to stop typing during meetings, or to turn off their microphones when not talking.

SMS is a form of text messaging communication on phones and mobile phones. Very few students used SMS in the international collaboration on either side of the Atlantic. A small group of students in Sweden used it quite regularly, however. This is quite surprising since generally many students regularly use SMS quite extensively. It is interesting to note, in this context, that the "Group SMS" feature was used extensively for communication when the first year IT engineering students did a small collaboration project studying their seniors working in the IT in Society course.

TeamLabs is an open-source platform for project management and business collaboration. TeamLabs was chosen by the students themselves as a collaborative platform, and one student described the choice in this way: "They have a quite flashy introduction video, and I think that that is what caught everyone's interest". The vast majority of the students had never used a project management tool before, and they reported that it initially took some considerable time to understand what they were supposed to use it for. The reflections also reveal that the use of TeamLabs as a collaborative tool varied: "The members of the project have adopted the use of TeamLabs to different degrees, which result in a lack of communication"

Most students used TeamLabs about once a week, and they rated it as functional (an average of 3.31 out of 5). All students reported the time they had put in the project on TeamLabs, and they also kept track of the different milestones that the students had decided to have in a calendar with TeamLabs. Some students miss functionality in TeamLabs, such as the possibility to do Gantt diagrams. However, others described

that TeamLabs also contained features never used in the project such as chats and forums.

The team leaders and the project leaders reported that they have used TeamLabs to keep track of time in their group, and to get information about and set new milestones in the project. From the reflections it seems that team leaders and project managers appreciated TeamLabs to a very large extent, which is also verified by reflections from team members: "I see it more of a tool for the team leaders and project leaders to help manage their team and track progress of the project"

Some also described TeamLabs as difficult to use and stated "it isn't exactly clear where you need to go in order to do certain things. There are too many different tabs that you can navigate". This was also illustrated in the quote: "getting to some features is just flat up confusing".

It is also noteworthy that many students described their use of TeamLabs as a way of showing others what they have done, and not for finding information written by their peers. "I used it mainly to add documents for the full group to see", "Very few members read all documents that are uploaded to teamlabs". The reflections regarding TeamLabs reveal that many of the students thought their use of TeamLabs was not particularly valuable, as there was "too much information in TeamLabs and it is difficult to find information you need quickly". Others noted that, after having uploaded the material found or written to TeamLabs, it was forgotten, and not used in the project: "I'm under the impression that information uploaded into teamlabs is distanced from the project members, and then forgotten". Another student reflected on the same problem, and stated that a simpler file sharing tool such as Dropbox would have changed the use of the documents. "Dropbox could have been used instead of TeamLabs to maintain a document archive. My personal belief is that this would have rendered a higher relationship on all documents created within the project /.../ This way all documents would have been available closer to the actual usage situation"

It is noticeable that many of the students thought that TeamLabs could have been replaced by the use of Dropbox as a common document library. This reveals that most functionality provided by TeamLabs were not appreciated, and that the document storage was the most useful functionality. "I see the point of having the whole project located on a single site, but personally I'd rather just used a shared dropbox".

ULL, the university's laboratory classroom, is described earlier in this paper. Most students really appreciated ULL, and when valuing the usefulness of the classroom in the collaboration the average was 3.82 on a scale from 1 to 5. Faculty also noted that the general feeling from using ULL had a positive impact in terms of increasing motivation and commitment to the course. The first reactions when entering the classroom was one of amazement at the high-level of technical equipment. Use of the classroom significantly enhanced student motivation as well as other affective reactions to the course, and there was considerable appreciation for the opportunity to use the state-of-the art facilities. However, from a purely technical perspective the classroom's impact on their use of CTs was limited. ULL's staff assisted in setting up some of the Adobe Connect and Skype meetings,

providing cameras and speakerphones. On one occasion, students used an interactive whiteboard when presenting their work to other students in the hall. However, the technologies most frequently used in the project were not connected to ULL, and one student describes their use of the classroom in the following way: "We haven't really used it as much as we should". However, the students' comments regarding the classroom are very positive as for example: "Great for collaboration" and "With the technology available in the learning lab it has been great for project meetings and as well as for the presentations".

VI. DISCUSSION AND CONCLUSIONS

One conclusion from the study is that students use numerous examples of CTs in their collaboration and that, during the semester, their choice of particular technology depended on their previous experience of its use, and the activities that needed to be done. Many used several CTs in parallel and multitasked in order to collaborate. Another interesting result was that student perception of usefulness depended on factors such as the possibility of using the CTs on a smart phone. In this respect, a CT without an app-technology was perceived as less practical. In addition, being forced to log on to a web page before being able to use a technology affected the perceived usability in a negative way. Indeed, many students simply did not log into those systems that used this method of access. Choice of CT was also much colored by the possibility of combining synchronous and asynchronous communication, such as the choice of Skype chat in comparison with similar technology.

Very few students appreciated that CTs were complex, multifaceted with many different features. Adobe Connect was replaced with Skype for meetings, even though former had more extensive functionality than the latter. In one of the teams, Teamlabs was abandoned for Dropbox, and most students reported that they would recommend the use of Dropbox in future projects despite the fact that Teamlabs had more features specifically designed for collaborative projects. Most students in the study preferred to put together a package of CTs which suited their needs for the project, and which had the lowest possible accessibility threshold, as described thus: "Use simple tools for the collaboration" and "KISS. Keep It Simple Silly". Despite many students' view of TeamLabs as something they would not recommend, faculty nevertheless strongly believe that a tool that enhances the awareness of other students' work and give a context to one's own work is necessary for a good collaboration. This is in accordance with much research on computer supported collaborative work, (e.g. [22])

Surprising results revealed that email was much less frequently used than expected and had been replaced by asynchronous use of Skype chats. A further interesting finding is that the students chose not to use online social networking technologies in their collaboration. The forums available at TeamLabs were all silent, and the students did not use Facebook, blogs or Twitter for the project. Other researchers have noted that students are increasingly inclined to use social networking sites such as Facebook, Xanga and MySpace. Active engagement in these websites to establish virtual

relationships provides individuals with access to a diversified set of information from multiple sources [23]. Nevertheless, these technologies were not chosen by the students despite the fact that many of the students met new friends, and are planning to continue social interaction in the future. Selg's [13] discussion concerning the differentiating between professional and private use of CTs may be relevant here.

One cause of irritation in virtual group conferences was that many participants were unaccustomed to using shared microphones/speakerphones. This might be a contributing factor behind the counter-intuitive but recurring observation made by ULL staff that open discussions and exchange of ideas using Skype or Adobe Connect seem to work better if the participants take part from computers in their own homes. Participation from one's own computer tends to favor a more open climate, and allows for additional communication by way of chat. An alternative to Skype and Adobe Connect is the professional video conference, which allows for video and audio of a quite superior quality, and where students gathered together to participate works smoother - but at a price.

It is interesting to look at the use of scaffolding with regard to use of CTs and student collaborative projects. From the discussion of Digital natives or Homo zappiens, it is evident that the basic view and underlying assumptions of faculty in relation to effective use of CTs might be mistaken. Faculty's use of CTs is not the same as the student's use, and consequently, scaffolding in this area is something that needs to be done with care, with more attention to the general principles of communication than to specific technology. Wiggberg [24] elaborates in his thesis that students often experience something quite different from what the staff expects in project courses, and this might also be the case with the use of CTs.

Another interesting results from the study is the reported usefulness of LaTeX despite the fact that most students spent considerable time trying to integrate its operation with Github. This can be contrasted with the perceived lack of utility of Adobe Connect that was abandoned when problems occurred in two meetings. It would appear that LaTeX and Adobe Connect are seen by students as two different kinds of CTs and that they apply different criteria for utility to each. Perhaps one reason for LaTeX perceived usefulness is that most students believed that mastering LaTeX is a competence which is relevant for their future careers. Faculty also felt that discussion about LaTeX in relation to MS Word or similar programs, was, for many students, akin to a political discussion with many layers of values affecting what was being said.

Abstract—This paper discusses our ongoing experiences with teaching software engineering through an inverted classroom. This course format moves traditional lectures out of in-class hours and into the student's personal study time with prerecorded lectures. We support the inverted classroom with complementary techniques, such as structured discussions, weekly quizzes to ensure students watch the lectures before discussion, an innovative Lego-based workshop, a term project, and guest lectures by industry professionals. The inverted classroom allows the students to have an effective educational experience that encompasses both traditional lectures and an active learning environment. To evaluate the efficacy of this format, we use surveys and interviews of both instructors and students. We examine the time commitment of teaching with this method, from both the instructors' perspective and the students'. We also discuss the time commitment for instructor preparation, and quantitative measures of how the inverted classroom helps smooth the variance in the quality of each instructor's teaching. We also analyze the effectiveness of this technique and our methods for mitigating unintended consequences, such as students having an inexact understanding of the material. Through this evaluation, we distill the effects on student learning and instructor teaching.

Index Terms—Instructor experiences, Inverted classroom, Software engineering education, Student experiences

I. INTRODUCTION

The software industry expects fresh graduates to enter the workforce with an ever-increasing amount of knowledge. Universities struggle to balance program length with content, often teaching fundamentals in lieu of hyper-focused tools and techniques that are popular in the moment. To give their students the right balance of abstract and concrete understanding, faculty members must constantly innovate within the classroom and provide more value to the students per hour of instruction.

One such innovation is the inverted classroom format [1]. By taking the traditional lecture out of the classroom and putting it online for students to consume during their study time, educators can provide concrete lessons through active learning activities like workshops [2], interactive work time with the instructor [3], and interactive demonstrations [4].

We implemented an inverted lecture format for our senior and graduate-level software engineering course. After using the format for eight quarters, we discovered interesting questions regarding the burden placed on students by an inverted

classroom, the preparation time for instructors, the homogeneity of the instruction quality across instructors, the quantity and quality of discussion within the classroom, and methods to ensure that the students watched the prerecorded lectures before class.

This paper addresses our attempts to answer these questions. Section II provides background and related research for this work. Section III describes our inverted classroom and the materials used. Section IV discusses the purpose of this study. Section V lists the methods we used to acquire data for analysis. Section VI illustrates our data analysis. Section VII describes our results and section VIII lists our conclusions and ideas for future work.

II. BACKGROUND

This section presents work related to this research.

A. Inverted Classroom

Instructors have used the inverted classroom in a number of contexts. Lage et al. originally intended to address the breadth of learning styles found in introductory economics courses [1]. The course format allowed the instructor to present diverse material in a manner that is attractive to a broad audience, yet still maintain control over course content.

Within engineering disciplines, Gannod et al. used the format in a software engineering program as a pilot to revamp their department's curriculum [3]. In this paper they discuss a framework and its possible implementation in eleven courses in the software engineering curriculum, and addresses proposed arguments against the inverted classroom. We have provided an evaluation of the authors' issue of whether students watch the pre-recorded lectures.

Day and Foley conducted an in-depth analysis of Web lectures for learning [5]. Their quasi-experimental study evaluates the efficacy of online lectures versus a traditional lecture-based course. This setup parallels the inverted classroom, where shorter lectures are provided for the students to watch during their study time. The experiment showed a significant increase in student grades, indicating that the method was successful. We have expanded upon this base of validation to further investigate the effects of pre-recorded lectures.

The inverted classroom has also been used to instill lifelong learning skills in electrical engineering students [6]. The

reactions of our students parallel the results found in this usage. Additionally, Toto et al. utilized the inverted classroom to teach select lectures within a junior-level industrial engineering course and showed significant correlations between student learning styles and attitudes toward the format [7]. We have similarly analyzed student reactions to the inverted classroom to verify their claims.

B. Instructor Concerns

A notable trend in education research is the student-centric viewpoint that most research assumes. Since, ultimately, education is about teaching the student, this view is acceptable. However, to the best of our knowledge, there is a lack of research on the effects and unintended consequences of distance learning on the instructor. We feel that the impact on the instructor is also important in evaluating teaching methods and thus we include this in our analysis.

III. THE INVERTED CLASSROOM

This paper focuses on the student and instructor experiences in a course redesigned to use the inverted classroom. This course is a senior and graduate level software engineering course.

In an effort to bring a more industry-centric view to software engineering, this course was redesigned to be an end-to-end course focused on enterprise architecture. The addition of this content to an otherwise large set of material proved to be unattainable in a traditional lecture-based class.

A. Course Demographics

The course has a diverse population of students, as it is cross-listed in both the undergraduate and graduate curricula. For most of the undergraduate students, the course is required as part of the Software Systems option for the B.S. in Computer Science and Engineering. The graduate students primarily take the course as an elective, though some are required to take it by their advisor.

In the case of this study, the students were distributed across three sections that were fairly equal in total enrollment but disparate in enrollment by standing, with 36 (19 graduate, 17 undergraduate), 38 (3 graduate, 33 undergraduate), and 32 (15 graduate, 17 undergraduate) students respectively. The first section was taught in the morning, while the latter two were taught in the evening. All sections met twice per week.

B. Course Structure

The structure of the course attempts to motivate students to keep up with the lectures during their study time. We provide electronic lectures to the students before the module is assigned. These lectures come in three forms: as a video, as a slide presentation with audio attached, and as lecture notes with the slides. Each week, the students are expected to consume a lecture in any of the three forms, take notes, and engage in discussion in an email discussion group. The instructor uses the in-class time during the week to add his or her personal experience to the lecture in discussion, conduct

activities with the students, and answer any questions the students have about the lecture content.

To motivate students to watch the lectures before the class session in which the lecture is discussed, we issue a quiz each week on the topic. These quizzes consist of one or two short essay questions and make up 10% of the students' grade. The wording is such that the students' answers are more about their argument and the support for it than whether they have a completely correct answer. The intent of this type of quiz is to motivate the students to internalize the concepts and think about how they interact, rather than have them focus on memorizing vocabulary and definitions.

The main component of the course is a project where the students go through all of the non-programming phases of the software development life cycle. First, the students must do a business analysis of a company of their choosing and develop an IT portfolio for that business. The students then choose one application from their portfolio and conduct each of the standard software development life cycle phases. The result is a project report detailing their work. A secondary goal of this project is to provide them with a reference for project proposals and workbooks later in their career.

C. Lecture Materials

In order to incorporate the new material within the fixed time frame of a one-quarter, three-credit-hour class, we designed the curriculum as an inverted classroom. The idea was, if we have the students watch lectures during their study time, more time would be available in the class sessions for activities and discussion.

The first iteration of the curricular materials simply consisted of slides with audio recordings that captured an entire traditional lecture. The audio was recorded to run in one contiguous segment for each slide. This produced a user experience that mimicked the problems in classroom lectures, such as the instructor not wanting to be interrupted or students forgetting questions by the time the instructor is ready to take questions; the format provided no good affordance to replay a piece of the lecture.

In addition to being frustrating for the students, the above mode of production was difficult for the instructor creating the lectures as well. Interruptions or background noise within the recording environment were more common and likely when recording long segments of dialogue, requiring major segments of the lecture to be redone.

The creation of these initial presentations provided a valuable experience in the creation of such resources. For our second iteration on the lectures, we broke the recording into smaller segments corresponding to sections of the slides that could be clicked on to replay. The shorter recordings allowed students to easily review specific sections of the lecture without having to listen to content that they already understood.

D. In-class Activities

Dale [8] found that students learn better from hands-on experiences, when compared to traditional passive methods.

This finding, called the Cone of Experience, shows that concrete experiences help inspire learning more than mere transmission. Because the inverted classroom frees up in-class time from the constraint of lecture, we utilize the in-class time through active, hands-on learning modules, as follows.

The most complex of these in-class activities is an interactive workshop in the form of a game, as discussed in [2]. In this game, the students form into small groups and learn about agile development principles. This activity takes an entire day of class, but results in the students having fun and enjoying the learning experience. Our evaluation in [2] requires further validation of whether the activity helps the students to learn better than a lecture.

Simpler experiential learning methods are also used. One instructor created an activity where the students simulate a call center. A small set of students are picked to stand in front of the class and act out the software architecture that the class as a whole designs based on the instructor's requirements. The instructor introduces conflicting requirements that the students must decide how to mitigate. After developing an architecture that meets the requirements, the students then determine how the architecture handles various incoming calls.

This short overview does not cover the entire course curriculum. For more information, see [9].

IV. PURPOSE OF THIS STUDY

After utilizing this curriculum over eleven quarters, we formulated several unanswered questions. Does the inverted classroom place a greater time burden on student study habits? Does the inverted classroom increase the quantity of discussion? What about the quality of discussion? Are weekly quizzes an effective means of ensuring students watch the lectures? Does the inverted classroom lessen the preparation time for instructors? Does the inverted classroom help make instruction quality more homogeneous across instructors than a traditional lecture format? The purpose of the present study is to address these questions and discover where the method succeeds and where it fails.

V. TEACHING AND EVALUATION METHODS

This study was designed to capture student and teacher experiences across three simultaneous sections of the senior-level software engineering course. A different instructor taught each section of the course. One instructor was an investigator in this study and is the course coordinator for the software engineering curriculum. The other two instructors were lecturers teaching in the department for the first time. Both of the instructors had teaching experience; one of them had previously taught university courses and had also taught in industry, while the other had no university teaching experience, but had taught in the Distinguished Engineer program at his company.

Each instructor used the same basic lecture for the ten course learning units. These lectures were made available in three formats: YouTube videos, PowerPoint presentations with attached audio, and written notes for each presentation.

All formats were available on the course website hosted on Google Sites. The students freely chose their own method for consuming the lecture material, but were provided an incentive to actually do so by the presence of a quiz on each topic prior to the topic's designated discussion day.

Interim questionnaires, as developed by the authors, were distributed to the students in each section at three points throughout the quarter. Each survey was distributed in class to the students in attendance. Post-quarter interviews were scheduled with nine students — three from each section — and both of the new instructors. Students were recruited via an email sent to the discussion group for each section. Interviews were conducted by the graduate student first author, rather than the faculty PI, to provide a more comfortable atmosphere for the interviewees and have them speak more candidly about their experiences. The students were provided a \$15 Amazon gift card for participating, whereas the instructors were not compensated.

VI. DATA ANALYSIS

This section discusses our analysis of the data obtained from three sources: surveys, interviews, and student grades.

A. Surveys

Descriptive statistics were computed for the surveys to explore the workload the inverted classroom placed on the students, as well as the level of engagement the students had for each topic. The overall response rate for the surveys was 90% (83% for the morning section, 95% for the first evening section, and 91% for the second evening section).

The surveys consisted of four items measuring three different variables of interest: two items measured time commitment, one item measured student learning, and one item measured student engagement. Time commitment was measured by one closed-ended item and one open-ended item, whereas student learning and engagement were both measured with a single closed-ended, 5-point Likert scale item.

The procedures for analyzing the surveys were as follows:

- 1) Compute frequency distributions for all surveys with classes aggregated to report general findings for the effect of the inverted classroom on student time commitment, learning, and engagement.
- 2) Compare differences between the classes for each topic to explore the effects of the inverted classroom in instruction homogeneity.

B. Interviews

The post-quarter student interviews were analyzed to check that the results of the surveys matched student experiences in the classroom. The analysis also yielded a qualitative measure of instruction homogeneity by comparing responses across the three sections.

The student interviews consisted of semi-structured question sets pertaining to five different topics: student satisfaction with the inverted classroom format (six questions), student evaluation of the in-class discussion (six questions), the efficacy of

the quizzes as a motivator (four questions), the value of the active learning activities (six questions), and the impact of in-class presentations on student projects (two questions). Three questions were in 5-point Likert scale form and the others were open-ended.

The instructor interviews, which were conducted during finals week, were analyzed to provide a measure of instructor satisfaction with the inverted classroom technique. In addition, the analysis afforded a qualitative measure of the effect of the inverted classroom on instructor preparation time.

The semi-structured question sets for the instructor interviews pertained to five topics: knowledge elicitation about instructor background (two questions), teaching preparation (three questions), the efficacy of techniques to motivate students to watch the lectures (two questions), and the effect of the inverted classroom on the instructor's teaching (six questions). One question was in 5-point Likert scale form and the others were open-ended.

C. Student Grades

The anonymized grades for the three sections were compared via a one-way ANOVA. There were eight quizzes, each covering a different topic. Each quiz was taken as a variable for analysis, with missing grades excluded.

Student grades provide a quantitative measure of instruction homogeneity. As the instructors were free to grade the student projects as they saw fit, the projects were ruled out as indicators. The quizzes for all three sections were graded by teaching assistants under the guidance of the authors, so the quality of the grading between classes was equivalent; thus the grading bias across sections was judged to be minimal.

VII. RESULTS

The analysis for this study amalgamates the results of the three data sources to provide a holistic view of the student and instructor experiences within the inverted classroom. Qualitative data, in the form of interviews with both instructors and students, provides grounding for the quantitative data obtained from surveys, student evaluations of instruction, and student grades.

A. Impact on Student Study Time

The course in question is a three-credit-hour, senior level software engineering class. It is intended to be of average difficulty; this fact, combined with the popular heuristic of three hours of study per credit hour says that students should expect to spend nine hours studying per week.

The student interviews included three questions about the time impact of the inverted classroom on the students' study practices. Of the nine students interviewed, two students said the class required significantly more (1.75 and 2.00 times as much, respectively) out-of-class work than a standard class. Four students believed the course required about the same amount of out-of-class work as a comparable course, and two said that the course required less work than a comparable one.

The differing opinions of the students stemmed from many reasons. Three students said that they appreciated the lectures

because they were forced to keep up with the work from week to week; this resulted in less cramming for the final exam. One undergraduate student said he felt an increased burden from the course format and that the burden affected his study in a negative way. However, he also stated that he was taking 22 credit hours in an effort to finish his courses before the university transitions from quarters to semesters. Additionally, the students rated their time commitment in relation to their study habits for other courses; depending on the study habits of the interviewed students, there could be a hidden bias within their responses.

Because the interviews provided conflicting data about whether the inverted classroom format placed more study burden on the students, surveys were administered to check whether students spent more than nine hours studying per week. Out of 128 responses, 84.4% of students responded that they spent one to six hours per week studying outside of scheduled class time. Broadening the window to six to twelve hours increases the percentage to 99.4% of the responses; only one response (0.06%) indicated more than twelve hours of study for the week.

Between the interviews and the survey data, there is evidence that the study burden is, on average, no more than that of a comparable course. That is, none of the data indicate an unacceptable increase in the amount of time required by the inverted classroom.

B. Quantity of Discussion

One of the stated goals of the inverted classroom was that it helped to increase the amount of two-way dialogue during class time, as the instructor was freed from lecturing and was thus able to hold hour-long discussions. In order to verify whether this was actually true, we asked students during the interviews about their beliefs regarding the quantity of discussion in the inverted classroom in comparison to discussion in a comparable, traditional course.

Of the nine students interviewed, eight of them said that there was noticeably more discussion during class than in a comparable class. The one dissenting student stated that there was often the traditional long pauses while the instructor waited for students to add to the discussion, but that discussion did eventually occur. His account does not match with the other two students from his section, thus weakening the conclusion that more discussion did occur than in a traditional class. However, the evidence did suggest an increase in the quantity of discussion.

C. Quality of Discussion

In addition to increasing the quantity of discussion, the inverted classroom was intended to increase the quality of discussion. To test whether this truly happened, we asked students during their interviews about the quality of discussion in the course relative to a traditional course.

Four of the nine students said the quality of discussion was better than in a comparable course. One of those four students said that she felt discussion was better, even when

compared to a traditional course that has a large discussion component. However, none of the students felt that the quality of discussion was substantially better.

The other five students said that they felt the quality of discussion was not necessarily improved by the inverted classroom, but was highly dependent on the questions that they and their classmates had for each topic. Since the course does not have a rigorous set of prerequisites, students enter the class with widely different knowledge bases. As such, the five interviewees said that some of the questions that their peers posed ranged widely afield from the heart of the course or were too simplistic to ask. They felt that the quality of discussion was lowered, not due to the inverted classroom, but due to the variance in the questions that were asked.

Based on these results, the evidence is inconclusive whether the quality of discussion is measurably better in the inverted classroom than in a comparable, traditional course.

D. Quizzes as Motivators

One concern within the inverted classroom is that students do not watch the lectures outside of class. To counter this, we introduced quizzes on each lecture that occurred at the beginning of the discussion day for each lecture. To test the efficacy of the quizzes as a method of motivating the students to watch the lectures, we asked the interviewed students and instructors whether or not the quizzes were effective.

Eight of the nine students stated that they felt the quizzes were effective. They also said that the quizzes helped to guide their study, once they were acclimated to the format of the quizzes. One student did not think the quizzes were effective as a motivator because he felt that one could skim the lectures and get “good enough” partial credit on each quiz.

Both instructors considered the quizzes effective. However, they both disliked the anxiety that the quizzes introduced. One instructor said that the time limit on the quiz made the students feel rushed and felt that their performance was degraded by that worry. The other instructor thought there were too many quizzes during the quarter and that the students felt too pressured by the presence of a quiz each week.

From these results, we concluded that the quizzes were effective as a means of ensuring students watched the lectures before the discussion date. However, there were unintended consequences in the form of increased student anxiety. Course instructors who wish to implement an inverted classroom must weigh that concern against the benefits of the format.

E. Instructor Preparation Time

Preparing for a traditional class requires creating a lecture and anticipating student questions on that lecture. However, in the inverted classroom, there is no in-class lecture, but either a discussion or activities intended to hone student understanding. As such, an important question is how the inverted classroom affects the preparation time for the instructor. To study this, we relied on self-reporting in the form of interview questions with each instructor.

TABLE I
THE MEANS AND P-VALUES FOR QUIZ SCORES BETWEEN THE THREE SECTIONS. QUIZZES WERE GRADED ON A SCALE OF 0–3.

| Quiz | μ_1 | μ_2 | μ_3 | p-value |
|------|---------|---------|---------|----------|
| 1 | 2.47 | 2.37 | 2.67 | 0.353 |
| 2 | 2.44 | 2.63 | 2.12 | 0.0307 |
| 3 | 2.36 | 1.71 | 2.82 | 5.31e-07 |
| 4 | 1.83 | 2.08 | 1.42 | 0.0301 |
| 5 | 2.33 | 1.84 | 2.27 | 0.0504 |
| 6 | 2.42 | 2.03 | 2.58 | 0.0237 |
| 7 | 2.58 | 2.03 | 2.70 | 0.000672 |
| 8 | 1.83 | 2.26 | 2.76 | 8.45e-05 |

One instructor was experienced with teaching in academia, while the other was only accustomed to teaching in the context of his industry career. Both instructors stated that there was radically less preparation time required to teach this course than a traditional course, but for very different reasons.

The academic instructor found that he spent two to three times less time preparing for each class because he focused on finding the weaknesses in the recorded lectures and spent class time addressing those weaknesses. To address the lecture weaknesses, he first watched each lecture while taking notes, and then found freely available videos from outside sources to cover the topic, which consumed most of his preparation time. He used in-class examples from his industry experience to provide some grounding for his students.

The non-academic instructor teaches a very similar curriculum for his industry career, so did not have to spend much time solidifying his understanding of the inverted lectures. He focused on finding good examples of the course concepts in practice, in order to ground the material for the students. Most of his preparation time was spent on arranging time for coworkers to come in and present their work to his class. He also spent time finding job-related work products that he could share with the class to show the students what each topic looked like when translated to a real work process.

Because the instructors did not have to prepare a lecture for each day of class, the preparation time was less than for a traditional class. However, the depth to which the instructor went to address perceived lecture weaknesses varied depending on personality. Thus, the inverted classroom lessened preparation time in some respects compared to a traditional class, but highlighted additional preparation challenges for the instructors.

F. Homogeneity of Instruction Across Instructors

The inverted classroom takes the responsibility of creating lectures out of the hands of the instructors and places it into the curriculum designers. As such, the quality of instruction for different instructors should be more homogeneous than in a traditional classroom where different lectures are used by different instructors. To test this, we used the anonymized student grades as indicators of the instruction quality.

The student grades were analyzed via a one-way ANOVA between each quiz for each instructor. The null hypothesis was that the means for the two sections were equal. The

alternative hypothesis was that the means for the two sections were not equal. As seen in Table I, for quizzes 1 and 5, there was insufficient evidence to reject the null hypothesis ($p = 0.05$), whereas there was sufficient evidence to reject the null hypothesis for quizzes 2, 3, 4, 6, 7 and 8. Thus, as a measure of instruction homogeneity, the student grades suggest that the quality of instruction varied across instructors.

VIII. CONCLUSIONS

The inverted classroom is a new method of teaching that requires a different balance of commitment from both the students and the instructors. As such, we had several questions that came to light after teaching in the format for several quarters. We designed metrics to validate our hypotheses about each of these questions.

Since students are required to watch lectures during their own time instead of during scheduled touch points with the instructor, we wanted to ensure that the students were not overburdened by this single class. We issued surveys to measure how much time the students were spending each week on the course. We also interviewed students to provide qualitative data on the subject. No indication of overburdening was present in any of the instruments, so instructors looking to implement an inverted classroom approach should not be concerned with it creating a burden on students.

A goal of the inverted classroom is an increase in the quantity and quality of discussion in the class. By interviewing students, we were able to assess the general feelings students have about discussion within the classroom. The evidence shows that there is a measurable increase in the quantity of discussion. However, we were unable to show an increase in the quality of discussion. According to the student interviews, the quality of discussion was highly dependent on the students in the class. As such, we must further investigate the question of measuring discussion quality.

One of the concerns with the inverted classroom approach is that students do not watch the prerecorded lectures. In order to combat this concern, we implemented a series of quizzes that were held on the discussion day for each topic. We validated the efficacy of this technique via our interviews with students and instructors. Students stated that the quizzes were an effective means of ensuring they watched the lectures. However, instructors noticed student anxiety regarding the quizzes. This shows that there is a trade-off inherent in this enforcement policy, where instructors must consider the ramifications and whether the increase in students watching the lecture is worth the additional anxiety associated with quizzes.

Given that the inverted classroom changes the way instructors have to prepare for class, we interviewed two instructors to confirm our hypothesis that the inverted classroom lessened the burden of preparation on the instructors. Both instructors indicated that it was easier to prepare for this class than for a

traditional one, additionally stating that they were free to look for examples of the course concepts to share with the students.

Lastly, we hypothesized that the inverted classroom made instruction quality more homogeneous between different instructors. We were unable to validate this claim by using quiz grades as an instrument. We believe that the variance between classes is related to the instructors' use of supplementary materials, such as industry examples, extra in-class videos, and the discussion within the classroom. We will work to provide a better measure of instruction quality to further investigate this claim.

In the future, we will perform a longitudinal study to see how much of this course the students retain and can later apply. We also will investigate extending the longitudinal study into the workplace, as several students from the course graduate and begin working for local companies. Additionally, we will convert and extend the curriculum into a professional development series for local professionals.

ACKNOWLEDGMENT

This material is based upon work supported by the National Science Foundation under NSF CCLI Grant No. 0837555 and the CERCS IUCRC Center for Enterprise Transformation and Innovation (CETI), supported by the NSF-IUCRC Program, Grant No. 0630188. We would also like to thank the course instructors and students in the course for participating in this research and CETI students for their continual support.

Abstract—Students notoriously struggle with common misconceptions in Engineering Mechanics curriculum that negatively impact later courses in Mechanical Engineering and related disciplines. Moreover, traditional, lecture-based curriculum for Statics and Dynamics does not promote sustained student engagement. This paper presents a series of Guided Discovery modules that target key concepts.

Guided Discovery is a methodology that borrows aspects of challenge-based instruction and discovery learning. The method is designed to facilitate students paths to discovery of key concepts that are often misinterpreted or not readily mastered. This is accomplished by facilitating students timely discovery of the underlying fundamentals through physical or virtual interaction with Statics and Dynamics challenges.

The key difficulty to insuring positive impact on concept mastery is sustaining student engagement throughout the process. When students actively participate in every step, there is a significant improvement on comprehension and retention of commonly misinterpreted concepts. In this paper the authors summarize existing modules and present some of the results. Additionally, the authors detail typical shortcomings that resulted in early implementations of the modules and strategies for overcoming those shortcomings.

I. INTRODUCTION

Part of the difficulty of encouraging students to think critically about Engineering Mechanics is that some view the material as disconnected facts and formulas as opposed to an interconnected web of concepts [1]. There is a tendency to approach Mechanics problems by identifying the applicable equations as opposed to recognizing underlying concepts. It is not always students' tendency to critically evaluate the information given and methodically analyze it using their engineering intuition. Even when they do, often times they have preconceived misconceptions that hinder effective analysis. Effort must be made to refocus students so they approach Mechanics as an interconnected web of concepts. Traditional pedagogical approaches alone do not encourage this. As such, alternative methods must be devised.

A number of studies have developed strategies to improve mastery of Mechanics concepts. Elby et al. [1]–[3], researched the role of students perceptions of Physics in hindering concept mastery. The North Carolina State University Physics Education Research and Development Group, the largest physics

education research group in the Nation, developed and researched the use of animation to assess physics concepts mastery [4], [5]. Gray et al. [6], [7] devised a format for Dynamics curriculum deemed Interactive Dynamics. The format involved collaborative learning, computer simulations, and experimentation. Magill of Purdue University designed a series of inexpensive bench-top exercises used to demonstrate basic Mechanics principles [8], [9]. Steif and Dollár devised a series of simple experiments and web applets used to demonstrate Statics concepts [10]–[13]. Everett et al. [14], [15] developed counter intuitive Dynamics examples designed to expose students misconceptions.

Challenge Based Instruction (CBI) [16]–[19] utilizes backward design to develop challenges that target specific student learning outcomes. The challenges are implemented through a process known as the STAR.Legacy Cycle. The steps of the cycle include look ahead (or reflect back), generate ideas, gather multiple perspectives, research and revise, test your mettle, and go public. The challenges are designed to instill an increasing depth of knowledge through enhanced student engagement and the method is synergistic with the How People Learn framework detailed in [20]. They typically involve several lectures and homework assignments

Education experts continue to urge Engineering educators to transform from a lecture-based paradigm to one that is more inquiry-based. Despite advancements, widespread reform has not taken place because of (1) a reluctance to implement pedagogical changes and (2) deeply rooted student misconceptions.

Guided Discovery is a methodology that borrows aspects of challenge-based instruction [16]–[19], discovery learning, and counter-intuitive examples [14], [15]. The method is designed to facilitate students paths to discovery of key concepts that are often misinterpreted or not readily mastered. The method is optimized for short, in-class activities and is intended to strategically target specific misconceptions in a focused and timely manner.

The authors contend that through the use of well-devised Guided Discovery modules, students become more engaged and are more prone to correctly interpret Engineering Mechanics concepts. Such modules can better engender properly conceived engineering intuition and better help contextualize

concepts. These modules place emphasis on understanding the problem and not on simply trying to find the right answer(s). Moreover, they require the student to be actively involved in the process of discovering the answer.

II. GUIDED DISCOVERY METHODS AND PROCEDURES

Guided Discovery is an active-learning method intended to bring laboratory-like experiences into the classroom to improve concept mastery and student engagement. The modules target concepts that students commonly fail to master and that negatively impact learning outcomes in later courses. This is accomplished by facilitating students timely discovery of the underlying fundamentals. Throughout the process, students are consistently prompted to answer probing questions and exchange ideas.

The methods and procedures described herein were originally introduced in [21] and are discussed in more detail in [22], [23]. The intent of these modules is to complement but not fully supplant existing curriculum.

The modules share some common characteristics:

- *Inquiry-Based.* Modules, when possible, are purposely posed with open-ended questions that force students to demonstrate concept mastery by expressing through tasks and words a deeper understanding.
- *Collaborative-Learning.* The modules incorporate steps that require students to share knowledge, discuss answers, and arrive at conclusions through collaboration.
- *Interactive.* The modules require students to interact physically or virtually with the physical system to solve problems.
- *Common Misconceptions.* The modules target common misconceptions or fundamentals that students struggle to master early on.
- *Discovery.* The modules are designed to guide students to discover underlying principles and build properly formulated engineering intuition.

In addition to having common characteristics, these modules are implemented using similar processes developed by Kypuros et al. [22]. The overall process involves lecture, a pre-module assessment (to establish a baseline), a primary exercise, an intermediate assessment, a secondary exercise, and a post-module assessment. Each module includes the assessment questions, handouts, supporting materials (such as videos, worksheets, reading material, etc.), list of equipment, and procedures.

The primary exercise is the actual Guided Discovery activity. A flowchart and detailed description of the process are provided in [21]. The procedure is summarized below for convenience:

- A problem or challenge is posed with a set of seemingly plausible answers,
- Students are polled for an initial answer,
- Students are asked to discuss the problem,
- Students are allowed an opportunity to change their answer based on their discussion,

- A bench-top or virtual experiment is conducted to allow the students an opportunity to discover the answer,
- The instructor or assistants observe and pose probing questions to help redirect or reinforce students' critical thought process,
- Students are allowed a final opportunity to change their answer.

The experiment may be the actual challenge posed or a problem that operates on the same basic principles that are targeted by the module.

The modules, whenever possible, center around a real-world, semi-open-ended challenge. The challenge for the Pulley Module, for example, is,

"You stalled your prize 6500 lb, heavy-duty, 4x4 in a creek bed at the bottom of an embankment about 15 ft away 9 ft down and 12 ft over. The engine will not turn over because the ignition circuit was damaged when it got wet. Unfortunately the only winch available is attached to your friends ATV. It is only rated at a maximum 1750 lbs and operates with a constant line speed of 15 feet per minute (FPM). However, it has plenty of cable (200 ft), and you have access to a winch kit with one heavy-duty pulley block (rated at 10,000 lbs), two light duty pulley blocks (rated at 2500 lbs), two 10-ft tow straps (rated at 20,000 lbs), and two shackles (rated at 3000 lbs). Shackles and two straps may be used to attach cable, pulleys, or tow straps to the bumper of the truck. There are numerous trees that could be used to anchor the ATV and to attach tow straps with pulley blocks. From the choices provided, choose an option that will pull your truck up the embankment without exceeding the rating of any of the components used. Determine the tension in the cable and the time that will be needed to move the truck up the embankment. Also, explain any assumptions you made."

The students are provided four possible configurations illustrated in Figure 1 two of which will work – one requiring the least amount of force and the other the least amount of time.

A series of modules have been developed and tested including the following:

- The Gravity Module [22],
- The Vectors Module [22],
- The Pulley Module [23],
- The Free Body Diagram Module [24],
- The 2D Particle Kinematics Module, and
- The Moment Module [24].

Of these, the Gravity and Vectors Modules have been implemented at least two semesters and have matured through at least one iteration.

III. RESULTS

The results presented herein are just a subset of a larger data set. Results for just a few modules and their initial

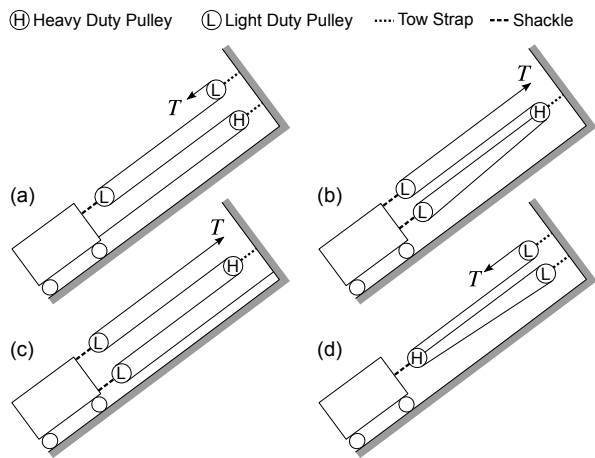

Fig. 1. Pulley Module possible solutions

implementations are discussed below. A more comprehensive review is in preparation for a forthcoming journal publication.

A. The Vectors Module

Students have difficulty understanding, visualizing, and differentiating position, force, and unit vectors in 3 dimensions. They often fail to connect numerical solutions with physical concepts. Case in point: students may miscalculate the unit vector along a direction of a supporting cord resulting in a vector that is obviously in the wrong direction. The students do not always take a moment to step back and assess if the result makes physical sense. The concepts and mathematical constructs are treated as abstract without contemplation of their physical implications.

In the first implementation of this module, the instructor presented the concept of unit vectors in lecture and reviewed several examples. A pre assessment was administered to establish a baseline. The pre assessment measures whether students can identify an appropriate unit vector from a list of options just by looking at a figure. The students were posed the following question and given three minutes to answer:

“A block is hanging at point A and held in static equilibrium by three cables as shown in Figure 2.

The unit vector from point A to D could be:

- (a) $\mathbf{u}_{AD} = 0.47\mathbf{i} + 0.69\mathbf{j} - 0.56\mathbf{k}$
- (b) $\mathbf{u}_{AD} = -1\mathbf{i} - 1\mathbf{j} + 1\mathbf{k}$
- (c) $\mathbf{u}_{AD} = -0.47\mathbf{i} - 0.69\mathbf{j} + 0.56\mathbf{k}$
- (d) $\mathbf{u}_{AD} = 0.74\mathbf{i} - 0.60\mathbf{j} + 0.30\mathbf{k}$
- (e) $\mathbf{u}_{AD} = 1\mathbf{i} - 1\mathbf{j} + 1\mathbf{k}$ ”

In a separate lecture, the students experimented with a setup similar to that depicted in Figure 2 using a mass, string, load cells, rods, and clamps. They were tasked with measuring tension in each chord and expressing each as a vector using a coordinate system of their choosing.

Immediately after the exercise and later as a follow-up on the final exam, the students were again administered the same or similar question as that posed above. The assessment results

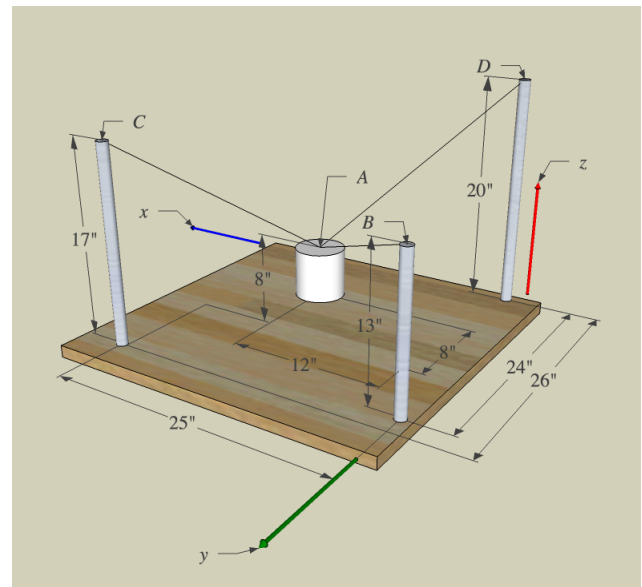

Fig. 2. Schematic of Vectors Module challenge

for pre, intermediate, and post assessments are provided in Figure 3.

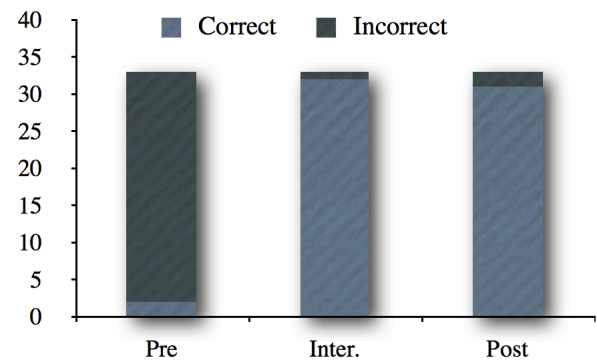

Fig. 3. Results for pre, intermediate, and post assessments for Vector Module

For this study, 33 students participated in all three assessments. In the pre assessment, 2 of the 33 answered correctly. In the intermediate and post assessments, 32 and 31 students answered correctly. The results imply that the exercise had a positive and statistically significant impact on the immediate understanding and longer term retention of knowledge. However, results for subsequent semesters varied and did not show quite as drastic a positive impact. This can be traced to modifications made in an effort to improve the module which had unanticipated negative influence. This will be discussed later in the section titled “Lessons Learned.”

B. The Gravity Module

Students tend to struggle with the idea that the size of an object is not what dictates its vertical acceleration. It seems counter-intuitive that, barring the influence of air drag, a feather

will fall at the same rate as a bowling ball. It may be inconceivable that acceleration due to gravity is mass independent because students tend to associate acceleration directly with force (or weight in this case) and do not always distinguish the subtle differences between the two. Moreover, it is not entirely intuitive that when looking at two dimensional (2D) particle motion in a gravity field the horizontal displacement is decoupled (independent) from the vertical displacement.

This module is intended to demystify some of these misconceptions and elucidate the nuisances that do cause vertical acceleration to change. In this module, students experiment with a variety of spheres of varying size and mass. They are presented a challenge. For example, they are presented two spheres and asked which will hit the ground first if released simultaneously from the same height. The variety of spheres is chosen to illustrate the concept and its exceptions. That is, spheres range from solid wood to a wiffle ball. This module, its assessments, process, and preliminary results are detailed in [23].

The process utilized for this module was similar to that used for the Vectors module. The instructor discussed basic one- and two-dimensional particle motion. In a subsequent lecture, the following pre assessment question was administered to establish a baseline:

“Two metal spheres are the same size but one weighs twice as much as the other. The spheres are dropped from the roof of a single story building at the same instant. The time it takes the balls to reach the ground below will be

- (a) about half as long for the heavier sphere as for the lighter one,
- (b) about half as long for the lighter sphere as for the heavier one,
- (c) about the same for both,
- (d) considerably less for the heavier sphere, but not necessarily half as long, or
- (e) considerably less for the lighter sphere, but not necessarily half as long.”

As a homework assignment, the students were tasked with experimenting with a variety of spheres of their choosing. Additionally, in the next lecture, some demonstrations were conducted with pairs different spheres. They were then re-administered the same or similar question. As a follow-up they were then posed the ensuing question:

“The same metal spheres roll off a horizontal table simultaneously. In this situation

- (a) both hit the floor at nearly the same horizontal distance from the ledge,
- (b) the heavier sphere hits the floor at about half the horizontal distance from the ledge as the lighter sphere,
- (c) the lighter sphere hits the floor at about half the horizontal distance from the ledge as the heavier sphere,
- (d) the heavier sphere hits the floor considerably

closer to the ledge than the lighter, but not necessarily half the horizontal distance, or

- (e) the lighter sphere hits the floor considerably closer to the ledge than the heavier, but not necessarily half the horizontal distance.”

Unlike the Vectors Module, the follow-up assessment was administered soon after the intermediate and not as a final exam question.

The results for all three assessments are illustrated in Figure 4. The pre assessment showed a near even split between those who answered correctly and those who did not, 13 versus 12. After the homework assignment and demonstrations, 19 answered correctly versus 6 incorrectly. The follow-up question showed a decline, 12 versus 13. This pointed to a key issue. Students failed to connect one-dimensional motion in a gravity field with two-dimensional motion in the same gravity field. There was a conceptual disconnect between the two related problems. Several strategies were implemented in succeeding iterations with similar mixed results. Though subsequent implementations have shown better results when comparing the pre and intermediate assessments, the students regularly answer incorrectly on the follow-up assessment. This too is discussed further in the section “Lessons Learned.”

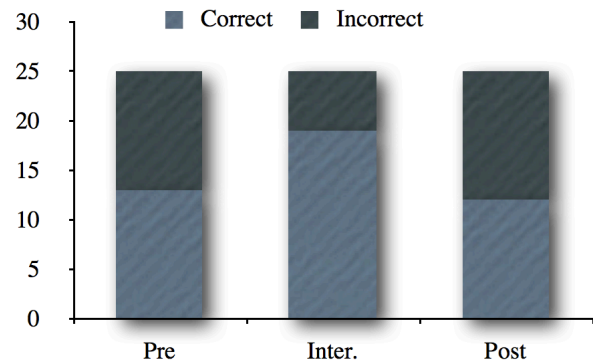

Fig. 4. Pre, intermediate, and post assessment results for Gravity Module

IV. LESSON LEARNED

Preliminary implementations pointed to some clear challenges and shortcomings. The key challenge to insuring positive impact on concept mastery is sustaining student engagement throughout the process. When students actively participate in every step of the process, there is a significant improvement on comprehension and retention of commonly misinterpreted concepts.

Both modules discussed in “Results” were implemented over the course of several lectures. In subsequent iterations, videos and materials were prepared for students to review before the primary exercise was conducted. A video was provided for the Vectors Module which details how to setup the experiment and collect data. The intent was to minimize the time in lecture necessary to collect data and maximize time for discussion and probing questions. For the Gravity

Module, a similar video was prepared, however, the focus was to demonstrate the basic principles for one- and two-dimensional particle kinematics. Unfortunately, in both cases less than 50% of the students actually came prepared to the lecture having reviewed the materials provided.

The Vectors Module in particular can be excessively time-consuming. Until recently, the day of the primary exercise, the module was implemented such that students would come into lecture and set up the experiment. The instructor had hoped that the hands-on experience of setting up the experiment would help the students with other important skills. However, those skills are not strategic to the misconception that the module is designed to target. Hence, in future implementations, the experiment will be set up and ready for the students to measure and collect data. This allows more time for the student to discuss results and allows the instructor(s) and teaching assistants more time to interact with each group to ask probing questions that redirect them along the path to discovery.

The Gravity Module has consistently shown that students do not associate one-dimension vertical motion with two-dimensional vertical motion. Though most are convinced after the primary exercise that the vertical motion of a particle is independent of its weight, they appear to think otherwise if the motion is two-dimensional. Even after several demonstrations with varying spheres released from rest atop a ramp placed on a table edge as illustrated in Figure 5 the students were still not uniformly convinced that the two spheres would travel the same horizontal distance. Even the slightest difference in results due to the spheres not being released at exactly the same moment or in the same manner was reason enough for many to believe the spheres would travel different horizontal distances before impacting the ground. Despite the theory and equations supporting the contrary, many students failed to see the connection between one- and two-dimension particle motion in a gravity field.

The authors continue to investigate this phenomena and formulate strategies to overcome this misconception. One of the strategies that will be tested in future iterations is to task one group of students with theoretically and experimentally proving what many believe to be the case – the heavier sphere should travel further horizontally before impacting the ground. Yet another group will be tasked with proving the actual truth. Each group will present their case to the class and the class must judge which is in fact the properly conceived fundamental concept.

In implementing the various modules, the authors have identified a number of issues that should be considered when designing a module:

- Some modules, in their current design, span several class periods which can result in inconsistencies if students miss a lecture or fail to complete an associated homework assignment.
- Lack of consistent student participation throughout the process has severe ramifications on results.
- If the scope of the module is not strategically limited to addressing the key concept/misconception the module

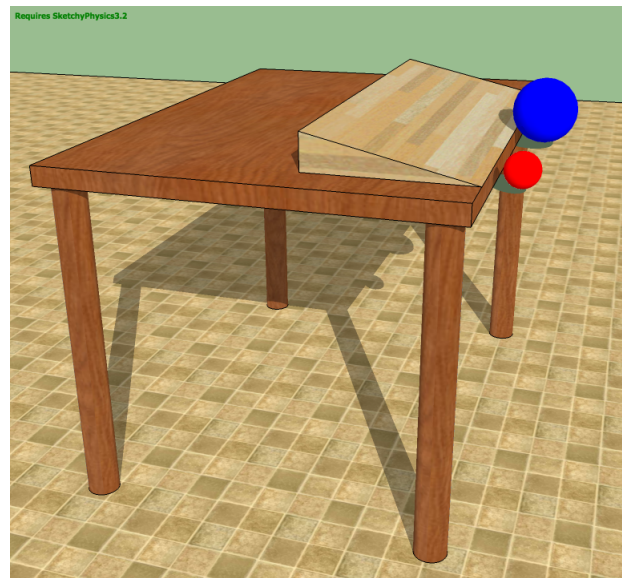

Fig. 5. Gravity Module secondary exercise

becomes unwieldy.

- Sufficient time must be allotted for probing questions and student interaction.

Though modules have shown to be effective at elucidating misconceptions or challenging concepts, success is contingent on active student participation. Modules must be designed to insure that each student actively participates otherwise results can vary. Students must come to recognize the cost benefit and be vested in participating. The following outlines some strategies to insure consistent student engagement and persistence throughout the process:

- *Limit the scope.* Start with the expected student learning outcomes which should not exceed but a few items and limit the scope of the module so that it targets only those outcomes. Avoid ancillary objectives that are not critical to the primary student learning outcomes. Make sure the module is self-contained to insure student engagement and persistence from start to finish.
- *Get students vested.* Do not assume they recognize the benefit at the start of the module. Minimize the amount of work they must expend in preparation for the module. Rather, back load the effort because they may begin to see the benefit later in the process. Remember that the goal is not the lab-like exercise but rather mastering the concept in a timely manner.
- *Limit to one lecture.* The most significant impediment to persistence throughout the process is the lack of participation at all stages of the process. By extending the module over several lectures, the instructor runs the risk of students dropping in and out of the process because they miss a class or do not complete an assignment associated with the module. Though it would be ideal for students to think critically about the challenge outside the classroom, it is more important that most if not all of the

students are on the same page.

- *Do not forget the probing questions.* Instructors should anticipate the most common mistakes or misinterpretations and develop a series of prescribed questions that elicit the desired thought process and discovery.
- *Optimize data collection.* The procedure includes several steps where students select an answer and the results are reported to the class. This can be done by a show of hands and a quick count, but one should make sure whatever the method used, it should not consume too much time. The focus is on the results and not the data collection. Survey systems or clickers might minimize the effort and time expended.

V. CONCLUSIONS AND FUTURE WORK

Guided Discovery shows much promise in overcoming misconceptions and improving properly conceived engineering intuition. Persistence throughout the process is key to insuring positive results. Modules need to be optimized to minimize time and maximize student engagement.

Each of the modules described herein have been implemented at least once. Some shortcomings have been identified and need to be addressed in subsequent iterations. Many of the modules in their current form require more than one lecture. To expedite the process, pre-module material in the form of handouts, videos, and the like have been used, but have not proven to be effective. Students do not uniformly complete these activities before coming to class. These inconsistencies have undoubtedly had a negative impact on assessment results. In future iterations, measures must be implemented to insure consistent participation throughout the process.

In future implementations, we will adapt strategies to improve persistent participation and separate out the assessment results of those who do not complete pre-module activities. Moreover, module procedures will be minimized to include only critical steps deemed necessary to improve understanding.

Abstract — An increasing focus in K-12 educational outreach is on the fields of science, technology, engineering, and mathematics (STEM). A challenge in educating students about STEM topics is the ability to communicate the key concepts on a level that engages the students. The student-directed learning approach allows the students to create educational content and the teacher to oversee the development. The student's peers serve as the audience, shifting the interface of students and teachers, as well as increasing student to student interaction. The proposed approach is based on the outcomes of a preliminary internship, which challenged students to develop a week-long module to communicate one of four sustainability concepts: green building, energy, water and green materials. The proposed study will focus on a larger sample of middle school students developing educational modules focused on sustainability and engineering. In-depth assessment of the student developers will provide information on audience awareness, self-efficacy, as well the effectiveness of the approach.

Keywords—sustainability; engineering education

I. INTRODUCTION

Through partnership between the University of Pittsburgh's Learning Research and Development Center (LRDC) and the Mascaro Center for Sustainable Innovation (MCSI), a proposed approach for student-directed learning is explored to increase student engagement in sustainability and engineering topics. The approach stems from the preliminary study in which an NSF funded program provided rising tenth grade high school students with the opportunity to serve as interns [1]. The interns were tasked with development of a sustainability and green building module for their fellow peers in the hope that students would share the best ways in which they learn. The internship provided them with a unique opportunity to develop a module for a high school class, while learning about sustainable engineering topics. This paper discusses this less common approach to engineering education, as well as future studies to further assess the impact of student as developer on student learning.

Based on the preliminary internship an additional study, presented here, was developed to further explore what motivates students to engage in extracurricular course content and how to meaningfully impact student learning. The study expands on established methods (i.e. active, collaborative, and problem based learning) of engaging students in engineering [2]. The approach aims for students to independently achieve high levels of synthesis and evaluation through self-directed

learning. The approach allows the students to create content and the teacher to oversee development. The student's peers serve as the audience, shifting the interface of students and teachers, as well as increasing student to student interaction.

II. STUDENT AS DEVELOPER

A. Approach

Designing materials for other learners may have potential as another strategy for K-12 engineering education. While conceptually, "student as teacher" has been considered in the reciprocal teaching model, "student as developer" has received little attention. Design-based learning shifts the role of the student from "consumer" to "designer" in an effort to teach engineering. While students remain consumers of a "prescribed" curriculum, the design of the unit gives them a sense of autonomy to "design a product that meets a need in your own life." This approach has shown to increase student engagement and motivation for learning science [3]. In addition to a design based approach, methods which relate the topic to real-world context also an increased impact on student learning. This is essential to introduce and teach students the concepts of sustainability and engineering.

Traditionally, curriculum is created by an external source (*developer*) and imported into the classroom. The teacher (*user*), an internal classroom source, is tasked with translating and communicating the developed curriculum to the students (*audience*). The LRDC-SSOE model, as shown in Fig. 1, integrates the role of developer and user through teacher experience. Teachers develop curricular material, which translates their own engineering experience into classroom learning. In this way the teacher assumes a dual role of developer and user for their students who remain in the role of audience. The student as developer approach (Fig. 1) explores how shifting the role of a student impacts student learning.

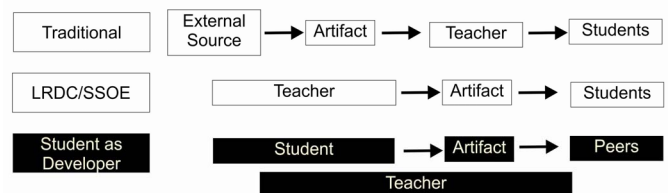

Figure 1. Comparison of Curriculum Development Models and Internship Design Framework.

The approach places students in the role of developer, while their peers remain in the audience (Fig. 1). The teacher assumes a role in which they are able to oversee the development and facilitate a learning experience for both the developer and the audience. The student as developer approach seeks to be a bridge between individual student learning and classroom, or peer, learning by tapping into the ways in which students communicate and understand. Rather than a top down approach from external curriculum developer to students, this approach may be a more organic way to access student interests and understandings about sustainable engineering topics.

I. STUDENT-DIRECTED LEARNING

To explore the student-directed learning approach, in the proposed study, the peer review process will be utilized to determine the impact of student as developer on individual and on peer learning. The use of peer assessment aims to provide students with skills of recognizing an audience, as well as communication and evaluation skills [4]. The proposed study will build on the outcomes from a preliminary internship and will further assess the impact of student as developer on student learning.

A. Preliminary Internship

The preliminary internship design included specific constraints designed to address the difficulty of integrating engineering education into existing curricula. The students were required to develop a week-long module to communicate one of four sustainability concepts: green building, energy, water and green materials. Additionally, the students were required to link the topic to one of the following content areas: math, science, and history. In this way, the interdisciplinary nature of sustainability would be naturally integrated and provide a lens through which to situate their module. In contrast to the content requirements (proposal letter; teaching plan and materials; assessment tools; summary presentation and poster), the students were not constrained in the methods used to engage students learning of the concepts, (such as hands-on demonstrations, experiments, games, etc.).

At the start of the preliminary internship, the students stated they were unfamiliar with the subject of sustainability. The selection of a content area (often a favorite subject) served as a lens to situate their module and supported their emerging understanding of the concept. For example, one of the female interns enjoyed mathematics and used that as a lens for her unit on Energy, which utilized mathematical models that describe energy conversion to help understand sustainable energy concepts [1]. Curricular materials were created for teachers, which included lecture and review notes (PowerPoint to support classroom discussions), in-class worksheets (word searches, fill in the blank about, and well specified word problems), and homework assignments. The materials reflected the traditional tools and methods that the student developers associated with teaching. In the approach of student as developer (Fig. 1), the development of an artifact served as the process in which the interns deepened their understanding of sustainability engineering through the lens of a self-selected alternate discipline area. This supported the

widely accepted belief that we understand at one level when we learn for ourselves, but at a different, often deeper level, when we have to “teach” that understanding to someone else [5]. An additional outcome of the study was an intern, who previously showed no interest in engineering, developed a new intent to pursue engineering as a field of study. The outcome suggests that the impact of student-directed learning may expand beyond comprehension of the concepts and increase accessibility to engineering.

B. Proposed Internship

The proposed study will focus on a larger sample of middle school students developing educational modules focused on sustainability and engineering. The four content areas will be implemented in the Science and Social Studies classes as part of a larger program to explore engineering. Assessment will include an iterative peer review process, through which the interns (n=10) will obtain feedback from a community of their peer interns. The iterations will provide the opportunity for optimization of the material, as well as reveal the impact of the act of creating as a learning tool. Through pre- and post-surveys of the peer review community (n=60), student learning as a recipient and reviewer will be assessed. In-depth assessment of the student developers will provide information on audience awareness, self-efficacy, as well the use of the engineering design process. To address the dynamic field of sustainable engineering and technology, the modules from the previous year will be utilized and revised by the new interns. The revisions will provide additional layers of assessment and the understanding of the depth of knowledge gained over three years. External assessment will be obtained through classroom observations, intern and teacher interviews.

II. SUMMARY

In summary, this paper explores the less common approach that has students design materials for other peer learners. The preliminary internship approach explored the potential of student as developer of materials for other learners as another strategy for K-12 engineering education. The student as developer module has the potential to impact K-12 engineering education, through an approach that increases student engagement and motivation for learning sustainable engineering concepts.

Abstract—Teamwork skills are recognized internationally as important skills for engineering professionals. Literature shows that professional skills, especially teamwork skills, have not been included into the curriculum design and assessment in Chinese engineering programmes, and little work has been done to find the effective way to learn teamwork for engineering students in academic settings in China. This work attempts to implement successful cooperative learning practices from the West to a Personal Development Plan module with teamwork skills as one of its main teaching objectives in a joint Sino-UK degree programme in China. This paper reports the real situation of cooperative learning for Chinese engineering students. Experimental results indicate that there is no significant difference between different grouping methods on both academic and teamwork performance, although self-selected groups do not appear to be the best approach for Chinese students. No statistical correlation was observed between peer rating and the mark obtained for the task. Students can rate themselves and others, and different genders without bias. In the MBTI test, we found higher frequencies of Feeling over Thinking, and Judging over Perceiving. These students need more knowledge and training on conflict resolution skills and multi-task management skills to overcome their intrinsic weakness in cooperative learning.

Keywords- Chinese engineering students; cooperative learning; teamwork skill; MBTI; peer rating; correlation; grouping methods

I. INTRODUCTION

The study was initiated by a complaint in 2007 from a top Year-3 student on the Joint Programme (JP) between Queen Mary (QM) and Beijing University of Posts and Telecommunications (BUPT). She complained about her teammates not pulling their weight in a group coursework. After an interview with her, it was found that she was really upset about having to complete a coursework exercise in a group, although she performed very well in leading a student union department and in relating with her peers. She preferred individual work, or self-selected groups. In her words, “teamwork and communication skills can be practiced in extra class activities or sharing dormitories, but should not be included in the academic arrangement”.

This caused a re-consideration of engineering education in China. In such a highly collective society, almost all activities are organized in groups. Has it been a problem for young people to cope with others? Is the cooperative spirit in

daily life the same as the technical teamwork in academic or working settings? The answer seems to be “No”.

In China, more than 600,000 engineering students graduate in each year [1]. However, many western countries are not producing enough engineers; in America, nearly two-thirds of industries reported that the engineering and science related jobs are the hardest posts to fill [2]; in Australia it is even worse with Engineers Australia estimating a shortage of 20,000 engineers [3-4]. Chinese engineering students should be prepared for the global work force as there will be plenty of opportunities out there for them.

Compared with the quantity (the enormous number of annual graduates), the quality of Chinese engineering education is not rated that highly. One study [1] showed that “only 10% of Chinese engineers can compete in the global market”. Engineers educated from the Western countries have more advantages in interpersonal skills and innovation; they understand better customers and markets, and are productive from the time they graduate [2]. Chinese engineering education need to be enhanced in the soft skills (professional skills) although they are good at hard skills in mathematics and physics.

China’s engineering education has not formally included professional skills, especially teamwork skills, into its curriculum design or assessment. Such kind of soft skills are mainly fostered in after-class activities and moral education, so that this research on effectively teaching technical teamwork to large cohorts of engineering students in China is a pilot work with great significance. This work might be the first concerned with professional skills training in engineering education from mainland China.

The paper describes research on how teamwork can best be learned in an academic setting on the BUPT/QM joint programme, which aims to mix the best of teaching approaches from China and from the UK; in achieving that mix it includes more emphasis on professional skills than is usual in Chinese degree programmes. One of the important skills that need to be studied is team working.

This work attempts to implement successful cooperative learning practices from Western education to a Personal Development Plan (PDP) module that takes team working as one of its key teaching objectives and tries to find out how successful that is in a Chinese context.

II. RELATED RESEARCH

The usual strategy instructors adopt to teach teamwork skills is *Cooperative Learning*, defined by Johnson, Johnson, and Holubec [5] as an “instructional strategy that draws benefit from the interaction of students working in small teams to maximize their own and each other’s learning”. Unlike the Individualistic Learning or Competitive Learning, Cooperative Learning involves students working together in teams towards a common goal and emphasizes cooperation, positive interdependence and individual and group accountability [6]. It is also different from Collaborative Learning, which has a “social constructivist” philosophical base. Collaborative Learning believes that learning is the construction of knowledge within a social context, and encourages the participation of individuals to a learning community [7]. Cooperative Learning is a more structured form of group work, and requires individual accountability whereas Collaborative Learning does not [6].

Cooperative Learning was first introduced to engineering education by Smith in 1981 [8] and in the time since then, it has become widespread practice in America. As indicated by the UCLA Higher Education Research Institute Survey of Faculty [9], almost 60% of the faculty used CL in their classes in 2008.

In China, most of the teaching and learning is organized individually or competitively. Students are encouraged to join a learning community to learn collaboratively in a social context or to finish lab experiments in groups, but the evaluation is based on individual work, and no interdependence or individual accountability are structured into their work.

Chinese pedagogy is quite different from the rest of the world, with emphasis traditionally being on individual study of complex mathematics, physics and the deduction process of equations and theories. However, to work in the global workforce, Chinese students need to know how to consult, compromise and negotiate with others, but not always to accept that the other’s view is always right. Superficial unanimity is not the kernel of teamwork: teamwork encourages different opinions. In Chinese companies, the boss makes the decision and nobody would disagree with the boss as they do not want to make the boss lose face; moreover, the boss tells the workforce specifically what they should do, but in the global industry, a greater degree of self-motivation is expected. Students, therefore, need the abilities of problem-solving and synthesis in addition to their basic scientific and mathematical knowledge.

Many studies report successful practices in classroom-based teaching of team work, the most popular practice being to assign group projects in technical modules. Many approaches to design and manage group projects can be found from the literature, for example [10-11]. Researchers often comment on the teacher-controlled factors that influence students’ team experience [12-13], and many computer systems have been developed to help the process of group formation, administration and teamwork assessment [14-17]. Lingard and Barkataki suggested an approach to teach team working skills using free web-based tools [18].

Students communicate, manage the project, and share information online; they are assessed using the message records generated through that process.

However, other researchers and educators argue that teamwork skills cannot be learned through ad-hoc project experience without teaching; it is a learned skill, and should be taught, practised and assessed as other academic skills. Among the ways suggested to teach teamwork skills as directly as academic skills are: (i) setting up a project module with teamwork as its main objective [19]; (ii) developing a specific programme that teaches interaction skills [20]; and (iii) building up a minor in Engineering Communication and Performance [21].

The research on Cooperative Learning in the Chinese context mainly focuses on language study and management course, but seldom on engineering education. A few instructors also assign group projects in engineering modules, but none by purposely developing strategies and mechanisms to enhance team working and cooperation; the team effectiveness is also not generally assessed.

Moreover, when an educational method is imported to a new country, it should be culturally appropriate [22]. Such kind of research has been done in other Confucian Heritage Cultures (CHC), like Vietnam, Singapore, and Hong Kong, but not in mainland China. Economic globalization and opening has brought many changes in people’s thinking in China, especially to those of the youth. Cultural analysis should be based on the current approach of the population involved, and the BUPT/QM Joint Programme can well reflect that current position.

III. EXPERIMENT STRATEGY

The experiment is conducted in a Personal Development Programme (PDP) module for Year 1 students. One of its main objectives is to learn and practise teamwork skills within the PDP task. Four classes (134 students) from a total of 16 classes (around 500 students) were selected to do the experiment. Students are put into groups of 5 or 6 by a different method for the 4 classes:

- self-selection;
- random assignment;
- academic merit (grouping students with the same ability range);
- fair system, mixing the academic rank with good, middle and bad together.

Students work in groups to produce an advertising video for a Chinese product to be sold in the UK in order to develop their ability to make a point succinctly, a skill all engineers need. At the end of this course, students will play the video and make a short presentation introduce their work in front of instructors and other students.

In the experiment, we adopted many practices suggested by Barbara and Richard [10]. The detailed strategies can be found in one previous paper [23]. Introduction on teamwork skills and instructor guidance were provided and students

were asked to designate different roles in their group instead of a single leader. The instructor formulated the policies for taking responsibilities and for the practices expected, and each group drafted their own agreement of expectation at the beginning. During the process, a teamwork evaluation form and a peer rating form were distributed to groups to complete.

IV. PARTICIPANTS

The participants are all formally registered students of both BUPT and QM, having been recruited through the national Chinese university entrance examination system achieving a score above the BUPT minimum, which is above the top line¹ in the examinations. They are, therefore, representative of Chinese students in a national key university.

There are about 500 students in each cohort, divided into 16 classes. The four classes that were chosen all contain students studying for the degree of Telecommunication Engineering and Management, where the management is an add-on subject. The particular four classes were chosen for the convenience of timetabling and they do not perform better or worse than the other classes not used for the experiment.

V. RESULTS

A. MBTI Test

Before the task, students were asked to do the Myers-Briggs Type Indicator (MBTI) test that indicates personality styles. This appears to be the first MBTI test done to mainland Chinese engineering students, and many interesting results have been found.

The MBTI assessment is “a psychometric questionnaire designed to measure psychological preferences in how people perceive the world and make decisions” [24]. It indicates personality types but not personality traits; it does not represent ability or aptitudes. All types are equal, and there is no type better or worse than the others.

The MBTI sorts the psychological differences into four opposite pairs based on the following [25]:

- *Favourite world*: Do you prefer to focus on the outer world or on your own inner world? **Extraversion (E) or Introversion (I)**.
- *Information*: Do you prefer to focus on the basic information you take in or do you prefer to interpret and add meaning? **Sensing (S) or Intuition (N)**.

¹ The results in the Chinese university entrance examinations are group in bands, and to be admitted to a national key university (universities in the 985 or 211 groups) a student must achieve above the top line. This line varies by province and in addition each university may have a requirement (like BUPT does) of scoring at a certain level higher than that line.

- *Decisions*: When making decisions, do you prefer to first look at logic and consistency or first look at the people and special circumstances? **Thinking (T) or Feeling (F)**.
- *Structure*: In dealing with the outside world, do you prefer to get things decided or do you prefer to stay open to new information and options? **Judging (J) or Perceiving (P)**.

The interaction of preferences results in 16 distinctive personality types and the description of these types can be found from [26].

The MBTI test result of the 134 Chinese students is shown in Fig. 1; the type ISFJ forms the largest group 16%.

The most popular type of personality cannot show the overall preference difference. We summarize the result and compare the frequencies in each opposite pair of preferences as shown in Table I. It was found that in the categories of *Favourite World* and *Information*, there was not much difference overall in distribution between the two opposite preferences.

However in the category of *Decisions*, 71.64% of the 134 students chose “Feeling” indicating that the majority had the inclination to “instinctively employ personal feelings and impact on people in decision situations, naturally sensitive to people needs and reactions, naturally seek consensus and popular opinions, unsettled by conflict; have almost a toxic reaction to disharmony” [27]. This finding is consistent with the characteristics of people in CHC cultures: (i) they prefer to react to their feeling about people rather than logic and consistency when making decisions; (ii) they are easily

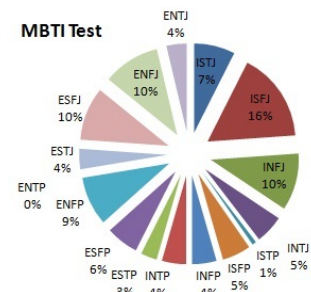

Figure 1. MBTI Test result of 134 Chinese university students

TABLE I. SUMMARY OF STUDENTS' PERCENTAGES IN EACH OPPOSITE PAIR OF PREFERENCES

| Category | Type | Total |
|----------------|------------------|--------|
| Favorite World | Extraversion (E) | 54.48% |
| | Introversion (I) | 45.52% |
| Information | Intuition (N) | 47.76% |
| | Sensing (S) | 52.24% |
| Decisions | Feeling (F) | 71.64% |
| | Thinking (T) | 28.36% |
| Structure | Judging (J) | 67.16% |
| | Perceiving (P) | 32.84% |

influenced by others; (iii) they are more likely to have group thinking; and (iv) they try their best to avoid confrontation and feel upset and helpless in a conflict.

However, team working requires objective judgments, critical analysis, and the capability to solve conflicts. It is necessary to explain this clearly to these students, and to teach them conflict resolution skills.

In the category of Structure, 67.16% of the students chose “Judging”. This means that two-thirds of the students prefer (i) planning in detail in advance before moving to actions, not planning on-the-go; (ii) focussing on task-related actions (but they do not like multiple tasks); (iii) working best without stress when working ahead of deadlines but cannot tolerate time pressure; and (iv) using targets, dates and standard routines to manage life (but they do not like flexibility, freedom or variety) [27]. This may relate to the characteristics of people in CHC countries - high uncertainty avoidance; they feel threatened by uncertainty and unknown situations [28]. The lack of people preferring “Perceiving” hinders the performance of groups in staying open to new information and options.

Though the majority instinctively prefers working with plans and ahead of deadlines, it does not mean they will definitely be able to achieve this, because that requires more self-discipline and time management skills. There are quite a few students on the JP who only start to work hard on an assignment just before the deadline. Phuong-Mai, Terlouw and Pilot also found out in their study that Hong Kong students started to work just before the deadline [22]. People in CHC countries value a time rhythm in which they might often change plans and deadlines [22] and it is difficult to manage and cope with time pressure with this fluid time habit. The MBTI result also found that two thirds of students did not tolerate time pressure. However, coping with time pressure is required in cooperative learning in the Western model.

Students on the JP often complain when several pieces of coursework from different modules are due in the same period of time. The MBTI result also reflects this in that many students do not like to multitask, even though around 30% are female and women (in the West) are generally thought to be better at multi-tasking than men. Though the deadlines were near to each other, each coursework was assigned at a different time and all had sufficient time before the submission date. Students need to learn to get used to this kind of multitasking model as this is the situation in the work place.

A similar test was done in America [29], but the type distribution is different as shown in Table II. The case that

TABLE II. ESTIMATED FREQUENCIES OF THE TYPES IN THE UNITED STATES POPULATION FROM[29]

| E | I | S | N |
|--------|--------|--------|--------|
| 45-53% | 47-55% | 66-74% | 26-34% |
| T | F | J | P |
| 40-50% | 50-60% | 54-60% | 40-46% |

shows a significant difference is that of S-N, where it was found 66-74% of the US population prefer Sensing (S) over Intuition (N), whereas almost half of the experiment group in China prefers Intuition. This indicates that more American people live for now and attend to present opportunities, use common sense to create practical solutions, recall memories of facts and past events and like clear and concrete information [27, 30].

B. Comparison of Team Formation Methods

There were 32-35 students in each class, divided into 6 groups with 5-6 members in each group, so it is statistically a small sample. A future experiment with a big sample is being planned. The same group mark of the PDP task was given to all members of a group.

Analysis of variance (ANOVA) was used to evaluate whether the PDP result and the average group peer rating result were significantly different between groups that were formed by the 4 different methods. ANOVA showed that there was no statistically significant difference between team formation methods on PDP result and peer rating result:

- PDP result: $p=0.09>0.05$, $F=2.484$, $df=3$;
- Peer rating result: $p=0.281>0.05$, $F=1.369$, $df=3$.

The means of PDP result and average group peer rating result are provided in Table III. Groups formed by the “fair system” got the highest score for PDP task of 82.5, “by random” 78.3, “academic merit” 77.5, and “self-selection” the lowest of 70. For the average group peer rating results for teamwork, groups formed by “academic merit” got the highest mark of 94.4, and “self-selection” the lowest mark of 90.1. The interesting point is that the self-selection groups performed worse in both the PDP task mark and the average group peer rating.

Students prefer to choose their own groups by themselves. However interestingly in the class where self-selection was allowed, groups are either all male or all female. During the lecture, a male student tried to persuade a female group to mix with their group, but was refused. Self-selection may shorten the time of getting the team acquainted

TABLE III. PDP RESULT AND AVERAGE GROUP PEER RATING RESULT BY DIFFERENT GROUP FORMING METHODS

| | | N | Mean | Std. Deviation |
|----------------------------------|----------------|----|---------|----------------|
| PDP Result | self-selection | 6 | 70.0000 | 7.74597 |
| | by random | 6 | 78.3333 | 7.52773 |
| | academic merit | 6 | 77.5000 | 8.21584 |
| | fair system | 6 | 82.5000 | 8.80341 |
| | Total | 24 | 77.0833 | 8.83627 |
| Average Group Peer Rating Result | self-selection | 6 | 90.1167 | 5.33850 |
| | by random | 6 | 92.9933 | 2.99515 |
| | academic merit | 6 | 94.4433 | 3.70390 |
| | fair system | 6 | 92.2483 | 2.41191 |
| | Total | 24 | 92.4504 | 3.86487 |

with each other, but it is also likely to stop the possibility of being grouped with new people, as people generally choose to join the same group with friends, roommates or acquaintance. This situation is very typical in China: people avoid losing face for both themselves and others. They would not like to upset friends by choosing others as group mates instead of the friends; neither would they leave their friends to join a new group as that would seem like a betrayal. In China, self-selection groups may not be selected as student really wish for doing the work, but are influenced by “face” and “guanxi” (relations). The results indicate that self-selected groups can neither cooperate better nor perform better academically compared with other formation methods, indeed they are worse.

Phuong-Mai, Terlouw and Pilot suggested affect-based grouping (based on existing friendship, geographical origin, family connections, etc) for Asian students and involving extended social identity in the CL process [22]. Universities in China always deliberately break the original affinity relations (such as geographical origin, middle school attended) at the beginning of enrolment, mixing students up in different dormitory rooms and class units. In this way students should make new friends and learn more from different people.

C. Teamwork performance and academic performance

Running a Pearson product-moment correlation test showed that there was no correlation between teamwork peer rating results and academic PDP result ($r=0.15$, $\text{Sig.}=p=0.485>0.05$, $N=24$).

D. Teamwork peer rating

The students in the experiment are in Semester 2 of Year1. The academic result of the previous Semester² is regarded as their previous academic performance. A Pearson product-moment correlation test was conducted to find out the correlation between previous academic performance and individual teamwork peer rating result. It showed that there was a weak positive correlation between previous academic performance and teamwork peer rating result ($r=0.2$, $\text{Sig.}=p=0.021<0.05$, $N=133$). This indicates that if a student performs better academically he/she is more likely to cooperate well as a team member.

It also tested the gender differences on teamwork performance (individual peer rating mark). The means of individual peer rating marks for male and female are listed in Table IV. Individual peer rating marks for male and female do not follow a normal distribution, the box plot indicating that the data has a skewed distribution. Independent samples test showed that there was no significant difference between genders on the teamwork performance ($t=-0.442$, $df=131$, $\text{Sig.}=p=0.659>0.05$).

It has often been doubted whether self-rating is objective: people may over-rate or under-rate themselves. Two Related-Samples test showed that there was no significant

TABLE IV. MEANS OF INDIVIDUAL PEER RATING MARKS FOR MALE AND FEMALE

| gender | N | Mean | Std. Deviation |
|--------|----|---------|----------------|
| male | 85 | 92.2915 | 4.46501 |
| female | 48 | 92.7698 | 8.02904 |

difference between self-rating and average peer rating for individuals ($Z=-1.509$, $\text{Sig.}=p=0.131>0.05$). This indicated that the Chinese students in the experiment did not over-rate or under-rate themselves when evaluating their team working.

At the beginning of the experiment, two classes were told that an individual mark based on peer rating would be given at the end of the task; the other two classes were told that peer rating would not be used for differentiating individual marks but only for research purpose, and no individual mark would be given³.

This difference aims to test whether peer rating bring more competition within groups or coherence, and whether the marking scheme will influence the objectivity of peer rating. The Independent Samples test showed that students did not rate individual task mark differently when they know the peer rating will change their individual task mark ($t=-1.633$, $df=131$, $\text{Sig.}=p=0.105>0.05$). For the students who were told individual mark would be given, they did not compete to give lower rating to others or to raise themselves, neither did they collude together to give higher rating to all.

E. Team roles

Through class observation and final presentation questions, it was found that students got used to single leader groups even though they were assigned different roles immediately after the groups were formed: the coordinator was often considered as the sole leader. The task was often parcelled out into parts and each member did one part. Students got used to do and be responsible for their part of the academic task that they were assigned to do, but did not know how to undertake other responsibilities to the team. Therefore, getting them to perform the other roles (such as checker, sceptic) seems like a vain hope.

During the final presentation, one group made several typographical mistakes (Beijing Duke instead of Beijing Duck) in their slides. When the Checker and Sceptic were asked whether they checked the slides, they shook their heads and looked at a third person who made the slides. This implied that they thought this was the responsibility of the one who made the slides, but not theirs. In another group, when they were asked about the meaning of a sentence in the slides (“Wish you a fair wind” in a kite advert), nobody in the group could answer and all explained that the one who made the slides was ill and did not show up.

³ The contribution of this whole task to the overall Honours classification of the degree is only 0.2% so minor differences in the marking scheme between different classes would have no noticeable effect on a student’s overall degree result.

² On the JP there are examinations every semester.

In groups, members did not normally understand other's contributions. For example, students did not know what software was used to edit the video and how it worked except for the one who made the video. This is not the essence of teamwork suggested in the Western Cooperative Learning model.

VI. CONCLUSION AND LIMITATION

This is the first study of this kind conducted in China. The main objective of the work is to reveal the real situation when an attempt to use the Western Cooperative Learning strategy is made in a Chinese engineering programme, albeit a joint programme with an English university.

From the preliminary results, it is fairly obvious what Chinese engineering students tend to do and what they lack. There are no statistically significant differences (i) between genders on team performance and self-rating, (ii) between self-rating and peer rating, nor (iii) between grouping methods on peer rating and PDP task result. However it was found that self-selected groups achieved the lowest results academically and on teamwork performance.

There are no significant correlation between peer rating and PDP task result. We also found that some students gave ratings of 100% in self and peer rating; however, they justified the mark using literal commentary. This issue will be looked at in detail later to decide whether the peer rating is reliable.

Work in Progress: Understanding Professional Competency Formation in a Service-Learning Context from an Alumni Perspective

James L. Huff^{1,2}, William C. Oakes^{1,2}, and Carla B. Zoltowski²

School of Engineering Education¹ and Engineering Projects in Community Service (EPICS)²
Purdue University, West Lafayette, IN, USA

Abstract— Engineering educators daily negotiate the formidable task of developing the twenty-first century engineer's competence to enter and thrive in the workplace. With this focus, many have conducted investigations into both *what* defines such professional competence and *how* such competence forms within students. In this investigation, we study how professional competence has developed among alumni of Engineering Projects in Community Service (EPICS), as understood through their retrospective perceptions. We are conducting a mixed methods study in order to understand competence development, and this paper presents the design and administration of a survey questionnaire that is informing the qualitative portion of the study. Findings from both aspects of the study will be presented at the conference.

Keywords- alumni research, professional competence, service-learning, mixed methods

I. INTRODUCTION

The adaptability and readiness of students to enter the engineering workforce has played a central role in the current, national discourse on reforming engineering education. Noting that the National Academy of Engineering (NAE) and the ABET Engineering Accreditation Commission (EAC) have articulated calls for such change in post-secondary engineering education, such appeals may be characterized by their desire for engineering education to be more reflective of engineering practice [1]-[2]. They recognize that, in addition to disciplinary knowledge, graduates need professional skills such as multidisciplinary teamwork, communication, lifelong learning, understanding of professional and ethical responsibility, and understanding of global and societal contexts. Such calls reify and situate in an engineering context Dall'Alba's claim that, alongside the emphasis on appropriate knowledge, the emphasis of *being* a professional should characterize pre-professional education [3].

In light of these recent calls, some posit service-learning as a model for engendering competencies required for engineering practice by creating a learning environment imbued with authenticity [4]-[6]. However, given the flexible structure of such situated learning environments, the actual competencies that develop within students may extend those that are intended outcomes of the learning context [7]. Understanding how professional competencies form in such flexible settings is not a trite task.

The particular context of this investigation is a nationally recognized, engineering-focused, vertically-integrated, multidisciplinary service-learning program known as Engineering Projects in Community Service (EPICS) [5]. This program is intentionally designed to allow students to develop professional competencies while reinforcing the mathematical and scientific principles that define the traditional engineering education curriculum. Specifically, this program seeks to develop the students' engineering design, teamwork, communication, social awareness, and leadership skills. While emphasizing service, EPICS creates a simulated industrial experience for students who participate in the program. Students can participate for multiple semesters, which allows for a variety of experiences and opportunities to take on more significant leadership roles. Although EPICS regularly assesses and investigates the experiences of students within the program, we sought to explore alumni's perceptions of their experiences in EPICS.

The purpose of this study is to examine diverse experiences of EPICS alumni, investigating the research questions:

- RQ1: In what ways did EPICS prepare alumni for professional practice?
- RQ2: How did this preparation compare to other undergraduate experiences?
- RQ3: How have alumni perceptions of EPICS's professional preparation changed over time?
- RQ4: How do RQ1, RQ2, and RQ3 vary by gender?
- RQ5: How do RQ1, RQ2, and RQ3 vary by the semesters of experience in EPICS?

Studies that investigate engineering competence often investigate the formation of competence in students [6]-[7], or the nature of competence according to experts [2],[8]. In our study, we investigate how alumni—with up to 17 years of work experience—develop professional competency in order to assess what features of EPICS are most salient toward this development. These alumni provide a dual perspective by reflecting on both what competencies are required in their practice and what undergraduate experiences may have formed such competencies. This study has been approved by the university's Institutional Review Board (IRB).

II. METHODS

We approach the research questions of this study using an embedded mixed methods design. According to Creswell, such an investigation consists of primarily qualitative study with an embedded quantitative investigation designed to support the overall investigation [9]. The research questions, which primarily ask the overarching question about *how* EPICS contributed to competencies, are best understood by a qualitative approach [10]. However, we first conducted a survey-questionnaire in order to (1) understand the overall, quantifiable influence of EPICS alumni, (2) corroborate and generalize the themes that emerge from the interviews, and (3) collect information about participants in order to generate a meaningful purposive sample for interviews. The 78-item questionnaire was developed through multiple iterations of refinement within the authors' research group as well as pilot testing among undergraduate engineering alumni (that did not participate in EPICS). The questionnaire was designed to collect data on the alumni's:

- involvement in EPICS,
- experiences in their undergraduate years,
- initial and current work situations,
- perceived influence of EPICS on their professional practice (example provided in part A of Table I),
- perceived comparison of EPICS to other undergraduate experiences regarding professional preparation,
- open-ended reflective questions (provided in part B of Table I)

The survey was administered to every alumni of EPICS, since the program's inception in 1995 who had an address registered in the alumni database and who had not requested to be removed from EPICS's contact list ($n = 2667$). Those with registered email addresses on this contact list ($n = 1633$) received more frequent solicitation and could more readily take the survey by clicking a link within the email. Those who had not registered their email address were sent a postcard with the link of the survey printed on the card ($n = 1034$). Disregarding 77 invalid email addresses, the overall target population was 2590. Of these, 528 completed the survey, and as shown on Table II, these alumni represent a considerably diverse population with respect to their undergraduate majors and number of semesters in EPICS. We will further compare the breakdown of the sample population, as shown in Table II, with the overall alumni population of EPICS to assess sample and coverage errors.

III. RESULTS

Questionnaire responses suggest that alumni view their experiences in EPICS as having a significant influence in developing their professional competency. As evidence of this claim, for 15 of the 17 items on the questionnaire in the format of part A in Table I, over 70% of all respondents attributed EPICS to having *some*, *large*, or *very large* contributions to the development of that item's professional competency.

Additionally, approximately 1 in 5 respondents ($n = 109$) responded that EPICS influenced his or her career choice and elaborated on *how* EPICS did so.

As 73% of participants ($n = 388$) have agreed to be contacted for an interview, we are enthusiastic about the quality of upcoming interviews in terms of breadth of experience and depth of reflection. We analyzed data from the survey to purposively sample participants as well as inform the development of the interview protocol for the qualitative study. Particularly, we are ensuring that we oversample minority groups reflected on Table II for interviews. Additionally, we coded the questionnaire's open-ended responses (shown in Table I, part B) to ensure that the interview participants reflect a broad range of competence development that they attribute influence by EPICS. We conducted semi-structured interviews, coding their transcribed responses iteratively to achieve convergence among investigators, and classifying their responses into general themes that address the research questions. At the FIE conference session, we will present (1) a more detailed methodology of this interpretive thematic approach, (2) themes emerging from participant interviews, and (3) statistical analysis of the questionnaire responses.

TABLE I
EXAMPLE OF QUESTIONNAIRE ITEMS

| | | | |
|---|----------------------|-------------------|--|
| A. Participants answered 17 items in the following format with the <u>underlined portion</u> varying across each item: | | | |
| To what extent have your experiences in EPICS contributed to the following: <u>an ability to effectively communicate my ideas to my co-workers.</u> | | | |
| 1) No Extent | 2) Small Extent | 3) Some Extent | |
| 4) Large Extent | 5) Very Large Extent | 6) Not Applicable | |
| B. The following open-ended questions are being analyzed thematically in order to purposively sample interview participants: | | | |
| (If applicable) How did your experience with EPICS influence your career choice? | | | |
| What ways has EPICS influence you personally and/or professionally? | | | |

TABLE II
DESCRIPTIVE STATISTICS OF SURVEY PARTICIPANT DEMOGRAPHICS

| Type | Value | n | % |
|------------------------------|------------------------------------|-----|------|
| Gender | Male | 370 | 70.1 |
| | Female | 146 | 27.7 |
| Race | African American / Black | 14 | 2.7 |
| | Asian | 104 | 19.7 |
| | Native American / Alaska Native | 1 | 0.2 |
| | Native Hawaiian / Pacific Islander | 2 | 0.4 |
| | White | 371 | 70.3 |
| Ethnicity | Hispanic | 8 | 2.7 |
| | Not Hispanic | 493 | 93.4 |
| Number of Semesters in EPICS | 1 semester | 118 | 22.5 |
| | 2 semesters | 186 | 32.5 |
| | More than 2 semesters | 220 | 42 |
| Major | Non-Engineering | 96 | 17.5 |
| | Engineering | 428 | 81.7 |

Abstract—“Incorporating Communication Learning Outcomes Across the Computer Science (CS) and Software Engineering (SE) Curriculum” is an NSF-funded project that aims to identify the communication skills, specifically those involving reading, writing, speaking, and teaming, needed by CS and SE graduates and then determine how these skills can be taught within CS and SE curricula. This paper presents the results of our first two years of studying the programs at Miami University and North Carolina State University to determine the kinds of communication utilized in our courses and how communication is taught and assessed. When looking at student attitudes towards communication our analyses suggest that students do not consider technical (professional) activities such as code reading, writing, and inspections as communication activities, and the same applies to more complex genres such as software testing or design. They also appear to have difficulty relating writing and reading that may take place in the context of the courses to what they might be doing as software engineers and computer scientists once they start working. On the other hand, initial results indicate that our students’ communications skills increase steadily throughout their stay in the university. We have also identified potential strategies for improved instruction in communication.

Keywords—communication across the curriculum, situated learning, software engineering, computer science)

I. INTRODUCTION

In our experience, one of the most common “desired” soft skills cited by employers for computer science (CS) and software engineering (SE) students is the ability to communicate. Successful CS and SE professionals need to be able to communicate with their clients, managers, and teammates. The importance of communication is indicated by its presence in the program outcomes identified by major accrediting bodies such as the Accreditation Board for Engineering and Technology (ABET), which evaluates US-based education programs in engineering, technology, computing, and applied science. Two of the eleven program outcomes for ABET’s Computing Accreditation Commission (CAC) explicitly involve communication [1]:

(Demonstrate) an ability to communicate effectively with a range of audiences

(Demonstrate) an ability to function effectively on teams to accomplish a common goal

Similarly, the SE2004 Software Engineering curricula guidelines highlight the importance of reading, writing, speaking, and teaming [2], while the CS2008 Computer Science curriculum guidelines recognize the importance of professional practice and communication skills through teamwork and presentations [3]. While ABET requirements and the SE2004 and CS2008 guidelines are not used in every part of the world, the demand for college graduates of CS and SE programs who are effective communicators spans the globe. Many studies have concluded that frequently engineering and computer science graduates lack the basic communication and teaming skills needed to succeed in their professional careers [4][5][6]. Companies typically require their employees to work on teams to complete a project. However, entry-level engineers may not have the experience to be fully successful in these situations if their academic experience does not foster teamwork [4]. New hires also often lack ability in written and oral communication. These problems seem to arise especially with students who focus their studies only on technical courses [4]. The problems may be exacerbated by students’ attitudes toward communication, insufficient course content, or poor teaching methods [7].

“Incorporating Communication Learning Outcomes Across the CS and SE Curriculum” is an NSF-funded project that aims to identify the communication skills needed by CS and SE graduates in order to determine how these skills can be taught within CS and SE curricula. We are focusing on four types of communication skills: **Reading**, **Writing**, **Speaking**, and **Teaming** (RWST).

The project is being led by CS and Communication across the Curriculum (CAC) faculty at Miami University, which has a relatively small CS and SE program (approximately 40 graduates a year), and North Carolina State University (NCSU), which has one of the largest programs in the country (approximately 250 graduates a year, about half with B.S.).

This work was funded by NSF CPATH-II Awards CCF-0939122 and CCF-0939081. Opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation (NSF).

Both programs are ABET-CAC accredited. We have partnered with CS and CAC faculty at eleven other institutions to assure that our results will be useful at a broad range of programs.

In this paper, we focus on our efforts during the project's first two years to characterize the communication instruction at Miami and NCSU. We illustrate the value of such characterizations as a tool programs can use to improve the ways they prepare students to communicate effectively in their careers. To begin, we describe the ways RWST skills are expressed in the program-level learning outcomes at the two schools (Section II), the courses in which Miami and NCSU incorporate RWST assignments and instruction (Section III), and student perceptions of the importance and instruction of RWST skills (Section IV). In Section V, we summarize strategies we have developed that any particular program could use to enhance its attention to communication at whatever points its characterization suggests would best increase students' abilities. In Section VI, we briefly outline plans for our project's next stage.

II. COMMUNICATION IN THE OVERALL CURRICULUM

In this project, we consider two varieties of communication skills: domain-specific skills and conventional skills. The former refers to types of communication one might engage in while performing a technical task specific to computer science and software engineering [8]. Reading program specifications or writing a test specification are communication tasks peculiar to CS and SE professionals. In contrast, making formal presentations is a conventional communication task important for CS and SE professionals but performed by specialists in other fields.

A first step in characterizing communication's role in a program could be to examine the program's high-level outcomes that identify abilities students must possess upon graduation. Miami has ten. Two of the ten (20%) explicitly address communication:

(Demonstrate the ability to) Work effectively as a member or leader in a team

(Demonstrate the ability to) Communicate technical information effectively, both orally and in writing

In contrast, at NCSU, 13 of the 20 (65%) primary program outcomes explicitly include RWST outcomes.

Examining more detailed program specifications reveals another difference. The Miami program has 29 performance criteria used to measure student ability upon graduation. Eight (roughly 25%) are explicitly related to communication. Of the 8 learning outcomes that explicitly mention communication, 7 are part of the program's core curriculum and therefore receive substantial attention in lower-level courses. At NCSU, the lower division undergraduate courses emphasize technical knowledge. As a result, students who took lower division courses and faculty who taught them would not have been expected to think of these courses as directly contributing to students' RWST skills—even though such domain-specific communication skills as code commenting and specification writing and comprehension figure prominently.

Even this very high-level characterization of the role of communication in our (or any) programs can yield potentially helpful insights. For example, the difference in the percentages of program outcomes that refer explicitly to communication (65% for NCSU and 25% for Miami) suggests that Miami might consider adding more. Similarly, the greater attention given to communication in lower-division courses at Miami suggests that NCSU might consider enhancing its emphasis on writing for newer students. Neither program has an outcome that refers explicitly to reading, which suggests that they should consider devoting time to teaching students reading skills that are specific to computer science, such as reading system specifications or APIs.

Of course, formal statements of program and course outcomes may not accurately reflect actual teaching practices. When we suggest possible interpretations of data from our two programs, we are merely illustrating the potential uses of such data, not making judgments on our curricula. Only persons in a program can correctly interpret data generated by characterizing it. Also, our illustrative characterization involves only six courses. At both institutions, students learn RWST skills in other classes as well as in internships and co-ops.

III. COMMUNICATION IN CORE COURSES

To characterize the presence of communication assignments and instruction in a program, one could also estimate the amount reflected in the learning outcomes for individual courses. We found more attention to communication abilities in our programs than many would have predicted.

In this project, we are focusing on six courses commonly included in CS programs. Five are offered at both schools: CS1, CS2, Software Engineering, Data Structures, and Capstone (Senior Design). At Miami, the sixth course is Database Systems. At NCSU, it is Automata, Grammars, and Computability.

When analyzing learning outcomes for these courses, we identified the number of *explicit* RWST items and the amount of *total* RWST (explicit plus implicit) coverage, relative to the overall number of outcomes. *Explicit* RWST outcomes are clearly communication oriented. Examples are, "Read and understand code written by people other than themselves" and "As a team, design and implement a data structure to solve a problem, coming to a consensus approach." *Implicit* RWST outcomes involve communication in some form but do not explicitly state this. For example, they use the words "describe," "explain," and "compare," but do not explicitly say to do this orally or in writing. Examples would include: "Apply asymptotic notations (e.g., O , θ) to analyze and compare algorithms." For reading, we chose to include reading code as well as documents.

Table 1 gives the percentage of explicit and total RWST coverage for the five focal courses shared by the two universities plus the sixth for Miami. At both schools, the capstone had a very high number of communication outcomes, as did software engineering. Some differences are striking. At NCSU, data structures had the highest number of communication-related outcomes while it had the lowest number at Miami. Perhaps Miami might consider the

possibility of missed opportunities in that course. Miami might also note that NCSU had more total outcomes for all five of the courses the two programs have in common, while NCSU might consider that Miami has more explicit outcomes for all five.

TABLE 1. Explicit and Implicit RWST Outcomes

| Course | Miami | NCSU |
|-------------------------|-------------------|-------------------|
| | Explicit/Implicit | Explicit/Implicit |
| CS1 | 13%/43% | 10%/40% |
| CS2 | 34%/14% | 0%/87.5% |
| Data Structures | 24%/5% | 0%/90% |
| Software Engineering | 100%/0% | 25%/50% |
| Database Systems | 6%/58% | |
| Senior Design, Capstone | 50%/15% | 25%/50% |

IV. STUDENT PERCEPTIONS OF COMMUNICATION

Student perceptions provide another important indicator of the place that RWST skills occupy in computer science programs. Consequently, as part of our characterization, we studied students’ perceptions of the importance RWST abilities would hold for them after graduation, the amount they would learn about these abilities in the core courses, and the amount they did learn. These data was gathered through surveys administered by our project’s external evaluator, Ohio’s Evaluation and Assessment Center for Mathematics and Science Education. Other means programs could use to assess student attitudes include focus groups and interviews [9].

Importance of communication abilities and amount of learning anticipated. Students’ perceptions of the importance of communication skills in their careers indicate the extent to which they understand the real work of CS professionals and influence their motivation to improve their RWST abilities in college. Similarly, the amount they expect to learn in their courses about communication reflects the level of emphasis they expect their program to place on developing their communication abilities. At the beginning of each core course, we posed questions on both of these topics. First, we asked students, “When you begin your first job after graduation, how important do you believe the following abilities will be to success in your career?” Our list of 36 skills included writing or speaking “to other computer specialists about computing-related concepts, methods, or projects” and “to help people complete computing-related projects or complete computing-related tasks.” In a slight variation, questions for students in the capstone course began, “When you begin your first job after graduation....” Students responded on a 5-point Likert-type scale ranging from unimportant (1) to important (5).

We also asked students how much they expected to learn about 15 communication and technical abilities using a 5-point Likert-type scale ranging from strongly disagree (1) to strongly agree (5).

Table 2 shows the composite results of students’ responses to the appropriate questions from each group. NCSU students begin with a higher perception of communication’s importance in their careers. Miami students’ perceptions grow as they progress through the program so that by the Senior Capstone

Courses their results match those from NCSU. At both schools, students’ expectations about how much they will learn generally increase as they progress through their programs.

TABLE 2. Average perceptions of the Importance of Skills at the Beginning of Six Courses and the Amount They Expect to Learn about These Skills in the Courses

| Course | Miami | | | NCSU | | |
|-------------------------|-----------------|------------------|-----|-----------------|------------------|-----|
| | Import- ance | Expect- ation | # | Import- ance | Expect- ation | # |
| CS1 | 3.9 | 3.2 | 122 | 4.3 | 3.4 | 169 |
| CS2 | 4.3 | 3.5 | 61 | 4.1 | 3.4 | 86 |
| Data Structures | 4.4 | 3.1 | 35 | | | |
| Software Engineering | 4.5 | 3.9 | 34 | 4.3 | 3.7 | 57 |
| Database Systems | 4.6 | 4.7 | 34 | | | |
| Senior Design, Capstone | 4.3 | 4.1 | 19 | 4.4 | 4.1 | 63 |

Seeking a more detailed understanding of changes in student perceptions, we found 12 domain-specific abilities for which the average responses by Miami students in both CS2 and SE were higher than the average response from students in CS1 at $p < .001$ according to Tukey’s HSD post-hoc test. Three were for reading (e.g., “Reading computer documentation such as comments in code and computing-related reference materials”); three for writing (e.g. “Using the style, organization, and formats employed in my workplace to communicate about computing-related concepts, methods, or projects”); four for speaking (e.g., “Speaking to other computer specialists about computing-related concepts, methods, or projects”); and one for teaming (“Using my computing-related knowledge to help a team of coworkers complete projects or solve problems”). Similar, but not identical, results were found in data from NCSU.

These results from both schools suggest that faculty are effective at persuading many students that communication is an essential part of their careers. The results also suggests that students are more aware of the importance of communication than many faculty believe—a significant possibility with practical implications. Perhaps the resistance they may show to communication assignments in CS courses arises from skepticism that the particular assignments being made will improve their career-related communication abilities, a possibility that suggests the value of explaining the purpose of communication assignments and also of replacing assignments that feature conventional communication with ones that are domain-specific.

Abilities gained in three core courses. At the end of each core course, we asked students to indicate how much their abilities in technical and communication areas increased as a result of their studies. Table 3 summarizes responses to selected questions by students in the three courses for which we have data from both universities.

While the differences among the mean scores in Table 3 are not statistically significant, the data do suggest several avenues of investigation for our two programs. For example, students seem to perceive that these three courses provided

greater gains in some RWST areas than others, with the largest gains in teaming and the smallest in reading. Our two programs could use other methods to determine whether these differences in student perceptions arise from the emphases of our courses or, perhaps, from differences in what students define as teaming versus what they define as reading. They may see any group work as teaming but perceive domain-specific reading tasks, such as reading code comments as technical activities, not communication ones. The data also suggest that students perceive that software engineering offered the largest gains in all four RWST areas, a point to which we will return later in this report.

TABLE 3. Students' Perceptions of Selected Communication Abilities They Gained in Three Core Courses (respondent numbers are the same as in Table 2)

| Experience in This Course | Course | MU | NCSU |
|---|--------|------|------|
| TEAMING ABILITIES | | | |
| This course prepared me for working on a collaborative team in my career. | CS1 | 3.4 | 3.7 |
| | CS2 | 3.7 | 3.9 |
| | SE | 4.4 | 4.3 |
| READING ABILITIES | | | |
| This course prepared me for the reading I will do in my career. | CS1 | 3.4 | 3.1 |
| | CS2 | 3.7 | 3.1 |
| | SE | 3.8 | 3.4 |
| SPEAKING ABILITIES | | | |
| This course prepared me for the speaking I will do in my career. | CS1 | 2.7 | 2.4 |
| | CS2 | 3.1 | 2.4 |
| | SE | 4.00 | 2.6 |
| WRITING ABILITIES | | | |
| This course prepared me for the writing I will do in my career. | CS1 | 3.2 | 2.9 |
| | CS2 | 3.6 | 2.9 |
| | SE | 3.9 | 3.1 |

Not shown in Table 3 are the means for students' perceived gains in their technical abilities. Generally, these means are higher than the means for their perceived gains in communication abilities. However, there are exceptions. For the software engineering course, students indicated greater gains in their abilities to work on teams than in their technical abilities, perhaps because their understanding of what is considered technical may not be broad enough to encompass the non-coding related technical topics covered in that course.

The differences among the results from our two programs may suggest that they attract distinct student groups, that cultural or context differences between the programs cause students to interpret differently the scales used in the surveys, or that the programs have different emphases that are reflected in their teaching. Investigation of the causes of these differences may identify strategies for enhancing the learning of students at both universities.

V. STRATEGIES FOR IMPROVING STUDENTS' COMMUNICATION ABILITIES

The results of our characterizations of the place of RWST abilities in our two programs demonstrate the ways computer science educators can use program characterization to identify strengths and possible weaknesses in the communication instruction they provide students. Our project also involves the next step of developing strategies programs can use to more

fully prepare their graduates for the communicating they will do in their careers.

Others have suggested various ways of achieving this goal, including creation of specialized courses in the technical curriculum that teach written and oral communication skills focused around technical outcomes. These courses teach beginning engineering students how to write technical documentation, such as design proposals, project management plans, status reports, instructions, and collaborative writing [10], as well as how to enhance their oral communication skills with technical presentations to various audiences [6] and group presentations and projects [11]. While these courses, like the technical writing courses taught by English departments, are helpful, one or two courses that focus on writing are insufficient for developing the sophisticated, domain-specific communication abilities employers want new CS graduates to possess. Some programs are also adding communication instruction into existing courses [4][5][7][10][11][12][13], often by adding oral communication assignments in technical courses [12] or having students work on client-based projects that involve a good deal of documentation, reporting, and presentations [10]. Having these skills taught by their technical instructors is thought to help students see the value of having the ability to communicate effectively [11].

Our project focuses on creating ways that programs can incorporate communication assignments and instruction broadly across their curricula and coordinate work on communication among their courses. This program-wide approach has the potential for continuously and progressively developing students' domain-specific communication skills throughout their college years. To enable programs to realize this potential, we are concentrating on addressing the feeling of many CS faculty that they are not capable of teaching and evaluating student writing. We are also seeking to devise ways that CS faculty can add instruction in communication skills to their courses without significantly decreasing the time allowed for technical skills. We have made initial steps towards addressing these concerns by developing a set of assignments that focus on communication that is situated within workplace scenarios in the domain that require students to communicate by reading, writing, speaking, and teaming as part of achieving the technical outcomes of the assignment. We have also identified where instructional supports are necessary to assist CS faculty in teaching communication.

At the heart of the approach is the concept of *Legitimate Peripheral Participation* [14]. As defined by Lave and Wenger, Legitimate Peripheral Participation indicates that students move from being novices to experts via engagement in learning activities placed within context. Specifically, through peripheral, but authentic and relevant tasks, novices become more experienced and eventually gain full membership into a community of practice. Our most significant application of this approach is to embed technical assignments in scenarios that reflect the contexts in which professionals perform the technical tasks the students are learning. Instead of merely turning in the solution to a technical problem, students communicate their results to a co-worker or client who must use the solution to perform his or her own technical work. One reason students perceive greater gains in their communication

abilities in software engineering than in other courses may be that in this class each technical task is studied in the context of the overall work of designing software systems. In contrast, technical tasks are often presented in a decontextualized manner, as if they were problem sets in a calculus class.

A. Example Assignments with Integrated Communication

In the six courses addressed by this project, writing assignments include creating development artifacts like software architecture documents or UML diagrams, which would be done in a software engineering course. Code documentation is another form of written communication taught in both introductory computer science courses. This documentation is taught by requiring students to write documentation as well as interpret and understand others' documentation. More conventional forms of workplace writing are taught in courses like software engineering and the capstone. These include writing memos, team meeting agendas and minutes, and progress reports as well as individual logs.

Reading assignments have a domain-specific focus, such as reading comments or navigating, understanding, and using technical documentation such as APIs.

Speaking assignments involve presenting a technical topic to a variety of audiences, conducting interviews, and participating in small-group discussion. Formal presentations occur in courses like software engineering, databases, and capstone. Small-group communication is taught when guiding students through the process of completing team projects, which occur in courses like software engineering, databases, and the senior capstone.

Teaming assignments are prevalent in all courses. These assignments range from large projects to ones completed in a single class period. Team code inspection is an example of an in-class teaming assignment, while a semester-long software engineering project is an example of a long-term team project. Each kind of assignment teaches students different aspects of working in teams. Teaming also overlaps with each of the other communication modes. In introductory courses, code inspections can be performed as a team, providing a way to work teamwork into low-level courses. Among formal presentation assignments, team presentations are prevalent. Team assignments in many courses involve preparation of written communications.

B. Preparing Faculty to Teach Domain-Specific Communication

Most faculty in the disciplines, computer science included, conceive communication as outside their domain, the territory of faculty in English or communication departments. But what is most important about communication is that it be effective in achieving a specific purpose for a particular audience in response to distinct situations. For computer science, faculty in the domain know much more about the professional purposes, audiences, and situations than faculty in English and communication. Teaching field-specific communication skills is important because it is through them that students learn what it means to think like computer scientists and to be professionals in the field.

NCSU used a process with three sequential goals to build faculty confidence for teaching communication. Goal one was to work with the faculty to identify communication already embedded in the courses. This was accomplished by an analysis of the technical outcomes of the courses and the explicit and implicit communication activities in those outcomes. Goal two was to engage the faculty in generating technical outcomes for the program and then derive communication outcomes from the technical ones: what all students are expected to be able to do by the time they graduate. Goal three was to identify the types of communication all computer science students should master (problem definition, program requirements, design document, etc.) and analyze the courses to determine how to distribute instruction throughout the curriculum to best prepare students for the senior design capstone course. This process was designed to help faculty see themselves as experts in communication in their field.

To develop tools faculty can readily use to teach domain-specific communication skills, we have focused on the instructional power of rubrics. For scenario-based assignments, the rubric identifies the criteria the faculty member will use to evaluate students' success in conveying the results of their technical work in a useful way to a colleague, client, or other audience. The skills required to select the details to include or omit, organize the communication, determine what should be conveyed graphically and what in prose are precisely the domain-specific communication skills the students are to develop through the assignment. They are also the communication skills that CS faculty are uniquely equipped to teach. While rubrics are most often used for evaluating student work, faculty can turn them into instructional tools by conducting discussions in which they and the students apply the rubric before students begin to prepare their communications. In the discussions, faculty can point out the strategies used in a sample communication of the type students are preparing to make it effective—and also good strategies that might have been used. For writing assignments, a sample document can be used. For speaking and teaming assignments videos can be used, including ones available at YouTube and similar sites. By using scenario-based assignments and rubrics as teaching tools, faculty situate students in Lave and Wenger's legitimate peripheral participation, i.e., a professional context. The instructor is a professional mentor guiding students in learning professional practice.

C. Instructional Supports

While working directly with faculty via workshops, meetings, and other small-group activities helps prepare them for providing communication instruction, the long-term viability of this project is dependent on the development of instructional supports and guidebooks that provide resources on communication pedagogy. These instructional supports form the foundation of how the results of this project will be disseminated to an audience that goes beyond the two main institutions and the project affiliates.

To date, communication specialists on the project have developed (or are in the process of developing) supports in each of the RWST areas. These instructional supports include

examples of embedded assignments and their associated rubrics, other resources for teaching the specific skills, as well as ideas for evaluation of student outcomes. In addition, these instructional supports will include community-created FAQ's and other materials meant to provide faculty with high-level strategies to address issues they are likely to encounter as they incorporate communication into their courses and curricula.

VI. SUMMARY AND FUTURE WORK

Participants of the CPATH project come from Miami, NCSU, and 11 partner institutions in the US and other countries. In this paper, we demonstrated some ways to characterize the role of RWST in CS and SE curricula, using our programs as examples. Our data are preliminary in the sense that we have not yet observed a student cohort that has received the full battery of RWST-enhanced courses over the four years of a degree program. While some students come to understand the value of developing their communication skills, many do not appear to believe that the communication activities in their courses are related to their future profession. Insights gained from characterizing communication's place in a program can lead to curricular improvements. If the characterization involves all of a program's courses, not just six as used in our example, it could foster a fully integrated, curriculum-wide approach to developing students RWST abilities. We have been preparing and piloting work-based assignments that simulate the practices of computer scientists, activities that researchers Lave and Wenger identify as necessary steps in moving towards membership in a community of practice. In the next stage of our work, we will move from analyzing student perceptions of the communication in their studies to evaluation of their work. Our goals include further development of instructional supports, so we can disseminate our outcomes, learning activities, assignments, and assessment tools to institutions outside the project team.

ACKNOWLEDGMENT

We would like to acknowledge Dr. Sarah Woodruff, Emily Ryan, Hsin-Chih Kao, and Yue Li of Ohio's Evaluation and Assessment Center for Mathematics and Science Education for

the administration and analysis of the evaluation instruments. We would also like to acknowledge the invaluable contributions of our project participants.

Work in Progress: A Case Study of the Types and Frequencies of Conflict in Engineering Design Dyads

Joi-Lynn Mondisa, Nicholas D. Fila, Emily Dringenberg, Tasha Zephirin, Şenay Purzer
School of Engineering Education
Purdue University
West Lafayette, USA

Abstract—Conflict is a common subject of research on engineering teams. While some conflict may improve team creativity and productivity, it can also detract from team member satisfaction, perceived team efficacy, and overall team performance. In this paper, we present a preliminary framework for identifying conflict within engineering design dyads using a case study approach. Using this framework, we identified instances of conflict in one male-male and one female-male engineering dyad performing a brief engineering design task. We identified more instances of conflict in the male-male dyad than the female-male dyad; however, this conflict appeared to be productive. An implication of this research for educators is to encourage argumentation within the teamwork occurring in their classroom. Students should understand that conflict can be constructive and improve their team's ability to move iteratively through the design process.

Keywords: *engineering design, conflict, teamwork*

I. INTRODUCTION

Within engineering, there is a longstanding belief that teams consisting of members with different perspectives and skills are better equipped to solve difficult problems and make effective decisions. Gender diversity may indicate different perspectives, but studies within engineering education and meta-analyses of organizational literature have failed to demonstrate a significant positive effect on team outcomes [1-4]. Observations of mixed gender teams in engineering and science courses indicate that team conflict may decrease team participation, satisfaction, and performance [5-7]. In order to benefit from gender diversity, such conflict must be mitigated. As a first step, this exploratory study investigates team conflict within engineering student dyads. This study was guided by the following two research questions: (1) what types of conflict do female-male and male-male engineering student dyads experience during an engineering design task and (2) how frequently does conflict occur in female-male and male-male dyads?

II. LITERATURE REVIEW

Team conflict is often described as disagreement or incompatibility among members of the same project team [8]. Researchers classify team conflict into three categories: task, process, and relationship [8-10]. While a moderate amount of task-related conflict can improve teamwork outcomes,

relationship conflict is generally perceived as negative [8, 10]. In a more recent study, Jehn, Neale, and Northcraft [9] found that all three types of team conflict were negatively correlated with satisfaction, perceived performance, and actual performance.

Researchers suggest that demographic diversity, and gender diversity in particular, may result in all forms of team conflict because of differences in behavior, values, and perspectives among team members [8, 9]. An increase in conflict is especially evident in engineering course settings where male students have been observed to deny female students opportunities to contribute [5], respond critically to female speech acts [11], and rate female contributions to teamwork as less valuable or effective [6].

Researchers have also studied the context of the task in conjunction with conflict [8, 9]. These researchers have investigated whether task type influences the amount of conflict experienced by work teams. We propose that in addition to their teammates, team members can also experience conflict directly with their task. The operational definition of conflict in this study, described in the following section, allows for person-to-person and person-to-task conflict, with task, process and relationship as subcategories for each of the two dimensions.

III. METHODS

Research Setting and Data Collection. This study was performed in a laboratory setting at a research university in the Midwestern United States. Two dyads of first-year engineering students (one male-male, one female-male) completed an hour-long engineering design task. The design task prompted students to develop a way to reintroduce clean water into a small Midwestern town whose water supply had been contaminated in a flood. Students had access to relevant engineering texts and the Internet and were compensated \$10 for their participation. The dyads were aware that their discussions were audio- and video-recorded. These discussions were then transcribed verbatim.

Data Analysis. We began data analysis by coding the transcripts for instances of conflict. Coding consisted of two phases. First, each author open coded the transcripts for instances of conflict rather than relying on any preexisting

conflict framework. Here, we used a working definition of conflict: any instance when both members of a dyad did not demonstrate homogenous thought or purpose. Four unique types of conflict emerged from the data: conflict with partner, conflict with information, conflict with certainty, and conflict with process. Informally, conflict with partner maps to person-to-person conflict and the latter three types map to person-to-task conflict. We observed no instances of what could be classified as relationship conflict or person-to-person process conflict.

During a second round of coding, each author identified instances the four types of conflict on a portion of the data. As a team, we discussed any instances of conflict for which individuals were uncertain. After reaching consensus on those instances, we tallied the instances of each type of conflict within both the male-male and female-male dyads.

IV. INITIAL RESULTS AND FINDINGS

Table 1 provides descriptions of the four types of conflict we identified during open coding.

TABLE I. TYPES OF CONFLICT IN DYADS

| Type of Conflict | Description |
|---------------------------|---|
| Conflict with Partner | A participant vocalizes or implies that something the other participant has said or done is incorrect. |
| Conflict with Information | A participant does not trust the veracity of the gathered information or that it is feasible in the context of the problem. |
| Conflict with Certainty | A participant requests clarification of something the other participant has said, the problem statement, information previously gathered, or topics previously discussed. |
| Conflict with Process | A participant proposes new tactics or a new approach. |

Figure 1 displays the frequencies of each type of conflict in each dyad. We found 124 total instances of conflict. The male-male dyad accounted for 86 of these instances and the female-male dyad accounted for 38 instances. The male-male dyad demonstrated more instances of all four types of conflict. The largest differences were in *conflict with process* and *conflict with information*.

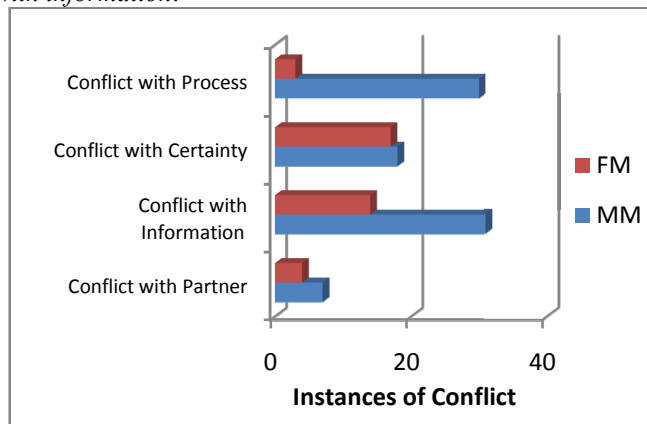

Figure 1. Instances of Conflict in Female-Male and Male-Male Dyads

Though the male-male dyad experienced more conflict compared to the female-male dyad, informal observations showed this conflict tended to be productive (i.e. it led to further discourse and iterations through the design process). A possible implication of this research is that both educators and students understand that constructive conflict can improve a dyad’s ability to move iteratively through the design process. Gender composition may reduce a dyad’s initial capacity for constructive conflict.

V. LIMITATIONS AND FUTURE WORK

This preliminary study was limited by a small sample size and a lack of formal reliability measures during data coding. While transcript data was the best standalone data source at hand, the use of videos and notes will be used to add context. Future work will include an increased sample size (adding female-female dyads), verification of a coding scheme, and analysis of the interplay of gender, argumentation, and patterns of conflict in collaborative design outcomes.

ACKNOWLEDGMENT

This paper uses research data from a project supported by funding from Purdue Research Foundation.

Work in Progress: Enhancing Broader Communication among Courses Linked with Prerequisites

Ziliang Zhou

adonaldson@calbaptist.edu

Abstract— This paper continues our previous study on addressing the communication barrier among courses linked with prerequisites. By proposing an active feedback system, the instructor teaching the prerequisite can proactively report the student performance at each detail subject level and make it available to instructors requiring the course as prerequisite. This active feedback system serves three purposes: (1) the instructors receiving such information have a better understanding of the incoming student readiness for the class, and if necessary, can offer a review session before starting a new chapter; (2) the prerequisite instructor can assess and improve their teaching effectiveness at each subject level by re-assigning the appropriate amount of time in each chapter; (3) the academic advisor can also use this information to recommend additional study between semesters in certain weak performance areas to help student to achieve academic success. The actual course adopted for this active feedback system was an entry level engineering math course. In this work, we outline a plan that will allow us to expand this active feedback system into other engineering courses linked by prerequisites.

Keywords– Active Feedback, Advising, Prerequisites.

I. INTRODUCTION

The use of prerequisite is an important part of the academic process ensuring student academic success. Over the years, attempts were made to create innovative ways to enhance its' effectiveness and student retention. This includes Lanning's work [1] on Prerequisite Skills Testing in his Solid Mechanics class, Ohland's work [2] on adjusting calculus prerequisite requirement to reduce the bottleneck in Clemson's general engineering curriculum, and the consortium led by Klingbeil [3] on teaching engineering math by engineering faculty. Prerequisites are designed to ensure that students taking the course are adequately prepared. As indicated in our previous work [4], the prerequisite system works well for A-level students who have a good understanding of the broad subjects covered in the prerequisite course. However, a barely passing grade of C does not provide the detailed information on their understanding of the subject required to be successful in completing the subsequent courses. For example, a student performing poorly in trigonometry and complex analysis but did reasonably well in rest of engineering mathematics may still be ill-prepared for Circuit Theory. To compensate for this deficiency, we presented an active feedback system, where the instructor teaching the prerequisite proactively report the

student performance at each detail subject level and make it available to instructors requiring the course as prerequisite. We adopted this approach in our entry level engineering math course and improved the communication among courses linked by prerequisites. Our first implementation of the system was completed in 2010 with the following sample data (with only the C level performance students listed) in Table 1:

Table 1: student performance in subject areas 2010-2011

| grade | algebra | trig | vector analysis | complex analysis | derivative | integral |
|---------------|---------|------|-----------------|------------------|------------|----------|
| C- | 60% | 46% | 80% | 90% | 21% | 19% |
| C+ | 65% | 55% | 75% | 100% | 100% | 25% |
| C | 72% | 40% | 66% | 89% | 67% | 35% |
| C | 60% | 50% | 88% | 90% | 63% | 43% |
| C | 53% | 67% | 80% | 88% | 71% | 82% |
| C- | 78% | 35% | 90% | 95% | 21% | 52% |
| C+ | 70% | 62% | 84% | 88% | 21% | 45% |
| class average | 84% | 72% | 91% | 92% | 74% | 62% |

One noticeable observation from the table is that the average performances among different subjects are not even. The entire class on average did very well in vector analysis and complex analysis (both above 90%) while at the same time exhibiting some weakness in integrals (62%). Integrals were the last chapter of the course and usually suffered from not having enough time near the end of the semester. Efforts were made to increase the amount of time allocated to this chapter during the subsequent year. The following class average performance was achieved and is listed in Table 2. Students with failing grades of D and F are not included. The final grades also include performance in homework and lab reports.

Table 2: student performance in subject areas 2011-2012

| grade | algebra | trig | vector analysis | complex analysis | derivative | integral |
|---------|---------|------|-----------------|------------------|------------|----------|
| C | 63% | 58% | 100% | 70% | 25% | 38% |
| A- | 89% | 88% | 88% | 70% | 95% | 80% |
| B | 61% | 85% | 91% | 80% | 100% | 50% |
| B+ | 91% | 65% | 72% | 60% | 75% | 80% |
| A | 100% | 100% | 84% | 80% | 15% | 80% |
| B- | 70% | 94% | 59% | 70% | 95% | 63% |
| A- | 89% | 96% | 88% | 90% | 100% | 63% |
| A- | 95% | 73% | 94% | 50% | 95% | 68% |
| B | 94% | 77% | 50% | 70% | 100% | 50% |
| A | 97% | 92% | 100% | 90% | 90% | 80% |
| B+ | 52% | 96% | 94% | 80% | 100% | 25% |
| average | 82% | 86% | 81% | 79% | 84% | 68% |

It is clear that the class average performance among different subjects are more evenly distributed (all around 80%) except the last chapter on integral, which is particularly important to the calculus based Physics class. We are still having ongoing dialog between College of Engineering and the Physics Department on ways to improve the situation. One

approach we adopted was to make a B- as the minimum grade the students have to achieve in the engineering math course in order to enroll in Physics class. For students with performance below that, we recommend that they complete the regular calculus class before enrolling in Physics. The feedback from the Physics instructor shows significant improvement on overall class performance from the most recent semester.

Selected performances below C level in each subject area were highlighted for advising purpose. One student was advised not to take Physics course due to his poor performance on both integration and differentiation. The entire class performance was forwarded to the instructors requiring this course as prerequisite.

To reap the broader benefit of this work, we plan to expand this approach to other engineering courses linked with prerequisites.

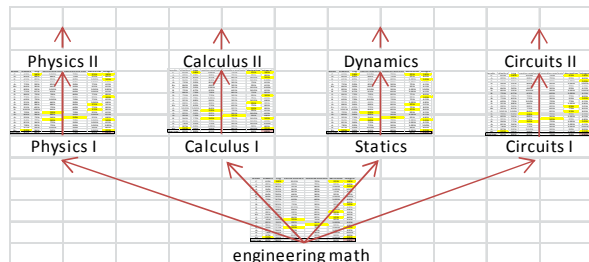

II. PLAN, METHOD AND PRCESS

We propose to expand the active feedback system used in our initial study in Engineering Math to subsequent courses as outlined in Table 3.

In order to establish a successful active feedback system among those courses linked with prerequisite, we shall follow the following steps:

1. Invite instructors of potential courses to join the study and solicit input;
2. Review and determine specific subject areas for feedback;
3. Determine frequency and method of assessment of performance in the determined subject areas;
4. Determine an reporting frequency of the overall performance among instructors linked with prerequisites;
5. Determine the objective method of student overall performance assessment to evaluate the impact of the active feedback system.

Table 3: Future Implementations

We plan to implement this system in the fall of 2012 and invite other institutions to join us on this project for a potential NSF grant to support the effort.

III. CONCLUSIONS

The active feedback system provides a simple tool in uncovering the weakness in student learning at the detail subject level, and therefore, facilitating better communication among instructors linked with prerequisites. The information included in this system is not new. The instructor records the performance at such detail subject level routinely for grading purpose. It is also related to the broad discussion on evaluating instructor's teaching through student grades in later courses [5]. The active feedback system presented here helps to standardize the process for advising as well as teaching improvement.

The active feedback system was initially adopted in an engineering math course and helped us to balance the time allocated in different subject areas of the class. It also helped us on our student advising process. The instructors who received this information are now better prepared in dealing with deficiencies in certain subject areas important to his or her teaching. We propose the current work so that the effectiveness of the system can be further verified and the benefits can be shared among other engineering courses with similar prerequisite structures. The implementation results will be reported in future FIE conferences once the relevant data are collected.

Abstract—A proactive recommender system pushes recommendations to the user when the current situation seems appropriate, without explicit user request. This is suitable in e-Learning scenarios in which a great amount of learning objects are available but it is difficult to find them according to the user's needs. In this paper, we present a model for generating proactive context-aware recommendations in the Virtual Science Hub (ViSH), a educational platform related to the GLOBAL excursion European project. The model relies on domain-dependent context modeling in several categories to generate personalized recommendations to teachers and scientists that will produce the learning resources the students will consume. The recommendation process is divided into three phases. First, the generation of the social context information related to the users in the platform. Then, the current situation considering the social, location and user context is analyzed. Finally, the suitability of particular learning objects to be recommended is examined. Therefore, details about the recommendation model proposed and advantages related to applying the model in ViSH can be found in the paper, in addition to some conclusion remarks and outlook on future work.

Index Terms—Learning Objects Recommendation; Context-awareness; Proactivity; Personalized Learning

I. INTRODUCTION

Traditional educational platforms usually have had a problem related to find the most suitable learning objects among all the items available for a specific user, taking into account his/her interests. Moreover, when this kind of platforms store a huge number of learning objects, it is difficult for users to difference between high and low quality pedagogical content. Sometimes the learning objects are gathered by categories using taxonomies or folksonomies. Despite this, it is still hard to find the best learning objects inside those groups as the number of them to check is commonly overwhelming.

This problem has been solved (or at least mitigated) by using recommender systems in areas such as book sale (e.g. Amazon) or video on-demand (e.g. Netflix). In these fields, the number of items to be analyzed is also huge and it is needed a system that recommends the best items to users in a personalized way considering their tastes and consumer history. However, the application of recommender systems in the e-Learning area is currently limited.

A proactive recommender system pushes recommendations to the user when the current situation seems appropriate, without explicit user request. This is suitable in e-Learning scenarios in which a great amount of learning resources are available but it is still difficult to find them according to the user's needs.

In this paper, we present a model for generating proactive context-aware recommendations in e-Learning systems. Our scenario is the GLOBAL Virtual Science Hub (ViSH), the social platform related to the GLOBAL excursion (Extended Curriculum for Science Infrastructure Online) European project. Its aim is to provide students and their educators across Europe with a range of e-Infrastructures and access to expert knowledge on its usage for a joyful exploration of e-Science. Specifically, ViSH contains a selection of e-Infrastructures, learning objects and a social network where scientists, teachers and students will be able to exchange and establish collaborations.

Bearing in mind the aforementioned scenario, we propose a model that relies on domain-dependent context modeling in several categories (i.e. social, location and user context) to generate personalized recommendations to teachers and scientists that will produce the learning objects the students will consume. As a result, simple pedagogical contents (e.g. videos, slides or images) and complex activities (e.g. virtual excursions or flashcards) can be recommended, as well as users registered in the platform that can be interesting for the target user (e.g. the system could recommend a biologist from London to a teacher from Madrid who wants to generate specific material related to the same area).

The rest of the paper is organized as follows. The next section reviews related work in the area of recommender systems and its applications in e-Learning platforms. Section 3 describes the GLOBAL excursion project and the ViSH scenario. Section 4 explains our proposed model. In Section 5, we discuss the advantages of applying this model to ViSH. Finally, the last section provides some concluding remarks and outlook on future work.

II. RELATED WORK

A great variety of research and practical applications exist in the area of recommender systems and context-awareness (see e.g. [1], [2] or [3]), especially in the mobile guides field [4] or the shopping domain [5].

However, proactivity has not gained much attention in personalization and recommender system research. Most systems require the user to perform some kind of action to trigger the generation or retrieval of recommended items. As an example of proactivity in an existing system, Hong et al. [6] proposed an agent-based framework for proactive personalization services. This approach proposes a model according to which a user profile is deduced from a user's context history. The model enables proactive recommendations in the future. However, training time is very important in the proposed model.

Ricci discusses proactivity and its role in recommender systems to transform them from topic oriented information seeking and decision making tools, to information discovery and entertaining companions [7].

Regarding to proactivity models, Woerndl et al. [8] recently proposed a model in mobile context-aware recommender systems. And Gallego et al. [9] carried out a study on proactive delivery of restaurant recommendations for Android smartphones based on that model, with good results regarding usefulness and effectiveness.

Although recommender systems have been traditionally applied in different domains such as shopping, TV programs, books, etc. [10], the use of recommender systems provides useful applications in the educational field [11], [12]. It has potential to assist students in finding the best possible courses into enrolment applications [13], [14].

On the other hand, recommendation approaches for learning objects repositories have been proposed. For example, Ruiz-Iniesta et al. [15] proposed a proactive recommendation approach adapted to the student profile. Cheng [16] presented a type of recommendation agent based on cognition inference. The semantic web also offers new possibilities for recommender systems, and ontology-based learning object recommendations have been presented [17], [18], [19].

Some authors aim to integrate multi-agent recommendation systems into a mobile learning platforms [20]. Others findings [21] presents research on personal recommender systems for lifelong learning. User profiles, learning contents and preferences are usually relevant in a recommender system. However, Bobadilla et al. [22] take into account the student's opinion as input for further recommendation of the learning object.

III. SCENARIO: RECOMMENDING IN THE VIRTUAL SCIENCE HUB PLATFORM

The GLOBAL excursion project [23] will develop a common understanding, teaching use cases, as well as pedagogical and technical artifacts. The main purpose of the GLOBAL excursion project is to enable students and teachers access to the experimental laboratories and resources of

selected e-Infrastructures in order to improve science curricula by enriching school's existing teaching and learning materials. GLOBAL excursion will develop a platform called Virtual Science Hub (ViSH) to host all the activities carried out by the teachers and researchers in the project and to foster collaboration between them. With the intention of continuing after the project ends, being a meeting point between science and schools, researchers and teachers, and teachers themselves. That is why ViSH will be a social network, where every user will be able to follow another user and to be followed by other users interested in their activity. Users will also have a profile with their activity (e.g. learning objects uploaded, users followed and following, etc.) and a wall compiling the activity of their contacts network.

On the other hand, some science fields can be very difficult for young students. The initial fields covered in the project are nanoscience, biotechnology, volunteer computing and grid computing. To enhance the students interests and make this topics enjoyable and amusing for them, a new kind of complex learning objects called virtual excursions have been defined. These virtual excursions are created by the teachers and consumed by their students. A virtual excursion can be one of the following:

- a virtual meeting via videoconference between the classroom and the researcher, where the researcher explains a specific topic with the contents available in the platform.
- the use of a remote lab or microscope with the supervision of a researcher.
- a compilation of simple resources, like texts, images or videos together with interactive objects such as quizzes and flash objects into a slides presentation.
- interactive resources or applications based on specific topics developed by the project partners like virtual experiments or flashcards.

To create a virtual excursion the teacher will have to select among contents hosted in the ViSH. The number of resources available in the ViSH platform can be very high, and higher with time, because when new researchers and teachers join ViSH they can upload new resources from their institution. Recommendation will be very important here to make this task as easy as possible. Besides, as the teachers and researchers community grows, ViSH should recommend interesting users to follow. They could be other teachers or researchers with common interests or that have uploaded content that can be interesting. Finally, a virtual excursion can be directly recommended to the teacher to use it with his/her students if it is related, for example, to the teacher's subjects.

IV. INTRODUCING PROACTIVE CONTEXT-AWARE RECOMMENDATIONS IN E-LEARNING SYSTEMS

Our model for generating proactive recommendations in e-Learning systems incorporates contextual information to assess whether a recommendation is suitable in a given situation. It also evaluates which learning objects from ViSH are interesting for the user that is being recommended. We

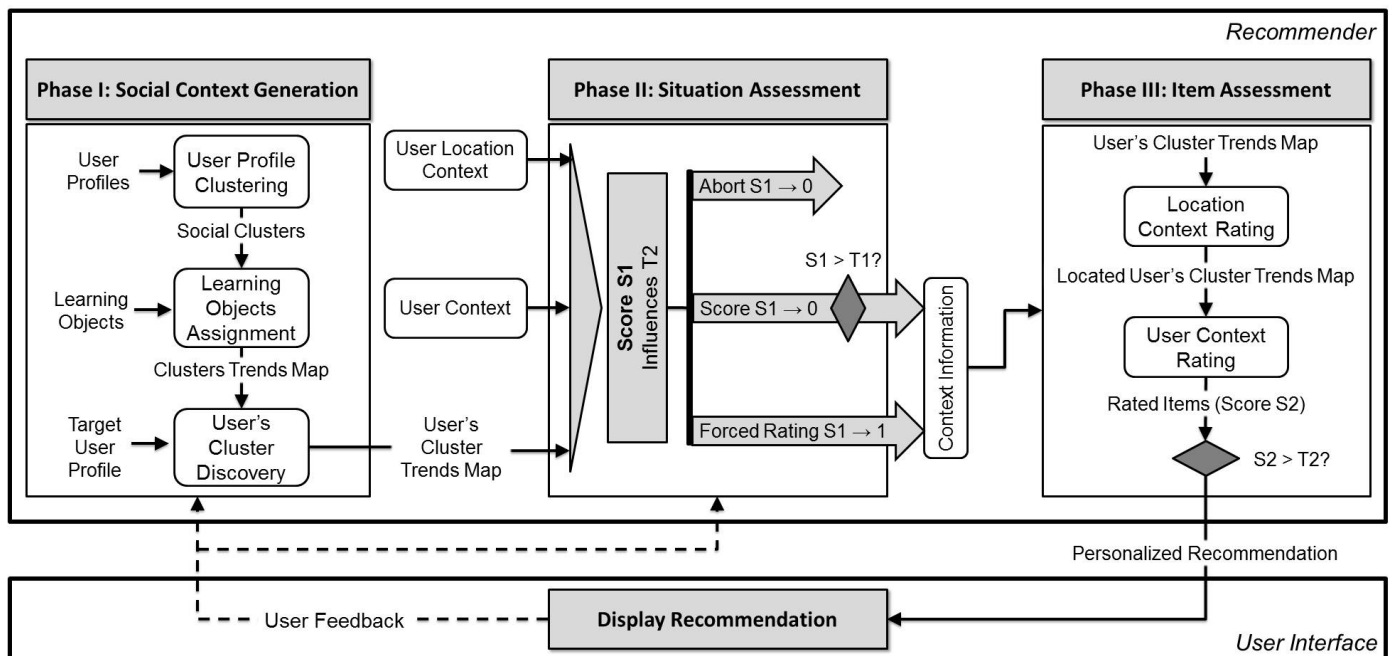

Fig. 1. Model for generating Proactive Context-aware Recommendations in e-Learning Systems.

first define what we mean by context and then we develop our model.

A. Context

As we have seen in Section 2, using context-awareness information is now a common feature to improve recommender systems on the basis that the more information you have from a user, the more personalized and accurate will be the results provided.

There has been much research on the area of generating context-awareness and different definitions of the term *context* exist (e.g. [24], [25]). We follow the definition proposed by Dey [26], in which context can be defined as characterizing the situation of entities that are relevant to the interaction between a user and an application. To generate proactive recommendations we are utilizing the following context categories:

- 1) Social context: the links (e.g. common interests, related profiles, etc.) among users in the ViSH platform that allow us to gather them into clusters by similarity.
- 2) Location context: temporal (e.g. current time) and geographical information (e.g. nationality or language).
- 3) User context: the current activity of the user (e.g. if he/she is consulting the ViSH platform through a mobile device or a desktop computer).

B. Model: process overview

Fig. 1 summarizes our three-phase model to handle proactive context-aware recommendations in e-Learning systems. The model analyzes the current context and generates a personalized recommendation that determines not only the best item(s) in a given situation, but also whether the situation

warrants a recommendation at all. It combines previous work in the area of proactivity proposed by Woerndl et al. [8] and in the area of context-aware recommender systems proposed by Gallego et al. [27].

In the first phase, the system generates the social context related to a user by analyzing all the users and learning objects present in the e-Learning platform in order to gather them in clusters by similarity. This phase is executed from time to time (e.g. once a day), as the social context does not change quickly.

In the second phase, the system determines whether or not the current situation warrants a recommendation considering social, location and user context information. This phase is executed periodically in the background when the user is active in the e-Learning platform.

The third phase deals with evaluating the candidate items to be recommended. If one or more items are considered good enough in the current context, the recommender system would communicate it to the user. This phase is only executed when the second phase indicates a promising situation and the corresponding score exceeds a threshold.

Finally, the user has the possibility of giving feedback about the recommendation provided in order to allow the system to take that information into account for future recommendations.

C. Phase I: Social Context Generation

It begins with the system taking the user profiles provided by the e-Learning platform so as to apply a clustering segmentation to them. In the ViSH case, two users are similar when their profiles are alike in terms of educational interest (e.g. nano- and biotechnologies), role in the platform (e.g. teacher or researcher), students' age, curricula, etc. Once the

social clusters have been generated, the system calculates the clusters trends map by considering which learning objects have been created or consulted by every user belonging to the clusters. We assume that in the platform there is an unequivocal relationship between a learning object and its creator, and also between a learning object and the users that have consulted or used it.

Hence, in this second process, we create a map of learning objects where the relationships among them and the clusters are shown, noticing this way the educational trends of every cluster. In other words, we know what learning objects are consumed in every cluster.

When the target user enters the first time to the e-Learning platform, his/her user profile is retrieved and the user's cluster discovery process is activated. The system checks the information profile extracted from the user ViSH account and calculates the similarity between it and the social clusters available in order to assign him/her to any of the existing clusters. After these steps the system knows the social context of the user because he/she has been assigned to one of the social clusters previously generated. Every cluster has a set of learning objects assigned that are interesting for the users belonging to the cluster. Therefore, the system knows which learning objects (that have not been generated or previously consulted by the user) are candidates to be recommended (represented by the user's cluster trends map). This set of candidates learning objects is rated taking into account how many times a pedagogical material has been queried and by whom, so as to recommend first the items that are trendier in the user's social cluster.

Finally, bearing in mind that this kind of information does not change continuously (e.g. the user profile usually is a constant information), this phase is not restricted to a real-time execution. For that reason, despite the fact that the data mining procedure could be heavy if we have a lot of users and/or learning objects, it is not necessary to calculate these clusters in every recommendation process.

D. Phase II: Situation Assessment

In the second phase, the system calculates a score $S1$ which is a number between 0 and 1. If $S1$ exceeds a threshold $T1$, the third phase will be initiated. If $S1 = 1$, the highest possible value, then a recommendation will be triggered in any case. If the current situation does not warrant a recommendation, no matter how high a particular item would score, $S1$ is set to 0 and the recommendation process is aborted without considering items for recommendation. Note that this phase does not take properties of single items into account. However it considers general properties of the set of candidate items in a current context (e.g. availability of learning objects in English that can be consulted in a mobile device).

Each contextual attribute is weighed depending on the relative importance of the parameter to the recommendation process. The higher the score for a context attribute, the higher the indication that a proactive recommendation could be useful. That contextual information related to the user is

needed as a prerequisite to calculate $S1$. In our model, the social context information is provided by the user's cluster trends map generated in the previous phase. The location context (i.e. temporal and geographical information about the user) is extracted from the platform or in the worst case, from the browser or from the mobile device (if the application is being consulted from a smartphone or a tablet). The user context is provided by the platform. In the ViSH case, as it can be consulted through desktop and mobile devices, the platform is in charge of providing this information as well as other context parameters like what is the current activity of the user (e.g. completing a virtual excursion, having a videoconference session, etc.) in order to avoid disturbing him/her if the user is focused on other important task.

Furthermore, the score $S1$ has an impact on the threshold $T2$ of the third phase, i.e. the higher $S1$ is, the lower $T2$ is set. Therefore, the threshold $T2$ is a function of $S1$ in the simplest form:

$$T2 = |1 - S1| \quad (1)$$

This means that when the situation is considered appropriate for a recommendation, $S1$ is high and it is more likely that at least one item score $S2$ in the third phase reaches the required threshold $T2$ and an item will be recommended to the user. On the other hand, if the situation assessment leads to a mediocre score $S1$, phase III might still be initiated but only an extraordinary high rated item might score good enough to be recommended.

E. Phase III: Item Assessment

If the current situation is considered suitable for the user, then the third phase is started by passing it the context information previously used to calculate $S1$.

In this phase, the suitability of particular items is evaluated. To do so, the rated learning objects provided by the user's cluster trends map are now rated taking into account the location context. Consequently the learning objects that are in the same user's language or have to be consulted at a specific time (e.g. synchronous learning objects such as remote experiments under the supervision of a researcher), will have a higher rating compared to other educational contents that do not fit the location context properly.

After that, the system applies a new rating process to the located user's cluster trends map considering the user context. Again, a learning object that fits better the current user context will have a higher rating. For instance, if the user is consulting the application in his/her smartphone, the educational content has to be adapted to be consumed in a mobile device.

Therefore, the result of phase III is a score $S2$ for each item in the candidate set. To determine this score, a combination of the previous contextual ratings (i.e. *socialCtxScore*, *locationCtxScore* and *userCtxScore*) is done as a linear weighted combination:

$$S2 = w_s \times socialCtxScore + w_l \times locationCtxScore + w_u \times userCtxScore \quad (2)$$

Where *socialCtxScore*, *locationCtxScore* and *userCtxScore* are numbers normalized to [0, 1] and $w_s + w_l + w_u = 1$.

Consequently, S2 is again a number normalized to [0, 1], with S2=1 being the best possible score. An item can be immediately eliminated from the recommendation process (then S2 is set to 0), for example if a learning object is not available right now.

The candidate items will be ranked according to S2 and tested against the threshold T2. If $S2 > T2$ for an item, then this item is finally considered for recommendation and the user is notified. Depending on the application scenario, the best k items above the threshold will be displayed. If no item score S2 exceeds the threshold T2, then no item is recommended. The process is aborted and restarted with phase II at the next configured interval. If the score S1 from the first phase is 1, the best-ranked item will be proposed in any case, since the threshold T2 is 0.

F. User Feedback

Once the recommender engine has generated a personalized recommendation composed by the best-ranked learning objects, the user interface is in charge of displaying the recommendation. The model is not restricted to how the visualization is carried out, as it will depend on the device used, as well as the design and layout available in the application.

After the recommended items are communicated to the user, he/she can optionally give feedback on the recommendation. The feedback is a rating for an item that can be utilized when assessing the relevance of the item, so as to be taken into account as social context information for his/her social cluster in phase I.

In addition, the user can give feedback on the point in time of the recommendation by rejecting or ignoring the whole recommendation. In this case, the feedback influences the thresholds T1 and T2: a negative feedback on the point in time results in higher thresholds, and thus decreases the chance of a proactive recommendation in the future in a similar situation.

V. DISCUSSION: APPLICATION IN ViSH

The application of the model described above to the ViSH platform brings several advantages against traditional recommender systems methods. First of all, users do not need to set up the system with initial information as it learns from their activity in the platform. The recommender engine works in a transparent way to end users since it retrieves the required data from ViSH to generate the recommendations, without being necessary an explicit training process.

In addition, by using this model the system can recommend not only learning objects, but also users from the same cluster as interesting people to follow in the ViSH platform. This can

be done by using the social clusters generated in the phase I of the model. All the users belonging to the same target user's social cluster are by definition similar in terms of educational interest, profile, type of students, etc. Hence, although the system is focused on recommending learning objects, it is also possible to recommend people so as to increase the collaboration and social relationships among ViSH users, achieving in this way one of the main purposes of the project.

On the other hand, the model allows different ways of accessing the application as it is not restricted in how the recommendations are displayed and how the location and user context information is retrieved. In ViSH, desktop and mobile user interfaces are available. For that reason, different visualizations and context parameters will exist providing richer information to enhance the context-aware recommendations and the proactivity features.

Finally, despite this model is focused on generating proactive recommendations, it is also possible to activate the recommendation process by a user request. One of the features that are supposed to be available in ViSH is a recommender tool in which users can set a personalized request to generate a recommendation about learning objects whenever they want. This can be done in our model by skipping the phase II (Situation Assessment). As the user is requesting a recommendation, that means that the situation is completely suitable, and for that reason by setting $S1 = 1$ we can skip the analysis of proactivity, passing directly to the phase III in which the items are evaluated considering the context information and the user request parameters.

VI. CONCLUSION AND FUTURE WORK

In this paper we have presented a new model for proactivity in context-aware recommender systems focused on the e-Learning domain. We have described an innovative way of recommending learning objects to users belonging to an e-Learning platform. It takes into account their current social, location and user context to select the most suitable situation to consume that objects, without being needed a training process as the system learns from the users' activity.

As we have seen, the application of this model in ViSH (a real scenario related to the GLOBAL excursion European project), provides several advantages compared to traditional recommender systems. It allows not only the possibility of recommending learning objects, but also users belonging to the platform that share the same interests considering a target user. The model additionally provides the possibility of recommending in two ways: proactively and following a user request, achieving the uses cases required in ViSH.

Future work includes the implementation of this model in ViSH to test it in the user evaluation phase. It is going to be carried out inside the GLOBAL excursion project in the present year. This will allow us to evaluate the usefulness, effectiveness, accuracy or reliability in the recommendations provided.

In regard to enhance the social context generation, the application of network science techniques to analyze

relationships and links among users and learning objects in the ViSH social network could be also an interesting point to investigate. The appearance of power law distributions, small-world [28] or scale-free network properties [29], or users acting as social hubs, would provide us important information to improve the social context information.

An additional open issue related to the application of this model in an e-Learning scenario is the possibility of recommending a personalized composition of related learning objects. This will allow to create complex learning objects (or virtual excursion like are called in ViSH) focused on one specific topic to provide extra value to end users interested on it. For instance, several learning objects (e.g. videos, slides or images) related to the biology of the cell could be joined in order to offer a complete pedagogical material that could be used by teachers giving a lesson on that subject.

ACKNOWLEDGMENT

We wish to acknowledge our gratitude and appreciation to all the GLOBAL excursion project partners, and each one of the project team members, for their contribution during the development of various ideas and concepts presented in this paper. This work is financially supported by the European Union under FP7, Infrastructures.

Aural Instruction with Visualization in E-Learning

Dr. Fuad Alhosban, Professor Liz Burd
Durham University, fuad.alhosban@durham.ac.uk, liz.burd@durham.ac.uk

Abstract—This research investigates the effectiveness of using aural instructions together with visualisation in teaching some concepts of data structures to novice computer science students. A prototype learning system, known as the Data Structure Learning (DSL) tool, was developed and used first in a short mini study that showed that, used together with visualisations of algorithms, aural instructions produced faster student response times than did textual instructions. This result suggested that the additional use of the auditory sensory channel did indeed reduce the cognitive load. The tool was then used in a second, longitudinal, study over two academic terms in which students studying the Data Structures module were offered the opportunity to use the DSL approach with either aural or textual instructions. Both the quantitative data provided by the automatic recording of DSL use and an end-of-study questionnaire showed appreciation by students of the help the tool had provided and enthusiasm for its future use and development. These findings were supported by qualitative data provided by student written feedback at the end of each task, by interviews at the end of the experiment and by interest from the lecturer in integrating use of the tool with the teaching of the module.

I. INTRODUCTION

One of the first challenges that faces novice computer science (CS) students when they start their course is to acquire the skills required to write or compile computer programs. Consequently, the Introduction to Programming and the Data Structures (PDS) modules are compulsory for first year CS students at Durham University, UK. Within these modules, object-oriented programming (OOP) is a widely used paradigm for software development.

OOP is defined by [1] as “a practical methodology that encourages modular design and software reuse.” data structures, on the other hand, offer memory based organization of information for better algorithm efficiency [2]. Understanding the concepts of OOP and data structures is crucial because they enable students to reuse existing code and to create objects that form the building blocks of their programming projects.

The starting point towards students acquiring professional programmer skills is to make sure that they participate in high quality learning. Students need to interact with their learning environment by talking, listening, reading, writing and reflecting on their own knowledge as they approach the course content [3]. Active learning theories [4] support teachers and students to be actively engaged in their learning environment if they are exploring, experiencing, experimenting with, testing

and applying the knowledge they gain in class to solve real life problems.

A. Use of Visualisation in E-Learning

Visualisation is one of many attempts to use technology to improve learning by creating a mental image of how things work. It is also a common learning style that many students prefer as a way to increase their comprehension of concepts, bearing out the proverb “a picture is worth a thousand words.” As an active learning approach [5], interactive visualisation tools increase the interaction between the learner and the subject being studied. However, there are problems with many of the existing visualizations [8]. These include loss of focus if the level of abstract representation focuses concentration on low-level steps rather than on high-level properties like invariants.

B. Use of Audio in E-Learning

The use of audio, either musical or spoken sound, was presented by researchers [7,8,9,10] as a means of aiding visualisation in learning environments. Its usage in CS learning and in algorithm animation started as a way to describe what visualisations are currently showing. It can also help students to focus on their learning task. This means that the use of both aural instructions and visual components can improve students’ awareness of their learning environment.

C. Cognitive Load in E-Learning

Cognitive approaches to human methods of learning, on the other hand, have highlighted the transformation that occurs on different mental representations of situations and tasks. The concept of mental load was based on the concept of a communication between two channels with limited capacity [11]. The Dual Channel Assumption [12] posit that humans process information in two separate channels, visually or aurally. Research shows that the use of animation and an associated aural narration were most effective when presented simultaneously rather than successively. In short, to provide students with an effective and active learning environment, the cognitive load should be reduced to the minimum.

II. OBJECTIVE OF THE RESEARCH

Previous research [12,14,15,16] in this field examined the use of visualisation tools to assist students’ learning experience. This research investigated the reduction of cognitive load by providing an intensive visualisation environment. However, not all visualisation environments reduce the cognitive load, and [17] argues that a “visualization environment that requires users to handle additional information and tasks, which increases cognitive load, offers similar performance advantages to that of a user who has no visualization at all.” Other research [9, 10, 18] investigated the use of sounds or audio feedback to improve the interaction

between users and their systems. However, their investigation did not exploit the dual channels of working memory to speed the learning process.

The main goal of this research is to investigate the effectiveness of using aural instruction together with visualisation in teaching the concepts of data structures to novice CS students. The research tries to provide enough evidence to support three main hypotheses:

- Reducing cognitive load improves student engagement and outcomes when learning data structures.
- The use of aural instructions in teaching data structures to CS students has a positive effect on student perception of data structure concepts.
- Students perceive a positive benefit to their learning by using the DSL tool.

III. IMPLEMENTATION

The design of the DSL tool is based onto three main components namely: Basic Objects, Nodes, and Integration of Audio with Visualisation. Figure 1 shows a snapshot of the DSL tool, it shows both basic object and node structures.

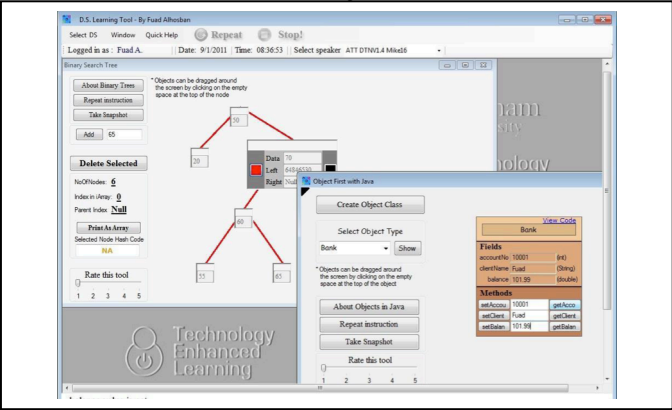

Figure 1. A Snapshot of DSL tool

A. Basic Objects:

This component is designed to help students in understanding what is meant by objects in Java, and how they are created. The design of this object simulates BlueJ’s presentation of Java classes in order to build a relation with the programming environment that students will be working with during the academic year.

Created object is made in a way that it is dynamically changed according to the student’s specification of its attributes. When creating an object, a student can name the object class. Based on that, an object is created that simulates the run-time state of the Java class. Student can then interact with the object by setting and getting its values.

B. Nodes:

In object oriented programming, nodes are referred to as the data record in the computer memory that forms the basic form of data structures such as Linked Lists, Binary Trees. Nodes are used to simulate how DS actually work and are stored in the memory.

Figure 2 illustrates two types of nodes used in the DSL tool in their run-time state. Figure 2-A shows the full size and the reduced size of the Linked List node that contains both the value stored in the node and a single Hash Code (address location in memory) of the next node connected to it. The red square box shows that the node is linked to another node, but a black box is shown if the node is not connected to any other node (leaf node). Figure 2-B illustrates a Binary Tree node that works as a Linked List node; however, it holds the left and right memory location of its children.

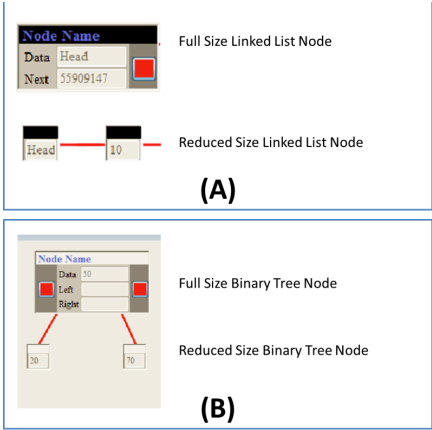

Figure 2. (A) Linked List Node (B) Binary Tree Node

C. Integration of Audio with Visualisation:

As aural instruction is a key factor in the DSL approach, it is important to present how the audio component is used as an instructional method. The use of speech technology allows the integration of aural instructions and the rendering of any text as spoken audio. The voice used in this research was chosen because it sounds the most natural of the voices available and it was the favorite voice of both staff and students.

D. Use Case:

When students opt in to use the DSL tool, first, they logs in to the tool to supply and verify his or her user information. Then, they choose their desired format for the instruction. The tool is then set to deliver textual or aural instructions while the student is learning any of the visualized data structures approaches available in the tool. When students finish working on a visualization task, a snapshot of their screen can be taken and saved for later reference.

IV. METHODOLOGIES

Several research methods were used in this research. Studying the effectiveness of aural instructions with visualization in the DSL environment depends mainly on collecting quantitative data, but some qualitative data also needs to be collected to support the findings based on the quantitative data based on triangulation methods. Two experiments were conducted to find enough evidence to support the research hypothesis, a preliminary study and a longitudinal experimental method.

A. The Pilot Study

The main objective of the pilot study was to investigate relationship between response time and cognitive load, and how can the DSL tool keeps learners cognitive load to the minimum. Based on [12] model of information processing in multimedia learning, the Cognitive Theory of Multimedia Learning and its three assumptions, the research looked at prior studies in the field that concluded that higher levels of cognitive load resulted in increased response times to instructions.

The experiment was conducted during the first practical session of the Introduction to programming module when most CS students had little or no previous contact with computer programming. A total number of 30 students were involved in this experiment (out of 40 students who were enrolled in this module). The experimental procedure applied was based on dividing the students into three conditions in a between-subjects design. In the first and second conditions, at the beginning of the practical session, each student in the two groups was given a laptop and a headset. In the third condition, the remaining group used the non-audio version of the DSL tool, so they were given only laptops. The aim was to investigate how students' responses can be affected by the type of instructional method used (Aural Only, Textual Only, and combination between Aural and Textual instructions), and how can the DSL tool achieve the lowest cognitive load while maintaining successful task completion.

B. Longitudinal Research

The DSL tool was later used in a second, longitudinal, study over two academic terms in which students studying the Data Structures module were offered the opportunity to use the DSL approach with either aural or textual instructions. Their use of the approach was recorded by the DSL system and feedback was invited at the end of every visualisation task.

As the experiment ran over two academic terms, the DSL tool was made available through a network connection to a CS Department local server (SMART), which is run by the Technology Enhanced Learning (TEL) group. The Information Technology Service (ITS) at Durham University limited access to the DSL tool so that only students using the network computers in the PDS labs had access to it. This provided all the students taking the PDS module unlimited access to the tool. Students were also provided with instructions on how to start the DSL tool. Two types of data collection methods used in the second experiment:

Quantitative data collection (The DSL usage data):

The research observed student behavior by automatically gathering information about their usage (Automated collection of usage data). This helped to provide general feedback from students about their overall learning experience. In addition, at the end of every data structures task, they were asked to provide comments on the tool's usefulness and rate the task based on the usefulness of the tool. At the end of the experiment, a questionnaire with students was conducted, to check the conclusions based on the collected usage data and to gain a deeper understanding of their views and experiences in engaging with the DSL approach.

Qualitative data collection:

It was hoped that the qualitative data collected would enable an understanding of the benefits of the DSL environment which integrates aural instructions into a visualized learning setting, how students use the DSL tool, and whether it helps them to achieve what they were trying to do. Three main types of usage data were scheduled: each student's usage of each visualisation task, written feedback within the tasks, and interviews with users.

This part of the research was conducted over the second and third terms of the academic year, that is, from 15 January to 25 June 2010. The students had access to the prototype tool whenever they wished to use it. The total number of participants decreased from 30, who took part in the pilot study, to 27 who actively used the tool in this experiment. The term "actively" means that they used the tool more than once. After reviewing the students' usage data at the end of the experiment, it was seen that a small group of students had used the tool only once. This indicated a lack of interaction with the tool and these students were excluded from the results and their analysis.

Conducting follow up interviews:

A sample size of interviews was limited to three students. Although this is a small sample of the participants, the interviewees provided valuable feedback about student engagement with the DSL approach. However, because of the small sample size, generalizations cannot be made about the student population at large.

The students were carefully selected from among those who volunteered to be interviewed about their experience of using the DSL environment and after reviewing all the students' usage data. Before the interview, a profile of each student's usage was sent out to them to remind them of what they had done. Each profile also contained snapshots of the DSL tool screens that the student had generated or they were replicas based on the student's action list. In addition, the profile contained all the written feedback the student had generated throughout the experiment.

V. ANALYSIS OF RESULTS

A. Discussion of the Pilot Study Results

Table I shows the post-hoc multiple comparisons among the three instructional methods used. As shown in the table; there was a statistically significant difference between the audio only and text only instructional methods. However, was no statistically significant difference between the text only and text with audio instructional methods. These results indicate that students who used the DSL environment responded significantly more quickly with a successful outcome to audio instructions than to other types of instruction. This leads to a conclusion that aural instructions do benefit students in a visual interactive learning environment.

TABLE I. POST-HOC MULTIPLE COMPARISONS TABLE

| Multiple Comparisons Dependent Variable: Response Time in Seconds | | | | | | |
|--|----------------|----------------|-----------------------|------------|------|-------------------------|
| | (I) Group | (J) Group | Mean Difference (I-J) | Std. Error | Sig. | 95% Confidence Interval |
| | | | | | | Lower Bound Upper Bound |
| Tukey HSD | Audio Only | Text and Audio | -1.52000 | 1.17772 | .413 | -4.4401 1.4001 |
| | | Text Only | -3.36000(*) | 1.17772 | .022 | -6.2801 -.4399 |
| | Text and Audio | Audio Only | 1.52000 | 1.17772 | .413 | -1.4001 4.4401 |
| | | Text Only | -1.84000 | 1.17772 | .279 | -4.7601 1.0801 |
| | Text Only | Audio Only | 3.36000(*) | 1.17772 | .022 | .4399 6.2801 |
| | | Text and Audio | 1.84000 | 1.17772 | .279 | -1.0801 4.7601 |

* The mean difference is significant at the .05 level.

Based on this result, the research continued into its second part, using audio only instructions with visualisation and abandoning the use of text with audio instructions. It is expected that using audio only instructions will produce an improvement in students' interaction with the DSL approach.

B. Discussion of the Longitudinal Study

Having established, through the pilot study, the effectiveness of aural instruction for computer science students in a visual learning environment, this research moved on to investigate the effectiveness of the main feature of the DSL environment, which is visualizing the concepts of data structures in conjunction with aural instructions.

Usage Time: The first type of data collected was information about the usage time and the number of times each student used the system. The experiment recorded the time and date of each student's session. It also recorded which data structures visualisation was accessed and whether any audio assistance was used to accompany the visualisation.

Figure 3 summarizes the overall usage data. The mean average time spent on engaging with the DSL tool was about 40 minutes, which equates to one third of a practical session. The results show that, during ten practical sessions over two terms, students spent an average of 3.3% of practical session time using the DSL tool. However, usage by different students varied greatly. The longest time a student spent using the tool was 127.92 minutes (about 2 hours and 8 minutes) and the least time was about 4 minutes. This implies that students do choose to use the DSL tool while studying data structures.

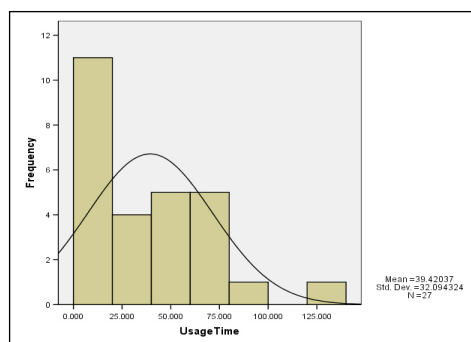

Figure 3. Students' usage time

Task Choice: Although the previous data provides an overview of the tool's usage, more investigation was needed to assess what sort of visualisations were more likely to be used by students and what was their effect. To answer this, the DSL environment was designed so that the prototype tool records each student action while working on the three available tasks, Binary Tree Traversal (BTT), Binary Search Trees (BST), and Linked Lists (LL). The results shows that the students engaged with the BTT visualisation task the most and with the LL visualisation the least, but the DSL tool was well used in all three tasks.

Table II provides further details of the collected data and shows the number of actions performed on each visualisation during the course of the task. In order to avoid discrepancies in the system's usage data, all the tasks where less than 5 actions were performed were eliminated from the results. This was because, after checking these instances, it became clear that they were not genuine interactions with the tool and the students did not perform valuable actions with it. Thus, it was unrepresentative data.

TABLE II. EFFECTIVE USAGE OF DSL APPROACH

| Task Type | Task Total Runs | Total number of actions |
|------------------------------|-----------------|-------------------------|
| Binary Search Trees | 46 | 367 |
| Linked Lists | 42 | 404 |
| Binary Trees Traversal | 54 | 710 |
| Total Effective Usage | 142 | 1481 |

The data in Table II shows that students made substantial use of the DSL tool to help them study all the three types of data structures. They ran a total number of 142 tasks and, within these, they performed nearly 1,500 actions while interacting with the tool. However, the BTT visualisations attracted the largest number of both runs and actions and these accounted for 38% and 48% of their respective totals.

Task Rating: The DSL environment also allowed students to rate each task they engaged with and to produce feedback that was specific to the task. For this, a rating scale was offered with each visualisation task. The scale allowed the student to rate each task with 1 to 5 stars, with 1 being poor and 5 being excellent. Out of the total of 142 effective tasks undertaken, the students used the rating scale on 60 occasions (23 BTT task, 19 BST task, and 18 LL task). The overall rating for the three visualisation tasks was as follows (BBT:3.8, BST:3.2, and LL:2.8). The BTT task achieved a higher rating than the other two tasks, which correlates with the previous data about the greater interaction with that task. In addition to the rating, written feedback showed appreciation from students of the contribution of the DSL approach to an active learning environment.

Audio Usage: Students were given the choice to use the tool with or without aural instructions. At the login screen, students could choose either to have aural or written instructions, but they could not have both. However, there is a known risk of a student choosing to use aural instructions without having headphones on, or taking the headphone off

when switching between visualisation tasks. The only way used to avoid the risk, was by continuous monitoring of students usage of the DSL tool during the practical session by the main researcher conducting this research. However, there was no case found where students have reported that they are using audio without actually using it.

Table III shows the percentage of audio usage with visualisation versus using visualisation alone. Again, these results were based on the number of students who engaged actively with the DSL tool, as defined previously. The overall usage of audio in all the tasks performed by students was 54.11%. Looking back at the data generated by the students' engagement with the DSL approach, it was noted that most of the audio usage (77.77%) was from tasks that generated less than ten actions. This means that most students used audio in short tasks, whilst students involved in longer tasks requiring a high number of actions were less likely to use audio with a visualisation.

TABLE III. PERCENTAGE OF AURAL INSTRUCTION USAGE AGAINST TEXTUAL INSTRUCTIONS

| Visualisation Type | Percentage of Audio Use |
|----------------------------|-------------------------|
| Binary Search Trees | 56.52% |
| Linked Lists | 59.52% |
| Binary Trees Traversal | 46.30% |
| The overall usage of audio | 54.11% |

A question is raised here, that is “do CS students perceive benefits from aural instructions along with visualisation when studying data structures?” The perception of benefits was measured from student responses to a questionnaire and interview questions. Students’ responses to the questionnaire at the end of the academic year showed that they perceived that the DSL environment helped them to build mental models of data structures. A majority (93%) of the students who responded to the questionnaire reported that the aural instructions were clear and easy to follow. The results of the interviews, discussed later, also confirmed this finding. However, some external factors may have resulted in reducing the choice of aural instructions over the textual instruction, such as the students’ own learning styles, students forgetting to bring their headphones to the lab, and previous unfavorable experiences with audio based learning materials.

Questionnaire Results: The questionnaire results provide evidence that the students perceived benefits from using aural instructions and visualisation by engaging with the DSL tool. 93.8% of students reported that their use of the DSL tool helped them to create a mental model of the three data structures.

In the written feedback about the DSL experience, one student reported that the DSL tool “*was a very easy to use tool that provided a good visual aid for linked lists and binary search trees.*” This comment shows a deep understanding of the approach and his positive interaction with it. However, he also added that “*the linked list program was quite buggy and sometimes left the program prone to crashing.*” It should be noted here that there are no records of how many system crashes occurred because the data was saved only upon normal and error free closure of a visualisation task.

There were mixed reviews about the usage of audio to support visualisations. Some found it good and useful, for example, “*audio instructions and descriptions were very useful, as well as the ability to add and remove nodes into an existing list.*” The students who experienced technical issues with integrating audio and visualisations tended to be deterred from using it, with one student explaining, “*Audio didn't work first time, and I haven't used it since then.*”

Students Marks vs. Engagement: The student participants in this experiment did not do a pre-test and post-test to see if the DSL environment had a direct effect on their learning. This was because there were other types of learning inputs to the PDS module so it would not have been possible to isolate the effect of the DSL environment. In any case, the DSL environment was not part of the PDS module and it was not considered a formal learning approach. Instead, the research looked at students’ results in their PDS end-of-year assignment to investigate possible correlations between these and their engagement with the DSL environment, keeping in mind that correlation does not necessary mean causation, and the researcher had no information about the students’ abilities and weaknesses.

To compare students’ assessment marks with the duration of their engagement with the DSL tool, Figure 4 shows the linear regression of the scattered marks against engagement with the DSL approach. This shows, in general, that students who spent more time using the DSL tool obtained lower marks in the end-of-year assessment.

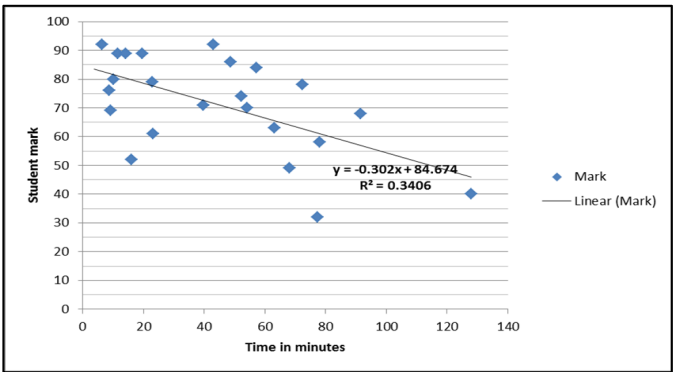

Figure 4. Student marks Vs. Time spent using DSL tool

This result may suggest that less able students used the DSL tool as an additional resource to help them to understand the concepts of data structures, rather than that their use of the tool contributed to their lower marks. If true, this finding confirms the need for learning methods like the DSL to provide students with an extra support system if and when they need it. Although there is no clear indication about whether or not using the DSL tool affected the students’ marks, it is important to note that the less able students used the tool repeatedly, and found it valuable to their study. It is also possible that these students could have gained even lower marks if they had not used the DSL tool.

Students’ Interviews: in the student interviews, the interviewees agreed that the aural instruction was clear and easy to understand. However, they had some reservation about

using aural instructions all the time. One stated a personal preference for textual instructions and the way in which this was expressed revealed that she was conscious of her own preferred learning style. Though investigation of possible relationships between students learning styles and the DSL environment was not part of the study, it is recommended, that this should be included in any future work.

VI. CONCLUSION

A. Research Summary

This paper presented a study of the effectiveness of using aural instructions with visualisation in an interactive learning environment (the DSL environment). It concentrated on the use of this approach when teaching novice computer science students the concepts of data structures. This approach aimed to reduce cognitive load on students' memory by exploiting the dual sensory channels for information processing.

A triangulation method was used to explore the relationship between the results obtained by the qualitative and quantitative research methods described in this paper. The results showed the benefits of using this research environment on students' learning experience. Data was collected by using a prototype tool created for this purpose, by testing students' perception of this approach through an end of term questionnaire and by conducting a group interview with a sample of students.

The implementation of the DSL environment provided enough evidence of the value of aural instructions to show that this is a research channel that is worth pursuing and that its development would extend its benefits. The research also demonstrated a substantial interest from the students and the lecturer in continuing to use the DSL environment as an extra resource in learning the concepts of data structures.

B. Future Work

While the DSL environment proved to be useful to students and the successful results support the use of aural instructions with interactive visualisation, there were some technical limitations that could be removed by future work. For example, adding visualisations that help students in learning AVL Trees and Graphs algorithms would improve its usefulness. These additions were recommended by the students themselves in comments they made while using the DSL approach as well as later in answers to questionnaires and in interviews.

The following suggestions would improve the scope and methodology for future research on this topic:

- This research will further be extended by including a comparative study of students who experience the environment and those who choose not to participate.
- Multiple cross-sectional studies could assess each aspect of the DSL approach individually in shorter experiments instead of conducting a longitudinal study.
- The results of this research can be supported by investigating the impact of students' learning styles on the choice of instructional method.

- The research results can also be enhanced by conducting pre and post-tests to evaluate students' level of achievement before and after using the DSL environment.

Abstract— Due to the impact that Information and Communication Technologies have in the current society in general, and in academic institutions in particular, there is a growing need for effective creation and management of digital content. But content authoring is known to be an effort and time consuming task.

Digital contents used inside Technology Supported Learning Systems with learning purposes are often referred to as Didactic Resources, or Learning Objects if they are annotated with metadata. One of the main advantages of Learning Objects is that they can be reused to support learning in different platforms or environments.

Along this paper an experiment carried out with ErauzOnt, a system that automatically builds Learning Objects from electronic textbooks using Natural Language Processing techniques, ontologies and heuristic reasoning is presented. ErauzOnt was able to gather definitions, examples and exercises for the topics of the Object Oriented Programming subject –a compulsory subject studied at the first year of the Computer Engineering degree at the University of the Basque Country– using as a starting point a textbook written in English.

Keywords – *Learning Objects, Knowledge Acquisition, Content Authoring, Semi Automatic Authoring*

I. INTRODUCTION

Academic institutions, aware of the impact of information and communication technologies in nowadays lives, are adopting technology based solutions to enhance learning and to promote more active learning methodologies [1], [2]. Technology Supported Learning Systems (TSLs) enable teachers to move from the classical lecture-based approach to more active learning methodologies.

To be effective, any TSL requires the learning materials (didactic resources) that will be used during the learning process. Content authoring is known to be effort and time consuming, but the development cost might be lightened by promoting the content reuse [3]. Nowadays, there are plenty of electronic documents for any domain that can be reused to build new learning material suitable for TSLs.

Traditionally, teachers have used a set of textbooks for preparing their lectures and providing reference information to their students. Teachers usually combine fragments of different textbooks to provide information about each topic to be mastered. In a similar way, electronic textbooks can be used to generate Learning Objects (LOs), i.e., reusable didactic

resources, by identifying and extracting the meaningful (appropriate) fragments of the documents.

Object Oriented Programming is a compulsory subject studied at the first year of the *Computer Engineering* degree at the *University of The Basque Country (UPV/EHU)*. This subject tackles with the principles of Object Oriented programming including classes, objects, inheritance, etc. Although at present the subject is taught both in Basque and Spanish languages, nowadays the UPV/EHU is immersed in a multilingualism program and some subjects of the degree can be also studied in the English language. Moreover, students are expected to understand and, even write, technical reports on computer science in foreign languages such as English.

The *Principles of Object-Oriented Programming* textbook¹ [4], licensed under the Creative Commons Attribution License, covers the theoretical topics of the subject and introduces Object Oriented Programming with Java. This textbook might be used as reference book for the lessons as well as the source for generating the didactic resources employed in the *Object Oriented Programming* subject.

Along this paper an experiment carried out with ErauzOnt [5], a system that automatically builds LOs from electronic textbooks using Natural Language Processing (NLP) techniques, ontologies and heuristic reasoning, is presented. ErauzOnt was developed with the aim of being domain-independent and easily extendable to support new languages. ErauzOnt was firstly used for the Basque language and tested with textbooks about *Natural Science* [6]. This is the first experiment processing textbooks in the English language to gather definitions, examples, and exercises for the topics of the *Object Oriented Programming* subject from the above-mentioned book.

The paper is structured as follows. First, for the sake of contextualizing this work, the use of LOs and LO Repositories (LORs) as a means to support knowledge reuse is presented. Then, the motivation for using automatic or semi-automatic tools for building learning material is introduced. Next, ErauzOnt, the system used to build LOs, is briefly described. Then, the experiment is depicted and the results presented. To finish, some conclusions and future lines are pointed out.

II. REUSING LEARNING MATERIAL: LEARNING OBJECTS AND LEARNING OBJECT REPOSITORIES

The IEEE Learning Technology Standards Committee (LTSC) defines a Learning Object (LO) as “any entity, digital or non-digital, which can be used, re-used or referenced during technology supported learning” [7]. However, as Wiley [8] states, this definition may be too vague as almost everything matches it, i.e., the notes a teacher uses for his/her classes, may be considered a LO since it can be referenced during the learning process, even though its reusability in an application is quite limited. He instead recommends considering LOs as “any digital resource that can be reused to support learning”.

Downes provides sound argument about the need of using LOs in educational applications, especially in on-line courses [9]. He claims that we can find several courses about the same topics, e.g. “Introductory Trigonometry”. All those courses may describe the sine function, in a very similar way. If all these courses are available on-line, we will be able to find hundreds of similar resources. However, if LOs are used, there will be only a few similar resources that are shared and used in all those courses.

In order to facilitate the reuse of LOs, these digital didactic resources must be described in a common format before storing them, so that any learning system can retrieve the appropriate didactic resource for the learning process. LOM [7] is the standard used for the annotation of LOs.

For storing and sharing LOs, Learning Object Repositories (LORs) are needed. Many LORs such as ARIADNE [10], Edutella [11], or MERLOT [12] exist, and even LOR alliances such as GLOBE² are proliferating to promote the reuse of educational material.

III. SEMI AUTOMATIC CONSTRUCTION OF THE DOMAIN MODULE

TSLs require an appropriate representation of the knowledge to be mastered, i.e., the *Domain Module*. The *Domain Module* includes the topics to be mastered, the pedagogical relationships among the topics, which may be employed to guide the learning sessions, and the learning material to be used. Authoring the *Domain Module* requires some knowledge engineering expertise and it is not a task that any average teacher could face easily [13]. Hence, tools that enable the (semi-)automatic construction of the *Domain Module* to lighten the workload and engage average teachers to profit from the use of TSLs in their lectures should be provided.

Natural Language Processing (NLP) techniques can be used together with heuristic reasoning and ontologies to enable the semi-automatic construction of the *Domain Module* from textbooks. In the approach here described, the *Domain Module* entails knowledge at two different levels: the *Learning Domain Ontology (LDO)*, which contains the knowledge for planning the learning sessions, and the LOs to be used as learning resources. The development of the *Domain Module* comprises three tasks:

- **Textbook pre-processing:** Electronic documents are available in many different formats. In this task, the textbooks are prepared for the subsequent knowledge

acquisition processes and, therefore, they are transformed to the standardized internal representation that the system uses. Besides, this internal representation of the document is enhanced with the *part-of-speech* information that will be used for the knowledge gathering tasks.

- **LDO Gathering:** In this process, the domain topics to be mastered as well as the pedagogical relationships among them are identified and represented in the LDO [14]. The LDO will allow instructional TSLs, such as Intelligent Tutoring Systems, to plan the learning sessions, or the students to guide themselves during the learning process in exploratory TSLs. The LDO might allow the student to observe what has to be learnt and provide hints about the order that should be followed to prevent getting lost.
- **LOs Gathering:** At this stage, the LOs - *definitions, examples, exercises*, etc. - to be used during the learning process are identified and generated. The LO generation process here described is carried out by ErauzOnt [5]. The LDO defined in the previous process is used to conduct the acquisition of LOs. The LOs Gathering task is described in the next section.

Both the acquisition of the LDO and extraction of the LOs rely on the identification of syntactic patterns. The automatically obtained results can be supervised by the instructional designers both individually or collaboratively using Elkar-DOM [15], a concept map-based tool designed to supervise the *Domain Module* authoring process. This paper presents the experiment conducted with ErauzOnt, the subsystem responsible for the third task. Therefore, the process for extracting LOs from the electronic textbooks is described.

IV. GATHERING LOS FROM DOCUMENTS USING ERAUZONT

The generation of LOs for the domain topics is accomplished through the identification and extraction of Didactic Resources (DRs), i.e., consistent fragments of the document related to one or more topics with a particular educational purpose. The identification and extraction of these pieces is carried out combining the use of ontologies, heuristic reasoning, and NLP

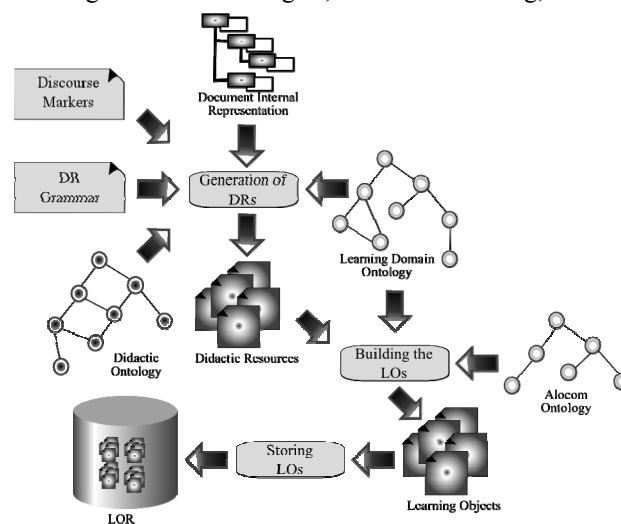

Figure 1. Generation of the LOs from Documents

² <http://globe-info.org/>

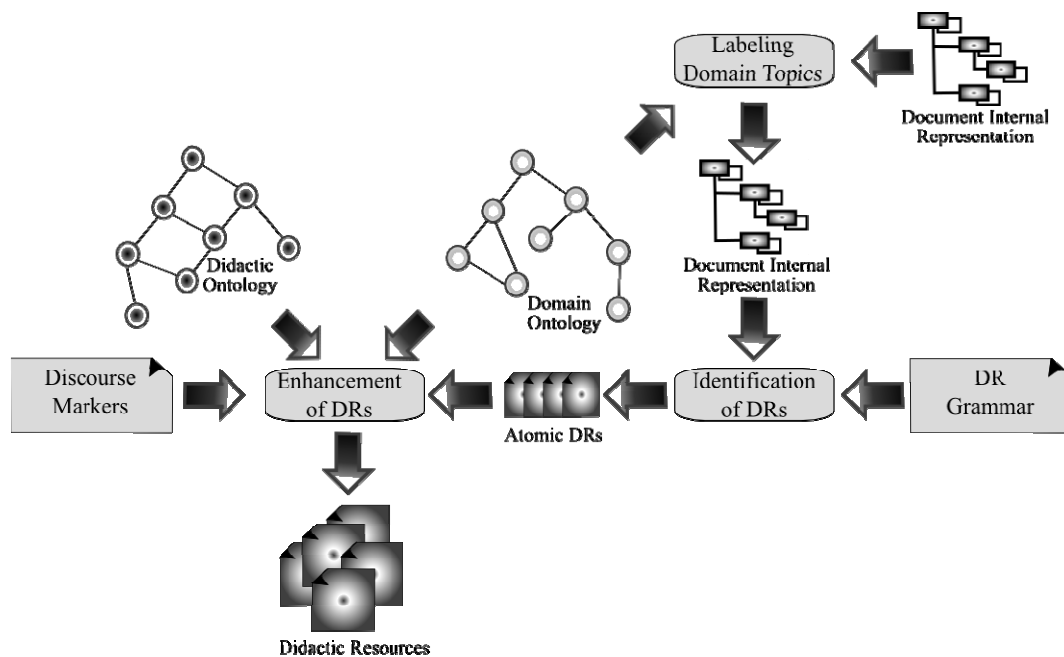

Figure 2. Generation of Didactic Resources

TABLE I. EXAMPLE OF A PATTERN FOR DEFINITIONS

| | |
|---------|---|
| Pattern | <u>@Topic</u> + is are + [determiner] |
| Example | A <u>class</u> is an abstract description of a set of objects |

techniques. From now on, a DR will refer to a piece of the document meant to be used during the learning sessions (e.g., *definition*, *exercise*,...) while a LO refers to a reusable DR enriched with metadata.

ErauzOnt aims to be applicable to any document no matter the domain it relates to. It does not rely on implicit domain-specific knowledge. The domain topics and the relationships among them, described in the LDO, are all the domain-specific knowledge used for the extraction of LOs from textbooks.

Fig. 1 describes the process for gathering the LOs from the electronic document, which entails the following tasks: generating DRs from the document, building reusable LOs from the DRs, and, finally, storing the generated LOs in a LOR for further use/reuse. The LDO, a DR grammar, discourse markers and a didactic ontology [16], [17], an ontology that defines the different kinds of DRs, are used to gather DRs from the internal representation of the electronic textbook.

The identification of the DRs is carried out by finding relevant text fragments that correspond to *definitions*, *examples facts*, *theories*, *principle statements* and *problem statements* for

TABLE II. EXAMPLE OF A PATTERN FOR EXAMPLES

| | |
|---------|--|
| Pattern | for instance e.g. for example as an example + [,] + [adverb] + @Topic |
| Example | For instance, the <u>Apple class</u> would extend the <u>class Fruit</u> . |

the topics included in the LDO, as shown in Fig. 2. First, the appearances of the LDO topics are labeled in the document internal representation with the *part-of-speech* information. Next, the set of DRs are identified using the DR grammar. The DR grammar includes a set of rules that recognize the different patterns or syntactic structures that were identified by manually analyzing a sample of documents. These patterns are the most common syntactic structures found in several topic *definitions*, *examples*, etc. TABLE I. shows a pattern that identifies a *definition* if a domain topic (@Topic) is followed by the **to be** verb and some text that describes it. Similar patterns have been also used for the identification of definitions in electronic documents written in English [18]. TABLE II. presents one of the patterns for examples. The grammar for identifying DRs from electronic documents was developed using the Constraint Grammar formalism [3].

Given that the DRs identified by the grammar, atomic DRs, are usually quite elemental, they are enhanced in two ways to make them more accurate and reusable. On the one hand, consecutive DRs are combined in a new composite DR if they are similar, to which end similarity measures have been defined [19]. These similarity measuring methods rely on the UKB algorithm [20–22] and use the LDO to obtain the resemblance of two DRs according to the referred topics and the kind of the DRs; the Didactic Ontology [16], [17] determines if two DRs are suitable to be combined based on their kind. TABLE III. shows two DRs suitable for being combined in a new composite DR. On the other hand, and in order to keep the cohesion of the DRs, previous fragments are added to each DR if it contains references to preceding DRs or sentences. The cohesion maintenance relies on the use of discourse markers, i.e., words or expressions that connect part of a text with its context.

TABLE III. EXAMPLE OF TWO ATOMIC DRs THAT MIGHT BE COMBINED

| | |
|------------|---|
| DR1 | Array variables are declared like other variables: declaration consists of the array's type followed by the array's name. |
| DR2 | For example, <pre>double[] [] matrixOfDoubles;</pre> declares a variable whose type is a two-dimensional array of double-precision floating-point numbers. |

Once the final set of DRs has been built, each DR is turned into a LO to facilitate its reuse. The ALOCOM formalism [23], [24] is used to represent the content of the LOs and to enable its flexible repurposing and reusing. The facility to find and retrieve the appropriate LO is essential for reusability issues, to which end each LO is annotated with descriptive metadata. ErauzOnt can gather LOs of different granularity. Whenever a composite LO is generated, all its finer grained LO components are also labeled. The annotation of each gathered LO is made automatically using SAMgl [25], an automatic metadata generator, except for labels such as *Keywords* or *Learning Resource Type* which are filled with the information elicited during the DR construction phase. The *Keyword* label specifies not only the domain topics referred in the LOs but also the semantically closest topics in the LDO. To label the *Learning Resource Type*, the most confident rule among the ones that fired during the identification of the DR is chosen. The *Learning Resource Type* is specified in terms of the ALOCOM ontology [26]. All the generated LOs are stored in the LOR so that they can be used for *Domain Module* authoring.

V. IMPROVING ERAUZONT TO SUPPORT ENGLISH

The ErauzOnt framework was developed to enable the automatic extraction of LOs from electronic textbooks following the approach mentioned above. The framework aims to be applicable on any document no matter the domain it relates to. None of its components relies on implicit domain-specific knowledge. All the used domain-specific knowledge are the domain topics and the relationships among those topics described on the LDO, which is semi-automatically gathered in the previous phase of the *Domain Module* authoring [14] and is the input for the LO extraction process together with the document to be analyzed. Furthermore, the LDOs might be built semi-automatically from the document [14].

Besides, although originally ErauzOnt was evaluated with textbooks written in the Basque language, it was designed to be easily extended to support new languages. In fact, the work here presented required to enhance ErauzOnt to support the English language.

ErauzOnt relies on NLP techniques to identify the relevant DRs in the textbooks, so an analyzer must be integrated for each supported language. ErauzOnt was enhanced to use FreeLing [27], an analyzer that supports several languages such as English or Spanish. In addition, it was necessary to define the DR grammar that contains the syntactic patterns used in English for the DRs and the Discourse Markers for English. ErauzOnt uses the appropriate resources, i.e., NLP analyzer,

DR grammar and Discourse markers, for each document according to the language it is written in.

The development of the DR Grammar for English took a Computer-Engineer's 4 day work, while the integration of FreeLing was carried out in 4 days and the Discourse Markers were defined in 1 day.

VI. EVALUATION

ErauzOnt was tested to assess its performance over a textbook written in English and oriented to Computer-Engineering students. The *Principles of Object-Oriented Programming* textbook, which tackles the basic concepts of *Object-Oriented Programming*, was used for this evaluation. The main goal of the experiment was the evaluation of the acquisition of text-based LOs, so an adapted version of the textbook, in which the images were removed, was processed instead of the original document. The analyzed book consists of 67 pages and 29300 words.

The experiment was carried out in the following procedure: the teachers of the subject defined the LDO that describes the topics to be learnt as well as the pedagogical relationships among the topics. The teachers manually analyzed the textbook to identify and label the set of DRs (*definitions*, *examples*, etc.) that would like to use for mastering the main topics of the subject. Then, the LDO was used to process the textbook with ErauzOnt, and a set of LOs was obtained and stored in a learning object repository. The set of automatically elicited LOs was assessed by instructional designers to determine their adequacy, to which end the set of DRs manually identified by the teachers was used.

Given that this was the first experiment with ErauzOnt over documents written in English, both the DR grammar and the gathered LOs were tested as a means to assess the performance of the system.

A. Evaluation of the DR Grammar for English

The DR grammar was evaluated by analyzing the atomic gathered LOs, i.e., the finest grained LOs. Each LO was inspected to determine which rule were used to identify it and, therefore, to obtain the accuracy of the DR grammar.

TABLE IV. shows the statistics about the evaluation of the DR grammar. The DR grammar is able to identify *definitions*, *examples*, *problem statements*, *principle statements*, *facts* and *theories*. However, not every kind of DR is always used. Neither *facts* nor *theories* were used in the analyzed textbook. The DR grammar built for identifying the syntactic patterns commonly used in DRs achieved 80.09% accuracy. The average of the rules ranges from 100.00% for the *examples* to 58.33% for the *problem statements*. The DR grammar achieved

TABLE IV. ACCURACY OF THE DR GRAMMAR

| | Definitions | Examples | Problem Stat. | Principle Stat. | Total |
|-------------------|-------------|----------|---------------|-----------------|-------|
| Found | 164 | 1 | 12 | 49 | 226 |
| Correct | 138 | 1 | 7 | 35 | 181 |
| Accur. (%) | 84.15 | 100.00 | 58.33 | 71.43 | 80.09 |

TABLE V. RECALL OF THE LO ACQUISITION PROCESS

| | Definitions | Problem Statements | Combined DRs | Total |
|-------------------|-------------|--------------------|--------------|-------|
| Real | 35 | 2 | 17 | 54 |
| Found | 22 | 2 | 17 | 41 |
| Recall (%) | 62.86 | 100.00 | 100.00 | 75.93 |

similar results to the previously conducted experiments over textbooks in Basque [6], except that the accuracy for *problem statements* was considerably lower, mainly because imperative cases, frequently used to state *problem statements*, are easier to identify in Basque, which uses an auxiliary verb for that purpose. The identification of the *problem statements* in English mainly relies on the appearance of keywords such as *exercise*.

B. Evaluation of the LO Acquisition Process

Finally, the gathered LOs were evaluated. This evaluation was carried out comparing the manually identified DRs with the automatically gathered ones. The evaluation of the gathered LOs considered both their appropriateness (*precision*) and the quantity of the manually defined DRs that were automatically identified (*recall*). An aspect to be considered to evaluate the gathered LOs is that while a LO might be the most accurate in a particular context, one of its components or a more complex LO (a composite LO that comprises it) might fit better in other situations.

In order to obtain the *recall* of the LO acquisition process, the automatically gathered LOs were compared to the manually identified ones. The teachers identified 54 DRs, 35 *definitions*, 2 *problem statements* and 17 *combined DRs*, i.e., DRs that entail two or more DRs of different kind. ErauzOnt achieved a 75.93% *recall*, i.e., 41 of 54 manually identified DRs were automatically gathered. 100% of the *combined DRs*, 62.86% of the *definitions* and 100.00% of the *problem statements* were automatically gathered. *Problem statements* proved to be easy to find, while *definitions* were more difficult. *Problem statements* are presented using verbs in imperative case or keywords such as *exercise*, while *definitions* may appear in many different forms that make them more difficult to find.

Determining the *precision* was not so straightforward, and all the gathered LOs and their components had to be analyzed. While a particular LO could be the most appropriate for a certain context, one of its component LOs or a more complex LO, a composite LO that comprises it, might fit better in other situations. Therefore, each generated LO was observed to determine whether it was valid, not only considering the subject for whom the textbook was analyzed but any other context.

TABLE VI. PRECISION OF THE LO ACQUISITION PROCESS

| | Definitions | Problem Statements | Combined DRs | Total |
|----------------------|-------------|--------------------|--------------|-------|
| Found | 140 | 2 | 229 | 371 |
| Correct | 121 | 2 | 199 | 322 |
| Precision (%) | 86.43 | 100.00 | 86.90 | 86.79 |

TABLE VI. summarizes the information of the analysis of the automatically elicited LOs. ErauzOnt gathered 371 LOs, 140 *definitions*, 2 *problem statements*, and 229 *combined LOs*, i.e., LOs that comprise LOs of different kinds. Although the DR grammar also identified fragments that may be part of *principle statements*, these were elements of other kinds of LOs, either *combined* or not.

The overall achieved *precision* was 86.79%, i.e., 322 of the 371 LOs were considered usable for this course or any course that might be developed in the future. *Problem statements* obtained 100% *precision*, while *definitions* got 86.43% and *combined LOs* 86.90%. Considering these results, the pattern-based approach used by ErauzOnt to gather LOs from electronic textbooks prove to be accurate and useful.

VII. CONCLUSIONS AND FUTURE WORK

This paper has presented ErauzOnt, a framework for the automatic extraction of Learning Objects (LOs) from electronic textbooks. ErauzOnt uses Natural Language Processing (NLP) techniques, heuristic reasoning and ontologies. It was firstly used for the extraction of LOs from textbooks in Basque, but it has been extended to support English, and has been tested over the *Principles of Object-Oriented Programming* textbook, used in the *Object-Oriented Programming* subject, to evaluate its performance.

ErauzOnt was developed with the aim of begin domain-independent and scalable, i.e., easy to enhance to support new languages. Therefore, improving ErauzOnt to enable the acquisition of LOs from textbooks in English was quite simple.

Given that this was the first attempt to use ErauzOnt for building LOs from a textbook written in English, and oriented to university level students, both the DR grammar that facilitated the identification of DR fragments and the generated LOs were evaluated.

The analysis of the results proved that the DR grammar is an appropriate means to identify the fragments of the document that may contain relevant content to achieve an instructional objective. The DR grammar achieved 80.09% accuracy, i.e., correctly identified and classified fragments of the document with educational purpose.

The gathered LOs were also analyzed both individually to determine their appropriateness and comparing them with the set of Didactic Resources manually identified by the teachers of the subject. The LO acquisition process extracted 75.93% of the manually identified Didactic Resources, and 86.79% of the gathered LOs were considered valid.

ErauzOnt had already been tested over textbooks in the Basque language, covering different areas of the *Nature Sciences*, for secondary education students. The results of the English experiment were quite similar to the previous experiments, so it might be deduced that ErauzOnt is neither tight to a particular language nor a concrete domain.

Further work on ErauzOnt comprises improving the treatment of images in the LO generation. Although ErauzOnt is currently able to process images in the electronic document, it only considers their position in the text, unaware of where the image is referenced and, therefore, useful. Hence, the treatment of the images must be improved so that they can be

combined with the fragments of the document that reference them to get more accurate LOs.

Machine Learning methods are planned to be used to infer new rules that might improve the identification of the LOs in the electronic textbooks.

The construction of multilingual *Domain Modules* is being also addressed. The Learning Domain Ontology supports the multilingual representation of the domain topics, and machine translation might be used to get approximate translations of the gathered and employed LOs that would be looked for either on the Learning Object Repository or different resources.

ACKNOWLEDGMENT

This work is supported by the University of The Basque Country (UPV/EHU09/09), the Spanish Ministry of Education (TIN2009-14380), and the Basque Government (IT421-10).

Improving Collaborative Learning by Personalization in Virtual Learning Environments Using Agents and Competency-Based Ontology

V. Bremgartner, J. F. de Magalhães Netto

Computer Institute, PPGI
Federal University of Amazonas,

{vitorbref, jnetto}@icomp.ufam.edu.br

Abstract—With the spread of distance education courses or blended, an increasingly common problem is the lack of a personalized accompaniment to the student and the delay in responding by mediators and other colleagues the doubts and requests from students in Virtual Learning Environments (VLEs), usually posted on forums or manifested via e-mail. The approach taken to solving this problem presented in this paper is based on multi-agent systems and a competency-based ontology of the learner model. Through such technologies, the student's doubts are identified and these are directed to community members who have the profile with best suited skills and competencies to resolve it, decreasing the response time of doubts from students. A Petri Net has been developed in order to represent interactions among agents. The system was tested in a Numerical Analysis class that makes use of the VLE Moodle. The results of the tests were used to prove the validity of the system and the viability of the solution. Survey questionnaires were passed in the classroom in order to obtain and evaluate the students' impressions about the resource available to them in the VLE.

Keywords—*Learning Management System (LMS); competency; ontology; multi-agent systems; Petri Nets*

I. INTRODUCTION

The advancement of Information and Communication Technologies (ICTs) and the increased demand for e-learning platforms, which enable interaction between students and teachers, sharing knowledge, have transformed the Internet into an important tool for teaching purposes. However, a Learning Management System (LMS), or Virtual Learning Environment (VLE), generally provides learning resources in the same way for all students, where learning cannot become effective for all students by the several cognitive characteristics that each learner has. Therefore, this creates difficulty of knowledge acquisition for some students.

For a better understanding about the problem addressed in this paper, let's imagine this scenario: consider a group of students participating in a Distance Education course or blended, which uses in these classes a VLE. There are teachers and tutors monitoring the course and interacting with students in this environment via forums and e-mails, but there is not an automatically and effectively management with regard to the

doubts that students may have when they are performing some activity. These doubts could be detected by the incorrectness of students' answers to questions. The difficulties of the student to perform the proposed tasks can also be evident if a task is not delivered until the date specified for delivery. Nor is there an automatic service of experts indication to answer these doubts, not allowing the teacher or tutor being free to do other activities relevant to the course.

As a strategic solution, it is proposed in this paper the support of student activities in educational environments by the personalized indication of some student of the same course. Personalization in the context of this work is the search for one or more students with an adequate profile, i.e., students who have desirable skills and competencies to address questions about certain subject matters of students. The approach taken to solving this problem is based on multi-agent systems and a learner model ontology that extends the IMS Learner Information Package (LIP) [1] specification from the theory of skills and competencies developed by the Swiss sociologist Philippe Perrenoud. The proposal is based on the idea that the completion of certain activities from the collaborative learning among students in a VLE is a way to build the student's knowledge, in addition to several teaching tactics in the literature, such as recommending materials studies for the student and adaptive tutoring strategies. Furthermore, the interaction between learners is a strategy employed in order to build knowledge more significantly. This is because learners develop intra and interpersonal skills, not being independent to be interdependent [2].

Moreover, with the aid of Artificial Intelligence techniques, as agents and ontologies that constitute the pillars of the Semantic Web [3], is added to this e-learning environment a characteristic of STIs, the personalized recommendation [4] students proactively and dynamically. The recommendation feature is inserted in the context of adaptive learning systems, and modified according to the learner needs [5].

In addition to this section of Introduction, this paper is structured as follows: Section II describes related works; Section III presents the system architecture, explaining how the recommendation process of students is and also illustrates a Petri Net modeling of the system; Section IV reports on

experiments conducted in a VLE system and Section V, conclusions and future work.

II. RELATED RESEARCH

There are several studies related to adaptive learning systems that reinforce our proposal in this paper. Among them we highlight [6], where is shown a proposal for an adaptive environment in which students must achieve certain skills, but without going into detailed features how to get them, only infer them through the evaluation results. This work uses the IMS standards and in accordance with the assessments of student grades, activities and study materials (e.g., learning objects) are recommended, aiming to increase the level of learning and skills of the student, not doing use of multi-agent systems. A work that makes use of multi-agent systems in association with Semantic Web is [7], in which uses crawlers RSS feeds to generate content and learning objects to students depending on their areas of interest and their cognitive levels in the LMS Intelligent Web Teacher (IWT). LORSE [8] consist of a set of intelligent agents developed in the JADE [9] framework, whose responsibility is to deliver to users different learning objects from several learning objects repositories in response to specific searches requested by teachers and students. The LUISA project [10] consists of a semantic ontology-based architecture which is used in the LMS Moodle [11], where users enter and perform the login to the environment in a course for the first time, select the skills that they intend to develop and for those that were marked, learning objects and activities are recommended for the user study and achieve the desired competence.

We can see, with these works described above, there are several techniques for customizing VLE based on the recommendation of educational resources to students in order to make learning by students more effectively. In the case of adaptive systems, there are many works based on student information such as interests, competencies and skills, but there is no data detailing of these skills. Thus, the learner model may not be able to inform to the e-learning environment what are the deficiencies of the student more accurately. Regarding the recommendation process resources, many studies in the literature present recommendations for learning objects, which not always the student will be interested in using them. Consequently, the e-learning environment may not make decisions that cannot assist the student completely.

This work differs because we consider specific competencies and skills in courses or subjects that students take part, in order to obtain a more accurate diagnosis of the students' situation in the educational environment. Moreover, the recommendation of learners to help other students with questions turns out to be a different solution and complements the traditional techniques of content adaptation in VLEs.

III. SYSTEM ARCHITECTURE

A. Overview

The system architecture [12], composed of the agents developed in JADE [9], ontology, VLE and its MySQL database, is shown in Fig. 1. The personalized recommendation

process begins when the teacher elaborates the activities in the VLE, selecting what skills and competencies, and their levels (which are normalized in the range of 0 to 10) are needed to resolve them. The teacher can also select the level of initial skills and competencies of students, which is useful in cases where the teacher already has some knowledge of their students. The learner, in turn, interacts with the system, either by registration of his/her personal data, by posting something on the forum or resolution of proposed activities on the e-learning environment.

The agents of updating, that are responsible for changing the learner model, are:

- *Initial Skills Agent*: query the database about the students' initial levels of skills and competencies set by the teacher and sends this information to the *Update Profile Agent*;
- *Activity Assessment Agent*: responsible for the assessments of the answered questions, and sends scores of students to the *Update Profile Agent*;
- *Update Profile Agent*: responsible for updating the learner model data by the interactions with the environment, such as upgrading their levels of skills and competencies through the information obtained from the *Initial Skills Agent* and the *Activity Assessment Agent*.

The agents of recommendation, responsible for the recommendation process of students who can help their colleagues, are:

- *Doubt & Error Profile Agent*: agent that searches for students' doubts and errors based on the results of the activities answered in the e-learning environment and that maps such errors in skills and competencies needed to perform the tasks. With this information, the agent sends a message to the *Recommended Profile Agent* containing data about the existence of learners with doubts and errors;
- *Recommended Profile Agent*: agent that searches for students with levels of skills and competencies (greater than or equal to those suggested by the teacher in the registration of new activities) capable of resolving the questions proposed based on requests made by *Doubt & Error Profile Agent*. A student can be recommended only if he/she is frequent in the blended course. The recommendations' data of students selected by the *Recommended Profile Agent* are saved in the database and then are listed in the VLE for students with errors or doubts concerning the proposed activity.

Finally, the agents of tutoring that send messages to students in the e-learning environment, are:

- *Notifier Activity Agent*: agent notifier of new activities requested by the teacher to keep students informed about new activities;

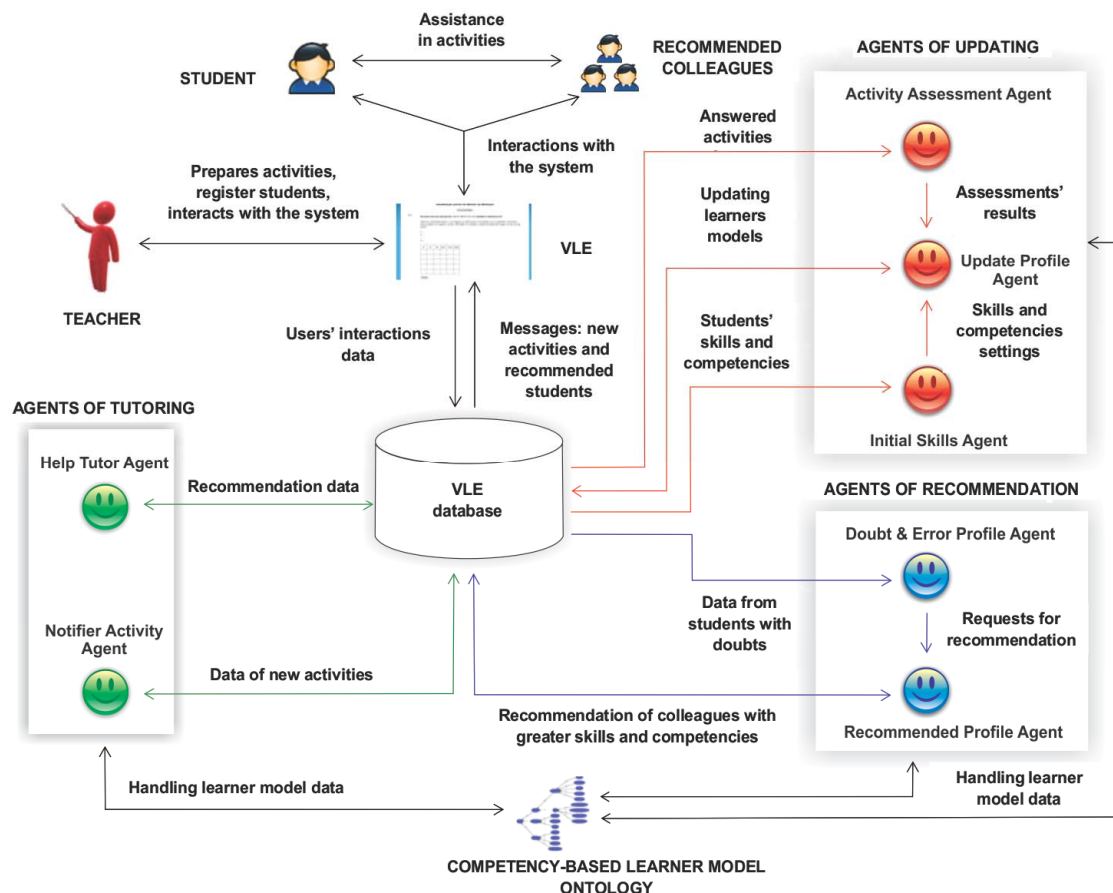

Figure 1. System architecture.

- *Help Tutor Agent*: responsible for sending two types of messages. The first type consists of messages to students with doubts by sending a link that they can access to see their recommended colleagues. The second type of message is for those learners who did not deliver the job within the deadline set by the teacher. Fig. 2 shows a message sent to a student with doubts by messaging service using the LMS Moodle.

All agents use the learner model competency-based ontology presented in [13] and created in Protégé [14]. For integration between JADE agents and the ontology we used the *BeanGenerator* plugin in Protégé. The ontology contains rules of inference that complies with the IMS LIP standard. The ontology is also useful for the correct handling of message exchanging between agents and allows reuse, but modifications are necessary according to the discipline.

For the learner model ontology was used the LIP standard, which is supported by examples and implementations of the model, besides being a standard commonly used nowadays and allows extensions. However, data such as student skills and competencies in LIP are generic, and for certain subjects or specific courses, may not reflect directly how level the student knowledge is. Thus, although using LIP, this standard has been extended to the needs of this project, emphasizing the skills and competencies of the student.

In our work, the definition of competence is consistent with the criteria cited by the Swiss sociologist Philippe Perrenoud, who says that competencies may consist of a set of skills, whose skills are in the student's ability to know and do certain tasks [15]. Thus, each student's competence is composed of a set of specific skills. For example, in the Numerical Analysis [16] subject, curricular component of Engineering and some Science courses, the competency "Finding roots of functions by the bisection method" consists on the following skills: "Handling the calculating machine", "Understanding of functions (continuity, the Intermediate Value Theorem, plotting graphs, convergence and divergence)" and "Understanding the bisection method operations (choice of the initial interval, the formula and criteria for selecting the new range)".

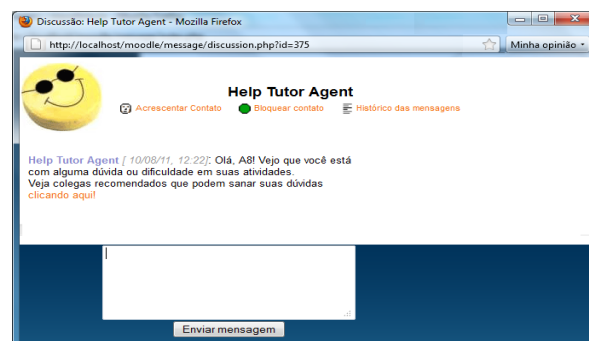

Figure 2. Message sent by *Help Tutor Agent*.

B. Modelling the System Using Petri Nets

Petri Nets (PN) is a modeling technique that allows the representation of systems, using as its foundation a strong mathematical background developed by Carl Adam Petri. This technique has the particularity to enable modeling parallel, concurrent, distributed discrete and non-deterministic systems.

The use of Petri net is justified once that it is a well-established tool for the specification of an information system of any type, specially those that need to specify concurrency and synchronism. Its graphical representation is formed by two types of nodes, places and transitions, and tokens that are used to make the system dynamic. Places are represented by circles and transitions by bars or squares. Tokens are represented by dots inside the place, when the predicate associated with the place is true [17].

To our system we developed a modeling in a non-deterministic marked Petri Net, with the aim of show the correct execution order and synchronism of the agents, as well as users' interactions within the VLE, which directly influences the agents' behavior. Fig. 3 presents a part of the non-deterministic marked PN regarding to the detection of students with doubts, the search of recommended students and the recommendation feature being shown to students in the VLE. The validation of the PN developed was done in the Snoopy [18] software. The non-determinism of PNs applies in cases such as correct activities done by students or the teacher has not yet created new activities, justifying the fact that the simulations not always have the final places (recommendations and messages to students) been achieved.

IV. SOME EXPERIMENTS

The tests were divided into two stages: a simulation in a fictional class and a second test, consisting of the use of agents and ontology in the e-learning environment in a real class of Numerical Analysis from Mathematics course at Federal University of Amazonas (UFAM). Both tests were carried out in the LMS Moodle.

A. Simulation on a Fictional Class

Simulations were done in our system to test the effectiveness of the ontology and agents within a fictitious Numerical Analysis class in Moodle containing 15 students (S1 to S15) that had different profiles. The VLE has been available on the server of Educational Robotics Laboratory (LaboREAm), Federal University of Amazonas. We prepared two activities involving matters of Bisection Method (activities 1 and 3) and an activity involving the False Position Method (activity 2).

As indicated in Table I, the skills related to the activities (1) and (3) are "Handling the calculating machine", "Understanding of functions" and "Understanding the bisection method operations". In activity (2), the skills involved are the first two mentioned for activities (1) and (3), also "Notion of absolute error" and "Understanding the false position method operations".

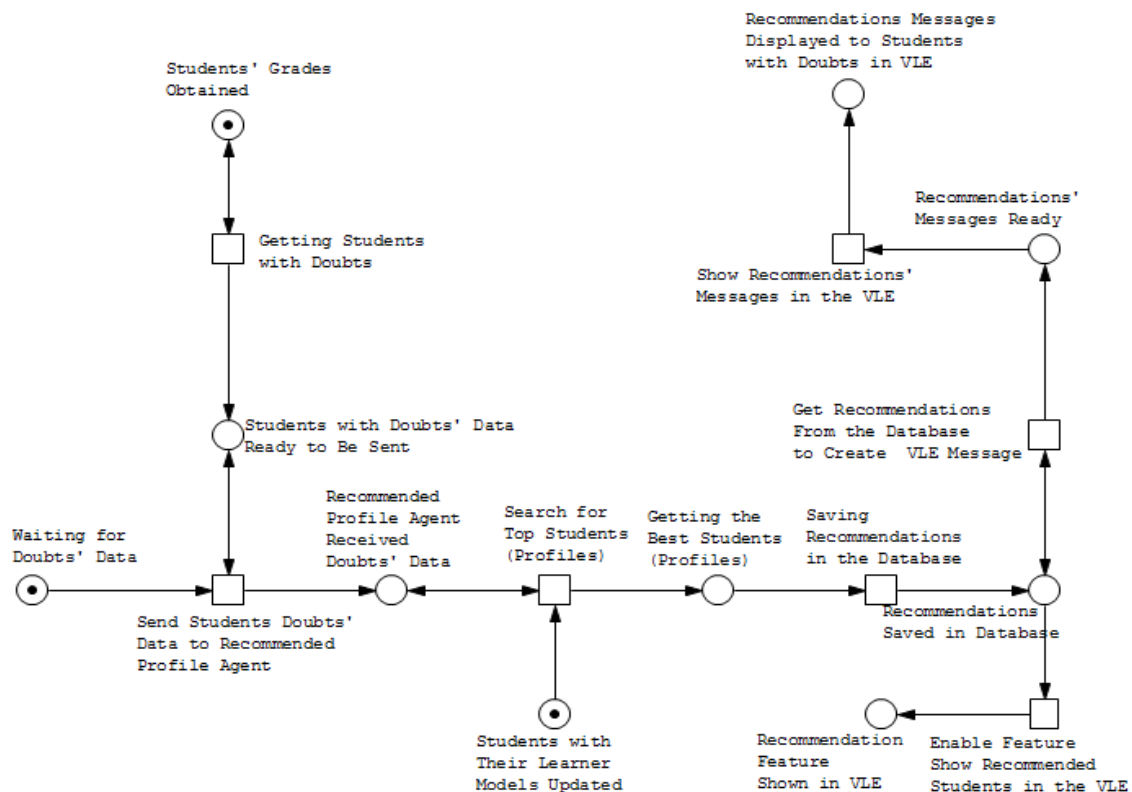

Figure 3. Agents of recommendation modeled through Petri Nets.

TABLE I. INITIAL/FINAL LEVELS OF STUDENTS' SKILLS

| Student/Activities Done | Skills Levels Initial/Final | | | | | | | | | |
|-------------------------|--|---|--|---|---|---|------------------------------|----|--|---|
| | Handling the calculating machine (1) (2) (3) | | Understanding of functions (1) (2) (3) | | Understanding the bisection method operations (1) (3) | | Notion of absolute error (2) | | Understanding the false position method operations (2) | |
| S4/1,2,3 | 1 | 4 | 1 | 4 | 1 | 3 | 1 | 2 | 1 | 2 |
| S8/ <u>1,2,3</u> | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| S14/ <u>1,2,3</u> | 0 | 1 | 0 | 1 | 0 | 0 | 9 | 10 | 1 | 2 |

Table I summarizes the settings of initial skills levels (before the execution of activities by students) and final (after the execution of activities and agents) for three students, S4, S8 and S14. The students' initial skills are in the first column of each required skill for the activities, while the final skills are in each second column. The identification of activities which each student did until the end date is in the first column of Table I, and the activities highlighted (and underlined) are those that the student missed.

We can observe in Table I, for comparisons between each of the two columns of the required skills for activities, that the levels of skills and competencies of students have increased one unit to each correct answer, while there was a decrease of one unit for each one of the wrong activities. Furthermore, to the activities (1) and (3), the student that is able to be recommended is S4, while in activity (2) is S14.

With the simulation results, we noticed that the system have succeeded in upgrading the skills levels according to the students' interactions in Moodle.

B. Tests in a Real Class

After the test in a fictitious class, it was time to test the system in a real class comprised of 33 students of the Numerical Analysis discipline from Mathematics course at Federal University of Amazonas, delivered in a blended learning using the LMS Moodle. Fig. 4 shows the VLE used by the class.

Two activities were passed: one involving the Bisection Method and another involving False Position Method. In the VLE were also some links, like forum postings for questions/doubts and the link of recommendation, to show who are the students who can assist in case of doubts or errors in activities.

The real test in the class was divided into two steps. The first stage was make available the LMS Moodle on LaboREAm server for students to do activities in a pre-established time, with the agents running in parallel to Moodle in order to make the environment more adaptable to students and to show the recommendation resource, useful for students with difficulties. The second step was to evaluate and verify the process of interaction with students after the recommendation of students assistants in the same class,

checking if students who missed in the first stage (after contact with colleagues who can assist them), did the exercises correctly in second time, via collaborative learning.

At the end of the tests a questionnaire survey was passed in order to students express their ideas about the system presented to them. Some responses from the questionnaire and the percentage of errors and successes of students before and after the recommendations are shown in Table II.

We can note in Table II that there was an improvement in the results of the exercises done by the students, since more students were able to make the proposed activities after the recommendation process. Although the percentage of students who scored questions even after the recommendation process is low (37%), we can see an improvement by 180% of correct answers. The low level of correct answers is also due to the fact that some students have escaped the LMS Moodle during the course of Numerical Analysis.

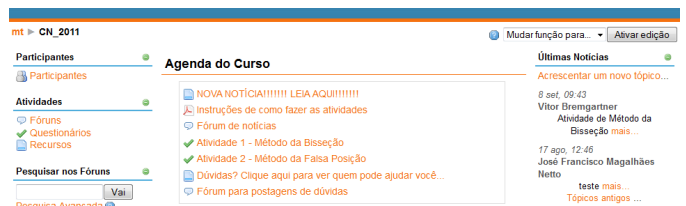

Figure 4. LMS Moodle used in a real class.

TABLE II. CLASS' ANSWERS OF THE QUESTIONNAIRE

| Question | Before Recommendation (%) | After Recommendation (%) |
|--|---------------------------|--------------------------|
| Could you do the exercise posted on the LMS Moodle? | 70 | 90 |
| Did you feel the interface "friendly" to perform the exercise? | 79 | 79 |
| Did you have any difficulty or doubt to do the exercises? | 50 | 10 |
| Percentage of correct answers (from activities) | 13 | 37 |

V. CONCLUSIONS AND FUTURE WORK

This paper shows a strategy of personalization that uses competency-based ontology integrated into a multi-agent system characterizing a learner model in the IMS LIP standard able to update, analyze, and recommend student profiles in the LMS Moodle. This proposal allows greater customization of content presented by means of personalized recommendation of students with desirable specific skills which constitute their competencies (based on the Perrenoud's concepts) to help other students with weaknesses. Simulations with the Petri Net that models the multi-agent system validated the correct order of initialization of the agents, as well as collaboration between them. The recommendation process described in this paper increases the interaction among students of the same course or

subject, thus increasing the knowledge level of learners as a whole and greater correctness in the tasks performed.

The tests with a fictitious class were performed in order to explore the efficiency of competency-based ontology with multi-agent system. The tests in a real class showed that the recommendation of students to assist others with questions through collaborative learning is a useful and effective solution to the problem of aid to students with questions in VLEs, improving student learning. This strategy can be another way to improve the teaching of students using modern Information and Communication Technologies, in addition to several techniques in the literature. The approach of the multi-agent system together with the learner model ontology can be applied to other VLEs, since the agents and the e-learning environment share the same database.

As future work, the proposal is to improve the system for adaptation in mobile devices. Also, whereas the ontology and multi-agent system work under the IMS standard, we intend to make interconnections with several e-learning systems, as virtual laboratories for telerobotics, scheduling services between students, and forums in VLEs, using this standard or compatible in order to allow data interoperability from students. Thus, personalized recommendations of students with the best profiles based on their skills and competencies will be made from reuse of student data in other LMSs to assist learners with learning difficulties.

Abstract— Distance learning boosts the development of Web-based software aimed at supporting teaching and learning processes. More recently, information technology became part of pedagogies since their conception, especially for those called “pedagogical architectures” focused mainly on learning and on the processes of creation, discovery and invention. This scenario presented a new challenge: software tools need to facilitate the expression of individual idiosyncrasies and teams as well as incorporate multiple fine-tuned ways of working. It became necessary to design flexible virtual environments that meet the needs of its users, allowing runtime changes in their structures and interfaces. In this paper we present a platform designed under a novel paradigm for designing virtual environments, with flexibility to be combined and to define several virtual environments, runtime changeable without loss of data. As proof of concept, a software platform was developed and used to model and implement a total of 11 well-known virtual environments spanning from usual ones like forum, blog and wiki, to more complex examples. Finally, in order to evaluate the platform’s ability to accommodate changes, a case-study was carried out in a real-world event with a class of 10 multipliers (teachers responsible for training other teachers) that reported their use of the platform’s resources available so far.

Keywords- *Distance Learning, Flexible Virtual Environments, Tailorability*

I. INTRODUCTION

In the last ten years, the Web has changed from an ordinary medium to a complex platform, from a read-web to a read-write-web and these days Web 2.0’s ideas are in line with modern educational theories such as constructivism and connectionism, making its applications very attractive for teachers and learners [1]. This is fulfilling Berners-Lee’s original vision of the Web – ‘a system in which sharing what you knew or thought should be as easy as learning what someone else knew’ [2].

Although technical characteristics of those tools lead to specific pedagogical characteristics especially when considering Distance Learning scenarios, traditional learning management systems (LMS) tend to replicate conventional forms of teaching, especially on its focus on content organization and student activity management, both issues based on a knowledge-transfer perspective.

More recently, some pedagogical approaches take into account the technological support since its conception.

This is the case with “pedagogical architectures” [3] that are focused mainly on learning and on the processes of creation, discovery and invention, as well as encouraging subjects to perform experiments and simulations while searching for solutions to significant problems connected through different situations.

This scenario presented a new challenge: software tools need to facilitate the expression of individual idiosyncrasies and teams as well as incorporate multiple fine-tuned ways of working. In a collaborative context, software developers are not able to predict all user needs at design time [4]. That means that even if a developer is able to develop an optimal application for a group, it will eventually become inadequate due to new situations and problems that eventually will appear [5]. Thus, users should be able to adapt their applications according to their pace and work methods [4]. It became necessary to design flexible virtual environments that meet the needs of its users, allowing runtime changes in their structures and interfaces.

Developers of virtual environments tackle this problem by using approaches like component-based development, software production lines and web-services-based services. However, they do not manage to deal with the kind of dynamic modification their users are now demanding. All these approaches take an application as a finished product, without need for modifications after it is ready for use. These approaches are still not flexible enough to tackle new demands of highly dynamic domains.

In this context, a distinct approach called MORFEu (from a Portuguese acronym for Flexible Multi-Organizer of Virtual Spaces) was proposed and has been evolving [6][7]. MORFEu’s perspective is that virtual environments should be composed of simple elements that, when combined, can define tools for communication, interaction, organization of knowledge and so on. This simplicity of composition gives MORFEu-based tools, flexibility to define several virtual environments, which are runtime changeable without loss of data.

In this paper we describe a web-based software platform developed upon MORFEu’s perspective and aimed at highly dynamic collaborative scenarios. This platform is described here using a Model-View-Controller (MVC) pattern and as proof of concept we implemented a total of 11 well-known virtual environments, spanning from usual ones like

forum, blog and wiki, to more complex examples, used in pedagogical architectures for which there was no direct implementation reported. Finally, in order to evaluate this platform ability to accommodate changes in its elements, a case-study was conducted in a real-world event with a class of 10 multipliers (teachers responsible for training other teachers) that reported their use of resources available so far.

II. RELATED WORK

Software developers have been addressing suitability of virtual environments to user needs through techniques such as: modular development, component-based development, software product lines and web-services. However, the problem is still not solved.

Modular development relies upon services, libraries and frameworks that encourage reuse and focus on the goals of an application. Among virtual environments developed with this approach, Moodle¹ is one the most used. It has an atomic core of basic services and all communication and interaction tools are installed as modules, making easy to install a new module. However, these modules are available by a developer community in not so large numbers. If a group of users demands modification on any of these modules, all users of that environment would be affected.

The main idea in component-based development is to encapsulate many of the technical difficulties faced by virtual environment developers [8]. The focus of this approach is on the reuse of infrastructure aspects like protocols, synchronism, session management and others, leaving time to implement innovative solutions. Components assembled according to a group needs imply that a certain virtual environment would be developed to that specific group. Unsurprisingly this approach will have limitations when dealing with new demands resulting from different patterns of interactions and natural evolution inside the original groups. The works reported in [9], [10] and [11] are examples of component-based development.

Software product lines (SPL) present a more systematic approach than the ad-hoc criteria frequently seen in component-based [8]. SPL span over all stages of groupware development and like the component-based approach, it allows customization of applications, but also it considers a virtual environment as a finished, unchangeable product.

Virtual environments can also be developed using web-services in a distributed architecture. Examples of this approach are reported in [12] and [13], with development of applications by composition of distributed services over the Web. The work reported in [4] proposes a tailorable groupware architecture that enables the dynamics composition of services into a collaborative application. Nevertheless, as happens with the other approaches, there is no thought on how to modify one of the services, but only how the services might be composed, dynamically or not.

These approaches are still not flexible enough to tackle new demands of highly dynamic domains already into the web.

¹ <http://moodle.org>

In Table I we present a synthesis of the characteristics of current approaches and of MORFEu's, considering typical issues like when new tools can be integrated to an existing environment, how a customized environment can be made, how an existing tool can be modified, and how much time is needed to make some modification.

TABLE I. COMPARISON OF VIRTUAL ENVIRONMENT APPROACHES

| | Module based | Component based | Web services | MORFEu |
|--------------------------------|--------------|-----------------|--------------|----------|
| Deployment of new tools | run-time | project-time | run-time | run-time |
| Customized environments | no | project-time | run-time | run-time |
| Modification of existing tools | no | project-time | no | run-time |
| Modification time | – | Slow | – | fast |

III. A FLEXIBLE MULTI-ORGANIZER OF VIRTUAL SPACES

MORFEu [8] has individual production of users as its central focus, and building virtual environments will be guided by the organization of that production. Using simple elements, MORFEu can define a great variety of virtual environments that can be made flexible and able to deal with runtime changes in specification.

MORFEu has the following premises:

- Users interact with each other through virtual environments, in a knowledge construction setting;
- Interactions are materialized through user production stored in these environments;
- User production is organized in virtual environments as documents, shared according to predefined elements such as: structure, responsibility table and interaction order.

In this way, a basic item of individual production does not need to be subdued by a specific document. The same production item can be reused to form different group documents.

Conventional virtual environments organize their work spaces according to communication/interaction tools used. Tying up a production to a specific document or tool has been reason of complaining by a web pioneer that stated: “every time I write something with a computer, I have to choose whether to open the *electronic mail* application or the *net news* application or the *Web editor* application” [2].

We introduce the concept of **Intellectual Production Unit (IPU)** as the basic artifact to support authoring and registration of individual production. The IPU's can be produced in different languages, text, graphics, sound, etc., so that each IPU may be of a different type. Any production made by a user into an application can be considered an IPU. For example, forum's posts, a blog's comments, an e-mail message sent to a friend, all of them are IPU's.

In a virtual environment, interaction starts when a user shares an IPU with others. This leads to another central concepts in MORFEu: The act of sharing an IPU in a virtual

environment is called ‘publishing’, and these virtual environments defined by IPU composition are called **Communication Vehicle (ComV)**. ComV are responsible for ‘materialization’ of production generated by interaction between users following certain **interaction protocols**, and are transposed to user view according to individual **templates**.

Template is another key concept. Any visualization of data within a ComV’s document is made through a template. Instantiation of a ComV generates a hypermedia document jointly generated from publication of organized IPUs, visualized through templates.

These concepts can be used to describe conventional communication/interaction tools, as follows:

- A *chat* conversation, for example, will produce a document (ComV) generated by participants of that chat session. Posts (IPUs) are usually done one after other, with no predefined intervention order, carried out synchronously. Usually a chat has just one page, which is generated by a template.
- In a *blog*, authors create several posts (IPUs) organized by publication date. Each one of these posts is open to get comments from other users (IPUs), which in their turn will become co-authors of that document (ComV). Basically, a blog has two kinds of pages (both generated by templates): the main page with a posting list and the comments for every posting.
- In a discussion *forum*, productions (IPUs) are organized in tree organization (from graph theory). An IPU replies to other IPU or starts a new thread of publication, in a hierarchical way. The final document in this ComV is the set of all productions in the tree structure. Templates generate a page with the list of threads and one page for each thread showing its posts.

IV. PEDAGOGICAL ARCHITECTURES

Aiming at breaking away from conventional praxis around educational software – that of schools adopting artifacts (contents and program) available off-the-shelf – a novel approach was introduced in [3]. In that work, Pedagogical Architectures (PA) are described as a matching of a pedagogical approach (a group-based dynamic driven to knowledge production, devised to address a specific learning situation also considering the subjects and a specific context) with a computational support (software, communication networks, Artificial Intelligence tools, etc). Thus, is not enough to have a generic pedagogical approach (a meta-PA) and apply it to a new situation (contents, subjects and context) – it is necessary for a PA to be in consonance with its elements and that it could be modified through its use, in order to comply with new demands risen from that use.

MOrFEu [6] was proposed to tackle this challenge – production of software artifacts for cooperative learning – with the following PA requirements:

- A software artifact where is possible to describe interaction patterns combined with document generation;

- Support for supervision and intervention by a teacher;
- Support for storage and retrieval of individual and group productions;
- Resources could be modified and tuned during its use.

V. A PLATFORM FOR THE DEVELOPMENT OF FLEXIBLE VIRTUAL ENVIRONMENTS

Grounded upon MOrFEu’s principles, we propose a software platform for developing web-based virtual environments that makes it easier to build ‘tailorable’ social interaction tools, runtime changeable without loss of data. We discuss how those principles have been instantiated with current technology and used to define a platform described and prototyped using MVC development model [14].

Starting with organization of IPUs published in ComVs, behavior and data from the application domain need to be managed by a moldable element, with a data scheme that cannot be fixed since it should allow editing or adding new data types on the model. Conventional relational database are not suitable for this, once changes on its scheme are inefficient or not allowed at all. ‘NoSQL’ database are recommended, especially scheme-free ones, for example XML and document-based ones.

Each user must have its own way of accessing data, and several templates will act on a same set of data. For instance, data in a spreadsheet can be seen in several ways: a table, a row graphic, a pizza graph, a histogram, and so on.

An important element in this platform is related to management of interaction protocols and regulation of issues like: user roles, permissions, interaction rules and other constituents of formally represented workflows. Functionalities like these are requirements for current social inspired web applications [5][15][16].

Finally, MOrFEu’s principles state that IPUs exist independently of where they are published, and should be available for publishing at any ComV. Thus, there should be an IPU Database managed by the system and in ComV there are references (publications) to IPUs that constitute it. A MVC representation of these elements can be seen on Figure 1.

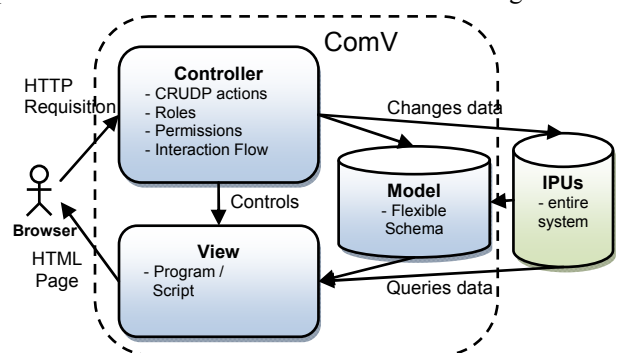

Figure 1. A MVC representation of the platform.

A Prototype of a MOrFEu-based Platform

Using MVC development model we have implemented a platform for development of ComVs. In this platform, every user can manage their IPU's and related publications. An user can access existing ComVs and create their own. Every ComV has its own MVC elements, as follows:

- **Model:** it was implemented through a XML file, stored as an IPU. This model has a flexible scheme and IPU's are published as reference to IPU's on an IPU database.
- **View:** views are IPU's in XSLT – a Turing-complete programming language for XML processing. Views process Model and display HTML pages with information in the Model.
- **Controller:** CRUDP (Create, Read, Update, Delete + Publish) actions were implemented as well as View manipulations. Permissions deal with authors and readers of a ComV.

A prototype was implemented using PHP as programming language and MySQL as DBMS. A PHP processor with modules for XML/XSLT processing is required. A software development framework called Yii² was used to speed up the prototype development. The prototype³ can be installed on any Apache-MySQL-PHP hosted either by Linux or Windows with active XML/XSLT processing on PHP.

Figure 2 shows the layer architecture of the prototype with relations between elements.

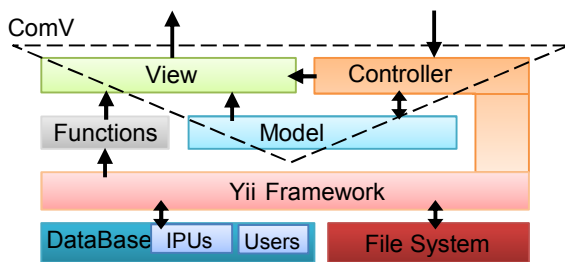

Figure 2. Layer Architecture of the Prototype.

In the prototype there are ComVs already implemented and they are used as 'models' for new ComVs. For example, if a user wants to create a discussion forum, they can copy a model from the standard forum in the system. Thus, modifications done on a ComV are valid only at each specific instance. To modify a ComV, a user may use the ComV editor and alter ComV elements: View, Model and Controller.

Interface modifications are done through View. On views also are found the links for IPU publishing and functions to obtaining system information like name of an user accessing data, IPU data, date of last modification of a ComV, etc.

Model modification includes inclusion of publishing schemata – short pieces of XML code that are included in the model at the moment of publishing.

Controller modification can refer to permissions or configurations. At the prototype, only simple permissions were implemented like who are authors and readers of a ComV.

Each ComV might have its configuration set adjusted to match an expected behavior. Simple modifications, like interface ones, can be done by the user and requires some knowledge of HTML and ComV architecture. More complex modifications, like inclusion or modification of ComV functionalities might involve several modifications on views and model, or even inclusion of new views, and should be done by developers or more specialized users.

VI. DEVELOPING FLEXIBLE TOOLS FOR INTERACTION

As concept proof, we have described and implemented 11 software tools. In this section, we illustrate the ComV development process, from design up to runtime modifications in its functionalities. To do that, we show the development process for a tool supporting a pedagogical architecture called "Thesis Debate" (TD) [17].

TD was developed as an experimental activity, in a stepwise way. After each stage, the following one was included according to what happened in that stage. As a result, a five-stage activity was devised.

In the first stage the moderator (teacher) selects theses to be debated from a survey on student previous knowledge. A chart with the thesis assigned to each student (stage 2) is prepared and each student must states whether he/she agrees or disagrees with it, along with a correspondent justification. Next (stage 3), each opinion must be evaluated by two or more members of the group and they must compose a short review. In stage 4, authors of the initial justifications can, if they want to, answer to evaluators' comments. At stage 5 users can presented a new/revised version of their positions and arguments.

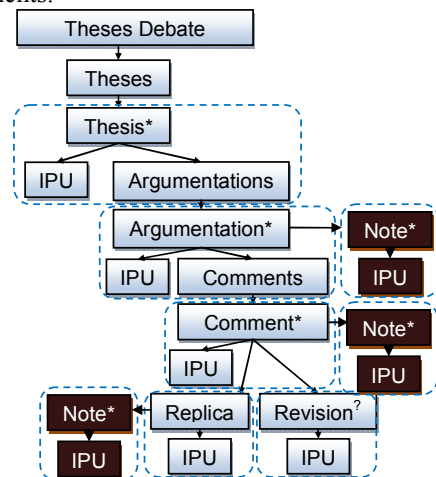

Figure 3. Data Scheme for Thesis Debate (TD)

² <http://www.yiiframework.com/>

³ <http://gsiufam.com/>

A. Project

Our ComV development platform includes a tool modeling scheme comprising data modeling and web navigation. Figure 3 presents a data model for the discussion chart of TD. Its tree-like shape makes easier to map it to a XML scheme, using for it a notation similar to ancient Jackson representation diagram [18]. On that representation, arrows mean “composed by” and a star means “one or more”. Dotted line represents publication schemes. Dark colored boxes are modifications after initial modeling, carried out during runtime. Modification process will be described later.

Figure 4 shows the navigation diagram (between webpages) for this tool. It consists of three states: the main page; a “participants list”; and “charts I have commented”. Parameters are represented along connectors.

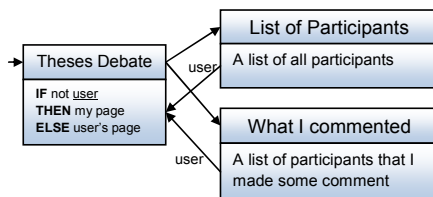

Figure 4. Navigation Diagram for a TD tool.

B. Implementation

Implementation process involves development of views, model and controller. First it is necessary to implement an initial model and publication schemes in XML. Next comes the development of a view for each of the three pages, written using XSLT. A view must “extract” data from the model and present them as a web page. The view must have links for publications specifying which publication scheme must be used, what sort of IPU and “where” in the model publication must be made. It is also possible to show system information and IPUs currently in the IPU database. Publication links and information display are done through a specific function used by the view processor.

C. Modifications

The first modification tested was the inclusion of text notes for direct interaction between moderator and participants, a situation not anticipated in the original version of TD [17]. To do this, a new Note publication scheme was added (see Figure 3). After that, a publication link was added in the chart for situation when user is a moderator. In this view an exhibition code for published notes was also added.

Other feature wanted in the tool was suggestion of charts for evaluation, since each participant should evaluate only two charts from other participants. Thus, a generation of a random list of pairs of participants was included.

A third modification was done to parameterize ComV configurations and allow informing how many charts each participant should comment upon.

These three modifications have been carried out as a straightforward task – a simple programmer working two hours at each modification. These modifications could be done

by most of the users and are supported by a versioning tool. As result, Figure 5 shows a chart of one user of this ComV, generated at the Case Study described in the next section.

D. Using ComV to develop other virtual cooperative tools

As concept proof, we have described and implemented other 10 software tools. Description for some of these tools can be easily found on the web: forum, blog, wiki, questionnaires, glossary and whiteboard. For others, there is no specific description: simulated jury [19], problem-solving virtual diary [20], soccer world-cup betting tool and a simple LMS-like course manager. The later spans over various application contexts and functionalities and are aimed to represent real world situations. These ComV have from 1 to 4 views and were implemented by one programmer working up to two days in each view. The resulting code is about 260 lines for each view.

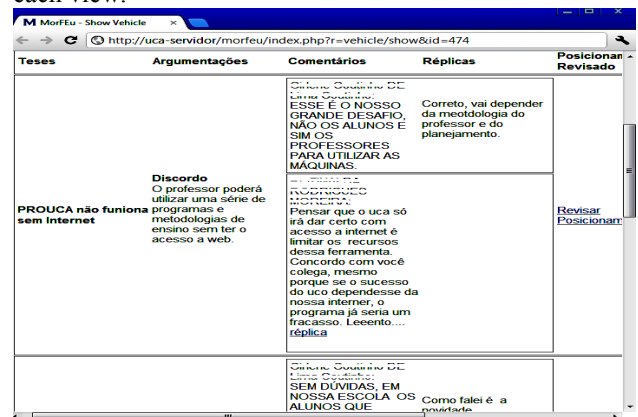

Figure 5. A TD runtime modified chart.

VII. FORMATIVE EVALUATION

An exploratory Case Study has been carried out in order to determine how the platform would tackle real-world demands for modification. The main goal was to develop hypothesis and related propositions for a following study on what sort of virtual environments can be build using the platform.

The scenario for the Case Study was a course with 10 multipliers (teachers responsible for training other teachers) on using of Information and Communication Technology on elementary school. Those participants had to reach proper skills level before to go back to their own schools and replicate the strategies and materials there. All participants agreed to be observed and to use our prototype.

Among several activities planned for that course, some time was allocated for exploring pedagogical architectures described here, built using our prototype. Two tasks were observed: using of Thesis Debate and evaluation of learning objects using forums to discussion and wiki for reporting. Participants had little knowledge on using internet-based tools, so the first task had a preliminary step: after discussing how Thesis Debate works, a structured debate was done using only 3 participants (the others stayed as observers) with conventional materials (pen and paper). By the end of the process, all participants (3 operators and 7 observers) have

said that it was too complicated to apply that pedagogical architecture with no computing support.

Next, we presented a Thesis Debate supporting tool built using our prototype and all 10 participants started the activity. We assisted the participants with technical support and questions about that pedagogical architecture, taking notes on all problems reported or functionalities the participants would like to have on that tool. The same assistance was given in the second task.

By the end of those activities we have identified a total of 31 modifications. From those, 10 were simple bugs and 11 were variations on the ComV to better accommodate personal preferences. All these 21 modifications were easily done (about 6 working hours) and checked upon by users in the following day.

All remaining modifications were concerned with variations on the pedagogical architecture, especially interaction rules, that participants thought would better suit their application scenarios (students and teachers at their own school) and not implemented because they require modifications over the controller, a component not yet incorporating formal definitions allowing runtime alterations in current prototype.

In addition to these variations on Thesis Debate, some participants suggested other ComV that they thought would be used in related contexts like a synchronous, cooperative and multi-operated text editor; or an educational-oriented social net.

VIII. CONCLUSION

In this paper we described a web-based software platform developed upon a novel software development perspective called MORFEU and aimed at highly dynamic collaborative scenarios.

Results of a concept proof implementing a total of 11 software tools gave evidence of: (1) feasibility of the proposal – there is a running prototype; (2) flexibility of the proposal – several tools, in various contexts, were implemented and used in a real-world situation; (3) ease of use – considering the amount of code, time and personnel involved in the development task.

A Case Study developed as formative evaluation gave evidence that even non-experts can present a challenging demand for modification in virtual environments (a need for flexible approaches), which support our initial assumption that even if a developer is able to develop an optimal application for a group, it will eventually become inadequate due to new situations and problems that eventually will appear.

Traditional approaches for development of this kind of tools are not flexible enough, and as we checked in a prototype stage, our platform already allows developers to implement several runtime modifications.

Our Case Study also brought out some issues related to the interaction protocols of the activities that are supported by those tools. Therefore, deeper formalization of user templates and interaction patterns, as well as other real-world case studies are the next steps on this investigation.

ACKNOWLEDGMENT
