student data for seven years (2001-2008) showed that 78% of native freshmen students had graduated within 4 years after reaching junior status, 15% were still enrolled or had dropped out, and 7% had changed to a major outside the college (total sample size in the cohorts was 3,057). However, the graduation rate for those students who had entered as community college transfers was substantially lower: 54% had graduated within 4 years, 39% were still enrolled or had dropped out, and 7% had changed to a major outside the college (cohort sample size 2,951). These statistics indicate the importance of understanding the factors leading to persistence for community college transfer students on our campus, and if these factors are similar or different for native freshmen students. The results of our study can inform program coordinators, professional advisors, and campus administrators which extra- or co-curricular activities best serve the needs of both groups of students in terms of connecting to the campus.

II. UNDERGRADUATE RESEARCH EXPERIENCES

In this study, we examined associations among academic and social integration into campus life (known factors that have been identified by researchers as contributing to persistence) through participation in extra-curricular and co-curricular activities during the undergraduate career of engineering and computer science students. An additional area of interest was the role of undergraduate research experiences (UREs) in making friends on campus. A benefit of participation in UREs is the quality and frequency of interaction with faculty and URE peers through a cohort experience.

Four authors of this paper are program staff for the YES (Young Entrepreneur and Scholar) Scholarship program. YES is an S-STEM (Scholarships in Science, Technology, Engineering, and Mathematics) program funded by the National Science Foundation. YES offers eligible STEM junior and senior students the choice of two pathways: the Research Path (paired with a faculty mentor) or the Entrepreneurship Path (paired with an industry mentor). As of Fall 2011, 124 people had participated in the YES program: 49 STEM students, 41 faculty mentors, 8 industry mentors, 15 External Advisory Board members, and 11 program staff. Most students (84%) selected the Research Path, 8% the Entrepreneurship Path, and the remaining 8% switched

between Paths. The demographic profile of the YES students showed a diverse representation of 41% women, 33% Hispanic, 14% African American, 8% Asian, 2% Multiracial, 43% White, and 51% first generation college students. All students ($n=10/10$) who completed the YES program through Summer 2011 continued on to advanced studies at the university or found employment in their field upon graduation, whereas for non-completers, it was 18% ($n=2/11$). (The next group of YES students is due to graduate Spring 2012.)

In focus groups conducted for the past two years, YES students have reported that one of the benefits of the program was forming friendships with other YES students. YES students described that working in the similar environment was beneficial and they learned through interacting with each other; friendships were strengthened when friends had classes together; they liked being able to interact with graduate students in labs; and overall, they had positive relationships with their mentors. An outcome of the focus groups was that they requested additional social opportunities to interact with each other. Due to the limitations of the small sample size of the focus group ($n=10-14$), we were unable to determine if the experience of making friends was unique to the YES program or representative of research experiences for STEM students at the university. It is for this reason that participation in UREs was an additional area of interest in this study which utilized a larger sample size. Our hypothesis in this study was that a statistically significant relationship would be found between participation in UREs and making friends on campus.

III. LITERATURE REVIEW

The theoretical framework for this study is based on Tinto's model of student departure which emphasizes the importance of academic and social integration on student persistence [1], and Astin's theory of student involvement and its role in student development (e.g., highly involved students study a lot, spend a lot of time on campus, participate actively in student organizations, and interact frequently with faculty members and other students) [2]. New students entering a university are often transitioning between support systems and acclimating to a new environment. This transition to college life can be compared to the grieving process – shock followed by eventual recovery and integration for most people [3]. Many of these students suffer from what Paul and Brier [4] refer to as “friendsickness.” Coping with the loss of their support system is a traumatic event that can delay a healthy adjustment to college life for many students [4].

Additional studies have contributed to understanding the role that social integration plays in students' adjustment to college life. These findings provide the conceptual framework for this study. Bean [5] suggested that men and women college freshmen dropout for different reasons and recommended a different course of action to retain each population: for women, encourage them to join campus organizations, emphasize the usefulness of the degree in securing employment, and maintain an active and effective placement program; for men, offer educational programs to develop personal, intellectual, creative, and interpersonal skills, and offer a flexible schedule during the first semester. Aspinwall and Taylor [6] found that social support as a mediating variable

predicted better adjustment to college. Walton and Cohen [7] conducted a three-year longitudinal study of college freshmen who were asked to read a report based on the survey of senior students about difficulties they experienced in transitioning during their first-year as freshmen. They found that reading the report about the common challenges experienced by senior students had a positive impact on freshmen sense of belonging and physical health and well-being, and most significantly on African American students. Other studies on under-represented students indicate similar patterns of the importance of social experiences on adjustment to college life. Latino students rated academic adjustment and social relationships as the most difficult aspects of their first-year college experiences, and college peers (boy/girlfriend, roommates, and other students) and family as the individuals who provided the most support during their first year [8]. Eimers and Pike [9] found that satisfaction with academic and social experiences had a significant effect on intent to persist for minority freshmen students, while Nora and Cabrera [10] found that they exerted an indirect effect on persistence. First-generation freshmen students achieved better adjustment to college life through intellectual activities, whereas second-generation freshmen achieved better adjustment through the support of on-campus college friends [11].

The term “transfer shock” appeared in a study by Hills [12] and referred to a drop in grades experienced by students transferring from a junior college (now known as community colleges) to a university. Cejda [13] found that community college transfer students majoring in business, mathematics, or the sciences were more likely to experience greater transfer shock and suffer declines in grade point averages compared with education, fine arts and humanities, and social sciences majors. More recent studies on community college transfers have expanded to include other factors that impact successful adjustment to a university campus. The mechanisms by which transfer students achieve social integration into campus have been one such focus. Rhine, Milligan, and Nelson [14] suggested that academic and social factors (other than a drop in grades) contributed to transfer student attrition. Flaga [15] identified four dimensions of transfer students' transition from community college to the university: Learning Resources, Connecting, Familiarity, Negotiating, and Integrating. Transfer students reported native university students as the most frequently used resource for negotiating the academic, social, and physical environment of the campus, and participation in campus involvement through academic clubs, student organizations, and sporting events to connect to the campus [15]. Laanan [16] proposed establishing a peer mentorship program sponsored by student affairs or student organizations to ease the difficulties associated with acculturating to university life for transfer students. Difficulty in making friends was cited as one barrier to social integration into campus life – transfer students reported finding it easier to make friends at the community college than at the university [17]. Community college transfers are not similar to freshmen students, for one, they tend to be older [18] and may be less inclined to participate in social activities on campus [19]. Therefore, in our study, we hypothesized that participation patterns in extra-curricular and co-curricular campus activities for community college transfer students would be different

from those of native freshmen students; and native freshmen students would be more likely to form friendships with other students and on average have higher GPAs. Understanding these differences will be useful in determining which campus-sponsored programs can provide the most benefit to these populations in terms of connecting to the campus.

IV. METHODOLOGY

Data were collected from the university-administered 2009-10 and 2010-11 senior exit survey (completed one semester prior to graduation) for engineering and computer science students (n=1,117) at the University of Central Florida (UCF). Sixty-two percent (n=693) of respondents had entered as native freshmen, 31% (n=349) as transfers with an AA or AS degree and 7% (n=75) without an AA or AS degree. For the purpose of this study, only 1,042 students were used in the analysis – native freshmen and transfer students with AA or AS degrees. The demographic characteristics of under-represented groups for native freshmen students were 14% (n = 99) women, 11% (n = 77) Hispanics, and 5% (n = 37) African Americans. For transfer students, the profile was 17% (n = 58) women, 14% Hispanics (n = 47), and 4% African Americans (n =14). In terms of age (at the time of completing the survey), 80% of native freshmen were <24 years old (30% for transfers); and 20% were 24 years or older (70% for transfers).

Ten questions from the graduating senior exit survey were used in this study which asked students about participation in various engagement activities during their undergraduate career. These activities were categorized as academic (undergraduate research experiences, student organizations related to major, student leadership programs, experiential learning opportunities, and honor societies) and social (sororities and fraternities, community service and involvement, spiritual/religious activities, intramural sports, and other clubs). Survey respondents could select participation in more than one activity. As the options provided on the survey was not exhaustive, an “Other club” option was provided for students to report any club affiliation not listed.

Two items from the survey were considered as a measure for social integration: a) “To what extent would you say you developed close personal friendships at UCF?” where an endorsement of “almost all or most of my friends are from this institution” defined that they had; and b) “How would you rate your social experience at UCF?”, where a rating of “excellent, very good or good” by the student suggested a positive social experience.

Responses from the survey, in conjunction with cumulative GPA from student records, were used to determine associations among participation in social and academic engagement activities, social integration, and academic success. To evaluate associations between social integration and academic success of graduates, analysis of variance (ANOVA) was used to identify statistically significant differences in mean cumulative GPA for various levels of social integration. Additionally, comparisons were made between native freshmen and transfer students with respect to their social integration and participation in co-curricular and

extra-curricular activities. These comparisons were made using difference of proportion tests of hypothesis. A less restrictive significance level ($\alpha = 0.1$) was used in this analysis as this study was exploratory in nature.

V. RESULTS

A. Participation in Co-curricular and Extra-curricular Engagement Activities

As was expected, native freshmen and transfer students participated in very different co-curricular and extra-curricular activities during their undergraduate careers. As shown in Table I, native freshmen had a higher participation rate compared to transfer students for most of the activities. The one exception was participation in experiential learning activities, although the difference was very small. The activity with the largest difference in participation was intramural sports, with transfer students at 15% and native freshmen at an overwhelming 41%.

TABLE I
EXTRA-CURRICULAR AND CO-CURRICULAR
ENGAGEMENT ACTIVITY PARTICIPATION RATES
FOR NATIVE FRESHMEN AND TRANSFER STUDENTS

| | | Freshmen | Transfer |
|---------------------|--|----------|----------|
| Academic Activities | Undergraduate research experiences | 19% | 7% |
| | Student organizations related to major | 33% | 19% |
| | Student leadership programs | 11% | 3% |
| | Experiential learning opportunities | 41% | 42% |
| | Honors societies | 12% | 9% |
| Social Activities | Sororities and fraternities | 13% | 1% |
| | Community service and involvement | 16% | 11% |
| | Spiritual/religious activities | 14% | 8% |
| | Intramural sports | 41% | 15% |
| | Other clubs | 37% | 22% |

B. How Social Integration Is Defined In This Study

Table II summarizes endorsements by native freshmen and transfer students for the two questions pertaining to social integration.

TABLE II
POSITIVE RESPONSES FOR MEASURES OF SOCIAL INTEGRATION
FOR NATIVE FRESHMEN AND TRANSFER STUDENTS

| | % Positive Response | |
|---|---------------------|----------|
| | Freshmen | Transfer |
| To what extent would you say you developed close personal friendships at UCF? | 55% | 29% |
| How would you rate your social experience at UCF? | 93% | 90% |

“To what extent would you say you developed close personal friendships at UCF?” is a more direct way of asking about student connections to the campus than “How would you rate your social experience at UCF?” The response options for the close personal friendships question (almost all of my closest friends are from UCF, most of my closest friends are from UCF, ... , almost all of my closest friends are from elsewhere) quantify how much integration a student has made on campus. The survey item pertaining to social experience is simply a rating of their social experience (excellent, very good, good, fair, poor). Lastly, developing close personal friendships was more discriminatory between native freshmen and transfer student groups; therefore, for this study it was used to define social integration during the students’ undergraduate career.

C. The Relationship Between Social Integration and GPA

Table III summarizes the impact of social integration on cumulative GPA for native freshmen and transfer students. Using ANOVA, the mean cumulative GPA of 3.16 for the 485 students who reported higher levels of social integration was statistically higher than 3.11 for the 556 students who reported lower levels of social integration. The mean cumulative GPA was higher for native freshmen students ($n=384$, mean GPA = 3.17) who reported high levels of social integration when compared with transfer students ($n=101$, mean GPA = 3.14), but it was not statistically significant. The largest differences existed between female native freshmen who reported higher levels of social integration ($n=57$; mean GPA = 3.30) and those who did not ($n=42$; mean GPA = 3.18). A similar

pattern was found among female transfer students; however, the small sample size limited our ability to test for statistical differences endorsing high levels of social integration. No statistical differences in mean cumulative GPA were detected for male native freshmen or male transfer students with respect to social integration.

D. Co-curricular and Extra-curricular Engagement Activities Associated with High Social Integration

Using difference of proportion tests of hypothesis, we compared rates of high social integration for participants and non-participants for each engagement activity. Table IV summarizes rates of high social integration by participation in various co-curricular and extra-curricular activities for native freshmen and transfer students. For instance, 67% of the 110 native freshmen participants in community service and involvement reported high levels of social integration whereas only 53% of the non-participants ($n=583$) reported high levels of social integration. For native freshmen, activities that were strongly associated with social integration were: organizations in their major, sororities and fraternities, intramural sports, student leadership programs, experiential learning, honors societies, community service, and other clubs (data on the specific clubs in this group were not collected). For transfer students, participating in organizations in their major, experiential learning, intramural sports, and other clubs were significant. The engagement activities with the largest difference in rates of high social integration were sororities and fraternities and intramural sports for native freshmen and transfer students, respectively. Participation in UREs and spiritual/religious activities was not significant with social integration for either native freshmen or transfer students.

TABLE III

MEAN CUMULATIVE GPA BY SOCIAL INTEGRATION AND GENDER FOR NATIVE FRESHMEN AND TRANSFER STUDENTS

| | | Social Integration | | Total |
|------------------------------|-----------------|----------------------------------|----------------------------------|-----------------------|
| | | No | Yes | |
| Freshmen | Male | 3.11 ($n=267$) | 3.14 ($n=327$) | 3.13 ($n=594$) |
| | Female | 3.18 ^a ($n=42$) | 3.30 ^a ($n=57$) | 3.25 ($n=99$) |
| | Total Freshmen | 3.12 ($n=309$) | 3.17 ($n=384$) | 3.15 ($n=693$) |
| Transfers | Male | 3.10 ($n=203$) | 3.10 ($n=87$) | 3.10 ($n=290$) |
| | Female | 3.12 ($n=44$) | 3.37 ^c ($n=14$) | 3.18 ($n=58$) |
| | Total Transfers | 3.11 ($n=247$) | 3.14 ($n=101$) | 3.12 ($n=348$) |
| Total Freshmen and Transfers | | 3.11 ^b ($n=556$) | 3.16 ^b ($n=485$) | 3.14 ($n=1,041$) |

a. difference in mean GPA for female native freshmen is statistically significant at $\alpha=0.1$

b. difference in mean GPA for aggregate native freshmen and transfers is statistically significant at $\alpha=0.1$

c. hypothesis testing not performed due to insufficient sample size

VI. CONCLUSION

In this study, we found different rates of participation in co-curricular and extra-curricular activities for native freshmen and transfer students. Native freshmen students had higher participation rates across all engagement activities compared with transfer students, with the exception of experiential learning (Table I). Both groups were as equally likely to participate in experiential learning, and this activity was found to be statistically significant in terms of social integration (Table IV). Although native freshmen and transfer students rated their social experiences similarly (Table II), the native freshmen rate (55%) was almost twice that of transfer students (29%) for developing close personal friendships on campus. At least one in five native freshmen had participated in student organizations related to their major or intramural sports. These findings confirm our hypothesis and previous research that native freshmen students are more likely to connect to the campus through extra- and co-curricular activities more frequently than transfer students.

TABLE IV
RATES OF HIGH SOCIAL INTEGRATION BY ENGAGEMENT ACTIVITY PARTICIPATION
FOR NATIVE FRESHMEN AND TRANSFER STUDENTS

| Engagement Activity | Freshmen | | Significant Differences Found | Transfers | | Significant Differences Found |
|--|--|------------------|-------------------------------|--|------------------|-------------------------------|
| | % reporting high social integration among... | | | % reporting high social integration among... | | |
| | Participants | Non-participants | | Participants | Non-participants | |
| Undergraduate research experiences | 57% (n = 124) | 56% (n = 532) | .4200 | 10% ^a (n = 21) | 29% (n = 296) | |
| Student organizations related to major | 63% (n = 229) | 52% (n = 464) | .0016* | 39% (n = 66) | 27% (n = 282) | .0196* |
| Student leadership programs | 71% (n = 77) | 53% (n = 598) | .0012* | 55% ^a (n = 11) | 28% (n = 320) | |
| Experiential learning opportunities | 59% (n = 275) | 53% (n = 399) | .0441* | 33% (n = 138) | 23% (n = 192) | .0236* |
| Honors societies | 61% (n = 83) | 54% (n = 610) | .0297* | 40% ^a (n = 30) | 28% (n = 318) | |
| Sororities and fraternities | 75% (n = 91) | 53% (n = 602) | .00003* | 60% ^a (n = 5) | 29% (n = 343) | |
| Community service and involvement | 67% (n = 110) | 53% (n = 583) | .0320* | 27% (n = 37) | 29% (n = 311) | .6114 |
| Spiritual/religious activities | 57% (n = 95) | 55% (n = 598) | .3813 | 35% ^a (n = 29) | 29% (n = 319) | |
| Intramural sports | 61% (n = 282) | 52% (n = 411) | .0109* | 41% (n = 54) | 27% (n = 294) | .0195* |
| Other clubs | 63% (n = 256) | 51% (n = 437) | .0012* | 41% (n = 76) | 26% (n = 272) | .0053* |

* indicates that participants of the activity reported higher instances of social integration (developed close personal friendships during their undergraduate career) compared to non-participants. Differences are statistically significant at $\alpha = 0.1$ using one-tailed difference of proportion hypothesis tests.

a. hypothesis testing not performed due to insufficient sample size

Students who reported higher levels of social integration were inclined to have higher cumulative GPAs near the time of graduation (Table III). This relationship between social integration and GPA was significant among female native freshmen students but not their male counterparts. A similar pattern was found among transfer students (though the small sample size for female transfer students limited our ability to test for statistical differences endorsing high levels of social integration). This finding suggests that social integration (defined in this study as making friends on campus) plays a larger role in the academic success of female students than male students. It also validates the results of the study conducted by Bean [5] that men and women college freshmen dropout for different reasons (i.e., retention factors may be different for each group).

Evaluating the interaction of social integration and student participation in co- and extra-curricular activities helped identify activities with potentially the greatest impact on student academic success. Seven activities were found to be strongly associated with social integration for native freshmen, and three activities for transfer students (Table IV). (Other clubs was also common to both groups; however, it was

excluded as a category because the description of these clubs was not collected in the data.) For native freshmen, activities that were strongly associated with social integration were: organizations in their major, sororities and fraternities, intramural sports, experiential learning, honors societies, student leadership programs, and community service. For transfer students, participating in organizations in their major, experiential learning, and intramural sports was significant. Three activities – participation in organizations in their major, experiential learning, and intramural sports – were common to both groups. These three activities seemed to benefit both native freshmen and transfer students of traditional and non-traditional ages in terms of social integration. For participation in organizations in their major, 86% of native freshmen were <24 years old (33% for transfers), and 14% were 24 years or older (67% for transfers). For experiential learning, 83% of native freshmen were <24 years (35% for transfers), and 17% were 24 years or older (65% for transfers). For intramural sports, 80% of native freshmen were < 24 years (48% for transfers), and 20% were 24 years or older (52% for transfers). These results suggest that an added benefit to promoting participation in experiential learning experiences,

organizations in their major, and intramural sports is their potential to connect native freshmen and transfer students of traditional and non-traditional ages to campus.

Participation in undergraduate research was of particular interest in this study given the quality and frequency of interaction of faculty and URE peers through a cohort experience. Our hypothesis was that a statistically significant relationship would be found between participation in UREs and making friends on campus. Native freshmen students were twice as likely to participate in UREs compared with transfer students. However, the relationship between participation in UREs and social integration was not statistically significant for either native freshmen or transfer students. This finding may be limited by the sample size or other factors such as self-selection bias or the structure of the URE program. Perhaps, students who chose to participate in a URE already had a support system of friends in place (students often begin a URE experience in the junior year) and were not necessarily looking to form more friendships. Also, the characteristics of various URE programs may be structured so that there is less interaction with faculty and students for some more than others. Some UREs may have a one semester duration (summer is a popular time period) or, like our NSF-funded, YES S-STEM program, a longer duration, fall and spring semesters (with summers optional) over a one- or two-year period.

Future research should include a longitudinal study following a cohort of students to further assess how participation in various activities affects student success. In particular, the study should focus on how participation affects female, under-represented minority, and community college transfer student groups' adjustment to college life. It may also be useful to look at student success at the course level rather than as an aggregate measure of cumulative GPA.

VII. LIMITATIONS OF THE STUDY

This study was conducted in the College of Engineering and Computer Science at a large, public institution. The findings may be specific to our college and not representative of other institutions. Another limitation of this study was the lack of a direct measure for social integration. Ideally, we would like to have a direct measure of our students' social integration and connection to campus rather than self-reported data. Future work on this topic would include identifying and collecting such a measure on social integration. Once a more direct measure is collected then analysis regarding the validity of our measure may be of interest. A third limitation of the study was the question of self-selection bias in participation in the various activities. Students who are more extroverted and sociable and have higher GPAs may be more likely to participate in extra- and co-curricular activities than those who do not have these characteristics. An empirical study that randomly assigns students to groups could investigate if participation in extra- and co-curricular campus activities is equally beneficial in terms of social integration and academic success to students with both low and high GPAs, under-represented groups, and extroverted and introverted students. If this hypothesis could be validated, then it would be important to understand which engagement activities would be more likely to attract these groups.

Abstract - Responses from open-ended survey questions regarding undergraduate students' connections to community were collected from five different institutions, ranging from a large research institution in the Pacific Northwest to a small teaching college in the Northeast. Our results show that, regardless of institution or U.S. geographical location, STEM students felt connected to family more than any other community in their undergraduate experience. At institutions where faith plays a role in the institutional mission and culture, connections to religious organizations (especially church) were a close second in the strong connections to community that students reported in their lives. Across institutions, friends played a strong role in the communities in which students participated, and traditional extracurricular activities (non-academic clubs within the institution itself) also provided a significant source of connection for many students.

Index Terms— Community, Belonging, Extracurricular, Family, Friends, Sports, Church, STEM education

I. INTRODUCTION

A community is defined as a “social, religious, occupational or other group sharing common characteristics or interests and perceiving itself as distinct in some respect from the larger society within which it exists” [1]. STEM students participate in communities that are directly related to their academic endeavors such as class, lab, and study groups, but they also participate in a variety of non-academic communities, both on and off campus. This study looks at the communities in which STEM students participate and feel most connected. Communities, both non-academic and academic, serve an important purpose in the lives of these students, providing connections to others and fulfilling needs

not readily met in the STEM classroom. Understanding which communities are most important to students can allow educators to encourage and support participation in these communities from inside the classroom and thus improve the subsequent academic benefits.

The National Survey for Student Engagement [2,3], now conducted for more than a decade, provides a critical overview of the scope of collegiate participation in community. Results from the 2007 NSSE survey of more than 300,000 students at more than 500 institutions across the United States and parts of Canada revealed that more than 50% of collegiate students have frequent contact with close family members including parents and siblings [2]. The study also revealed that more than half of students surveyed spend at least one hour per seven-day week participating in co-curricular activities such as organizations, campus publications, student governments, fraternities, sororities and intercollegiate or intramural sports. Notably, more than 10% of students spend more than 10 hours per week engaged in these outside activities. These findings persisted through the 2010 NSSE [3], providing overwhelming evidence of the integration of outside activities with collegiate life. These activities, prevalent in students' lives, have also been shown to provide certain benefits, including improving educational outcomes as well as individual affective experience and outlook.

Given the high level of student participation in outside communities, the impacts of these activities on the quality of education and student outcomes have been the subject of numerous investigations. At the K-12 level, research has shown that participation in extracurricular activities leads to positive academic outcomes including increased engagement and test scores [4], higher SAT performance [5] as well as higher grades and better attendance [6]. Numerous studies at the undergraduate level have looked at how participation in outside communities improves the quality of education and outcomes. Studies have shown that much learning is socially

based; therefore, researchers argue that outside activities significantly impact undergraduate education [7,8]. Studies to test this hypothesis include one by Whitt et al. [9] which showed that non-classroom peer interaction significantly impacted self-reported gains in writing and thinking and composite scores for standardized measures of mathematics, reading, and critical thinking. An analysis of data from six of 23 institutions surveyed by the National Center for Postsecondary Teaching, Learning, and Assessment [10] found that participation in outside extracurricular activities had a significant positive impact on standardized measures of critical thinking skills. Another study of more than six thousand University of California students [11] found that time spent with family was associated with higher GPAs. Looking at broader educational outcomes, persistence in engineering careers has also been found to be connected to extracurricular service, as seen in the study of female engineering students by Wilson et al. [12].

The benefits of participation in community participation outside the classroom are clear. The types of communities students chose to connect to and the degree to which they participate are emphasized in this study and analysis.

II. RESEARCH METHODS

Participation of STEM students in various types of community at the undergraduate level was captured as part of a survey distributed to five very different institutions across the United States. These institutions are (a) a small minority-serving institution in the Southeast (HBCU); (b) a small faith-based private institution in the Northwest (Faith Based); (c) a large research institution in the Northwest (Research); (d) a moderate-size teaching institution in the Midwest (Teaching); and (e) a small women's college in the Northeast (Womens).

Over 900 students from engineering, computer science and other science-based majors from these five institutions were recruited at random to participate. The survey consisted of demographic questions, questions regarding participation in communities both in and outside of school, as well as Likert-scale items regarding students' feelings about the degree to which they do, or do not, belong in these communities. Students were either asked to complete the survey in or outside of class. At times, small incentives like gift cards or cash were used. Students were mostly white (Caucasian) and mostly male, although significant gender and ethnicity distribution differences were present within the Womens and HBCU institutions (Table I).

Survey participants were recruited during the Spring 2010, Fall 2010, or Spring 2011 quarter/semester. Participation in the study was voluntary and students' confidentiality was assured. Most subjects were recruited from core (major required) classes in each discipline, primarily at the sophomore and junior level (although some in targeted classes were seniors). Most participants were majoring in engineering disciplines, although non-engineering majors (mostly biology and chemistry) made up approximately 15% of the sample. All students in this study were asked to complete a paper survey, regardless of recruitment technique. The participation rate

(including consent to release results for research) in all classes was 90% or higher, with a completion rate of 95% or higher. All results were cross-sectional; no attempt was made to capture longitudinal responses from across quarters/semesters in the study. Response rates by e-mail recruitment were approximately 20%.

Two questions from the survey, in conjunction with demographic information were analyzed for this study:

1. To which communities in your life (such as family, religious organization, class, extracurricular organization) do you feel most connected?
2. On average, how many hours do you spend per week in extra-curricular activities (religious organization, book club, fraternity, professional societies, etc.)?

TABLE I. CHARACTERISTICS OF STUDY POPULATION

| Category | | N | % |
|-------------|-----------|-----|--------|
| Total | | 944 | 100% |
| Institution | Faith | 74 | 7.84% |
| | HBCU | 139 | 14.73% |
| | Research | 455 | 48.20% |
| | Teaching | 189 | 20.02% |
| | Womens | 87 | 9.22% |
| Gender | Male | 623 | 66.00% |
| | Female | 320 | 33.90% |
| Ethnicity | Asian | 179 | 18.96% |
| | Black | 149 | 15.78% |
| | Caucasian | 491 | 52.01% |
| | Hispanic | 17 | 1.80% |

1. Ethnicities not listed had populations less than 10
2. Gender may not add to 100% because of non-responses

In responding to the first question, students were free to list any number of different communities. Although examples of communities were provided, students did not limit themselves to these communities and listed many others. Typically one or two was listed, with an actual range of zero to six. Responses to this survey question were coded into the categories shown in Table II (next page).

Each community type was assigned a score of "1" when listed. For example, if a student reported that family, friends, and classes were the most important communities, then each community type was assigned a "1" for the frequency analyses. Note that the None category numbers are the sum of instances where the question was left blank (46/54) and those with the word "none" or the equivalent written in (8/54). Frequency analyses were broken down by gender and institution. In the second survey question, descriptive statistics were extracted from the responses and various groups were compared using standard ANOVA and independent samples t-tests with a significance level of 0.05.

TABLE II. COMMUNITIES TO WHICH STUDENTS FEEL MOST CONNECTED

| Community | Total | Institution | | | | |
|--------------------------------|--------------|--------------|--------------|--------------|--------------|--------------|
| | | Faith-Based | HBCU | Research | Teaching | Womens |
| Class & Lab | 13.2% | 18.9% | 10.8% | 12.8% | 13.8% | 13.8% |
| Extracurricular Clubs | 20.2% | 17.6% | 28.8% | 18.5% | 19.6% | 19.5% |
| Family | 71.7% | 75.7% | 71.2% | 70.8% | 71.4% | 74.7% |
| Friends | 23.1% | 28.4% | 12.2% | 30.1% | 15.3% | 16.1% |
| Living Area* | 6.7% | 14.9% | 0.7% | 10.3% | 1.6% | 1.2% |
| Local Academic (Major)** | 2.7% | 2.7% | -0- | 3.5% | 1.6% | 4.6% |
| Professors & Advisors | 0.1% | -0- | 0.72% | -0- | -0- | -0- |
| Religious Organizations | 16.5% | 29.7% | 28.1% | 14.7% | 10.6% | 9.2% |
| ROTC & Military | 0.64% | -0- | 0.7% | 0.7% | 1.1% | -0- |
| Volunteer Organizations | 0.7% | -0- | 0.7% | 1.1% | 0.53% | -0- |
| Work Community | 3.3% | 2.7% | 0.7% | 3.3% | 4.2% | 5.8% |
| None | 5.6% | 4.1% | 4.3% | 4.6% | 9.5% | 5.8% |
| Other | 0.8% | -0- | -0- | 1.0% | 1.1% | -0- |

Percentages may sum to over 100% because students may cite multiple communities in their responses

* Includes housemates, fraternities, dorm mates, etc.

**Includes research groups, design competition teams, and similar communities.

III. RESULTS

In analyzing all survey results (Table II), students reported by an overwhelming margin that they felt most connected to their families. At all institutions, over 70% of students felt most connected to their families, followed by friends a distant second at 23.1%. Students also frequently reported feeling most connected to extracurricular clubs (20.2%) and religious organizations (16.5%). Very few students (< 1%) reported strong connection to professors or to volunteer or service organizations. Class and Lab, although following behind religious organizations (13.24%), still are worth noting. Communities poorly represented in students' reports include work communities (3.3%) and local academic (major) communities (2.7%).

Table III reports hours per week spent in extracurricular communities. The overall average hours per week spent participating in these communities was 7.8 (with standard deviation of 8.9); some students spent no time at all in these outside communities while others participated 80 hours per week.

TABLE III.
HOURS SPENT IN EXTRACURRICULAR COMMUNITIES (PER WEEK)

| Institution | Hours: μ (σ) | |
|-------------|---------------------------|-------------|
| | Male | Female |
| Faith-Based | 9.6 (7.2) | 8.3 (7.5) |
| HBCU | 12.0 (10.7) | 11.3 (11.4) |
| Research | 6.8 (7.8) | 6.9 (7.1) |
| Teaching | 7.2 (10.6) | 7.5 (7.6) |
| Womens | -0- | 6.0 (7.9) |

Most students, however, spent five hours or less in extracurricular activity per week (Figure 1).

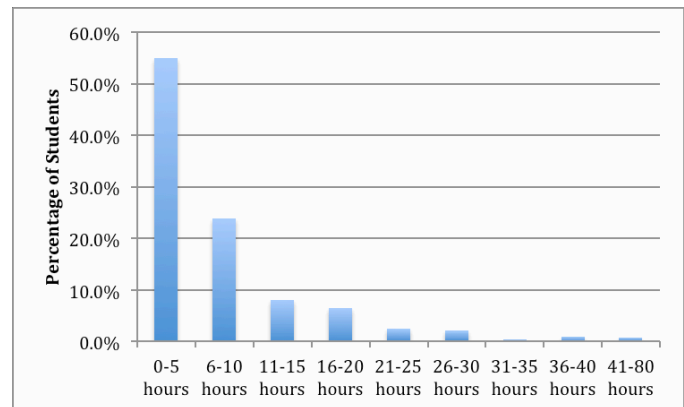

FIGURE 1:
DISTRIBUTION OF HOURS SPENT IN EXTRACURRICULAR ACTIVITIES

Differences across institutions: Despite strong similarities among institutions, some differences did emerge (Table II). Although family remained the dominant community for most students regardless of institution, the community that students reported with secondary frequency varied widely. Students at the HBCU and Faith-Based institution frequently reported strong connections to religious organizations. Others seemed to rely on religious organizations far less frequently (15% or less). At the Research institution, communities of friends seemed to take the place of religious organizations (30% of students reported being most connected to friends), although the Faith-Based institution students had nearly as high (28%). At the

Teaching and Women’s institutions, students did report strong connections to either friends or religious organizations, though not quite as often as at the three other institutions studied. Participation in extracurricular clubs was more uniform across institutions with less than 20% of students reporting they felt most connected here except at the HBCU where over 28% of students reported such a connection. About 5% of students at the Faith Based, Womens, HBCU, and Research institutions reported no strong connections to any community while at the Teaching institution, the percentage of students who had no such connections jumped to almost 10%. Students at the HBCU reported that they spent significantly more hours in community ($p < 0.05$) than any of the other institutions studied. No statistically significant differences in hours spent on extra-curricular activities were found among the Womens, Teaching, and Research institutions. The only other statistically significant difference in this data showed that students at the Faith-Based institution spent more hours in extracurricular activities than those students at the Womens and Research institutions but significantly fewer hours than students at the HBCU.

TABLE IV. GENDER DIFFERENCES IN COMMUNITY CONNECTIONS

| Community | Gender | |
|---|--------|--------|
| | Male | Female |
| Class & Lab | 12.84% | 14.06% |
| Extracurricular Clubs | 19.74% | 21.25% |
| Family | 69.80% | 78.43% |
| Friends | 22.00% | 25.31% |
| Living Area | 7.54% | 5.00% |
| Local Academic (Major) | 2.25% | 3.44% |
| Religious Organizations | 16.20% | 17.20% |
| Work Community | 2.25% | 5.31% |
| None | 6.42% | 4.63% |
| Percentages may not sum to 100% because not all communities cited are included in this table. | | |

Gender differences (Table IV): Men and women report connections to various types of community at surprisingly similar frequencies. The most notable difference among men and women appears to be in family connections where 78.4% of women report strong connections to family compared to men at 69.8%. Although not as distinct, women tend to report stronger connections to friends and to their work communities more frequently than men. In the remaining communities, men and women report strong connections with similar frequency. In terms of hours spent in outside community, no significant differences were found between men and women at any of the five institutions studied.

IV. DISCUSSION

Regardless of institution type, level in school, or major, most students cited *family* as a community to which they were most connected. Strong family connections that extend into adulthood can support mental health in adults, including

reducing fatigue, insomnia, and nervousness [13]. Strong family support is also frequently cited as a major factor in enabling women [14] and other under-represented minority groups [15] to succeed in engineering fields. The fact that STEM women, more than men, are showing strong family support in this study is encouraging for their continued persistence in rigorous programs. For other under-represented minorities, strong family ties can have the added advantage of counter-acting socioeconomic inhibitors that often affect immigrant families and minority populations in the United States [16]. Friends, while also playing an important role in students’ lives, make an expanded and slightly different contribution to the quality of students’ lives. Friendships provide social support that is more likely than family to be “received and interpreted in the spirit in which it is intended,” since it is provided by someone with whom the recipient shares a sense of voluntary social identity [17]. Haslam et al. [17] also tell us further that friends by giving “... sense of place, purpose, and belonging...give us a sense of grounding and imbue our lives with meaning. They make us feel distinctive and special, efficacious and successful” (p. 2-3). On average, over a quarter of students mention friends as an important community in their lives. While most students generalize friends regardless of how they met or where they live, some students specifically point to particular types of friends that make the most difference in their undergraduate experiences (Table V).

TABLE V. TYPES OF FRIENDS CITED BY STUDENTS

| Types of Friends | Male | Female |
|---|-------|--------|
| General | 78.4% | 75.3% |
| Hometown | 7.2% | 1.2% |
| Romantic | 1.4% | 1.2% |
| Hobby or Gaming | 2.9% | -0- |
| Peers | 10.1% | 22.2% |
| Percentages may sum to over 100% because some students report strong connections to multiple types of friends | | |

A notably higher percentage of students at the Teaching institution reported feeling strongly connected to no communities (9.5%) (‘None’) versus 4-6% for the remaining schools, with 5.6% overall. This may be attributed to the specific character of the average student. It appears that these students are more involved in outside work, so may not have sufficient extra time to feel as strongly connected even though they may be involved to some degree.

On a similar level to friends, connections to religious organizations are also frequently reported to be important communities. According to Saroglou and Cohen [18], religious community provides “a point of reference for what is normative, and provides validation for what is new”. Religious communities provide a connection to a community that has a “(glorious) past, present and eternal future,” thus joining the participant to a community with a long, shared, meaningful past [18]. In addition to these big picture benefits, connection to religious organizations has also been proven to have a number of educational benefits

including protection from behaviors that negatively impact educational performance, better grades, increased quality of time invested in academic pursuits, and improved sense of purpose and meaning [19]. Participation in church and other religious organizations seems to provide students with a sense of the ‘big picture’ that reduces stress and anxiety and provides a meaningful motivation for persisting in their studies.

Table VI.
EXTRACURRICULAR COMMUNITIES CITED BY STUDENTS

| Extracurricular Organization | Gender | |
|----------------------------------|--------|--------|
| | Male | Female |
| Student Government | 0.8% | -0- |
| Trade/Honor Societies(e.g. IEEE) | 10.6% | 8.8% |
| Sports | 36.6% | 19.1% |
| Music | 5.7% | 10.3% |
| Unspecified** | 35.8% | 30.9% |
| Other*** | 10.6% | 29.4% |
| International Groups | -0- | 1.5% |

Percentages may sum to over 100% because some students report strong connections to multiple extracurricular communities

**Students who simply stated “extracurricular club” or a similar generic response were grouped into the Unspecified category

***Responses that occurred less than two times were grouped into Other (e.g. 4H, ADPA, AnimeClub)

Participation in non-religious extra-curricular activities, while not necessarily providing the ‘big picture’ perspective of religious involvement, is also common among STEM students in our study. Students participate in a broad range of extracurricular clubs and organizations (Table VI). Participation in student government is rather poorly represented among STEM students, while men seem to integrate into sports communities far more frequently than women and women seem much more often to be strongly connected to music-based activities. The K-12 literature informs us that participation in clubs and sports provide students with opportunities to develop independence from their families as they “plan and arrange; make and correct errors; have real responses to real problems; and develop a sense of control” [20]. However, at the college level, while extracurricular activities have often been shown to positively impact academic outcomes [7-12], not all participation in extracurricular clubs has a uniform positive impact. In fact, contrary to the idea that social and academic integration enhance each other, some efforts to enhance social integration (through sports, for example) can compete with academic integration. Other factors, such as size of school and number of commuting students, also make it difficult to draw strong conclusions [21].

Gender Differences: Interestingly, women tend to more frequently (22.2%) cite peers as important friendships in their lives compared to men (10.1%), perhaps demonstrating the particular importance to them of belonging within their academic communities while in school. In these traditionally male-oriented disciplines, men likely need less peer affirmation. Although relatively low in percentage, the

difference between men and women with respect to hometown friends and hobby or gaming friends is also worth noting. Men named hometown friends at 7.2% and women at only 1.24%; this could reflect women’s incrementally greater emotional flexibility in making new personal ties. Men named hobby and gaming friends at 2.9% and women not at all; this may reflect a slight bias toward action activities for men versus a bias toward more personal relational ties for women.

Institutional Differences: The **Faith Based** institution tends to be characterized by a sense of community, especially within the STEM disciplines. Classes are small and access to professors is very good. Significant efforts are expended both inside and outside the majors to nurture students academically, socially, and spiritually. There tends to be high satisfaction among students with the programs. In addition, the character of the students who attend tends to be oriented and influenced by the Christian faith and values. Some of the results of the responses from the students seem to correlate well with cited research in this paper. Specifically, there appears to be an across-the-board elevation of community involvement among the various categories.

The **Teaching** institution is “typical” in that the strongest community connection identified by students is family. Its geographical location is known for strong family relationships and expected participation in family activities. Since the majority of students are from the local area, strong family involvement is logistically possible for many students and may reduce time spent with friends. Non-traditional students, a significant minority, have community with both their family of origin and immediate family. For some students, this fills all time not spent studying. Students also typically live on campus their first year but are usually living off-campus by sophomore year, reducing the impact of living area communities thereafter.

The **Research** and Teaching institutions are very similar overall, likely reflecting the predominant impact of student size on the ways that students choose and participate in communities. Interestingly, students at the Research institution report far more connections to friends than the Teaching institution which could reflect the fact that the Research institution has fewer students whose family home is local or it could reflect the dependence on friends to compensate for the impersonal nature of large classes and a demanding curriculum.

The uniqueness of the **HBCU** is that it connects students of an American ethnic minority. Similar to the other institutions, HBCU students’ strongest connection is to family but religious organizations and extracurricular clubs also emerge as important. The HBCU does not have a faith-based mission but studies show that African Americans are more religious than the United States population as a whole [22]. Thus, by concentrating African Americans, it seems that the values that are concentrated within the culture emerge independent of the mission of the university. The students also report spending more hours in extracurricular communities than the other institutions which plays a role in

student connectedness. Based on anecdotal evidence, this observation seems to be a result of the complex mixture of the culture of HBCU's, the culture of college-educated African Americans (>75% of mothers and >60% of fathers have attended college, including those who attended but did not graduate, based on demographic data in our survey) and the students' perception that participation in extracurricular organizations enhances employability.

Other than 'family', many of the distinctly mentioned community categories at other institutions are conflated at the **Womens** institution. Because the college is small, many students share living space and clubs with their friends. Of the four communities specifically mentioned in the survey prompt (family, religious, class, extracurricular), students at the Womens institution mentioned religious communities at the lowest frequency (9.2%). Although there are vibrant religious campus organizations, students may think of them as just another student group shared with friends. Notably, a higher percentage of students at the Womens college report a work community connection (5.8%). This may reflect this private college's limited financial aid resources versus other schools.

V. CONCLUSIONS

We can learn from the differences among our five institutions and work to leverage the best we find in each, but we also see that despite the differences, all people share the same needs when it comes to reaching their best potential as students, with family being the universal winner in terms of importance. In addition to expanding the number of participants to include more institutions or more majors within STEM, future work will also include understanding differences in community among disciplines and ethnicity (as well as among institutions and between genders as described in this paper) in the hope that such understanding can enable faculty and administrators to both create more effective community within an academic context and also to support and encourage participation by students in outside communities that meet essential needs for belonging and connection. Most students find meaningful community one way or another. However, a notable number apparently do not. It may behoove schools to respond to this by looking for ways to intentionally encourage more community engagement for those students.

Why Do Some Engineering Students Study Alone?

Elizabeth Burpee, Cheryl Allendoerfer, Denise Wilson, and Mee Joo Kim

Seattle, Washington, USA

eburpee@uw.edu, callendo@u.washington.edu, denisew@u.washington.edu, mjk5ad@u.washington.edu

Abstract - This paper looks at undergraduate engineering students who have solitary study habits and do not frequently engage with classmates. These students, referred to as ‘academic solitaires,’ explicitly state that they do not interact or study much with their academic peers and may find a sense of belonging elsewhere. Using a mixed methods approach (including interviews with students and surveys), our data show that while some students are happy studying alone and do so by choice (‘preferred solitaires’), others universally express feeling like an outsider and study alone as a result (‘outsider solitaires’). We argue that many of these outsider solitaires may be at risk of dropping out or changing fields over short, moderate, or long-term time scales. As part of our mixed methods study, we have identified a unifying set of indicators that can be obtained by survey at much lower self-select bias than recruiting students for interviews. We found that this approach allows greater success in identifying outsider solitaires at potential risk of dropping out. In this pilot study, we show that using these affective indicators in survey form can potentially allow practitioners to identify students at risk of dropping out long before they reach the point of leaving.

Keywords – *belonging; community; engagement; isolation; solitude*

I. INTRODUCTION

Studies have shown that while studying in groups facilitates the learning of many students, students lacking community connection and feelings of belonging may be at risk of dropping out of STEM majors or professions. However, some students do study alone for a variety of reasons, and these reasons can be predictive of whether or not they will remain in their STEM field. This paper draws on data from a five-year study that examines how students’ feelings of connection to community and belonging influence both their study patterns and persistence in their major field, and seeks to understand how at-risk students may be easily identified.

II. BACKGROUND

The importance of working in groups compared to working alone has been demonstrated in a wide variety of K-12 studies. For example, in a study of sixth graders

randomly selected for inclusion in cooperative learning exercises, both high and low achieving students demonstrated better performance and attitude toward group learning than solitary peers [1]. In higher education, however, findings are mixed. Hansen [2] found that while some team learning experiences grow student motivation and achievement, others might be less than beneficial. For example, when undergraduate instructors place students in work ‘teams’ without first educating students on team skills and competencies, teams are more likely to lack leadership and development, providing little benefit to students. In contrast to team learning, studies which examine study habits show that some students may actually perform better when working alone [3]. Other studies in higher education have shown that students working in groups can be vulnerable to social loafing where individual responsibility is diffused into the group responsibility, allowing students to do less than they would do if working individually [4]. Thus, studying or working alone, while often viewed as a negative, clearly provides some individuals with stronger and more productive experiences.

Despite mixed findings regarding the impact of studying alone, it remains a concern because studies show that this behavior may be related to non-persistence in STEM majors or professions, as well as limiting students’ academic performance and individual fulfillment. The significance of community connections in regard to undergraduate academic retention is supported by Tinto’s model of social integration, in which student goals and commitments formed by pre-college attributes interact with their college experiences to indicate whether students are likely to complete an academic program [5]-[7]. This link between belonging and persistence is also consistent with studies that have shown isolation or lack of community as a primary reason why women leave engineering fields after graduation [8]-[9]. Fouad and Singh [10] also show that many women with an undergraduate degree in engineering either never enter the field or eventually drop out due to unfavorable workplace culture, amongst other factors.

These explanations of why students may drop out of STEM majors or professions are useful, but we are also interested in finding specific indicators that may help us identify these students early on in their STEM education in order to better facilitate their sense of community and belonging. In looking to prior research on indicators for STEM dropout or switching, indicators have been primarily focused on academic achievement, not necessarily

correlated with a student's sense of community or belonging. For example, in a study conducted at a Texas research university, Scott et al. [11] found a significant correlation between an undergraduate's high school rank, combined mathematics and reading SAT scores, and their retention in mathematics and science majors. Thompson and Bolin [12] implemented a 7-year cohort study with freshmen matriculating into STEM majors at a large public university in Texas. Their results confirmed Scott et al.'s findings that high school rank is correlated with whether or not a student would drop out of college, switch majors, or graduate. Though these indicators are helpful, they lack qualitative insights as to 'why' these actually matter and avoid the larger issues of isolation and community that other researchers [5]-[8] have identified as reasons why some students may leave STEM fields.

By digging deeper into why students study alone, we seek to find ways of easily identifying those within this group who really are at risk of leaving STEM majors and professions. If we can successfully identify these students, we can streamline interventions for them, reaching them more quickly and effectively than broader-based interventions with more generalized appeal.

III. RESEARCH METHODS

The present analysis was guided by the following questions:

- *What are the primary differences between engineering students who study alone by choice and those who do not study alone by choice?*
- *How can engineering students who study alone not by choice be easily identified?*

These questions were addressed using quantitative and qualitative methods, including a survey and follow-up interviews.

This paper draws on data from a larger, five-institution study; however, in order to limit contextual variables, data from only one institution figures into the present analysis. This institution is a large research university in the Pacific Northwest. This institution offers a wide range of engineering and computer science majors and is characterized by densely populated groups of students (class sizes of 30-500) who enter the program (competitively) during mid-sophomore year. Teaching assistants are common in core courses and complement limited faculty time per student. Instead of focusing on all STEM majors, this paper focuses only on the study habits of students in engineering fields.

Survey participants were recruited during the Spring 2010, Fall 2010 or Spring 2011 academic quarter. Participation in the study was voluntary and students were assured that their survey responses would be confidential. Most subjects were recruited from core major (required major) classes in each discipline, primarily at the sophomore

and junior level (although some seniors were also taking the target courses and were not explicitly excluded from the study). All students who were recruited from target core classes were asked to complete a survey (on paper) during each of these classes. The participation rate in all classes was 90% or higher, and almost all students who offered to participate completed almost all of the survey (95% completion or higher). All results were cross-sectional; no attempt was made to capture longitudinal responses from across quarters in the study.

Survey respondents were then recruited via email to participate in follow-up interviews (some conducted with individual students, other conducted with more than one student) in Spring and Fall 2011. The response rate by e-mail recruitment was approximately 20%. The characteristics of students at the research institution who completed surveys and those who participated in interviews are seen in Table I. Student interviews were audio recorded and transcribed, and students were assigned numeric codes to assure confidentiality. Interview questions covered a range of topics, including student participation in academic and nonacademic communities, student sense of belonging to their major, and student participation in class.

Interview transcripts were coded and analyzed using the constant comparison method [13]-[14] to identify emergent themes and trends. In analyzing the interview transcripts of participants at the research institution, it became apparent that a subset of 7 participants reported studying alone. This subset of students was characterized as 'academic solitaires.'

Within the academic solitaires group, there emerged major differences in the reasons students gave as to why they studied alone. In order to further explore these differences, the survey results of the 7 academic solitaires were compared to the full set of all survey results from participants at the research institution. From this comparison, four constructs were identified as differentiating the academic solitaires from the rest of the participants, and also differentiated two distinct sub-groups within the academic solitaires group: 'preferred solitaires' and 'outsider solitaires.' A construct was considered to be of interest only if all of the outsider solitaires' scores fell two or more standard deviations away from the mean for that particular construct. A total of four constructs were

| Data Collection Instrument | | Interview | Survey |
|----------------------------|----------------------------|-----------|----------|
| Total | | 38 | 435 |
| Gender | Males (%) | 28 (74) | 296 (68) |
| | Females (%) | 10 (26) | 139 (32) |
| Major | Electrical Engineering (%) | 12 (32) | 100 (23) |
| | | | |

TABLE I. CHARACTERISTICS OF STUDY POPULATION

identified in this way as being indicative of 'outside solitary' status.

After identifying these four constructs, we returned to the survey data and identified additional respondents whose survey results fit the 'outsider solitary' profile, meaning that they had scores two or more standard deviations away from the total mean (in the same direction as the original outsider students) for at least three of the four constructs of interest. We then contacted these newly identified students, using the original interview recruitment protocol. Individual interviews with these students were then conducted, using the same original interview questions and protocol.

IV. RESULTS

Of the 38 students who participated in interviews at the focus institution, the large majority (82%) reported that they regularly chose to study with peers, whether in formal lab groups or teams or in informal study groups. However, the responses of 7 students (18%) stood out in the data by reporting that they typically studied alone. These students fall into the category that we are calling 'academic solitaires.' In examining more closely the ways in which these academic solitaires talked about their study habits, differences in the reasons behind their choices emerged.

A. Research Question #1: What are the primary differences between students who study alone by choice and those who do not study alone by choice?

The existence of two distinct types of academic solitaires first emerged through analysis of the interview data. In the interviews, four of the seven academic solitaires asserted that they chose to study alone because they felt they worked better that way, or saw studying with peers as a hindrance to their learning. These students, who were all male, will henceforth be described as 'preferred solitaires.' Examples of explanations given by these preferred solitaires include:

"Study groups do not work out. ... The thing is, first of all people talk, people chat and that becomes a problem and eventually you are the ones that have to figure it out. ... So I think studying alone actually is a lot more efficient. ... When you spend too much time helping others, you don't have time for yourself to study."

"I'd rather trust in my ability to figure it out on my own with the assistance of the book than to go to a different student who I don't know how competent they are and get their help on it."

In contrast, the remaining three academic solitaires indicated in their interviews that although they currently studied alone, this was not necessarily their preference. It is notable that all three of these solitaires were women in the electrical engineering major. These students will henceforth be referred to as 'outsider solitaires.' These outsider solitaires reported that their solitary study habits were due to certain barriers in the academic environment that kept them

from participating in academic communities. Regardless of whether these barriers were perceived, self-imposed, or based on fact, these barriers made the students feel alone and outside of the realm of their peers, thus affecting how they studied and sought academic resources. For example, as one student related, a barrier to participation has been feeling (justified or not) academically inferior to her peers:

"For engineering classes, I don't talk at all. I'm one of those students who sits in the first row and don't talk at all. ... I feel a lot more reluctant to ask any questions because I feel like, 'Oh everyone already knows the answer.'"

Along similar lines, another student identifies her gender as a reason for feeling like an outsider in her major. She describes it as a barrier to engagement and belonging with her peers, recalling that:

"I didn't really ask too many questions in my group either because, part of the reason was probably that I was the only girl in my group and one of the kids in the group would every now and then say something about girls and, you know, how they couldn't really do engineering and stuff, so that made me feel like, if I was confused, I didn't want to ask for help to show that I was confused, and not understand. ... So I didn't really get help very much in the class."

The third student made a similar comment, indicating that although she appreciated getting help from other students, she felt like an outsider when trying to connect to her peers:

"I might need someone to...kind of show me what's going on and that helps majorly. And in that case, yeah, having people that I'm designated, that you are allowed to talk to these people, like a small lab group or something. Whereas in, like, a large class where you don't have...established people that you can talk to because there's just too many people, then it's difficult to keep that structured response under control. You feel really kind of alone."

She then talked at greater length about the dilemma of wanting to work with peers but being inhibited by large groups:

"I actually think labs would be better if it were only two people instead of three people, because ...if it's just three people, I tend to be the one left out of the two. ... I'm able to follow along, but it makes me feel really bad if I'm not contributing as much as I feel like I should or if it seems like they're doing everything, because I want to help, and I want to learn as much as they do. I just need a little more time."

As illustrated by these example quotes, all three of these outsider solitaires exhibited a desire to study with their peers, yet were hesitant to seek out groups for study or help. The three women attributed this to barriers such as self-identified intellectual ineptitude, a fear of being shunned by peers, and/or not knowing who they are 'allowed' to talk to

in academic communities. Additionally, though these women talked about academic resources being available to them (e.g. office hours), they referenced perceived barriers in seeking out those resources or comfortably accessing them.

To further understand the differences between the two types of academic solitaires, we looked at their survey responses. In doing this, consistent differences emerged between the two groups' responses along the four constructs described in Table II. The constructs 'Belonging Class Total' and 'Emotional Engagement Positive Class' were measured by four survey questions, while 'Emotional Engagement Negative' was measured by five survey questions, and 'Emotional Engagement Positive' by six survey questions. All questions were answered using a 5-point Likert scale.

TABLE II. CONSTRUCTS USED TO IDENTIFY OUTSIDER SOLITARIES

| Construct | Description |
|---|---|
| 1. <i>Belonging Class Total</i> | Refers to the student's sense of support, acceptance, comfort, and membership in a specific class in their major. <i>Example survey question:</i> "I feel that I am supported in this class." |
| 2. <i>Emotional Engagement Positive</i> | Refers to the level of a student's positive affect about learning and being in their major classes and lab/study groups. <i>Example survey question:</i> "I enjoy learning new things in my major classes." |
| 3. <i>Emotional Engagement Positive Class</i> | Refers to the level of a student's positive feelings about a class in their major. <i>Example survey question:</i> "When I'm in this class, I feel good." |
| 4. <i>Emotional Engagement Negative</i> | Refers to how often a student feels frustrated, angry, overworked, or insecure in their major. <i>Example survey question:</i> "When I'm in my lab/study group, I feel worried." |

Fig. 1 shows the mean survey scores for these four constructs for all survey respondents at the research institution, for the preferred solitaires, and for the outsider solitaires. While there is little difference in the mean scores between all survey respondents and the preferred solitaires across the four constructs, the outsider solitaires exhibit, on average, lower class belonging, lower overall positive emotional engagement, lower positive emotional engagement in their major classes, and higher negative overall emotional engagement. When compared to all survey respondents, outsider solitaires' responses were two or more standard deviations away from the mean on each of the four constructs.

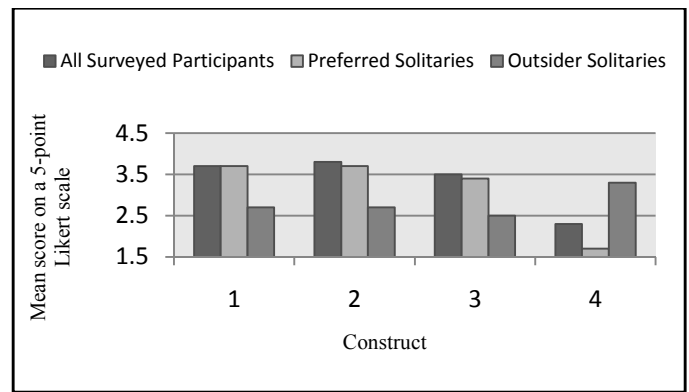

FIGURE 1. SURVEY RESPONSE MEANS BY GROUP

B. Research Question #2: How can students who study alone not by choice be easily identified?

Using these four constructs as possible indicators for identifying outsider solitaires, we returned to the full set of survey data and identified additional students whose scores fell two or more standard deviations away from the mean in at least three of these four constructs (in the same direction as the original outsider solitaires' scores). We then interviewed four of these identified students.

Similar to the three original outsider solitaires, the newly identified outsider solitaires discussed a variety of reasons why they were not (or had not been) engaging with their peers. Though all four of these newly identified students felt like outsiders in one way or another, three also showed a desire to work with other students and, based on the literature, seemed to be at risk of dropping out. One student interviewed had already switched out of her engineering major since taking the survey and commented on her new level of comfort and engagement:

"I think I belong better maybe than a year ago [when in previous engineering major]. Before, I didn't really go to lab because I didn't really know anyone there and would work home on my laptop. Now that I have friends the lab is like my second home and I feel pretty comfortable."

She further commented on her desire to connect meaningfully with other people, distinguishing her from preferred solitaires:

"People are the most valuable things in your life. If you don't have people around you, you'll feel lonely and life will become miserable."

Another newly identified outsider solitary indicated his perceived intellectual ineptitude as a barrier for approaching other students, mirroring the statements of the originally identified outsider solitaires. He stated:

"I like school much less than the average person. ... There are many times when I feel like I'm super lost and everyone else around me knows what's going on, and I'm the dumbest person in the class."

In reviewing the similarities in interviews and survey responses from these newly identified outsider solitary students in comparison to the original outsider solitary students, we conclude that we successfully identified new outsider students via the four survey constructs. Fig. 2 shows how these outsider solitaires were found through our mixed-methods approach and how they may be found only using surveys.

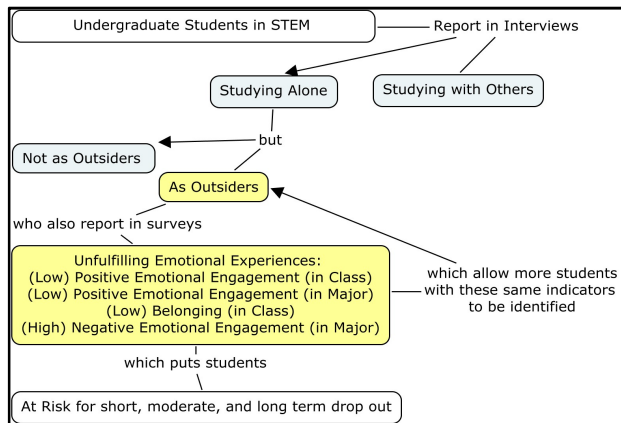

FIGURE 2. CONCEPT MAP: IDENTIFYING OUTSIDER SOLITAIRES

V. DISCUSSION AND IMPLICATIONS

The findings of this study provide insight into the differing characteristics of students who study alone by choice (preferred solitaires) and those who study alone not by choice (outsider solitaires). The findings provide further insight into how outsider solitaires differ from their rest of their academic peers, as well as how institutions might identify the at-risk outsider solitary students via easily administered quantitative methods while students are still in their academic STEM major.

We have found that engineering students who feel like outsiders and thus study alone have low feelings of positive emotional engagement, high feelings of negative emotional engagement, and an overall low sense of belonging to their major. These outsider student are not only studying alone, they also feel alone in that they are emotionally disconnected from their major peers and perceive academic resources (such as faculty) as unavailable to them.

The literature shows that engineering students, especially women, who feel isolated from their academic community are at risk of dropping out of their major or field. Our findings confirm this theory; of the eight outsider solitaires identified through our research, the majority have already seriously considered dropping out: one student dropped out of her engineering field after taking the survey; one is already planning to go into a non-engineering field upon graduation; and two are currently questioning whether or not to continue in an engineering field once they graduate.

We acknowledge that while our sample pool of outsider solitaires is small, we hypothesize that similar results would be found if using the four constructs as indicators to identify outsider solitaires from a larger pool of students. Additionally, we acknowledge the potential for response rate bias in our research as students who were interviewed actively responded to recruitment emails. Finally, we acknowledge that the majority of the outsider solitaires identified were women, many of whom were electrical engineering majors. Though we do not seek to make any specific inferences based on gender or major in this paper, we do feel this is prudent to note for further research.

VI. CONCLUSION

Our research shows that while some students are fine or even happy studying alone, others do so because they feel like ‘outsiders’ in their major. In feeling like an outsider, students report poor feelings of belonging and engagement, putting them at greater risk of dropping out from both their major and the engineering profession post-graduation. These findings are supported by literature that shows belonging and lack of community as related to student persistence [8]-[9]. Thus, we argue that identifying students with lagging engagement and belonging indicators can be an effective technique for reducing drop-out when used in conjunction with targeted interventions to help these students feel less like outsiders and more like part of the group.

In a time when universities are tightening budgets and admitting fewer undergraduate students into engineering majors, it seems in the best interest of engineering departments to ensure student retention not only in the major while these students are still in school, but also in the profession over the long term. We no longer have the luxury of turning out large numbers of engineering degrees than we need engineers in the workforce. While other studies have shown that poor academic performance often leads to drop-out, an increasing number of studies in STEM point to affective indicators as even earlier indicators of the risk of dropping out. This study adds to this growing body of literature by characterizing a specific type of student who can be identified as at-risk through surveys regarding engagement, belonging, and study habits. While this study clearly lacks the numbers of participants to make conclusions as to how prevalent the outsider solitaire is among STEM students, it provides a means for identifying this type of solitaire efficiently in future studies and interventions.

Thus, while this study is limited in that it does not allow us to identify how many students are at risk from solitary study habits, it does allow us to avoid targeting all those studying alone under the presumption that studying alone by itself creates risk for dropping out. A natural next step of this study would be to identify the number of students who fit the profile of the outsider academic solitaire by using the

survey items described herein along with an additional series of survey items targeted toward identifying solitary study habits. Our study has shown that, due to self-select bias, interviews identify a much smaller percentage of outsider solitaires in a population than are actually present. Surveys reduce this self-select bias and may be the most efficient method to identify this group of at-risk students.

The self-select bias that we see in this study also has implications to intervention with outsider solitaires. These students are likely to resist direct confrontation to change their study habits into more group-oriented modes. Thus, interventions are likely to be more successful if done more gradually, perhaps using electronic bulletin boards and other online options to transition the student into the 'insider's' circle of learning and thriving within the academic environment.

Work in Progress: An Interactive Online Educational Support System Considering Real-World Human Relationships of Students

Asako Ohno

Osaka Sangyo University, Japan. ohno@eic.osaka-sandai.ac.jp

Abstract—This study aims to make university lectures more enjoyable and fruitful by providing a virtual discussion space closed to outside participants. This web-based educational system has the appearance of an online game, similar to a quiz show. Fearing humiliation, some students hesitate to state their opinions or ask questions in front of unfamiliar classmates. This study tries to resolve this issue by protecting the anonymity of students, thereby providing them with an interactive and cooperative learning environment free from the influence of real-world human relationships, which can significantly influence student engagement. Students can view and compare each other's opinions, answers, response time, and confidence levels, without individual identification. Additionally, I report the results of a questionnaire administered to 107 university students regarding the integration of educational games into my classroom lectures to evaluate the effectiveness of my approach, and present a brief explanation of the educational system I am developing.

Keywords - active learning; on-line system; educational game; half-anonymity

I. INTRODUCTION

With a downward trend in birthrates, a diversification and personalization of educational services is required in universities. At the same time, students are less interested in classroom lectures because of a decline in their academic abilities. Active learning [1] is one solution to these problems. Many findings and success stories have been reported by researchers, as illustrated by [2] and [3]. As many case studies have demonstrated, instructions in the form of a game have a beneficial effect on attracting the interest of students in any generation, although [4] noted that many educational games are not based on a coherent theory of learning. I used an online educational quiz game [5] as a part of instruction in computer literacy classes between April 2008 and March 2012 and obtained some positive feedback. The students showed more positive attitudes toward the course contents than when I employed other education methods and tools, such as oral explanation, group work, online surveys, and audiovisual aids. Moreover, my preliminary survey of 17 students who had experienced each of these four methods and tools showed that 50% found game-based instruction to be the most engaging education method and that 93% supported its effectiveness. Yet, although educational games are attractive, some students remain reluctant to participate, even in the context of an online, game-like education system, involving quizzes and discussions. To resolve this issue, I propose an online educational game open to class members only, where students

are protected by a specified level of anonymity to exchange their opinions without constraint.

In this study, I clarify the following questions: (1) What makes students passive or reluctant to participate in classroom discussions? (2) Can a half-anonymized online discussion system help to deal with this issue? (3) What level of anonymity effectively encourages students' positive attitude toward class work?

I discuss these questions along with the findings from a questionnaire investigation into the effectiveness of this type of educational support system. I also give a brief explanation of the development of this half-anonymized online discussion system.

II. QUESTIONNAIRE INVESTIGATION

I administered a survey to 107 university students to investigate what discourages students from participating actively in classroom discussions, how students place educational games among many other kinds of teaching methods, and to what degree the educational game I propose meets students' needs. To examine what makes students reluctant to present their opinions in class, I asked students to rate the following statements: Q1: I actively give my opinion during class, Q2: I like to engage in discussion with a small group (if they are randomly chosen classmates), and Q3: I like to engage in discussion with a small group (if they are all my friends). The answers are shown in Fig. 1. According to the free descriptions provided, students are reluctant to state their opinions in front of less friendly classmates, since they are afraid of being humiliated.

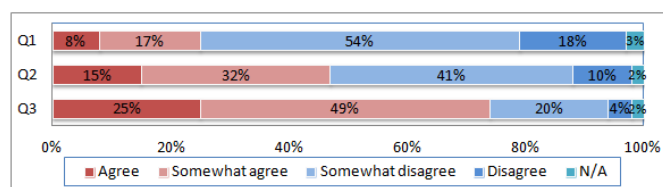

Figure 1. Students' shyness prevents them from expressing their opinions.

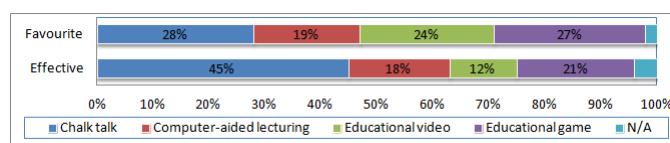

Figure 2. Student views on education methods, in terms of popularity and effectiveness.

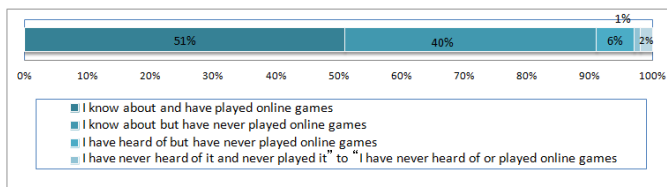

Figure 3. Popularity of online games

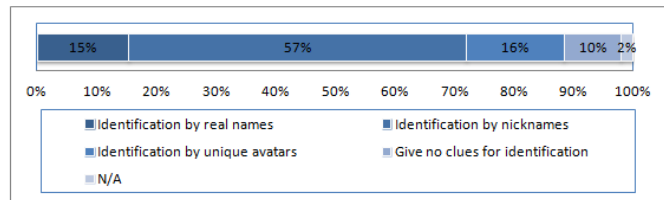

Figure 4. The desirable anonymity rating differs among students

Fig. 2 shows that educational games were ranked second in terms of popularity and effectiveness as an educational method, after “Chalk talk”. Fig. 3 shows the popularity of online games. Surprisingly, 97% of students played or knew about online games—many played such games on PCs and smart phones.

I asked students whether they would want to identify each other while conducting discussions on an online educational game open only to classmates and the instructor. The results are shown in Fig. 4. Only 15% of students wanted to use their real names, while 10% wanted to give no clues to their identification, and 73% wanted half-anonymity by displaying nicknames or using a unique avatar to identify themselves purely in their role as players of the game.

Based on the questionnaire investigation, I confirmed that educational games are supported by students, since they make classroom lectures more interesting, and because they believe that such games are effective for their learning.

III. IMPLEMENTATION

I am developing a half-anonymized, online classroom discussion system, using HTML5 and JavaScript. I use JavaScript packages [6] [7] that enable scalable, real-time chat functions. The system currently runs as a simple web system, as shown in Fig. 5, and employs a graphical user interface (GUI) with an appearance and functions similar to a quiz show to make online discussions more convenient and enjoyable. In a modified version, students log in to an online 2D quiz game and use individual avatars to answer multiple choice questions related to the course content. Students can log in to the same online quiz simultaneously and observe the behavior of one another’s avatars. The system enables participants to observe others’ decision-making process, including which options other students choose and how long it takes others to make their final decisions. While answering quizzes, students can share their opinions and publicly ask questions by sending a short message displayed as a speech balloon beside their avatar.

Fig. 5 displays our current version of the client interface for students. Students input their answer or opinion with the level of sureness using the web form shown in (A); messages submitted by students are listed in (B). Students can view and compare answers, opinions, time taken to make decisions, and

confidence ratings of other students, without being able to identify them.

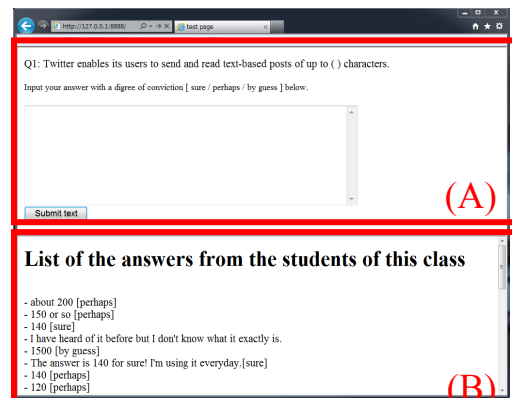

Figure 5. Current version of the client GUI (under development)

IV. FINDINGS AND FUTURE WORK

According to the results of the survey, educational games are supported by many students.

While other studies have utilized online discussion systems to enable people in different places to exchange opinions as if they are together, I focus primarily on the anonymity of the online game. A certain level of anonymity seems to help students communicate with each other without being affected by real-world relationships. Additionally, an appropriate level of anonymity might contribute to mitigating the over-competitive nature of educational games. As my immediate task, I am developing a GUI to make the system more like a quiz show and therefore more attractive and usable for students.

Additionally, a minor concern is that some educational games make lectures over-competitive so that students feel the pressure of being ranked and therefore lose confidence and interest. In future work, I will investigate how adjusting anonymity levels might lessen the impact of this issue.

Managing International Student Collaborations

An Experience Report

Åsa Cajander, Mats Daniels
Uppsala University
Uppsala, Sweden

Can Kultur, Lori Russell Dag
Bilkent University
Ankara, Turkey

Cary Laxer
Rose-Hulman Institute of Technology
Terre Haute, USA

Abstract— Knowledge and experience from working in international collaborative projects prepares engineering students for their future careers in a global market. Hence this is an important element in higher education, although seldom provided in the curriculum. One reason for this lack might be uncertainty in how to manage international collaborations and to create a good learning environment for the development of skills related to international collaborations. Therefore this article describes our experiences from managing international student collaborations including theoretical underpinning for our choices when relevant. Having given the context of, and the strategies for running our two collaborations, we provide an analysis of our experiences. This includes observations of differences in the two collaborations, both when due to use of different strategies and when due to different contexts, as well as observations of similarities. With this in mind, we present recommendations for running international student collaborations.

Keywords— component; International student collaboration, open ended group project, experience report

I. INTRODUCTION

Our experiences stem from two international student collaborations in projects with real clients based on the Open-Ended Group Project (OEGP) concept [1, 2]. One collaboration is between an American site and a Turkish site (US-TUR) and the other between the same American site and a Swedish site (US-SWE). The former has run twice and the later seven times. Both collaborations include real clients and open-ended problems but the courses have different syllabuses and the collaboration between the universities is based on informal grounds. While neither international student collaborations nor the OEGP concept are new ideas, they are in the authors' opinions underused in learning environments.

Running international collaborations typically means having to deal with differences between the educational settings, e.g. learning objectives, course durations, contexts in curriculum, and grading schemes. Other general issues are cultural differences, having different holidays, few if any face-to-face meetings, and being in different time zones. In our collaborations we also have to deal with having clients local to one site, which means having language issues and students having different access to the client, and how to handle that some students are being graded by faculty from another site. Other educational issues include how to motivate students, how to provide scaffolding, how to use collaborative technology, and having a learning process focus or end-product focus for the project.

The aim of the paper is to inspire others interested in running international student collaborations by sharing our experiences from working with international student collaborative projects from a management perspective and to relate our choices in creating learning environments to relevant engineering education research.

II. CONTEXT

A. Bilkent University (BU), Ankara, Turkey

The University is the first private non-profit university in Turkey and was founded in 1984. With its approximately 12,000 students, the university is well known as a pioneer research oriented Turkish university. Starting from spring 2009, the collaborative International Term Project course has been held during the spring semester that runs from early February to the end of May, and has generally between 5 and 10 students per semester. This is a required course in a computer science education focused program in the Faculty of Education. The course aims to allow students to collaborate with peers from different cultures as part of an international team and work with a client to assess their needs and requirements to develop a technological solution. Students gain experience with interpersonal communication and conflict resolution within teams [3].

B. Uppsala University (UU), Uppsala, Sweden

The university has approximately 40,000 students and is hence one of the largest universities in the country. The IT in Society course is given in the fall semester of the IT engineering program. It runs for the whole semester, i.e. beginning of September to Christmas. It is a 15 credit course, i.e. representing half of the 30 credit study load for a semester. The course is elective and the number of students has varied between 10 and 25 during the years we have had an international collaboration, i.e. since 2005. The course has been presented elsewhere; see for example [2, 4 - 7]. The learning objectives for the course are in short to provide students with substantial knowledge and ability concerning the interplay between technology, users and organizations based on relevant areas in human-computer-interaction, psychology and system construction, as well as experiences in real systems developing projects.

C. Rose-Hulman Institute of Technology (RHIT), Terre Haute, IN, U.S.A.

A private engineering school in the United States, it was founded in 1874. The Computer Science and Software Engineering department offers undergraduate programs in

Computer Science and in Software Engineering. The Computing in a Global Society course is an elective for both majors. Learning outcomes of the course include being able to explain the importance and relevance of globalization, in particular as it relates to computer science and software engineering. Other goals are to be able to communicate effectively with teams from other countries and cultures and to demonstrate effective work with these teams to complete a project.

D. Collaboration between Swedish and US Students

The collaboration started in 2005, and has evolved using an action research framework since then. This includes a constant iteration of plan, act and evaluate which has resulted in many improvements of the course as well as some changes not contributing to improvement.

The client of the student project is the county council in charge of health care in the Uppsala region of Sweden. They have provided the student projects with different open-ended and complex problems relevant for the use of IT in the healthcare sector. Some examples of problems have been to help the county council to prevent and recognize data intrusion problems related to the use of a common patient record. The majority of students had their major in computer science or IT, but some students had other majors such as mechanical engineering. Most students had studied for three or four years at the university.

E. Collaboration between Turkish and US Students

This collaboration started in spring 2009, and is currently in its 3rd offering. For each of the collaborations, student teams complete a software project for a non-profit international organization located in Turkey. The International Children's Centre has been a client for all collaborations, and UNICEF (Turkish National Committee) for one of the collaborations.

Students from the US visit Turkey twice during the semester, once at the beginning of the project and once at the end. Students meet with the client at least once during each visit, at the beginning to analyze the problem and present their proposal, and at the end of the project to present their completed project to the client.

Although the courses are not identical to each other, the client proposal and the software design and development process form the basis of the student collaboration. During the semester, students are monitored through weekly meetings and other activities, such as progress reports.

III. INTERNATIONAL COLLABORATION CONSIDERATIONS

This section describes identified management issues regarding the collaboration including relevant theoretical underpinnings.

A. Educational Setting Differences

Running international collaborations typically means a few challenges when it comes to dealing with the differences in educational setting. The collaboration could be set in a joint course, but institutions typically want to have their courses

defined according to their own standard. Different courses mean having to overcome differences in learning objectives. This doesn't mean that it is an objective to have the courses as similar as possible, but rather that the collaborators need to be aware of the differences and have strategies for dealing with them. The challenge is to turn the differences into advantages, or at least into something that does not jeopardize the collaboration.

Other differences to manage might be different course durations, contexts in their curriculum, and grading schemes. The difference in course duration could be that one cohort continues with their course after the other has finished, which in the US-SWE collaboration is solved by the American students enrolled agree to work to finish the project after their study period has ended. A similar issue with the course duration in the US-TUR collaboration was solved by redesigning the course. That the contexts for students in the collaboration are different can either be an issue for each student to cope with, or for the faculty to try to smooth out.

B. Cultural Issues and Communication

Cultural differences affect the project in many ways including the communication and work styles of the participants. Culture impacts people's interpretation situations and how they react to them [8]. Language differences are part of this; they are experienced to different degrees within each of the collaborations. The communication language for all projects was English. While all participants in the collaborations are proficient in English to varying degrees, some students find it difficult to communicate remotely in their non-native language. Non-verbal cues may be missed, and often lead to frustration and misunderstandings. One method to address this in the US-SWE collaboration was the introduction of an external expert in intercultural collaboration and communication starting in 2007. In the US-TUR collaboration, the same expert was part of the collaboration in 2011 and other speakers with experience in both cultures have also been invited. The work with intercultural competence has been elaborated in other publications; see for example [9, 10].

In the US-TUR collaboration, although there were cultural differences, more important were the observed interdisciplinary cultural differences within the team. The Turkish students have an IT focus with a view of instructional processes and have a tendency to focus on user and learning needs. In contrast, the US students being computer science majors have a more technical focus and expectation. The Turkish students often felt that there was not enough discussion of the interface and the design components, where the US students often felt that the time would be better spent starting the implementation and working on the interface design details at a later point in the project. Although students felt the impact of these differences, they were rarely, if ever, discussed among them. The issue was addressed in part by coaching the team members, and encouraging them to recognize the different strengths and act as leaders in their specialty areas.

Issues such as different semester schedules, break weeks and holidays are important considerations in the management of the project. Time changes, holidays, and school breaks, if

they are unexpected, might lead to missed deadlines and considerable frustration within the teams. One strategy used was the preparation of a common schedule that could be accessed by the students and instructors throughout the project. The schedule included holidays, break weeks and the different dates for daylight saving switches. This allows students (and instructors) to be aware of and plan in advance for any downtime in the project.

When working in globally distributed projects, the difference in time zones makes collaborating in real time difficult and increases the response time in getting feedback from teammates [11]. As described by Holmstrom et al. [12], 'despite flexible work hours and communication technologies that enable asynchronous communication, extensive delay in responses brings with it a feeling of "being behind" and "missing out" – even losing track of the overall work process'. In most local projects, students are able to access their teammates whenever necessary to ask a question or to get immediate feedback on any issue that comes up. With global projects, students do not have this immediateness of communication and the different time zones often create difficulties for the team as they require the students to plan and prepare in advance. One strategy is to provide guidelines to the students about email/communication etiquette such as the time frame for replying to messages, the importance of replying to messages, etc. Another way the issue was addressed was to establish regular (in this case, weekly) full team meetings. This has drawbacks as well because students often wait for these meetings to get the necessary feedback instead of arranging informal sub team meetings or sending messages as needed, leading to delays.

According to Smith and Blanck [13], 'an effective team depends on open, effective communication, which in turn depends on trust among members'. They suggest that if a team can get together for face-to-face interaction, they should do it at the beginning of the project where trust can be established while planning the project. During the collaborations the US students are required to visit the partner university at least once in the project. During the visit weeks students are encouraged to spend as much time together as possible to encourage team building. Especially at the beginning of the project the face-to-face meetings are very important and they help students to establish a social interaction, and makes communication throughout the project more efficient. In cases where all students have not visited the partner institution at the outset, it has been observed that there is little social interaction, and students have a difficult time initiating communication and bonding as a team [2, 5].

C. Client Selection

After examining many current instructional models, Merrill [14] underlines that the most effective learning products or environments are those that are problem-centered. Having an external client is one way to add work related aspects [5] to the collaboration. This will, in most cases, mean that the client is local to one of the collaborating sites. One issue with such a setting could be around language, since it might be that much information is only available in a language not master by the non-local site(s). This has been the case in the past and has

been addressed by the local students providing English summaries of all relevant information.

Another issue to have strategies for is the uneven access to the client. The local students can have face-to-face meetings with the client and other personnel in the client's organization. There need to be ways to share information obtained locally, which is the same issue irrespective of the location of the client and the organization even though it is more difficult to solve. The potential for a sense of unfairness is however a unique issue to deal with that is due to the locality. There is a definite danger that the motivational reason to include the client might turn into a de-motivational factor for the non-local students. It is thus important to provide opportunities for the non-local students to feel that they can contribute with something extra that is due to them being from another place. This could, for example, be to add internationalization aspects to the project. Having the client from another city or from a third country may help to decrease the possibility for de-motivation, however this decision would increase the complexity of the settings. An ideal client may be an international organization that has units in the cities of the collaborating universities.

One issue raised by interaction with real clients is that they have other obligations and consequently it can be difficult to get reasonable access to them. This particular aspect has been mitigated in the US-SWE case by use of a single, reliable client and requiring all students to work on different aspects of a single project.

A further potential issue with a real client is that some students may feel ethically unable to help certain clients, e.g. for political, religious, or competition reasons. Because of this, we have chosen to work with the public health sector, in the US-SWE collaboration. Similar considerations in the US-TUR collaboration lead to selection of an international non-profit organization with a focus on children's rights as client.

D. Student Assessment

There are different possibilities for how to grade the students, but it is likely that faculty from a remote site will have a say in how a student is graded.

A related issue is that students might have different grading schemes. This might cause disharmony between the student cohorts. As in the US-SWE collaboration, where the Swedish students were graded on a pass/fail scale, but the American students had a much finer grading scheme. There was a rubric for how credit was earned and how it resulted in grades on the American site. The issue that almost broke the collaboration was that much of the credit was earned based on how well a group did and that the American students feared that the Swedish students would not be motivated to contribute once they had passed the pass level (as the American students saw it). This was not seen as an issue on the Swedish side, since they would not pass the course if they didn't contribute throughout the whole collaboration. A surprise exercise at the end of the project, where the students were asked to pay each team member according to how they had contributed in the project, saved the collaboration. This was because even the American students paid the Swedish students better than they paid their fellow Americans. See [15] for more details. Similar

issues were experienced in the US-TUR collaboration, which underlines the importance of making the assessment criteria clear at the outset, for all participants in the project.

E. Student Motivation

To improve motivation, Morales [16] believes that learners' free-flowing expression and sharing ideas are encouraged in learning environments and creation of these environments is facilitated with constructivist instructional design. Principles for constructivist instructional design referred to here are described by Honebein [17] as seven items: (1) provide experience with the knowledge construction process, (2) provide experience in and appreciation for multiple perspectives, (3) embed learning in realistic and relevant contexts, (4) encourage ownership and voice in the learning process, (5) embed learning in social experience, (6) encourage the use of multiple modes of representation, (7) encourage self-awareness in the knowledge construction process. These seven principles can be observed in many aspects of the course designs and activities in both collaborations. For example, embedding learning in realistic and relevant contexts principle is supported by having real clients and projects, ownership and voice is encouraged by students' own determination of the topic/scope of the project, or encouraging self-awareness is supported by reflection assignments and meetings. It is also supported indirectly through explicitly discussing the Open-Ended Group Project pedagogy [1, 2] underpinning the courses, which aids in taking ownership of the learning process.

The underlying pedagogical approach is based on the concept of the Open-Ended Group Project (OEGP) that is designed to address the type of activities where a central concern is to balance the complexity of the problem with the multiplicity of possible approaches to its solution. An important aspect of the educational setting is that the project is placed in a real environment with a real client. This provides an authentic level of complexity and also is shown to increase student motivation [18].

F. Project Scaffolding

For a satisfying learning experience in open-ended global collaborative project cases, students are expected to acquire and use various capabilities. Considering the complexity and variety of competencies required, instructional scaffolding was chosen as one of the primary strategies. Scaffolding is defined as "a variety of methods that include a sequence that gradually reduces and removes supports of various kinds (fading) and a sequence that gradually increases the acceptable standards of performance (shaping)" [19]. Simons and Klein [20] refer to scaffolding as a valuable instructional tool to enhance student performance and they emphasize its important role in problem based learning (PBL).

From a scaffolding perspective, in both collaborations, the semester was divided into phases and some milestones were enforced. Early assignments, lectures and guest speakers were also organized during the initial phases of the course. As Greening [21] points out, PBL involves a slower startup which may be due to the development of important "hidden" skills, and that at this stage of the PBL, ensuring the existence of

adequate scaffolding is critical. Throughout the semester, including the initial phases, regular reflection assignments or meetings were used to highlight students' own responsibilities and to improve the process for the following phases.

The use of scaffolding mechanisms may differ due to various settings such as students' schedules, class sizes, and resources such as the number of mentors. Such differences in scaffolding may include the pace of weekly progress meetings, the amount of resources from the previous experiences or use of structured templates. One example of scaffolding was the use of mentors. Subgroups had a faculty assigned as mentor and project leaders had an external mentor, which differ according to number of mentors and class size. Another example from the US-TUR collaboration was the use of recommended templates for the initial phases of software development. In such cases, scaffolding using templates helps a lot in order to save time for the implementation phase.

To enhance the learning, it is important to keep in mind to reduce the level of scaffolding during the process was important. For example, while making interviews with the clients, depending on readiness of the students, the mentors may prefer attending to the first or second interviews but it is also important to let students continue interviews independently later on.

G. Collaborative Technologies

Collaboration and communication tools are critical components of such global intercultural project courses [22]. Most of the communication and collaborative work is handled through technologies. General uses of technology in both collaborations (US-SWE and US-TUR) can be categorized into five groups: 1. The use of a course management system as the official platform of the course and the collaborative project (e.g. Moodle, TeamLabs), 2. Synchronous communication tools (e.g. Chat, Video conference room, Skype, Google+ Hangout) 3. Asynchronous communication tools (e.g. Moodle Forums, Facebook, e-mail) 4. Document sharing (e.g. SVN, dropbox) 5. Collaborative writing (e.g. Moodle wiki, Google docs, Trello).

As a course web page or virtual classes created on institutional course management systems (like Moodle), an official platform is provided to the students. Instructors' weekly meetings are organized and handled by using video conference rooms or tools like Skype. In addition to these, students generally decided the appropriate technology for their communication and collaboration during the first face to face meeting week. Although the official platforms and tools provide many opportunities for communication and collaboration, it is observed that students may prefer alternative tools various reasons such as: a) to have an opportunity for informal communication (since instructors are not there), b) student habits and their regular use of popular tools like Facebook, MSN Messenger, c) the tool has a user friendly interface and fun components in it, and d) the tool has specific features appropriate for the tasks (not available or not easy to use in the course management system).

From a management point of view it is critical to consider the needs and motivations behind the selection of technology.

In addition, it is also important to have a set of technologies, which can be offered at different phases of the project. For example, technology to support the generation of ideas and to build consensus may be more critical at the beginning of the project but technology to support individual work, workflow management and document sharing may come later [23].

H. End-product and Learning Process

Deciding on the type and scope of the end-product is critical. With a strong motivation to satisfy the client, there is a potential to focus more on the end-product than on the learning process. This is known as the process vs. product dilemma.

The types of outputs for the collaborations has an impact on the decision making process of the teams. In the US-SWE collaboration, the final product is a report and presentation, whereas the output of the US-TUR collaboration is a software system with user guides and a presentation. This difference can be critical because of the time and resource limitations. For example in the case of the report, students can be more free and objective when exploring and recommending solutions to the client, but in the case of developing a software they naturally limit their solutions, consider their skills-sets and knowledge in order to develop the software product before the end of the semester.

In both collaborations, while there is a strong focus on the learning process and development of competencies, the end-products are also used to grade and motivate students and to fulfill the clients' expectations. The challenge will be to maintain a balance throughout the semester.

IV. DISCUSSIONS AND RECOMMENDATIONS

From a management perspective, similarities and differences between the collaborations can provide a base to discuss various issues and may help to understand the dynamics behind the global collaborative project courses.

The two collaborations shared many similarities. In both, the client was the same for multiple semesters. This simplifies the collaboration as both the client and the faculty know their roles and expectations. With one exception, all collaborations had one project (that may or may not be divided into subprojects) and one client. For each project, the students from the US visit the partner site twice, in the beginning and towards the end of the project. In addition, they are run as separate courses, where each site maintains their own course syllabus; however the focus of the collaborations is the same. Both collaborations take a constructivist view and use the Open-Ended Group Project approach. Scaffolding is used when appropriate, and depending on the project attributes (size, product, number of students, etc.).

The effects of major differences between the two collaborations appear in the course design, during the implementation period and through the outcomes. In the US-SWE collaboration students from both sites are engineering students, however in the US-TUR collaboration, the Turkish students have computer science education focus at the faculty of education. This brings out interdisciplinary issues in addition to intercultural issues. Although the emphasis on process and

product is similar in terms of the course implementation, they are different from client's point of view. While a presentation and a report are targeted in US-SWE collaboration, a software product is targeted in US-TUR collaboration. In US-SWE collaboration the team size is typically 20 or more which results in a higher number of subgroups and their mentors, however in US-TUR collaboration, team size is 12 or less with no external mentors guiding the students.

The complexity of global collaborative project courses both for students and teachers may change a lot depending on some initial critical decisions. As an example decisions about "offering a joint course or not" or "having one project topic from one client for the whole team or having a few different projects from different clients" may affect many aspects of the course and implementation period. Another critical issue, which is directly related to many other issues like motivation, topic or client selection, is building trust and understanding among faculty, students and client. In addition to these, better planning for the visit weeks and/or the initial phases and having mechanisms to build consensus around expectations is worth seriously considering because of huge impact they may have.

There are a number of important considerations when planning for a successful collaboration. Details such as holidays, breaks, time differences, scheduled meeting times for the visit week preparation can have an impact on the success of the project. It is important that collaborators pay attention to the details, however to what degree the faculty or students are responsible for the details leads back to the discussion of whether to manage or not manage. As discussed, care must be taken to choose a project and client that is engaging for all cohorts. The client plays a key role; therefore care should be taken when selecting the client. Once selected, collaborators should have a clear idea of what is expected of the client, and the client should be informed of these expectations. Finally, while students will establish various tools for informal communication, it is important to establish a formal communication channel for faculty, students and in some cases, clients. Because the cohorts may have different preferences when it comes to collaboration tools, it may take time and effort to encourage effective communication. It may be useful to allow the student group to select the formal communication tool; however it may be difficult to achieve consensus.

Setting the level of scaffolding depends on the complexity of the educational settings and the project expected by the client. Especially when the complexity of the project is high and when there is a gap between the students' profiles and the requirements of the client, more scaffolding would be needed. To increase the learning experience satisfaction in terms of intercultural issues, project life-cycle management issues or documentary issues can be supported through working in phases or using well defined templates. If these issues and relevant competencies are considered to be the part of the course goal, deciding what to manage or support would be critical. Sharing previous years' experience and expertise of external speakers are always suggested.

Because of the challenges that communication and cultural issues bring to the collaboration, it is important that there is an

agreement on the expectations of the course between and among all participants (faculty, students and clients). This helps to establish trust and understanding from the beginning of the project.

Establishing early informal communication among the students is difficult but it is important to the success of the project and the satisfaction of the participants. When developing a collaboration, an important consideration is how to establish informal communication, and how large of a role faculty should play in this. The best way to establish this communication early is with face-to-face meetings at the beginning of the project. This meeting establishes trust and understanding among the faculty and students and helps when communication is remote and the project becomes complex.

To manage or not to manage represents a common dilemma in global collaborative project courses. For a satisfying outcome and to fulfill the expectations of the client, students are expected to perform well in various areas. The expectation of a high number of competencies, limited resources, and the challenge of a real life project forces stakeholders to manage and guide the teams efficiently. However, for a satisfying learning experience, it is meaningful to have more tolerance for failure and to encourage students' learning through experience or through interaction with other cultures. This approach enforces stakeholders to focus on learning experience and manage the production process loosely, which may easily result in decreasing quality of the end-product prepared for the client. Managers should also consider that even faculty who are teaching these courses for many years improve similar expected competencies through experience. When considering undertaking similar courses, as teachers or managers deciding whether to manage or not to manage such courses, what to manage and what not to manage, or what level of management to apply are initial questions that should be answered.

V. CONCLUSION

International collaborations are challenging for both students and faculty alike. However it is a rewarding experience that improves with each offering.

Work in Progress: On Entrance Test Criteria for CS and IT UG Programs

Richa Singh and Mayank Pundir

IIIT Delhi, New Delhi, India

Email: rsingh@iiitd.ac.in and mayank09025@iiitd.ac.in

Abstract—Indian universities broadly follow an entrance process for undergraduate engineering process in which physics, chemistry and mathematics based questions are asked. Either the individual scores or some combination of these scores is used to set the admission criterion for different engineering streams. However, it has not been analyzed whether this is a good predictor of undergraduate performance or not, especially in Indian context. The broad goal of this research is to understand the relationship between entrance criterion and undergraduate Computer Science/Information Technology performance. The analysis includes data collected from the students who appeared in the entrance exams and took admission in IIIT-Delhi in between 2008 to 2010. The scores obtained in entrance exams and cumulative grade point average earned during the first year of their studies are analyzed. Preliminary analysis suggests that for computer science undergraduate studies, mathematics or numerical understanding is an important aspect. Further, logic and aptitude based tests are better correlated in context of computer science education.

I. INTRODUCTION

In India, for decades, it has been implicitly assumed that Physics, Chemistry, Maths (PCM) are the subjects that should be used for testing student's knowledge in engineering entrance tests of different universities including IITs. However, there are two fundamental questions: (1) is this assumption valid, and (2) do these tests form a good entrance test particularly for computer science? Many countries including USA admit students based on their performance in aptitude and thinking ability tests. Since the curriculum of information technology (IT) or Computer Science (CS) programs is primarily based on aptitude, logic, and computing, the insistence on PCM for entrance in Indian universities is more anomalous for these courses.

In United States, several studies are going on to understand the impact of several admission criteria such as objective and subjective in undergraduate engineering [1], [2], [3], [4]. Many of them attempt to understand the high school grade and college performance as well as finding relationship with entrance exams such as SAT. However, to the best of our knowledge, there is a lack of such analysis in Indian context. Indian context is different than United States model, primarily in terms of admission process. As mentioned previously, Indian universities conduct PCM based engineering entrance exams and successful candidates are selected for different engineering streams including computer science. However, to the best of our knowledge, there is a lack of such analysis in the Indian context; which is different than United States model primarily

in terms of the admission process. To understand it better, in this research, we have analyzed how strongly the performance in these entrance tests predicts the performance during their undergraduate studies. We also study the effect of logic and numerical based entrance exam with the undergraduate study performance.

II. RESEARCH METHODS

To perform this research, following five sets of data are collected from three different batches (year 2008 - 2010).

- 1) Performance in class XII exams, particularly in Physics, Chemistry and Maths (PCM XII),
- 2) Performance in the PCM based all-India entrance test for engineering colleges (PCM Test),
- 3) Performance in aptitude and logic based entrance tests which is specifically conducted in IIIT-Delhi (Logic Test),
- 4) Prior experience/knowledge in computer programming - it is divided into three levels, "have never written, compiled and executed a program", "have written, compiled and executed small programs, have written, compiled", and "executed larger programs in C/C++/Java".
- 5) Student's Cumulative Grade Point Average (CGPA) after second semester of their undergraduate education. The courses they have taken are Discrete Mathematics, Linear Algebra, Introduction to Programming, Basic Electronic Circuits, Data Structures and Algorithms, Digital Circuits, Theory of Computation, and System Management.

To understand if there is any relation between the performance of students in different entrance tests and their performance during undergraduate studies, four different analysis have been performed: (1) are class XII marks good predictors of student's performance, (2) are PCM based entrance tests good predictors of student's performance, (3) are aptitude and logic based entrance tests good predictors of student's performance, and (4) does prior experience in programming play any role in student's performance in Computer Science?

Statistical analysis is performed to analyze these different sets of data along with their performance in the first year of undergraduate studies in Computer Science. The results are reported in Tables I, II, III. Some key observations are as follows.

- Table III shows that the rank correlation of a major all-India test for engineering (based on PCM) with perfor-

TABLE I
ANALYZING THE SEMESTER PERFORMANCE OF STUDENTS WITH THEIR PRIOR PROGRAMMING EXPERIENCE.

| | | Have never written, compiled, and executed a program in C/C++/Java | Have written, compiled, and executed a few small programs (that fit in a screen) in C/C++/Java | Have written, compiled, and executed larger programs in C/C++/Java |
|------------|----------------|--|--|--|
| 2008 Batch | All students | 15.1% | 41.5% | 43.4% |
| | Above 8.0 CGPA | 12.5% | 20.8% | 66.7% |
| 2009 Batch | All students | 23.3% | 37.2% | 39.5 % |
| | Above 8.0 CGPA | 10.3% | 17.2% | 72.4% |

TABLE II
CORRELATION ANALYSIS OF STUDENTS ADMITTED IN IIIT-DELHI.

| Batch | GPA Condition | GPA vs Entrance Test | GPA vs PCM | PCM vs Entrance Test |
|-------|---------------|----------------------|------------|----------------------|
| 2008 | All | 0.45 | 0.51 | 0.4 |
| | Above 8 | 0.35 | 0.17 | 0.23 |
| | Below 6 | 0.005 | 0.39 | 0.33 |
| 2009 | All | 0.53 | 0.38 | 0.34 |
| | Above 8 | 0.45 | 0.07 | 0.3 |
| | Below 6 | 0.6 | 0.13 | 0.2 |
| 2010 | All | 0.46 | 0.5 | 0.4 |
| | Above 8 | 0.15 | 0.07 | -0.11 |
| | Below 6 | 0.55 | 0.41 | 0.65 |

mance in the first two semesters of undergraduate studies is extremely weak. This implies that the performance in this entrance exam had no direct predictive value for performance in the computer science undergraduate program.

- Further, it is also observed that the students who performed better in class XII also performed better in their first year of undergraduate computer science courses.
- The performance in aptitude and logic based entrance test was better correlated with students performance in the first year of undergraduate program. In another interesting observation, we found that all the top performing students (in their first year) had computing background in their class XII or before. As shown in Table I, more than 66% students had written, compiled and executed larger program in C/C++/Java.
- Detailed analysis of grades obtained in individual subjects further validated our hypothesis that the performance in Mathematics has high correlations with students performance in the undergraduate program. Therefore, it is our assertion that there is a need to understand the criterion for undergraduate admission into engineering programs, especially in the computer science program.
- For some batches, CGPA and numericals test have high R^2 values. Further, the marks obtained in XII maths and numerical section of IIIT-D entrance are correlated.

Overall, the analysis suggests that for computer science education, entrance test criteria may be based on maths, aptitude and logic, and performance in class XII.

ACKNOWLEDGMENT

The authors would like to thank Prof. Pankaj Jalote for his constant guidance and support in this research.

Work in Progress: International Teacher Development: Engineering into the Classroom in the Dominican Republic

Abstract— The IEEE Teacher In Service Program (TISP) enables teachers to effectively introduce engineering into the K-12 environment. The program consists of training for engineers to hold in-service workshops for teachers who then take hands-on engineering projects into their classroom. Teachers are provided with lesson plans (available in English and Spanish), tied to educational standards in the United States, all accessible on the website tryengineering.org. Each activity is designed to be inexpensive (often less than \$10 for a classroom). This program has been successfully implemented throughout the United States for over ten years. Additionally, workshops have been implemented in other countries, including Malaysia, South Africa and Chile. The IEEE teamed with electrical engineering and engineering education faculty and students from Ohio Northern University to implement the TISP activities in a series of schools in impoverished regions in the Dominican Republic. This project allows the team to visit five schools and directly impact over 2000 students. The team will offer the initial workshops in May 2012, then visit the teachers to interview and conduct focus groups to assess the effectiveness of the workshops. A final assessment plan will be developed that will assist in assessment of other international offerings. This work-in-progress should be of interest to anyone working with international engineering education, especially within impoverished or developing countries.

Keywords; engineering education, IEEE, international, teacher workshops

I. INTRODUCTION

A. IEEE Teacher In Service Program

The IEEE Teacher In Service Program (TISP) has been in existence for over ten years. The aim of the program is to use IEEE members (mainly electrical and computer engineers) to hold training sessions for teachers during in-service times, demonstrating the use of hands-on activities to introduce or enhance engineering concepts in the K-12 classroom [1]. Most of the training opportunities have been held within the United States, but some have been held internationally. For example, recent efforts using IEEE professionals in the classroom in Hong Kong successfully allowed the introduction of engineering principles into rural schools [2]. Lesson plans are available for download and are translated into 8 languages, including Spanish.

Surveys assessing participants' satisfaction after these workshops show great promise; for example, surveys of a large implementation of TISP activities for a school district in central Indiana showed teachers agreed or strongly agreed that the activities added to their knowledge base, and nearly 90% claimed that they would implement the activities in their classrooms [3].

B. Solid Rock International in the Dominican Republic

Solid Rock International [4] is a 501c3, not-for-profit organization whom Ohio Northern University (ONU) has partnered with in a number of initiatives, including medical, education and engineering projects. They operate exclusively in the Dominican with a mission to holistically serve the poor in the Dominican Republic by focusing on all aspects of health. Solid Rock operates six schools in the Dominican, each highly sought after given the state of public education. Most of these schools are within an hour of each other in the western half of the Dominican. They include:

- Two schools in San Juan de la Maguana (San Juan) including CCED and Lucille Rupp (preschool – high school)
- Elias Piña (preschool – grade 8)
- El Cercado (grades K-4)
- El Rosario (grades K-8)
- Santo Domingo (K-12, 3-4 hours from San Juan).

The largest school, CCED in San Juan, is a complete K-12 and vocational facility with approximately 90 teachers and 2,000 students. Workshops were offered exclusively through Solid Rock schools; the implementation methodology to offer workshops in public schools is uncertain at this time.

II. INITIAL IMPLEMENTATION

A team of faculty from engineering, education and communication will accompany a team of eight engineering students, including two majoring in Engineering Education [5] to conduct a series of three workshops in the Dominican in May 2012. The team met and reviewed lesson plans available from tryengineering.org and narrowed the possible projects to be implemented to those for which materials may be obtained by local teachers. Planned lessons include:

- *Rotational equilibrium*: students calculate the balancing point of a stick with a series of distributed weights
- *Build a Robot Arm*: students use materials such as cardboard, paper clips, tape and string to design a robot arm that can transport a water bottle
- *Assembly Line*: Students design a manufacturing line to build a small project efficiently.

The team will purchase materials to implement any of the selected lessons and leave these with the schools; however, the activities must use materials that may be obtained if they are to be sustainable.

ONU and IEEE will attempt to hold a meeting of engineers who are members of IEEE from the Dominican Republic, and will attempt to engage these members in the teacher training sessions. The model where engineers are trained, then engage the teachers in training, is typical and preferred. There are fewer than 100 IEEE members in the Dominican, and most are assumed to be from Santo Domingo (3-4 hours from San Juan).

Schools will not be in session during these workshops. Workshops are planned at three locations. All teachers from each school are invited, and most are expected to participate since teachers will be offered lunch and a small stipend (500 pesos) for their participation. This is modeled after similar workshops held in the U.S. The first (CCED School in San Juan) will involve 90 teachers, seven translators and the entire team. The following two workshops (Elias Piña and El Cercado) will involve about 15 teachers with a smaller cohort of translators. The team will lead discussion on how the activities can be implemented in any classroom, and how they relate to math, science or engineering concepts. Each teacher will be surveyed and will be given a set of lesson plans for the next school year.

III. ASSESSMENT

A. Initial assessment

Initial assessment of the activities will follow a typical process: teachers and other participants will be surveyed for their appreciation of and plans to implement the activities, and how they see each activity supporting their classroom instruction. Questions on the teachers' appreciation of engineering and their perceptions of student understanding of engineering will be included.

As the workshops are underway, the team will continue to develop an assessment plan for follow up visits in November and May 2013. This round of assessment will be a mixed methods approach. We will collect quantitative data on number of students, ages and specific activities implemented at each grade level. We plan to interview teachers and a selection of students across different grade levels. Student interview data will be interpreted and "chunked" to investigate common themes, investigating instances where an appreciation of math, science or engineering concepts seems evident. Teacher interview data will be assessed to look for explanations of improvements in their perceptions of student performance. Principals and administrators familiar with the activities will be

interviewed to assess their perception of teacher "buy-in". Finally, any differences between schools/locations will be explored.

At the time of the initial assessment (expected in November 2012), additional workshops are planned for CCED (the largest school) and at least one additional site (most likely Rosario due to its proximity).

The research questions to be addressed at this assessment point include:

- Which activities were successfully implemented, in which grades and at which schools?
- Is there evidence of improvements in student performance in math, science or topics dealing with technology/engineering?
- Is there evidence of any change in teacher or student appreciation of engineering?

It is anticipated that our return visit will serve two purposes: assessment and emphasis that we intend these activities as a sustainable means to address math and science in the curriculum rather than a one-time activity. Americans serving in the Dominican over a long term have agreed that a return visit is the most applicable way to demonstrate this concept.

B. Final assessment

The assessment will be repeated toward the end of the 2012-2013 school year, with further quantitative and qualitative assessment of the effectiveness of the activities. A visit is planned in May 2013. Initial assessment results of the additional school (Rosario) will be compared to initial results from the initial implementation.

This visit will also allow the team to meet with teachers to further emphasize that these activities should be incorporated into the curriculum each year, and offer our assistance via email.

ACKNOWLEDGMENT

This work would not be possible without the involvement of the IEEE Educational Activities Board and from the staff and volunteers at Solid Rock International.

Abstract— Collaborative Technology (CT) plays an important role in overcoming the challenges of globally distributed projects. It enables collaboration, but the specific choice of technology also imposes constraints on how projects are conducted. Over the past decade, we have engaged in an action research programme to develop an Open-Ended Group Project situated in an educational framework in which international collaboration, including interaction with a real world client, is an essential component. This paper investigates the manner in which students reflected on their patterns of CT use within the collaborative setting. In general, these reflections were found to be superficial and descriptive, exhibiting a reductive view of CT as a set of technological features, which acted as a neutral medium for communication and participation. One consequence of this was a lack of awareness of the ways in which the technology influenced the behaviour of individual students or the collaborative nature of the group. We explore some potential causes for this and reflect on some difficulties faced by the students. These have important pedagogical implications for courses in which the learning objectives include the development of suitable competencies for working in a global collaborative environment.

Keywords—*reflections; collaborative technology; open-ended group projects; global collaboration; scaffolding.*

I. INTRODUCTION

The aim of this paper is to investigate the ways in which students use collaborative technology (CT) in the context of a globally distributed group project. By CT, we mean those electronic technologies that are designed to enhance communication and cooperation over long distances. We seek to address the problem of whether the use of CT, which is essential given the geographically separated context, affects metacognitive behaviour, such as the ability of students to reflect on their own patterns of use.

Information technology now pervades most social, academic and professional environments and its availability is taken for granted across much of the world. Advances in technology facilitate communication in almost all areas of life and allow geographically separated individuals to work together across multiple time zones. From an educational perspective, this has led to a requirement for students from a wide range of disciplines, but especially those associated with science and engineering, to be proficient in CT and be able to apply this technology to enhance collaboration in teams that often work on globally distributed projects.

The experience gained by working on projects such as these can be seen as part of the relatively broad concept of digital

literacy which is now central to almost every graduate position in which university students find employment, and is crucial for effective use of CT for international collaboration. It is, therefore, an essential learning objective that students become capable of examining, criticizing and evaluating the potential benefits and consequences of CTs. Conversely, ascertaining the views and reactions of students to this technology is an important input for staff engaged in the creation of effective learning environments.

The experience gained by working on projects such as these can be seen as part of the relatively broad concept of digital literacy which is now central to almost every graduate position in which university students find employment, and is an absolute necessity for effective use of ICT for international collaboration. It is, therefore, an essential learning objective that students become capable of examining, criticizing and evaluating the potential benefits and consequences of ICTs. Conversely, ascertaining the views and reactions of students to ICT is an important input for staff engaged in the creation of effective learning environments.

One such environment, which seeks to enhance a range of professional competencies, including digital literacy and team-working skills, is a semester-long collaboration between Computer Science students at Rose-Hulman Institute of Technology in USA and IT engineering students at Uppsala University in Sweden. This learning environment is based on the Open-Ended Group Project (OEGP) concept [1, 2] in which the students gather and expand knowledge about a complex real-world issue in the healthcare domain on behalf of an external client. Close and genuine collaboration is essential for the success of this project and use of CT is a necessary component in achieving this due to the geographical distance between the two cohorts. On one level, this view is well appreciated by the students. One of them depicts the importance of CT thus:

"I don't think this project would exist without the communication tools available to us".

However, it is interesting to look more closely and ask about the perceptions students have concerning the type of group interaction that result from the adoption and use of collaborative technologies. One issue is the way in which CT, while enabling long-distance communication, still requires, for effective use, adherence to certain social protocols. For example, in order for a team to be successful, participants need to develop positive dispositions about issues such as trust, and this means finding some way of establishing mutual knowledge

in a distributed setting. These types of issues are subtler than mere appreciation of technological benefits, but are potentially more important for the successful outcome of group projects.

Methods of global communication have undoubtedly become both more sophisticated and easier to use since the collaboration first started in 2005. While there is an ongoing need to maintain and upgrade technology, this process provides new opportunities to study the way in which students interact with different tools. One of these changes occurred during the 2011 instance when Swedish students were given access to a high tech communication room. This provided data on a variety of issues concerning the adoption of specific collaborative technologies. These have been reported elsewhere [3] but one result has been a greater understanding of the multifaceted ways in which students perceive communications technology as a collaborative tool.

Data collection for this study used two assessment exercises, the first focussing on student perceptions of cultural difference and the second on their use of technology. These were submitted by the students in the course of their academic work and were supplemented by a voluntary survey regarding the use of collaborative technologies. While the first set of assignments on culture showed a significant depth of reflection, the second set about technology use showed a remarkable lack of reflective content, quite puzzling given the high level of technical proficiency displayed by the students.

The organisation of the paper is as follows. We first present the local setting to provide the reader with an understanding of the context of the study. This is followed by a general theoretical framework relevant for a discussion of the unexpectedly low level of student reflection on the value of CTs. We propose possible reasons to explain this lack of deep reflection and comment on some of the observed difficulties faced by students conducting group projects in this kind of distributed environment. Finally, we suggest possible ways in which this problem may be overcome.

II. BACKGROUND

A. The Student Collaboration

The context for this study is a collaboration between students at Uppsala University, Sweden, taking the IT in Society course and students at Rose-Hulman Institute of Technology, USA, taking the Computing in a Global Society course, where the two cohorts are almost 7000 km and six time zones apart. The educational setting, as well as different operational aspects of the project, have been described elsewhere [2, 4, 5, 6, 7, 8], but a summary is given here to provide the reader with a short review.

The main aim of the exercise is to develop those professional competencies that are essential for working in a global, collaborative environment. The underlying pedagogical approach is based on the concept of an Open-Ended Group Project (OEGP) which is designed to address the type of activities where a central concern is to balance the complexity of the problem with the multiplicity of possible approaches to its solution. An important aspect of the educational setting is that the project is placed in a real environment with a real

client. This provides an authentic level of complexity that can be shown to increase student motivation [9].

One issue raised by interaction with real clients is that they have other obligations and consequently it can be difficult to gain reasonable access to them. This particular aspect has been mitigated by use of a single, reliable client and requiring all students to work on different aspects of a single project. From an OEGP perspective, this solution has the added benefit that it adds to the complexity of the task leading to increased “open-endedness”. A further potential issue with a real client is that some students may feel ethically unable to help certain clients, e.g. for political, religious, or competition reasons. Because of this, we have chosen to work with the public health sector, i.e. the Uppsala County Council and the associated academic hospital, which was perceived very positively by participants.

Another factor, relevant to this paper, is the high level of freedom given to students to decide upon the specific communications technology that suited their task. While there were some constraints imposed by staff, e.g. some form of collaboration platform should be used and that there should be weekly synchronous meetings that should preferably include video, the choice of CT and how it was used was chosen by the students. This aspect has varied over the years and for this cohort, the team leaders also required the members to keep track of the time they spent on the project.

The students participating in the course in 2011 were all male, aged between 20 and 37. The American cohort varied between the ages of 20 and 22 years, and all but one member of the Swedish cohort was in the 21 to 24 year range. The majority of students had their major in computer science or information technology, but some students were pursuing other technical majors (e.g. mechanical engineering). This year there were ten Swedish students and eight American students. Most students had studied for three or four years at the university.

B. Critical Thinking and the Role of Reflection

An important part of the educational setting is the use of assignments where the students are asked to reflect on a relevant issue. There are both practical and pedagogical reasons for this approach. An example of the former was to alleviate an observed tendency to blame slow progress or failure on others, especially those members of the group from the other institution. We wanted to help the students see their own part in any problematic situation by analysing their role and reflecting on what they themselves actually did to contribute to progress. From a pedagogical perspective, the development of those professional competencies described in the course learning objectives is closely linked to metacognitive ability. As pointed out by Fincher, Petre, and Clark [10], “*Reflection on experience underpins the process of successful learning and is essential to the success of education.*” Using reflection as an educational tool is also supported by ideas presented by Schön [11], where he characterises effectiveness in professional work as the product of an ongoing process of reflective practice which involves self monitoring, continual improvement and action cycles (plan, act, observe, reflect).

The modern emphasis on critical thinking can be traced to Dewey’s focus on reflective thinking [12]. His characterization

of these thought processes as active, persistent and carefully considered, has formed the foundation of many later attempts to distinguish critical thinking from other modes of cognition, and laid the basis for investigation of the mechanisms by which they are promoted. Moreover, the development of a specific competence in critical thinking has come to be seen as one of the primary goals of higher education [13] and, indeed, one that has been increasingly promoted on social and economic grounds [14, 15]. Unfortunately, it is also reported, e.g. [16] that the development of these competencies by students is not a guaranteed outcome of tertiary education and this has led to the inclusion of thinking skills as a specified graduate attribute in many university programmes.

Over the past two decades, there have been significant attempts to classify the factors that lead to good critical thinking. A report by the American Philosophical Association [17] suggested that the subject could be conceptualized in two dimensions by the requisite cognitive (and metacognitive) skills, and the affective dispositions that allow the appropriate skills to be used. The precise specification of the cognitive abilities themselves, including the definition of terms, often varies depending on the details of the research study but it includes capacities for interpretation, analysis, evaluation, inference, explanation and self-regulation. These abilities are often translated into a cluster of competencies concerning the identification and analysis of pertinent issues and assumptions in an argument, recognition of important relationships, the ability to make correct inferences and deduce conclusions from information or data, and to interpret whether conclusions are warranted on the basis of data [16]. Proficiency in the use of a critical thinking skill and the disposition to exercise it are clearly interdependent and, as a result, developing an aptitude in this area depends upon affective factors. Descriptions of critical thinking dispositions mirror those found more generally when investigating positive attitudes to learning, e.g. Claxton's 'four Rs': resilience, resourcefulness, reflectiveness and reciprocity [18]. Importantly, the disposition of reflectiveness finds counterparts in a cluster of concepts around metacognition, self-regulation, self-direction, and self-efficacy [19], which are exhibited at the highest levels of critical thinking.

Barnett [14] extended this conceptual base to connect elements of cognition, metacognition and praxis in the notion of 'critical being'. *"Critical persons are more than just critical thinkers. They are able critically to engage with the world and with themselves as well as with knowledge."* The goal of the learner, therefore, becomes not only to analyse and evaluate information, but also to develop powers of critical self-reflection, which then allows the individual to take appropriate action. Here again, the process of reflection, specifically in the form of reflective practice, such as that described by Schön, acts as a fundamental link between the acquisition of critical thinking competencies and the metacognitive goal of learning self-regulation. Assessment of reflection on performance of assigned tasks then provides student and faculty with one possible mechanism for monitoring the development of competence in critical thinking, and for the self-regulation of engagement in subsequent learning activities.

Barnett also highlighted the need to consider the collaborative nature of skill development in shared activities, and in the type of learning that occurs within a community of practitioners. This analysis connects with the work of Vygotsky, his theory of the Zone of Proximal Development [20], the processes by which social interactions fundamentally shape and transform the way a learner acquires and assimilates knowledge, and so to the concept of scaffolding [21] by which a teacher or peer provides interactional support for learning. As a form of scaffolding for the development of critical thinking skills, reflective activity allows knowledge to be externalized by expressing concepts either verbally or in written form. While this kind of articulation is crucial to the organization of a student's knowledge, according to Vygotsky, the act of choosing words to represent thoughts also allows the further consideration and deliberation on the ideas being expressed. Written expression of a student's reflective comments should therefore promote critical thinking by providing students with an opportunity to articulate and refine their conceptual understanding of the learning process. As Flower [22] put it: *'writers do not simply express thought but transform it in certain complex but describable ways for the benefit of a reader'*.

Various forms of reflective activity have been used in the course over the years. While a final summative reflection followed by an individual meeting with the academic supervisor has always played a part of the assessment process, short written reflections and a varied number of individual meetings were also used. These reflections provide the staff with specific information and ideas for the development of the learning environment. In addition, they generate insights into how the educational setting functions to develop and enhance the desired professional competencies. In the 2011 instance, there were three such assignments.

III. METHOD

The data collection in this study is based on the results of two written assignments and a survey. The first assignment focused on student perceptions of cultural differences within the group, while the second sought reflections on the positive and negative aspects of different forms of collaborative technology use. This material was submitted by the students as part of their academic work. The survey concerning the use of CT was done half way through the course, shortly after the second assignment.

In both assignments, assessment was accomplished using a categorization framework based on the work of Hatton and Smith [23]. This scheme classifies writing according to the depth of reflective analysis, from an initial stage of non-reflective "descriptive writing", through basic "descriptive reflection" to the more sophisticated "dialogic reflection" and, at the deepest level, "critical reflection". This last stage is demonstrated by the elaboration of reasons for personal learning decisions that take into account a mature understanding of the psychological and pedagogical factors affecting the learning process. As such, it requires a high degree of metacognitive proficiency. The levels in this framework can be related to other classification schemes for reflective writing such as that of Moon [24], as well as those

which attempt explicitly to measure progression in critical thinking, such as that of Greenlaw and DeLoach [25].

Identification of reflective markers in student writing is often problematic and normalisation of the assessment criteria across the different supervising faculty was needed to provide a fair assessment of the assignments. This was achieved by detailed discussion, which correlated the different views on evidence identifying the different levels in the Hatton-Smith framework.

IV. RESULTS AND DISCUSSION

The first assignment, on student perceptions of issues concerning cultural differences between group members, resulted in submissions that showed a significant depth of reflection (level 3: dialogic, and level 4: critical reflection, in the Hatton-Smith framework). This differed sharply from performance on the second assignment. In this case, students were provided with a description of the Hatton-Smith framework and were explicitly asked to write reflective accounts of their CT use that specifically addressed the factors characterising higher level reflection. The results from this second exercise demonstrated a much lower level of reflective content (Hatton-Smith levels 1 and 2), with hardly any submitted work attaining the third level. This poor level of reflection in the second student assignment was somewhat unexpected given the good performance in the first assessment.

The high level of technical proficiency displayed by the students throughout the project also suggested initially that the second assignment would prove less problematic. The students were, in general, quick to grasp the possibilities and limitations of each collaborative tool they encountered, and classified them in terms of stability, user-friendliness, and their perceived potential to further the ends of the project. Critically however, it was rare for a student to show an explicit awareness of how the various tools, and the communicative contexts that they supplied, influenced the project process itself. One student observed that the *"quality of communication is mainly evident in the fact the situation does not seem personal so you do not feel connected with anyone else"*, which caused *"a lack of responsibility to the team"*. Yet, the same student also claimed that the communication tools *"allowed the group to work well together"*, and helped to *"build a better understanding of each person as a colleague and a friend"*. This seeming contradiction may mirror a gap between the general, team level, whose formal meetings sometimes suffered from a combination of poor communication and insufficient organization, and the level of work groups, whose members seem to have communicated informally and more efficiently about their more narrow areas of responsibility. A higher degree of reflection on the interrelationship between communication structures and project requirement might, if acted upon, have improved team building, to the benefit of the project.

A. Potential Causes of the Low Level of Reflection

A number of possible reasons for the observed results can be proposed. One suggestion is that information technology has become an almost invisible tool [26, 27, 28], and consequently

it is possible that the cohort was so accustomed to ubiquitous access to communication media that they saw all difficulties in long-range communication as essentially technical problems.

According to Selg [29], the Web 2.0 culture is characterized by two-way communication patterns, where users are both consumers and producers of digital content. Blogs, on-line communities, and file sharing are typical forms of activities. This contrasts with a Web 1.0 culture where CT is used for such activities as information searching, ordering products, and, predominantly, using e-mail for communication. While email is used in both cultures, instant messaging and the use of SMS as an almost synchronous communication mode are characteristic of the Web 2.0 culture where they seen as complementing each other. Furthermore, this form of technological proficiency can be seen an example of the generally high level of competence in the use of CT in that culture. This proficiency also manifests itself as an understanding of the benefits of information technology, such as the value of a large network of "weak ties" in community building, and the need for strategies for handling technology misuse. Much of what Selg reports about the behaviour that differentiates between the cultures is related to how the Web 2.0 users are able to make distinctions between personal life and professional/public life in their use of technology.

It is also possible that the low level of reflection is a consequence of how the assignment was formulated. The rubric for submission, stated that students should *"[r]eflect on the positive and negative aspects of the use of [the] different communication technologies in [the] project. What are they good for? What are their drawbacks?"*. This led predominantly to descriptive reflections, even though students were asked to address those causal and correlative factors which characterise reflection at the upper levels. It is possible that students misconstrued the assignment as being directed to efficacy of the software tools and therefore interpreted this task as a request for an appraisal of the (software) products rather than the processes involved. This may have given rise to a submission based on commentary about products, rather than reflection on communication as a process itself. The former requires comparatively lower-level cognitive skills such as categorization, querying evidence, assessing claims and stating results, whereas reflection on the process itself would need the higher-level, evaluative, cognitive skills as well as access to the metacognitive skills necessary for the higher levels of the Hatton-Smith framework.

B. Establishing Mutual Knowledge in Distributed Collaboration

Central to the effectiveness of geographically distributed collaboration is the concept of "mutual knowledge" or "common ground", as described by Cramton [30]. This type of shared understanding can be established in a number of ways. Individuals can interact directly, in which case the knowledge is grounded in their shared first-hand experience. Alternatively, individuals can interact indirectly, e.g. through a proxy or through some experience both share with a third party [31]. Finally, mutual knowledge can be based on category membership, i.e. assumptions about the knowledge someone possesses by virtue of the job they do or the role they play [32].

Establishing such mutual knowledge in a distributed collaboration in which only the last two elements are available is not an easy task. There are difficulties in conveying nuances of meaning when compared to face-to-face communication [33] and these are exacerbated by the fact that communication using information technology is slower [34]. Cramton identifies a number of problems that contribute to the difficulties in establishing mutual knowledge, such as the failure to communicate and retain contextual information, unevenly information distribution within a message, a need to understand and communicate the salience of information, differences in speed of access to information, and difficulty interpreting the meaning of silence.

The problem with mutual knowledge in distributed collaborations is compounded when collaborators are themselves unaware of the difficulties associated with this particular issue. In the study, most of the problems with establishing mutual knowledge were clearly influenced by the characteristics of the CT used, e.g. having a low capacity for providing back-channel feedback was likely to lead to misunderstandings. In this regard, the low level of reflection about CT is worrying since it may indicate a naivety concerning the impact that technology has on the ability of students to engage in establishing this mutual knowledge. There were, however, some glimpses of insight, such as this quote related to an occasion when the students were forced to use the text-only mode of Skype:

“... I realized something important after we had ended. I noticed that, despite not insignificant cultural and language differences, we still communicate using a large percentage of nonverbal cues. I did not realize just how much we can convey with spoken conversation even across a cultural barrier.”

It is interesting, however, that the student who made this remark omitted to pursue this point further by speculating about differences with regard to other forms of CT, e.g. video, or to face-to-face meetings.

C. Types of Collaborative Technology used in the Project

Clearly, technology plays a crucial role in supporting communication in globally distributed projects, and an increasing collection of collaborative tools is available. These range from ubiquitous email facilities, through wikis, blogs, text chat systems, version control systems, video-conferencing systems (from desktop applications such as Skype to dedicated rooms and services), cloud-based file sharing such as Dropbox, and virtual learning environments (which often themselves incorporate a range of these features). Personalized social networking services such as Facebook, Youtube, and Twitter also complement the more group-focused collaborative technologies. However, this abundance of choice does not necessarily contribute to effective communication in the context of a globally distributed team. There are significant challenges and, as the authors of [35] and [36] note, it is necessary to establish common ground with respect to “collaboration readiness” and “technology readiness” in order to use them successfully [3].

This may go some way to explain why students did not make extensive use social software in the collaboration. Social

networking was not used for academic purposes despite the students clearly belonged to the digitally native culture. The forums, available as part of the TeamLabs technology, remained silent, and students did not use Facebook, blogs or Twitter for the project, despite other researchers having noted an increasing use of social networking websites for academic work. It is known that active engagement in these sites can help to establish virtual relationships and provide individuals with access to a diversified set of information from multiple sources [37]. We believe that a higher level of reflection on their use of collaborative technology would have led to investigation of the capabilities of social media in order to find alternative communication mechanisms, especially since they were already very familiar with such tools.

V. CONCLUSION

The ability to evaluate the use of technology-based environments that enable communication and collaboration in globally distributed student projects is, as mentioned in the introduction, an important skill for students to learn. Reflections were chosen to help students attain this learning objective and to develop their digital literacy. However, the reflections provided by students were quite shallow, merely describing the collaborative technologies used.

This raises an important issue, namely, under what circumstances can this type of reflective exercise be used to promote the development and exemplification of critical thinking skills. As critical reflection is itself a high-level metacognitive skill associated with learning self-regulation, its exercise requires a mature engagement with a wide range of purely cognitive skills. If a student does not have the opportunity, or disposition, to exemplify enough of these, there will not be sufficient cognitive content to allow substantive metacognitive activity to take place. It would appear that reflective activities, such as those described, act as good support for critical thinking provided the person doing them has the opportunity to illustrate a significant number of the requisite cognitive skills within the reflective process itself, especially those higher level evaluative skills.

In the case of this study, despite a clear statement that the objective for the assignment was high-level reflection, most students interpreted the task in terms of superficial description of the context and operation of the software. The result was a focus on the products that mediate communication rather than processes that enable it. Given that students find the experience of this kind of reflective activity both unfamiliar and difficult, it is, perhaps, not unexpected that they would attempt to reduce the task to simpler descriptive modes of expression. However, this does not explain why they managed to do much better in the first assignment. It also highlights the need for care in articulating the learning objectives of assignments, and providing suitable scaffolding to enable engagement.

From a pedagogical perspective, activities that scaffold engagement in reflection, and so promote the development of critical thinking skills, could be based around opportunities for students to recognise cognitive conflict between contrasting or distinct sets of data (e.g. assumed conditions and reality, student and staff perspectives). Such scaffolding should

promote the dialectical aspects of critical thinking such as clarifying meaning, challenging ideas and conjecturing alternatives, and may be contrasted with activities that primarily serve to expand the number of ideas under consideration, with the consequent need for further preliminary categorisation and classification, before more advanced critique can take place.

In conclusion, results from the study indicate that these students found it more difficult to reflect on their use of CT than, for example, on intercultural communication or the personal development of other professional competencies. Most students seemed unaware of the impact such technology has on their communication and collaboration, and they appear to view CT as, for example, gender neutral, and a tool that can be used and modified according to their needs. This simplistic view has most likely influenced the collaboration in a negative way, e.g. by leading to difficulties in establishing mutual knowledge. The results of our study indicate that there may be a need for more scaffolding related to reflective writing and further work to investigate if this will impact on their use of CT is underway.

Abstract— While internationally there is an awareness that we need new, innovative approaches to engineering education, it is unclear whether a pioneering pedagogy within one cultural context will readily transfer and find acceptance in a very different cultural context. In this paper, we report on a three-site, collaborative experiment in using problem-driven learning in an introductory engineering class. Our three sites are universities in the United States, Abu Dhabi and China. In each location, first year students in biomedical engineering begin the major by joining a team of students who tackle real-world, open-ended problems. Our paper will report on 1) the development and exchange of problems across the three sites, 2) the different constraints, realizations and outcomes of the problem-driven approach at each of using problem-driven learning as a transnational pedagogy for 21st century engineering education.

Keywords- problem-based learning, global education

I. INTRODUCTION

In a recent report from the National Academy of Science, five essential 21st century skills were identified: *adaptability, complex communication/social skills, non-routine problem solving, self-management/self-development* and *systems thinking* [1]. These identified competencies are echoed in the UNESCO's 1996 Report titled "Learning: The Treasure Within" [2] and the European community's report identifying eight key competences [3] for achieving flexibility in the labor force. Students will not develop these competencies by sitting passively in lecture halls, taking notes and memorizing content. Even more interactive methods like Personal Response Systems or Student-centered Active Learning Environments for Undergraduate Programs (SCALE-UP) [4], both of which promote greater student interaction, are not specifically designed to help students develop these competencies. This is because the nature of the problems in traditional engineering classes that students are expected to master, while a first step in becoming successful engineers, are not sufficiently complex to allow students to practice essential 21st century skills. This insufficiency is not just a national concern, but also an international educational challenge. Across the globe, the urgency to transform engineering education is becoming more and more recognized.

Here we report on a collaborative transnational effort at Georgia Tech in Atlanta, Peking University in China and

Khalifa University of Science Technology and Research (KUSTAR) in Abu Dhabi to develop and deliver an introductory course in biomedical engineering. Biomedical engineering (BME), an exemplar interdisciplinary, poses significant educational challenges. Bioengineers must integrate a broad base of knowledge from several disciplines including engineering, computer technology, and cell and molecular biology. They must apply quantitative, analytical methods and representations to systems understanding. Irrefutably, adaptability, non-routine problem solving, systems thinking, and complex communication skills are essential attributes of a biomedical engineer. In the workplace, they routinely both participate in but translate across the disciplinary borders of medicine, biosciences and engineering. In this field, we cannot afford to have our students graduate without these 21st century skills.

Fostering these competencies while promoting integrative thinking and problem solving skills should be a central objective in the design of an undergraduate biomedical engineering curriculum, but arguably, just as relevant to any engineering major. Obviously new models for what happens in classrooms and what happens across a whole set of courses is desirable and necessary to achieve these ends. The questions we address in this paper are 1) whether and how new 21st century models for engineering education can be developed and 2) how readily these models can transfer across national boundaries, cultures and institutional contexts. To answer these questions, we undertook a transnational experiment in reforming engineering pedagogy at the freshman level. Here, we present the evolution of a required BME course designed at Georgia Tech to foster 21st century competencies. We then address the challenges experienced as it was exported and implemented at two offshore sites, the alterations made to accommodate cultural and institutional differences, and the shared outcomes of this educational experiment. This is not a standard research report on an educational intervention, so we do not (at this time) offer hard, quantitative data to substantiate our observations and claims about student learning and change. Rather, this work reports on a model for global collaboration in the design, development and refinement of new learning environments for engineering education that can be relevant and effective across national borders. It also illustrates how a perceived problem in engineering education is likely to be

global rather than local, so we need such collaborative efforts worldwide to produce the engineers needed to tackle the compelling global problems of food, water energy and healthcare.

II. PROBLEM-DRIVEN LEARNING

One could easily argue that problem solving is at the core of engineering education. Students in statics, dynamics, heat transfer, bio-transport and signal processing courses are all learning to solve textbook problems using an engineering approach. It is improbable, however, that such textbook problems and the associated classroom activities of lecturing or the faculty member solving a problem on the board will promote adaptability, social competencies or self-management skills, for example. This is because traditional engineering practice problems are not designed to build 21st century competencies; they are designed to build the essential fundamentals. And while these fundamentals are certainly necessary, they are no longer sufficient which poses a problem for engineering education generally. Where and how will students practice and develop the necessary fundamentals for the 21st century workplace?

In response to this need, problem-based learning or PBL has started to make inroads into engineering education [5,6,7]. First developed for medical education [8] to better prepare future doctors for clinical practice, this educational approach comprises

- An authentic, ill-structured complex problem with multiple possible routes to multiple possible solutions
- Varied but unscripted opportunities for students to identify personal knowledge gaps as starting points for individual inquiry and learning
- A team or group that works collaboratively on the problems.
- A facilitator who guides the learning on a team through asking probing questions that model expert cognitive reasoning and problem solving strategies

PBL is used in a number of ways—to engage students deeply with content [9], to apprentice them to the practices of a particular community and to practice a specific skill set such as spoken and written communication. One could easily argue that the capstone design, so prevalent in the engineering community is an excellent example of problem-based learning.

For our purposes, we adopt a slightly different term—problem-driven learning. We take this term from the work we have been doing in trying to understand reasoning, problem solving and learning in engineering research labs and then translating those findings into new models for engineering education [10]. What we see in these sites of authentic engineering activity is that learning is driven, propelled actually, by the need to solve non-routine, ill structured, and ill-constrained problems. And this problem-driven learning is what advances knowledge and drives breakthroughs in the labs. Laboratory problems are inter/multidisciplinary, which requires researchers to integrate knowledge and skills across the bioscience/ engineering divide. Researchers continually need to adapt to new and changing

conditions both in terms of personnel, problem types and the ever-present impasses encountered in frontier science. They need to manage what, when and how they learn and they need to work with others when the magnitude of the problem demands a variety of heads and hands. If engineering majors are to effectively participate as non-routine problem solvers in industry or research, they need to practice early and often the skills of tackling, defining, constraining and working through complex, interdisciplinary problems. Thus in our design of the introductory course in our biomedical engineering curriculum, we seek to *Empower students to be agents of their own learning who are fearless in the face of a complex problem.* This is a tall order and needs to start in the first year and be practiced throughout the curriculum. We contend that a single capstone experience while necessary is not sufficient.

III. PROBLEMS IN BIOMEDICAL ENGINEERING ACROSS CULTURAL CONTEXTS

Over the past ten years, we have iteratively designed and developed a set of three complex, ill-structured problems that constitute the basis for an entry-level course. In working through these problems students 1) practice the reasoning and problem-solving strategies employed by engineers with the help and scaffolding of facilitators; 2) experience the need to integrate the biosciences with engineering and 3) try on the identities of biomedical engineers. This course and the problems, first developed at Georgia Tech, have morphed and changed in response to the different cultural contexts of China and Abu Dhabi. The same learning outcomes, scoring sheets and rubrics have been passed across the continents. The best way to tell this story of international collaboration is to move from site to site, illuminating the possibilities and the challenges at each.

A. The Georgia Tech Experiment

With the inception of inaugural undergraduate and graduate degree programs in biomedical engineering in 2000, the Wallace H. Coulter Department of Biomedical Engineering at Georgia Tech (GT) committed to developing new educational models suited to educating students for integrative thinking and problem solving across engineering/biosciences. Approaching this challenge from the cognitive and learning sciences, the curriculum designers determined that working on interdisciplinary problems beginning in year one and throughout the curriculum was the way to insure this cognitive integration by year four. Separate streams of bioscience and engineering classes would not give students the needed practice of applying the quantitative engineering analysis and design to bioscience and healthcare problems. Nor would students develop the *cognitive flexibility* [11,12], or the ability to apply knowledge in diverse contexts and to engage a problem flexibly from different perspectives because building these habits of the mind takes practice. Moreover, having students work on authentic, complex interdisciplinary problems with the guidance of a faculty facilitator rather than a teacher would create the desired *cognitive apprenticeship* [13], a powerful and well-researched model for learning. In such an apprenticeship, the facilitator models her cognitive strategies by asking probing questions, by challenging the learners, by coaching the learners

and by monitoring activity and giving feedback. This pedagogical model was best suited to the learning objectives of this freshman-level required class in the biomedical engineering curriculum.

Over the years, numerous problems were developed, run and analyzed for the course until a stable set of three for each term were established that serve specific, desired learning goals. The learning outcomes for the course address four skill areas: *inquiry skills*, *problem-solving skills*, *knowledge building skills* and *team skills*. Assessment rubrics for the course as well as a number of problems can be found at <http://pbl.bme.gatech.edu/assessment.php>. Each of the three problems has a central core over which different “skins” or story lines can be affixed. For example, the first problem focuses on screening in the context of disease. The problem brings together issues of sensitivity/specificity/positive predictive value (probability) in health screening, issues of scale in the context of disease, and the development of quantitative methods of analysis for evaluation/decision-making in the face of conflicting and changing information. A significant intended learning outcome for the whole course generally but this problem very specifically, is the development of efficient/effective inquiry skills. Each term, a new disease can be explored. Generally cancer of one kind or another has been used but more recently endometriosis and sickle cell disease have been topics. The second problem has experimental design at its core and the third has mathematical modeling and computer simulation. These core problems offer enough flexibility that each semester is very different for both students and faculty. For example, one semester students might determine through modeling and simulation whether an outbreak of an infectious disease could occur on campus and whether particular measures would be effective in halting the spread while the next semester they might look at the potential for experimental viral traps to halt the spread of HIV. (See two versions of this problem at the end of this paper.) This potential to redo the core problem each term with a different story line keeps the course fresh and current for both faculty and students. Since faculty are not expected to teach the material but to facilitate the problem solving process, they find the kinds of interactions with their students to be very similar to those they have with their graduate students during lab meetings. Significantly, as all faculty in the department teach this course and see the capabilities of the undergraduate students first hand as facilitators, they are eager to have undergraduates in their research lab accounting for the fact that significant numbers find work in research labs before graduating.

At Georgia Tech, unparalleled resources support the course. First, special rooms were designed for the team problem solving that measure approximately 25 feet by 25 feet. Importantly, the rooms have writable walls to the ceiling designed to support a *distributed cognitive system* [14] among team members as they work in defining the problem, gathering the necessary resources, applying those sources, developing a problem solving strategy, determining a solution, designing a presentation for other teams and then writing a technical report. In addition, it was determined early on that the team size would be eight students and that enough faculty, graduate students and post-docs would be assigned to the course so that every team

had their own facilitator. At the time of this writing, this class has 165 students divided into twenty-one teams with fourteen faculty and post-docs assigned to the course. Finally, over the years, scoring rubrics for each type of problem presentation and report were developed and tested as well as guidelines for developing the technical reports. Further, self and peer assessment sheets used at the end of the problems and at the end of term were also developed. Taken together, these course resources provide a significant scaffolding system that allows first year students to take on and tackle authentic complex, interdisciplinary problems in biomedical engineering.

Augmenting the three hours of class time devoted to the team working on the problem is a weekly one-hour lecture carefully timed to infuse important skills or knowledge into the problem space. For example, two weeks into a cancer detection problem, a faculty member whose research area is cancer will give a talk on the cellular mechanisms involved in the disease. Interestingly, students always applaud after these lectures indicating that somehow this faculty presentation is more like a research presentation than a traditional lecture class.

Measuring the efficacy of this learning experience has been a challenge as its intent is to build skills not mastery of a certain content area. One measure, we believe, of the course’s success is the significant number of students who go on to seek research experiences as undergraduates. By the fourth year, we find that 65% of our 1200 undergraduates have worked in labs. We propose this as an appropriate measure of course success as it has been designed to simulate a research lab experience. Another measure is an alumna survey in which 60% of respondents spontaneously credited this problem-driven learning experience as making them better prepared in the workplace. Finally in an end-of-course student survey, the majority of the students indicate that they have learned “more” or “much more” in this course than a traditional lecture class. While these measure techniques are not rigorous, they do attest to the value of this course.

B. The Abu Dhabi experiment

Similar to Georgia Tech, Khalifa University of Science, Technology and Research (KUSTAR) developed a new degree program in biomedical engineering beginning in 2009. Wanting to infuse problem-driven learning in the curriculum, they decided to follow the established GT model and use the previously designed problems, scoring rubrics and assessment strategies. At the time, no university in Abu Dhabi was experimenting with problem-driven approaches and the cultural educational norms experienced by students prior to coming to the KUSTAR were very different from those of the United States. To assist KUSTAR in developing this approach, a strong collaboration was established that involved 1) an on-site workshop in Abu Dhabi by the lead author to introduce faculty to this approach, 2) access to copies of all assessment and support resources developed at GT; 3) access to the GT course management system so the KUSTAR faculty could see the GT students’ work for calibration purposes 4) Skype meetings to assist KUSTAR faculty in developing culturally relevant problems. Even with all this support, it was unclear how difficult the transition to this novel educational approach would

be. Given the limited space of this conference paper, we discuss two issues: the design of problems for a different context and the local resource and cultural challenges.

The Abu Dhabi team was able to work with the core concepts of the three problems from GT and affix “skins” relevant to the Abu Dhabi context. Specifically, diabetes mellitus type II, obesity and trauma from road fatalities—all important issues to this UAE—became the contexts for developing inquiry skills, problem-solving skills, knowledge building skills and team skills. Using the problem prompts from GT as templates, a faculty member was able to design culturally relevant and timely problems for their first year students to address. The chance to work as engineers on problems facing their nation was very motivating to the KUSTAR students. However, unlike GT, KUSTAR faculty lacked certain essential resources. They used small conference rooms not PBL rooms and while these worked, lacking the expansive writing space constrained group interactions to some extent. The students did not have access to the Pub Med and Medline databases needed to do effective inquiry. For the first time in their education, men and women students were sitting in the same room working together. English for these students is not their native language and yet the course and the materials were all in English. And finally, prior educational experiences had only prepared them for listening passively in lecture with no idea how to be agents of their own learning. Naturally it was necessary to develop additional scaffolding for this student population and institutional/cultural context. Firstly, the faculty had to special order bibliographic resources for the students or provide a set of possible resources for them to sift through and use as required. Facilitation had to support the interaction across genders as students transitioned to a co-ed environment of learning and working. Facilitation was also needed in encouraging and transitioning students to become independent self-directed learners.

Now in its second year, the problem driven learning experiment has become a central feature of the biomedical engineering curriculum at KUSTAR. The second author of this paper describes below outcomes of this educational experiment from her experience designing problems, facilitating student teams and observing them in follow-on classes.

- Empowerment and ownership of learning were invaluable to some students in terms of raising their confidence level with respect to the ability to solve the problems and the ability to present the solution to an audience. This is of particular importance for females in our culture, as cultural constraints may hinder the development of their confidence level and soft skills in parallel with their male counterparts.
- The diverse composition of teams taught the students how to work effectively with others. Furthermore, peer mentorship was also observed in teams throughout the problem cycle, where students were helping each other develop or improve certain skills.
- Exposure to real-world hands-on engineering /clinical problems with cultural and societal impact not only motivated the students to learn, but also exposed them to the iterative engineering design and design thinking

approach critical for solving open-ended, ill-posed, complex problems.

- The PBL class encouraged students to do research, design and development. The direct outcomes included one ASME conference publication (Creating a Mathematical Model to decrease Obesity in the UAE. ASME Meeting, Seoul, South Korea, June 2011), the modification of the design of commercial pedometer to increase precision and accuracy, and the design and development of an intelligent system to control traffic accidents.

C. The China Experiment

Like KUSTAR, in 2009 Peking University (PKU) in Beijing was developing an undergraduate program in biomedical engineering. At that time, GT and PKU were also building a joint PhD program that would foster research collaboration and exchange through PhD students transiting between the two institutions. After visiting the GT problem-driven learning classrooms, the PKU faculty also decided to follow the GT model thinking that since PKU students are in the elite class of highly talented Chinese students, they would bring impressive capabilities to this learning environment. Similar to KUSTAR, PKU received significant mentoring and support from Georgia Tech in the form of an on-site workshop, assistance in developing locally relevant problems, access to the course management system and course materials and just-in-time Skype consultations. Interestingly, PKU was able to use the GT problems with small changes. For example, breast cancer is a significant health problem in China like the US, so when this GT problem was given to PKU students rewritten to foreground the Chinese context, students were highly motivated to help their nation. One student wrote to his facilitator:

After class, I talked to my classmate. We both thought that we are doing something really meaningful: we are thinking deeply and thoroughly about solving China's breast cancer. We thought that maybe except for our class, no one else in China would actually try to systematically and deeply research on the current conditions of China's breast cancer, as well as how to make the conditions better. We were discussing, getting more and more excited, feeling as though we were really burdened with some huge responsibility!

However, as would be expected, there were significant local challenges associated with this educational experiment. PKU students take a very heavy load of eight or more courses each term, which means that class time is approximately one and a half hours a week while the GT classes meet a total of 4. This course load also means that PKU students have to study for a number of courses simultaneously, leaving less time for a problem-driven course which often requires a lot of time outside of class to find the appropriate sources, to digest them and to determine how the resources can be used in the problem. In Chinese high schools, teamwork and discussion are for all purposes nonexistent, so working on a team for a whole term on problems that require constant discussion and negotiation is a very foreign concept and experience for these students.

Finally, a traditional lecture style classroom was the available space for this class with no white boards for distributing the cognitive task and load.

Over three terms, the PKU faculty was able to make important adjustments to better approximate the GT conditions. First, they added a recitation period and office hours, which they used to augment the time that the facilitators meet with the students. These meetings were often in their offices so they could use the white boards there. For one problem that requires GT teams to buy a biomedical device for testing and experimental design, the PKU faculty bought the devices and distributed them to the teams.

The third author on this paper shares the following unexpected outcomes of the problem-driven learning experiment at PKU:

- Unlike USA students who are assigned tasks to investigate very broad topics even in elementary school, the students in China seldom have such an opportunity. For the tradition of education, the students are even regarded as threatening or not respectful to the teacher if he/she asks a question without the teacher's invitation. Therefore, the students are very excited to solve such broad questions. We find how we organize the just in-time lecture component of the course is very important. For example, when we invited the breast cancer-imaging physician to give the lecture, the students asked her questions for about 2 hours after 2 hours' class!
- The practice of giving a speech improves the students' communication skills and prepares them for future career needs. Especially, we have requested them to give several final presentations in English. We found that it helps the students to break the language barrier when communicating with foreigners.
- Chinese students are not very comfortable with discussion—they feel embarrassed to challenge or be challenged about their thinking until they establish friendship that makes them feel safe. This also delays the initial group working efficiency.
- For cultural reasons, the Chinese students have no experience to evaluate other students/collaborators. If they have to do so, they tend to speak only the positive side. Therefore, we have to encourage them to do so, and emphasizing that this will help their friends to growth. Once they started to self/peer reflection, they can sense the feedback really helps them to work more efficiently.

IV. DISCUSSION

In this paper, we presented a story of educational and cultural exchange and collaboration towards building new global models for engineering learning. What we have collectively discovered is that problem-driven approaches applied to engineering classrooms can positively motivate students across the globe to take on challenges, adopt new behaviors and become engaged in major problems facing their cultures. Another lesson learned is that a local faculty

champion is necessary to best address the local differences and challenges. While the off-site GT mentor could help with problem development generally, it was the country-based team that could identify local problem topics that would quickly resonate with the students. A third lesson is the need to share exemplars of desired student work. For both faculty members at KUSTAR and PKU being able to see what the GT students were producing in terms of presentations and reports helped them in adjusting their expectations and scaffolding strategies. This access also gave them a benchmark against which they could evaluate the fidelity of their learning environment to the GT conditions. Importantly, we found that with careful design, problems from one classroom can be rewritten for a different cultural context with the same learning benefits.

At this stage in our transnational experiment, we have reached a kind of steady state that will allow us to take the next steps. These are to collect solid comparative data that measure the outcomes of engaging in open-ended complex problem solving in the first year of an engineering major. A challenge for our group is to translate the five 21st century competencies that frame this paper into measures that can be turned into authentic performance assessment strategies. While it is easy to test isolated engineering concepts like a free body diagram, developing measures and instruments for 21st century skills is critical to preparing the next generation of engineers. In fact, this is perhaps the most significant challenge facing all of engineering education globally. How do we show through careful design and measurement that we are doing our best to build 21st century competencies?

PROBLEM III

Version 1: In 2011, Ron Fouchier, a Dutch scientist, created a mutant H5N1 virus, which has the capability to be transmitted from person-to-person. Fouchier wants to publish his findings in *Science*, but many warn that this work could be replicated and used for bioterrorism. Your team has been hired by the National Science Advisory Board for Biosecurity to launch a quantitative engineering analysis to determine what effect publishing Fouchier work. Develop a mathematical/computational model and test various scenarios to determine whether he should publish or not.

Version 2: Zombies infected with something called "Rage" (developed at the U of I campus) are moving towards and threatening your campus. This virus is readily transmitted via blood-to-blood contact from zombies to humans. Once infected, humans rapidly (in about 1 minute!) become zombies. The zombies seem incapable of holding down food, so eventually they starve to death. Develop a strategy to protect the campus using mathematical and computational modeling.

Work in Progress: Can Bourdieu's Habitus provide a theoretical framework for Engineering Education Research?

Jo Devine

Agricultural, Civil and Environmental Engineering
University of Southern Queensland
Toowoomba, Australia
devinej@usq.edu.au

Abstract— This paper explores the use of Bourdieu's Theory of Habitus as a theoretical framework for a PhD study on the dispositions enabling non-traditional students to succeed in their first year of engineering studies. It provides a review of Bourdieu's sociological Theory of Habitus and the application of this framework to higher education settings and in particular to engineering education.

Bourdieu's theory of Habitus provides a framework for exploring and analyzing the behavior of individuals within a particular environment. It can provide insight into the behavior, and subsequent academic performance, of an increasingly diverse student cohort in the Australian higher education system. Bourdieu's theory offers researchers the opportunity to understand the complexity of human interactions within the education system. Moreover it is currently an underutilized tool for developing research methodologies as well as providing a framework for subsequent analysis [1].

Keywords- Bourdieu, habitus, disposition, student diversity

I. INTRODUCTION

Pierre Bourdieu was a renowned French intellectual of the late 20th century. He had a passion for social justice and much of his work involved the study of social inequality and the ways in which it is perpetuated, mostly without conscious recognition [2-4]. Bourdieu drew on the fields of philosophy, social anthropology and sociology [2] to develop his own sociological theories dealing with the stratification of contemporary society and its implications for individuals. His writings were voluminous and not terribly accessible to the those who are new to his work [4], which may explain why his concepts have been widely used in sociological explorations of higher education but not yet been widely adopted within the field of engineering education research.

II. BOURDIEU'S THEORY OF HABITUS

Bourdieu is notorious for not succinctly defining the concepts on which his theory is based and for using them in a fluid manner throughout his writing. However a working description of habitus, which is appropriate for the intended application, is that it is a collection of mostly subconscious dispositions which an individual initially acquires in early childhood via familial interactions and which are then

constantly modified by subsequent life experiences [4]. An individual's dispositions will be expressed as their thoughts, preferences, beliefs and aspirations, concerning themselves and the structure of the social world around them [5]. These dispositions then influence how a person will behave in a particular situation. Habitus is both shaped by the social structures within which it is formed and regulates the actions of an individual within those social structures [6]. Thus, individuals from a particular socio-economic group will usually have many dispositions in common. A person's dispositions will include beliefs about their chances of success in a given endeavor. Bourdieu postulates that one's aspirations, and subsequent actions, are then adjusted to the perceived chances of success. He refers to this idea as the "causality of the probable" [4].

Bourdieu uses his concept of 'Field' as a metaphor for all the organizations and individuals involved in a particular social or cultural arena and the interactions between them [4]. He sees every field as a situation of struggle, competition or conflict, the objective for each individual being to optimize their accumulation or retention of 'capital'. Bourdieu's concept of capital extends beyond mere economic capital to also encompass symbolic, cultural, social and linguistic capital. Each of these types of capital has a social value and can be 'inherited', through the circumstances of one's early upbringing, or accumulated, exchanged and leveraged much like economic capital [4].

Bourdieu's work is acclaimed by Rogers Brubaker [6] as one of the most significant attempts to adapt sociological theory to the empirical study of contemporary society. He articulated a 'reflexive, post-structuralist' position whereby individuals influence the fields within which they operate while concurrently being influenced by their own habitus; a construct of societal structures (including various fields) both past and present within which they have interacted [4, 6, 7].

III. BOURDIEU AND EDUCATIONAL SYSTEMS

Bourdieu sees the sociology of education as the foundation of sociology; a key setting through which cultural stratification is perpetuated. Bourdieu sees education as a form of cultural capital, which can be acquired through time, effort and money and which can be exchanged for a prestigious and profitable career [5]. Cultural capital can be acquired through education,

but more easily so by students already possessing large amounts of cultural capital through inherited wealth and/or position [4, 8]. Educational settings are also responsible for reinforcing the social class system or hierarchy through the classification systems adopted (admission & assessment) [5].

Bourdieu proposes that the educational decisions made by students (where and what to study) are the result of their dispositions, which in turn have been developed as a result of their personal habitus [5]. Student achievement or success is also addressed by Bourdieu. He proposes that whether students stay in school or drop out is largely determined by their perceptions of the probability of success for students of their background [4]. This is reflected in current expectancy value theory studies showing the importance of student expectations on academic achievement (e.g. [9]). Bourdieu further argues that a child's expectations of education and career are largely determined by their parents and early educational influences during the formation of their habitus.

Having been used by Bourdieu in the context of the French educational system the validity of Bourdieu's theories for applications in other cultures has been raised [7]. However Bourdieu was very interested in the applicability of the particular to explain the universal in society and his latter writings address the adoption of his concepts by English readers [7]. Reay [1] and Robbins [7] both point to extensive use in British educational sociology research. Berger [10] discusses the increasing popularity in the USA of Bourdieu's framework for exploring inequities in educational achievement, higher education organizational studies, student persistence and retention.

It has been argued [1, 7] that Bourdieu's theories have been widely misused, particularly by English speaking sociologists, who tend to examine their data using Bourdieu's theories rather than underpinning their research methodology with the theoretical framework that they can provide. Reay [1] argues that Bourdieu's theory of habitus is meant as a research methodology: a means of informing the investigations undertaken rather than simply as a lens through which to view the data collected in a study. Bourdieu's own data collection methods combine statistical techniques with observations and interrogation of relevant interactions, discourses and documentation [11]. He advocates the use of the methodological procedure that is most appropriate to the question at hand, close attention to the underlying theory of the research design and implementation and continual methodological review and refinement [11].

IV. THE PROPOSED APPLICATION OF BOURDIEU'S THEORIES

The recent Bradley Review [12] of higher education in Australia, makes recommendations for increasing participation in higher education. This coupled with the high demand for engineers has created a diversity of students enrolling in engineering programs. This trend requires extensive research as faculties attempt to develop appropriate systems, curricula and pedagogies to support non-traditional students. i.e. those who may not share the habitus and dispositions of existing engineering faculty and the academy at large. This proposed study targets those students who perform better academically that Bourdieu's theory of capital and habitus might predict.

Moore [13] discusses the exceptions which arise when using cultural capital alone to explain the excellent academic performance of these students. He explores Bourdieu's statements regarding such exceptional students in terms of the recognition of different groups within a given social class and the existence of 'particularities' or 'exceptional qualities' that enable these students' academic performance. This study will focus on the identification and explanation of these qualities, on which Bourdieu does not elaborate [13], using an ethnographic style methodology, based on Bourdieu's framework.

V. CONCLUSION

This paper presents only a preliminary introduction to Bourdieu's complex work and is intended to generate discussion about the possibilities it presents for engineering education research. As yet, Bourdieu's concepts have not been used as a framework within Engineering education research in Australia, where the field of engineering Education Research is dominated by academics with a technical engineering background and an interest in education. The disciplines and theories associated with sociology and education research tend to be secondary to their core training, so the adoption of these theories presents a challenge to such researchers. Bourdieu's call to English readers regarding the adoption of his theories (in his 1998 work *Homo Academicus*, as cited by Robbins, 2004) can be extended to engineering educators as a call to adopt or adapt this theoretical framework for underpinning new research methodologies and analyses of engineering education phenomena.

Abstract—The development of systems which adapt to the needs of student learning is a complex task. Learning involves several factors, including effective communication in a specific context. In this paper, we propose a conceptual framework to allow the integration of adaptive hypermedia in learning management systems from a cognitive-semantic perspective.

Keywords - *adaptive learning systems, Relevance Theory, ontology*

I. INTRODUCTION

The use of computers in education aims to promote student learning and help him develop important skills to achieve an active participation in society. One of the problems, reported by [1], is that students are treated as having always the same profile, goals and knowledge. Conventional applications, in general, do not take student's current context into account. One of the problems, reported by [1], is that students are treated as having always the same profile, goals and knowledge. In this research, we are dealing with cognitive contexts. Considering this, we propose a conceptual framework to allow the integration of adaptive hypermedia in learning management systems from a cognitive-semantic perspective based on some Relevance Theory principles. The semantic perspective considered the use of a domain ontology as the knowledge structure. The chosen domain is the area of preparation for JLPT (Japanese Language Proficiency Test) certification.

II. RELATED WORK

Some candidates to JLPT pointed out that they had difficulties in finding specific support to study in the Web. There are many software with material on the Japanese language, especially about *kanji*, which may make the study and preparation handicapped by the lack of appropriate material and guidance. Although, there is some software available in the Internet which supports JLPT preparation. Table I presents some features considered important in this type of software.

TABLE I. COMPARISON OF JLPT SOFTWARE

| System | Features | | | |
|--------------------|----------------------------|---|----------------------------|---------------------------|
| | <i>Kanji-only oriented</i> | <i>Satisfactory amount of questions</i> | <i>Cognitive construct</i> | <i>Adaptive resources</i> |
| JLPT Oficial Page | | | | |
| JLPT Study Page | | | | |
| Study Japanese | X | X | X | |
| Renshuu | | X | X | X |
| JLPT Kanji Project | X | X | | |
| e-JLPT System | | X | X | X |

The use of a cognitive construct or the existence of tutoring shows interest in customize the learning process, exercise and test preparation. There are three systems that use these resources: Study Japanese, Renshuu and e-JLPT system. The first two use the spaced repetition learning technique [2]. The e-JLPT system uses Relevance Theory as cognitive support and only Renshuu and e-JLPT system have adaptive resources. The e-JLPT system adapts navigation through the method of suggesting relevant topics of study. By the comparison table, e-JLPT seems to be an interesting option to be considered and explored by candidates to JLPT.

III. ADAPTIVE FRAMEWORK

Frameworks are techniques used in the design of object-oriented software. The great advantage of its use is the potential for reuse of parts of software already developed and the development of new software components.

The development of software for a specific implementation consists in instantiate the referred framework, through the specialization of its components.

A. The Conceptual Framework and its instantiation

The proposal to develop a conceptual framework came from the need to organize e-JLPT system, integrating the various components developed.

The proposed computational model uses domain ontologies as knowledge structure. This usage is largely related to portability, capacity to add new concepts and features as well as clarity, reuse, among others. The idea of using ontologies in the field of education is well-founded, as can be seen in [3][4] [5]. The proposed framework can be seen in Fig. 1. Its main components are:

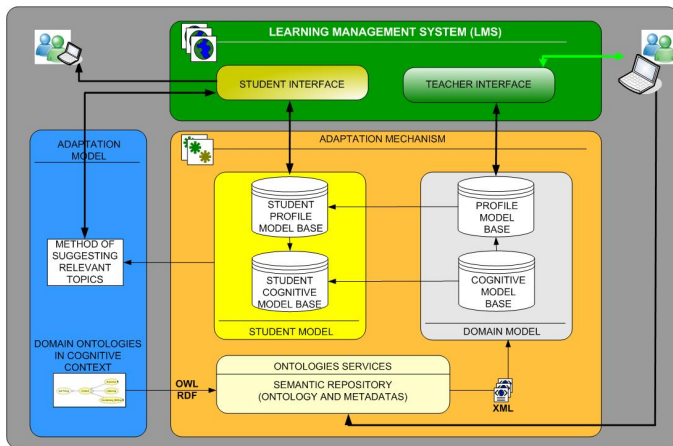

Figure 1. Conceptual framework

Learning management system – is a subsystem containing the hypermedia base and the students and teachers classes. It is the system interface layer with the actors involved which allows the definition of profiles rules to adapt to student's needs and the visualization of hypermedia adapted semantic-cognitively.

Adaptation Model – is the model that establishes policies for the environment adaptation, specifying the necessary components to the base of the adaptation mechanism. It consists of two components: the method of suggesting relevant topics and the domain ontology from the perspective of Relevance Theory.

Adaptation Mechanism – is formed by the user and domain bases obtained from the ontologies services, which are responsible for storing ontologies (semantic repository). Associated with these bases are the specific bases, with the rules for students' adaptation, consisting of Student Profile base and Student Cognitive base.

The instantiation of this framework took place in the area of preparation for certification of proficiency in Japanese language. It was implemented using a partial functional validation of use cases for adaptation scenarios identified in the environment. The validation was made using a study case.

The e-JLPT system is not a complete learning management system but it has the main functionalities to simulate a JLPT. It is based on JLPT domain ontology under Relevance Theory perspective. The profile and domain bases were modeled with features associated to JLPT. The proposal is to model the domain taking into consideration the several possibilities to navigate in the context.

Next subsection describes the development process of e-JLPT system and the tools used in the process.

B. Development Process and Tools

To implement the framework, there were five development stages. Each stage had its testing phase, with the help of the "Test::Unit" tool. These stages are described next:

a) Programming Language Migration

The proposed framework was originally built in ASP. The system went through a migration process to Ruby on Rails. This greatly improved the structural organization of the system, and has given a design pattern basis to work at, the MVC (Model-View-Controller).

b) First version – New Layout and Functionality Enhancements.

After migration, a version was created with a new usability perspective. This first version has benefited from new versions of web technologies like HTML 5, which allowed us to work without *plugins*. Functionalities such as registration procedure and first access to the system have been simplified.

c) Second version – Non-adapted Module and Function to Ontology Import

With the stable version already in operation, it was implemented the import function of JLPT domain ontology in RDF format, beginning the transformation of the system in a LMS with the proposed Adaptation Model. RDF.rb was the library used for RDF parsing.

With the domain ontology integrated to the system, in the form of JLPT topics of study, the Non-Adapted module was developed, with the creation of JLPT tests from a questions database, free choice of the student.

d) Third version – Adapted module.

In the development of the Adapted Module, two new functionalities were created: the permission of Japanese experts to define the relevance of each of topics of study presented in the ontology and the adaptation of the generation of tests, based on Relevance Theory.

e) Deployment and Maintenance.

For this work, Git was used to manage e-JLPT versions. Its branching model and flexibility assisted us on our goals, making each version well encapsulated from the other.

At the end of the development process, e-JLPT was available on the web and released for use. Bug fixing and improvements, result of suggestions and observations, were implemented, without any interference in the main goals of the framework, for a better interaction between user and environment.

IV. FINAL CONSIDERATIONS

This paper presented the evolution of a system which included a proposal for an adaptive conceptual framework. Its first instantiation was done in the Japanese Language Proficiency Test case study. The main components of this instantiated framework are: an educational system called e-JLPT, an adaptation model based on JLPT domain ontology and an adaptation mechanism based on the proposed method of relevance suggestion. This case study allowed a partial functional validation of the proposed framework.

Work in Progress: A Constructivist Didactic Methodology for a Humanoid Robotics Workshop

Alexandre Miranda, Yolanda Bolea, Antoni Grau, and Alberto Sanfeliu

Automatic Control Dept
Technical University of Catalonia UPC
Barcelona, Spain
yolanda.bolea@upc.edu

Abstract— This paper presents a constructivist methodology oriented to training Robotics in its wide sense, and its implementation in higher education. A humanoid robotics workshop is included as a part of the curriculum of ‘Industrial Robotics’ in the Industrial Engineering. This workshop covers one third of the laboratory practices of this subject. A constructivist view for learning is adopted, whereby robotic technologies are not seen as mere tools, but rather as potential vehicles of new ways of thinking about teaching, learning and education at large. Students, in a constructivist learning environment, are invited to work on experiments and authentic problem-solving; with selective use of available resources according to their own interests, research and learning strategies. The authors, as trainers of this workshop, chose ROBONOVA humanoid robots, among other devices, which attempt to partner technology with ideas of constructivism. The materials used in the workshop offer building parts, sensors thus connecting a robot with the external environment and programming software with a simple graphical interface intended for the creation of robot behavioral movements. The idea is “learning by design”, which is central in the constructivist pedagogy introduced firstly by Resnick. In this workshop we corroborate this idea through the project-based learning approach in robotics. Learning tasks of the workshop are organized as projects (small and large) that encourage students to develop their own designs. Projects are either instructor led or completely arisen from students.

Keywords- *Constructivism, Robotics, Humanoid robots*

I. INTRODUCTION

Robotics is a synonym of progress and technological development. Countries and companies with a strong presence of robots not only achieve high productivity, but also convey an image of modernization. It is for this reason that in developed countries investment resources in robotics have grown significantly in recent years. The application fields for robotics are becoming broader. Among these fields, one of the most investigated is humanoid robotics. These robots are characterized by their human appearance or by performing human functions. Although it may take the form of an entire human, many humanoid robotics projects are based on the study and behavior of a specific body part body such as hands, arms, legs or head (including eyes, mouth, ears or even artificial intelligence). The main application field of humanoid robots is human interaction, with an increase in its human like appearance, people are more willing to work with this type of

robot. Other areas where humanoid robots are being used include research. The need to understand the movements, behavior, cognition or the response of humans to some stimuli in order to incorporate them into a robot; also leads to a better understanding of the human body and brain. Humanoid robotics has provided new perspectives for the study of cognitive science. Last but not least, humanoid robots are being used in teaching. In the last few years, robotics is being introduced in school education from kindergarten to high school either as interdisciplinary, project-based learning activity or focused on school subjects; such as science, mathematics, informatics and technology [1]. The University has been working within this field for a number of years; research into educational robotics is an ever increasing area due to the social necessity of knowledge in this discipline. Engineering students should understand and be able to develop and solve real problems of human-machine engineering, in a cognitive way that will translate to professional life. A team of lecturers and instructors of Robotics in different degrees at the Technical University of Catalonia have analyzed the present situation of the students that enter at the University. They have detected, among other things, a lack of previous and basic knowledge related with robotics (mathematics, mechanics, electronics, automation) that any student at high school with a technological profile should have acquired prior to enrollment in an engineering degree.

In this work our main objective is the successful introduction of robotics to classrooms in an entertaining way. The role of the instructor is crucial for achieving this success in the teaching-learning process. A constructivist pedagogical methodology is used, [2] with the aim that the students achieve cognitive skills and abilities as well as the generic competences (sustainability, English) of the curriculum, in a solid way by learning resources of real-life, occupational situations and promoting the creativity and ideas of the student encouraging the cooperative learning [5][7]. This paper mainly presents a novel humanoid robotics workshop for high school pupils. A constructivist methodology is used. We will explain in detail some interactive experimental sessions designed to introduce students in the humanoid robotics world. In Section II, the context and objectives of the whole project are presented. Section III states the laboratory equipment needed to carry out the experimental sessions which description is on Section IV. It ends with the assessment of the workshop and the most relevant conclusions.

II. ROBOTICS WORKSHOP

A. Context: Robotics and Constructivism in Education

In this workshop a constructivist view for learning is adopted, whereby robotics technologies are not seen as mere tools, but rather as potential vehicles of new ways of thinking about teaching, learning and education at large [2]. This didactical methodology promotes the idea of “learning design”, which is central in the constructivist pedagogy introduced firstly by Resnick [1]. In this workshop we corroborate this idea through the project-based learning approach in robotics [8]. Learning tasks of the workshop are organized as projects (small and large) that encourage pupils to design and develop their own ideas are either instructor led or completely arisen from students. In our workshop we support this idea through the project-based learning approach. Pupils, in a constructivist learning environment, are invited to work on experiments and authentic problem-solving with selective use of available resources according to their own interests, research and learning strategies. Seeking solutions to real world problems based on a technological framework means to engage students’ curiosity and initiate motivation [6]. Learning tasks of the workshop are organized as small or large scale projects that encourage trainees to design and develop their own ideas. The active involvement of the trainees in all the parts of the workshop is another objective of the workshop [4].

To offer a good education it is necessary to ensure that the faculty remains at the cutting edge of relevant technologies, such as humanoid robotics, because technology changes rapidly over time. For this reason it is crucial that universities include this field in their engineering education. As it is said in [1] and [3], pedagogic robotics contributes in education:

- As knowledge and applied skills from several areas are needed, students expand their studies and interests.
- The use of the scientific method for solving problems and proposed exercises promote creativity, planning and organization of thinking strategies.
- Students, as a part of an active learning in which decisions are reached continuously and where errors are a key factor, are encouraged to supply new ideas and alternative solutions.
- Because robotics experimental sessions are often faced in small groups, students create a collective and cooperative consciousness, learn to appreciate their colleagues work and establish constructive dialogues in order to take decisions.
- Since this kind of learning is interactive and fun, students show more availability which makes teaching easier.

B. Motivation and Objectives

This project was born from the desire to expand the content of the experimental sessions of the Industrial Robotics course carried out in the Engineering degree in the Industrial Engineering School of Barcelona (ETSEIB) with some introductory sessions to humanoid robotics. Previously these

sessions consisted in working with some robotic arms and a brief introduction to computer vision and image processing. Nevertheless, the increasing integration of humanoid robotics in our society gave the chance to add this field to our education by means of some experimental sessions in an understandable and entertaining way. As a consequence, students will have another Robotic area to experiment with.

Moreover, with these practices, students carry out controlled activities in which they apply their previous knowledge to new situations and acquire basic skills and procedures of how to confront some problems related to the subject under study.

The main goal of this project is the design, development and implementation of some experimental sessions that provides to students a first contact with humanoid robots. These sessions consist of several creative and interactive activities that facilitate memory, transfer and generalization of learning. Besides, it will offer to students a practical way to apply their theoretical and cognitive concepts from courses already taken or that will be taken in a future, for example Automatic Control, Computer Science, Electronics or Mechanics.

Each experimental session remains open in order that the students increase and consolidate the corresponding skills; however every session has its own objectives that are expressed to the students at the beginning of the script. Following this scheme, the script is divided in two parts. The first one presents some essential concepts needed for the practice. Some of them will be only as a reminder while other ones have not been seen in prior courses and must be understood for the proper running of the session. It also includes commands and orders that students may not know, in order to use the working material and are deemed necessary as a helping hand. The second part of the script includes a series of exercises related to the previously explained theory, students will have to face up, implement a solution and finally test on the robot in order to check if the program designed works as required.

III. LABORATORY EQUIPMENT

The practice sessions with humanoid robotics are held at the Robotics Laboratory that the Automatic Control Department has available in the Industrial Engineering School. The laboratory has seven Robonova humanoid robots equipped with an ultrasound sensor, an infrared sensor, a sound sensor and an accelerometer.

A. Hardware

Robonova-I from HITEC is a humanoid robot designed specifically to get started in this area of robotics. However, it is also a robot for more experienced people. Its control board permits upgrading both the software and the hardware leading to new possibilities of utilization. The robot is 45 cm tall and it weighs 2 kg.

Robonova has 16 operative HSR-8498HB servomotors located as shown in Fig. 1 (6 in arms and 10 in legs). Nevertheless, the control board allows up to 24 servomotors.

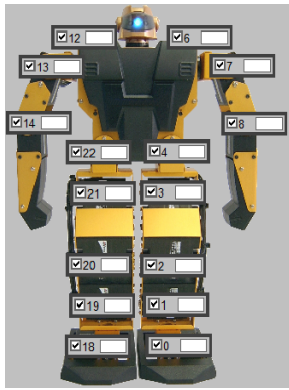

Figure 1. Servomotors Location at Robonova-I HITEC.

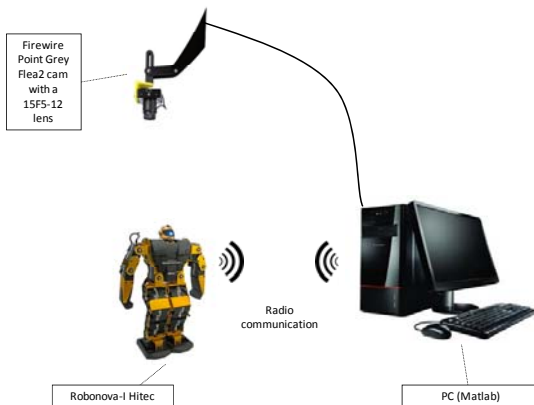

Figure 2. Stage of the visual-servoing experimental session.

Over the basic robot, various sensors have been incorporated. First, an infrared sensor (SHARP GPD12) with distance measurement range from 10 to 80 cm. Second, an ultrasound sensor (Maxsonar EZ1) with distance measurement range from 0 to 6.45 m. Third, a two-axis accelerometer (ADLX322) with g-force measurement range from -2 to +2 g. Lastly, a sound sensor can measure sound from 80 dB.

B. Software and Programming Language

RoboBasic is the language used for programming Robonova. This code is a variation of the BASIC language designed specifically for humanoid robots. The commands needed to control a robot have been added to the general BASIC programming language, although most of the language still resembles to BASIC. In addition, the default software has some applications in order to create and download programs in the control board so that they could be executed autonomously. The first one is also called RoboBasic. It is the most used programming environment and this application is utilized in the script of the experimental sessions.

C. Visual Servoing Session

For the realization of the visual-servoing practice, it is necessary to incorporate some extra devices to the robot and prepare a special stage. Fig. 2 shows this stage set to perform this experimental session. So that the robot can walk

independently it is necessary to use some wireless communication with the computer. In our project, we have used radio communication. For this reason, the communication is realized by means of two YS-C10U receiver/transmitter devices that transform the ETX/EX serial signal into radio and vice versa. In addition, in order to capture the robot motion we have fixed a Firewire Point Grey Flea2 camera with a 15F5-12 lens in the ceiling.

IV. ASSESSMENT OF THE WORKSHOP AND DISCUSSIONS

The workshop has been organized for three weeks in the summer (45 hours), when the regular course in high schools is finished. Over 20 students have participated in the workshop, selected from high schools that have demonstrated their interest in this new didactical experience. All the students have finished the workshop with excellent grades showing high interest in the new robotics approach. After a set of questions, it is concluded that they found the experience very fruitful and their interest in enrolling in an engineering degree is higher than ever. The authors are already preparing a second edition of the workshop because the experience has been also very enriching for all the instructors involved.

V. CONCLUSIONS

In this article the novel workshop, "Humanoid Robotics" for high school pupils has been presented. This workshop has been carried out based on a constructivist pedagogical methodology and four experimental sessions have been prepared. From the assessment of the workshop it appears that the training methodology ensured the students active participation and this encourages the authors to repeat the event. These practices were also carried out successfully as a part of the Industrial Robotics course at the Industrial School of Engineering at the UPC.

ACKNOWLEDGMENTS

This work has been funded by the Spanish Ministry of Science Project DPI2010-17112.

Work in Progress: Identification of Misconceptions governed by Emergent Phenomena in Photovoltaics Content using the Delphi Method

Katherine G. Nelson, Sarah K. Brem, Jenefer Husman

Arizona State University, kmuto@asu.edu, sarah.brem@asu.edu, jenefer.husman@asu.edu

Abstract— With the emphasis and growth of solar energy, there is a rising need to educate students to perform in PV engineering. However, the curriculum for PV Engineering has not been well-articulated - needing both a focus on what that content is, and also what learning challenges students face when they learn it. Misconceptions, primarily those resulting from a limited understanding of emergent phenomena, can act as significant barriers to learning, and as such should be considered in curriculum development. The purpose of this work-in-progress is to use the Delphi Method to identify emergent phenomena in PV that is critical to the understanding of PV, while highlighting the resulting misconceptions that can result when students learn this content.

Keywords—*photovoltaics; semiconductors; emergent processes; complexity; misconceptions; delphi*

I. INTRODUCTION

At the top of the list of Grand Challenges released by the National Academy of Engineering (NAE) is the development of solar energy. The NAE states that, if left unanswered, these challenges could have a significant deleterious effect on our way of life (NAE). Photovoltaics (PV), solar cell devices that convert the sun's energy into electricity, is the technology poised to meet this challenge. At the current growth rate of 40% per year, solar cells could be fulfilling all of the U.S.'s additional energy needs within 5 to 10 years [1]. The most significant limiting factor at this time, however, is not technology, but human capital. The advances made in the PV industry have outpaced the rate at which universities prepare students to fill the many positions that PV creates, from research and development to installation and maintenance. Few degree programs are offered within the field of PV. Further, because PV content is often taught building on semiconductor fundamentals, it does not thoroughly address the knowledge needed for an accurate understanding of PV. If we are to meet the need for human capital in PV, steps must be taken to develop a PV curriculum that effectively engages students and promotes learning [2].

The photovoltaic curriculum is in its earliest stages of development, which presents a challenge, but also an opportunity—to build an entire curriculum for the field from scratch, incorporating cutting-edge educational research from cognitive science, educational psychology and engineering education. Although there are many facets to curriculum development, a reasonable first step is to identify the critical

concepts, processes, and procedures that provide fundamental understanding of PV. In addition, we need to identify the conceptual challenges that students face when they encounter this content. These challenges can act as potential learning barriers for students, both cognitively and motivationally.

Some of the most tenacious problems in understanding scientific concepts are the presence or development of misconceptions. Unlike procedural errors or lapses of memory, which are relatively easy to detect and remedy, misconceptions often go unnoticed by students and instructors, and can be extremely difficult to unlearn [3]. Thus, we are particularly interested in identifying misconceptions as we go forward in determining the key PV content.

Understanding PV (and semiconductors more generally) relies heavily on understanding emergent, as opposed to direct, processes. Emergent phenomena are those processes that result from the interaction of numerous lower level interactions, not resulting from a singular direct causal factor [4]. Research in other areas of scientific content has shown that emergent phenomena frequently lead to the development of more robust misconceptions than do direct phenomena [5]. Although we do not yet have a set of critical concepts for PV education, we suspect that emergent phenomena will be central to the challenges of mastering PV, and we will be paying particular attention to misconceptions relating to emergence while developing a comprehensive map of the critical concepts and challenges PV creates.

The aim of this work-in-progress, therefore, is to describe our use of the Delphi method for the purpose of identifying the most significant and challenging phenomena for the ongoing development of the PV curriculum, with an emphasis on emergent phenomena. As we will elaborate below, we believe that the Delphi method is the best way to achieve expert consensus.

II. METHODS

A. The Delphi Method

The Delphi method is a well-established process for finding solutions to complex problems that do not lend themselves to quantitative or algorithmic solutions. Instead they require qualitative approaches [6]. The Delphi method has been used in numerous fields; in engineering education, it has been successfully employed in the development of concept inventories [7]. The method requires a group of subject matter experts (SMEs) to come to consensus through a rigorous,

iterative process in which each wave of inquiry influences the scope and direction of further investigation - revising and refining the problem space until consensus is reached. The Delphi method can be implemented in a number of ways [6]. We will be using a face-to-face approach because the curricular problems are not well known.

This study will be conducted in three phases. The purpose of Phase I is to develop preliminary materials to provide a starting point for expert discussion, and, in doing so, identify the SMEs needed for a broad examination of PV content. The preliminary materials, drawn from existing texts and syllabi will provide a succinct yet detailed account of the current state of PV education, and introduce the SMEs to the cognitive and motivational landscape underpinning students learning of PV.

Phase II, which will take place during an intensive 2-day workshop, will alternate the SMEs between meetings as a complete group and in focus groups of approximately 8 participants. The larger assemblies will be used to provide background information and to report out and discuss the results of the focus groups. The goal will be to collect the data needed to develop a preliminary account of the critical concepts in, and challenges to learning PV.

In Phase III, the data will be analyzed and further elaborated and refined through small online meetings about specific topics. Ultimately, the goal will be to organize and rank the critical concepts and challenges, especially those challenges regarding misconceptions related to emergence.

B. Subject Matter Experts

Essential to the Delphi method is the recruitment of experts from all areas relevant to the question at hand. Experts must be willing and capable of articulating not only explicit knowledge, but also the tacit knowledge and practices that contribute to a problem and its solution. The group must be large enough to ensure breadth, and small enough to facilitate in-depth conversation and debate [6]. We anticipate recruiting a group of approximately 25-30 experts in the areas of PV and semiconductors, to address the specific content, and experts in cognitive and motivation psychology to address the learning issues associated with mastering that content. Because of the transdisciplinary nature of the project, these experts must be willing to engage in the hard work of cross-disciplinary talk, and learning at least the basics of the disciplines involved. In Phase I, this work will begin with providing all participants with a basic grounding in the relevant disciplines. In Phases II and III, balanced groups will be created that ensure all areas of expertise are represented in all conversations.

C. Data Analysis

The information gathered in Phases I and II will be qualitatively analyzed from artifacts, audio-visual data, and field notes. The researchers will be responsible for extracting both the explicit and tacit content from these data sources for expert evaluation and feedback in Phase III. Initially, Phase III will also rely on qualitative coding methods, leading up to the development of a survey that will be quantitatively analyzed to measure the degree of consensus and to identify areas of greatest and least consensus.

III. OUTCOMES, LIMITATIONS, AND FUTURE RESEARCH

The results of this study will represent only the first step in identifying how to best design an effective PV curriculum. Without a clear picture of the content and challenges involved in PV education, incorporating such issues would be premature; nevertheless, the researchers will be looking for areas of potential opportunity and impasse related to these areas.

A second limitation is that, although the project is intended to culminate in a closed-ended survey, it may prove that this step is not yet indicated. We cannot know how complex the results will be, nor how much or little consensus will be achieved. Still, we believe we will be closer to that goal at the end of the project than we are now.

Regarding future research, our goals are as follows: (a) use the knowledge gleaned here to build the PV curriculum and test its effectiveness in limiting learning barriers, (b) develop interventions to help students overcome misconceptions from incorrect conceptualizations of emergent phenomena, and (c) determine how to overcome misconceptions through promoting intentional conceptual change[8].

Work in Progress: A Developmental Approach to Better Problem Solving: A Model for Bridging the Alverno Gap

Stuart Kellogg, Jennifer Karlin
Industrial Engineering
South Dakota School of Mines and Technology
Rapid City, SD

Abstract— The department has adopted a holistic student-centered approach to support attributes of the Engineer of 2020. Among these include a culture that embraces intellectual diversity, better team skills, improved problem solving skills, and better complex thinking skills. Strategies incorporating classroom inversion, active learning, and team projects have demonstrated remarkable gains in retention, intellectual diversity, and general problem solving skills. While well above the national average, continued intellectual growth has stagnated over the past three years and remains below that desired both by industry and by the department. In an effort to improve complex thinking skills the department is adopting a developmental approach modeled by Alverno College which has demonstrated substantial growth in many of the attributes of the Engineer of 2020. As a first step towards reducing this "Alverno Gap", the department has adopted a developmental approach which is focused on improved problem solving skills within a team environment. In this paper, we describe the Alverno model, discuss an explicit developmental approach to team skills and processes, and provide some initial insight into using embedded assessment as an integral component of transformative curriculum.

Keywords—component; developmental; problem solving skills

I. THE NEED FOR TRANSFORMATION

As a result of a global economy and the move to lean enterprises, industry has taken a stronger stance in asking for a different type of engineering graduate that has the leadership and complex thinking skills needed by today's industry. To maintain the nation's economic competitiveness and improve the quality of life for people around the world, engineering educators and curriculum developers must anticipate dramatic changes in engineering practice and adapt their programs accordingly [1]. This report and a companion phase II report [2] identifies some of the ideal attributes of the engineer of 2020 as well as recommendations for curricular innovations that begin to address these attributes. Further, this is not an isolated study. The Accreditation Board for Engineering and Technology (ABET) implemented a revolutionary approach to accreditation by focusing on what is learned rather than

what is taught, thereby fostering innovation [3]. Industry increasingly demands development of team skills, leadership skills, a better understanding of business processes, an ability to innovate and think outside of the box, and an ability to communicate effectively in a diverse environment (see, for example, [4]). In short, industry needs engineering graduates that can help solve and implement solutions to the complex problems industry is faced with today. Figure 1 below provides a conceptual framework for skill development for the engineer of 2020.

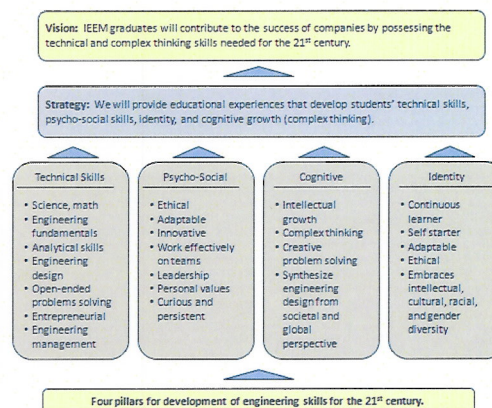

Figure 1. Four Pillars of Development of the Engineer of 2020

While Figure 1 displays the skills and attributes for the engineer of 2020, it provides only a limited framework for development of these skills. In this regard, the department has incorporated a research based approach to engineering education, assessment, and best practices. For nearly a decade the department has adopted a best practice approach for pedagogies of engagement [5], intellectual diversity [6], and intellectual development [7-10]. Department courses routinely integrate cases, role plays, simulations, active/collaborative learning, multi-disciplinary team projects, and service learning components.

As a result of these initiatives, the department has seen remarkable results in terms of intellectual diversity and improved problem solving. For example, of the last 144

students completing a typological index in the first semester, the program has lost only 5 students, which roughly translates to a 95% four year retention rate. More importantly, by explicitly stating an expectation for intellectual diversity the department has seen a corresponding increase in intellectual growth using the Reflections on Current Issues instrument. Nevertheless, complex thinking skills remain below level 5 which is a stated goal of the department. By incorporating an explicit developmental framework to student learning, Alverno College graduates consistently achieve higher levels of intellectual development. We refer to this gap as the Alverno gap and we have launched a stronger developmental approach for improved problem solving by incorporating a similar approach.

II. THE ALVERNO MODEL

The Alverno model consists of a conceptual shift from a course-based distribution of what is taught to a curriculum-based, metacognitive approach to what is learned by students as developing learners, thinkers, and performers within the engineering profession. By placing the learner at the center of the curricular enterprise and how she/he experiences the curriculum and demonstrates learning outcomes shifts the focus from teaching content alone to integrating content and knowledge in a more constructive manner.

A key component of the Alverno model is reframing assessment as an opportunity for student learning. Consider, for example, a traditional view of curriculum development: we note a problem for improvement, devise an intervention strategy, and assess the result. In this approach, assessment is viewed as a necessary burden for demonstrated efficacy of the intervention. Alternatively, by explicitly stating required performance outcomes, one provides a learning environment where student self-assessment coupled with faculty and peer feedback provides a construct for learning that lasts [11].

In order to shift from a knowledge transmission curricular system to a system where students integrate and transfer learning outcomes across courses and discipline content areas, one must consider learning outcomes along developmental lines. For example, a goal of every university is that students can demonstrate a capacity to transfer understanding of different problem solving techniques into a variety of contexts and it is in that manner that we typically teach. However, the ability to transfer and adapt across different contexts is a high level thinking skill and is not likely to be achievable if lower skills are not developed and reinforced along the way. If a student cannot articulate the problem solving process, it is not possible to transfer the problem solving framework from one context to another. Consequently, we must explicitly state these outcomes for students and require demonstrated performance along developmental lines as the student progresses through the curriculum. A rubric defining a developmental approach for general problem solving is shown in Table 1 below.

TABLE 1. DEVELOPMENTAL RUBRIC FOR PROBLEM SOLVING

| Attribute | Demonstrated Abilities | Level |
|----------------------|--|---------|
| Problem definition | Can articulate the problem solving process by making explicit steps to approach a problem | Level 1 |
| Problem articulation | Can identify and detail appropriate alternatives and constraints | Level 1 |
| Define elements | Practices elements of a disciplinary process to approach problems | Level 2 |
| Problem analysis | Can independently analyze, evaluate, and select various approaches to develop solutions | Level 3 |
| Problem evaluation | Performs all phases within a disciplinary problem solving process including evaluation and real or simulated implementation | Level 4 |
| Problem transference | Demonstrates a capacity to transfer understanding of different problem solving techniques into a variety of contexts | Level 5 |
| Applies frameworks | Applies methods and frameworks from a variety of disciplinary perspectives and adapts them to a specific context; demonstrates independence and creativity in problem solving activities | Level 6 |

ACKNOWLEDGMENT

We would like to thank Ruth Streveler, Purdue University, Marcia Menkowski, Tim Riordan, and Alverno College for initial templates and continued guidance using embedded assessments to guide student development.

Abstract—Work began in late 2010 on a project to revise the ACM/IEEE-Computer Society Computer Science volume of Computing Curricula 2001 and the interim review CS 2008. The new guidelines for computer science are scheduled for release in 2013. This interactive session will give the computing education community an opportunity to review current working documents created by the CS2013 Steering Committee and thus influence the CS2013 volume scheduled for release in 2013. The Strawman draft of CS2013 was released in early 2012, containing new knowledge areas as well as significant updates to previous knowledge areas. The Steering Committee will present the Strawman draft and discuss changes to that draft that are being considered as a result of the first round of public comments. The majority of the session will be devoted to engaging attendees in guided discussions of sections for which additional community input is particularly relevant.

Keywords—computer science education, computing, curricula, CS2013.

I. INTRODUCTION

Since the publication of Curriculum 68 [1] over 40 years ago, the ACM/IEEE-CS Computing Curricula volumes have helped to set international curricular guidelines for undergraduate programs in computing. The most recent complete Computer Science curricular volume was released in 2001 (CC2001) [2] and was followed by a review effort that concluded in 2008 (CS2008) [3]. The next curricular volume in the series is targeted for publication in 2013. This panel seeks to update and engage the computing community on the Computer Science 2013 (CS2013) effort.

The rapid changes and expanding diversity in the computing fields makes the development of guidelines challenging. Moreover, the growing diversity of topics in Computer Science and the integration of computing with other disciplines create additional challenges and opportunities in defining computing curricula. Balancing this topical growth with the need to keep recommendations realistic and implementable in the context of undergraduate education is particularly challenging. It is vital to the success of the project that the new volume be based on broad participation by the community of CS educators.

By considering both the current state of the field and promising future directions, and by rethinking the knowledge and skills essential for a CS curriculum, CS2013 strives to

provide advice and guidance to the computing education community throughout the current decade.

The high-level themes on which the CS2013 effort is based include:

- *The “Big Tent” view of CS* – As CS expands to include more multi-disciplinary work and new programs of the form “Computational X” are developed, it is important to embrace an outward looking view in computing that sees CS as a discipline actively seeking to work with, draw from, and integrate into other disciplines.
- *Managing the size of the curriculum* – Although the knowledge base of CS has expanded dramatically in the past decade, it is not feasible to proportionately expand the size of the curriculum. CS2013 must re-evaluate “essential topics” without requiring more total instructional hours than the previous guidelines. The circumscription of curriculum size is necessary to promote more flexible models for curricula without losing the essence of a rigorous CS education.
- *Actual course exemplars as opposed to stylized course guidance* – CS2001 took on the significant challenge of providing descriptions of stylized courses incorporating the knowledge units defined in that report. While this was a valiant effort, it was felt in retrospect that such course guidance did not have much impact on actual course design. As a result, CS2013 takes a different approach: identifying existing successful courses and curricula as fielded exemplars of how relevant knowledge units can be addressed in actual programs. This bears similarity to the report by CRA-E [4], although that report focused on preparing students for research careers.
- *Institutional needs* – Curricula exist in the context of specific institutional needs, goals, and resource constraints. As a result, CS2013 allows for explicit flexibility in curricular structure through a tiered set of core topics, where a small set of Tier 1 topics are considered essential for all CS programs, but individual programs have flexibility with regard to their coverage of Tier 2 topics.

II. CS2013 BODY OF KNOWLEDGE

The Strawman draft of CS2013, available in spring of 2012, focuses primarily on updating the Body of Knowledge in computer science, organized around 18 Knowledge Areas, outlined below:

- Algorithms and Complexity (AL)
- Architecture and Organization (AR)
- Computational Science (CN)
- Discrete Structures (DS)
- Graphics and Visual Computing (GV)
- Human-Computer Interaction (HC)
- Information Assurance and Security (IAS)
- Information Management (IM)
- Intelligent Systems (IS)
- Networking and Communications (NC)
- Operating Systems (OS)
- Platform-Based Development (PBD)
- Parallel and Distributed Computing (PD)
- Programming Languages (PL)
- Software Development Fundamentals (SDF)
- Software Engineering (SE)
- System Fundamentals (SF)
- Social and Professional Issues (SP)

Two substantial reorganizations in the Body of Knowledge include introductory programming and systems. In the area now called Software Development Fundamentals (previously called Programming Fundamentals), we have extracted fundamental software development concepts, including topics in algorithms, design, programming, and software development processes. In systems, we have identified common themes among operating systems, networking, and computer architecture that are captured in a new area called Systems Fundamentals. Additionally, specific developments in the field in the past decade (such as the pervasiveness of parallel computing and the need for better understanding computer security) have given rise to the development of knowledge areas in Parallel and Distributed Computing, Information Assurance and Security, and Platform-Based Development.

III. DESCRIPTION OF THE SPECIAL SESSION

The goal of this panel is not simply to provide an update on the state of CS 2013, but to actively engage the community in

work that will eventually manifest in the final published volume. Holding this panel at FIE is an important step in further engendering that engagement in a broad forum. Indeed, the CS2013 effort has already reached out to a number of communities, holding presentations at SIGCSE-12, SIGCSE-11, CSEET-11, FIE-11, FCRC-11, EAAI-11, as well as being involved in curricular discussions at SIGCOMM-11 and SPLASH-11.

The desired outcomes of the session include

- Increased awareness and participation in the CS 2013 Project among the computer science community;
- Review of several sections of the Body of Knowledge, including revision of outcomes;
- Review of comments and responses generated from the open comment period for Strawman; and
- Discussion of and guidance on the identification and documentation of course and curricula exemplars.

The session will start with a brief overview of CS2013 and the Strawman draft. Participants will then break out into small groups based on their areas of interest to review sections of the draft. Members of the Steering Committee will facilitate these discussions. In this way, session participants will have the opportunity to influence the next draft of CS2013 and the ongoing work of the Steering Committee.

Abstract—Research questions in STEM disciplines are frequently strongly contextualised in the teaching and learning practice of the researcher. In this paper we chart a number of possible paths a researcher can follow from a single research proposition, or fundamental research question, to results which can vary significantly in nature. In order to do this, we establish a theoretical framework for research activity and examine the meaning of "theory" as a cognitive and research tool that helps engineering education practitioners and researchers. The paper reflects on the nature and role of different types of theory at four distinct stages of engineering education research: disciplinary, methodological, analytical, and interpretive. We illustrate how theory applies to the framing and integration of study results, and assists in the process of relating theories of learner development and learning to results of empirical data analysis.

INTRODUCTION

In this paper, we respond to criticism of engineering education research (EER) as methodologically unsound and contribute to a nuanced understanding of the nature of engineering education research by discussing how it draws upon different types of theory. The goal is to understand how theory is used in our research field and to provide opportunity for self-reflection about the philosophical and epistemological commitments that underly engineering education research.

The structure of a teaching and learning study, and the nature of the evidence it produces is important for the relevance to the target audience of a piece of research. We argued in Daniels and Pears [1] and Thota et al. [2] that the relationship between the research question and the nature of expected research outcomes are central to the process of resolving alternative epistemological positions and in choosing research method, and data collection and analysis approach.

In our previous work, we propose meta-level frameworks, which can be used to reason about the implications of epistemological and methodological choices on the nature of the results that can be obtained. The tree metaphor proposed

by Kinnunen illustrates the epistemological implications of data collection methods, linking types of data collection to theoretical positions and the methodological root which a study implicitly acquires as a result of research design choices.

This paper combines these results and illustrates their complementary applications. The remainder of this paper is organized as follows. In section 2, the implications of theories and hypotheses of tertiary learning processes, and the role and meaning of the term "theory" in that process are examined. Section 3 illustrates different ways to research the same question, and how this results in different choices and outcomes. In section 4 we discuss how the practitioner-researcher gap can be bridged through the use of theory. We commence with a discussion of theory related to learning of the discipline itself. Following this, is a discussion of theory as it applies to methodological choices and to data collection and analysis of data, and theory as a tool to reason about the meaning of results. Finally we summarise our contribution to the discourse on relationship between research questions and results.

EPISTEMOLOGICAL ROOTS AND THEIR IMPLICATIONS

The implications of theories and hypotheses of tertiary learning processes in the disciplines, and the role and meaning of the term "theory" in that process, is not a new topic in educational research. We commence our discussion with examples of classifications proffered by two prominent scholars as a background to a discussion of the role and significance of different types of theory to the pursuit of EER.

One view of the discourse on the role of theory is that of Cohen et al., adapted from Barr Greenfield (1975) [3]. They discuss two major types of theory.

- Theory as objective: A rational edifice built by scientists to explain human behaviour.
- Theory as subjective: Sets of meanings which people use to make sense of their world and behaviour within it.

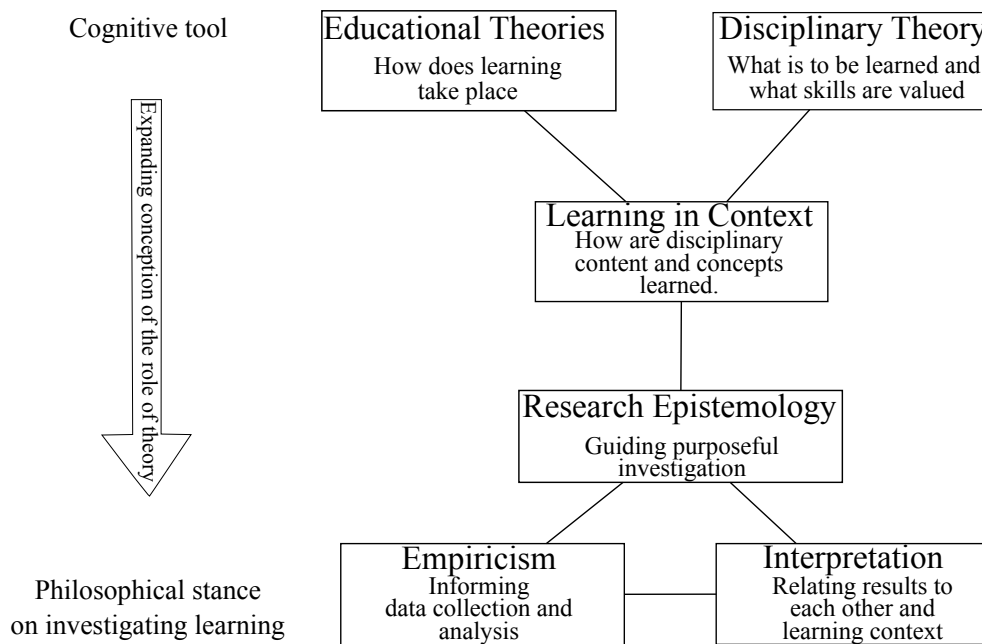

FIGURE 1. Roles of theory and relationship to researcher conceptions of theory

In his critical evaluation of sociological theory, Mouzelis [4] also identifies and discusses what he distinguishes as two distinct kinds of theory:

- Theory as tools for thinking.
- Theory as a set of statements telling us something new about the social world and which can be proved or disproved by empirical investigation.

The common feature of these classifications is that they focus on the manner in which theory is used. So, what do we mean by using the term “theory” in EER? To answer this question we commence with an attempt to define the term and how it is applied in the EER context. Looking at how the EER community literature reports on its research, we suggest that one can define theory as, “a way to reason about the nature and structure of observable learning phenomena, and their operation and inter-relationships”.

We also propose that the contribution of theory be viewed in two ways. The first of these is explanatory power, which is related to the richness of the theory as a tool for explaining and reasoning about the properties and interrelationships of the phenomena being observed. The other is the utility of the theory as a means to structure activity and guide structured investigation. In both cases a key property is the relationship between theory and empirical study.

Theories are adopted and discarded by research communities based on their perceived explanatory power and utility in relation to empirical investigation. Part of the process of harnessing theory in the service of EER is to discuss these two aspects of theory in relation to research in our discipline. To do this however, it is necessary to provide a structured approach to theory, and how theory is used in our research.

We suggest that the focus of the research activity has an

influence on the importance attached to the explanatory power and structural utility of different types of theory, and that theory means slightly different things depending on the type and level of abstraction of the research activity. To explore this series of claims we provide a classification of modes of use of theory in EER. In figure 1, we integrate the views of theory advanced by Cohen and Mouzelis and combine these with our own views of the development of EER. The top section of our diagram integrates objective theories, which are often related to the discipline and describing learning.

As theories are combined and used by researchers earlier theoretical stances give rise to domain specific theories which are used to reason about learning of a specific discipline area. These theories can relate to learning specific concepts and skills, for instance in Physics, Maths or Computer Science. There are a number of examples of such studies across disciplines of which we are aware, some examples include the following papers [5]–[7].

The lower half of figure 1 relates theory to investigative purpose in a research study. Epistemological and ontological works often guide our research providing structure and coherence. They also establish the grounds for collecting and arguing from evidence, providing a value system within which to consider what constitutes evidence, how claims are made and supported, and upon what constitutes “proof”. However, these types of theories do not operate in a vacuum. They form a research ecology in relation to theories and methods for data collection and analysis that generally derive from an epistemological stance or research tradition.

Finally, higher level theories allow us to reason about the broader implications of the results of individual studies, often allowing us to combine results which were obtained

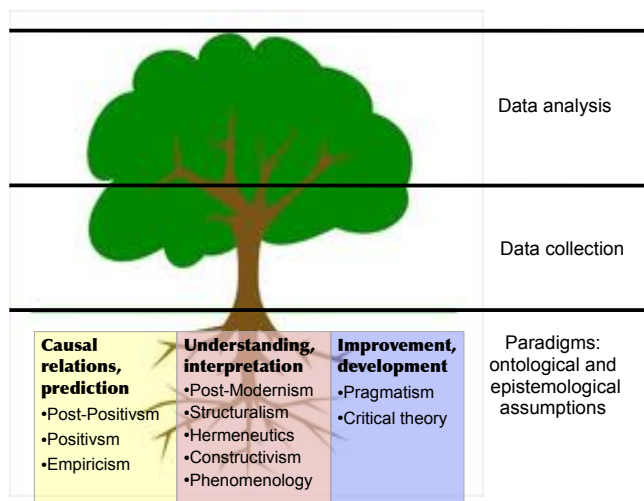

FIGURE 2. Implications of epistemological basis for method and outcome

by methods drawing on different epistemological roots. An example of such a theory might be Wenger's social theory of learning [8] which might be used to integrate results related to identity derived from interview data using phenomenography [9], with other results on social position in a community of practice [10] obtained from classroom observation and ethnographic analysis.

THREE PERSPECTIVES

In this section, we discuss three perspectives on research that provide different views of the overall model presented in figure 1. As we have already argued, the impact of the tacit epistemological basis upon which much pragmatic educational research in engineering is conducted has profound influences on the results. This impact can be discussed from three different viewpoints, namely data collection, research question, and research ecology. After the discussion of the three frameworks, the current paper adds to the discussion by focusing on how the practitioner-researcher gap is bridged through use of theory.

Noting that many research studies commence with a choice of data collection and analysis method, Kinnunen proposes a tree analogy, which provides a vivid representation of the manner in which choice of data collection method is strongly connected to an underlying epistemology. This observation has far reaching theoretical implications for the entire research enterprise (See figure 2).

The tree can be viewed as a metaphor for the research process. In its simplest interpretation it allows us to visualise how methodological choices are connected to the ontological and epistemological beliefs of the researcher (whether they are conscious of them or not). For example, if a researcher chooses to collect data through interviews (semi-structured/open) that reflects what the researcher believes to be valid information.

At a more advanced level, the tree can be used to analyse research examples by overlaying them on the three levels of abstraction that the tree is a metaphor for. This makes it possible to discuss the implications of choices made at all

three levels of abstraction in a structured manner. For example, a study that has its roots in phenomenology and hermeneutics, can be expected to have a trunk in phenomenography, the leaves include interviews as a data collection method and thematising and categorizing (and building up the outcome space) as data analysis "strategy". This constructs a coherent line from roots to the leaves¹.

The next viewpoint (figure 3), takes its point of departure in the research question, and the nature of the enlightenment the research is designed to gain. The type of answer a study provides depends on the path that is chosen through the levels depicted by the figure. Each path in this figure is analogous to following one of Kinnunen's research trees, and uses the research question to identify and reason about choice of a suitable root.

What does following one of these paths actually involve? Since each path represents the study of an aspect of our question, the design in each case will be strongly influenced by the research approach. The point of using methods from other disciplines in EER, is to be able to address different aspects of the research question at hand. Each possible path results in distinct answers, but they will have different properties depending on the approach taken.

In general, the nature of a research approach lifts some facets of the question into sharp focus while others remain blurred and in the background [11]. Richer answers to any question can be expected if more of the relevant facets are explored. Informed choice of research approaches in a multi-method study provides the researcher with a richer set of data. Such data, in turn, helps to build a stronger case by providing several types of the support for claims in regard to improving learning outcomes.

Astute readers will perhaps wonder why the research question is not completely enclosed in figure 3. The lightly sketched segments are a reminder that EER is not the only research field interested in such questions. Other candidate areas might be education or social sciences, where studies based on the same question, can be expected to generate results which might have little relevance for the learning and teaching of engineering, but contribute to a broader understanding of how learning takes place.

The final viewpoint in figure 4, depicts a mixed-methods research framework as an interaction of research elements rather than as a linear process. In any research study, the research purpose, philosophical assumptions, and research design choices made by the researcher influence the research outcomes. The researcher's theoretical, personal and/or professional goals determine the problem and aid in formulating research questions which are then refined through the process of literature review. The philosophical assumptions that a researcher adopts include world views that shape methodological choices. The research validity and credibility criteria used in a study also stem from the researcher's conceptual orientations.

¹As examples cumulated we noted how many different roots there are (and how there are certain root families).

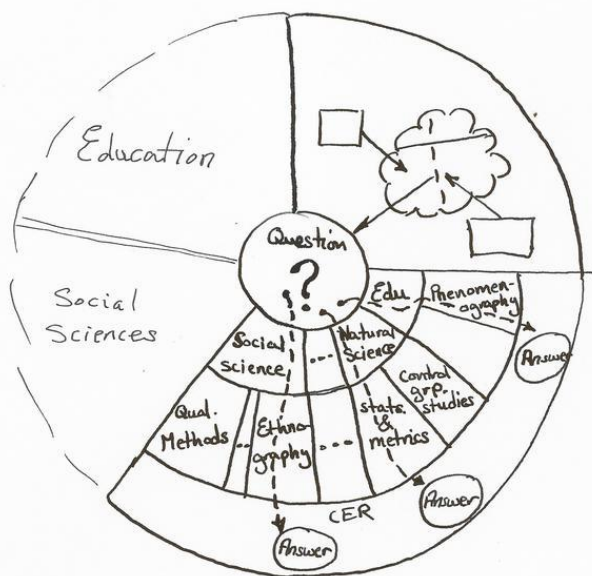

FIGURE 3. An holistic model of pragmatic EER

Figure 4 shows that the research purposes and the underlying philosophical assumptions in turn, influence the nature of the design typology, the selection of the data collection instruments, and the analytical methods that are followed. Research studies, that include the collection of qualitative and quantitative data collection, undergo an iterative process as the findings get integrated at various stages. The conclusions and inferences from such studies are a synthesis of the research study elements as the researcher revisits the research questions/issues and justifies the methodology for each of the data collection method and the analysed results.

BRIDGING THE PRACTITIONER-RESEARCHER GAP

Why is the choice of underlying theoretical approach important for a practitioner turned researcher? In pragmatic EER, the point of departure for a majority of research studies is a desire to investigate a teaching and learning situation and to obtain illumination regarding aspects of a problem that faces the practitioner/researcher. In common with other families of embedded research, of which action research is an excellent example, the researcher is actively engaged in both research and the activity on which the research is being conducted. The implication of this standpoint is that the choice of research approach derives from the nature of the research question facing the researcher, and the type of insight the researcher deems will be most useful in helping to resolve the issue (with the subsequent impact on improvement of the overall learning environment in which the research question is situated).

Extending these ideas we discuss how theory is used in practice when we conduct investigations, and reason about

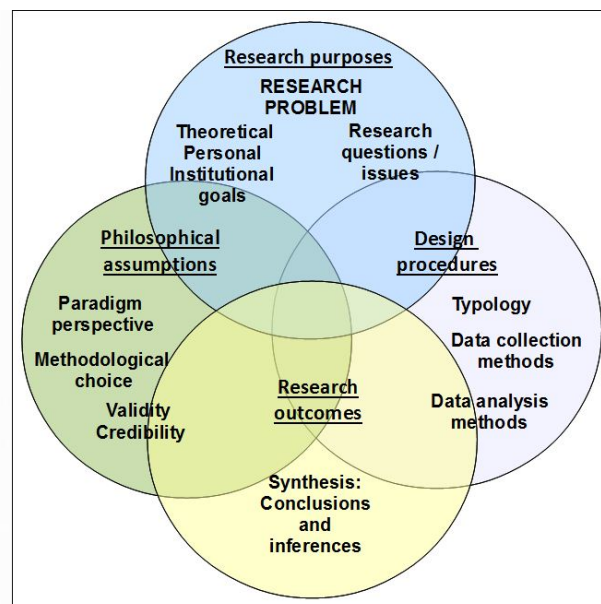

FIGURE 4. Illustration of the interaction of research elements [2]

the implications of study results for teaching and learning in engineering. We position the role of theory in computing/engineering education research in terms of the following:

- 1) Cognitive tools that help to map areas in learning and teaching computing/engineering.
- 2) Methodological guideline to define research approach, and methods for data collection and analysis.

Theories, as cognitive tools, help computing/engineering education practitioners by providing:

- Teaching theories related to computing and engineering i.e. Theory of the discipline (Body of Knowledge). They include the what and how of learning in that area, and the theories of the discipline itself.
- Guidelines to develop pedagogic frameworks for courses and lessons (laying the groundwork for scholarly curriculum and instructional design).

Theory related to understanding learning in engineering appears to have a more complex nature in its manifestations in the research literature. We have been able to identify several categories of theory use based on a broad sample of research literature which we have collectively reviewed over the last ten or so years.

On the level of more general EER, theories can be seen as methodological guidelines which help computing/engineering education researchers in their work. Our categorisation of theory in the lower section of figure 1 assists the researcher-turned-practitioner by distinguishing between:

- meta-theory, dealing with paradigm and methodological choices e.g. pragmatism, critical theory.
- support for structured data collection and analysis, e.g. interview techniques, population sampling.
- helping to integrate and interpret the results of investigations e.g. phenomenography, content analysis.

- For interpreting outcomes of investigations and relating them to a broader educational context e.g. activity theory, grounded theory.

CONCLUSIONS

In this paper we explore several aspects of how theory is used to support research activity, both with different purposes and at different levels of abstraction. A general research model is proposed, and its implications explored in relation to research activity of different types using three different analogies, or metaphors.

We conclude that there are several ways in which theory can be experienced as having value in the engineering education research endeavour. Practitioners have immediate use of engineering education research theories as cognitive tools, which guide innovative curriculum and instructional design. In this paper, by suggesting categories of theories as methodological guidelines for research. Our work contributes to a discourse which bridges the practitioner-researcher gap, and contextualises the use of theory in pragmatic engineering education research activity.. Understanding the philosophical stance of EER, and the expression of this philosophy in the manner in which theory is defined and used, contributes to the systematic and structured development of our research paradigm. In particular the models we propose provide a focus for structured reflection, and discussion about the nature and future development of EER. Finally, the models provide multiple views of research, and research validity and quality. Discussion of these values informs an ongoing discussion about what constitutes rigorous engineering education research.

ACKNOWLEDGMENTS

The authors wish to acknowledge the contributions of Dr. Mats Daniels through many thought provoking conversations on this topic over the last 10 years.

Work in Progress: Theoretical Approach to Characterizing Changes in Students' and Engineers' Conceptual Understanding and Personal Epistemologies

Devlin Montfort, Shane Brown, Nadia Frye,
Department of Civil and Environmental Engineering
Washington State University
Pullman, WA
dmontfort@wsu.edu

Abstract—Successfully preparing students to become practicing engineers requires the development of their conceptual and epistemological approaches to the world around them. This paper describes a robust, flexible and empirically testable framework developed to characterize engineering students' conceptual understanding and personal epistemologies as they develop from their sophomore year to their second year of engineering practice. The strength of the framework lies in the balances struck between firm commitments that can be confirmed or falsified, and open-endedness where existing theories are too contradictory to warrant such a commitment. The frameworks were developed through literature review drawing from the fields of cognitive science, educational psychology, science education, philosophy and learning theory.

Keywords- *epistemology; conceptual change; qualitative research; personal epistemology*

I. THEORETICAL FRAMEWORKS

Successfully preparing students to become practicing engineers requires the development of their conceptual and epistemological approaches to the world around them. Conceptual understanding of various topics could be considered akin to the tools students have to interpret, explain and predict phenomena in the world around them. In this analogy the students' personal epistemologies would be the ways they think about those tools in terms of their organization, purpose and limitations. Taken together, an individuals' conceptual understanding (CU) and personal epistemology (PE) determine how they will try to solve problems, and as engineers are expected in large part to be problem-solvers both conceptual understanding and personal epistemology need to be developed during undergraduate engineering education.

The purpose of this paper is to describe theoretical frameworks developed in the context of a longitudinal study of CU and PE from the sophomore year through the second year of engineering practice. The frameworks can both be defined in terms of three key assumptions. These stances are based on existing theoretical and empirical works [1-21].

CU and PE are assumed to be unstable across time and contexts [19, 22-26], despite a small set of tantalizingly powerful common patterns [1, 6, 14, 27-34]. These theoretical frameworks define conceptual understanding and personal epistemology as responses to particular circumstances, as perceived by the participant. Conceptual understanding is defined as the resources available to an individual for the interpretation, explanation and prediction of phenomena, while personal epistemology is defined as the collection of stances an individual takes on issues of knowledge and knowing. Conceptual understanding and personal epistemology are assumed to consist of the smallest components proposed by theorists, but again the data collection is organized and designed with potential larger groupings in mind. Similarly, personal epistemology is defined in terms of stances on issues. Inspired by work tracing the philosophical roots of personal epistemology [35], this approach does not assume any connections between individuals' stances across issues, although consistency would be easily recognizable. Both conceptual understanding and personal epistemology are assumed to be communicative behaviors in order to avoid the problematic assumption that researchers can infer unobservable cognitive phenomena [27, 36-40].

II. METHODOLOGICAL IMPLICATIONS

The open-endedness of this theoretical approach to conceptual understanding and personal epistemology needs to be balanced by more diligence in data collection. If CU and PE are assumed to vary across domain and interview context, but identifiable patterns are expected, then participants CU's and PE's must be explored in a variety of domains and contexts (which need to be carefully documented), and be characterized longitudinally over a meaningful amount of time. The importance of exploring different contexts, and the difficulty of expressing epistemological stances requires that data collection be somewhat opportunistic. Carefully designed interview protocols must be balanced with the freedom to occasionally derail those protocols in pursuit of a new way of approaching the data.

Work-in-Progress: Exploring the essential nature of engineering education through philosophical inquiry.

Russell Korte

University of Illinois at Urbana-Champaign, Champaign, IL
korte@illinois.edu

Abstract—In regard to the ongoing efforts to reform engineering education, this working paper proposes the methods of philosophical reasoning and argumentation for constructing and analyzing educational beliefs about the ontology and epistemology of engineering and engineering education.

Modern views of philosophy tend toward an instrumental perspective—one that believes that philosophy provides a rigorous method for describing and evaluating our understandings of knowledge and truth. Philosophical reasoning can help reconcile diverse beliefs resulting in more coherent and comprehensive statements about the nature of engineering and education.

Employing philosophical reasoning in the articulation of one's philosophy of engineering education can lead to a more coherent and consistent statement about what it is that engineering educators aim to achieve. This paper briefly describes the methods of philosophical reasoning and argumentation introduced in workshops on the philosophy of engineering education conducted at previous FIE conferences. A follow-up workshop focused on these methods is planned for this year's FIE conference. The outcomes of the upcoming workshop will be included in a final version of this paper on the topic of developing a philosophy of engineering education.

Keywords- *argumentation; rhetorical criticism; philosophy of engineering education; ontology; epistemology*

I. INTRODUCTION

There has been an ongoing discussion about revising engineering education for nearly a century. Some of the recommendations advocate for a greater emphasis on practical matters, others for a more liberal education for engineering students. And then there is the prevailing view that science and math form the core knowledge base of engineering. Different positions in this discussion generally stand on two questions: (a) What is engineering and (b) what is the best way to learn to become an engineer? The first question is a type of ontological question about the reality or nature of engineering. The second question is a type of epistemological question about what counts as knowledge and how do we come to know it. Ontology and epistemology are major branches of

philosophy with an immense history of development and debate. This paper describes methods useful for constructing and analyzing reasoned arguments about the ontology and epistemology of engineering and engineering education.

II. CONTRIBUTION

As mentioned above, there are two important questions that affect the teaching of engineering students: (a) What is engineering and (b) what is the best way to learn to become an engineer? While educators can usually provide immediate answers to these questions—when probed more deeply there appear additional questions and assumptions about which there is little agreement. This is especially so regarding how to educate students aspiring to be engineers.

These deeper questions cannot be answered fully with empirical evidence, the scientific method, or by appeals to history, authority, or prior beliefs [1]. At the deepest levels, they are philosophical questions and require the use of rigorous methods developed for philosophical reasoning and argumentation [1, 2, 3]. Philosophical reasoning and argumentation are analogues of the scientific method useful for sorting out and making sense of difficult ideas and concepts, which are not open to empirical verification and generalization [1]. Critically working out the conflicts and inconsistencies among the concepts and ideas that make up one's belief systems is a way to achieve a better understanding for better practice [2].

In the practice of education, educators continually make decisions based on their beliefs about how students learn. These decisions can proceed from an uncritical acceptance of an educational technique or from a critical understanding of the complexities undergirding the educational process [4, 5]. The contribution of philosophical reasoning to the educational process has enormous potential to enhance the development and quality of the educational enterprise for engineering faculty and students alike.

III. DESCRIPTION

The stream of this research on the contribution of philosophy to engineering education goes back several years including FIE papers and special sessions [5]. Several colleagues have presented various arguments at FIE

supporting the need for the philosophical development of engineering education.

A. Context

Three years ago, a special session at FIE, co-facilitated by the author, focused on the notion of philosophical inquiry as a means to strengthen and enhance the critical examination of engineering education. It was our belief that educators could develop their critical reasoning skills in the pursuit of a more rigorous and efficacious practice of engineering education, which in turn would contribute to the development of the field. This purpose was the core of a two-day workshop prior to last year's FIE conference. That workshop, organized by the author and colleagues, included keynote presentations by four eminent philosophers focused on engineering and engineering education: Steven Goldman (Lehigh University); William Pitt (Virginia Tech); Larry Bucciarelli (MIT), and Billy Van Koen (University of Texas, Austin). Along with lively discussions, there appeared little consensus—except to continue to pursue this line of research. One point of agreement that came from this workshop was the need to develop the participants' skills in philosophical inquiry. Thus, the author proposed a pre-conference workshop at this year's FIE (2012) and developed this working paper describing the methods for this workshop.

B. Methods

McCarthy [6] described philosophy as the critical quest for genuine knowledge about our world. Philosophical reasoning can help reconcile diverse views resulting in more coherent and comprehensive statements regarding our beliefs in what is engineering and how best to educate students in engineering.

Working out the differences and inconsistencies between conceptual frameworks is a goal of philosophy facilitated by methods of philosophical reasoning and argumentation [2]. Employing philosophical reasoning in the articulation of one's philosophy of engineering education can lead to a more coherent and consistent statement about what it is that engineering education aims to achieve. The philosopher is an artisan working with concepts assessing which ones are viable, which are arbitrary and inconsistent, and which survive the test of time [7]. In addition to philosophy, one can employ other fields such as communication studies, linguistics, psychology, computer science [8], as well as education, management, and organization studies.

Aristotle identified three forms of argument: apodictic—the demonstration of reliable knowledge based verifiable evidence; rhetorical—typically a one-sided effort focused on persuading an audience to accept the speaker's claims; and dialectical—a dialogue among participants for the purpose of settling on a consensus or compromised position [9]. Forming rigorous arguments is a primary means to working out the conflicts and incoherencies in competing belief systems. In the service of engineering education, the rigorous assessment and critique of one's belief systems regarding engineering and education is essential to the advancement of the profession of engineering and the field of engineering education.

C. Research Questions

The questions driving this project stem from the earlier work to clearly articulate a philosophy of engineering education. Specific to this paper, the primary question is: *How can the methods of philosophical reasoning and argumentation be used to articulate a clear and coherent philosophy of engineering education?*

D. The Contribution of Philosophy to Engineering Education

There is a growing tension between engineering and science [10]. For example, engineering scholarship is increasingly recognizing the contingent, contextual, values-driven, and pluralistic characteristics of engineering practice. This contrasts with the universal, context-free, values-neutral goals of science [6, 10]. And while many do not dispute the multifaceted nature of engineering—composed of science, math, practical, and social dimensions—integrating these different concepts is a difficult task.

Philosophical reasoning and argumentation are essential to the development of science and knowledge. It is a form of thinking and sense-making that helps foster conceptual change allowing for greater understanding and accommodation of alternative perspectives. Advancing one's facility with argumentation skills enhances one's ability to solve difficult, ill-structured problems [9]. Certainly the debate around alternative perspectives on engineering and engineering education are ill-structured problems having multiple solutions and multiple criteria for resolution. Developing these skills can benefit the articulation of a more coherent view of engineering and engineering education.

Abstract—Conceptual change is often approached with a concrete epistemology in which students must replace their misconceptions with correct conceptions. Drawing upon the literature and our research, we propose that we need a new, discursive epistemology that describes conceptual change as language acquisition.

Keywords—philosophy; epistemology; discourse; language; conceptual change; engineering education

I. INTRODUCTION

“The real problems of the differences between scientific concepts and those characteristic of everyday life have less to do with conceptual difficulties or misconceptions... and more to do with the problem that people do not have access to contexts in which science talk is functional and necessary.” [1]

When conceptual knowledge is discussed among educators, it is often described as a concrete object that resides within students’ minds. This concrete epistemology is often conveyed through the verbal imagery of terms such as *mental models* or *replacing* students’ misconceptions with correct conceptions.

In this work-in-progress, we propose that this concrete epistemology by itself is inadequate to describe and explain the learning process, and in particular, conceptual change. Drawing on multiple theoretical traditions that describe the role of language in cognition, we describe two key implications of changing to a more discourse-focused epistemology: (1) expert’s perception of students’ conceptual difficulties is as much a function of language as it is a function of science and engineering and (2) engineering students’ conceptual difficulties are rooted in their difficulties in distinguishing the engineering dialect of English - “Engineering-ese” - from colloquial dialects of English.

Many words from colloquial English (for example “stress” or “if and only if”) mean subtly different things in Engineering-ese, and students who are unaware of this difference struggle to develop accurate, consistent concepts and communicate these concepts. We provide evidence from the literature and our previous research to demonstrate that students struggle to switch between colloquial English and Engineering-ese and that this ability to switch between dialects may be critical to conceptual change and learning.

This analysis was sponsored by NSF grant #1129460, drawing on data collected under NSF grant #0618589, #0943318, and #0837749.

II. FOUNDATIONAL THEORIES: LEARNING

A. Constructivist theory

Constructivist theory argues that students need to build their knowledge upon their own prior knowledge. Hence, the emphasis of constructivism is the knowledge which a student possesses. Constructivists argue then that learning happens when students are “forced” to access their prior knowledge, wrestle with it, and purposefully construct new knowledge. Constructivist theory is built on a concrete knowledge epistemology, so conceptual change is the process of students replacing their misconceptions through reasoning [2].

B. Sociocultural theory

The sociocultural perspective argues that new knowledge is only truly meaningful within the context of a group of people. Consequently, conceptual change and development is not so much the creation of new knowledge within a student, but the ability to learn the values and distinctions that are important to a certain group. All knowledge, it is argued, is immutably situated in contexts of learning and application, and efforts to abstract or generalize outside of recognizable social contexts will interfere with learning [3].

C. Language in Conceptual Change

Saljo argues that conceptual change research should move to an emphasis on discourse rather than concepts or other intangible constructs [1]. This stance has not inspired a great deal of language-centric research efforts, although some conceptual change researchers are now concerned with the role that writing and speaking play in conceptual change [4].

III. FOUNDATIONAL THEORIES: LANGUAGE

The philosophy of language is vital and central to this inquiry, but is currently a source of questions rather than answers [5]. We are continuing to investigate philosophical works on the nature of language in order to understand the broader context and develop conscious, informed stances in the development of this research

However, studies demonstrate the interconnectedness between language and concepts. For example, native German and Spanish speakers conceive of objects differently based on the gender that their languages attribute to the object. Germans describe bridges (feminine in German) as “beautiful” and “slender,” but Spanish speakers describe bridges (masculine in Spanish) as “sturdy” and “towering [6].”

IV. TWO IMPLICATIONS OF ENGINEERING-ESE

A. Expert's Interpretations of Novice Language

Researchers interested in students' ways of thinking almost universally access that thinking through language. Thus, research efforts are colored by an as-of-yet invisible process of interpretation and translation from the students' language (which may be entirely engineering-ese, entirely colloquial, or a mixture of both) to the researchers' engineering-ese.

Research methodologies and instruction must consider how experts' use of terms and distinctions differs from students' use. When exploring conceptual change interviews, we have found that pairing a content novice with a content expert during analysis has revealed that experts struggle to understand the difficulty that students have in acquiring new vocabulary in a discipline [7]. For example, when analyzing students' understanding of mechanics of materials, the novice researcher could better understand what the students were saying about stress and strain and would perceive that the students possessed a higher quality of conceptual understanding than the expert.

B. Students' Learning Through Engineering-ese

Based on how the gender of nouns moderates conceptions, we propose that language moderates conceptual change by directing the formation of concepts and how we access or use them. Furthermore, these distinctions must be seen as relevant and important to communication. For example, we might assert that the concept of an *emergent* process, processes such as diffusion and equilibrium [8], will form concurrently with the acquisition of the term *emergent* into a students' discourse.

Similar to how the gender of a noun influences a speaker's perception of an object or concept, the linguistic context in which certain terms were learned can affect our perception and understanding of the concept as well as what features we consider to be important about that concept.

The concept of shear stresses and strains in Mechanics of Materials and the concept of exclusive-OR in Boolean logic provide two examples of the importance of the creation of linguistic distinctions [7].

When students develop their initial conceptions of shear stresses and strains, they initially connect the term shear with arrows in the vertical direction. For example, students have said, “the stress is vertical, so it would be shear stress.” This failure to distinguish “shear” from “vertical” may be caused by a lack of situations in which a distinction between vertical and shear were linguistically useful. Shear appears to be a difficult concept to acquire because it lacks linguistic purpose

– students are not placed in situations where messages of importance rely on the distinction between the words *shear* and the idea of vertical forces [7].

In contrast, students are taught the difference between inclusive-OR (I can own a cat or a dog OR BOTH) and exclusive-OR (I can turn left or right, BUT NOT BOTH) by making the distinction that exclusive-OR *excludes* the case when both conditions are true. Students quickly learn this distinction as it proves relevant in conversation [9].

The emotional and linguistic implications of language also impact what students perceive about terms and concepts. For example in Boolean logic, the concepts of “A *if and only if* B” and “A *if* B” are distinct. However, they are the same concept in English, except the “*and only if*” is emphatic. When translating technical specifications into logic expressions, students rarely perceive the presence of the phrase “and only if” and automatically retranslate the specification into A *if* B. Because the “*and only if*” is an emotional tool rather than an informative tool in English, students fail to see its informative importance in Engineering-ese. Students who can parse “*if and only if*” as a unique Engineering-ese term, could also conceptually distinguish “A *if and only if* B” from “A *if* B”.

V. FUTURE CONSIDERATIONS

If conceptual change in engineering is fundamentally the acquisition of a new dialect, then should instruction emphasize communication as more than “just a soft skill?” Can we provide evidence that the best-practices for language acquisition and communication may actually be the best-practices for learning engineering?

Work in Progress: Abstraction as a Vector

Distinguishing Engineering and Science

John Krupczak, Jr.
Department of Engineering
Hope College
Holland, Michigan USA

Gregory Bassett
Department of Philosophy
Aquinas College
Grand Rapids, Michigan USA

Abstract—A goal of the philosophy of engineering and engineering education is to more clearly distinguish engineering and engineering education from science and science education. This paper advances the suggestion that one distinction between the activities of science and engineering is the role of abstract thinking. Engineering and science both engage in abstract thinking, but the direction of the abstraction process points in different directions for the two disciplines. The view advanced in this paper may help to clarify the difference between engineering and science in a way that is less prone to value judgments based on supposed differences between pure and applied activity. Science proceeds towards abstract theory; engineering proceeds from the abstract idea of function.

Index Terms—philosophy of engineering education, philosophy of engineering.

I. INTRODUCTION

Current efforts to develop the philosophy of engineering and engineering education intend to help clarify the nature of engineering activity and to demonstrate how engineering differs from applied science. In addition, a well-developed philosophy of engineering is expected to aid in resolving the perceived imbalance between the status attributed to scientific inquiry and that associated with the engineering design process [1,2]. It is anticipated that an articulation of the philosophy of engineering and engineering education will also inform the practice of engineering education [3,4].

II. SCIENTIFIC METHOD AND ENGINEERING DESIGN

Frequently engineering and science are distinguished by reference to differences in the output products of engineering and scientific work. A common explanation is that science creates theories about the natural world while engineering creates artifacts to provide for human needs and wants [5-8]. Although this distinction is a useful place to start an inquiry, it leaves a number of questions unanswered. There is little reason offered by this distinction to think that the two fields share much in common; in addition, the processes of science and engineering are left undefined, and thus any difference in the education required for the respective disciplines is unclear. Although there may be reasons to question this common explanation of the distinction between science and engineering, the purpose of this paper is instead merely to help fill in some of its gaps, paying particular attention to the role of abstract thought in each discipline.

A primary objective of scientific activity is the development of theories which are about a set of natural phenomena, but which are abstracted from those phenomena. “The scientific method” is the term generally applied to the processes by which such theories are developed. The roles of abstraction in these processes are complex. The collection of any particular observational data depends in part upon at least tentative prior acceptance of abstract theory; but acceptance or rejection of theory is justified in part by successful application to particular experiment. A scientist must be able to understand an abstract theory distinct from its particular instantiations in order to recognize new experimental results, but must also be able to perceive and imagine particular instantiations of theory in order to design an experiment. Theories are sometimes created to fit prior technological successes, such as the development of optics to fit the success of the telescope; but technological successes often rely upon prior acceptance of approximately accurate theory. Nevertheless, the theory-oriented nature of science suggests that scientific activity places a premium on articulation of abstract theory. That does not mean that the work of individual scientists is more theoretical than applied; it only indicates that an individual scientist’s work is understood to be scientific largely by the extent to which it promotes successful development and articulation of theory. As such, the scientific process can be seen as aimed towards abstraction even if not all individual scientists create abstract theory.

In engineering activity, the goal of the design process is to create a solution to a human problem or need. Thus, the engineer must first grasp the abstract or generalized description of the problem or need prior to designing the particular physical object or technological system that would solve it. This requisite abstraction of the problem to be solved – a problem with perhaps multiple possible solutions – from the particular circumstances presented to the engineer indicates that the process of engineering depends upon the ability to engage in abstract thought prior to engaging in the design of a solution taken as characteristic of the discipline. In other words, abstract function is grasped prior to creating a functional object.

The process of devising a solution involves creating an object that produces needed outputs from the required, desired, or available inputs. In order to create such an object, an engineer must have a prior conception of how function is related to the physical or technological structure of objects. In addition, insofar as overall function is a compilation of

subfunctions, and insofar as the overall structure of the object is a compilation of its components, an engineer must be able to grasp these relations, so that the inputs and outputs of each component or subfunction match at each component interface. The conceptual design phase may even explore alternative configurations of subfunctions as well as alternative choices for the types of components to achieve those subfunctions. Thus, the design process requires an understanding of the relationship of function and structure, and of the relationship of whole and parts, abstracted from the particular case. Abstract thought is therefore required not only for understanding of the problem to be solved but also as part of the design of a solution.

III. UNITY IN ABSTRACT THINKING

Consideration of the role of abstraction or abstract thinking in both science and engineering leads to a more symmetric valuation of the thought processes required by these two different disciplines. Abstract thinking is central to both science and engineering but its role in each differs. If abstraction is considered as a vector quantity, scientific and engineering abstract thinking are of the same magnitude but differ in direction.

Abstraction is an output of scientific activity, and prominent among science's goals are the development and articulation of theory. Thus, one of the primary outputs of science is abstract theory, and the success of scientific activity is measured largely in terms of what is valued in theories. The processes of science are devised to a significant degree for such theoretical successes. Individual scientists must therefore be guided in part by consideration of the contributions they make towards such theoretical successes. In this way, they proceed towards abstraction.

In contrast, engineering begins in abstraction, but abstraction is not one of its primary outputs. Engineering design starts from abstract concepts of function and creates the specific physical objects that are the products of engineering. The success of engineering activity is measured largely in terms of what is valued about those products, and the processes of engineering are not devised for theoretical success. In this way, engineers are guided by abstraction but do not proceed towards it.

These different roles of abstraction helps to illustrate that science assumes that universal principles exist and these can be discerned if only in approximate fashion and are subject to refinement. Science assumes there are universals to be abstracted from particulars; engineering assumes that abstract concepts of function are universal and can be projected back into the particular. Examples of such functions include supporting load, conducting current, or amplifying signal.

While this work-in-progress has outlined a potential starting point of inquiry, a more detailed review of this issue might consider whether types of abstraction differ across disciplines, whether learning style is a factor in developing abstraction

skills in students, and whether abstraction ability transfers across disciplines.

IV. CONCLUSIONS

A clarification of the role of abstraction in engineering can help inform the philosophy of engineering education by demonstrating how the practice of engineering requires abstraction abilities different in kind but not degree from science. In addition clarification of the abstract function as the starting point for the engineering design process can help to avoid a common problem among student engineers. Novice engineers have a tendency to leap to one specific hardware implementation of a perceived solution, often forgoing the potentially richer spectrum of design concepts which can emerge from a more reflective analysis of functional requirements achieved through abstraction.

jay.goldberg@marquette.edu, mark.nagurka@marquette.edu

Abstract— This paper summarizes the results of our investigation into the feasibility of increasing the level of discovery learning in the College of Engineering (COE) at Marquette University. We review the education literature, document examples of discovery learning currently practiced in the COE and other schools, and propose a Marquette COE-specific definition of discovery learning. Based on our assessment of the benefits, costs, and tradeoffs associated with increasing the level of discovery learning, we present several recommendations and identify resources required for implementation. These recommendations may be helpful in enhancing engineering education at other schools.

Keywords: *Discovery learning, student-centered learning, active learning.*

I. INTRODUCTION

The College of Engineering at Marquette University is on a mission to increase the level of discovery learning in our curriculum. Until recently, there was no clear definition of “discovery learning,” prompting a survey to determine how faculty defined the term. The results indicated that the pure form of discovery learning (unguided by the instructor, as described in the education literature) was not being practiced. Faculty members were employing a wide range of student-centered and active learning methods, all under the umbrella of discovery learning.

An investigation into the use of the term “discovery learning” in U.S. engineering programs showed that the term is used inconsistently. Some schools have their own, institution-specific definition of the term that includes a variety of learning approaches, such as undergraduate research projects, co-ops and internships, and other forms of experiential learning. Other schools include student-centered learning methods, such as active, problem-based, application-based, and collaborative learning, in their definition. Based on our investigation we concluded that a Marquette-specific definition of discovery learning was warranted.

II. WHAT IS DISCOVERY LEARNING?

A. Definitions from the Education Literature

The education literature reveals different definitions of discovery learning. Presented here are generally accepted

definitions of active, collaborative, cooperative, and problem-based learning, terms often associated with discovery learning. (The definitions are drawn from several sources, primarily Prince [1].) Figure 1 summarizes three student-centered learning methods, including inductive learning, which encompasses discovery learning. Although there are no universally accepted definitions of discovery learning in the literature, the accepted view is that discovery learning is a form of student-centered learning in which the focus shifts from the teacher to the learners.

Active learning is an instructional method that engages students in the learning process. In active learning students conduct meaningful learning activities and think about and are connected to what they are doing [2]. While this definition could include traditional activities such as homework, in the education literature active learning most commonly refers to activities that are introduced in the classroom. The core elements of active learning are activities that engage students. Active learning is often contrasted with the traditional lecture format where students passively receive information from an instructor.

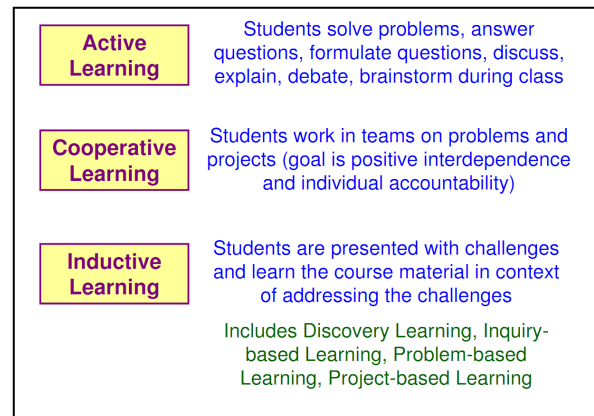

Figure 1. Summary of three student-centered learning methods. Note that discovery learning is classified as a form of inductive learning.

The more active students are in the classroom, the more engaged they are in the learning process and the more they remember. Edgar Dale’s “cone of learning” [3] suggests that student retention, as measured two weeks later, depends on the level of active learning. Classroom activities in which students

simulate a real experience or “do the real thing” involve them the most in the learning process and result in them remembering more of what instructors do and say [4].

Collaborative learning refers to an instructional method in which students work together in small groups toward a common goal [5]. As such, collaborative learning encompasses all group-based instructional methods, including cooperative learning [6-10]. In collaborative learning the emphasis is on student interactions rather than on learning as a solitary activity.

Cooperative learning is a structured form of group work where students pursue common goals while being assessed individually [6,11]. The most common model of cooperative learning includes five specific tenets: individual accountability, mutual interdependence, face-to-face interaction, appropriate practice of interpersonal skills, and regular self-assessment of team functioning [12,13]. The common core element among models is a focus on cooperative incentives rather than competition to promote learning.

Problem-based learning is an instructional method where relevant problems are introduced at the beginning of the instruction cycle and used to provide the context and motivation for the learning that follows. It is always active and usually collaborative or cooperative per the above definitions. Problem-based learning typically involves significant amounts of self-directed learning on the part of the students [1].

B. Discovery Learning in Higher Education [14-16]

In discovery learning, students are confronted with a challenge and left to work out the solution on their own [17, 18]. Students are presented with a question to answer, a problem to solve, or a set of observations to explain, and then work in a largely self-directed manner to complete their assigned tasks and draw appropriate inferences from the outcomes, “discovering” the desired factual and conceptual knowledge in the process [17]. The instructor may provide feedback in response to student efforts but offers little or no direction before or during those efforts. The lack of structure and guidance provided by the instructor and the trial-and-error approach consequently required of students are the defining features of discovery learning relative to other inductive methods.

In the purest form of discovery learning, teachers set the problems and provide feedback on the students’ efforts but do not direct or guide those efforts. This form of inductive teaching was developed for pre-college education and has not been embraced in undergraduate classes. The method is rarely used in higher education, among other reasons because instructors who hear about it fear – probably with good cause – that they would only be able to cover a small fraction of their prescribed content if students were required to discover everything for themselves. The only way to counter this fear would be to present solid evidence that discovery learning improves learning outcomes without requiring a major sacrifice of content.

There is little empirical evidence for the effectiveness of discovery learning in higher education. What instructors are more likely to adopt is a variant of discovery learning – sometimes called “guided discovery” – in which the instructor pro-

vides some guidance throughout the learning process [19]. In this case, the distinctions between discovery and guided inquiry or problem-based learning tend to disappear [14].

Student-centered methods have been shown to be superior to the traditional teacher-centered approach to instruction, a conclusion that applies whether the assessed outcome is short-term mastery, long-term retention, depth of understanding of course material, acquisition of critical thinking or creative problem-solving skills, formation of positive attitudes toward the subject being taught, or level of confidence in knowledge or skills [16]. Although many studies suggest that discovery learning can enhance students’ retention of material, others reach the opposite conclusion. For example, Leonard [20] studied the use of guided inquiry and discovery learning in science laboratory courses, and found no statistically significant differences in student scores on tests and lab reports.

The studies that show a positive effect also suggest that retention is improved only when the learning task is based on previously understood principles. Singer and Pease [21] compared the effectiveness of guided inquiry and discovery learning on the acquisition, transfer and retention of motor skills. They concluded that for learning new tasks, guided inquiry was more efficient, and for transferring learned skills to tasks of similar or greater difficulty there was no difference.

Prince and Felder [14] state:

“We do not recommend using the pure form of discovery learning – in which students work with little or no guidance from instructors — in undergraduate engineering curricula.

While the quality of research data supporting the different inductive methods is variable, the collective evidence favoring the inductive approach over traditional deductive pedagogy is conclusive. Induction is supported by widely accepted educational theories such as cognitive and social constructivism, by brain research, and by empirical studies of teaching and learning. Inductive methods promote students’ adoption of a deep (meaning-oriented) approach to learning, as opposed to a surface (memorization-intensive) approach. They also promote intellectual development, challenging the dualistic type of thinking that characterizes many entering college students (which holds that all knowledge is certain, professors have it, and the task of students is to absorb and repeat it) and helping the students acquire the critical thinking and self-directed learning skills that characterize expert scientists and engineers.”

There is significant evidence for the benefits of involving undergraduate students in independent research [14]. Undergraduate research does not usually qualify as discovery learning because the advisor typically provides significant structure and guidance [22]. The literature supports the use of student-centered learning and teaching methods. However, there is little empirical evidence for the effectiveness of the pure form of discovery learning at the undergraduate level and it is not recommended for use in that setting [15].

C. Definitions from the COE Faculty

In 2010, the Dean of the COE solicited comments from the COE faculty regarding their definitions and impressions of

discovery learning. Specifically, the Dean posed the following question: "What is Discovery Learning and what is your opinion of it at Marquette University?" The responses revealed different definitions of discovery learning among the faculty, underscoring the need for a compelling, unifying definition. Responses included many common themes and attributes, as indicated by the following faculty-suggested definitions of discovery learning:

- Giving students opportunities to solve open-ended problems/challenges that require them to put theory into practice with real-world constraints, and providing them with the tools needed to solve these problems.
- A method of inquiry-based learning in which students utilize their existing knowledge and past experiences to identify new relationships and facts through a process of investigation and self-discovery of the world guided by the instructor. In this framework, students learn to "teach themselves," promoting a philosophy of life-long learning.
- Student-centered learning, more applied and more hands-on. There is less reliance on the traditional lecture as the primary means of communicating. Students are actively engaged in authentic, real-life projects.
- Allowing students to learn through experimentation that reinforces lectures and text-based learning.
- The education practice in which students play an active role in learning. Students are expected to (i) apply what they know (from previous courses, from experience, from books and the Internet, etc.), (ii) ask questions and formulate their own tentative answers, and (iii) deduce general principles from practical examples and laboratory experiences.

Based on these responses and other comments from the COE faculty, we concluded that the pure form of discovery learning was not actually being practiced in the COE. Instead, a guided form of discovery learning, active learning, cooperative learning, and other forms of guided inquiry-based learning were being employed.

III. EXAMPLES OF DISCOVERY LEARNING

A. *Examples of Discovery Learning in the COE*

There are many examples of student-centered learning methods, including guided discovery learning, being practiced in the COE. These range from student projects to in-class activities in courses in each department. A few examples are presented here.

Extracurricular Student Projects

Faculty-mentored teams of students are currently involved in a wide range of extracurricular projects that give students the opportunity to apply what they have learned in their undergraduate experience (be it from the classroom, laboratory, co-op position, internship, etc.) to the solution of a problem. Many of these projects are part of national and international student design competitions such as the Formula I Race Car, Concrete Canoe, Solar Powered Boat, and Human Powered

Vehicle, sponsored by professional organizations and societies, such as:

- American Society of Civil Engineers (ASCE)
- American Society of Mechanical Engineers (ASME)
- Association of Computing Machinery
- Biomedical Engineering Society
- Engineering World Health
- Engineers Without Borders (EWB)
- Institute of Electrical and Electronics Engineers (IEEE)
- Institute of Transportation Engineers
- National Collegiate Inventors and Innovators Alliance (NCIIA)
- Society of Automotive Engineers (SAE)
- Society of Manufacturing Engineers (SME)
- Solar Energy Society

In the past few years students participated in the SAE Aero Competition, NASA Lunabotics Challenge, Rocket Competition (Wisconsin Space Grant Consortium), MATE International Remote Underwater Vehicle competition, BMEstart design competition, and others.

Courses and Programs

In the COE many courses in the curriculum include attributes of discovery learning methods. The following represent only a small sample of such courses.

- BIEN 1100 and 1110: Introduction to Biomedical Engineering Methods I and II. These courses include open-ended design challenges, lectures, readings, and exams. Students are presented with problems and customer needs and are encouraged to find the information needed to solve the problem. Design challenges reflect the multidisciplinary nature of the biomedical engineering curriculum and require students to solve problems involving physiological monitoring, data acquisition, medical imaging, biomaterials, and rehabilitation engineering. Students are encouraged to apply the tools and information provided to them through class lectures, readings, and laboratory experiences. The course includes a module on business and entrepreneurship and uses an application-based approach to teach students about the design process. The resources needed to successfully teach this required freshman course include TAs, administrative support, and many guest speakers.
- BIEN/ELEN/COEN/EECE/MEEN 4920/4998: Principles of Design/Senior Design. This capstone design course is the culmination of the undergraduate biomedical, electrical, computer, and mechanical engineering curricula and requires students to apply what they have learned from previous coursework and co-op, internship, and research experiences. Students work on multidisciplinary project teams for two semesters to solve real-world problems. Projects are advised by COE faculty members who provide technical guidance and assistance to student teams. Required course deliverables mimic those that are used in industry and required by ISO 9001. This team-based project design experience allows students to learn about the design process, apply knowledge acquired in previous

courses, and develop communication, teamwork, and project management skills.

- Construction Engineering Management Program. This program provides students with a hands-on, applications-based learning experience through the use of guest lecturers, field trips to construction projects on campus and throughout Milwaukee and Chicago, Associated General Contractors (AGC) student chapter meetings and trips, American Society of Civil Engineers (ASCE) student design competitions, and many open-ended team project assignments. Significant financial resources required to run the program are provided by an endowment.
- ELEN/COEN/EECE Courses. Many courses taught in the electrical and computer engineering program contain elements of student-centered and applications based learning. These courses include projects that require students to design, simulate, and build prototypes, create useful databases, write programs in various languages to perform various functions, and test a CPU. These courses require students to synthesize and apply what they have learned.
- MEEN 2210: Electromechanical Engineering Systems. This required sophomore course is heavily studio based with open-ended design challenges. Students work in teams of two to investigate and solve real-world exercises involving electrical circuits (electronics for sensors, actuators, and controls), electromechanical actuators (solenoid, vibration exciter, DC motor), and control systems. Industrial examples emphasize integration. Students are encouraged to apply analysis, simulation, and hardware tools that they learn through class lectures, outside readings, independent investigations, and laboratory experiences.

B. Examples of Discovery Learning at Other Schools

The following is a small sample of how discovery learning is defined and incorporated in engineering programs at other schools.

- University of Delaware. At the University of Delaware (<http://www.ugs.udel.edu/DLE/>) all students are required to participate in a Discovery Learning Experience, defined as experiential learning that involves instructional experiences (out-of-class and beyond typical curriculum courses). These enrichment experiences exist for students under the supervision of a faculty member. Discovery Learning Experiences include internship, service learning, independent study, undergraduate research, and study abroad.
- University of Colorado. The Discovery Learning Program (<http://engineering.colorado.edu/dlc/about.html>) at the University of Colorado enables students to develop critical thinking, problem solving, and research skills while sharing fresh perspectives as members of integrated research teams. The discovery learning model established by the College of Engineering and Applied Science creates collaborative teams involving undergraduate and graduate students, faculty, and industrial partners. This

advances student learning through an inquiry-based approach that complements the academic curriculum.

- Rose-Hulman Institute of Technology. At Rose-Hulman, discovery and student-centered learning appear in extracurricular student projects and in-class, hands-on experiences. Student teams work on competitive project teams for the Eco-Car, Formula SAE, Human Powered Vehicle, and the design/build/fly AIAA national student design competitions. Students do not receive credit for these activities. Faculty mentors and team advisors volunteer their time to work with the students on these projects and do not receive additional salary for their involvement. The school provides a budget of at least \$10,000 per project, space to work, and access to test facilities (wind tunnel, composite testing, and other facilities). In addition to extracurricular projects, students are engaged in in-class activities such as fluids laboratory demonstrations and projectile motion modeling, measurement, and validation experiments ending with an in-class competition. A lead equipment technician is employed to design and maintain technical equipment used in classes, laboratories, and student projects.

Of the three schools mentioned above, there is no consensus on the definition of discovery learning or what activities qualify as discovery learning. The University of Delaware considers experiential learning (study abroad, internships, co-op experiences, etc.) to be a form of discovery learning. The University of Colorado regards undergraduate research activities to constitute discovery learning. Rose-Hulman views extracurricular student projects and in-class, hands-on activities to be forms of discovery learning. The disparate use of the term underscores the need for agreement on what constitutes discovery learning within the Marquette COE.

IV. CONCERNS AND TRADEOFFS

Student-centered learning requires a culture in which students take responsibility for their education and shift from passive to active learners. It also requires faculty commitment ("buy-in") to change from traditional "tell-and-test" pedagogies to more active teaching methods. Whether students and faculty embrace these cultural changes is a concern.

Discovery learning will not necessarily replace all lectures, as not everything students must learn is amenable to classroom discovery. Even when students have the capacity to discover complex knowledge, there may not be sufficient time or appropriate resources to complete the task. Formal lecture presentations provide a fairly efficient way of conveying complex knowledge to a large group of diverse learners [23]. A question to be resolved is the appropriate mix of lecture and student-centered methods.

Discovery and other student-centered learning methods involve increased faculty time and resources. A common concern among faculty regarding discovery learning is that they would only be able to cover a small fraction of their prescribed content if students were required to discover everything for themselves. According to Cornell and Clark [24], "Less teacher talk requires more teacher time." Even though motivation and

student learning are enhanced through discovery and student-centered learning methods, it requires more work for teachers when designing projects and preparing for class. From interviews we conducted, faculty indicated a need for additional support personnel to successfully implement student-centered learning methods as well as resources such as additional teaching assistants, technical support staff (e.g., technicians to develop and maintain equipment), and space.

V. IMPLEMENTATION ACTIVITIES

A. Defining Discovery Learning within the COE

The term “discovery learning” (based on its strict definition) does not appropriately capture the current practice in the COE. A more accurate term to reflect what is currently being practiced would be “student-centered learning,” which includes active, problem-based, application-based, and collaborative learning.

Our investigation found that other schools use the term “discovery learning” to describe activities and teaching methods that do not fit the traditional definition of discovery learning. These schools have their own, institution-specific definitions of the term. What they are describing would be more correctly described as “student-centered learning.”

We proposed that a COE-specific definition of the term “discovery learning” be developed. This definition needed to incorporate the following activities and teaching methods that include student-centered learning components:

- Class activities such as hands-on demonstrations, case studies, student projects and presentations, design competitions, laboratory experiments, field trips, and other activities that require students to apply what they have learned in the class.
- Extracurricular activities such as student design projects for national student design competitions, co-op and internship experiences, and other activities that provide opportunities for students to “learn by doing” and apply what they have learned throughout the engineering curriculum.

We adopted the following COE-specific definition of discovery learning, which reflects our strong focus on student-centered learning:

Discovery learning within the Marquette University College of Engineering consists of student-centered learning methods that employ in-class and extracurricular activities that allow students to learn by doing and to apply what they have learned.

We retained the term “discovery learning” for multiple reasons, including its broad meaning and consistency with prior mission statements.

B. Implementing a Plan

The goal of increasing student-centered learning in our curriculum is similar to that of many European Union (EU) countries as part of the Bologna Process intended to improve higher

education in the EU [25]. We are accomplishing this goal by meeting four main objectives:

- Increase the use of student-centered learning in the classroom. We are providing faculty with resources for course redesign including educational support in the form of seminars to make faculty aware of the best practices in student-centered learning, and a course development consultant to work with faculty.
- Increase the number and variety of mentored extracurricular projects. Additional opportunities for students to work on project teams outside of class are being provided. To optimize the learning experience, these projects include some level of guided instruction provided by project mentors (faculty members, alumni, or industry sponsors). Various types of extracurricular student projects are encouraged and supported by the COE such as:
 - Projects that allow students to explore areas of interest to them
 - Projects in which students compete in national design competitions
 - Projects sponsored by and of benefit to local industry
 - Assistive technology projects to benefit a single client with a specific disability
 - Service learning projects to solve problems of the developing world or local community
 - Projects based on ideas generated by students with entrepreneurial interests
- Support the current cooperative education and undergraduate research programs. The COE has a successful cooperative education program and provides opportunities for internships and undergraduate research. The COE is continuing to support these activities that provide valuable student-centered learning experiences.
- Overcome institutional barriers to implementation. It is essential to obtain institutional, faculty, and student “buy-in,” develop incentives, and reform promotion-and-tenure criteria to reflect the value and importance of a higher level of discovery learning in the COE. To help promote dialogue, solicit ideas for implementation, and foster a change in culture we are initiating a seminar series, conducting focus groups, and considering other activities.

C. Adding Resources

To reach our goal of increasing the level of discovery learning in the COE, we identified the following needed resources:

Educational Support for Faculty

- Course development consultant(s) to assist faculty with course redesign.
- Technicians responsible for design, construction, storage, and maintenance of demonstration equipment, laboratory experiment hardware, course “props,” etc., used for in-class demonstrations, laboratory exercises, etc.
- COE seminar series on discovery learning to include guest speakers from within and outside of MU to present best practices in student centered learning.
- Graduate and undergraduate student TA(s), if needed.

Space and Equipment for Student Projects

- Space for student team collaboration and design work, including videoconferencing capabilities.
- Space for storage of prototypes, hardware, etc.
- Facilities for prototyping and testing (machine shop, rapid prototyping equipment, wind tunnel, materials testing, hand tools, etc.).

VI. SUMMARY

The term “discovery learning” as used in the education literature refers to unguided discovery learning and is not what is currently practiced in the COE. Instead, a guided form of discovery learning, active learning, cooperative learning, and other forms of guided inquiry-based learning are being employed. A more appropriate term would be “student-centered learning,” which includes methods of active, problem-based, application-based, and collaborative learning.

Our investigation found that other schools use the term “discovery learning” to describe activities and teaching methods that also do not fit with the formal definition of discovery learning. Schools have created their own, institution-specific definitions of the term. What they are describing would more aptly be described as “student-centered learning.” We adopted a COE-specific definition for “discovery learning.”

The goal of increasing the level of discovery and student-centered learning in the COE is being accomplished by (1) increasing the use of student-centered learning in the classroom, (2) increasing the number and variety of mentored extracurricular projects, (3) supporting our cooperative education and undergraduate research programs, and (4) overcoming institutional barriers to the proposed plan. Implementing this plan requires (1) educational support and resources for COE faculty, (2) faculty as well as student “buy-in” to a culture which shifts responsibility to students for their education, and (3) space and equipment for use by student project teams. The process presented here may be helpful in enhancing engineering education at other schools and is recommended for faculty working to increase the level of active and student-centered learning in their engineering curriculum.

ACKNOWLEDGMENT

We thank the Lafferty family for their generous support of our efforts to increase the level of student-centered learning in the College of Engineering at Marquette University.

Abstract— Learning Through Service (LTS) is a pedagogical method that encompasses curricular and extracurricular service learning in engineering. Though the numerous benefits of LTS are apparent to those who engage in it, the barriers are also plentiful, as evident by the reluctance of many instructors to engage in LTS. As a joint effort to create a community of LTS scholars, a summit held in Fall 2011 brought together faculty members actively engaged in LTS activities in a wide variety of capacities and from a wide variety of disciplines. In addition to the many workshops conducted as part of the summit, three semi-structured focus groups were held during which open dialogue ensued regarding the best practices and challenges in the execution of LTS. The current study presents thematic findings that emerged from these focus groups.

Keywords—*Learning Through Service; Faculty Perspective; Focus Group; Qualitative Methods; Service-Learning*

I. INTRODUCTION

Learning Through Service (LTS), an innovative pedagogical method that incorporates service as a means of meeting academic learning outcomes, provides an avenue for a much needed paradigm shift in engineering education. Organizations such as the NAE [1], ASCE [2], AAEE [3] and ASME [4] are all calling for the more comprehensive training of a holistic engineer to include various technical and non-technical skills, as well as a community-oriented professional vision. LTS is one tool that can be used to help meet these learning objectives [5] [6] [7] [8]. Service learning “spawns development on multiple levels, ultimately leading to maturation, heightened self-awareness, and greater complexity in cognitive thinking,” and results in highly motivated students with a professional passion [9]. Such attributes are important for future engineers who face a rapid pace of technological

progress as well as future challenges in globalization, sustainability, and increased complexity of engineering projects.

LTS is becoming an increasingly popular pedagogical method in engineering education [10]. The widespread use of LTS is exemplified by such organizations as Engineers for a Sustainable World Engineering World Health, and Engineers Without Borders, among others. Despite the growing prevalence and interest in LTS among both faculty and students, a thorough understanding of faculty’s experience with LTS is lacking [10] [11]. Nonetheless, we do know that faculty tend to be split on whether or not LTS should be tied to accreditation, and frequently cite time, money, promotion, and tenure as obstacles to implementing LTS in the curriculum [11]. In addition, previous research strongly indicates that faculty also recognize numerous benefits of LTS, such as increased student learning outcomes, deeper engagement with the material, and stronger affiliation with the engineering profession [8] [9] [12]. According to a recent survey, factors such as departmental support and improved learning outcomes function as catalysts for implementing LTS [13]. Next, we describe a collaborative effort launched to improve the understanding of a multi-faceted nature of LTS.

A multidisciplinary LTS Experts Summit was organized by the NSF funded Engineering Faculty Engagement LTS (EFELTS) project to explore issues that faculty face in regards to benefits and barriers to LTS engagement [14]. At this summit, three focus groups were conducted to further probe these issues; the resulting discourse forms the data for this study. The ultimate goal is to enable more faculty across disciplines to share their experience with one another, engage in more productive and informed LTS efforts, thus making a positive impact on student learning through authentic and

meaningful service. Acknowledging disciplinary differences and the diversity of existing LTS efforts, the focus group protocol was semi-structured to allow for a broad range of input regarding the best practices and challenges associated with the LTS efforts. The preliminary findings from these focus groups offer a rich understanding of the benefits and barriers faced by faculty who have engaged in LTS activities. We anticipate that continued review of the focus group transcripts will lead to development of a framework upon which LTS-interested faculty can be empowered to strengthen or initiate their own LTS efforts.

II. PURPOSE

The purpose of the current study is to obtain a deeper understanding of faculty's experience with LTS, including benefits, barriers, and strategies associated with the successful execution of LTS. Through a better understanding of the experiences of faculty who are already engaged in LTS, we can formulate strategies to enable and better support future faculty who wish to also conduct LTS activities in their classroom. This effort also provides insight into the sources of barriers for faculty- personal, professional and institutional- that potentially dissuade faculty from implementing LTS methods. In order to gather this information, we held three focus groups, which are an effective and efficient method for gathering qualitative data [15]. In particular, we were interested in the personal stories, anecdotes, and observations based on the faculty members' experiences with LTS.

III. METHODS

In order to encourage natural dialogue and an open exchange of ideas between participants, three semi-structured focus groups were held during the EFELTS summit in the Fall of 2011. To facilitate the discussion, the following prompts were used: What stands out to you the most out of your experience with LTS; How did you become involved with LTS; What are the most challenging aspects of LTS? The focus group facilitator monitored the discussion while keeping her interventions at a minimum. With the participants' consent, focus groups were recorded and later transcribed. The resulting qualitative data are in a form of a free-flowing narrative, touching upon a variety of topics. Thematic analysis of the resulting narrative allowed for a deeper investigation of faculty members' experiences with LTS.

A. Participants

Faculty members who did not participate in the individual interviews conducted concurrently were invited to participate in the focus groups. Purposive sampling was not employed for recruiting participants for interviews or focus groups; therefore, focus group participants can be considered randomly selected and representative of all EFELTS attendees. All faculty members invited agreed to participate in the focus groups and gave their consent for audio-recording. The first focus group consisted of three males and three females representing engineering, English/Media Studies, K-12 education, and Higher Education Administration. The second focus group had two female participants; both directors of LTS related programs. The final focus group consisted of three participants,

two male and one female, who all represented different engineering disciplines.

B. Analysis

Three researchers worked independently on the analysis of the focus group data: one transcribed the audio-recordings, and two served as primary coders. An emergent coding approach was employed in this study, meaning that themes were not defined a priori, but rather emerged freely from the data [16]. The emergent coding, rooted in the methods of grounded theory [17], was deemed most appropriate given the exploratory purpose of the study.

IV. RESULTS

The main themes that emerged from the thematic network analysis of the three focus group transcripts are presented below.

A. Theme I: Defining LTS

"LTS is work that has both academic value and community-based value." (Focus Group Participant)

The focus group participants grappled with issues of defining LTS. Faculty overwhelmingly agreed that LTS is a form of "adventure learning" that is "alternative," "experiential," and "expeditionary" that results in both "civic and academic outcomes." As ardent advocates for LTS, faculty spoke liberally about the value of LTS as a pedagogical method. For instance, one participant referred to LTS as "a power platform for liberal learning regardless of the major, which expands the personal transformation, moral, spiritual, as well as intellectual and it also provides a way for students to think about their place in society." Another participant simply noted that LTS is "the best thing pedagogically since sliced bread." Yet another commented that LTS not only promotes "a sense of civic responsibility" in students, but also brings them a step closer towards conducting "authentic intellectual work."

Although participants unanimously agreed on the value of LTS, the issue as to what exactly constitutes LTS remained unresolved. Everyone agreed with the expressed notion that LTS is "curriculum-based service learning" that involves "direct contact with the community" but also that LTS could encompass "a whole spectrum of possibilities." LTS was compared and contrasted to similar alternative pedagogical methods such as problem-based or project-based learning, and inquiry-based learning. Direct contact with communities and academic credit surfaced as critical aspects for defining LTS and as possible differentiating elements from the aforementioned pedagogical methods. Exemplifying the difficulty of defining LTS, many commented on having struggled with definitional boundaries and, when considering a community-based project, often pondered – "is that a service learning program or not?" At the heart of the discussion around defining LTS was the attempt to define the bounds of the term "service". One participant posited a common misconception that LTS has to involve "work with underrepresented minority communities otherwise it is not considered service". Another agreed, stating a misconception that with "service learning... you only work with poor people". These misconceptions, and

others, may be why some LTS opponents refer to it as “forced volunteerism”. However, the question remains – does it have to be *pro bono* to be Learning Through Service? Does the community organization served have to be strictly non-profit? Consider the following excerpt from one of the participants’ accounts:

Well this is one that I learned something about in terms of the definition. So I had been working in this small city in upstate New York and we had been working with the neighborhood housing agency and we had looked at housing needs and conditions in a number of neighborhoods, many of them lower income. A certain percentage of the grade was assigned by the community partners and they would jury the projects as students presented the projects. Anyway we had done several semesters of working and one of the recommendations that came out of those previous projects was a viable downtown or the older neighborhoods were really going to be in trouble. The next semester we decided to work with the downtown businesses and the merchants association. We were looking at parking issues and asking people about their perceptions on how long they would want to park. Anyway one day after having toured the downtown businesses after we had spoken to the chamber of commerce and laid out some of the research questions one of my students said in class, “Can I ask a question?” And she said, “Well it says here in the syllabus that this is a service learning course, so why are we working with these businesses and the capitalism and all of that?” Well, it was a great question and it involved bringing in some of the neighborhood people and taking a look at who these sort of greedy capitalist pigs were. They were candle makers in a little hardware store and they were candy stores and a little drugstore, all local businesses. But it made me think about being careful about terminology, checking assumptions, and having an open discussion with students on how this feels to them because one of the ideas of service learning is you only work with poor people and you only do direct work. I consulted with the University and it had to be underrepresented minority communities otherwise it wasn’t considered service. That ethos was always there so this student asked this wonderful question that lead to a couple of weeks of wonderful teaching.

The lack of clarity regarding the boundaries of “service” is not limited to faculty, but also seems to challenge students themselves. As an umbrella term, “learning through service” encompasses various community clients, regardless of whether they draw profit or not. However, it appears to be the case that conceptualizations of LTS vary from campus to campus, and the common, agreed-upon, definition has not yet been clearly delineated.

B. Theme II: Increased Contextual Learning

“In order to really learn, you have to problematize the situation” (Focus Group Participant)

This recurring theme pertains to the benefits of LTS for students’ learning of skills, rather than content. Both civic and academic outcomes came up frequently as student benefits resulting from LTS. Furthermore, faculty noted that students who graduate with LTS experience have a heightened “sense of

social responsibility.” Alluding to John Dewey [18], one participant noted that “in order to really learn you have to problematize the situation.” Another participant said the following regarding problem-based learning: “In going out and solving a problem you have to be able to understand the problem and it has to be in a contemporary context so you know that is something that we really need to think about in terms of affecting some change that really promotes community based learning.” Moreover, others emphasized the role of LTS in promoting critical thinking skills, “the ability to do problem-solving and analysis.” Consider the opinion of this participant:

We need to focus more on learning skills and providing students with the opportunity to learn about lifelong learning skills and to get that mentality, that attitude that their learning does not stop when they graduate. I think that some of that can come from service learning and the ability to look at community based problems and think about how the world evolves and changes.

The emphasis on life-long learning and long-term effect of LTS was also evident when participants discussed the career paths that their students chose. LTS was said “to challenge students’ maturity level” and prompt them to seriously consider future occupations. According to the faculty participants, LTS itself has become a career path for some students, and “it expanded the personal, moral, spiritual, as well as intellectual transformation, and provided a way for all students to think about their place in society”.

C. Theme III: Increased Motivation for Learning

“If you could in fact have a carrot why would you insist on only using a stick?” (Focus Group Participant)

Faculty participants spoke at length about the motivational power of LTS. Although often demanding for students both in terms of cognitive challenge and emotional strain, LTS projects appeared to inspire a hunger for learning. According to one participant, “the authentic need inherent in the project” drove students to “actually want to learn.” Another participant commented that his students enjoyed working on an LTS project building a wheelchair because “it was real, not a fictitious sort of thing.” For another illustrative example, consider the following account from a professor whose students conducted a project at the homeless shelter while learning the concept of distributive justice:

The room was abuzz with conversation. People were leaning over and talking to each other. I couldn’t get any of the conversation to die down and all of it to do with what they had experienced during their week at the shelter. Some of them were really shaken to their core. They were shaken by the moral assumptions that they had brought in and that were challenged while they were there. They were shaken by the physical resemblance between these people and people in their families. Some of them fell back into a hard defensive posture, “I didn’t cause that problem” but they were engaged wherever they came out on that. This was not simply a text that they were reading it was something that they had to process and it

had completely transformed the conversation on distributive justice.

Evidently, this experience touched students in ways that the faculty members had not seen in traditional course methods. Another participant commented on how contextualized learning naturally sparked students' curiosity:

All of a sudden they were inquiring out of their own curiosity, questions that we were studying at a particular level and what I discovered out of that was that I really wanted to create learning environments where I created a context where students were seeking learning or were trying to do a task that required their learning. I became a coach to have them do something they thought was important to do. Then they learn it because they wanted information as opposed to traditional instruction where I had to do singing or dancing or something to keep their attention, manipulating them or trying to coerce them into wanting to learn.

LTS appeared to provide a natural context for learning and engaging students, thereby making the instructors' job easier and the whole experience more beneficial for everyone. As one of the participants eloquently put, "If you could in fact have a carrot why would you insist on only using a stick?"

A participant who was an expert on LTS in the K-12 context commented both on the value of this pedagogical method and the challenges educators in K-12 face with LTS. She said: "We are really finding the actual achievement levels of our elementary schools as well as our high schools have actually been increasing when they use service learning." Sadly, she also mentioned that LTS is harder to maintain in K-12, that it "dissipates when a teacher leaves" and that happens quite frequently due to a quick turnover in public schools. Nonetheless, the teachers who attempted to engage public school students in LTS reported that for the first time they observed students "who did something because they wanted to do something."

D. Theme IV: Lack of Professionalism

"The job of an engineer involves writing and communicating with people who don't understand engineering." (Focus Group Participant)

In one of the focus groups, the issue of guiding students who did not know how to appropriately interact with community partners was discussed as a significant barrier to faculty members who use LTS. *Lack of Professionalism* emerged as a theme out of this discussion. For example, one participant noted that students struggle with differentiating "what is considered professional and unprofessional" and "telling the difference between a community partner and a friend". In the similar vein, faculty participants commented that students tend to lack "overall maturity and cultural sensitivity". Consider the following quote: "I think the bigger issue for us is that these are 18 year olds who are not always very culturally sensitive and who are not really familiar with the causes of some of the global issues, such as poverty". Another participant added that their faculty have "sensitivity filters in place for students". Several others agreed that

"maturity issues" among students are a significant issue for faculty to be aware of. Also, appropriate dress came up as an issue. Understandably, students did not pick up such unspoken rules of professional conduct in the classroom. It may be that offering cultural sensitivity training or professional behavioral standards of sorts to younger students starting with LTS is a worthwhile endeavor.

Related to the lack of professionalism mentioned above are the students' poor communication skills, which are another hurdle that faculty have to be aware of in conducting LTS effectively. More specifically, written communication skills are weak among the students, according to focus group participants. When discussing the challenges of writing, they mentioned that "putting together a credible argument that is well supported by evidence is very difficult" for students. Others said that this difficulty may be due to the lack of formality in writing. For instance, one participant said that "the challenge is that they are so used to texting that they don't find it offensive to start the email with 'hey' and just using short abbreviations". Language barriers also came up as an issue, especially when student teams are nationally diverse and one person's "first language is English and everyone else's first language is something else, usually Mandarin". Faculty also mentioned strategies they use to overcome these communication challenges. The most frequently mentioned strategy was using rehearsals for any student presentation that is to be given to an external audience. For example, one participant said that students first present to their peers, get feedback, rehearse again, and only present to the client after that. Another one said that instructors take an extra step and require students to "draft and submit the phone script to them before phoning a client". Consider the following account:

They have to write up a script for all of the questions they are going ask, how they are going to enter the room, how they are going to introduce themselves to the client. They write a script for that first meeting with the client, but not the second and third one. They have three meetings with the client but the first meeting with the client we get the script, before they are allowed to have their meeting with the client.

It is clear that written and oral communications skills are of ultimate importance to engineers-in-training, and that engaging in LTS forces faculty to confront the common shortcomings of students' communication skills. Another participant summarized the role of communication in the following way: "The job of an engineer involves writing and communicating with people who don't understand engineering". Overall, faculty participants agreed that technical competency in students is necessary but not sufficient for successful LTS projects; professional communication skills in students are also essential for successful collaboration with community members.

E. Theme V: Team Dynamics

Stemming from the conversation on professional communication, the next theme identified was *Team Dynamics*. Given that most LTS projects discussed by faculty are team-based, it is not surprising that successful functioning in a team emerged as another prominent hurdle that faculty must address in their students. Faculty spoke about the benefits and pitfalls of putting friends on the same team. Further, they discussed different social roles that students working on a team take on, such as “social loafers, hitchhikers, leaders, isolationists”. One participant commented on the importance of thinking long-term and considering the risk of team disintegration when they said:

If the team implodes then there is a decent chance the team will disintegrate. You don’t want them to lose the only social network that they’ve got at the university. You know, when you’re a first year, you might only have a very limited number of friends.

Everyone agreed that team work is a major component of any LTS project and is oftentimes one of the most difficult aspects. According to another participant, “teamwork and communication” are in the list of top ten skills most required by employers. Similar to communication skills and professionalism, LTS can be an effective tool to address teamwork skills in students, who seem to be falling short of industry expectations according to the focus group participants. The necessity for these professional skills in conducting effective LTS can be seen as both an opportunity and as a source of difficulty for faculty.

F. Theme VI: Community Partnerships

The final significant theme that emerged in the focus groups pertained to the nature of the partnerships with the community clients. The importance of articulating the expectations at the onset of the project was emphasized. For example, one participant said that sometimes clients have “unreasonable expectations”, mostly because they are not engineers themselves and are not used to dealing with students. According to one account, “community partners were town planners who didn’t necessarily understand what they could expect and it took some energy to discuss these expectations with them”. On the other hand, a different focus group participant noted that community partners from non-profit organizations are often pleasantly surprised with the level of professionalism and engagement that early career engineering students bring because they are “used to dealing with high school volunteers”. Yet another participant shared a story of the LTS project in which students completed the project that seemingly met clients’ needs, but the client was dissatisfied with the results, nonetheless. Although learning objectives tied to the project were met and students’ grades were not affected by the negative feedback, they were “really devastated from an emotional point of view”. Other participants agreed that, occasionally, such outcomes are inevitable and are a part of working on “real-world” projects. However, delineating the

conditions of the LTS project with the community clients is essential to minimizing such outcomes. These conditions may include strictly designating the time devoted by students to the LTS project, clearly articulating the client’s needs and requirements, deciding on who conducts the assessment of students’ progress, and agreeing on terms for future engagement on a volunteer basis. Taking these steps prior to commencing a partnership with the community client is a recommended LTS practice.

V. CONCLUSION

The thematic network analysis of transcripts from focus groups of faculty members actively engaged in LTS methods has been revelatory in terms of benefits, barriers, and strategies of LTS. A natural, free-flowing dialogue among participants allowed the following main themes to emerge: how to define LTS, benefits to students including increased contextual learning and increased motivation, difficulties including lack of professionalism, communication skills and team dynamics, and best strategies for maintaining community partnerships. All in all, these themes point to the fact that LTS efforts enable students to engage and learn from real-world and authentic experiences with real clients and stakeholders. Integrating LTS experiences in curricula is an ideal means to preparing students for engineering practice. The themes that emerged highlight how invaluable LTS experiences are to students’ cognitive and affective learning gains, but also to faculty. Whereas some of the findings (e.g., increased students’ enthusiasm) aligned with prior findings [10] [20], others (e.g., students’ lack of professionalism) are novel. Thus, the current study corroborates previous findings, as well as contributes to the growing body of knowledge of LTS and its multiple facets. Ultimately, it has been known that LTS experiences are invaluable, but what has been a challenge is understanding the practices that will lead to effective engagement of faculty, students, and the community in these partnerships. The work herein provides this in-depth insight through the stories told by LTS experts. Both LTS experts and LTS novices are likely to benefit from familiarizing themselves with the challenges and benefits encountered by seasoned LTS pedagogues. In tandem, prior and current findings will aid in the development of a framework to help other faculty members successfully implement LTS methods into their pedagogical practice. Such framework can be used in the upcoming training workshops organized by the EFELTS faculty participants. Ultimately, the end goal of such an empirically-based framework and rigorous workshops is to broaden and strengthen the community of faculty engaged in LTS activities.

Mankato, MN USA

Abstract – Despite strong evidence of the positive impact of active learning strategies, STEM faculty demonstrate a spectrum of receptiveness to incorporating active learning into their classrooms, and for a variety of reasons, engineering classes continue to be dominated by a passive lecture style. This paper draws on data from a four-year study that investigated the use of five social instruction strategies, including active learning. Twenty-four STEM faculty at 4 institutions were interviewed regarding their understanding of and attitudes toward these strategies. This paper focuses on the results of the active learning component of these interviews. Faculty most often interpreted active learning as what students *do* and viewed self-motivation as a key component of what students *think* while active learning. These results, while drawn from a small sample population, can nevertheless make an important contribution to understanding why passive learning remains predominant in the STEM classroom. This paper examines how the findings from this study can inform efforts to promote changes in STEM education that would bring more active learning to the classroom.

Index Terms –Active learning, classroom practice, faculty.

I. INTRODUCTION

The positive impact of active learning strategies on student learning has been demonstrated by numerous studies. However, faculty demonstrate a wide range of receptiveness to incorporating active learning into their classrooms. As a result, undergraduate STEM classes, particularly in engineering, continue to be dominated by a passive lecture style. Drawing on data from a four-year study that investigated the use of five social instruction strategies in STEM classrooms, this paper explores how faculty's conceptions about active learning can facilitate or inhibit their adoption of related teaching strategies.

II. BACKGROUND

Active learning has been shown to lead to better student attitudes and improvements in students' thinking and writing [1]. Active learning strategies often involve students' participating in class in ways other than passive listening, as well as thinking about the activities in which they are engaged. Students can become more involved in learning when they are given the chance to talk, discuss, write and apply what they are learning. For example, Hake [2] examined pre- and post-test data for over 6,000 students in introductory physics courses and found significant

improvement in student performance by using interactive-engagement in classes. Redish et al. [3] also demonstrated gains in learning from active engagement strategies, showing that such improvement derived from active student engagement rather than from extra time spent on learning basic physics concepts. Clearly, considerable support for the benefits of active learning exists, whether in engineering, other STEM fields, or elsewhere. Introducing active learning strategies into lectures can significantly improve information recall and increase student engagement which, in turn, can have other benefits for the student experience.

However, active learning strategies are not widely or frequently used in STEM instruction. As Prince [4] observed, the topic of active learning "frequently polarizes faculty," and while there are many advocates of active learning, "skeptical faculty regard active learning as another in a long line of educational fads." Faculty may also be concerned that content will have to be reduced from contact hours in order to add active learning, that pre-class preparation time will be higher, and that active learning is not appropriate for large classes [5].

In an attempt to better understand why more active learning is not successfully integrated into the STEM classroom, this study uses qualitative research methods to examine how faculty view active learning. A deeper understanding of faculty's perceptions of active learning may provide insight into unsuccessful or unsustainable attempts at incorporating active learning into the classroom, and into the barriers that cause faculty to revert to more traditional, passive lecture practices.

III. FRAMEWORK

This study draws on pedagogical frameworks of active learning that emphasize (a) what students *do*, and (b) what students *think* while they are engaged in active learning.

A. What Students Do

The engineering education literature emphasizes viewing active learning in terms of what students *do*. Thus, we draw on the engineering education literature to assess faculty's views of active learning as something students *do*. Prince's [4] review of engineering education literature identifies the four types of active learning most frequently discussed in that literature: active learning (defined broadly as active student engagement); collaborative learning;

cooperative learning; and problem-based learning (Table I). This view of active learning focuses on what students are doing in their courses.

TABLE I. WHAT STUDENTS DO IN ACTIVE LEARNING [4]

| Type of Active Learning | Description |
|------------------------------|--|
| Active Student Engagement | "[A]ny instructional method that engages students in the learning process. ... The core elements of active learning are student activity and engagement in the learning process." |
| Collaborative Learning | "[A]ny instructional method in which students work together in small groups toward a common goal. ... [T]he core element of collaborative learning is the emphasis on student interactions rather than on learning as a solitary activity." |
| Cooperative Learning | "[A] structured form of group work where students pursue common goals while being assessed individually. ... [T]he core element...is a focus on cooperative incentives rather than competition to promote learning." |
| Problem-Based Learning (PBL) | "[A]n instructional method where relevant problems are introduced at the beginning of the instruction cycle and used to provide the context and motivation for the learning that follows. ... PBL typically involves significant amounts of self-directed learning on the part of the students." |

B. What Students Think

In contrast, the K-12 literature tends to define active learning in terms of what students *think*. Therefore, we have chosen a framework from the K-12 literature to structure our interpretation of how faculty view active learning in terms of students' thinking. This framework, called Fostering Communities of Learners (FCL), is a highly successful intervention that has been nationally demonstrated at the K-12 level [6,7,8]. The FCL framework characterizes classroom activity in terms of students being *motivated*, *aware* of what they should be learning and why, and *strategic* about learning (Table II). All three components of FCL are necessary to make active learning both successful and sustainable in the classroom.

TABLE II. WHAT STUDENTS THINK DURING ACTIVE LEARNING [4]

| FCL Characteristic | Description |
|--------------------|---|
| Motivated | The student is self-motivated to learn, driven little by external motivators. |
| Aware | The student is aware of his or her learning style and how it applies to the learning activity at hand. |
| Strategic | The student considers options before choosing how to solve problems. Once identifying a strategy, they invest effort into using it. |

C. Research Questions

In the context of what students *do* and what they *think* as part of an active learning experience, we seek to answer the following questions by analyzing faculty interviews on the topic of active learning.

- Research Question #1: Do faculty favor a view of active learning that emphasizes what students *do* or what students *think*?
- Research Question #2: What activities do faculty favor among what students *do* as part of active learning?

- Research Question #3: What activities do faculty favor among what students *think* as part of active learning?
- Research Question #4: What does receptiveness to active learning (or lack thereof) look like among STEM faculty?

In summary, the engineering community's definitions tend to focus on the nature of the student's activity (what the student is doing), while the FCL framework focuses on the student's approach to learning (what the student is thinking). Examining faculty perceptions of active learning through these two lenses offers insight into what may be preventing engineering and other STEM faculty from using active learning more often in the classroom.

IV. METHODS

For this study, a cross-section of 24 faculty at 4 institutions were interviewed in order to understand their attitudes toward and understanding of five social instruction strategies: Active Learning, Legitimization of Differences, Reciprocal Learning, Collaborative Learning, and Guided Instruction. The four targeted universities were chosen to represent a range of institution types: 1) a Research Institution, 2) a Teaching Institution, 3) a Private Institution, and 4) a Faith-Based Institution. Interview participants were drawn from 6 different engineering disciplines, plus computer science, math, and chemistry, in order to represent a cross-section of STEM fields.

In most cases, interviews were recorded and transcribed. When recording was not possible, extensive field notes were taken by the researcher. All transcripts and field notes were coded using the constant comparison method [9,10] in order to identify emergent themes and trends. Views of active learning were extracted from responses to the interview questions detailed in Table III.

TABLE III. INTERVIEW QUESTIONS USED TO ADDRESS RESEARCH QUESTIONS

| Research Questions | Related Interview Questions |
|--------------------|--|
| #1, #2, and #3 | How would you define "active learning"? Where does active learning belong in the classroom? To what extent can it be practically implemented in the classroom? |
| #4 | What is your ideal teaching situation? Describe your teaching philosophy. What do you see as your strengths and weaknesses in teaching? |

V. RESULTS AND DISCUSSION

All participants demonstrated an awareness of the term "active learning" in that they understood it as student participation other than simply sitting and passively listening to a lecture. However, beyond this basic common understanding of active learning, responses about what active learning actually looks like in the STEM classroom varied widely. Details of this understanding, including predominant viewpoints and persistent gaps in understanding, are addressed by our research questions and are described below.

A. Research Questions 1 and 3

In analyzing the interview data, we looked at how faculty viewed the impact of active learning on how students think, using the Fostering Communities of Learners (FCL) framework: Are students *motivated* to learn? Do they become *aware* of what they are learning and why? Are they *strategic* in their learning? Participants were not specifically prompted to discuss these three aspects, but their responses to the broad question, “Define active learning,” gave insight into whether these aspects fit into their understandings of the concept.

Our analysis found faculty most often discussed the motivational quality of active learning, but placed the least emphasis on the strategic nature of active learning. Respondents conveyed expectations that students in an “active learning” classroom should be motivated in a wide range of ways. For example:

“I expect – near demand – a high level of commitment on their part. ... When we're in the room, when we're together, I want full focus, and I will bring my enthusiasm and I will bring interesting topics to bear. They need to show up ready, active, mentally awake and prepared. And I'll harass them in that sense. I kid them, needle them, if they're not, and I'm not afraid to do that publicly.” (Engineering, Teaching Institution)

“I strongly believe in active learning, that students have to be involved in their own learning, and ideally they take responsibility for their own learning.” (Engineering, Faith-Based Institution)

Fewer respondents emphasized that active learning techniques should involve helping students become more aware of why they are learning certain concepts or skills:

“I think they need to learn to work together as early on as possible because that is the work situation that they're going into. The companies are not interested in who is the star, who is the most talented. They just want to get the job done and we teach the students to compete with each other for a grade and that the highest grade will get rewarded. In industry, that doesn't have anything to do with it. It's the team, it's working together to accomplish that.” (Engineering, Teaching Institution)

“I really work at pulling theory to practice, just constantly. If you don't-- if you only know it in theory and you can't do the practice, you don't get it. If you can only do it in practice, you can't do it in theory, you don't get it. But helping them realize the value of doing both, and then actually coming up with projects and labs that merge those and help them to see the connection.” (Engineering, Faith-Based Institution)

Consistently, however, few faculty were likely to mention the strategic nature of active learning and even

those that did, spent less time discussing it than the motivational and awareness components of how students *think* while involved in active learning. Comments regarding strategy largely had to do with students learning how to learn and taking responsibility for their own education. For example:

“I can't tell what the content will be that they need five years from now. All I can do is teach them how to think, teach them how to react, get the basic concepts together and ready.” (Engineering, Teaching Institution)

“I like to teach the kids how to learn as much as I like to teach the kids what they need to learn. So, I have them, of course, you know, listen to what I have to say, but then I also make sure that they understand that, you know, I'm only teaching them a certain amount and I really encourage them to explore other resources to get more in depth...they have to have a little bit of self initiative to go out and discover things on their own.” (Engineering, Teaching Institution)

The fact that our interview data saturated at a level that favored the motivational aspects of student learning and neglected the strategic aspects clearly speaks to a need to incorporate the strategic aspect of active learning in faculty development and teacher training efforts.

B. Research Question 2

The interview data also revealed faculty's perceptions of what students should be doing during active learning, mapping data to Prince's framework of the engineering community's definitions of active learning (Table I). This analysis found that all participants recognized that active learning means that students become visibly engaged in the learning process. This basic understanding of active learning is consistent with the first and broadest definition of active learning identified by Prince [4]. However, participants' perceptions of other, more specific manifestations of active learning varied. Participants were more likely to understand active learning as including collaborative learning (67%) than as cooperative (53%) or problem-based (53%) learning.

As noted above, all participants recognized active learning in a broad sense as leading students to become actively engaged in the learning process. For 25% of the participants, their definition stopped at the most general level, perhaps indicating a limited understanding of the concept. For example:

“Ask questions of students ... [and] encourage students to answer. If a student answer is correct, I say, ‘great’ and move on. If they know a little bit, I'll give hints and encourage more response.” (Engineering, Teaching University)

“I guess active learning is about anything other than just sitting there listening passively. ... [A]sking questions, me answering questions they ask. (Computer Science, Research University)

The majority of the participants (75%) had more detailed definitions, indicating to various degrees broader conceptions of what active learning can include and how it benefits students. For example, these faculty often mentioned classroom activities that correspond to one or more additional elements of the engineering community's framework (e.g., collaborative learning, cooperative learning, or problem-based learning).

"Active learning is where the mind is actively engaged in dealing with a subject or a problem. Not just listening but using the knowledge to do something. Now, 'do something' may be communicating to a neighbor. It may be solving a problem. It may be putting a circuit together in the lab. It may be writing a report. But it's not just sitting while the information plays to you." (Engineering Faculty, Research Institution)

"I think that active learning would be giving students enough of the basic tools, basic ground rules tools, and then presenting them with a problem where they have to apply those tools, but in addition to that, find their own tools to help solve the problem." (Engineering, Teaching Institution)

"There were some projects that we did outside of class that involved them having to do some sort of active learning and participation rather than just sitting there like a sponge. But, I learned that I need to incorporate that into the classroom a little bit more and instead of preaching to them in class, have them sit down and figure things out for themselves in class." (Computer Science, Teaching Institution)

"[Active learning is] when the students are actively using the concepts that were taught to them and in so doing solidifies their understanding of the material.... It's a way of engaging students within the classroom to either practice or reinforce something that we worked on. ... I don't use it to generate new concepts. ... It's more of a, 'This is me telling you, and now it's your turn to do.'" (Engineering, Private Institution)

C. Research Question 4

Whether defined in terms of how students think or what they do, faculty's perceptions of active learning tend to influence how receptive they are to the concept, as well as whether or not they actually use active learning in their own classrooms. Analysis of faculty responses showed that participants fell into three categories:

- Those who were not receptive to the idea of incorporating active learning strategies into their classrooms (19%).

- Those who were receptive to the idea of active learning, but had not adopted these strategies to any significant degree (31%).
- Those who were receptive to active learning and were using these strategies in their own classrooms (50%).

1) Not Receptive

At one end of the spectrum were the 19% of participants who indicated that they were not very receptive to the idea of incorporating active learning strategies into STEM classrooms. None of these participants used these strategies themselves, for a variety of reasons. For example, as one engineering professor at the Research University stated:

"I could not see the value [of active learning]. I feel a little sorry for people who need active learning in order to learn better. I think it shows their weakness...that they need to explain to somebody. It's only for those types of people. ... I think active learning serves the weaker student population."

This professor went on to describe active learning as sort of a trend or buzzword – a perception which likely impacted his decision not to use it in his own teaching:

"[Active learning] is kind of pretty; oh, that's the thing to do and you should do it. ... But active learning is, let's say, a brand, right? ... So it's just one framework that was branded. ... And I think this is where I see...one of the problems of modern education. They find a new religion, and then they expect every class to follow this religion. So currently, active learning is one of the religions. If you talk to the proponents of active learning theory, they are religiously saying that every class should have it because it's a good thing. And this is when I think it's taken too far." (Engineering, Research University)

Other participants who were not receptive to active learning made similar comments. In various ways, they indicated that they did not feel that the benefits of active learning strategies were significant enough to warrant changing their teaching styles.

2) Receptive Non-Adopters

Nearly one-third (31%) of the participants fell into the middle category: They recognized the value of active learning, at least in theory, but were not using these strategies to any significant degree. These participants perceived various barriers that prevented them from incorporating more active learning into their classrooms.

For some, the barrier was a past experience with active learning that did not go as well as hoped:

"I've tried various things. I've tried having people work together in groups a little bit and having more of an open-ended discussion. But it hasn't worked that well for me. I find I have a lot of success with pretty much explaining things in lectures." (Math, Research University)

"I've tried things like that [active learning strategies] sometimes, and I get mixed reactions from the students. There are some who really object to it...then other people find it engaging. I guess I'm not sufficiently persuasive at explaining why this is so much fun to do, and so I've gotten some pushback." (Computer Science, Research University)

Others perceived the logistics or costs of using active learning strategies as barriers:

"Well, it [active learning] is hard in the classroom because then how do you define your measurements? ... How do you evaluate who does what, or what part of it?" (Engineering, Teaching University)

"I don't do that much of those activities where students have to somehow form little groups within the classroom and do things. I have nothing against it, but it hasn't been that convenient to do it and it takes time." (Computer Science, Research University)

"[If you have a] couple hundred people in the room, give them a lecture, as opposed to breaking them into groups of five and bringing them a free, creative environment and supervise that. They would cost so much more." (Engineering, Research University)

Whether these perceived concerns are realistic or not, they are salient enough that they prevent these individuals from attempting (or re-attempting) to fit more active learning into their classrooms.

3) Receptive Adopters

At the other end of the spectrum were the participants (50%) who were not only receptive to the idea of active learning, but were actually using active learning strategies in their classrooms. This was evident in participants' descriptions of their own teaching. For example, when asked to describe his teaching philosophy, one engineering professor at the Teaching University immediately replied:

"Active learning. I do not think that the instructor needs to have all the answers, or be the expert, but put students in ways so that they can creatively find the answers themselves. ... You have to give them the basics. But then you also need to give them the opportunities to apply those and find out that the calculation doesn't always happen in the real world." (Computer Science, Teaching University)

Similarly, an engineering professor at the Private University described his "ideal teaching situation" in this way:

"I like interactive lectures. My typical strategy is to use PowerPoint, but I like to facilitate active learning and I like to activate the students. ... Work with your neighbor. We'll do multiple-choice.

From time to time I'll use the audience response systems ...the clickers...and that type of thing. ... So I like to have an active classroom. I really don't like the days where I'm just up there talking and there's no interaction." (Engineering, Private University)

An engineering professor at the Faith-Based University described her teaching philosophy in a way that suggests active learning strategies, even though she did not use that specific label:

"I do a lot of, 'Okay, let me teach you a little bit,' for maybe 15 or 20 minutes, and then I turn them loose on some problems to start working on, usually computer based. And then I walk around and answer their questions as they work through the lab. ... And if I could have an exploration on every single topic I wanted them to learn, that would be how I'd want to teach." (Engineering, Faith-Based University)

Later in the interview, when asked about the place of active learning in the classroom, this professor replied:

"I think [active learning] can be in every class. To what extent really depends on the class. I mean, ideally a class would be 90 percent active learning. I probably am achieving about 50 percent in some classes. Other times-- if I've gone a whole week and I've almost done all the talking the whole week, I'm like, 'Oh, this is a bad week. How did that happen?'"

Overall, the interview data suggest that while some STEM faculty fall at the extreme ends of the spectrum, being either strongly unreceptive to active learning or enthusiastic adopters, most faculty fall somewhere in the middle. Faculty in this middle group hold conceptions of active learning that reach beyond the most basic level, at least to some degree, and they are open to the idea of using active learning strategies. However, they may be held back from doing so by perceived barriers. It is this group to whom we propose turning our attention.

VI. DISCUSSION

Although it is encouraging to see that all of the study participants were aware of active learning and half of them reported using active learning strategies in their classrooms, those figures do not tell the full story. It is important to look closely at how faculty talk about active learning. For example, are they simply asking questions in class and labeling that active learning? Or are they utilizing other strategies, moving beyond the most basic definition of active learning? We argue that this makes a difference, and we suggest that a deeper understanding of active learning and its benefits to students are likely to lead to greater receptiveness toward using active learning strategies.

As with any professional development, understanding practitioners' perceptions and internal beliefs is essential before introducing new or different practices. Findings from this study suggest that the perceptions and beliefs that

present the most significant barriers to adopting active learning strategies are limited conceptions of what active learning means, and concerns about barriers to using active learning in class.

The complexity of instructors' understanding of active learning strategies appears to be instrumental in their decisions about how (or if) to integrate these strategies into their own classrooms. Among our study participants, those who were most receptive to active learning *and* were using these strategies gave rich, detailed descriptions of active learning, indicating a broad understanding. Conversely, respondents who were least receptive to active learning described it in more limited ways. Therefore, one key to bringing more active learning to STEM classrooms would be to enrich faculty's understanding of what active learning encompasses, both in terms of what students are thinking and what students are doing.

However, even faculty who understand active learning fairly well may not adopt it because of beliefs about logistical barriers. Thus another key strategy for moving faculty not only toward receptiveness but also toward adoption appears to be demonstrating how to manage or overcome the various perceived barriers. For example, providing suggestions or strategies for working around high costs or the challenges of large class sizes may be helpful.

We acknowledge that the interview data discussed here represent a small cross-section of STEM faculty. Therefore, rather than making broad claims of generalizability about STEM faculty, we instead propose that the insights gained by exploration of these faculty's perceptions can be used as a starting point in understanding the possible conceptions and beliefs underlying decisions about active learning, and can provide guidance for targeting faculty development efforts in more efficient ways.

If we hope to see more active learning in STEM classrooms, our data suggest that the most efficient approach would be to first target faculty who are at least somewhat amenable to active learning, but who are not yet implementing these strategies in their own classrooms due to perceived barriers. Faculty who are already doing active learning will likely continue to do so without additional interventions. At the other end of the spectrum, it may be difficult to convince faculty who are strongly unreceptive to active learning to change their practices. However, those in the middle of the spectrum are a good place to start. These faculty are already receptive to active learning, and with some guidance on strategies to overcome perceived barriers, they may be more likely to incorporate active learning strategies into their own classrooms.

VII. CONCLUSION

Our findings support previous studies that assert that STEM faculty's conceptions about active learning are diverse, and can facilitate or inhibit their adoption of active learning strategies. Most faculty already have a basic understanding of active learning, both in terms of what students are thinking (FCL) and what students are doing

(Prince). However, faculty most often view active learning in terms of what students are *doing*. This view of active learning is very important for measuring improvements in academic outcomes that result from active learning. However, a lack of emphasis on what students are thinking limits how much students are likely to carry forward and expand the use of active learning in other courses and other instructional environments.

In addition, this basic understanding appears to be insufficient motivation for many STEM faculty to use active learning strategies themselves. Therefore, broadening faculty's conceptions of active learning – including what students think and do, as well as how to fit it within classroom constraints – is critical if we hope to see more active learning in STEM classrooms. With limited resources for faculty development, it can be difficult to reach all STEM faculty and change their perceptions of active learning in such a way that they will actually bring these strategies into their own classrooms. Therefore, we propose that the most efficient use of these limited resources would be to begin by focusing efforts on faculty who indicate at least some receptiveness to the idea of active learning but who are not yet using it themselves.

Abstract—We propose an introductory level teaching and learning curriculum for the ASEE COMPLEETE program (*COMP*etencies in *Learning for Engineering and Engineering Technology Educators*). COMPLEETE is an initiative for a national program to build and recognize educator excellence in engineering and engineering technology at three levels. The proposed curriculum for the introductory level is compared with curricula from nine well-established existing programs. The content is specifically targeted to benefit engineering and engineering technology instructors in higher education, integrate with the values and programs already offered within ASEE, serve as a foundation for further development at higher levels, and be flexible to suit the needs of a diverse instructional community. The nine existing programs were coded under the overarching COMPLEETE criteria and then analyzed for commonalities and alignment. The proposed core competency areas were found to comprehensively represent existing programs. They are: learning theory, student development, instructional design, instructional facilitation methods, assessing and providing feedback to learners, instructional technology, and reflective practice. The proposed curriculum lays a foundation for those offering faculty development services to compare against, and challenges the engineering and engineering technology community of educators to address key competency areas all faculty should develop within 3-5 years of beginning teaching.

I. INTRODUCTION

We propose an introductory level teaching and learning curriculum for COMPLEETE. The ASEE COMPLEETE Program (*COMP*etencies in *Learning for Engineering and Engineering Technology Educators*) was described in an award winning “Best Paper” at the 2010 ASEE conference under the name SPEED (Strengthening the Performance of Engineering and Engineering Technology Educators across the Disciplines) [1]. COMPLEETE is an initiative for a national program to build and recognize educator excellence in engineering and engineering technology. This recognition occurs as the educator progresses through three levels of achievement. The proposed curriculum in this paper targets a succinct set of core competencies representing the first level of achievement, yet remains flexible to serve the needs of faculty with diverse approaches to teaching and learning. This flexibility is achieved in part by inviting a wide array

of faculty development providers to contribute to COMPLEETE programming. In other words, there may be many paths (through multiple providers) for participants to reach each level of achievement in the COMPLEETE program, but all paths must satisfy the same set of competencies.

The national debate about how to move faculty toward achieving new levels of competency in teaching and learning for the modern world (and for what purposes) is fueled by several important publications over the past decade or so. These include the revised ABET accreditation criteria published in 2000 and 2004 [2], the reports for *The Engineer of 2020* and *Educating the Engineer of 2020* from the National Academy of Engineers [3, 4], and ASEE's two recent reports on *Creating a Culture for Scholarly and Systematic Innovation in Engineering Education* [5, 6]. The proposed curriculum responds to these calls by integrating curricula from many well-established, existing programs to form a single vision for a set of core teaching and learning competencies that all faculty can benefit from possessing, and which can move the engineering and engineering technology community of educators forward towards achieving the ideals proposed in these publications.

This work may be useful to faculty development practitioners to assist in planning curricula or individual workshop topics that are consistent with other programs and with generally agreed upon areas of competence. It may also be useful if they wish to contribute directly to COMPLEETE by offering programming that helps instructors build competence in the areas specified for the proposed curriculum. Finally, it may also be useful to educational researchers investigating instructional practices, and by instructors as a means to identify areas where they might strengthen their knowledge and skills.

Faculty development programs for which comparisons were made include STEMES [7], EXCEED [8], Pacific Crest [9], NETI [10], U-Michigan [11], Northern Illinois [12], and CIRTL's Delta program [13] within the US, plus international models from the UK [14] and IGIP [15].

These programs have informed the structure and content of the proposed curriculum, which is specifically targeted to benefit engineering and engineering technology instructors in higher education.

The COMPLEETE project proposes three levels of attainment for engineering and engineering technology educators. These are a foundational level representing critical areas of competence which contribute to building quality teaching and learning environments in any setting, a scholarly practitioner level where participants further strengthen their skills and begin to systematically investigate learning in their classrooms, and a reflective mentor level where participants contribute and give back to the engineering and engineering technology community of practice [1]. Here, we address only level one, defining the goals and outcomes associated with this level of attainment as consistent with the vision for the COMPLEETE program. We address only level 1 because the initial efforts of the COMPLEETE program will focus on this level, and further because the proposed curriculum will likely be adapted community input, implementation, and review, thus defining more detailed needs for levels 2 and 3 over time.

Level 1 – Foundations

A. *Proposed Level 1 Aims:*

- To provide an overview of teaching and learning practice and theory in Engineering and Engineering Technology Education, addressing the core knowledge and professional values educators are expected to have to be able to teach effectively and efficiently at their respective institutions.
- To begin to establish in participants a culture of reflective practice and evaluation of their own teaching practice, and of the learning of their students; and to build a broader community of practice among practitioners.

B. *Proposed Level 1 Learning Outcomes:*

Upon successful completion of Level 1 participants will:

- Have evaluated aspects of their current teaching practice within the context of learning and teaching literature (reflecting knowledge and critical understanding of the following teaching and learning activities: teaching and the support of learning; contribution to the design and planning of learning activities; assessment and giving feedback to learners; developing effective learning environments and learner support systems).
- Have gained an understanding of the learning process, drawing on recognized learning theories.
- Have developed an understanding of students, including issues of intellectual and social

development, learning styles and differences in student approaches to learning.

- Have been engaged in instructional design at lecture, module, course or curriculum level.
- Have been exposed to various methods of instructional delivery, including an overview of teaching methods appropriate for different instructional goals and environments, including both large and small classes.
- Have designed and used appropriate methods to assess student learning and give feedback to learners.
- Have developed an understanding of how to make effective use of educational technology.
- Have engaged in reflective practice and continuous learning.

The proposed curriculum which accompanies these goals and intended outcomes is built from the overarching criteria proposed in the COMPLEETE project as presented in various publications over the past three years [1, 16-19]. The curriculum revolves around seven areas of core competency which were first articulated as a synthesis of faculty development needs by an experienced faculty development expert in engineering on the original SPEED team and then revised based on discussion among others on the SPEED and, later, COMPLEETE project team. The seven areas or core competence are shown in Table 1.

TABLE I. CORE COMPETENCY AREAS

| Area | Title |
|------|------------------------------------|
| 1 | learning theory |
| 2 | student development |
| 3 | instructional design |
| 4 | instructional facilitation methods |
| 5 | assessing and providing feedback |
| 6 | instructional technology |
| 7 | reflective practice |

It is also consistent with previously proposed critical elements for successful faculty development programs at a national level in the US [20] and serves as one response to numerous call for national reform. Finally, it integrates with values and programming already present within ASEE [21], serves as a foundation for further development at higher levels, and is flexible to suit the needs of a diverse instructional community.

II. METHODS

The content of nine existing faculty development programs was coded for commonalities and alignment with the overarching COMPLEETE criteria using a qualitative methodology. This was first done individually by each of the authors. Then, two rounds of feedback among the group were utilized in order to come to greater consensus. The coding process used was based on a grounded theory approach [22-24]. The feedback process was designed to

follow, to the extent possible within a limited group of three experts, a modified Delphi procedure which has been used on other educational contexts to build consensus about complex concepts [25-28].

A. Producing initial individual rankings

The details of the process used to produce the individual ratings (before coming to consensus) in Table 1 are as follows:

1. Program materials for each "comparison curriculum" (in the form of publicly available basic program outlines that might be provided to potential participants in those programs) were assembled into a single document and distributed to each member of the rating team via email for printing.
2. Each content item listed in the program materials for each "comparison curriculum" was mapped to the "equivalent" content items in the COMPLETE curriculum using the pre-determined codes represented in Table 1. Content items in the comparison curricula could be words, sentences, or phrases present in the materials themselves. The coding process was simplified via the use of a number system to represent the codes and thus reduce writing on the "comparison curriculum" materials:

Each rater then wrote the appropriate number directly on the "comparison curriculum" materials. This process of assigning codes consisted, of course, of judgment calls, as text did not always match exactly. Rather, the general area or meaning of the wording in the comparison curricula needed to be interpreted by each rater. Further, it was possible to associated multiple COMPLETE curriculum items with a single "comparison curriculum" if needed, and vice versa.

If a "comparison curriculum" item did not match with any COMPLETE curriculum item, this information was recorded separately so a mechanism to track the items the COMPLETE curriculum did NOT cover was established.

3. Assignments for a level of agreement for the "comparison curriculum" with the COMPLETE curriculum were made. This was accomplished by ranking the relative frequency of the presence of each numbered content item and applying the matching scale defined below:

X = Not present in "comparison curriculum"

1 = Present by inference, or as subtopic of a major area

2 = present as a major aspect of the "comparison curriculum"

4. Results were recorded in a blank table with the same form as Table II.

B. Building Consensus:

Once the individual ratings were complete, a comparison table displaying the ratings from each of the three raters was produced and distributed. Two rounds of feedback were then conducted to produce a greater level of consensus.

First, a phone conference was scheduled to discuss ratings where both X and 2 appeared from different raters for the same "item" in a particular comparison curriculum (the term item here is used to represent a cell in table 1, where each cell is a comparison between one core competency in the COMPLETE curriculum with a particular comparison curriculum). There were eight items in this category. During the phone conference each rater discussed their rationale for their individual rating, and then an opportunity to change ratings was provided. Results from the discussion (along with any modified ratings) were recorded on a new spreadsheet. No items with both X and 2 remained after discussion. In other words, at least two of three raters had come to full agreement for each item, with the other rater differing by one level.

Second, remaining items where two raters agreed but a third had assigned a different level of curricular agreement were discussed. Approximately half of the items fell into this category. Discussion for these items occurred over two separate phone conferences (due to lack of time to complete the process in a single conversation). To help resolve those items where there were differences, the raters agreed that the person with a different rating than the other two should look at the materials a second time and either (a) change their rating to match the others, or, (b) write a short justification trying to convince the others why their rating (as based on their coding of curricular content) was correct. This process was completed for one rater before the first phone conference and the others at a later date. Approximately two thirds of the discrepancies were resolved in this manner.

Finally, the combined ratings for level of agreement on each item were tabulated through a simple numerical average of the three raters final scores at the end of the discussion process. In should be noted that in order to produce a numerical average, the "X" level of agreement was assigned a value of "0" for this purpose.

III. RESULTS

Table II displays the results of our curriculum comparison. The core competency areas compared are those defined in Table I: learning theory, student development, instructional design, instructional facilitation methods,

assessing and providing feedback to learners, instructional technology, and reflective practice. Results show that reflective practice and instructional technology have the lowest level of concordance with the COMPLEETE curriculum. Instructional design, and instructional facilitation and methods have the highest concordance. Also, it should be noted that the programs used for comparison vary greatly in length. A few details for each program are shown at the bottom of Table II. About half the programs are multi-day affairs where participants are together for several consecutive and intense days. Other programs consist of courses one takes during semesters over a period of one or more years (CIRTL Delta and U-Michigan), or modules to be completed either individually or with a group through various means over a period of one or more years (Pacific Crest, UK, and IGIP). This latter group is more consistent with the COMPLEETE approach where participants may progress through the level 1 curriculum over several years and continue to grow throughout their career at levels 2 and 3.

TABLE II. CURRICULUM COMPARISON

| COMPLEETE Core Module | STEMES | EXCEED | Pacific Crest | NETI | U-Michigan | Northern Illinois | CIRTL Delta Program | UK HE Certificate | IGIP |
|------------------------------------|---------------------------------|-----------------------|------------------------------|-------------------------|--|---------------------------------|--|-------------------------------------|---------------------------------------|
| learning theory | 1 | 1 | 2 | 1.7 | 2 | 2 | 2 | 2 | 2 |
| student development | 1 | 1 | 2 | 0.7 | 1 | 1.3 | 2 | 2 | 1 |
| instructional design | 1 | 2 | 2 | 1 | 2 | 2 | 2 | 2 | 2 |
| instructional facilitation methods | 2 | 2 | 2 | 2 | 1 | 2 | 2 | 2 | 2 |
| assessing and providing feedback | 2 | 1.7 | 2 | 1 | 1 | 2 | 1 | 2 | 1 |
| instructional technology | 1 | 1 | 2 | 1 | X | X | 2 | 2 | 2 |
| reflective practice | 1 | X | 1 | X | 0.3 | 1 | 2 | 2 | 1 |
| TOTAL | 9 | 8.7 | 13 | 7.3 | 7.3 | 10 | 13 | 14 | 11 |
| Program length | Three or more days, all at once | Six days, all at once | One year or more, spread out | Three days, all at once | Two or more semesters, consecutive or spread out | Three to five days, all at once | Two or more semesters, consecutive or spread out | Usually three consecutive semesters | Self-paced, usually one or more years |

After discussion about the overall results, the team selected a limited set of compulsory core competencies for the introductory level along with several additional optional competencies among which participants might choose to form their complete introductory level curriculum. Below, each competency (or module) is broken down into distinct components that might be addressed in single instance workshops of a half-day or less such that one might be able to piece together a complete curriculum by using a variety of faculty development resources. We derived these components from previously published descriptions of the competency areas and then refined them based on our discussions about the content of the comparison curricula. Details for the components of each core competency (or module) follow:

DRAFT MODULE STRUCTURE for LEVEL 1

The first five modules are proposed as required modules for all COMPLEETE participants. These modules are well represented in existing curricula and thus form a broad and generally agreed upon foundation of teaching and learning competencies desired for engineering and engineering technology educators.

A. Core Module 1 – Learning Theory:

Outcome: Understanding the learning process, drawing on recognized learning theories.

Narrative: A practical overview of theories of learning and teaching in Higher Education, with a focus on the disciplines of engineering and engineering technology. This includes an overview of current cognitive and constructivist learning theories with a focus on their application to undergraduate instruction.

- Understanding student learning
- Constructivism
- Approaches to learning: deep learning, surface learning, strategic learning
- The Kolb learning cycle
- SOLO taxonomy of levels of understanding
- Bloom's taxonomy of learning
- Learning styles
- Problem-based Learning
- Project-based Learning

B. Core Module 2 – Student Development:

Outcome: Understanding students, including issues of intellectual and social development, learning styles and differences in student approaches to learning.

Narrative: An introduction to understanding elements of student development which impact teaching and learning

such as students intellectual and social development, learning style preferences and approaches to learning.

- Encouraging student motivation
- Teaching and learning in small groups
- Teaching and learning in large groups
- Student supervision: one on one, e.g. projects, theses, dissertations, etc.
- Reflective practice
- Ethics

C. Core Module 3 – Instructional Design:

Outcome: Introduction to instructional design, including both course and curriculum design.

Narrative: An introduction to the theory of constructive alignment (of intended learning outcomes, learning and teaching methods and assessment) to be used in course and curriculum design.

- Organizing teaching and learning
- Outcome-based planning
- Module and course design
- Constructive alignment (Biggs)

D. Core Module 4 – Instructional Facilitation Methods:

Outcome: Instructional delivery, including an overview of teaching methods appropriate for different instructional goals and environments, including both large and small classes.

Narrative: An overview of instructional techniques that might be employed in large group or small group teaching situations, with an emphasis on approaches that might shift the environment of the classroom from teacher-centered instruction toward student-centered learning.

- Structuring lectures
- Increasing student-teacher interaction
- Managing the Classroom Learning

E. Core Module 5 – Assessing and providing feedback to learners:

Outcome: Designing and using appropriate methods to assess student learning.

Narrative: Purpose of assessment, principles of assessment, formative and summative assessment, methods of assessment, assessing groups, peer and self-assessment, devising assessment criteria, providing feedback.

- Assessment and evaluation
- Formative and summative assessment
- Methods of giving feedback

- Assessment methods/tools
- Developing rubrics

The next two modules are proposed as electives. A COMPLETEE participant would choose at least one of these two modules to attain level 1 in the COMPLETEE curriculum. Some, but not all, existing curricula address these modules in a significant way.

A. Elective Module A – Instructional Technology:

Outcome: Making effective use of technology.

Narrative: An introduction to available tools and the effective use of technology to promote learning, including principles of e-learning.

- E-learning
- Virtual Learning Environments

B. Elective Module B – Reflecting on learning and teaching:

Outcome: Engaging in reflective practice and continuous learning

Narrative: An introduction to the role of reflection in professional practice.

- Reflective practice (currently this topic remains distinct to this module, but upon further discussion will likely be distributed throughout the curriculum, with a focus reach in this elective module)
- Developing portfolios
- Classroom peer observations

IV. CONCLUSIONS

This proposal has the following implications: first, it lays a foundation for organizations/groups to compare against. When considering the needs of engineering and engineering technology educators, we have now established a comprehensive curriculum which encompasses input from many existing programs, is consistent with the literature calling for education reform, and represents a national platform for recognizing scholarly attainment in teaching and learning for engineering and engineering technology educators. Second, it lays a foundation to design levels 2 and 3 of the COMPLETEE curriculum. This curriculum is not intended to be offered as a "one and done" type of curriculum. Rather, it mirrors the journey one takes throughout their career as an educator. Third, it challenges the engineering and engineering technology community of educators to own up to what competency areas all faculty should be developing regarding their instructional responsibilities. One can sometimes improve from experience as an educator, but dramatic improvements across the entire community require mutual understanding of core competencies by everyone. In that way the entire community can work together to strengthen their skills and

foster measurable improvements in student success. Finally, we hope it extends the national conversation in this area and incites some debate. We invite comments and critique from faculty developers, researchers in engineering and engineering technology education, and individual instructors. As the COMPLETEE program moves forward we expect that the debate about how best to strengthen and recognize achievement in our community of educators will take shape at national conferences and in publicly visible space on the web. We hope you will join the conversation.

Abstract - Colleges of engineering increase accessibility to higher education in the Science, Technology, Engineering and Mathematics (STEM) fields. There is often a need to promote students' learning and thinking skills in order to maintain high academic standards and at the same time avoid high rates of failure and dropout. In addition, academic staff with high pedagogical qualifications is an essential requirement. Establishing a Teaching and Learning Center (TLC) is an increasingly frequent process for achieving these goals. Such centers offer various programs for the promotion of teaching and learning in academic institutions.

This article examines the factors that influence the significant role played by TLC in an institution, and the effectiveness of its curricula. The literature refers to several factors, such as the initiation of innovative programs and participation in the institutional strategy plan. In our college, the tight linkage between teaching and learning and the involvement of faculty members in TLC programs are highly influential factors.

Keywords - teaching and learning center; faculty development; learning skills

I. INTRODUCTION

One of the main challenges of higher education in general, and of colleges of engineering in particular, is placing the promotion of teaching and learning in a central position. ORT Braude College (OBC) confers degrees in several fields of engineering, and strives to increase accessibility to higher education in Israel's northern periphery. Accordingly, its policy is to accept students from diverse and multicultural populations and backgrounds while maintaining high academic standards. This results in high dropout rates, especially among students who begin their academic studies with inadequate learning and thinking skills and insufficient knowledge in mathematics and sciences.

OBC's Teaching and Learning Center (TLC) was instituted eight years ago to promote students' learning skills and to improve the quality of instruction. Establishment of centers in Israeli academic institutions was accelerated in recent years. While earlier established centers have focused on

faculty/instruction development, TLC's programs are aimed at both Teaching and Learning.

TLC influence is greatly determined by its position in the institution. The literature dealing with TLC's policies and activities reflects several factors that determine TLC effectiveness. Our experience shows that a significant contributor to TLC leading position is the high involvement of faculty in its programs.

II. WHAT PLACES A TLC IN A LEADING POSITION?

Being a part of institutional strategic plan: Sweet and Blythe (2010) describe how they manage to insert TLC into the strategic plans of their institution through the brainstorming process involving lecturers from diverse backgrounds [1]. In the UK, several Educational Development centers were involved in setting the strategic plans in universities, an indicator of their substantial role within the institutions [2].

Engaging stakeholders in TLC's activity: In order to reinforce the leadership of the Academic Development (AD) unit, the center should work with all its key stakeholders: academic staff, university management and the wider AD community [3]. TLC directors are accountable to the university's senior executive, and TLC's success is judged by its ability to support their expectations [4].

Initiation of innovative programs for promoting teaching and learning: According to a survey of TLC directors in Australia, the most important roles of TLC are to develop and implement teaching and learning plans and to promote professional development of staff [5]. TLC is expected to be a source for initiatives and innovation in promoting teaching and learning [2, 5].

The ability of the Center to demonstrate its value: It is important for TLC to be valued by the institution community, though this goal is difficult to achieve since the assessment of its impact is complicated. The center is more acknowledged if it has evident reputation of national and international collaboration [4].

III. LINKING TEACHING AND LEARNING - GUIDELINES

In OBC, linkage between learning and teaching is elaborated through the following guidelines:

- Involvement of faculty from different academic departments in the various stages of forming new programs for the promotion of teaching and learning.
- Professional long-term training courses for instructors are often dedicated to acquiring knowledge and skills for the purpose of integrating the instructors in the center's activities, not merely for general enrichment.
- Documentation and evaluation of activities to build a teaching-learning knowledge body (e.g. gaining insights into sources of students' difficulties).
- Creation of channels for reciprocal information flow between the engineering departments and the TLC staff.

To achieve its goals TLC operates several programs involving college faculty in each of them:

Courses for learning and thinking skills, compulsory for all freshmen students, are taught by lecturers from the engineering departments.

Students' peer-led workshops guided by exceptional students ("leaders") accompany courses with high failure rates, and focus on active learning and small-group and collaborative problem-solving. Leaders are trained and supervised by course instructors [6]. Workshop evaluations show satisfaction and improved performance of student participants. In addition the workshops contributed to the leaders and course instructors.

In a unique **procedure for supporting underachieving students**, their difficulties are examined and each student is advised of support tools suitable for his own needs. This program involves the Dean for Academic Affairs, academic advisors and department heads. Evaluation research shows that the program enables over 40% of the students, who are candidates for dropping out, to continue their studies.

Academic personal coaching for students with poor learning skills, carried out by college lecturers who have completed a professional training course.

A holistic **procedure for induction of new lecturers** through peer-support and training is especially valuable for those who have arrived at college directly from a career in research or industry.

Projects are initiated and designed by TLC committees comprised of faculty from each of the academic departments: Steering Committee, Faculty Development, Students' Learning, and Research on Teaching and Learning. The discourse that takes place and the interaction between lecturers generates mutual learning fostering discussion of issues raised within the departments, and the spread of perceptions and ideas from the committees to each department.

IV. RESEARCH AND EVALUATION

Over the past several years, data has been collected, using questionnaires and semi-structured interviews, to evaluate: (a)

the effectiveness of TLC projects as they relate to students' learning and achievements, and (b) faculty's perceptions of the influence of TLC's activities on their instructional development and on institutional culture.

Instructors reported that involvement in TLC's activities made them more aware of teaching methods that enhance students' thinking skills, gain a deeper understanding of students' difficulties, and develop skills such as interpersonal communication and management of instructional objectives.

Lecturers' satisfaction with the program is circulated throughout college, and as a result, additional lecturers request to participate. About 40% of college faculty is involved in TLC's programs and committees. An increased number of teaching-learning initiatives are referred to the center by students and faculty.

TLC program evaluation research is encouraged and supported by college management, as a basis for decision-making in college teaching and learning issues. Research outcomes are frequently introduced in management meetings and conferences.

V. SUMMARY AND FUTURE WORK

TLC's position at the institution is reflected by its growing number of programs, faculty participation and additional requests by the engineering departments for TLC's involvement in pedagogical issues. Evaluation research has been carried out for each of TLC projects. Until now focus has been mostly directed at students' achievements and instructors' acquisition of professional and personal skills that influence their teaching.

For further evaluation of overall influence of TLC and its position in the college, we would like to expand our examination to different stakeholders such as department heads and college administration.

We believe that the above-mentioned guidelines for linking teaching and learning can be adapted to other small and medium sized academic institutions, and to faculties/schools inside large academic institutions.

Abstract— Mobile communication technologies have fundamentally altered the concept of going to work. Work has been transformed from a place you go to a function you perform, whenever and wherever you are. Laptops, smartphones, and tablets enable users to transition seamlessly between work and personal activities anytime and anywhere. The effect of this capability on an individual's ability to balance their work and personal life and manage personal stress remains under study. One thing is clear. Modern societies are still in the early stages of this transformation. While 88% of Americans have cell phones, only 46% have Smartphones and just 19% have Tablet PCs. These devices are fast, powerful, and quickly become integrated into our lives as constant companions. This paper presents the results of a survey of engineering and technology students at a Midwestern university. No significant relationship between laptop use and personal stress was found and work-life balance was only negatively impacted when usage exceeded 3 hours on days off. While significant percentages of smartphone users reported increased stress, similar percentages felt the accessibility of the smartphone reduced their stress levels. Users overwhelmingly responded that smartphones improve their ability to balance their work and personal life.

Keywords- *mobile communications; smartphones; work life balance; stress; cell phones; laptop computers*

I. INTRODUCTION

The new reality of the world of work is any day, any time, any place. Mobile communication technologies have fundamentally altered the nature of work forever and workers, families, and employers are struggling to adapt to this change. Long gone are the days when you went to work, put in a full day's effort, and returned home to rest and relax until the next work day. For many workers, advances in mobile communication technologies (MCTs) have transformed work from a place you go to a function you perform, whenever and wherever you happen to be when a call, email, or social networking device reveals the next urgent assignment.

Laptop computers, smartphones, and tablet PCs are proliferating as the constant companions of young and old alike. They are no longer simply work tools utilized to polish a presentation or stay in touch while traveling. Instead, they are quickly becoming fully integrated into our personal lives and our dependence on them to manage our personal and work life is growing [1-3]. They are small, fast, convenient, and always close at hand as we move fluidly between personal and work activities throughout the day [4, 5]. Mobile communication technologies blur the boundaries between work and personal time enabling us to quickly switch between work and personal tasks at will. While employers and employees agree MCTs offer productivity benefits [5-7], the impact of this transformation on employee personal lives remains under considerable study.

We are still in the early throes of this transformation and there is little consensus on how these technologies impact employee work life balance. Further, the current generation is growing up in a world where universal accessibility and constant availability is assumed. College students in particular are often juggling school, work, and personal life commitments with 70-80% working at least part-time while enrolled in classes [8]. Various studies have identified the benefits of MCTs including increased flexibility, increased control of where and when work is performed, and increased productivity [1, 5-7, 9]. However, these and other studies also find increasing concerns over conflicts between an individual's work and personal commitments [1, 4, 10], increased expectations of availability and time greediness by employers [9, 11], and employees working during vacations and personal time off [1, 12, 13]. But what is the impact of this new reality on the personal lives of workers and their families? Does this rapid movement between personal and work activities increase or inhibit our ability to meet work and personal commitments? Many find it difficult to shut down these technologies after work and several studies have found workers consider personal time more malleable than work time further increasing pressure on personal and family commitments [1, 12-14].

II. PROBLEM STATEMENT

The effects of the proliferation of MCTs on work-life balance and personal stress are still being studied. It could be expected that the impacts are not uniform and that individuals balancing multiple major life events may be more impacted than those balancing simply their work and individual life. This study focuses on college students who have full or part-time jobs and may have family commitments as well. The constant multi-tasking required to balance these competing demands may lead to increased stress or difficulty achieving work-life balance.

III. SIGNIFICANCE

The importance of understanding the impact of MCTs on work-life balance cannot be overstated. In the U.S. while over 88% of adults have cell phones, only 46% currently have smartphones [15] which enable much closer ties to work activities. The iPad brought the tablet PC into the mainstream with 15 million sold since 2010 [16] and tablet ownership overall nearly doubled between mid-December 2011 and early January 2012 [17]. This device makes it even easier to perform personal and work activities anytime, anywhere. The impact of MCTs on society and individual work-life balance is just beginning. Employers need to understand the impacts so they can develop policies and work-life initiatives that benefit both employers and employees [9, 18]. Employees need to understand the impacts to develop strategies for managing the increased accessibility of MCTs while still enjoying the flexibility over working arrangements they provide [4, 9, 14]. Educators also need to understand the impacts as the number of traditional-age undergraduates working full and part-time jobs continues to increase [19]. Families must understand the pressures MCTs bring to students and impacts on the family. One study has found MCT users feel their families understand their need to work on holidays, weekends, and work nights [1] but a study among family members wasn't performed.

IV. LITERATURE REVIEW

The following literature review is divided into four sections beginning with the scholarly literature on MCT usage and how the concept of the work place and work time is changing. The next section reviews studies examining work-life balance, role conflicts, and boundaries between work and personal commitments. The third section examines studies that evaluate the relationship between MCTs and their impact on work-life balance and stress. The summary highlights areas where the literature is incomplete and additional research is needed.

A. Mobile Communication Technology Usage Patterns

Many companies now have extended work hours to support production goals and increased customer services into the evenings to serve customers. As a result company work hours are extended and MCTs enable employees to stay connected at any time and any place. Roberts [20] observed that once it is possible for an employee to be reached for work during weekends and time off, it can easily become an expectation and other studies have found that some employers now have that expectation [1, 5, 11]. MCTs make it easy for the work environment to spill over into the personal lives of workers, a phenomenon the literature refers to as the "blurring of

boundaries" [1, 5, 21, 22]. Working from home has been experimented with and MCTs seem an ideal tool to facilitate that work arrangement. However, a recent study found that workers fail in their attempts to separate their work and home life. 100% of respondents stayed connected during breaks, 92% remained contactable during the evening, and 76% were connected all weekend [22].

Other studies have found that MCTs have an undeniable impact on employee concept of working hours. Smartphones in particular are used to fill small gaps of time on the bus or waiting in line further blurring the lines between work and personal time [23]. Karlson et al., [13] found respondents checking email as the first thing they did upon waking up and made work email a higher priority than personal email. Other workers report that if they wake up in the middle of the night, they check email and respond to some items immediately [13]. Middleton & Cukier [24], found similar behaviors of checking email before going to bed as well as doing email while driving, attending meetings, on the golf-course, and while on vacation. The respondents frequently rationalized their behavior and were strongly committed to their pattern of use which Middleton & Cukier [24] felt showed evidence of compulsion.

B. Work-life Balance and Personal Stress

Work-life balance can be defined as having a healthy balance between work and home with a minimum of role conflict [6]. Role conflict occurs when simultaneous pressures from one role make it difficult or impossible to fulfill the demands of another role [4]. The literature contains a number of studies where workers enacted various strategies in an attempt to maintain a satisfactory work-life balance [1, 4, 6, 9, 14, 22] and those employees with role overload report higher work stress [25-27]. One study found the problem so severe that it described mobile email usage patterns as dangerous and anti-social while also infringing on work-life boundaries [24]. However, other studies suggest the problem is overstated and report workers show little interest in making a distinction between work and their personal life and add there is no uncontested evidence of increased work hours [28]. Other researchers agreed and argue that the feeling of being pressed for time is caused by "work intensification" or "time compression" rather than the number of work hours [3, 20]. This intensification could be a side effect of modern technology's ability to complete tasks more quickly which rather than increasing free time has instead lead to an increase in the number of tasks that must be completed [1]. However, Wajcman [3] feels MCTs may be the solution rather the source of time pressures and concludes that the separation between work and home is under reformulation and harnessing the possibilities of MCTs may aid our efforts to manage our time.

C. The Impact of MCT Usage on Work-life Balance and Personal Stress

A 2001 national work-life balance survey in Canada found over 25% of respondents believed technology had increased their ability to balance their work-life with about the same percentage reporting it decreased their work-life balance [5, 27]. The study concluded that MCTs can support or hinder work-life balance depending on the user. Towers, et al. [1], had similar results from a survey of Canadian Federal

Government employees where BlackBerrys were used by 89% of the sample. Among these users 46% said BlackBerrys increased their ability to manage their work-life balance while 38% said it decreased that ability [1]. A 2007 national survey in Australia was conducted to understand the social impact of the mobile phone on work-life balance. This survey found 51% of respondents believed mobile communications devices helped them balance their work and family lives while only 4% reported a negative impact [29]. They concluded that fears of work intruding into home life are exaggerated even though there was evidence of work intensification among men [30].

Concerning the impact of MCTs on personal stress, the Canadian national survey found 50% of respondents felt technology had increased their stress levels [5]. A separate study that analyzed the same data found that 25% felt work interfered with their ability to meet their responsibilities at home and 33% reported high levels of job stress [25]. In contrast, the Towers, et al [1] survey found 66% of respondents indicated no impact on their stress levels due to MCT and about the same number reported increased stress as those reporting decreased stress. The Australian survey also found that mobile phones did not dramatically increase stress levels. They found 61% believed their mobile phone did not affect their level of stress and 75% of those that reported an impact said it reduced their stress level [29]. A separate study of the same data concluded that the strategies mobile phone users establish to control when and how to interact with mobile messages is the key to reducing stress levels [31].

D. Summary

While these studies have begun to evaluate the impact of MCTs, it is clear there is much left to explore. There are few quantitative studies evaluating the relationship between MCTs and work-life balance and stress. The data that has been gathered are from surveys performed between 2001 and 2007 when smartphones were still novelties and tablet PCs were virtually non-existent. The literature suggests the impacts are changing over time and additional research to evaluate those changes is necessary. Finally, none of these studies were conducted among college students whose usage may represent how the next generation will integrate MCTs into their lives.

V. PURPOSE STATEMENT

The purpose of this quantitative survey study is to examine the relationship between the use of mobile communication technologies for job-related work activities and the individual's perception of their ability to maintain healthy work-life balance and stress levels.

VI. METHODOLOGY

This research used an on-line instrument to survey undergraduate and graduate students at the Purdue School of Engineering & Technology at IUPUI in Indianapolis with the primary focus on students that also have jobs.

A. Survey Design

The survey instrument utilized in this research was a modified version of a survey developed by Towers, et al., [1] and permission was obtained from Dr. Linda Duxbury to use the survey tool for this research. One question was added with

permission from Professor Judy Wajcman from a survey conducted in 2008 [29] which asked users how much they would miss their MCT device if it was taken away.

B. Survey Population

The survey was sent to 2,426 undergraduate and graduate students at the Purdue School of Engineering & Technology during the spring semester 2012. This population was chosen since a high percentage of college students are users of mobile technologies, reaching 100% in one study [32].

C. Survey Variables

The focus of this study was on the relationship between time spent using MCTs and the impact on stress and work-life balance. Table I details the variables and associated research questions used to gather this information.

TABLE I. SURVEY QUESTIONS RELATED TO THE INDEPENDENT AND DEPENDENT VARIABLES

| Variable Name | Research Question |
|---|---|
| Independent Variable 1: Time spent using a MCT device on work days. | On a typical WORKDAY, how many hours do you spend on your laptop computer (cell phone/smartphone/tablet PC) for job-related email and other applications? |
| Independent Variable 2: Time spent using a MCT device on non-work days. | On a typical NON-WORKDAY, how many hours do you spend on your laptop computer (cell phone/smartphone/tablet PC) for job-related email and other applications? |
| Dependent Variable 1: Stress | What impact has the use of your laptop computer (cell phone/smartphone/tablet PC) had on your stress level? |
| Dependent Variable 2: Work-Life Balance | What impact has the use of your laptop computer (cell phone/smartphone/tablet PC) had on your ability to balance your work and home life? |

VII. RESULTS

A. Demographic Summary

There were 468 completed surveys representing a 19.3% response rate. There were 325 responses from students who held jobs and used MCTs, representing 69.4% of all completed surveys. The age groups of the respondents were similar to the Engineering & Technology student population in 2011 [33]. However, working females comprised 24% of the sample as compared to only 10% of the overall population and graduate respondents were 19% as compared to 10% of the population. Laptops were used by 60% of employed students, while 68% used smartphones, 29% used cell phones and 18% owned tablet PCs. Only 2% of employed students did not use any MCTs.

B. Chi-Square Analysis Results Summary

A Chi-Square Test of Independence was calculated for each of the independent and dependent variables listed in Table I. Responses were grouped to ensure that no group had expected frequencies less than 5 as required for a valid analysis [34]. There were insufficient responses from users of cell phones and tablet PCs to achieve the minimum expected counts required for the Chi-square test, so they could not be conducted.

1) Laptop computer results summary

A chi-square test of independence was calculated comparing the work day and non-work day hours using a

laptop computer for work activities and the perceived impact on student stress and their ability to maintain work-life balance. No significant interaction was found between Laptop workday usage and stress ($\chi^2(2) = 1.396$, $p < .05$), laptop non-workday usage and stress ($\chi^2(2) = 2.839$, $p < .05$), or laptop workday usage and work-life balance stress ($\chi^2(2) = 0.033$, $p < .05$). Those relationships appeared to be independent. However, a significant relationship was found between laptop non-workday usage and work-life balance ($\chi^2(2) = 9.186$, $p < .05$). Students that performed work activities on their laptop more than 3 hours per day on non-workdays were more likely to report a decreased ability to balance their work and personal life than students who performed work activities on their laptop less than 3 hours per day. Twenty-nine percent of students in this group reported a decreased ability to balance their work-life as compared to 11% of students with usage less than 3 hours.

2) *Smartphone results summary*

A chi-square test of independence was calculated comparing the work day and non-work day hours using a smartphone for work activities and the perceived impact on student stress. A significant interaction was found between smartphone workday usage and stress ($\chi^2(4) = 42.650$, $p < .05$). Students that used their smartphone on work-days for more than an hour per day were more likely to report a change in stress levels than students who used their smartphone less than an hour per day. Thirty percent of these students reported an increase in stress while 29% reported decreased stress levels. A significant interaction was also found between smartphone usage on non-workday usage and stress ($\chi^2(4) = 46.733$, $p < .05$). Students that used their smartphone for work activities on non-work days were more likely to report a change in stress than students that did not use their smartphone on non-workdays. Twenty-eight percent of students that used their smartphone from 1 to 60 minutes reported increased stress compared to 21% who reported decreased stress. Twenty-four percent of students with usage over 1 hour reported increased stress compared to 27% who reported decreased stress.

Finally, a chi-square test of independence was calculated comparing the work day and non-work day hours using a smartphone for work and the perceived impact on a student's ability to balance their work-life. A significant interaction was found between smartphone workday usage and work-life balance ($\chi^2(4) = 27.419$, $p < .05$). Students that used their smartphone for work activities were more likely to report an increase in their ability to balance their work-life than those that did not use a smartphone for work. Eighty percent who used MCTs less than 1 hour for work and 83% who used MCTs more than 1 hour reported no change or an increase in work-life balance. A significant interaction was also found between smartphone usage on non-workdays for work activities and impact on work-life balance ($\chi^2(4) = 34.179$, $p < .05$). Students that used their smartphone for work on non-workdays were more likely to report an increase in their ability to balance their work-life. In this case, 82% who used MCTs less than 1 hour for work and 75% who used MCTs more than 1 hour reported no change or an increase in work-life balance.

A. *Demographic Observations*

The relatively high percentage of survey responses from female and graduate students compared to the overall student population may influence these results. It may also indicate MCTs are having more impact on these groups generating more responses. Over 98% of students on this campus had a smartphone or cell phone, a result similar to what was found in another college campus study [32]. Over 62% had smartphones as compared to 46% of American adults [15] but 68% of students that work had smartphones as compared to only 48% of unemployed students. Laptop use in this sample was 70% overall but 95% of unemployed students had laptops compared to only 60% of employed students. This may reflect the new trend among college students since 86% of unemployed students in this survey were aged 24 or less.

When working students were asked how much they would miss their MCT device if it "disappeared today", 61% percent of laptop, 63% of smartphone, and 55% of tablet users reported they would miss their device "often" or an "extreme" amount. This demonstrates how integrated these mobile devices are into their work and personal lives. One student commented that "I use my android smartphone and tablet a great deal, to the point that it would be considered an addiction. If I don't have the phone on me, I feel that I'm missing a limb." These extreme feelings closely aligned with the results of a 2007 survey in Australia where over 50% of respondents said their daily lives could not proceed as normal without their mobile phone and the overwhelming majority of this group would miss their mobile either 'often' or 'an extreme amount' [31]. In this study however, working students were much less enamored with their cellphones as 54% said they would only miss it "sometimes" or "not at all". Smartphones obviously provide users greater benefits and are more integrated into the lives of students.

B. *Laptop Computers*

Among engineering and technology students, the laptop computer was viewed as a useful tool that increased flexibility of when and where to perform work. It was mostly viewed as a positive communications and work tool to help balance work and personal life. The number of hours used did not seem to have any significant impact on users stress and only a nominal impact on work-life balance. Only when the laptop was used for work activities more than 3 hours per day on non-work days did users begin to report a significant negative impact on their ability to balance their work and personal life. Even then only 29% of that group reported a negative impact compared 39% who reported the laptop made it easier to balance their work and personal life. One laptop user observed "The technology tools themselves are not necessarily the point of increased stress for home/work; rather my increased stress and productivity challenges stem from expectations and higher demands of immediate communications from others (24/7)." This was consistent with the findings of Wajcman, Bittman, & Brown [31] who found job characteristics and working hours had a greater influence on work stress than mobile communications.

C. Smartphones and Stress

When students used their smartphone for work activities during the workday, they reported significant impacts on their stress levels. While 60% of students that used their smartphone for less than an hour reported no change in their stress, 22% of this group reported increased stress with about the same percent reporting decreased in stress. These results were similar to what Wajcman, Bittman, Johnstone, et al. [29] found in their survey, where 61% responded the mobile phone had no impact on stress. In their study however, only 9% reported increased stress versus 22% in this study. One key difference may be that their study did not distinguish between cell phones and smartphones which were less common when their data was gathered. Remarkably, when students used their smartphone more than 1 hour per day, those reporting increased stress rose from 22% to 30% but about the same percent reported a decrease in stress. When the data was broken down between full-time (>25 hours/week) and part-time workers a shift in responses was seen. The percent of part-time workers who reported increased stress rose from 5% to 28% when usage surpassed an hour, whereas for full-time workers the percentage actually declined from 37% to 30%.

A similar pattern occurred for those that used their smartphone on non-workdays for work activities. Once part-time workers began using their smartphone on non-workdays for more than an hour the percentage reporting increased stress rose from 6% to 18%, whereas it fell from 42% to 27% among full-time workers. Students that work full-time and used their smartphone infrequently during days off tended to feel increased stress when they utilized their MCT. However, those that worked full-time and used their smartphone frequently (> 1 hour) on days off were less likely to report increased stress and were just as likely to report a decrease in stress. These students tended to view the increased connectivity and capabilities of smartphones and laptop computers as the solution rather than the problem. About 28% of the student comments discussed the productivity benefits of their mobile devices with observations like "...it has allowed me to better manage my time, accomplish tasks at a faster pace and during periods of time that would have normally unusable." It seemed the more they used the device, the more they adapted to its intrusion into their personal life and felt less stress as a result.

D. Smartphones and Work-Life Balance

The impact of smartphones on work-life balance for students was also significant. The more working students used their smartphone on workdays the more likely they were to say it made balancing their work and personal life easier. Thirty-three percent of students that used their smartphone between 1 and 60 minutes during the work day indicated it was easier to achieve work-life balance. For those whose use was more than an hour a day, this percentage increased to 51%. These results were again consistent with the findings of Wajcman, Bittman, & Brown [31] who found that 54% of respondents believed that the mobile phone helped them balance their work-life. Towers et al. [1] also found 46% of Blackberry users felt it increased their ability to achieve increased work-life balance. The responses for working students were similar for non-workdays where 80% of students that used their smartphone for work between 1 and 60 minutes reported no change (42%) or

an increase (40%) in their ability to achieve work-life balance. For those whose usage was over an hour on non-workdays, this percentage declined slightly to 75% and those who reported an increased ability to balance work-life actually rose to 46%. It seems clear that student workers viewed the ability to connect to their personal lives as a significant benefit even when balanced against the possibility of work activities intruding into their personal life. Further, the more they used their smartphone for work activities, the more likely they were to view them as a positive influence in balancing their work-life.

IX. CONCLUSION

While the increased accessibility provided by MCTs have the potential to increase stress and negatively impact work-life balance that is clearly not always the case. Most students in this survey embraced the connectivity of MCTs and felt they increased their ability to balance their work and personal life. While some smartphone users felt increased stress as usage increased, similar percentages felt smartphones provided reduced stress. These results have a number of implications.

A. Implications for Employers

Employers should recognize that MCTs are now integrated into the lives of their workforce and can be a tremendous productivity tool. Over 30% of the comments student workers made in this survey discussed the productivity benefits of MCTs. Some studies found workers prefer the peace of mind this connectivity provides which enables them to perform work activities during times that would normally be "unusable" [13]. Employers should make these devices readily available to employees as work tools and encourage employees to utilize them to balance both work and personal commitments.

B. Implications for Educators

Educators should recognize that students carry these devices 24x7 and consider ways to enhance the educational experience through them. Web pages, systems, and class resources should be formatted to support access via smartphones and tablets. The tablet will quickly become the tool of choice for the majority of students who will desire books, class materials, and on-line collaboration projects to be accessible on their tablet. Users can become frustrated with systems that do not support transitions across devices [23]. Investments in on-line capabilities and state-of-the-art access may be the best way to attract the top students of the future.

C. Implications for Families

Families of student workers should recognize the demands placed on students attending classes while working. Some students felt increased levels of stress, in particular those that used smartphones related to their work activities. Stress is most often driven by personal life issues rather than work issues according to some studies [18, 35] but they also have an impact on work which is why many companies are providing work-life support resources [10, 26]. Families should take advantage of those resources to mitigate the potential impacts.

D. Implications for Students

Students embrace MCTs as a way to balance their busy lives and are early adopters of new technologies. As one student commented "Life is better and easier with a smart

phone!" However, there is some cause for concern when 30% of those using smartphones more than an hour during a typical workday reported increased stress. Currently, the benefits seem to outweigh the risks in the minds of students since 44% of smartphone users responded they would miss their phone "an extreme amount". However, students need to develop strategies to manage MCT use. While studies have started to explore some potential strategies [6, 14] more are needed to identify solutions to this likely problem.

Using eReaders and Tablets in the Engineering Classroom

Ladimer S. Nagurney
Department of Electrical and Computer Engineering
University of Hartford
West Hartford, Ct 06117, USA
nagurney@hartford.edu

Abstract—The use of eReaders, and Tablets is increasing dramatically by engineering students. As engineering and science textbooks become more available for these devices at costs significantly below the costs of traditional printed textbooks, even more students will use these devices. In addition to the text, students often use a professor's slides, handouts, assignments, laboratory exercises, and supplemental material as part of their studies. While some is prepared by the publisher, the material is more often locally prepared by the professor. Having this material available on the students' eReader or Tablet would significantly enhance the students' use of their device. During the past academic year, we have begun to develop supplementary materials for several courses for use with a Kindle or Tablet. In this paper, we will describe the techniques needed, beginning from the straightforward transfer of purely textual materials, to developing materials with highly mathematical and graphical content for display on the devices. In addition, we will describe how these techniques can be used to produce material for these multiple uses without placing a significant additional burden on the faculty member. The paper will report the results of a pilot project where students in several Fall 2011 and Spring 2012 Electrical and Biomedical Engineering courses were loaned Kindles and all material beyond the texts for the courses was produced for the devices. The results of the students' surveys on their use of the material and the eReaders will be presented and discussed.

Keywords—eReader, handouts, Kindle, Nook, preparing course content, tablet

I. INTRODUCTION

College students are beginning to use eReaders and small tablet computers in increasing numbers. Surveys show that roughly 1/3 of college students currently own a Kindle, Nook, or other eReader. The surveys also report that as soon as books for their courses become available in eReader format at a reasonable cost, students will immediately purchase an eReader. Additionally, the studies [1], [2], [3] have estimated the growth of eReader use to be almost exponential.

In addition to the course text, engineering (and science) students often receive handouts of lecture slides, supplemental materials, and problems sets (and associated solutions) and laboratory handouts as part of their courses. Laboratory assignments often require data sheets and instrumentation operating instructions and software requires manuals and possible sample programs. While much of this material is still handed out in printed form, it has become almost universal that such material be converted to pdf or another appropriate format and posted on the web or made available on the

institution's course management software such as Blackboard. The challenge then for the faculty is to make their material available to students while not dramatically increasing their lecture preparation time.

While it is straightforward to convert purely textual content to a form that it can be viewed on a eReader, most engineering (and science) content is both highly mathematical and contains substantial amounts of graphics. This poses challenges to a faculty member attempting to produce content for the eReaders. To complicate the situation, due to quirks in individual eReaders, content that looks totally acceptable on one eReader at times looks like gibberish on another eReader.

Finally, whatever method is used to create content, the lecture material must be available for projection in the classroom, and use on larger tablets (such as an iPad), on a PC, and be able to be printed by printing by normal methods. The challenges in creating content then include adding equations and mathematical symbols, graphics, taking into consideration the different aspect ratios of the tablets, dealing with the nuances for the various pdf rendering methods.

Since content needs to be transferred to the eReader in a seamless fashion, it would be useful if the eReader could directly connect with the institution's course management software like books are currently downloaded. Barring that, it should be straightforward to move the material to the students' eReaders.

In subsequent sections of this paper, there will be a brief overview of the characteristics of the eReaders, how to create purely textual material for an eReader, creating content using OpenOffice sWriter, and LaTeX, Creating Slides using Impress and Beamer, transferring material to the eReader and linking with course managements software. This work will conclude with the results of pilot trials of eReaders during 3 courses during the Fall 2011 semester.

II. CHARACTERISTICS OF EREADERS

While there are a plethora of eReader type devices available on the market, the devices used in this work are confined to three devices that could be purchased in June 2011, two eReaders, Amazon's Kindle, Barnes and Noble's Nook and a similarly sized Android tablet, the Dell Streak 7. By the time this work was written the two eReaders have been replaced with updated models. However the techniques used to generated content and the students' opinions are not likely to

change much by the technology evolution. Each of the devices are book sized devices that have a display with diagonal dimension of between 6 and 7 inches. The overall dimensions of the devices are about 5" x 8" and between 1/4" and 3/8" thick. They range in weight from 10 to 12 ounces. Thus, they are smaller and lighter than an iPad, a traditional tablet computer, or a laptop.

All of the devices come with USB ports that can be used for file transfer and charging. All have internal WiFi that can be used to connect to a majority of WiFi networks. The Kindle has a 3G version which automatically connects to 3G Wireless Networks without any additional costs or data plan. This allows data transfer without connection a WiFi connection. Most Android tablets, like the Dell Streak 7 have enhanced versions that connect to a data network. These are normally sold through a wireless provider and require an additional data plan.

Most eBooks are distributed in the mobi format. Most eReaders dynamically reformat the page based upon the font size chosen by the user. This allows the easy display of textual material, although it sometimes results in the page numbers on the eReader being different from those in the printed work.

In addition, all of the devices used have the ability of view a wide variety of other file types, including the .doc and .docx for word processed documents, .xls for spreadsheets, .ppt for presentations, .txt, and portable document files (.pdf).

In rendering pdf files, the default mode of most eReaders is to shrink the page to the width of the eReader display. Thues, depending on the aspect ration of the original document and the eReader, a single document page might be displayed or spread over multiple pages. By experiment however, it was found that not all pdf pages are rendered according to this algorithm, especially those will graphical content. Graphics are often rendered to exceed the normal width of the display and essentially wrap over to a new page. This was most noted in the display of PowerPoint slides that have been converted to pdf.

Most eReaders rotate the page as the eReader is physically rotated from the portrait to landscape mode. Therefore, it might seem possible just to rotate the eReader and display a slide in the Landscape mode with the eReader rotated. However, this does not always happen because the aspect ration of the eReader screen is likely different from the aspect ration of a typical PowerPoint slide and the scaling of the displayed file does always change as desired when the device is rotated.

In Table I below, the properties of the displays of the Knidle, Nook, Streak 7 are summarized and compared to paper and several types of books.

TABLE I. ASPECT RATIOS

| | Page Width | Page Height | Aspect Ratio |
|---------------|------------|-------------|--------------|
| Kindle | 3.56 | 4.75 | 1.44 |
| Nook | 3.6" | 6.25 | 1.74 |
| Dell Streak 7 | 3.6" | 6" | 1.67 |
| Letter Paper | 8.5" | 11" | 1.29 |

| | Page Width | Page Height | Aspect Ratio |
|---------------------|------------|-------------|--------------|
| Kindle | 3.56 | 4.75 | 1.44 |
| Letter 3/4" margins | 7" | 9" | 1.36 |
| Letter 1" margins | 6.5" | 9" | 1.38 |
| Couch [4] | 5.25" | 6.75" | 1.29 |
| Ingle/Proakis [5] | 5.5" | 6.75" | 1.22 |
| Trade Book [6] | 6" | 9" | 1.5 |

In some eReaders, although the documentation states that the page size is changed as the content is rotated, experimentally we have found that wrap occurs unless the aspect ratio of the eReader is less than the aspect ratio of the page it is trying to render. The pages of material thus are converted to two pages on the display.

III. CREATING CONTENT AND PORTING IT TO EREADERS

A. Converting Files to eReader formats

Purely textual material can be converted to the .mobi or other eReader formats by a program like Calibre. [7] [8]. Indeed it is straightforward enough that there are several how-to-do books on self-publishing one work to an eReader [9], [10], [11], [12]. A major caveat of these methods is that they apparently work well for textual material that can be generated in a pure text (.txt).

On the other hand, the online documentation for Calibre states while conversion of pdf files is possible, it is not recommended because, depending upon the complexity of the graphics and special characters in the pdf file, the ultimate rendering on the eReader is not guaranteed and the quality of the rendering will vary among eReader types. None of the guides mentioned above were particularly helpful in preparing highly mathematical content, content containing images, or powerpoint slides for the eReaders.

Another methodology for authoring is an automatic system as described in [13]. The infrastructure required for that system was beyond what was desired for this work.

B. Creating Engineering Content with Open Office sWriter

To develop textual material with limited graphics and equations a standard word processor such as Microsoft Word or OpenOffice [14] can be used where the document is displayed as is on the computer screen can be used. By proper formatting, the pages can be displayed on the eReader without magnification or wrap around. The goal in formatting is to create a document that, when saved in pdf format and displayed with the eReader its parameters are such that when the eReader is set to scale to page width, the pages will not overlap be cutoff either vertically or horizontally.

The most straightforward way to create a document that is easily viewable on an eReader is to set the word processor page size to the eReader screen size (for the Kindle 3-9/16" by 4-3/4"). The margins are then set to 1/4" on each side and the document is created. The document can then be saved as a pdf

and transferred to the eReader. Pages of the document will be displayed as single pages on the eReader and may be advanced using the Kindle page buttons or swiping on other eReaders.

To choose font sizes it was noted a direct mapping of font sizes was not possible. However, by experimentation, it was found that 12 point is rendered that most people feel is acceptable for reading at a moderate distance. Magnification of page on the eReader can be used if the reader desires a larger typeface. However the magnification would often cause overlapping and was not as convenient as documents saved in an eReader format.

Graphics that were included in the document were constrained to the page width which often resulted in them at times being too small for easy use. While a graphic could be rotated and displayed in a larger format, unless the eReader was configured not to rotate the page when the eReader was rotated, the rotation of the image was not satisfactory.

Content prepared in this form could be printed by insuring the option of "fit to printable area" was chosen. Thus, the handouts could be printed to serve students without an eReader without significant additional effort by the faculty.

C. Creating Content with LaTeX

The Gold Standard mathematical text processing program is LaTeX. LaTeX was developed by Donald Knuth in the late 1970s as a way to computer typeset mathematics and has gained almost universal acceptance [15]. Because Latex use proportional fonts, ligatures, and auto-hyphenation, material prepared in LaTeX looks like a fully typeset document. More importantly for Engineers (and Scientists) is the fact that LaTeX can typeset complex mathematical equations and structures easily. Most current LaTeX distributions output LaTeX documents as pdf files.[16]

There are several default page sizes for LaTeX. If a document is chosen to be set as a letter-sized document, then the scaling of the pdf file by the eReader often leaves the material unreadable.

To better create pdf files for viewing on a Kindle the page size had to be chosen to be the screen size similar to that used in sWriter. Unlike work processors, Latex, does not use absolute margins, rather one sets the upper margin, left hand margin and the text width. While not natural to those of us who regularly use WYSIWYG Word Processors, this choice of parameters is derived from how a classical typesetter sets up a page. With some experimental work with PCTex [16], it was found that the following parameters produced an appropriate looking page. When viewed by students, most agreed that the quality was acceptable.

TABLE II. LATEX PARAMETERS

| |
|--|
| <pre> \setlength{\paperwidth}{3.5in} \setlength{\paperheight}{4.75in} \setlength{\hoffset}{-.9in} \setlength{\voffset}{-.9in} \setlength{\textwidth}{3.3in} \setlength{\textheight}{4.in} </pre> |
|--|

IV. CREATING PRESENTATIONS FOR THE EREADER USE

A. Lecture Sildes

Lecture slides and handouts are likely to be the most created content for Engineering (and Science) courses next to problem assignments. The key to adding such content to an eReader is to make it straightforward and simple to create this content in eReader format. In addition, many texts include sample slides as aid to the instructor, often removing the need to scan text images.

B. Creating Content with Open Office Impress

Impress is the Open Office presentation program which is analogous and in most cases functionally equivalent to PowerPoint. In addition to saving to a plethora of file formats, Impress can directly output pdf files.

Since current presentation methodology is to use Landscape Mode, it might appear reasonable to create the presentation, then have the eReader rotate it, then rotate the eReader to view the slides in the landscape mode. However, this does not work for several reasons. The primary one is that most eReaders do not rescale the presentations when the display is rotated. Even if one disables the auto-rotating on the eReader, it still keeps the scaling as too small for ease of viewing. On some, eReaders, the slide is wrapped to 2 pages which makes it very inconvenient to use.

One workaround is to create a presentation using a page size with the same dimensions as the eReader screen, as was done for textual material in Section III but in the Landscape orientation. The presentation may be saved as a pdf file. The pdf file can be then opened in Adobe Acrobat, the pages rotated counterclockwise 90-degrees, and the file re-saved. The resulting file can then be displayed on the eReader and will not overlap pages. However when the eReader is rotated so that the screen is in the Landscape mode, the presentation will also rotate. This can be overcome by disabling the the auto-rotate content on the eReader. The presentation can be viewed on the eReader in the Landscape orientation without any page overlap.

The original un-rotated file can be displayed on a computer using Adobe Reader in the full screen mode and projected. The projected image will appear no different than one that is created at full page size. The original version can also be made available to students who are using laptops or tablet-based computers for their work.

Rendering problems on all eReaders, however do not allow the display of all presentations generated this way. It was found that use of certain color combinations, although displayed perfectly clearly on a PC or MAC, would not display properly on all eReaders. This was particularly frustrating, since files that are displayed correctly on a Kindle might not be displayed properly on a Nook and vice-verso. What was found after preparing several courses was that it was important to keep the color style as simple as possible. Choice of background colors was important, since for unexplained reasons, on some eReaders and for some background colors, the background color choice covered up the text and graphics. None-the-less, edited slides produced from sample powerpoint presentations

prepared by textbook, software, and hardware manufacturers were used with minimal problems.

C. Creating Content with Beamer

The Beamer style of LaTeX is the Gold Standard for creating presentations with significant mathematical content [17]. While not as flexible in adding graphics to a What-You-See-Is-What-You-Get presentation such as ImPress, LaTeX's ability to create slides with complex mathematical formulae, makes is a choice for many applications. Like ImPress, Beamer creates pdf files.

Beamer slides can be created with a variety of presentation backgrounds. In general, it was found that for unexplained reasons, the eReaders were much less sensitive to background color schemes for presentations created using Beamer than for presentations created using ImPress.

It was found, however, that because of the default font choices made by Beamer, if one takes the Beamer created pdf file of the full sized slides, rotated all pages by 90-degrees counterclockwise, and re-saved them, the resulting file could be displayed on all the eReaders without overlapping or page-wrapping. This meant that slides created for projection in class could be converted to the eReader format in a very short time, conserving valuable faculty time. Similar to ImPress, the original pdf file could be projected in class, viewed on a PC, or printed as hardcopy handouts.

V. TRANSFERRING MATERIAL TO THE EREADER

To successfully integrate the use of eReaders in the classroom, there should be an integrated method of transferring material to the eReader, just like books are transferred to the eReader. The University of Hartford currently uses the Blackboard platform for course management. When this work was initialed, no mobile apps for Blackboard were installed. Therefore, the students had to log into Blackboard, download the files to a local computer, and then transfer the downloaded files to their eReaders using a USB cable..

While each of the eReaders has some form or Web Browser implemented, primarily for logging onto the seller's site to purchase content, the browsers are by no means a full implementation of browsers that are expected Because Blackboard uses a significant number of popup windows, if the browser implementation does not full implement these, it will be difficult or nearly impossible to connect. The Kindle had the most difficult time with Blackboard and eventually most Kindle users decided to download the files to a PC and then connect the Kindle to the PC via the USB port to load files.

Another issue arose with the connection of the eReader to the University of Hartford wireless network. The failure to connect was identified as a multi-stage problem. The first dealt with the choices that were made by the eReader designer on what parts of wireless security to actually implement. The second was the Browser implementation and how it responded to the request for authentication by the University network. The final problem dealt with a conflict between the security certificate choices made by the University of Hartford network administrators and the security certificates implemented on the

eReader. Even with assistance from Computer Services, it was not possible to connect the Kindle to the campus WiFi network, although the Kindle connected seamlessly with networks in many other locations.

VI. USE IN COURSES

During the Fall 2011 Semester, materials for courses Bio-instrumentation, BE 401, Digital Signal Processing, ECE 440, and Communications Engineering, ECE 423 were prepared for use on the eReaders. Students who did not own personal eReaders were loaned Kindles. Each of the students was requested to fill out evaluation forms for each item used. No all studnets in the courses had access to or used eReaders.

The results of the survey administrated are summarized in the Table III below. Responses were collected in a 5 point Likart Scale, from Strongly Disagree, 1, to Strongly Agree, 5. 16 students participated in one (or in several courses two or more) courses. Because of the relatively small number of students and the desire of the Institutional Review Board to keep the survey anonymous, the data could not be broken out by gender or year.

TABLE III. STUDENT SURVEY

| Question | Weighted Response |
|--|-------------------|
| The textual material (as opposed to charts and graphs, etc) was clear and readable | 4.31 |
| The figures displayed were clear and readable. | 4.56 |
| Use of eReader helped me understand my Class Notes. | 4.38 |
| The material on the eReader helped me to better understand the key concepts. | 4.25 |
| Using the eReader enhanced my classroom experience. | 4.63 |
| Using the material on the eReader helped me complete an assignment. | 4.18 |

From these results, it was clear that a majority of the students who used eReaders concluded that having the course material on the eReaders enhanced their classroom experience. For one of the courses, Bio-instrumentation, the publisher loaned us copies of the text in pdf format which the students also loaded to their eReaders. In their reviews, the students were very satisfied that they could have all the course materials available on their eReader.

When asked what additional material the students would like on their eReaders, most students indicated that they added manuals or guides to the course software packages (MATLAB or LABVIEW). Several replied that having the software manual or guide on their eReader helped them even when they used the package on their laptops, since most of the time they carried both their eReaders and laptops with them

The main negative comments from the students dealt with the difficulty of transferring material to their eReaders and the occasional glitches in rendering pdf files, especially slides made with Open Office with colored backgrounds.

VII. SUMMARY AND FUTURE WORK

In this work I have outline the methods to produce engineering content in a form that can be displayed on various eReaders and Tablets in addition to Laptops, PCs and iPads. I have also investigated the integration of these devices with our Course Management Software. The work has shown that using readily available software, it is possible to format lecture handouts and slides in a format that can be displayed on the eReader without adding a significant burden on the faculty member. It was also shown that the students enjoy having the material available on the eReaders.

Future work will include evaluating updated eReaders as they become available and working to provide more seamless integration of the eReaders with the course management software to simplify the student's ability to receive the material.

ACKNOWLEDGMENTS

Purchase of the Kindles, Nook and Dell Streak7 used by students for this work was supported by an Educational Technology Grant from the Office of the Provost, University of Hartford. I would like to thank Professor Fred Sweitzer, Associate Provost and Dean of Faculty Development for his assistance in developing the Evaluation Instrument. I would like to thank the anonymous reviewers who assisted me in improving the presentation of this work. Lastly, I would like to thank Professor Patrick Qiang of Penn State for the initial gift of a Kindle which instigated this work.

Undergraduate Hands-on Senior Capstone Project Experience on Emerging Mobile IPv6 Technology

Nana Darko and Emil H Salib

James Madison University, Integrated Science and Technology Department

Harrisonburg, VA 22807

darkosny@dukes.jmu.edu and salibeh@jmu.edu

Abstract – In this paper, we detail how a senior student's desire to pursue a challenging Senior Capstone project in networking and mobility paved the way to the development of a networking environment where hands-on research at the undergraduate level on topics, such as, Mobile Internet Protocol version 6 (MIPv6) is readily feasible. Undergraduate students face many obstacles when pursuing hands-on projects requiring laboratory equipment not readily available in undergraduate laboratories. We describe how Open Source Software and Virtualization platforms were configured and deployed by a student and his advisor to successfully complete a MIPv6 hands-on project. The environment was developed using Linux, VMware, and GNS3. In addition to the technical aspects of this project a second unintended, but important, outcome is described. At the onset, the student and his advisor assumed that the student had the prerequisite Linux knowledge and skills necessary to create the technical environment required to complete this project. When it became clear, despite the student's best efforts, that his Linux knowledge and skills were insufficient to complete the project, the advisor, with no prior Linux Kernel related experience, had to learn it and provide guidance to the student. The student saw firsthand how his advisor, an experienced researcher, had to overcome a problem in a domain outside his core expertise as a normal part of the research process.

Index Terms – Hands-on, Undergraduate Research Experience, IPv6, Mobile IPv6, Open Source, Virtualization.

INTRODUCTION

A key goal of the Integrated Science and Technology (ISAT) program at James Madison University [1] is to prepare students to be professionally well equipped when entering the workplace or enroll in graduate programs. This is accomplished by developing students' ability to be problem solvers who are able to investigate local, national, and global issues not only from a science perspective but also from a technology and social context perspectives. The program provides students with a unique hands-on research experience through its Senior Capstone Project by requiring each student to partner with ISAT faculty to pursue a challenging undergraduate level project. The ISAT Senior Capstone project normally spans three semesters. The Senior Capstone program begins the 2nd semester of junior year for ISAT

majors' junior year; by then students have had the opportunity to declare a specific concentration among their top three sectors of study.

The major objective of the ISAT Senior Capstone project is to provide a constructive research and hands-on experience for students at the undergraduate level. Once a student has identified a number of potential projects that interest him/her, the next step is to seek out one or more ISAT faculty members who would be willing to become the student(s) advisor(s). The project requires at least one faculty member but can often include multiple ISAT faculty members if it is cross-area based project. Once a project team has been formed, a Memorandum of Understanding (MoU) is drawn and signed by all parties including the advisor(s).

The literature on capstone project experiences is fairly robust particularly in terms of the diversity of the approaches explored. Recently, at Miami University, a capstone project [2] engaged an alumnus as a co-advisor and a fund raiser. A team at Ohio Northern University (ONU) asserted in [3] that students who get involved in extracurricular design activities instead of the mandatory senior Capstone Projects tend to be highly motivated, gain the Engineering and Technology experience they need but at an earlier stage in their college careers and have better chances in finding jobs upon graduation. This paper focuses on the approach that an undergraduate student and his advisor adopted in the face of working on a high risk project, Mobile Internet Protocol version 6 (MIPv6) [4], where both the student and the advisor had limited familiarity. Consequently, it demanded an innovative approach in implementing a network test environment. It highlights how high motivation, reliability, and commitment of the student to take his networking skills to the next level compelled the advisor to accept the challenge and take on the project as a new experiment in Problem-Based Learning (PBL) [5] and research at the undergraduate level.

This paper documents our experience and approach creating a complete Mobile IPv6 test environment prototype with intensive use of network virtualization tools. The prototype constructed is easily portable, as the MIPv6 network test environment is fully virtualized. We share the details of how a collaborative and trusting relationship between a student and his advisor played a crucial role in the successful completion of this project. Finally, we cover major highlight and key learning by both the student and the advisor whose role started as a coach and transformed as a co-researcher.

This paper is organized as follows. The mobile environment and mobile IPv6 section provides a brief

background on IP Mobility with emphasis on current deployment and both commercially available and open source MIPv6 tools. In the next section, the objectives, the proposed mobile IPv6 environment solution and the methodology of the senior capstone project are described in details. The technical results section presents the Mobile IPv6 virtual test environment that was developed. The final two sections summarize our experience and propose future work.

MOBILE ENVIRONMENT AND MOBILE IPV6

Unlike 3G, which is based on two parallel infrastructures consisting of circuit switched and packet switched network nodes, respectively, 4G is based on packet switching only. Verizon Wireless claims that *"The performance and capabilities of 4G LTE will be unmatched in the marketplace; allowing customers to do things never before possible in a wireless environment"* [6]. Long Term Evolution (LTE) [7] is a 4G mobile specification for multimedia application designed to provide multi-megabit bandwidth, more efficient use of the radio networks, latency reduction and improved mobility. One of the advantages of 4G is the LTE's inherent support for Internet Protocol version 6 (IPv6) addressing.

IPv6 became a reality at the end of the 90s [8, 9]. Mobility support for IPv6, known as, Mobile IPv6 (MIPv6) [10] is an IETF RFC standard that has added the roaming capabilities of mobile nodes in IPv6 networks and thus permits an IPv6 node to roam across any IPv6 network without changing its address. In other words, the mobile node always appears to be connected to its home link even though the user is actually visiting many networks. In the heart of LTE is mobile support for IPv6 and more precisely Proxy Mobile IPv6 (PMIPv6) [11]. Mobile IPv6, along with fast-handoffs and context transfer mechanisms will be essential for the large scale deployment of real-time services, such as, Voice over IP (VoIP) and IP multicast services, such as, IP Television (IPTV). With more and more connected people, smart-phones, improved support of mobility and more, IPv6 has become the key for the next generation of mobile networks. 4G and LTE rely on IPv6 to provide enough addresses, and to support mobility.

A number of projects such as, KAME [12] and USAGI [13] were launched in the late 90s and early 2000s to make Mobile IPv6 accessible and improve its stack's quality and security on Linux Platforms. One specific implementation of Mobile IPv6 for Linux that was adopted for the project described in this paper is UMIP [14]. Together, these efforts led to the availability of Mobile IPv6 functionality as part of recent Linux Kernels. In addition to the introduction of Mobile IPv6 on Open Source Platform, commercial products such as Microsoft Windows Server 2003 [15] included Mobile IPv6 in 2004 and IPv6 Mobility has been supported on Cisco routers since IOS 12.3(14)T [16].

SENIOR CAPSTONE PROJECT

Objectives

The primary goal of the Senior Capstone project described in this paper was to demonstrate MIPv6's

capabilities in providing a mobile host with seamless transition as it migrated amongst different networks. To accomplish this goal, we had to first delve into the specifics of IPv6 [4], a topic not typically covered in depth at the undergraduate level. Second, we had to design and construct a MIPv6 network environment prototype in support of demonstrating how customers with IPv6 enabled devices can hold seamless Voice over IP (VoIP) conversations or data exchanges while roaming from their home network to other networks.

Proposed Mobile IPv6 Network Environment Solution

In light of resource limitations, the prototype was architecturally designed and constructed using Open Source platforms, such as Linux (Desktop and Servers) and Graphical Network Simulator Dynamips/(GNS3) [17] that allows simulation of complex network elements including Cisco routers. In addition, we used virtual network tools such as VMware Workstation [18] and/or Oracle VirtualBox [19] to facilitate the creation and management of virtual machines targeted at server, desktop, and embedded systems. This prototype has enabled us to demonstrate a number of other IPv6 features such as neighbor discovery, address auto-configurations in addition to advanced MIPv6 capabilities, such as, route optimization [4].

We selected Ubuntu [20] which is a computer operating system based on the Debian Linux distribution and distributed as free and open source software, for this project due to the ease of implementing the other required software tools in a Linux environment. Virtual Machines (VMs) [18, 19] were created from Ubuntu desktop 10.04 and 11.04 International Organization for Standardization (ISO) release images and were run primarily on VMware Workstation. Some of the Linux based VMs were configured as Mobile Nodes and others as Linux based Routers. VMware Workstation is a virtual machine (VM) software suite/environment that allows users to run multiple VMs simultaneously on top of a host Operating System (OS) such as Windows or Linux. Equally important, VMware allows these VMs to be interconnected in a variety of different complex network configurations.

In addition to the use of Linux based VMs to emulate MIPv6 Routers, we experimented with Cisco's emulated Internetwork Operating System (IOS) images. Dynamips/GNS3 was used to emulate Cisco Routers IOSs (these were provided by Cisco). We were also successful in integrating Mobile Node (Linux based VMs) with the emulated Cisco Router on GNS3. By adopting virtualization through Dynamips/GNS3, VMware, and Open Source OSs such as Linux, the project which would have required 5 to 6 network hardware nodes was successfully implemented using a single laptop or desktop. With this highly portable architectural approach, students in educational institutions that have limited access to real Cisco routers and desktop hardware can still perform high quality projects with minimum financial requirement.

Key features of the virtualization environment worth highlighting are "suspend/resume", "snapshots" and "network

team". The suspend and resume feature is useful to save the current state of a virtual machine and continue work later from the same state, even if you quit VMware Workstation in the interim. The "suspend" and "resume" feature provides the ability to conduct research virtually anywhere; all that is required is a laptop and an external USB drive. Multiple successive snapshots [21] of an operating system running under VMware Workstation can be taken and the virtual machine can be restarted in the state it was in when any snapshot was saved. Furthermore, VMware Workstation includes the ability to designate multiple virtual machines as a team. Through the team feature, users can configure an entire virtual network with multiple VMs grouped together in one single team, saving valuable time.

Overall, the virtual environment we constructed has been extremely effective and practical in allowing us to achieve and accomplish our ambitious objectives. It also allowed us to test mobility scenarios over a number of different network configurations all inside and on one *single* Linux or Windows machine, avoiding the investment and management complexity needed to create them using real hardware. It is worth noting that few weeks prior to our project's completion we identified another research group that had built a similar platform known as Virtual Network User Mode Linux (VNUML) [22]. Unfortunately, the VNUML project development and maintenance effort had been abandoned in favor of a new version of the tool Virtual Networks over Linux (VNX) [23]. The main reason stated for the migration was to overcome the following limitations of the VNUML tool identified by the VNUML team as its inability (1) to interact with the virtualization capabilities of the host (that is, the machine hosting the VMs) and (2) to integrate with Dynamips/GNS3 router virtualization platforms. This statement confirmed that our approach in building a virtual environment using Open Source VMs, VMware and GNS3 described above has been architecturally sound and viable for multiple purposes including teaching and research.

Methodology

To ensure that the project remained on course, the major milestones of the project were identified for the fall and spring semesters. At the beginning of each semester, the primary milestones and their associated tasks were revisited and reprioritized through the use of a running action items register. The student and his advisor met on a weekly basis. A weekly status report prepared by the student included a description of what he had accomplished during the week and provided a proposed activity plan for the following week. Each status report and the specific milestones that were completed were reviewed by the advisor. Tasks that were incomplete were reevaluated and reprioritized for the following week along with other newly assigned tasks. One of the major highlights of the weekly meetings was the push for "Demos", demonstrations of hands-on incremental building blocks that taken together comprised a final polished demonstration of the entire project.

In the early stages of the project the weekly status report methodology helped ensure the identification of issues where the student and the advisor had difficulties, particularly in areas where they had limited expertise, such as, IPv6 and expertise in recompiling a Linux Kernel from scratch. Some of these difficulties were mitigated when the advisor recommended the student to try certain networking arrangements using a more familiar IP addressing scheme, that is, IPv4. This traditional approach guaranteed that completed tasks were thoroughly documented and tracked as the weekly status report updates were uploaded onto the online Blackboard (BB) course tracking system. On a weekly basis, the advisor posted a grade on BB to ensure that the student received clear feedback on his progress.

At the end of the first month of the final semester (spring 2012), it became clear from the list of tasks remained unaccomplished for longer than 3 weeks that the student was facing issues beyond his current skill levels. In light of these challenges, it was necessary to decide on a new path forward. The student and advisor agreed to put aside the status report/action item register approach and focus instead on resolving the major issues stymieing progress. There were two major issues: (1) patching and re-compiling specific Linux Kernel releases with the Mobile IPv6 features and (2) figuring out how to accomplish the mobility functionality excluding the security measure that was tightly coupled in most recent implementations. Since neither the student nor the advisor had experience patching and re-compiling the Linux Kernel with the Mobile IPv6 features, the advisor took on the challenge of learning how to do so [24]. Once the advisor was successful accomplishing this task, he provided guidance to the student to do the same. Then it was a matter of searching for clearly documented scenarios of MIPv6 implementation without security. Within a week the student and his advisor were able to identify a number of scenarios, but ironically the scenarios [25, 26] were written in Spanish; an issue we resolved using Google Translate.

TECHNICAL RESULTS

Before constructing a virtual MIPv6 environment first intensive research on IPv6, IP Mobility and Internet Security (IPSec) was conducted to determine the scope of the project. In contrast to the 32-bit address space provided by IPv4, IPv6 has a 128-bit address space that allows it to support up to 2^{128} new devices requiring access to the Internet. IPv6 also provides auto-configuration which is a mechanism by which a node can be allocated an IPv6 address automatically whenever it attaches itself to a new network [4]. After gaining a solid foundation of IPv6 addressing scheme, the next step was to design the virtual MIPv6 environment which supported the mobile capabilities of IPv6 as shown in Figure 1A.

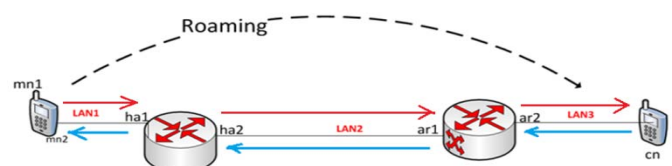

FIGURE 1A
VIRTUAL NETWORK TOPOLOGY

Figure 1A represents the network topology adopted in the implementation of a MIPv6 virtual test environment. Each node is a single Linux Ubuntu OS VM. To ensure all nodes have the same IPv6 and MIPv6 capabilities, a base VM was first created. Next, IPv6 and MIPv6 settings on the Linux Kernel of the base VM were selected (enabled). Following the kernel configuration, it had to be re-compiled [24]. The recompilation task had to be repeated a number of times due to missing dependencies. Once the Linux Kernel recompilation was successfully completed, the Router Advertisement (radvd) [27] and the MIPv6 daemons were installed unto the base VM. Following this preparation, the base VM was cloned through VMware Workstation to create a Mobile Node (MN), Home Agent (HA), Access Router (AR), and the Correspondent Node (CN) VMs. The network interfaces on these VMs were then configured according to Table I [28].

TABLE I
NETWORK INTERFACES

| Interface | Static IPv6 Address |
|-----------|------------------------------|
| mn1 | 2001:1:1:1::fcfd:ff:fe00:101 |
| mn2 | 2001:1:1:3::fcfd:ff:fe00:102 |
| ha1 | 2001:1:1:1::fcfd:ff:fe00:201 |
| ha2 | 2001:1:1:2::fcfd:ff:fe00:202 |

While the Mobile Node (MN) is attached to its home network, a stateless auto-configuration takes place where the Home Agent (HA) sends a Router Advertisement (using radvd

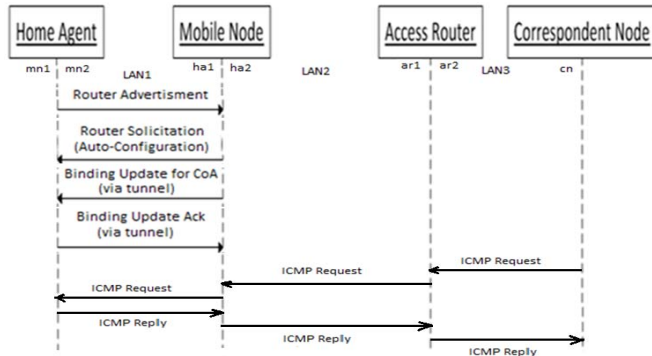

FIGURE 1B
SEQUENCE DIAGRAM FOR BINDING UPDATE

daemon) to announce the presence of its network. Through router neighbor discovery, an MN sends a router solicitation to automatically receive an IPv6 address [27] as shown in the first two steps in Figure 1B.

Once auto-configuration was setup and MIPv6 features were enabled in the proper order; first on the HA and then on the MN, a tunnel is automatically established between the HA and MN as depicted in the last two steps in Figure 1B. The binding update message sent from the MN consists of a Care

of Address (CoA) that the MN sends to the HA. Care of Address (CoA) is also a mechanism by which the HA can forward packets to the MN, no matter where it is located. The original binding update sent by the MN to the HA is then acknowledged by the HA through a binding update acknowledgement message as seen in Figure 1B.

When the MN moves to another network, be it the one the CN is attached to (that is, LAN3) or entirely different from LAN1 and LAN3, the MN sends a binding update message to the HA which confirms that the already established tunnel between the MN and HA as shown in Figure 2A along with the previously defined CoA are to be used for communications between HA and MN while MN is away from its Home network.

With an IPv6 tunnel setup between the HA and MN to provide a mechanism of communication, the CN sends packets to the MN's home network as shown in Figure 2B whenever it needs to communicate with MN. Figure 2C shows the path the pinging packets take from the CN to MN. All packets intercepted from the CN destined for the MN are forwarded to the CoA of the MN by the HA. As can be seen in Figures 2B & 2C, the communication is not always efficient as there are three pinging (ICMP) request messages before the packets from CN reach the MN at its new location and three more ICMP reply messages.

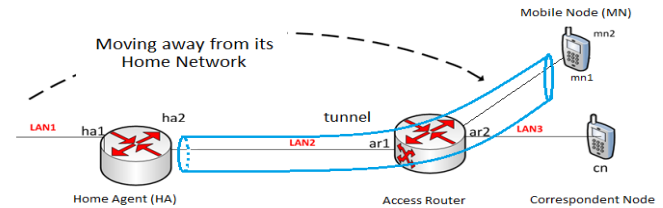

FIGURE 2A
MN TO HA TUNNEL AFTER MN MOVED TO LAN3

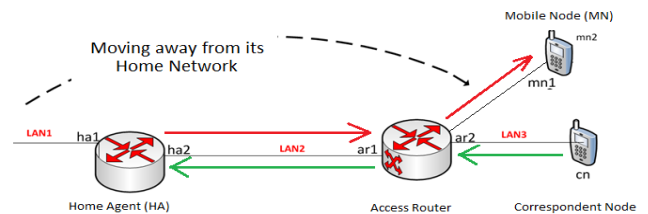

FIGURE 2B
CN TO MN COMMUNICATION VIA HA

To make communication more efficient, the MIPv6 daemon can be launched also on the CN with the route optimization option enabled. This triggers the establishment of a tunnel between the CN and MN. This allows direct communication between the two entities, initiating what is known as route optimization [29, 30] as shown in Figures 3A and 3B

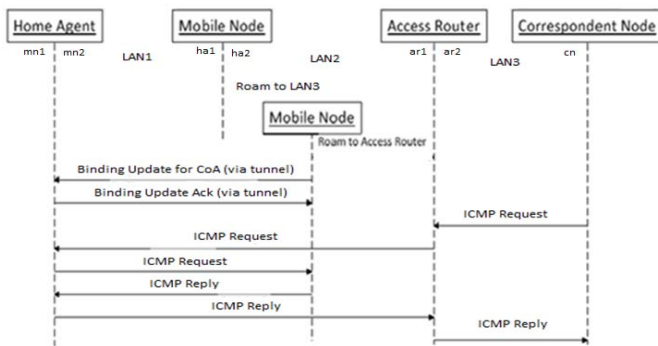

FIGURE 2C
SEQUENCE DIAGRAM OF CN TO MN COMMUNICATION VIA HA

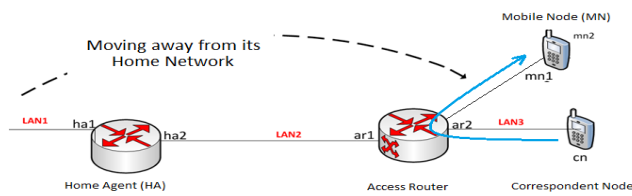

FIGURE 3A
COMMUNICATION VIA ROUTE OPTIMIZATION

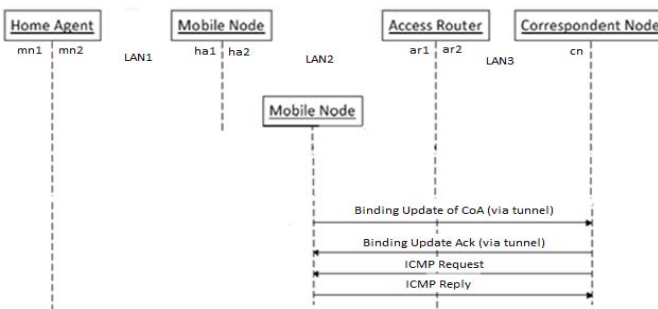

FIGURE 3B
SEQUENCE DIAGRAM OF ROUTE OPTIMIZATION

The results obtained using the virtual network environment described in this paper were consistent with those achieved in other environments such as the VNUML [22] and the test bed in [29]. For example, we verified that the launch of the MIPv6 daemon on the CN was necessarily if direct communication between the CN and MN is required.

SUMMARY OF OUR PROJECT EXPERIENCE

To properly configure an IPv6 capable network, routing was another challenging concept that had to be understood before a virtual network could be established with full end to end connectivity. To achieve full control over the virtual network, static routes were established on the virtual routers and hosts. Despite the early challenges faced while setting up static routes and establishing the virtual test environment, the most challenging of all was the configuration, recompilation, and installation of the MIPv6 enabled Linux Kernel. This was definitely the biggest challenge faced as it required much time and effort in both understanding and undertaking a task never

attempted before by either the student or his advisor. To achieve this task, the USAGI-Patched MIPv6, known as, UMIP was adopted as it had the most up to date version of MIPv6 for Linux [14].

The procedures documented by the UMIP organization in the implementation of MIPv6 required a higher level of experience with Linux and a deeper understanding of mobility for IPv6. Therefore, it took many weeks for the key obstacles to be clearly identified and resolved. This delay was partially due to the approach taken at first where the advisor allowed the student to research and implement the prototype without the advisor's hands-on involvement. Certainly, this provided the student ample opportunities to learn how to troubleshoot, especially in cases such as compiling small and simple applications which is a totally different task when compared to recompiling a Linux Kernel.

When it became clear, in spite of the student tenacity and willingness to do whatever it takes, that the issues facing the student exceeded his current Linux skills, a new approach was taken. The Linux Kernel compilation was done in parallel by the student and advisor on two different Linux Kernel releases to maximize the chances for success. The student ended up reconfiguring and recompiling the Linux Kernel on Ubuntu 11.04 while the advisor did the same on Ubuntu 10.04 release. During this process the advisor intentionally withheld certain information from the student in order to incent the student to find answers on his own.

MAJOR HIGHLIGHTS AND FUTURE WORK

From an innovative perspective, this project brought about a novel approach to undergraduate research and hands-on projects. The adoption of an Open Source and Virtualization network test environment enables undergraduate researchers to tackle major network research projects that otherwise would demand resource investments and management beyond most institutions' financial means. This environment enables budding researchers to complete major projects in a shorter time span and have better chances in finding jobs upon graduation.

One major benefit of this project is its potential to offer wide audiences at early levels of education, such as, high school a virtual appliance that can be downloaded on demand with very minimal configuration. This appliance would be comprised of a single VM team made up of four VMs networked to emulate the mobile capabilities of IPv6, in a portable virtual environment. The appliance can be made available to instructors and students, allowing them to conduct Mobile IPv6 projects in their own virtual lab environments, through the use of VMware Player or Workstation.

In this project, there were many learning opportunities for both the student and advisor. For example, this project was an excellent example of how high risk projects (typically excepted of graduate students) can be accomplished at the undergraduate level. This effort was a major undertaking for an undergraduate student. It was also a valuable learning experience for the student to witness firsthand how an

experienced faculty researcher approached and resolved an issue in a domain outside of his core expertise.

In terms of future work, a solid foundation has been established to enable junior students to explore IPv6 mobile capabilities on smart phones platforms. A natural next step is to secure the MIPv6 tunnel between the Mobile Node and Home Agent by making use of IPv6 built-in IP Security (IPSec). With the LTE-based 4G service being rolled out, it would be very timely to also explore and enhance the platform to incorporate the Proxy Mobile IPv6 (PMIPv6) capabilities. An extension to the PMIPv6 is to apply the constructed virtual environment in testing new IPv6 based services such as VoIP and Video Multicasting in support of IPTV. Yet another is to enhance the virtual prototype environment with the Return Routability (RR) and IPSec to protect the location information of a MN described in [31] and the Fast Mobile IPv6 (FMIPv6) [32] aiming to minimize MIPv6 handover latency.

ACKNOWLEDGMENT

The authors wish to acknowledge the ISAT Department for providing laboratory and funding support. In addition, we would like to thank the many online communities we have consulted, specifically, the Universal playground for IPv6 (USAGI), and the EDUC@REDES – Grupo de Innovación Educativa UPM project groups. Finally, the authors would like to recognize Dr. Harry Reif's thorough proof reading of this paper and his many valuable editorial comments and suggestions.

Work in Progress: Using Smart Mobile Tools to Enhance Autism Therapy for Children

Anthony Ellertson

Abstract – Autism and related communicative disorders in children are major issues facing parents, school districts, and government institutions. Autism now affects one in eighty-eight children in the United States, and treatment requires significant resources – time, expertise, and financial. This project seeks to enhance the reach of therapeutic efforts through a family of smart mobile tools created to assist therapists working with autism and communicative disorders. The system uses cloud services and a knowledge automation expert (artificial intelligence) engine to track patterns in treatment and visually display those patterns for clinicians, schools, and parents, thereby creating a space for cross-communication between parties that is tailored to the treatment needs of each child.

Index Terms – Autism, Communicative Disorders, Mobile Development, ABA or Speech Therapy

INTRODUCTION

In this work in progress, I describe the development of a grant-funded “smart” mobile application project to enhance therapeutic interventions and track biometric data for improved therapeutic intervention for children with autism and related communicative disorders. This system was developed to address in part the increasing challenges related to delivery of services for autism and communicative disorder therapies in the field.

Autism is the fastest growing developmental disability in the United State [1], and the Center for Disease Control currently estimates that 1 in 88 children between the ages of 3 and 17 have an autism spectrum disorder [2]. To date, 36 states have mandated some form of treatment coverage for autism therapy. It is expected that more states will follow as large numbers of children begin needing services. Most of the coverage goes for early intensive interventions, with the average cost of those treatments reaching \$60-70,000 per child per year. [3]. Although costly, early intervention is actually more economical for the states and medical insurers when considering that the average cost in social and medical services for a person on the spectrum is \$3.2 million over the course of their lifetime; 60% of those costs are in adult services. It is estimated that the cost of life-long care can be reduced by 2/3 with early diagnosis and intervention [4].

The intention of this project is to enhance training for therapists and educators in the field while also providing a space for cross-communication between professionals on treatment teams.

METHODS

This project arose from needs identified through observation of home-based intensive autism therapy services. These needs included more robust training for front-line therapists, more comprehensive tracking of therapy data for senior therapists overseeing a child’s program, and integration of multi-faceted treatment approaches.

Funded by the Wisconsin Technology Foundation in collaboration with industry partners, students from the Web & Digital Media Development program and I created a family of four mobile applications: Charting Dashboard, Video Behavior Recording, Video Conferencing, and Data Entry App.

Using a knowledge automation expert (AI) engine in conjunction with Cloud services, our family of mobile applications:

- Captures implicit knowledge of senior therapists to make their expertise more available to new therapists/educators in the field
- Creates enhanced inter-rater reliability for therapists through thick and descriptive multimedia data
- Identifies patterns in the interventions to improve treatment
- Facilitates collaboration between therapists, medical doctors, and parents in the treatment of children with autism and other communicative disorders
- Tracks both biomedical and therapeutic interventions

FAMILY OF SMART MOBILE TOOLS

The purpose of this project is not to provide applications for the delivery of therapy, but rather a suite of applications for evaluating the effectiveness of therapy and enhancing the real-time training of therapists in the field. Our project differs from most in its approach because it uses a knowledge automation expert system to track treatment, identify patterns in that treatment, and provide guidance on the best next steps based on each child’s needs. In addition, our applications are media rich and mobile ready, allowing parents, therapists, and medical doctors to record, track, and observe actual behavior in real time through interactive charting, video sharing, and video conferencing.

Currently, children undergoing intensive therapeutic interventions for autism are monitored almost daily by therapists, parents, or medical professionals. Behaviors such as social-cue tracking, sleep patterns, and reactions to medications are being recorded to help therapists and doctors tailor treatments for each child. Unfortunately, much of these data are still stored in paper formats that are difficult to share or track. Our family of mobile tools allows therapists/parents/medical professionals to securely enter data via mobile or desktop device. Once entered, these data can be charted, combined, and shared instantly between all parties working with the child.

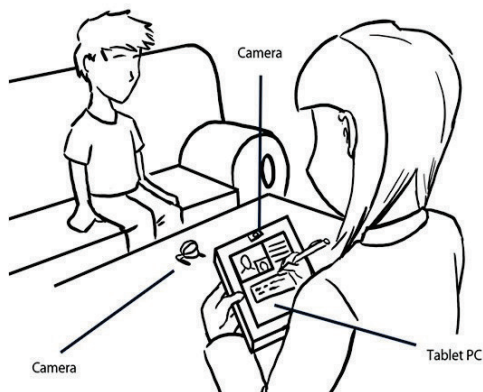

FIGURE 1
EXAMPLE OF THERAPIST USING TABLET

Figure 1 represents how the system currently is accessed and tracked by professionals treating the child. Using a combination of tablets and smart phones, patient behavior is recorded instantly into the cloud in natural environments such as the patient's home or school. Once recorded, these data can be tracked and shared among various professionals to help identify patterns of behavior and treatment.

Additionally, through tools like the Video Behavior Recording app, greater inter-rater reliability can be achieved by using the device to record actual behavior in real time so that all on the team can observe, identify, and agree on what the behavior is and means. For example, therapists will be able to agree on the criteria for what makes a particular child's behavior aggressive versus perseverative. Further, using a mobile device means that recording is convenient and can be done in real time. Figure 2 shows the Video Behavior Recording application in use. The application stores video of patient behavior into the cloud and allows the therapist to add cue points with behavior comments during significant portions of the recording. These cue points can then be charted so that when significant trends in the behavior are noted, the therapist also will have access to all videos related to that identified trend.

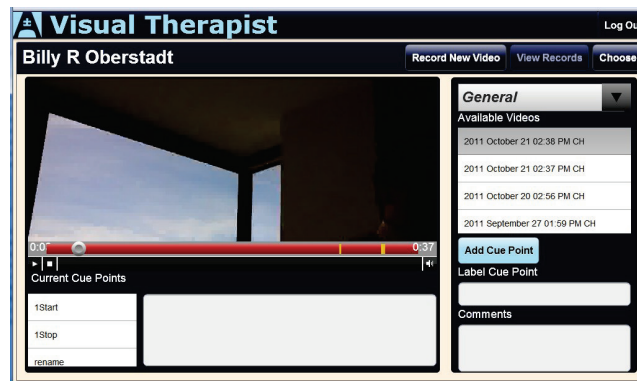

FIGURE 2
EXAMPLE OF VIDEO BEHAVIOR RECORDING

In addition to storing information and video into the cloud, all four apps are connected to our knowledge expert automation (AI) engine. The AI engine is currently being populated with rules from senior therapists and team leads in the field to enable the system to track changes and recognize patterns in real time. Once patterns are recognized, suggestions will be immediately fed back to the mobile applications so that front-line therapists/parents/medical professionals working in the field will be immediately alerted to avenues of treatment based on the experience and expertise of seasoned professionals.

FUTURE DIRECTIONS

Currently, we are field testing the suite of tools in conjunction with industry and academic partners. These field studies will help refine the rules in the AI engine, test usability, and hasten the training of new therapists thereby enhancing the treatments available for each child.

Work in Progress: Application Design on Touch Screen Mobile Computers (TSMC) to Improve Autism Instruction

Nancy Rasche and Cheryl Zhenyu Qian

Purdue University
nrasche@purdue.edu, qianz@purdue.edu

Abstract— This study identifies the areas of autism therapy that can be enhanced by using a touch screen mobile computer (TSMC) device to facilitate autistic children's learning experience. At an affordable price range, the simple touch screen of a TSMC has an immediate cause and effect response that enables these students to be more independent during the learning process. These key factors make the TSMC an ideal supplement for autism therapy in the classroom and for skill reinforcement at home. However, to identify a correct starting point is crucial for the success of this research. Our study aims to explore the most effective application design areas using a TSMC as an instructional tool for autistic children. To determine this direction, four main steps were identified. These steps include reviewing current literature on autism deficits, evaluating the interaction design of the TSMC, analyzing existing TSMC applications currently available, and designing a prototype application for evaluation. This paper reports our model of information processing interruption in autism learning, our target zones of instruction based on the literature review of autism deficits, and introduces our implementation plan of the application design to enhance autism therapy.

Keywords—autism therapy; computer aided instruction; instructional technology; cognitive deficits; cognitive information processing; application design; Touch Screen Mobile Computers

I. INTRODUCTION

Autism spectrum disorders (ASDs) are a group of developmental disabilities characterized by atypical development in socialization, communication, and behavior [1–3]. The significant increase in the prevalence of ASDs has led to an increase in research of related treatments. Currently, there are a wide range of assistive technology devices available that can be implemented by teachers, parents, and/or therapists. These items range from the low level visual cue cards to the high level computer assisted instruction (CAI) devices. Among the many assistive technology options, CAI provides the educational advantage of providing consistent and predictable feedback that can be repeated many times to reinforce skills. For such use, TSMCs stand out because of their potential price affordability, accessibility, and usability. The research topic of developing new applications for autism therapy on the iPad was inspired by Rasche's collaborative design experience with

Purdue University's EPICS (Engineering Projects in Community Service) program. The team was developing a suite of iPad applications to be utilized as communication aids for children with autism and other special needs [4]. The success of these applications encouraged us to go one step further – conducting research upon what autistic children most need to improve their current learning condition, investigate possible paths to satisfy these needs with TSMC technologies, identify patterns through our design experience, and then encourage involvements from the design society to improve the education resources for autistic children.

Our research started from reviewing psychology literature to understand cognitive deficiencies associated with ASDs to determine instructional needs. Through integrating these findings with human cognitive information processing model, we drafted an interruption model to illustrate the problematic regions. Reviewing different TSMC devices provided an understanding of their interaction strengths and weaknesses in relation to being an effective tool for different ASD deficits. The comparison table of the cognitive deficits and TSMC potential will help us to locate target instruction zones and prospective paths that are suitable for application design on the TSMC. These steps pave the way to provide credibility to our possible designs. The goal of this thesis research is to create an interaction design framework to explore the potential, boundaries, and directions of developing TSMC applications for autism therapy.

II. ENIGMA OF COGNITIVE DEFICITS

According to the literature review, we started to realize that ASD cognitive deficits constructed an enigma instead of an explicit list - every child diagnosed with autism will have a wide range of disabilities at many different capacities. Therefore, it is impossible to clearly list all the disabilities for all children with autism because it varies for each.

The summary of deficits list may be apparent in many, but not all of the individuals with an ASD with variable capacity. Therefore, it is necessary to have a detailed register of deficits for autism disorders that can be considered an area for needed focus in therapy instruction based on the individual's needs. The three general areas of cognitive deficits are theory of mind,

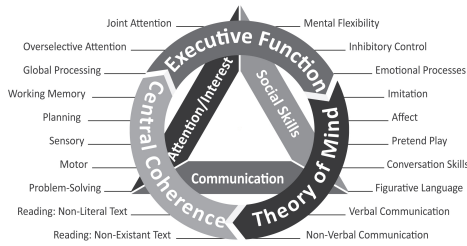

Figure 1. Target Zones of Instruction

executive function, and central coherence. These three deficit areas lead to the three most common areas of disabilities: communication, social skills and attention/interest. As shown in Figure 1, the deficits and disabilities create a long list of possible target zones of instruction.

Although, it is important to note that there is a connection between these deficits that can cause an increase or decrease in the capacity of the other disabilities. In other words, these deficits are linked, overlapped, and influence each other directly. To understand it further, we focus on the specific cognitive skills related with these deficits areas.

- Theory of Mind (ToM) can be described as an ability to understand the mental state of oneself and/or others [1], [5], [6]. ToM deficits are evident in children with ASDs as having difficulty understanding the perspective of others.
- Executive Function (EF) is the ability to make planning strategies to reach goals and having the flexibility to modify goals as necessary [1], [7], [8]. EF deficits are noted in children with ASDs as a strict coherence to routines and patterns.
- Central Coherence (CC) can be described as the ability to process information to achieve a whole, coherent meaning. Children with ASDs show exceptional skill at processing details, but the capacity to grasp inferred meaning in language and social settings is difficult [1], [8].

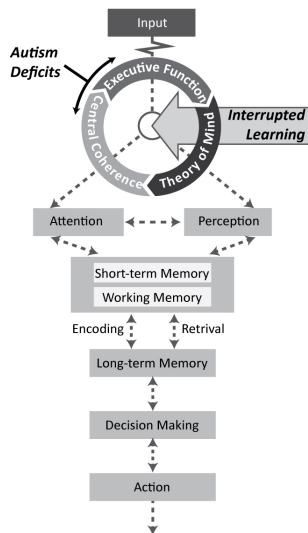

Figure 2. Information Processing Interruption Model

As a whole, it is clear that the cognitive deficits associated with autism cause an interruption in the processing of information [9]. As we illustrated in Figure 2, these deficits make attention and perception difficult to achieve and directly affect learning. Thus, the interruption in the processing of information reduces the amount of input translated to memory that can be later accessed to make appropriate decisions.

III. CONCLUSION

We are currently reviewing TSMC devices to understand their interaction and examining available applications. Early research is showing a weakness in social skill instruction with the TSMC. This skill is best taught with one on one behavioral therapy approaches. Communication and attention are two areas that show a lot of promise. In fact, the research we saw with the communication application indicates that it draws more attention for effective information processing. The outcome of the final evaluation of the research studies and reviews will determine the application design direction. According to the develop plan, the first round of design and prototyping will start in July. This phase will include an evaluation of the prototype application with students, their families, and their educators through GLASS (Greater Lafayette Special Services) [4]. We aim to develop TSMC applications that will help supplement ASD instruction and connect family members to the child's learning experience at home with the help of digital media.

Work in Progress: How Differences in Student Motivation Characterize Differences between Engineering Disciplines

Adam Kirn, Beshoy Morkos, Lisa Benson
Engineering and Science Education
Clemson University
Clemson, SC, United States

Abstract— The limited impact of many engineering education reforms may be due in part to treating engineering as a single monolithic discipline. We are using student motivation to characterize differences in engineering majors in order to inform educational practices and differences in student learning. Here we report on differences in student attitudes towards their engineering majors, elucidated through the use of survey data collected from first year students and longitudinal data on their majors 2 years later. We provide a detailed picture of the complexity of the engineering population, which will help direct more in-depth qualitative research to examine possible correlations between student motivation and learning in different engineering majors.

Keywords- attitudes; motivation; engineering disciplines

I. OVERVIEW

Studies of student retention and learning in engineering have been made in comparison to other majors and colleges within the university system [1]. Such studies are often used for implementation of evidence-based educational reform, but one factor limiting the success of such reforms is treating engineering as a monolithic discipline. Differences between cultural dimensions of engineering disciplines, such as a “newer” (software engineering) versus a more established discipline (electrical engineering) have been noted [2]. Although studies have identified differences between student attributes in engineering disciplines [3], research on the differences between factors that characterize them in terms of attitudes, behaviors and practices is lacking.

We are using achievement motivation as a theoretical framework. Achievement motivation, which can shape engagement behavior, examines students’ attitudes about their abilities and the value they place on tasks as indicators of their motivation to pursue academic and career goals. This study seeks to understand the fundamental differences between engineering disciplines in terms of student motivation, because motivation affects choice, persistence and performance [4].

II. RESEARCH ENVIRONMENT AND ACTIVITIES

A Likert-scale survey (Motivations, Attitudes and Expectancy Survey (MAE)) was developed to assess students’ attitudes related to their engineering studies. More information on the survey can be found in Morkos and Benson (J Engr Ed,

under review). The survey was developed based on the Expectancy x Value theory of motivation [4]. Survey constructs were analyzed for reliability and validity, and survey responses were collected for a single cohort of freshman engineering students ($n= 494$) at a southeastern land grant university. Additional data was collected on enrollment of these same students in engineering disciplines the following two years. This data was further analyzed to examine whether differences in student attitudes during their first year in engineering were observed based on their engineering major two years later.

Through factor analysis, three survey constructs were demonstrated to be reliable, with values for Cronbach’s alpha ranging between 0.85 and 0.92. Content validity analysis identified constructs as: Expectancy [4], attitudes about present tasks/goals in engineering (“Present”), and attitudes about future tasks/goals in engineering (“Future”). The latter two constructs are supported and explained by the Future Time Perspective theoretical framework [5]. Binomial regression of survey data was used to correlate constructs and persistence in engineering.

Students’ attitudes about their future was found to be a significant predictor of continued enrollment in engineering two years later by a factor of 2 ($\beta = 2.01$). However, the capability of student attitudes to characterize different engineering majors is limited, as no significant differences between chosen majors were found for any construct. Majors were grouped as traditional (mechanical, electrical, civil, chemical, and industrial) and interdisciplinary (material science, environmental, computer, ceramic, biosystems, and bioengineering). Traditional majors are well-established and have a well-defined canon of knowledge [6]; interdisciplinary majors draw from a more emergent body of knowledge. Differences in specific survey items for different types of engineering majors were analyzed to glean information for more in-depth future studies. Significant differences were found between traditional and interdisciplinary groups of majors for three items within the Expectancy (E) construct and one item within the Future (F) construct (Table 1). These results provide some insight into how student motivation might contribute to persistence in a major, but they do not provide enough insight to explain differences in motivation that may affect student choice of major.

Another source of insight on student motivation was data from administrations of an informal beginning of semester survey (BOS) given in freshman engineering courses at the same southeastern land grant university, which included questions about reasons why students chose engineering. Students self-reported the importance of factors for seeking to major in engineering (see examples in Table 2). The BOS data indicated differences in student perceptions about benefitting society, doing interesting work, and designing and building things (Table 2). The combination of differences observed between majors for specific MAE and BOS items, a clearer picture of differences in student motivation based on engineering majors emerges.

TABLE I. MOTIVATION, ATTITUDES, AND EXPECTANCY SURVEY RESULTS, ON A SCALE FROM -2 (STONGLY DISAGREE) TO 2 (STONGLY AGREE). SURVEY ITEMS FROM FUTURE (F) AND EXPECTANCY (E) CONSTRUCTS SHOWED SIGNIFICANT DIFFERENCES BETWEEN TRADITIONAL AND INTERDISCIPLINARY ENGINEERING GROUPS. * $p < 0.05$

| Construct | Survey Item | Traditional | Interdisc. |
|-----------|--|-------------|------------|
| E | I am struggling with my college courses. (Reverse coded) | 0.274 | 0.587* |
| F | I will use the information I learn in this engineering course in the future*. | -0.162 | 0.130* |
| E | I am having to work harder than many of the other students in my classes*. (Reverse coded) | 0.928 | 0.685* |
| E | I believe I will receive an excellent grade in this engineering course*. | 0.639 | 0.902* |

TABLE II. BEGINNING OF SEMESTER SURVEY RESULTS. STUDENTS WERE ASKED TO RANK THE FOLLOWING REASONS IN RESPONSE TO THE QUESTION, "PLEASE RANK THE FOLLOWING REASONS YOU WANTED TO PURSUE ENGINEERING, ON A SCALE OF 1-5, WITH 1 = NO INFLUENCE, 5 = TOP REASON." * $p < 0.05$, ** $p < 0.001$

| Statement | Traditional | Interdisciplinary |
|-----------------------------------|-------------|-------------------|
| More scholarship money available | 1.638 | 1.837* |
| Opportunities to benefit society | 3.554 | 3.753* |
| Engineers do interesting work | 3.864 | 3.692* |
| I like to design and build things | 4.097 | 3.515** |

III. DISCUSSION AND FUTURE WORK

We are applying achievement motivation as a framework for characterizing differences in engineering populations by discipline. The findings of the MAE show that students in newer, more interdisciplinary majors struggle less in their courses, value introductory courses less, do not feel they work as hard, and expect better grades than those in established, traditional majors. These results, while important, are limited. The MAE survey was developed to inform student persistence in engineering, and thus its constructs are not as useful for informing differences in choice of engineering major. Additional insights from the informal BOS showed the importance of making a difference and the availability of scholarship money for students in interdisciplinary majors, while engineering work and designing and building things were valued less than for students in traditional majors. Despite the limitations of the informal BOS, items in this survey can help identify appropriate frameworks such as intrinsic and extrinsic value (scholarship money), identity formation and possible selves (I like to design and build), and goal orientation (benefitting society). Our results also demonstrate the limitations of Likert-scale surveys to fully assess the complexity of student motivation. These findings will help direct more in-depth qualitative research (i.e. developing interview questions and quasi-experimental designs). Further elucidation of motivational differences between engineering disciplines will allow for examination of how these differences manifest themselves in terms of student learning.

Care Ethics in Engineering Education

Undergraduate Student Perceptions of Responsibility

ryancamp@uw.edu, yasuhara@uw.edu, denisew@uw.edu

Abstract—Engineering is not known to be a particularly caring profession, scoring significantly lower than science in this regard according to a poll of the American public. However, engineers have many opportunities through their work to show care and concern for both people and the ecosystem, such as by choosing to work on humanitarian or environmental issues and taking responsibility to ensure these issues are meaningfully addressed. When engineers do their jobs uncaringly, people and the environment often suffer. In this paper we argue that care ethics should be a part of engineering education and explore how care is reflected in student work. Specifically, we examine empirically how undergraduate engineering students care for others, as expressed through their writing about engineers taking responsibility for the adverse impacts on the environment and public health created by e-waste recycling in the developing world. We find that in our sample, most engineering students associated engineers with responsibility for this problem, but that many appeared to lack an appreciation of both the complexities that must be addressed, and the broadly interdisciplinary and collaborative approach necessary to meaningfully address them.

Keywords—ethics; ethics of care; humanitarian engineering; social justice; environmental justice

I. INTRODUCTION

One might claim engineering to be a caring profession by its very nature as a service profession, arguing that engineers apply their knowledge of math and science to solve human problems. However, care and concern for others has not traditionally been an explicit topic in the engineering curriculum as it has in other service professions such as social work, medicine, and nursing. Emerging engineering disciplines such as bioengineering and human-centered design & engineering appear to be fertile ground for care in engineering, but even the more abstract fields of electrical or computer engineering offer opportunities to manifest care through the application of their work to important issues such as studying climate change or enabling communication in post-disaster situations. Unfortunately, not everyone sees engineering this way. According to one study summarized in [1], the American public perceives engineers as being significantly less sensitive to societal concerns and less caring about the community than are scientists.

In the modern day, where technology is a critical element in addressing a wide range of global issues, bringing care to the forefront of engineering education and curricula is important

for ensuring that technology serves to improve social and ecological justice for all, rather than serving the few at the expense of the many (a coarse distillation of the basic argument for engineering and social justice made in [2]). Care may also hold a key to recruiting and retaining broader demographics to the engineering profession, which is a crucial step for increasing diversity of thought and perspective needed for reframing and addressing complex issues such as social justice, climate change, and many of technology's unintended consequences. As learning theory reminds us [3], understanding how to teach care and incorporate it into engineering courses and curricula requires pedagogical content knowledge comprised of both, in this case, what it means to care, as well as what students bring to the table in terms of their own knowledge and understanding prior to any formal instruction in care. Toward these ends, we present in this paper, findings from a study in which writing samples from sophomore and junior level engineering students in several engineering disciplines are analyzed in order to explore how an ethic of care might be manifest in engineering.

The “ethics of care” or “care ethics” is a normative ethical theory that has developed over the past few decades [4] and can be concisely defined as emphasizing “the importance of responsibility, concern, and relationship over consequences (utilitarianism) or rules (deontology)” [5]. Care ethics provides a conceptual framework for understanding both what it might mean to care in engineering and what students bring to the table in terms of care and concern for others. Specifically, we seek to understand how undergraduate engineering students care for others as expressed through their thoughts on taking responsibility (as engineers) for impacts on the environment and public health created by the “backyard” recycling of electronic devices that occurs in developing countries. Since these devices have historically been designed in, used in, and disposed of primarily by wealthy, industrialized countries, the problem framing employed to collect this data explicitly introduced a humanitarian and social/ecological justice context.

II. LITERATURE REVIEW

In the engineering education-related literature, care and care ethics have not attracted much interest to date. Perhaps the earliest mention of care ethics and engineering appeared as recently as 1995, when electrical engineering professor G. Moriarty, publishing in the field of professional ethics, highlighted the importance of care tempered with objectivity, to create a balanced notion of both good engineering and the

This work was supported by the National Science Foundation (NSF) under grants 0817625 and 0909817 at the University of Washington. Any opinions, findings, conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of NSF.

good engineer [6], [7]. Similarly, in 1997, civil engineering educators T. Broome and E. Peirce, stressed “caring” principles as the motivation needed for engineers to become good, responsible, and even “heroic” in their practice [8].

In a 1999 Ph.D. dissertation [9] and a later journal article [10], civil engineer R. Hyde addresses the need for educating engineering students for environmentally sensitive practice by developing an “ethic of caring” for the ecosystem that involves assessable attitudes and behaviors of caring. Also in 1999, civil engineering professor M. Pantazidou, in collaboration with professor of engineering & public policy I. Nair, showed how care ethics is relevant to engineering in general [5]. They highlighted the service-oriented nature of engineering and demonstrated care ethics’ applicability to engineering design and problem-solving methodologies by mapping aspects of these methodologies to elements of Tronto’s [11] framework for care ethics (described in the following subsection). In 2005, professional structural engineer D. Kardon, building on Pantazidou and Nair’s work, conceptualized care as a “standard of care” that essentially serves as a measure of ethical adequacy of the exercise of the engineer’s professional duties [12]. Kardon illustrated the application of Tronto’s framework to engineering using multiple ethics case studies on topics of engineering failure and liability. In 2008, engineering professor D. Riley provided a brief exposition of the importance of care ethics in relation to engineering and social justice [2].

Finally, while not focused on care ethics, but more broadly on conceptions of care and empathy, a collaboration of education and engineering education researchers, led by professor of engineering education J. Strobel, recently performed a systematic review of the literature on these topics, searching databases of research in education, social science, engineering, nursing, medicine and counseling [13]. They indicate a variety of ways in which care is conceived, even within engineering, and are optimistic about the prospects for more explicitly incorporating care in engineering. In the spirit of building on the existing literature, this paper, contributes insight into the student conceptions by looking at particular aspects of care as viewed through a theoretical framework of care ethics.

A. Tronto’s Framework of Care Ethics

As one of several significant contributors to the ethics of care, political scientist J. Tronto has demonstrated how care applies to not only the interpersonal micro-ethical situations we commonly think about in regards to caring, but to larger political/societal macro-ethical situations as well [11]. Tronto describes four interconnected and frequently overlapping phases of the care process: caring about, taking care of, care giving, and care receiving. These phases correspond to four moral elements of care: Attentiveness, Responsibility, Competence, and Responsiveness, respectively. In this paper, only the first two phases are utilized and discussed in detail, but for the sake of completeness, a brief description of the remaining phases is also given below.

Tronto’s first moral element of care, Attentiveness (c.f. caring about), involves awareness of the needs of others and makes the claim that neglect and even ignorance, be it willful or inadvertently habitual, are moral failings. Here Tronto

describes, as an example, the failure of many wealthy people in industrialized countries to notice (in spite of worldwide information technology and diverse media coverage) how “activities spurred by a global capitalist system results in the starvation of thousands” [11, p. 128]. Tronto’s second element, Responsibility (c.f. taking care of), involves the care-giver taking responsibility for involvement in the care relationship (be it voluntary or not). Here Tronto makes the point that responsibility differs from obligation, in that responsibility is contextual rather than universal, is more ambiguous, and may or may not be associated with prior actions of the care-giver. Tronto points, as an extreme example, to the benevolent actions of Europeans during the second World War who, at great peril, tried to rescue Jews from Nazi persecution because they felt responsible simply by virtue of being human [11, p. 132].

Tronto’s third moral element of care, Competence (c.f. care giving), indicates that the work of meeting an objective need must be not only performed, but it must be done competently so that the need is in fact met. Tronto’s fourth element, Responsiveness (c.f. care receiving), deals with the response of the care-receiver to the care-giver and includes consideration of the problems of inequality and vulnerability. To these four elements/phases of care, Tronto adds a fifth meta-level component, known as the Integrity of Care, through which the four phases must fit together as an integrated whole in a way that is sensitive to context and addresses the conflict that is inherent in any situation with moral implications. The interested reader is encouraged to refer to other sources, such as [11] for a fuller treatment of these concepts or [14] for a brief but helpful introduction.

III. DATA & METHODS OF ANALYSIS

A. Description of Data

A sophomore level electrical engineering class was given an optional extra-credit assignment to write a one-page paper in response to reading selections from a journal article [15] on the health and environmental impacts of waste electrical and electronic equipment (e-waste) in China and India. The writing assignment was scaffolded with prompts for three brief essay questions to guide and constrain the responses. The first essay question drew attention to a figure in the article depicting the ecological cycle and fate of pollutants generated by e-waste recycling and asked the students to discuss what concerned them the most about this figure and why. The second essay question asked the students to discuss the impacts on humans and the environment of that aspect of e-waste recycling identified in the first question. The final essay question, which is the focus of our analysis, asked:

“What do you think modern engineers producing these electronic technologies should do as an ‘ethical’ response to the waste electronics recycling dilemma? Comment specifically on how far in scope engineers should go to limit this impact.”

While the assignment was not designed with Tronto’s framework explicitly in mind, her phases/elements of care are useful for interpreting and perhaps even assessing the resulting student work. Reading the journal article on developing-world e-waste recycling in conjunction with the first two essay

questions set the stage to ensure Attentiveness to a problem that requires some level of ethical caring, while the third essay question served to prompt students to discuss what they felt to be appropriate levels of care-ethical Responsibility. Furthermore, from the students' conceptions of ethical responses to the problem, we gain insights into their potential for care-ethical Competence. Thus, our findings focus on the nature of the notions of Responsibility and Competence that undergraduates bring into the engineering classroom without prior study of or instruction in care ethics.

B. Sample Selection

Data analyzed in this study were collected in a course offered in 2010 at a large, public research university. 133 students enrolled in the course, primarily in the majors of bioengineering, electrical engineering, and pre-engineering. For this paper, data from a random selection of 19 of the 73 students who completed the assignment were analyzed. While a more purposive sample would have been preferred given the study's qualitative and interpretive nature, resource constraints necessitated a random sample.

C. Inductive Coding Approach

Inductive, data-driven coding was performed on the writing samples to extract the entities these students associated with responsibility for the e-waste dilemma. Using elements of phenomenography similar to those used in [16], the purpose was to discern the range of entities that students associated with responsibility for the e-waste dilemma. Coding was performed iteratively by a single coder using ATLAS.ti qualitative data analysis software, and verified by a second researcher. For further methodological details on phenomenography in general, see [17], [18], or the concise introduction in [19].

IV. FINDINGS

A. Entities Associated with Responsibility for the Problem

Table I summarizes the entities (mostly stakeholders) that students associated with responsibility for the proliferation, disposal, and/or improper handling of waste electronics. The number of students associated with each code is intentionally not provided because the purpose of this phenomenographic-style analysis is not to essentialize or reduce the codes to the most common responses, but to discover and "map" the entire range of responses. The first column of the table indicates codes that are "close to the data" (i.e., assigned with minimal interpretation of data and given names that match or closely resemble relevant wording where possible). The second column describes the meanings of the codes in more detail. The third column groups the grounded codes by higher-level categories. These are the phenomenographic categories of description that emerged from the data, labeled Business, Citizen, Government, Technical, Collaboration, and Non-responsibility (all described in the following paragraph). The fourth column gives example quotations from the students' essay question responses, which are numbered for ease of reference.

The Business category of Table I includes all stakeholders that are specifically economic- or business-related, including

businesspeople, design companies, companies that profit from toxic products, recycling-plan departments with a company, manufacturers, and recycling facilities, as well as the less tangible "market forces". The Citizen category comprises stakeholders who are unaffiliated, ordinary people, including consumers in developing countries, unspecified consumers (likely those in industrialized countries given the context, but both could also be intended), and people who live/work in developing countries. The Government category comprises stakeholders and entities associated with government or regulations, including governments of both industrialized and developing countries, international laws, unspecified governmental bodies, and politicians. The Technical category comprises stakeholders in the technical fields, including engineers, individual designers, innovators, researchers, and scientists, as well as the less tangible, drive of "technology". The Collaboration category is a meta-level category that captures indications of engineers working together with other stakeholders, including politicians, businesspeople, and recycling facilities. The Non-Responsibility category, unlike the other categories, is not an indication of responsibility but an explicit denial or strong limitation of engineers' responsibility.

B. Conceptions of Breadth of Responsibility

Table II depicts a mapping of the six categories of responsible entities from Table I to the responses contained in each student's essay, where each checkmark (✓) represents a unique entity the student associated with responsibility for the e-waste problem. The table is sorted by breadth of considerations as reflected in the number of categories covered. A number of observations can be made of these findings. First, the technical entities, including engineers, researchers, and scientists, are the most prevalently indicated. This was expected, given the focus of the essay question prompt on engineers' responsibility. In fact, only one of the students (Student 8) absolved engineers of all responsibility (a fact that is somewhat obscured by the table, which does not visually distinguish among codes within the Technical category to indicate engineers).

What was not expected was the relatively large number of other entities students associated with responsibility. The fact that the Business, Citizen, and Government columns of this table are not blank for a substantial number of students is encouraging because it indicates a more realistic conceptualization of the distributed nature of responsibility for this problem than if students simply indicated that the problem was solely an engineering problem. Less encouraging, however, is the Collaboration column, which indicates that only a few students appear to recognize the need for engineers to take a collaborative approach with non-technical entities to meaningfully address this complex problem. Mitigating the effects of e-waste recycling on health and the environment will require more than just minor technical changes in design or materials, as it involves politics, transnational relationships, market forces, and globalization. For example, as Student 19 indicated in quote (9) above, "Engineers, politicians, and businessmen must work together to develop solutions ..." and Student 7 even provided a concrete way that engineers might collaborate with others:

TABLE I. ENTITIES INDICATED AS ASSOCIATED WITH RESPONSIBILITY

| Grounded Code | Code Meaning | Category of Description | Example quotations |
|--|---|---------------------------------|---|
| Businesspeople | Businesspeople (non-specific) | Business | “Companies ... designing electronics that will one day end up in recycling facilities should set up funds to aid in the modernization of [those] facilities.” –Student 13 (1) |
| Companies that Design | Companies that design e-devices | | |
| Companies that Profit | Companies that profit from toxic products | | “However the market is driven by mass consumerism – in which customers are encouraged to buy new technologies even if there are only slight modifications to the previous versions. Nuances such as these are out of the hands of an engineer.” –Student 12 (2) |
| Company Policy | Company policy (e.g., on planned obsolescence or recyclability of products) | | |
| Recycling-Plan Department | A new department within a company charged with planning for recyclability of each product | | “An ethical response would always look to be greener however it is important not to overlook the root of the problem, uncontrolled [e-waste] recycling sites.” –Student 3 (3) |
| Manufacturers | Manufacturers of e-devices (may be implied e.g., by use of the word “manufacturing”) | | |
| Market Forces | Market forces or economics | | |
| Recycling Facilities | E-waste recycling facilities in the developing world and/or their owners | | |
| Activists | Activists raising awareness of the e-waste problem | Citizen | “Probably the most helpful would be if every person would try and go out of their way to recycle their old or unusable electrical equipment.” –Student 15 (4) |
| Consumers in Dev. Countries | Consumers of e-devices in developing countries | | |
| Consumers (unspecified) | Consumers of e-devices (location unspecified) | | |
| People in Dev. Countries | People living/working developing countries | | |
| Government of Industrialized Countries | Governments of industrialized countries or regulations mandated thereby | Government | “Local governments like in China and India should be made more aware of the waste electronics recycling dilemma and decide how to proceed themselves.” –Student 18 (5) |
| Government of Dev. Countries | Governments of developing countries or regulations mandated thereby | | |
| International Laws | International laws or regulations | | “... I think a more effective strategy would be to subsidize research in recycling processes. If a strict limit is placed on individual products dictating what can and cannot be used it will very likely hinder the advancement of technology...” –Student 14 (6) |
| Government (unspecified) | Unspecific government or regulations (may be implied e.g., by use of words “tax”, “subsidize”, “regulations”, “rules”, “law”) | | |
| Politicians | Politicians (non-specific) | | |
| Designers (Individuals) | Individual designers of e-devices | Technical | “Engineers should do as much as they can to help reduce the amount of hazardous byproducts, and if they could change the design of electronics so that they are easier to recycle, there might be less ‘backyard’ recycling.” –Student 1 (7) |
| Engineers | Modern engineers | | |
| Innovators | Innovators of new e-devices | | |
| Researchers | Researchers of materials or recycling process (may be implied by use of the word “research”) | | “It is apparent that it is not easy to simply switch the materials for every electronic device known and that there are probably some essential electronics that can only function with the toxic materials, but it is very important that research go into finding as many alternatives as possible.” –Student 7 (8) |
| Scientists | Scientists involved in research of materials or the recycling process | | |
| Technology | Technology itself | | |
| Collaborations | Collaborations of engineers with other stakeholders, including, politicians, businesspeople, and recycling facilities | Collaboration | “Engineers, politicians, and businessmen must work together to develop solutions to this problem...” –Student 19 (9) |
| Not Engineers ^a | Explicit indications of engineers having limited or no responsibility | Non-responsibility ^a | “I think that this dilemma is more of a regulation problem, rather than an engineering challenge. When engineers design a product, they do so with the expectations that it will be used and disposed of in a reasonable manner. For engineers to consider all of the ways a product could be disposed of could seriously hamper product development.” –Student 8 (10) |

a. Unlike the other codes and categories in this table, this is not an indication of responsibility, but one of denial or strong limitation of responsibility.

"It is also essential that the engineers communicate with the recycling plants to develop the best ways to transition from a used device to recycled parts." –Student 7 (11)

Student 17 is unique in indicating alternative ways that engineers might work together with others:

"... although the engineer could be active in community awareness or community policy or could help develop a proper policy for the company the engineer works." –Student 17 (12)

Another observation that can be made from Table II is that some students even resist or deny that engineers have responsibility for the e-waste recycling problem. In spite of the clear expectation built into the essay question prompt that engineers have some responsibility, Student 8, for example, was particularly keen to point the finger elsewhere in quote (10), placing responsibility on others and indicating that it is acceptable for engineers to expect devices "will be used and disposed of in a reasonable manner," since product development is paramount. This student then goes on to discuss the need to regulate e-waste recycling and concludes with a statement that businesses could opt to go green if they wanted to and thereby create a good public image:

"Even though I believe the onus of protecting people's safely should be placed on government, companies can chose to be eco-friendly in their product development decisions. This can be an ethical choice by those in charge of the company or their stock holders. This...can help a company stand out by showcasing their integrity and commitment to the customer." –Student 8 (13)

Other students in the Non-responsibility category were more moderate in their disavowal of responsibility by indicating the limits and boundaries of the engineer's purview:

"The engineers should not be held to responsibilities outside of their own duties of development and design, but must do their part to help in this situation as much as they can in their sector of the modern technical industry." –Student 4 (14)

"I believe that modern engineers have little responsibility for these improper disposal and recycling practices... One way engineers could limit the negative consequences of their products is to put more pronounced labeling on their packages. Engineers should not go much further than this, as their role is not political." –Student 18 (15)

V. DISCUSSION

As the findings above on the entities associated with responsibility for the e-waste dilemma (Table I) indicate, these students are collectively aware of a variety of responsible stakeholders and systems, beyond engineers. While this is encouraging, individual coverage is actually quite spotty: indeed, only two students indicated all five categories and many covered less than three. We can also observe that the empirically derived categories of description are incomplete with respect to possible entities/stakeholders of importance. For example, no mention was made in this sample of non-profit or non-governmental organizations (NGOs), such as humanitarian aid organizations, schools, or education in general.

TABLE II. BREADTH OF RESPONSIBILITY INDICATIONS

| Student | Category of Description ^a | | | | | | Qty of Categories ^d |

| 16 | | ✓ | | ✓ | | | 1 |
| 11 | | | | ✓✓ | | | |
| 4 | | | | ✓ | | ✓ | |
| 10 | | | | ✓ | | | |

a. For each student, a ✓ represents a unique entity associated with responsibility for the e-waste problem.

b. All students except one (Student 8) associated engineers with responsibility for the e-waste problem.

c. This category is not an indication of responsibility, but denial or strong limitation of responsibility.

d. The Non-Responsibility category is excluded from these counts (see footnote c).

It is also important to understand the distinction between awareness of the responsibilities of other entities and recognition of the need for engineers to collaborate with those entities. In other words, it is one thing to conceptualize responsibility as distributed but view others' responsibilities as independent from and unassociated with one's own responsibility, versus recognizing the need to coordinate and work together in ways that competently enact what is ultimately a shared responsibility. As the findings on breadth of responsibility (Table II) indicate, most of these students appear willing to take responsibility as engineers for solving the problem of e-waste recycling in the developing world. From the perspective of Tronto's second element of care ethics, most would appear to get high marks for the Responsibility element. However, most students gave no indications of the need for engineers to work collaboratively with others in understanding and addressing the problems. This points to a potential problem for caring engineers who wish to work toward saving lives and helping the environment: their effectiveness at doing so (Tronto's Competence) is seriously in question if they neglect consideration of the responsibilities and competencies of non-engineers or constrain themselves to technical actions when technical fixes would be inappropriate or ineffective. As [14] aptly explains this element of Tronto's framework, "competence means that one has the necessary knowledge, skills, and ability to assess the situation and carry out the chosen act(s) to fill the care needs". Complex problems like the e-waste recycling dilemma and the associated issues of neoliberalism, globalization, and environmental pollution are diverse, broadly interdisciplinary, and require that engineers collaborate with non-engineers in order to care competently.

VI. IMPLICATIONS AND CONCLUSIONS

This work has several implications on teaching and learning engineering. It shows a need to help students better understand and appreciate the complexity of the e-waste recycling problem, and to recognize the need for cross-disciplinary collaboration to address complex problems. Our application of Tronto's care ethics framework sheds light on serious inadequacies for ethical caring for many of the students in our sample. This work has value in making clear what elements of care engineering undergraduates can already exhibit and the extent to which they do so. It also points to what elements educators need to attend to in explicitly helping students learn to become more effective care givers in society. This work also provides a concrete example of how care ethics, which we have argued elsewhere [20] as a neglected dimension in traditional engineering ethics curricula, might be instantiated in the classroom. Furthermore, this work suggests that care ethics, as operationalized by Tronto's framework, may be useful for assessment purposes, i.e., that care ethics is not just abstract and feel-good philosophy but has practical use as a concrete way to think about stakeholders and their responsibilities, competencies, and interactions. Finally, given the recent initiatives and interest in situating engineering education in real-world contexts (e.g., problem-based learning and service learning), care ethics provides a way to articulate and leverage the educational benefits that real-world context can offer. Such context can help re-humanize engineering education by providing the learner with an important intrinsic motivational factor: the opportunity to care about the people engineers aim to serve and the environment on which we all depend.

The implications of this work also go beyond engineering education. For example, from a researcher perspective, this work shows that Tronto's framework can be a useful operationalization of care ethics that deserves further exploration and development. From the perspective of engineering practice, educating engineers to be attentive, responsible, and competent in their work will help to create a more ethical and caring workforce that is better able to engage in addressing modern issues, such as climate change, globalization, and social justice.

Additional work is in progress and includes performing a similar analysis of additional student essays, and examining indications of what engineers and other stakeholders should do in order to exercise their responsibility. Future work will also look at other data sets, such as capstone design project reports, in which other elements of Tronto's framework, such as Competence and Responsiveness, can be examined.

ACKNOWLEDGMENT

The authors thank the students who consented to their assignments' use as research data. Pedagogical and curricular exploration and innovation can sometimes create unfamiliar and even uncomfortable learning environments for both students and teachers. We are grateful to our students for their patience and flexibility, as it is only through experimentation that we can find new approaches to teaching and learning that meet the needs of a rapidly changing world.

Work in Progress: Does Motivation Matter for Conceptual Change?

Exploring the Implications of “Hot Cognition” on Conceptual Learning

Holly Matusovich

Assistant Professor, Engineering Education
Virginia Tech
matushm@vt.edu

Rachel McCord

Graduate Student, Engineering Education

mrachel@vt.edu

Abstract—This Work in Progress paper describes a five-year study where we apply a *hot cognition* framework to analyze the perspectives, experiences, and practices of faculty and students with regard to conceptual learning. Although this project focuses specifically on thermal sciences, the results are expected to be generalizable across engineering conceptual domains. The project involves three sequential phases, each guided by research questions and leading to five measurable outcomes that contribute to the understanding of intentionality and conceptual change.

Keywords— *conceptual understanding; intentionality; engagement; hot cognition; teaching strategies*

I. INTRODUCTION

One critical challenge facing engineering education is to develop graduating engineers with the extensive technical expertise needed to lead innovation. This challenge demands a robust understanding of how engineering students learn in order to create environments that best support technical mastery through deep, conceptual understanding of core concepts. Researchers and educators alike know that engineering students enter undergraduate programs with misconceptions about critical engineering concepts. We also know that some students effectively engage in learning and correcting misconceptions, while for others the misconceptions persist – often through graduation and into their professional careers [1,2]. To address this issue, educators need to better understand how students learn, and particularly how they engage in conceptual learning. “*Hot cognition*,” which merges traditional cognitive approaches with a robust exploration of learner’s *intentionality* – i.e. why and how they choose to engage in learning – provides a critical framework to span this gap. This powerful, holistic approach will enhance our existing understanding of students’ misconceptions and maximize the impact of on-going efforts to promote conceptual learning in engineering.

First introduced by Pintrich, Marx and Boyle in 1993 [3], *hot cognition* moves away from “cold” approaches that consider only knowledge structures to add intentionality, recognizing that learners make choices about whether to engage in learning and which learning strategies to use. In positing *intentional conceptual change*, Pintrich argued that “learner’s intentions can determine the likelihood of knowledge change” [4, pg iX]. While research among K-12 students has confirmed the importance of intentionality in conceptual

change [4-6], we know comparatively little about students’ motivation and the learning approaches they choose (i.e., learning strategies) in relation to conceptual understanding at the college level, and more specifically in engineering classrooms [7]. We know even less about what teaching strategies would support motivation to engage in intentional conceptual change.

Consistent with the idea of intentional conceptual change, Linnenbrink and Pintrich proposed a framework (Figure 1) to explain how *hot* conceptual change occurs [4]. The core precept of their model is that motivation for conceptual change determined how the learner will approach the task of learning. This model starts with a primary categorization of students’ motivation under *Achievement Goals* then considers *Other Motivational Beliefs* and the associated *Learning Strategies* as contributing to *Intentional Conceptual Change*.

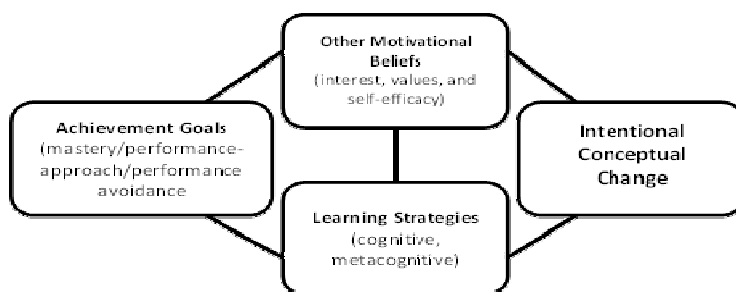

Figure 1: Framework for Intentional (*Hot*) Conceptual Change

II. PROJECT RESEARCH PLAN

The project involves three sequential phases, each guided by research questions ultimately leading to five measurable outcomes. Each phase is discussed in further detailed.

A. Phase I

1) Research Questions:

- What are the intentionality factors (i.e., student motivation and learning strategy choice) and relationships among these factors that lead to successful conceptual change? (RQ 1)
- What are the faculty beliefs about students’ intentionality in conceptual change and what teaching strategies do they use to promote conceptual change? (RQ 2)

2) *Data Collection and Analysis:* Data will be collected through a nationwide survey deployment (pre/post) that will measure student motivation and learning strategies (instruments such as, but not limited to, the Motivated Strategies for Learning Questionnaire (MSLQ) survey) and conceptual understanding using the Thermal and Transport Concept Inventory (TTCI) from an estimated 2,000 students (<http://thermalinventory.com/>) [8]. Survey data will also look at faculty beliefs about student motivation, learning strategies, conceptual understanding, as well as faculty teaching strategies from an estimated 60 faculty members. To gain deeper information from survey responses, follow up interviews will be conducted with approximately 35 students and 15 faculty members.

3) *Outcomes:*

- Identification of student intentionality factors and resulting synergy that leads to successful conceptual change
- Identification of faculty beliefs about students' intentionality in the conceptual change process and the teaching strategies used to promote conceptual change

B. Phase 2

1) *Research Questions:*

- What regular daily and/or critical incidents (instruction/learning experiences) precipitate conceptual change in a one-semester thermal sciences engineering course (RQ 3)
- What daily and critical classroom teaching and learning experiences do students say help or hinder development of conceptual understanding (Sub RQ 3a)
- What daily and critical teaching experiences do faculty say help or hinder development of conceptual understanding? (Sub RQ 3b)

2) *Data Collection and Analysis:* Data collection will consist of using real-time data collection methods through smart phone applications and online tools. Data from Phase 1 surveys and interviews will be used to inform the survey development for Phase 2. This data will be collected at 10 case study sites that will be determined from data collected in Phase 1. Sites will be chosen to provide for a variety of experiences from students and faculty members participating in Phase 1. Approximately 100 students and 10 faculty members will participate in Phase 2.

3) *Outcomes:*

- Descriptions of regular student learning experiences contributing to conceptual change.
- Categories and classifications of critical teaching and learning incidents contribution to conceptual change

C. Phase 3

1) *Research Question:*

- What teaching practices, based on Phase 1 and 2 outcomes, support and encourage conceptual change? (RQ 4)

2) *Data Collection and Analysis:* Using five test sites identified from Phase 2, teaching strategies will be developed

and implemented with the help of faculty partners. Pre/post surveys will be given to evaluate the effectiveness of each method. Surveys will be developed using motivation scales (like, but not limited to, the MSLQ) and TTCI survey instruments (<http://thermalinventory.com/>) [8]. This will be a quasi-experimental design when combined with Phase 2 data. An estimated 250 students (approximately 50 students from each site) and 5 instructors (1 from each site) will participate in Phase 3.

3) *Outcomes:*

- A list of tested strategies to promote intentional conceptual change

III. SUMMARY

A critical challenge of engineering education is to develop engineers with the technical expertise needed to meet industry demands. Many students graduate with an engineering degree with misconceptions on critical engineering concepts. Past research has focused on only knowledge structures when studying conceptual change. This study seeks to add students' intentionality in learning to develop a better understanding of why students engage in the classroom to move towards conceptual understanding. At the conference, we will present pilot data from surveys and interviews from Phase 1.

Work in Progress: Development of Computer Modules to Improve Student Metacognition and Motivation Strategies

Michele Miller, Laura Roberts, Kevin Hale, David Lanier, James De Clerck, William Endres, Sheryl Sorby

Mechanical Engineering—Engineering Mechanics Department

Michigan Technological University

Houghton, MI, USA

Abstract—This project aims to advance personalized learning by helping students to understand and regulate their own learning. The project is designed to equip students with the knowledge, skills, and attitudes of self-directed lifelong learning. We developed two online modules—one on learning styles and the other on motivation. We have begun to test the effectiveness of the modules in two mechanical engineering classes—a sophomore manufacturing class and a junior design class. The modules themselves record data such as preferred learning style, MSLQ scores, pre and post knowledge on topics presented in the module, and module evaluations. In addition, we administered brain dominance and lifelong learning readiness instruments to control and intervention groups. We intend to monitor the changes in brain dominance and lifelong learning readiness over time for the control and intervention groups.

Keywords—lifelong learning; e-learning; learning styles; motivation strategies

I. INTRODUCTION

Given the pace of technological change, engineering graduates of today must be prepared for a lifetime of learning and adaptation. Some argue that the skills they learn at the university are already outdated by the time they graduate. For this reason, the ABET outcome “a recognition of the need for and an ability to engage in life-long learning” may be one of the most important outcomes for a BS engineering graduate. However, few curricula explicitly teach life-long learning skills. Our approach is to develop computer modules that help teach these skills.

Personalized learning must take into account individual differences in learning style and motivational factors. Although no learning style classification scheme has 100% acceptance among educators, several classification schemes have achieved some degree of prominence. The Kolb learning style inventory measures a learner’s strength in four learning modes: concrete experience, reflective observation, abstract conceptualization and active experimentation [1]. Another instrument—the learning styles profiler—includes the effects of temperament and character and is used in work as well as educational settings [2]. Most familiar in engineering education is the work of Felder and Silverman [3] who proposed four learning style dimensions: active vs. reflective, sensing vs. intuitive, visual

vs. verbal, and sequential vs. global. The VARK learning style questionnaire identifies four primary learning modes: visual, aural, read/write, and kinesthetic [4]. The Barsch Inventory is similar to the VARK and identifies four learning styles: visual, auditory, tactile, and kinesthetic [5].

Even when learning and teaching styles are well matched, no learning will take place without the motivation to learn. Motivation comes from a variety of sources and is affected by a number of factors. Two primary aspects of motivation are value and expectancy [6]. The 81 question motivated strategies for learning questionnaire (MSLQ) probes the sources of motivation and includes questions in the areas of intrinsic goal orientation, extrinsic goal orientation, task value, control beliefs, self-efficacy, and test anxiety [6]. Teaching tips that correspond to each of the questions in the MSLQ have been developed [7]. These can be recast as strategies that students can apply themselves.

Pintrich identifies four areas for self-regulation: cognition, motivation/affect, behavior, and context [8]. The self-regulation cycle includes four phases: planning, monitoring, control, and reflection. This project focuses on the first two areas (cognition and motivation) and the middle two phases (monitoring and control). Our objective is to develop and test e-learning modules that raise student awareness of their own cognition and motivation and subsequently provide strategies for improving learning.

II. E-LEARNING MODULES

We developed two computer modules, one on metacognition (specifically learning styles) and the other on motivation. As shown in Figure 1, the metacognition module begins with the Barsch Learning Style Inventory, which could be used free of charge with permission. It proceeds to two biology tutorials (on mitosis and Punnett square). We chose two topics that most mechanical engineering students would know little about. At random, one of the two topics is presented in the most preferred learning style while the other is presented in the least preferred style. This gives students a first hand experience of the influence of learning style. Next, the module presents strategies that correspond to each learning style, and it concludes with reflection and module evaluation questions.

| Metacognition Module |
|--|
| <ul style="list-style-type: none"> • Barsch Learning Style Inventory • Pre-test on mitosis (or Punnett square) • Tutorial on mitosis (or Punnett square) using least (or most) preferred learning style (visual, auditory, tactile, or kinesthetic) • Post-test on mitosis (or Punnett square) • Pre-test on Punnett square (or mitosis) • Tutorial on Punnett square (or mitosis) using most (or least) preferred learning style • Post-test on Punnett square (or mitosis) • Present the results of Barsch Inventory to the student • Tutorial on strategies for different style learners • Post-test on learning style strategies • Questions asking students to reflect on the learning experience and to evaluate the module |

Figure 1. Content of metacognition module

| Motivation Module |
|---|
| <ul style="list-style-type: none"> • Motivated Strategies for Learning Questionnaire • Task value manipulation <ul style="list-style-type: none"> ○ Pre-test on osmosis (or northern lights) ○ Tutorial on osmosis (or northern lights) ○ Post-test on osmosis (or northern lights) ○ Repeat the above with northern lights (or osmosis) ○ Reflection questions on task value • Control beliefs manipulation <ul style="list-style-type: none"> ○ Pre-test on photosynthesis (or aluminum can manufacturing) ○ Tutorial on photosynthesis (or aluminum can manufacturing) with high or low complexity content ○ Post-test on photosynthesis (or aluminum can manufacturing) ○ Repeat the above with aluminum can manufacturing (or photosynthesis) ○ Reflection questions on control beliefs • Present the results of the MSLQ to the student • Tutorial on motivation strategies • Post-test on motivation sources • Questions asking students to reflect on the learning experience and to evaluate the module |

Figure 2. Content of motivation module

The motivation module, outlined in Figure 2, begins with the Motivated Strategies for Learning Questionnaire (MSLQ). To manipulate task value, the module presents tutorials on osmosis and the northern lights—topics chosen to elicit different levels of student interest. After reflection questions on task value, the module presents two topics that should differ in difficulty for mechanical engineering students. To further manipulate control beliefs, the module informs the student that many mechanical engineers find photosynthesis to be a difficult topic. Also, two versions of each control beliefs tutorial were created that differ in complexity level. In other words, there is a low complexity version and a high complexity version of both the photosynthesis and manufacturing tutorials. This is

followed by reflection questions on control beliefs. The module concludes with motivation strategies and evaluation questions.

III. DATA COLLECTION

In the spring 2012 semester, students in two classes participated in a study of the effectiveness of the e-learning modules. Early in the semester, a group of 137 students took a brain test that measures left and right brain dominance and a lifelong learning readiness test. Later in the semester, 56 students completed the metacognition and motivation modules. At the end of the semester, most of the 137 students re-took the lifelong learning readiness test. We are beginning to analyze the data from the spring 2012 semester. To determine how well the modules demonstrate the importance of learning styles and motivation, we will look at changes in test scores from pre to post as well as the student reflections. For example, we expect that material presented in the preferred learning style will lead to greater improvement in test score. We also expect students to report more difficulty in learning material when their motivation level is low. The results of this analysis will lead to improvements in the modules. In the longer term, we will continue to collect data on lifelong learning readiness from both the control and intervention (took modules) groups and monitor changes over time from the second to fourth years of the student's program.

Work in Progress: *Building a K-12/University Biotechnology Learning Community*

Carla Romney, Carl Franzblau, Donald DeRosa

CityLab

Boston University School of Medicine

Boston, MA USA

romney@bu.edu, franzbla@bu.edu, derosa@bu.edu

Abstract— In 1992, Boston University School of Medicine launched CityLab, its innovative biotechnology education outreach program that has been disseminated across the country. CityLab serves students in grades 7-12 and their teachers. Since CityLab's founding, approximately 200,000 students have participated in hands-on, discovery-oriented investigations and more than 2,000 teachers have attended professional development workshops at Boston University. As is typical for most STEM outreach projects, CityLab has developed extensive partnerships with public and private schools that are located near its main location. Recently, CityLab expanded its scope by forging a unique partnership with high school students and teachers from an under-resourced rural area in North Carolina located 1000 km from Boston. Through this experience, we have explored how to create, nurture, and sustain a long distance K-12/University partnership. Herein, we share the lessons learned from this project.

Keywords- *K-12; university; partnership; biotechnology; laboratory investigation*

I. INTRODUCTION

Since CityLab's inception twenty years ago, it has focused on improving students' interest in and understanding of the biological sciences through hands-on laboratory experiences. CityLab is housed at Boston University School of Medicine and its facilities include three on-site laboratories for students and MobileLab, a mobile laboratory that brings state of the art biotechnology experiences to students and teachers at their schools. CityLab has authored its own curriculum supplements and disseminates them widely. To date, more than 500,000 middle and high school students and teachers have worked with CityLab materials.

CityLab has always worked closely with public and private schools in its cachement area. Teachers have collaborated with CityLab staff on curriculum development efforts and have piloted new materials in their classrooms. CityLab has also offered professional development workshops for teachers who are interested in biotechnology. As is typical of most collaborations between institutions of higher education and K-12 school districts, the participants are located within commuting distance of one another. This geographical proximity facilitates early morning or late afternoon face-to-face meetings.

CityLab has provided assistance to university faculty throughout the U.S. and abroad who want to develop CityLab

programs on their own campuses. While CityLab remains in contact with these satellite programs, no on-going collaboration between the groups has emerged from these interactions.

In 2009, CityLab was contacted by members of the Bertie County, NC community who were not directly affiliated with the local schools. They recognized that student achievement in the sciences was inadequate and they sought assistance. The three authors of this paper traveled to Bertie County to meet with community and school district stakeholders. The Bertie-CityLab collaboration is CityLab's first attempt to establish a long distance K-12/University partnership.

II. DEVELOPMENT OF THE PARTNERSHIP

Most science education partnerships between university faculty members and K-12 teachers are formed through direct interactions of the participants rather than as a result of agreements made by senior administrators of the collaborating institutions. The NC-CityLab partnership is unique because the K-12 science teachers did not pursue the collaboration; a few science and mathematics teachers were invited to attend CityLab's presentation to the district's senior administrators that described CityLab and proposed possible collaborative efforts. Interestingly, the teacher who has been most engaged in this collaboration was not present at the initial meeting.

During the initial discussion, CityLab proposed that NC students and teachers come to Boston to participate in CityLab's SummerLab, a week-long inquiry-based program that provides students with an opportunity to learn and apply fundamental biotechnology concepts through an immersive biotechnology laboratory experience. For the NC-CityLab partnership, we coupled SummerLab with academic enrichment and an exploration of the college admissions process. The NC students and teachers lived in Boston University undergraduate dormitories and experienced college life.

Financial considerations were an immediate concern for this fledgling partnership. The NC students might not have participated if they had to pay for the program. Fortunately, a generous grant from the Biogen Idec Foundation provided funds to cover the travel costs, room and board, and tuition for the NC students and their teachers to come to Boston.

During the summer of 2010, eight students and two teachers from Bertie County, NC spent three weeks at CityLab. After the one-week SummerLab program in which students

learned about bacterial transformation, protein purification, and other recombinant DNA laboratory techniques, the students spent two additional weeks in Boston and explored additional topics in experimental science and mathematics as well as attended college preparatory seminars. During the same three-week period, the Bertie teachers learned the content, pedagogy, and logistics of using laboratory investigations to teach biotechnology to their classes.

We refined this program for the summer of 2011 and implemented an integrated two-phase program for the students and teachers from Bertie and neighboring counties in NC. The first phase was identical to the first week of the 2010 program and consisted of student and teacher participation in the SummerLab program. However, in 2011-2012 we eliminated the second and third weeks in Boston and instead launched an academic year program in NC that consisted of monthly meetings to explore advanced molecular biology topics. These sessions were led by a teacher who participated in the teacher program in 2010 and 2011 at a Bertie County high school.

In order to provide on-going professional development for the teacher in NC, we scheduled conference calls via skype (web-based video conferencing). These calls give the teacher a chance to ask questions about the laboratories and also provide an opportunity for additional content and pedagogical support.

III. EVALUATION RESULTS

Preliminary results from the first phase of the partnership were assessed using pre/post tests of content understanding, a survey of students' understanding of science and scientific inquiry (SUSSI)[1], and student focus group responses. Due to the small number of participants (n=8), statistical analysis was not performed, but the data show that students achieved small gains in their understanding of science content at nominal, structural, and functional levels of literacy. Students also valued the opportunity to modify protocols and design/perform their own experiments. This finding suggests that future programs incorporate additional opportunities for students to think and act independently in the lab.

A fortuitous re-alignment of teaching responsibilities for the key Bertie teacher allowed her to spend 2011-2012 building a biotechnology laboratory in her classroom. This made it possible to offer a monthly biotechnology enrichment program in NC. She also used this classroom laboratory to develop and teach a biotechnology class to her students.

IV. LESSONS LEARNED

While many scientists and teachers have opined about the characteristics of successful local or regional K-12/university partnerships to promote STEM achievement, there is a dearth of research on the characteristics of successful collaborations, whether local or long distance distances [2]. A recent attempt to assemble a comprehensive database of organizations involved in science education partnerships has resulted in the creation of the STEMconnector database. This resource, launched in November 2011, is available at www.stemconnector.org/stemdirectory and lists state by state STEM activities. The STEMconnector database is "a tool to establish partnerships with a broad cross section of

organizations working in STEM Education [by increasing] reach and connectivity in regions through working relationships" [3]. This effort focuses on local partnerships but fosters the development of long distance collaborations.

Four recent reports discuss the obstacles that are commonly encountered by science education partnerships [2, 4-6]. Among the most important challenges that need to be overcome are finding common ground and mutual understanding, creating a partnership that will last and evolve over time, aligning the activities to meet the needs of the participants, and allocating time to interact with one another. Garnering the support of school/district administrators is often thought to be essential for the success of the partnership [5].

Science education partnerships are fragile, even when they exist in one's neighborhood. Sustainability and persistence are integral to the success of a long-distance partnership, as are flexibility, good humor, and genuine rapport. We have learned that because schools are in flux- students, teachers and administrators move or are re-assigned frequently- it is important to involve those who want to participate and empower them to serve as ambassadors for the partnership. People who are part of the community are best suited to advocate for the partnership.

Moreno describes several models for partnerships including the Superman model, in which one partner single-handedly tries to rescue the other, and the Batman and Robin model in which a more experienced partner mentors or guides a less experienced partner [5]. She indicates that Superman-style partnerships rarely succeed but Batman and Robin-style partnerships are more likely to succeed. In many sense, the NC-CityLab partnership has evolved from a Superman to a Batman and Robin partnership.

ACKNOWLEDGMENT

We are grateful to the teachers and students from NC, especially Ms. Karen Sharpe of Bertie Early College High School. We also thank the Biogen Idec Foundation for its support of this partnership. Without their unwavering support, we might never have launched this long distance partnership.

Abstract— Active and project-based learning (PBL) strategies provide a great means for students to enhance their learning and further develop critical engineering skills. In order to guide students to a higher level of learning, a critical reflection process has been incorporated into upper level and graduate civil engineering classes that utilize PBL. This paper presents a model for classroom practice for enhancing student skill development through critical reflection as part of PBL that is based on existing theory on learning.

Keywords: active learning, reflection, critical thinking

I. INTRODUCTION: BACKGROUND AND MOTIVATION

Active and project-based learning (PBL) strategies provide a great means for students to enhance their learning and further develop critical engineering skills. PBL provides complex tasks based on challenging questions or problems that involve the students' problem solving, decision making, investigative skills, and reflection [1-8]. The activities are student centered and focus on real-world problems and issues, which further helps motivate students to learn. However, students still struggle with making decisions between approaches and when not given exact procedural steps want the reassurance they are "doing the correct thing" to meet the project requirements [2, 4, 9]. Higher-order thinking by students involves the transformation of information and ideas. This transformation occurs when students combine facts and ideas and synthesize, generalize, explain, hypothesize or arrive at some conclusion or interpretation. These skills are valued because they better prepare students for the challenges of professional practice and daily life, as well as for advanced academic work. Bloom's revised taxonomy is a multi-tiered classification system for learning that identifies six cognitive process categories in increasing complexity. Research indicates that PBL can frequently and reliably get students to reach the Applying level, student's struggle with the Analyzing and Evaluating levels, and frequently do not reach the Creating level of the taxonomy.

There is a need within engineering for our students to reach these higher levels of Bloom's on a more consistent basis. The importance of effective critical thinking skills has been recognized by many employers and educational institutions. The U.S. Department of Education stated as a goal that "the proportion of college graduates who demonstrate an advanced ability to think critically, communicate effectively, and solve

problems will increase substantially [10]." This goal was then incorporated as part of the "Goals 2000: Educate America Act" passed by Congress [11]. The importance of preparing students to think critically has also been advocated by educators at all academic levels [12-16], and a report from the American Association of Universities indicated the importance of preparing people to think critically and to solve problems were essential for college success [17].

The need for these skills are directly tied to the learning outcomes specified by the Accreditation Board for Engineering and Technology (ABET) [18], as well as desired outcomes specified by professional engineering societies, such as the American Society of Civil Engineering's Body of Knowledge [19]. This report defines twenty-four outcomes that make up the knowledge, skills and attitudes necessary to practice civil engineering and utilizes Bloom's taxonomy to outline the necessary level of achievement for each of them. However, intellectual development towards higher levels of thinking requires careful planning and is a slow process [20-23]. Research has shown that learning activities need to engage students in taking ownership of their own learning as well as address multiple learning styles to be effective at getting students to reach higher levels of thinking [24-40].

In order to guide students to a higher level of learning, a critical reflection process has been incorporated into upper level and graduate civil engineering classes that utilize PBL. When learners reflect, they thoughtfully consider (or reconsider) an event or experience. If the reflection is critical, it challenges the customary ways of understanding or explaining an experience.

Using reflection to improve thinking is not a new idea; Dewey stated, "Reflection involves not simply a sequence of ideas, but a consequence—a consecutive ordering in such a way that... 'thinking,' in its best sense, is that which considers the bases and consequences of belief" [26]. This definition of reflection was revised a couple decades later to "Active, persistent, and careful consideration of any belief or supposed form of knowledge in the light of the grounds that support it and the further conclusion to which it tends [26]." This definition fits well with the description of critical thinking by Diane Halpern: "Critical thinking refers to the use of cognitive skills or strategies that increase the probability of a desirable outcome. Critical thinking is purposeful, reasoned, and goal-

directed. It is the kind of thinking involved in solving problems, formulating inferences, calculating likelihoods, and making decisions [41].”

Dewey defined the educational process as a "continual reorganization, reconstruction and transformation of experience [27]." The ideas espoused by Dewey led Kolb and others toward a model of experiential learning, a model where learning occurs in a cycle of concrete experience, reflective observation, abstract conceptualization, active experimentation, and repetition [36, 37]. The processing of knowledge lies on a continuum between active experimentation (doing) and reflective observation (watching), and the perception of knowledge lies on a continuum between abstract conceptualization (thinking) and concrete experience (feeling). Reflection seems for many students to be a missing link in the learning process.

Critical reflection questions meanings and looks at assumptions. The opportunity to reflect on experiences develops critical thinking skills and helps students to learn things for themselves. However, students are not born knowing how to reflect on experiences, critically or otherwise. It is important to structure prompts that guide students to make in-depth considerations of their thinking process, including assumptions, various alternatives for the solution process, and how to improve their future work.

The outcomes of this process, as shown in prior research, include:

- **enhanced motivation:** to improve the quality of both the learning process and the ability to give (and receive) constructive feedback;
- **improved cognition and social outcomes in learning:** to encourage deeper level or higher-order thinking, and to develop collaborative skills;
- **an increased sense of responsibility for one's own learning:** to enhance ownership of the learning process and the constructed knowledge; and
- **improved metacognitive skills:** to enable students to reflect more critically on their learning.

This paper presents a model for classroom practice for enhancing student skill development through critical reflection as part of PBL that is based on existing theory on learning. Evidence of the effectiveness of this strategy is presented, through a qualitative assessment of student reflective essays. Additional results will include student perceptions of the process and its value.

II. IMPLEMENTATION

The critical reflection was incorporated as part of a project-based learning experience that incorporated a technical review of work-products by other students in the course. The technical review was performed prior to the critical reflection assignment, giving students a different perspective on the project prior to asking them to critically consider their own process and final product. This approach was implemented in a range of courses from junior through graduate levels.

For all courses the technical review required students to evaluate the available choices, with an emphasis on the rationale and impact of the engineering decisions made. The decisions include both modeling and analysis options as well as design alternatives and choices. Due to the variability built-into the projects, no single solution key is possible and should not be given to the students even in cases where a unique solution may be achievable as grading is not the goal. Students need to be guided on how to perform a critical evaluation of the technical content and provide meaningful feedback.

The critical reflection assignment then explicitly asked students to consider learning that occurred during the assignment. To guide students through the process, questions and prompts were given. While the details of the questions varied slightly to emphasize the specific course, they had the following common bases:

- What are the strengths of the work you submitted? Weaknesses?
- What assumptions did you make? What (other) assumptions did you consider?
- What (other) methods did you consider for analyzing this situation?
- How do you know your answer is the best available solution?
- If applicable, at what point in the process did you realize that there was an error in your process or solution? How did you get “stuck” working on the project tasks? How did you and your group get “unstuck?”
- How could you have approached the problem or situation differently?
- What made this exercise/problem/project easy/difficult?
- What lessons will you take with you to the next problem/project?

III. ASSESSMENT RESULTS

A. Analysis of Reflective Essays

A qualitative analysis of reflective essays was undertaken in order to gain an understanding of the student’s perspective on their learning. These were divided into three subcategories: (a) personal learning experiences, (b) learning experiences relating to skills and (c) professional learning experiences.

1) Personal Learning Experiences

Students reported that the technical review and reflection process resulted in personal learning experiences which they interpret as personal growth.

“The project served as a test of handling grand intricate tasks. It was an exercise which taught me how to systematically approach a daunting problem. In the little amount of time and in a midst of a heavy course load, this project was a show of time management.” (graduate dynamics)

Students also think that they obtain additional perspectives on the projects.

“Through the review process, I was able to see different methods used to generate an approximate SDOF (single degree of freedom) model. This led me to consider the pros and cons of their models and the one our group chose.”
(graduate dynamics)

“Seeing how other groups solved the same problems in different ways and having to comment on what they did took more thought than I had anticipated. When you see an alternate process, you naturally call your own process into question. So in order to give meaningful commentary, you actually have to go back and clear up any uncertainties in your analysis.” (graduate dynamics)

2) Learning Experiences Relating to Skills

Students gain many technical skills throughout a PBL experience. When multiple solutions and/or approaches are possible, reviewing the work of a peer allows students to more readily perceive alternatives. They also become more cognizant of the strengths and weaknesses of each approach, and how various skills must be integrated to solve a task.

“While performing the reviews I learned a great deal about various methods to performing a push-over analysis. The two groups that I reviewed as well my own group all solved the push-over analysis using a different method. One group used a completely linear push-over analysis, in which they would remove members from the model once they had failed, until they perceived that the building had reached failure. The other group used SAP’s push-over analysis by force-control option, while my group used SAP’s push-over analysis by displacement control option. From reading all three reports, I learned that no matter which method was used, it was always difficult to determine when your building had actually failed.

In all three cases failure of the building was based on engineering judgment of the results. In no method does SAP tell you when your building has failed. Throughout my studies, my professors have lectured on the importance of structural engineers to be able to understand how a building should act under prescribed loads. After performing my own push-over analysis and reading the other reports, I firmly believe this to be true if I want to be a good engineer. I would rate my learning” (graduate finite element)

3) Professional Communications

In this category, students reported about learning experiences regarding how communicating ideas and processes was critical to how their work was perceived.

“I realized how important it is to be completely clear when presenting an idea... If a classmate cannot understand the concept, a client will definitely not be able to understand.”
(undergraduate design)

“While reviewing others’ work, I continually thought, “We could have done a better job on our report had we considered

this,” or, “this would have been a better way to communicate this concept in our report.”” (graduate finite element)

“It is important to present your information in a way that is understandable for someone who literally just picks up your report and has no idea what you are doing initially. Anyone can make stacks and stacks of analysis and output, but until you present it in a manner that is easy to understand it literally means nothing to anyone outside your project group.”
(graduate dynamics)

“One paper that I analyzed referred to tables and figures much later than the figures and tables were presented. I found that it is much easier and effective to follow a paper if the tables and figures are shown immediately after they are described. I was unaware of how much a disorganized paper distracts from the analysis being presented prior to analyzing other groups.” (graduate finite element)

B. Faculty Perceptions

Most students can do a meaningful technical peer-review (even of a broad civil engineering project), while they are limited in what they can do in grading – they do not have the experience to judge partial credit well, they provide very good feedback and assessment). As they reflect on what they learned through doing the technical assessment of peer work as well as reviewing their own submission, students also gain insight into what makes a good (or bad) project; they learn what is required of an adequate description and realize how easy it is to detect lack of effort. Finally, the review process provides peer pressure to raise the bar.

“I also learned that it is painfully obvious when a report was rushed” (undergraduate design)

“I literally could compare my group’s work with others that were better or worse off than ours and how much effort some had put to create their memos” (undergraduate design)

“After reviewing other’s work, I could find out a lot many things that I could have done differently and reached better results” (graduate finite element course)

“one of the reports I reviewed was well written and masterfully done... it makes me feel like such a slacker”
(graduate finite element course)

A common thread in the reflections, or self-reviews, was that top students were more critical of their own work than their classmates. In contrast, weaker students self-review was consistently higher than that of their classmates on their work. This can in part be attributed to top students being more aware of their state of knowledge and how to improve their work, which is a component of student metacognition. However, both groups of students in general were able to identify areas that could be improved through the self-review, even before receiving the comments from their classmates. As a result of

both peer and self-reviews, the quality of the final work product improved.

IV. FUTURE WORK

An issue with the reflections, or self-reviews, was that some students were less able to do reflection than others. In some cases, student reflections were somewhat superficial and focused on facts rather than reaching a metacognitive level. This problem is particularly evident in reflections by international students, where language already is a barrier. Future implementations will include additional cycles so as to provide training and calibration of the review and reflection process. This should allow even the weakest reflections to touch on a metacognitive level.

V. SUMMARY

Critical reflection of both peer and own work products develops critical thinking skills and helps students to learn things for themselves. By first reviewing peer work, students can more objectively look at the work and see what could be improved. Since they are not emotionally invested in the work submitted, they have the benefit of perspective. It is then easier to look at their own work product more objectively and be more aware of alternatives and choices that were available during the process.

An important effect of the technical peer review cycle is that of raising the bar; once students see better quality work from some of their classmates, it is more difficult to assume that they can get by with inferior results. Not only do student motivation increase and the overall quality of the student work improve; but all desired learning outcomes show an improvement as a result of the technical review activity. Additionally, professionalism, communication, and other ABET outcomes also benefit in the process. ("a rising tide lifts all boats"... often attributed to JFK, 1963). This simultaneous improvement in all learning outcomes likely results from the increases in the metacognitive and critical thinking skills of the students.

Using Inquiry-Based Activities to Repair Student Misconceptions Related to Heat, Energy and Temperature

Bucknell University
Lewisburg, PA

Abstract— *This study examines the effectiveness of inquiry-based activities for addressing student misconceptions related to four concept areas in the thermal sciences that have been identified as both important and difficult for students to master: (1) temperature vs. energy, (2) factors that affect the rate vs. the amount of energy transferred, (3) temperature vs. perceptions of hot and cold and (4) the effect of surface properties on thermal radiation. Students' conceptual understanding was assessed using the newly developed Heat and Energy Concept Inventory (HECI). In the control sample, student performance on the overall HECI improved from 49.2% correct to a post-instruction performance of 54.4% correct. Using inquiry-based activities, the mean performance on the HECI improved from 46.6% correct prior to instruction to a post-performance score of 65.7%. Significant learning gains were found in each of the targeted concept areas when the activities were used. The study also examined the impact of the activities on near vs. far transfer of learning and found statistically significant improvements for both, but larger learning gains on HECI items involving near transfer.*

Keywords-component; formatting; misconceptions; heat transfer; inquiry

I. INTRODUCTION

There is broad recognition that meaningful learning requires that students master fundamental concepts. Understanding concepts and the connections among concepts is one of the primary distinctions between experts and novices [1; 2]. Conceptual understanding is also a prerequisite for students to transfer what they have learned in the classroom to new settings, something that is arguably among the most significant goals of an engineering education.

While there is little disagreement about the importance of conceptual learning, a wealth of evidence drawn from decades of research in the sciences [3-6] and a growing literature in engineering [7-12] demonstrates that students generally enter our classrooms with misconceptions and that traditional instruction is often ineffective for promoting sizeable conceptual change. Research, much of it in the sciences, has successfully demonstrated that a range of student-centered instructional techniques can significantly improve students' conceptual learning gains [4; 13-15] is a small but growing body of literature in engineering that supports similar conclusions [16; 17].

Several factors explain why engineering education has not yet fully capitalized on the research, primarily in

physics, for addressing student misconceptions. These factors include (1) the unfamiliarity of the relevant education literature to many engineering educators, (2) the lack of concept inventories with good estimates of internal consistency and validity that address core engineering areas and (3) the lack of tested educational materials in engineering similar to those that have been developed and tested in physics. However, significant progress is happening related to each of these issues. The lack of established educational materials specifically designed to repair important misconceptions in the core disciplines of engineering is arguably the predominant missing piece.

The study examines the extent to which inquiry-based activities promote conceptual learning gains in the four concept areas in the thermal sciences that have been identified as both important and difficult for students to master [18; 19]. Those concept areas are (1) temperature vs. energy, (2) factors that affect the rate vs. the amount of energy transferred, (3) temperature vs. perceptions of hot and cold and (4) the effect of surface properties on thermal radiation. In addition, the study examines the effectiveness of the activities for developing students' ability to transfer their conceptual understanding. Transfer relates to the students' ability to extend conceptual understanding acquired in one situation to new contexts [20]. Whether transfer really occurs is still hotly debated [21]. Resolving this debate is hindered by the confusion about how transfer is interpreted in the existing literature. Barnett and Ceci present a clear framework for characterizing transfer that was applied to the present study.

While conceptual change is difficult, a number of approaches have shown promise for promoting conceptual learning relative to traditional instruction. Most of those approaches are active engagement methods and many are inquiry-based. Bernhard [22] provides a good overview of the range of inquiry-based approaches that have been developed for physics education including Physics by Inquiry, Peer Instruction, Real Time Physics, Tools for Scientific thinking and workshop Physics. Prince and Felder [23; 24] provide extensive evidence that a variety of inquiry-based instructional methods are effective for promoting conceptual understanding as well as additional educational outcomes. The framework adopted for the activities presented in this study drew heavily on the Workshop Physics model, the defining elements of which [4] are shown in Table 1.

TABLE 1: Elements of Inquiry-Based Activity Modules [4]

- (a) Use peer instruction and collaborative work
- (b) Use activity-based guided-inquiry curricular materials
- (c) Use a learning cycle beginning with predictions
- (d) Emphasize conceptual understanding
- (e) Let the physical world be the authority
- (f) Evaluate student understanding
- (g) Make appropriate use of technology
- (h) Begin with the specific and move to the general

This approach is similar to that proposed by others [25; 26] and has extensive empirical support [4; 27]. Letters in parentheses in the following description of the activities refer to the elements of Table 1 in order to demonstrate the consistency of the approach employed here with the methods described in Table 1. Students were put in teams (*a*) and asked to predict what would happen in a number of scenarios (*c*). The students were then given physical experiments and/or computer simulations to test their predictions (*b*, *e*, *g*), after which they were asked to discuss how their thinking had changed if their predictions did not match reality. All the questions were conceptual in nature (*d*, *f*), using technology where appropriate (*g*). At the end of the specific activities, students were asked to step back and generalize what they had learned from the specific experiments and in some cases were asked to extend that knowledge to a novel application in order to determine if the learning was transferable to a new situation (*h*).

II. METHODOLOGY

This exploratory study examined the effect of eight inquiry-based activities for improving students' conceptual understanding in 4 targeted concept areas using the newly developed Heat and Energy Concept Inventory (HECI). The instrument was designed specifically to assess these specific concept areas and has demonstrated acceptable estimates of internal consistency reliability and content validity [4; 27]. An assessment of the internal consistency of the HECI was done with the entire post-test and each of the sub-post-tests using the Kuder-Richardson Formula #20 (KR #20) and split-half reliability. Estimates of the internal consistency reliability for the post-test can be found in Table 2.

TABLE 2: Estimates of Internal Consistency

| | KR #20 | Split-half Reliability |
|--|--------|------------------------|
| Total HECI (n = 740) | 0.87 | 0.84 |
| Temperature vs. Energy (n = 736) | 0.60 | 0.46 |
| Temperature vs. Perceptions of Hot or Cold (n = 736) | 0.57 | 0.44 |
| Rate vs. Amount (n = 736) | 0.79 | 0.84 |
| Thermal Radiation (n = 740) | 0.76 | 0.74 |

A quasi-experimental design with intact groups was used to assess learning gains. The two groups were a test group that were given the activities and a control group that was not. Each activity was designed to incorporate each of the elements of inquiry-based activities as defined by Table 1. There were 8 activities tested in this study, two targeting each of the four concept areas of the HECI. Students at each

institution used all of the activities. Participants completed the HECI prior to and after instruction. Measurements for the control group assessed pre/post changes on the HECI under normal conditions, that is, without the use of the activities. Student learning gains for this sample were compared to gains found for a test sample of students who experienced the activities in their heat transfer course.

Descriptive statistics examined changes in knowledge, as measured by the mean scores of participants on the entire concept inventory by activity group or control group as well as in each conceptual area sub-test. One-way analysis of variance (ANOVA) was used to examine the differences between pre and post-test scores of the two groups (e.g., difference in pre-test scores of control and test groups). Analysis of covariance (ANCOVA) was used to examine differences between the control and activities group on the post-test using pre-test scores as a covariate. Dependent t-tests were used to examine pre-post learning differences for both the control group without activities and for the test group with activities. Independent t-tests were used to study the differences between near and far transfer questions. Normalized gains were also used to compare the groups. In addition, effect sizes, using Cohen's *d*, were calculated to show the magnitude of the difference between the means of each group when t-tests were calculated and partial eta square was calculated to show the effect size when analysis of variance (ANOVA) or analysis of covariance (ANCOVA) was done. Each is the appropriate measure of effect size for those tests [28].

The HECI was administered as a pre-test of existing knowledge to a control group of 373 undergraduate engineering students at eleven different universities or colleges. The concept inventory was used in 21 course offerings, five of which were offered at the same institution in two different semesters. Of the 373 respondents, 344 completed the concept inventory again after instruction in a heat transfer course. The test group consisted of a sample of 463 students at ten undergraduate institutions. The HECI was administered as a pre-test of existing knowledge to this group. Of the 463 respondents, 392 completed the concept inventory again after instruction that included administration of the inquiry-based activities. The demographic make-up of both control and activities groups is summarized in Table 3.

TABLE 3: Demographic Information

| Demographic Variable | Control Group (No Inquiry-based Activities) | Activities Group |
|----------------------|---|---|
| Gender | 26.6% female, 73.4% male | 23.1% female, 76.9% male |
| Race | 80.9% White, next largest group, Asian/Pacific Islander 10% | 72.01% White, next largest group, Asian/Pacific Islander 13% |
| Major | 39.5% chemical engineering, 47.4% mechanical engineering, 13.1% other | 46.9% chemical engineering, 38.5% mechanical engineering, 14.6% other |
| Year in B.S. Program | Primarily junior (61.3%) and senior (30.5%) | Primarily junior (57.4%), sophomore (21.1%), and senior (19.9%) |

III. RESULTS

A one-way analysis of variance (ANOVA) showed a significant difference between the test group using the inquiry-based activities and the control group on the total pre-test scores, ($F(1, 834) = 5.37, p > .05$). The control group had a significantly higher mean score (17.70) than the activities group (16.77). Because the mean pre-test scores differed, analysis of covariance (ANCOVA) was used when examining group differences in the mean post-test scores because of its ability to compensate for differing pre-scores [29]. This analysis is also warranted given findings from physics education that indicate that differences in pre-test scores continue despite instruction. [30]. When pre-test was used as a covariate, there was a significant difference with a moderately high effect size between those who used inquiry-based activities versus those who did not on the total post-test, $F(2, 696) = 286.19, p < .01, \eta^2 = .451$.

TABLE 4. Mean Pre/Post Performance Data by Content Area, With and Without Activities

| Content Area | Mean Score, Control (no activities) | | Mean Score, Test (w/ activities) | |
|--|-------------------------------------|----------------------|----------------------------------|----------------------|
| | Pre-Test N = 373 | Post-Test N = 344 | Pre-Test N = 463 | Post-Test N = 392 |
| Temperature vs. Energy | 53.6% | 56.6%* | 52.4% | 62.2%* |
| Temperature vs. Perceptions of Hot or Cold | 61.1% | 70.4%* | 57.3% | 73.1%* |
| Rate vs. Amount | 36.8% | 42.6%* | 33.5% | 62.9%* |
| Thermal Radiation | 44.6% | 50.8%* | 40.9% | 63.0%* |
| Overall | 49.2% | 54.4%* | 46.6% | 65.7%* |

*significant change at the $p < 0.01$ level

Paired samples t-tests showed that there was a statistically significant improvement from pre- to post-test scores for both the test and the control groups. A summary of the results as assessed by pre/post measurements using the HECI for both the control and test groups is shown in Table 4. As can be seen from the table, while student learning gains in the control group were statistically significant, they were modest ($t(336) = -7.737, p < 0.01, d = 0.42$) with a moderate effect size. By contrast, the significant improvement with inquiry-based activities was larger (mean score of 46.6% on the pre-test to a mean score of 65.7% on the post-test), ($t(361) = -24.31, p < 0.01, d = 1.28$) with a very large effect size. Effect sizes of 0.50 or larger indicate important findings [29].

As can be seen in Table 4, paired samples t-tests showed significant improvement from pre- to post-test on each of the sub-tests with and without activities. However, effect sizes as measured by Cohen's d were uniformly larger for the activities group. For example, for the Rate vs. Amount of heat transferred sub-test, there was a significant difference from pre- to post-test for the control group, $t(323) = -4.328, p < .01, d = .24$ with a small effect size. For the Activities group, there was also a significant difference from pre- to post-test with a large effect size, $t(361) = -19.525, p < .01, d = 1.03$. What is also notable is that the mean score increased from 33.5% to

62.9% (pre- to post-test) for the inquiry activities group while only increasing from 36.8% to 42.6% for the control group.

One conventional measurement used in much of the conceptual change studies involving physics students is the normalized gain, defined as the improvement in student scores normalized by the possible gain. For example, the normalized gain for students in the control group is 10.4%, calculated by looking at the measured gain of 5.3% (54.4%-49.2%) divided by the total possible gain of 50.8% (100%-49.2%). This can be compared to a normalized gain of 36% with activities. A chart comparing normalized gains on the instrument as a whole as well as for each of the sub-categories of the HECI is shown in Figure 1. The data shows that the activities improved student learning gains in each of the four targeted concept areas as well as for the overall. These gains are significant, both statistically and in absolute terms.

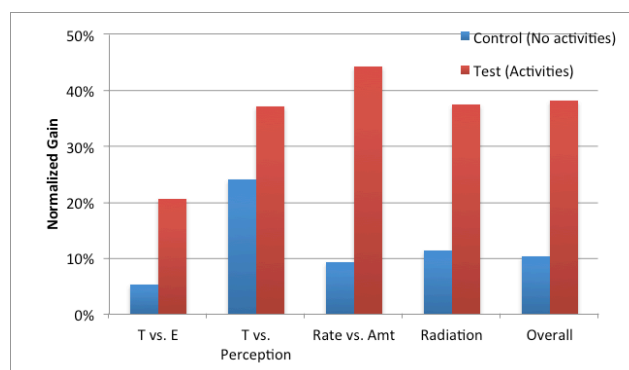

FIGURE 1: Affect of activities on learning gains

The study also examined the impact of inquiry-based activities on students' ability to transfer knowledge to different contexts. Each question on the HECI was characterized by content experts as requiring either near or far transfer of conceptual learning depending on the degree to which the question related to the inquiry-based activity. Near transfer questions were defined as those that assessed understanding using some of the same situations as those in the inquiry-based activities. Far transfer questions were those that extended concepts learned. Paired samples t-tests showed that the entire sample significantly improved from pre- to post-test on the near transfer questions, $t(668) = -20.302, p < .01, d = .79$ as well as the far transfer questions, $t(649) = -17.10, p < .01, d = .67$. However, results suggest that while the activities promoted both near and far transfer of learning gains, the activities were more effective for promoting near transfer.

There was a significant improvement from pre- to post-test on near transfer questions for both the control and activities groups. The control group had a mean pre-test score of 30.26% ($n = 307$) and a mean post-test score of 39.78% ($n = 307$); $t(306) = -6.066, p < .01, d = .35$. For the near transfer questions, the activities group had a mean pre-test score of 28.61% ($n = 362$) and a mean post-test score of 65.84% ($n = 362$); $t(361) = -24.880, p < .01, d = 1.31$. There was a large

effect size for the near transfer question improvement for the activities group.

There was a significant improvement from pre- to post-test on far transfer questions for both the control and activities groups. The control group had a mean pre-test score of 56.07% ($n = 289$) and a mean post-test score of 61.62% ($n = 289$); $t(288) = -6.948$, $p < .01$, $d = .41$. For the far transfer questions, the activities group had a mean pre-test score of 52.07% ($n = 361$) and a mean post-test score of 66.29% ($n = 361$); $t(360) = -17.103$, $p < .01$, $d = .90$.

When examining each type of question by control and activities groups, an independent t-test showed a significant difference on the post-test for near transfer questions with a large effect size, $t(645.31) = -12.647$, $p < .01$, $d = .97$. The activity group had significantly higher mean scores on the post-test than the control group. When examining the far transfer questions, the independent t-test showed a significant difference on the post-test with a small effect size, $t(691) = -3.349$, $p < .01$, $d = .26$. The mean post-test score for the activities group was significantly larger than the control group, although the magnitude of difference between the two mean scores was small.

It should be noted that near and far transfer questions are disproportionately distributed throughout the sub-tests which could impact some differences in activity effectiveness highlighted in Figure 1. For example, six out of eight questions in the Rate vs. Amount concept area are near transfer questions while none of the nine questions in Temperature vs. Perceptions concept area are characterized as near transfer questions. Therefore, it seems likely that the greater impact of the activities for promoting gains in the Rate vs. Amount concept area compared to the concept area of Temperature vs. Perception result (at least in part) from this difference in distribution of questions on the assessment instrument rather than the inherent nature of the targeted misconceptions or the construction of the activities for the given concept area. This issue needs to be examined in future work.

IV. CONCLUSIONS AND FUTURE WORK

This study builds on earlier research in a number of ways. Consistent with a large body of literature, the data from the control group demonstrates that students have significant misconceptions about heat, energy and temperature and that these misconceptions are frequently robust or resistant to change through conventional instruction. The modest learning gains found for the control group support that finding. At the same time and again consistent with a large body of literature in the sciences, it has been shown that the use of inquiry-based activities can significantly increase student performance on measures of conceptual understanding, even in those cases that are resistant to change through conventional instruction. Again, the significantly improved student performance, both in the aggregate and for each of the targeted concept areas of the HECI, supports this assertion. Taken as a whole, this work contributes to our understanding by adding to what is at present a small data-base of the effectiveness of such activities with undergraduate engineering students.

While these results are very encouraging, there is a need for significant future analysis. We are in the process of how effectively the activities promote conceptual learning gains immediately after their completion compared to student performance on the concept questions several weeks after the activity. In addition it would be beneficial to have additional measures of students' conceptual learning, drawn from additional venues such as concept maps or semi-structured student interviews.

Text heads organize the topics on a relational, hierarchical basis. For example, the paper title is the primary text head because all subsequent material relates and elaborates on this one topic. If there are two or more sub-topics, the next level head (uppercase Roman numerals) should be used and, conversely, if there are not at least two sub-topics, then no subheads should be introduced. Styles named "Heading 1", "Heading 2", "Heading 3", and "Heading 4" are prescribed.

ACKNOWLEDGMENT

The authors acknowledge and thank Ruth Streveler, Ron Miller and John Pershetti for their help in the construction of the concept inventory and for their ongoing feedback.

Abstract—Thermodynamics can be challenging to students, thus improving thermodynamics instruction and assessment is an important area of science and engineering education research. Constructed response assessments can reveal the complexity of students' ideas about thermodynamics. We investigate the use of lexical analysis software for examining students' constructed responses using a group of three questions related to reaction thermodynamics. These questions were administered to students in a large enrollment undergraduate introductory science course and examined learning at two levels of Bloom's Taxonomy: comprehension and application.

Our results show that students are able to identify correct statements about thermodynamics in a multiple choice context but fail to construct correct explanations using thermodynamic concepts. Lexical analysis revealed that students who provided correct explanations incorporated more correct concepts and/or made more connections among these concepts than did students with incorrect explanations. Lexical analysis provided insight into student understanding by revealing heterogeneous ideas that were masked in multiple choice versions of the assessment.

Keywords—component; lexical analysis, text analysis, thermodynamics, assessment, Bloom's taxonomy

I. INTRODUCTION

A basic understanding of thermodynamics is essential to learning in STEM disciplines in order to understand the relations between different forms of energy in physical, chemical and biological systems. Science and engineering education research has found thermodynamics concepts to be particularly challenging for students. Students have difficulty distinguishing among endothermic and exothermic reactions [1], and struggle with concepts such as entropy and reversible and irreversible reactions [2] and heat transfer [3].

The need for improved learning continues to drive instruction and assessment of thermodynamics. Current instructional research focuses on conceptual change through active learning including the use of models and simulations [3–5]. Assessment research has focused on the development of concept inventories such as the Thermodynamics Concept Inventory [6], the Heat Transfer Concept Inventory [7], and the Thermal and Transport Concept Inventory (TTCI) [8], [9]. For example, the recently developed TTCI is a 2-tiered multiple choice diagnostic test that seeks to identify student misconceptions and the reasons for these misconceptions.

Another approach to assessment in thermodynamics is the use of writing to allow students to represent their understanding in their own words and reveal the heterogeneity of their ideas [10], [11]. These written formative assessment give instructors insight into students' thinking by allowing students to generate ideas [12] and to present the heterogeneity of their ideas [13]. For example, students may hold more than one misconception along with correct ideas of a concept, all of which can be present in a written or constructed response. However, one obstacle to the use of written assessments has been the time and expense involved in grading these assessments.

The Automated Analysis of Constructed Responses (AACR) research group at Michigan State University explores student understanding expressed in constructed responses using computerized lexical and statistical analyses. Linguistic or text analysis can be conducted by vector space (such as latent semantic analysis), linguistic structure and feature-based methods [14]. We employ a feature-based approach that involves extracting and categorizing ideas from student responses, giving instructors insight into student thinking. This method can facilitate formative assessment and feedback in large-enrollment courses [15]. AACR has been exploring lexical analysis in evolution, genetics, cell metabolism and acid-base chemistry assessments [15–17].

In this study, we demonstrate the use of automated text analytics software to investigate students' understanding of thermodynamics in an introductory biology course. We examined student writing using questions targeted at two levels of Bloom's Taxonomy of the Cognitive Domain [18]: comprehension and application. This approach can be applied to other STEM disciplines and should be of interest to faculty who would like to use written assessments in large enrollment courses.

II. METHODS

A. Study Questions

Our study was conducted in an introductory cell and molecular biology course. At least one semester of general chemistry is required as a prerequisite for the course and students were expected to have a basic understanding of thermodynamics. We have collected thermodynamics data

using different questions over several semesters. Data for this study was collected from questions administered during Fall semester 2008 and Spring semester 2012. Prior to receiving this assignment, the students also revisited this topic in their current course. Students were given online homework assignments including a set of three questions relating to reaction thermodynamics – two closed-form items followed by explanation, and one open response question. Students received credit for completion of the assignment regardless of the accuracy of their answer.

B. Text Analysis

We use IBM SPSS Text for Surveys and IBM SPSS Modeler 14.2 Text Mining node to analyze constructed responses. These software identify *terms* from custom-built libraries, similar to dictionaries. Terms are classified into *categories* by predefined computer algorithms which are subsequently modified by the researcher. Each response can contain multiple terms, with each term belonging to one or more categories. The software also displays *web diagrams*, similar to those in Figure 2, illustrating the connections among categories within groups of responses. (For more details on the operation of the software see references 20 and 21).

C. Statistical Analysis

We conducted discriminant analysis to determine categories that predict correct and incorrect post-instruction responses for Question 1. The discriminant analysis used a stepwise-forward, Wilk's method with an F-in of 3.84 and F-out of 2.71 [19]. We used group sizes for prior classification probabilities and a leave-one-out cross validation. Discriminant analysis is similar to linear regression and results in a linear function that expresses the relationship between dependent and independent variables. However, in the case of discriminant analysis, the dependent variables are categorical instead of interval. For this analysis, we have a series of binary independent variables (presence or absence of a student's response in each lexical category) which are combined to predict categorical dependent variables (expert rating). In this analysis the dependent variable has two categories (correct and incorrect) which results in a single linear function. Discriminant analysis analyzes the covariance between independent variables, or whether the variables change together or not. Because of this, it is not the values of individual independent variables but the relationship among them that is critical in determining the discriminant functions.

For Question 2 and 3, we used cluster analysis [20], another classification approach, to determine how responses aggregate into distinct groups based on the combination of categories to which they are assigned. Cluster analysis differs from discriminant in that the identity of groups (clusters) is unknown prior to classification. Clusters are later examined for similar properties shared by responses in the cluster. We use *k*-means clustering which finds *k* clusters of cases (responses). Clusters are mutually exclusive. The responses are classified into the cluster that is closest to that cluster mean or centroid than to the centroid of any other cluster. *K*-means cluster analysis allows the recombination of cases and *k* user-defined cluster over repeated iterations. Recombinations are iterated until no further change occurs. The algorithm computes the F-statistic using

analysis of variance and specifies which lexical categories contribute most to differentiating among the clusters.

We use web diagrams to illustrate the frequency of and relationships among categories within a discriminant class or within a cluster.

III. RESULTS AND DISCUSSION

A. Question 1

The main objective of this part of our study was to investigate how students *describe* (Bloom's comprehension level) free energy change during an exergonic reaction using the graphic representation provided in Question 1 (Figure 1). We compared students' multiple choice and written explanations to Question 1. We analyzed 168 explanations from students who selected the correct multiple choice response. All responses were independently scored by two raters with expertise in biology and chemistry. Complete responses described the components of the system and the change in free energy (see below). The raters scored responses that had only correct ideas as 1. Responses with incorrect, incomplete or mixed (both right and wrong) ideas were scored 0 (this scoring group is hereafter referred to as "incorrect"). Raters demonstrated high scoring agreement (Cronbach's alpha = 0.88) and scoring disagreements were resolved by consensus.

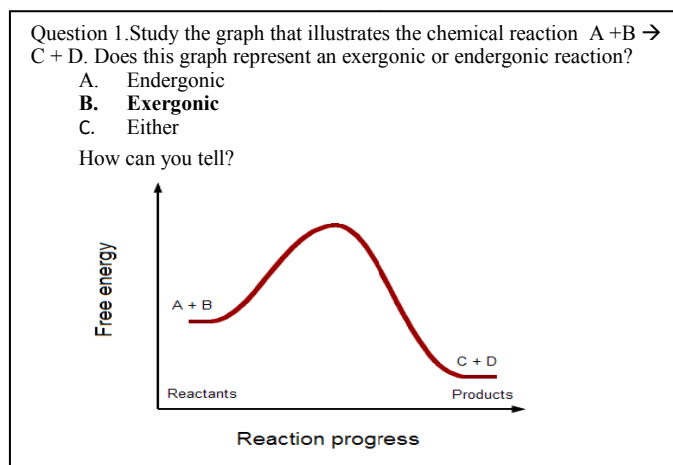

Figure 1. Question 1

The majority of students (84.9%) selected the correct multiple choice answer. However, 49% of these students had "incorrect" explanations for the type of reaction in the post test. Correct and complete responses compared the free energy of the reactants and products or referred to the net negative change in free energy for the reaction. The following are examples of correct responses:

Correct response 1: "energy is released as the reaction proceeds, with the products having less energy than the reactants"

Correct response 2 "The change in G is negative which implies the reaction is giving off energy"

Incorrect responses were either incomplete, completely wrong, or contained both wrong and correct ideas. The following are examples of responses scored as incorrect:

Incorrect Response 1 - Incomplete response: “releases energy” (This was the entire explanation submitted.)

Incorrect Response 2 - Only wrong ideas: “The energy is transferred from the reactants to the products”

Incorrect Response 3: Both correct and incorrect ideas, “You can tell because the reactants have more potential energy than the products. Also because there is a loss of free energy this reaction gives off heat.”

Text analysis successfully categorized all 168 responses into one or more categories. Categories (*in italics*) were first automatically generated by software and refined by researchers. For example, the category *products* was automatically created by the software to extract the word product and phrases containing the word product. This category was further modified by researchers to include the phrase “C+D”. This was important to capture, for in lieu of the word “products” several students mentioned C+D, the symbols representing products in the question diagram. The categories identified included

- components of the reaction (*reactants* and *products*),
- energy (*free energy* and *energy*),
- reaction types (*exergonic*, *endergonic*) and
- energy changes (*lower*, *release*, *higher*).

We used discriminant analysis to validate the categories from lexical analysis as the independent variables and expert scores (correct or incorrect) as the dependent variables. The use of a stepwise model allows only categories that are significant to the model to be included. We used a leave-one-out classification for cross-validation. The resulting discriminant function was significant (Wilk's Lambda = .629, Chi-square 47.111, df = 5, p <0.001). Discriminant analysis of post-instruction responses identified five categories that significantly predicted correct and incorrect responses. These categories and their standardized discriminant coefficients, which are similar to beta weights in regression, indicating relative weights among the variables, are reported in Table I. These categories were used to construct web diagrams illustrating the frequency of responses and connections among the categories (Figure 2).

TABLE I. STANDARDIZED DISCRIMINANT COEFFICIENTS FOR CATEGORIES PREDICTION OF HUMAN RATINGS

| Category | Standardized Discriminant Coefficient |
|--|---------------------------------------|
| Delta G | 0.525 |
| Energy of the products | 0.502 |
| Products | 0.492 |
| Lower | 0.469 |
| Reactants | 0.360 |
| Computer- Human Scoring Inter-rater reliability | Cronbach's Alpha = 0.75 |

Web diagrams illustrated distinct differences between correct and incorrect responses (Figure 2 a and b, respectively). Correct responses had considerably larger node sizes indicating the more correct responses contained these predictive ideas (i.e. *reactants*, *products*, *energy of products*, *lower* (energy). Correct responses also contained terms in the category *delta G* while incorrect responses did not.

We also observed more co-occurrences among categories in the correct responses than among categories in the incorrect responses web diagram. These co-occurrences are also more frequent as represented by the solid line between the nodes *reactants* and *lower* in the correct response web diagram.

These connections reflect the comparisons made by students giving correct responses, such as the response “...with the *products* having *less* energy than the *reactants*” which contained 3 ideas. In contrast, the fewer or weaker connections among incorrect responses were indicative of several incomplete responses such as “the *products* have *less* free energy”, in which students expressed fewer ideas.

Although most students could select the correct multiple-choice option post-instruction, only half of these provided complete and correct explanations for their choice. Problems understanding endothermic/exothermic process can be prevalent among students learning thermodynamics [10,13]. Our data show that this difficulty can extend to exergonic/endergonic processes as well. Additionally, the large number of students unable to describe the change in free energy in the system may have difficulty between the system and surroundings [1]. Our results demonstrate that this gap in student understanding could go undetected with only

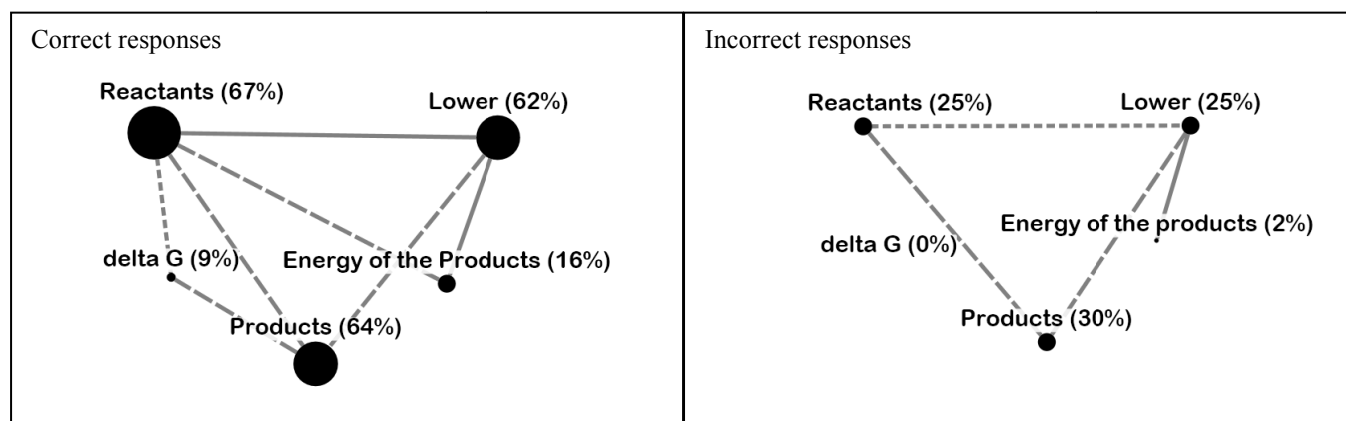

Figure 2. Web diagram of categories and links for a) Correct and b) Incorrect responses. Each category is represented by a node. The size of the node corresponds to the frequency of responses containing a category. Lines indicate the percentage of shared responses. Solid lines indicate that 75% shared responses; dashed lines 50-74%, dotted lines 25-49%. Nodes with fewer than 25% share responses were not linked.

multiple choice testing, but was revealed through written assessment, as has been observed in other fields [21,22].

B. Question 2

The main objective of Question 2 was to examine how students can use their knowledge of the definition of Gibbs free energy to *identify* (Bloom's comprehension level) conditions under which a reaction may become spontaneous.

Question 2. Can a non-spontaneous chemical reaction become spontaneous under different conditions? Explain your reasoning for your choice above.

Seventy five percent (n= 329) of students responded "Yes" to Question 2. We analyzed these 329 explanations using text and cluster analyses. Text analysis categorized the responses into 32 categories. Some of the most common categories were terms found in the question stem: *spontaneous* (70% of responses), *reaction* (45%) and *non-spontaneous* (36%). Other categories with high frequencies included *temperature* (48%), *change* (35%) and *conditions* (16%).

To identify groups among the responses, we used *k*-means cluster analysis. Values of *k* between 2 and 5 were examined. Categories from the question stem (listed in the previous paragraph) were removed from the cluster analysis as these ideas were not generated independently by students but may impact the results. With *k*= 2, the ANOVA indicated that the category *temperature* contributed the most to differentiating among the clusters. However, examination of the responses revealed a good deal of heterogeneity within the two clusters.

We decided to use three clusters, as trials with *k*=4 and *k*=5 showed little improvement in the distances among centroids and did not add much homogeneity to newly formed clusters. The *k*=3 cluster ANOVA identified the categories *change*, *energy*, *high*, *reactants* and *temperature* as contributing the most to differentiating among the models.

Cluster 1 identified 46 responses (14%) which demonstrated high quality explanations. These majority of the responses indicated that a non-spontaneous reaction could occur spontaneously at sufficiently high temperatures. This is observed in the web diagram (Figure 3a) showing that 58% of the responses in used the categories *temperature* and *high* (which in includes terms such as increased, greater and higher). These categories and the connection between them dominate the web diagram allowing a quick visualization of the main idea that is representative of Cluster 1.

A few students in Cluster 1 referenced the equation or definition for free energy, for example, "If temperature is increased in the $\Delta G = \Delta H - T \Delta S$ then the ΔG can go from positive to negative and become spontaneous."

However, some students also gave less detail, e.g. "Increasing the overall temperature of the reactants will cause a non-spontaneous reaction to become spontaneous."

Cluster 2 contained 112 responses (34%) in which students affirmed that under changed conditions, particularly temperature, a non-spontaneous reaction may become spontaneous. However, these students did not specify that a higher temperature was required and were less likely to refer to

the definition for Gibbs free energy. The strong association of *change* and *temperature* in Cluster 2 responses is shown in Figure 3b. We observe a change in the dominant variable and connection from *high* and *temperature* in Cluster 1 to *change* and *temperature* in Cluster 2. The following are representative of Cluster 2 responses

"Many times a non-spontaneous reaction can become spontaneous if the temperature is changed."

"You can change some reactions to become spontaneous by changing the temperature."

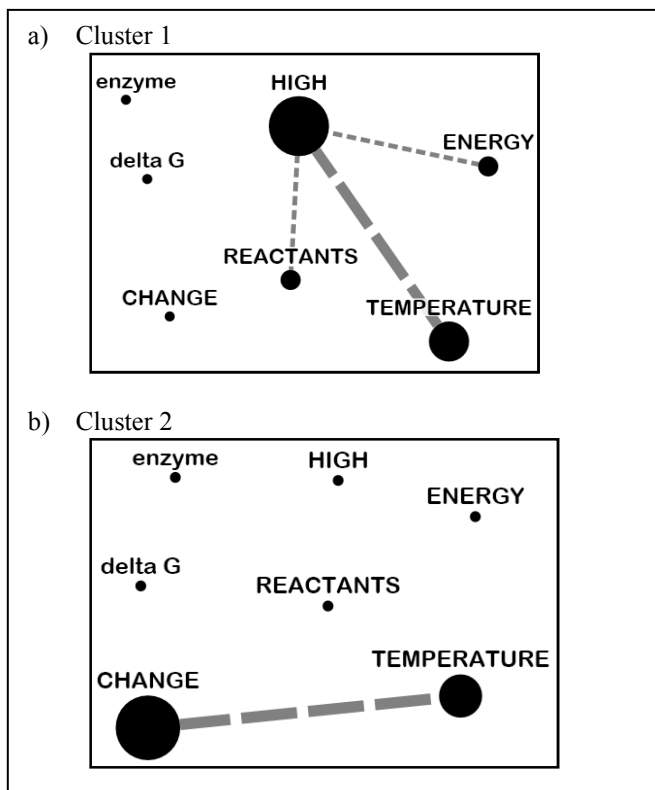

Figure 3. Web diagram of categories and links for a) Cluster 1 and b) Cluster 2 for Question 2: Spontaneous Reactions See Figure 2 caption for legend details.

Cluster 3 contained 171 responses (52%) that suggested reversing the reaction and selecting addition of an enzyme as a new condition. The use of *k*=4 analyses did not further divide these Cluster 3 into two distinct groups. Students who suggested reversing the reaction demonstrated knowledge of the free energy of the reaction but did not apply it correctly to the question. Responses suggesting the addition of an enzyme revealed a misconception held by students that enzymes alter the spontaneity of the reaction.

For example students stated that

"Added enzymes can make a non-spontaneous reaction spontaneous but not the other way around."

"catalysts lower the energy reaction pathway. An example of a catalysts [sic] is an enzyme. An enzyme reduces the transition energy pathway."

Keeping in mind that 75% of the students selected “Yes” - a change in reaction spontaneity is possible, we gain detailed information about student thinking from the use of the constructed responses. Coupling text analysis and cluster analysis, we were able to identify three groups of responses of varying content and quality. A subset of students in Cluster 1 presented a detailed explanation which included the definition or equation for free energy change. However, the majority of students did not reference this concept in their responses. Additionally, students hold misconceptions about the role of enzymes in reaction thermodynamics and kinetics.

C. Question 3

To observe how students *apply* (Bloom’s application level) thermodynamics concepts in biology contexts, we analyzed responses to question 3. Students were expected to use thermodynamic concepts to explain carbohydrate decomposition rate.

Question 3. A carbohydrate is composed of a string of covalently linked monosaccharides. Breaking those bonds between the monosaccharides is a chemically spontaneous reaction (ΔG for this reaction is -3.7 kcal/mol). However, this reaction occurs very slowly at room temperature. Why do you think this is so?

We analyzed 386 student responses. Text analysis generated 44 categories of terms. The most frequent categories containing terms not found in the stem were *temperature* (excluding room temperature) (34%), *energy* (25%), *high* (19%), *heat* (18%), *activation energy* (16%) and *catalyst* (13%).

For Question 3, we used *k*-means cluster analysis to identify groups, testing values of *k* between 2 and 5. We present the results for *k*= 3 which maximized the distance among clusters. The categories *enzyme* and *high* contributed most to differentiating among clusters.

Cluster 1 was the least well defined cluster. The 278 responses in this category were very heterogeneous. Some were vague, for example,

“This is because, the room temperature and the temperature of the reaction are very similar”

“Just because a reaction is spontaneous, does not mean it occurs fast.”

Other responses contained concepts such as phospholipids and descriptions of state changes of carbohydrates at room temperature that were unrelated to the topic.

Surprisingly, some correct explanations mentioning the high activation energy as a rate-limiting process were also included in this category. It is possible that the low number of responses (~10 %) using activation energy as the only or main idea made these cases difficult to classify. These did not form a separate cluster with *k* = 4 or 5.

The web diagram for cluster 1 is not shown as all connections observed shared fewer than 25% of responses for students connected few ideas.

Cluster 2 contained 71 responses (18%) expressing ideas about bond stability and the need for higher temperatures to

increase the rate of reaction (Figure 4). For example, students stated that:

“it is a more complex molecule with strong bonds. Though some bonds may break at room temperature, there simply isn’t enough energy to make it occur rapidly.”

“Since it is a spontaneous reaction it will happen without any added energy. A higher temperature might speed up the reaction because it would drive the reaction more than the lower temperature.”

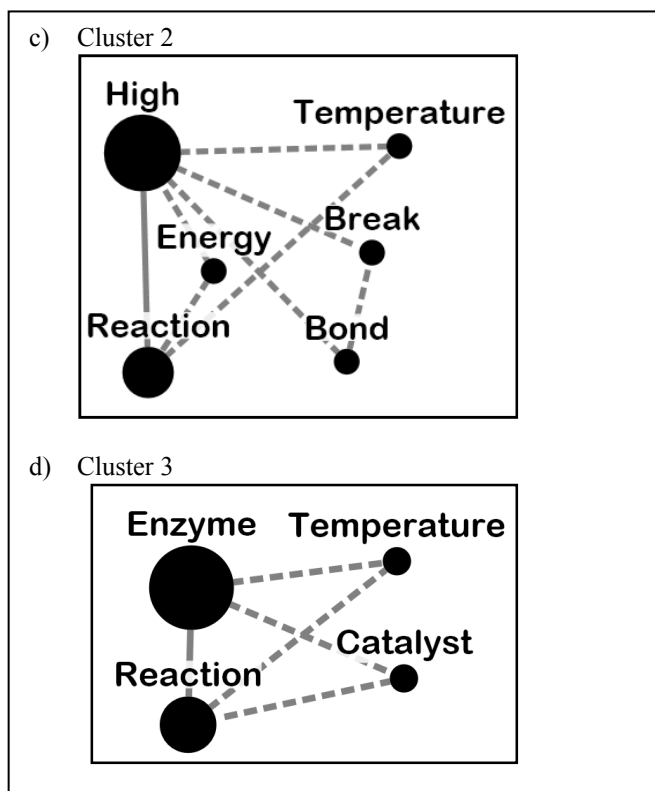

Figure 4. Web diagram of categories and links for a) Cluster 2 and b) Cluster 3 for Question 3: Reaction Rate. See Figure 2 caption for legend details.

Responses in Cluster 3 centered on the theme of enzymes and catalysts. About 10 percent of students described that a catalyst would help increase the rate. However, not all students detailed how the catalyst would change the thermodynamics or kinetics of the reaction. Some representative responses include

“because the room temperature is not high enough or it needs enzyme to speed up.”

“because in the body, where most starch is broken down, the temperature is greater than room temp, it has a different pH, and has enzymes that catalyze the reaction”

We observed in Question 3 that students give varied explanations of the scenario presented. Though instructors and/or researchers apply thermodynamics concepts to indicate why spontaneity does not determine reaction rate, students often gave vague or irrelevant surface-level responses. We also observed that some students drew only from their biology

knowledge and did not use thermodynamic concepts in answering this question. Students may require more explicit prompts to draw on knowledge from outside the domain of biology when answering problems within a biological context.

IV. CONCLUSIONS

Our analysis of students' written responses revealed that students held varied ideas that could not be observed from their multiple-choice responses. Though some students were able to articulate well thought-out responses incorporating thermodynamic concepts, others failed to identify, describe, and/or apply their knowledge of thermodynamics when asked to provide an explanation. Furthermore, when asked to apply thermodynamics concepts in a biological context, few students approached this question from an application level and most relied on surface-level descriptions, consistent with other research on conceptual change in novices [23].

Written assessment is an important component of thermodynamics and other STEM instruction [10, 21]. We have demonstrated that computerized lexical analysis, coupled with classification analyses, can be used to investigate large volumes of student writing. Lexical analysis allows patterns in student responses in the form of categories and their connections to be easily visualized. Statistical classification, with or without human scoring, can organize student ideas into related groups. One goal of the AACR group is to develop these assessment resources (questions, categories and scoring models) for STEM disciplines [15],[16]. As this body of work grows, it will be made available to instructors to facilitate rapid feedback and tailor their lessons to address student misunderstandings. Work in Progress: Audio Reflections Provide Evidence of Metacognition during Students' Problem Solving Attempts

Lisa Benson, Michelle Cook, Catherine McGough and Sarah Grigg

Department of Engineering and Science Education
Clemson University
Clemson, SC USA
lbenson@clemson.edu

Abstract— Creating instructional materials that facilitate students' metacognition (activities such as planning, monitoring, and evaluating) and critical thinking is challenging for instructors of first year engineering students. Students come into these programs at various levels of academic preparation, and students may experience cognitive overload when asked to simultaneously use mathematical skills and higher-order thinking skills. In order to demonstrate the effectiveness of new approaches to introducing complex, relevant contexts and skills, methods must be developed that can provide evidence of metacognition and critical thinking skills. These methods can also facilitate research into problem-solving strategies. The overall goal of this project is to design problems for first year students that introduce complex real world topics that are effective for building problem-solving skills for students at all levels of academic preparation. The study presented here is the preliminary qualitative analysis of students' audio commentary in which they reflect on their written problem solutions in a first year engineering course. These reflections were performed within 24 hours of completing written work. Our analysis provides evidence of metacognition retrospectively, as well as during the post-hoc think-aloud commentary. This research methodology effectively identifies student problem-solving strategies, including cognitive, metacognitive and procedural information, and provides evidence that think-aloud protocols are useful in eliciting metacognition and critical thinking.

Keywords: *first year engineering, problem solving, metacognition, think-aloud*

I. INTRODUCTION AND BACKGROUND LITERATURE

Problem solving is a critical skill in engineering, and identification of deficiencies is necessary to inform evidence-based educational reforms aimed at improving development of these skills. This project seeks to identify indicators of metacognition and critical thinking that occur with successful problem solving strategies for freshman engineering students. There is extensive literature available on engineering problem solving [1] but little on how students' academic preparation affects the development of their problem solving skills. The ultimate goal of this project is to design problems for first year students that introduce complex real world topics in a way that builds problem-solving skills for students at all levels of academic preparation.

"Think aloud" protocols, wherein students verbalize their strategies as they work through problems, have been applied in engineering education to track the progress of students' conceptual and procedural problem solving knowledge [2]. However, there is evidence that verbalizing one's thought process while working can alter the work produced [3]. Therefore, this study first collects written, temporal records of students' work, then records verbal audio commentary after the written work has been completed. This provides an authentic record of students' problem-solving processes (written work), with the additional benefit of the students' reflection on those processes (post-hoc "think aloud").

II. METHODS

The study was conducted as a phenomenography, an educational research method that categorizes subjects' descriptions of a "phenomenon" or event being studied [4]. In this study, the event is solving a problem. Students used custom-designed software on tablet computers to complete and submit selected assignments. They were then invited to review their work and add audio commentary reflecting on how they arrived at the solution, using an audio recording feature in the software. This feature allows audio recordings to be associated with specific strokes or erasures in students' written work. Written solutions were analyzed qualitatively by coding elements categorized as knowledge access, knowledge generation, self-management, errors, answers, and strategies [1]. Transcriptions of audio comments were analyzed by the research team while simultaneously replaying written work, including the codes associated with the work. Student audio comments that provided additional information or insight beyond what was evident in the written work were coded, using the coding scheme developed for the written work as a starting point. Codes related to problem solving strategies were added based on a set of non-domain-specific strategies [5]. Additional codes were added as needed by members of the research team while simultaneously analyzing three problems completed by three students randomly selected from a population of first year engineering students (n=28) who participated in this project. These mostly pertained to information in the audio commentary that did not appear in students' written work.

Supported the National Science Foundation Award # EEC-0935163

III. RESULTS AND DISCUSSION

While much of the audio commentary reflected what was evident in the written work, preliminary results showed that the students' reflections provided insight into their comprehension, confidence, confusion, and use of strategies while completing the written work. For example, where a student's written work showed that she added units to numbers after performing a calculation, she acknowledged in her audio reflection that she recognized the importance of labeling parameters throughout her work. This is an indication that this skill (consistent use of units) may carry forward to other problems and applications, as she did not do it simply because she was instructed to. In some cases where students erased work frequently, which indicates confusion, their audio commentary revealed what aspects of the problem the student found confusing. For example:

"Um, I understood part B of this [assignment] but A and C confused me. I wasn't really sure what the directions were asking for.... I know now...a little bit better since I've reviewed more on it what it was asking for but at the time I was very unsure...."

Table 1 includes examples of student commentary that provide evidence of metacognitive thinking, namely planning, monitoring, and evaluating [6], while the students were completing written work.

Students also identified resources used that were not apparent in written work alone. Use of external resources is an important aspect of dynamic transfer [7], which is useful in assessing long-term learning. For example,

"I was stuck when I thought that you had to use all of the resistors and as you can see from my work I scratched out, but I was very confused and then I was told by one of my group mates that you didn't have to use all of them so that made it quite a bit easier."

TABLE I. AUDIO REFLECTIONS THAT INDICATE METACOGNITION [PLANNING, MONITORING AND EVALUATION] IN WRITTEN WORK

| Code | Student Comment |
|--|--|
| Acknowledge importance: identify equations / knowns [planning] | <i>When beginning a problem I like to write out all the formulas, any given information or formulas that I will like need to actually complete a problem. It kind of helps me get in like the mindset of the problem itself and what I have to do to solve it.</i> |
| Acknowledge importance: check accuracy [evaluation] | <i>With that correction that stood as a warning to me that I may need to review my previous equations to make sure that I had not left anything out from what I had learned. And after checking I hadn't.</i> |
| Acknowledge importance: labeling/renaming [monitoring] | <i>And going back, I did an ohms sign right after the 25.45 because I kind of figured that was important. So I forgot it, and went back and added it.</i> |
| Acknowledge importance: draw a picture [planning] | <i>So I made a picture of the circuit and this is what it looked like. It helped visualize the entire problem for what it was worth.</i> |

Other findings in our analysis of audio commentaries allow a deeper understanding of students' written work, and show evidence of strategies such as trial and error or means-ends

analysis. For example, a student whose work was quite efficient and included direct calculations within a circuit problem added the following comment, which indicted a "guess and check" strategy:

"Yeah, I just kind of picked out a voltage and a resistor that I thought that might work."

Without this added insight, it would not be apparent that he did not actually predict that the value he chose would work in his calculation, but rather took a (lucky) guess.

Some students recognized errors or inefficiencies in their work during their audio commentary, which they were not aware of while completing their written work. For example,

"Honestly after just sitting here I have realized that I did make a mistake in my calculation...that would... affect the rest of my calculation throughout."

This demonstrates the value from an instructional standpoint of having students reflect on their work after completing it. It is also possible that a concurrent think-aloud would provide this benefit as well, for the purpose of promoting metacognition.

IV. CONCLUSIONS

Our analysis of students' audio reflections on their problem solutions revealed aspects of metacognition during students' written problem-solving activities (acknowledging the importance of specific steps or aspects of their problem-solving strategies). They also identified the use of external resources, which is useful in studying dynamic transfer of knowledge. During post-hoc think-aloud sessions, students also recognized errors that they had not detected while completing written work, which demonstrates the value of think-aloud protocols in promoting metacognition. Other comments provided during audio reflections allow more accurate definition of strategies than is possible by analyzing written work alone. These results can help instructors identify patterns of inconsistent or ineffective problem solving strategies to inform development of more complex problems for first year engineering students.

Work in Progress: Investigating Student Conceptual Understanding in Introductory Electrical Engineering Courses

Christian H. Kautz

Center for Teaching and Learning
Hamburg University of Technology
Hamburg, Germany
kautz@tu-harburg.de

Abstract—We report on an ongoing investigation of student understanding of basic concepts in the context of various first-year undergraduate DC and AC circuits courses. Through analysis of student responses to mostly qualitative quiz and examination questions, we have identified characteristic difficulties with different topics. The results from this research are being used to guide the design of active-learning instructional materials that are aimed at strengthening conceptual understanding of circuit quantities and the relationships between them. Up to now, an initial set of 18 collaborative-group worksheets have been developed and implemented in two different instructional formats: large interactive lecture settings with an audience of more than 400 students and small course sections with about 20 to 25 students. Data from post-tests suggest that the materials can be used successfully in both formats. We are continuing to administer post-tests to strengthen our claims about the effectiveness of these materials. In addition, we are hoping to broaden our research base through interviews and further written tests, thereby laying the groundwork for a more thorough understanding of the nature of the student difficulties that we have identified.

Keywords: *Engineering education research, conceptual understanding, student difficulties, AC circuits, phase relationships, threshold concepts.*

I. INTRODUCTION

For the past three decades, a substantial amount of research has been carried out on student understanding of electric circuits at the secondary-school level [1]. There have also been some investigations in the context of introductory university courses, both for technical and non-technical careers [2], as well as some research with in-service high-school physics teachers [3]. Most of the work so far has concentrated on student ideas about simple DC circuits. Engineering students at the university level, however, are generally also required to study AC circuits, a topic that for many presents some additional mathematical and conceptual challenges. This situation has prompted us to extend our work in this field to genuine AC concepts such as phasor notation and phase relationships. Results of this project have been published previously [4, 5]; below, we review some results and suggest some new directions for this investigation.

Parts of this project were supported through a grant from NORDMETALL Stiftung.

II. CONTEXT AND METHODOLOGY

A. Context of Research

Our research is carried out in the context of different first-year electrical engineering courses at two different institutions in Hamburg, Germany. While these courses are intended for students of different majors (electrical and IT engineering, and mechanical and naval engineering, respectively) they all cover essentially the same curriculum, albeit at slightly different levels of depth and rigor. As it turns out, differences between the results from the various courses are relatively small for most of the questions we asked (after standard instruction).

B. Research to Investigate Student Understanding

Initial observations during informal contact had suggested some student difficulties in understanding *phase shifts* in AC circuits in that students tended to compare signals of the same type (i.e., two *currents* or two *voltages*) at different places in a circuit. We then proceeded to administer written questions mostly as short quizzes during lecture hours. The layout of the circuits used in these quizzes and the specific quantities that we asked the students to compare varied from earlier to later versions. While most of the quizzes included multiple-choice questions, students were always asked to explain their reasoning. The participation in the quizzes was voluntary and did not affect students' grades. However, virtually all students present in the lecture on the respective days participated in the quizzes and seemed to make a genuine effort in answering the questions. We therefore feel justified in assuming that the answers given by the students accurately represent their understanding of the material on the day of the quiz.

C. Development and Implementation of Materials

Worksheets were developed to address specific topics that our research had identified as conceptually difficult. In these worksheets, students are given mostly qualitative questions that guide them through the conceptual steps that appear to be necessary to develop a functional understanding of these topics. The worksheets are modeled after a similar set of materials for physics [6] that have been developed by the Physics Education

Group at the University of Washington in a decade-long iterative cycle of research and assessment. Both sets of materials follow an instructional strategy that can be summarized by the terms *elicit, confront, resolve*: Student ideas about a certain topic are first elicited; partly incorrect ideas are then confronted with contradictory evidence, either through observation or consistency arguments; finally, the cognitive conflict thus created is resolved as a valid model is constructed [7]. The instructional interventions took place in later semesters of some of the same courses used to investigate student understanding, but only at one of the two institutions.

D. Assessment of Materials as Input for Further Research

For the assessment of our materials, we used very similar questions as in the investigation phase of our study, referring to the same or to different circuits. However, we always satisfied the requirement that tasks used in post-testing (for assessing the effectiveness of instruction) were not used in pre-testing or teaching of the *same students*. A quantitative comparison of the number of correct answers to similar questions with and without instruction using our worksheets was used as an indication of the effectiveness of these materials. In addition, a qualitative analysis of student explanations served as a starting point for new questions that are currently posed to students in quizzes and examinations.

III. RESULTS

A. Student Understanding of Phases in AC Circuits

1) *Failure to recognize the implications of Kirchhoff's voltage law*: Several of our questions related to a circuit, in which a resistance and a capacitance are connected in parallel directly across an ideal sinusoidal AC voltage source. The students were asked to compare separately the phases of the voltages across (i) the resistance and the source (i.e., u_R and u_0), and (ii) the capacitance and the source (i.e., u_C and u_0). While the vast majority of the students in four courses (ranging from $N = 49$ to $N = 268$) correctly stated that u_R and u_0 were in phase, that fraction dropped substantially for the phase comparison of u_C and u_0 , ranging from about a third to one-half of the students. We interpret these results as an indication that many of these students do not have a functional understanding of Kirchhoff's voltage law in the context of AC circuits.

2) *Failure to recognize the implication of Kirchhoff's current law*: Questions about phases of currents in series connections resulted in similar difficulties, although to a slightly lesser degree.

3) *Incorrect interpretation of phase behavior*: Students giving incorrect *answers* to the questions associated with the circuit described above frequently explained their reasoning by interpreting the "characteristic phase relationship" of resistive or reactive circuit elements not as a statement about current relative to voltage for the same element but instead as a statement about either quantity relative to some other current or voltage in the circuit. As this incorrect idea can lead to a correct answer for question (i) about the voltages across the resistance and the source, we are reminded that the students' incorrect responses are far from arbitrary.

B. Effectiveness of Tutorial Worksheets

In order to assess the effectiveness of the modified instruction using our tutorial worksheets, we administered a task about the phase relationships between different currents and voltages in a circuit consisting of series and parallel connections. In a course that used the worksheets in an interactive lecture section with more than 400 participants, the post-test was given as part of the final examination. In a course in which the worksheets were implemented in small sections of about 20 participants, the same post-test questions were given as an unannounced lecture quiz about one week after the respective section meetings took place. Questions that after traditional instruction were answered correctly by about 50% of the students or less now yielded a success rate of about three quarters. We interpreted these results as an indication that the use of our worksheets was beneficial to the students. As the results after traditional instruction were largely independent of the time spent on the topic considered (due to the fact that different courses yielded very similar results) we ascribe the effects of the worksheets to the instructional strategies used rather than the (possibly) slightly larger investment of time.

IV. FURTHER RESEARCH AND THEORETICAL FRAMEWORKS

While the development of instructional materials to teach a specific topic in an electrical engineering course has been somewhat successful, it seems likely that further progress can be made only after a deeper understanding of the prevalent student difficulties is achieved. At TUHH, we are therefore considering possible theoretical frameworks to explain student learning of these topics. A promising idea seems to be the theory of threshold concepts as proposed by Meyer and Land [8], suggesting that some concepts may act as a "threshold" to the understanding of subsequent course material.

Abstract— Microfabrication is a critical area to many branches of science and engineering. Beginning in 2009, we undertook a broad multidisciplinary approach to bring microfabrication into all aspects of the science and engineering curriculum. This program was coupled with a comprehensive assessment activity to evaluate the program's effectiveness and continuously improve it year to year. In this paper, we report on the details of our implementation process, the techniques we have found to bring a hands-on experience to large classes and the lessons learned from our attempts to make this topic a mainstream part of engineering and science education.

Keywords- *microfabrication, nanofabrication, engineering education*

I. INTRODUCTION

Microfabrication is inherently multidisciplinary. The processes for fabricating miniature structures of micrometer sizes and smaller are based on many disciplines including chemistry, physics, and optics. The devices they make also span the spectrum from completely electrical devices (like microprocessors), to completely mechanical devices (such as microfluidic channels) or mixed devices (such as accelerometers) which combine mechanical elements with electrical components. As such, the most appropriate way to introduce it is in a multidisciplinary way.

The science programs in Binghamton University's Harpur College of Arts and Sciences and the engineering programs in the Watson School of Engineering are very highly regarded. To maintain and enhance this reputation, and to continue to provide high-quality education, it is essential for classroom pedagogy to reflect the state of the art in science and engineering. In this paper, we report on a project to introduce microfabrication to the curricula of the physics, chemistry, mechanical engineering, and electrical engineering departments. In this new program, microfabrication is introduced in a fundamentally multidisciplinary way.

Unlike engineering-as-practiced, engineering education is frequently single-discipline and often lecture- and classroom-based. This cohesive set of activities that we introduce here is both multidisciplinary and project-oriented, which addresses those two common complaints about engineering education[1,2].

II. OVERVIEW

This topic was introduced in a cohesive comprehensive way in many the scientific and technical courses taken by science and engineering majors. Our general approach consists of an introduction to microfabrication in the freshmen year, pipeline modules in core courses in the sophomore and junior year, and an opportunity to take a capstone microfabrication class in the senior year [3,4,5].

The objective is to present microfabrication as part of science and technology by using it as a relevant example of a standard course topic; for example, diffraction can be taught using the example of resolution limits in microfabrication. The idea is to get students to think that making microprocessors and MEMS devices is a legitimate engineering and science endeavor, as much as physical chemistry or circuit design.

The pipeline modules consist of a small experiment or activity that is microfabrication-focused and is integrated into the course. This 'capstone' course attempts to tie together the miscellaneous acquire fabrication knowledge in a cohesive whole involving both theory and practice. It is designed as a lab-and-theory microfabrication course with a multidisciplinary emphasis. It is cross-listed in the Physics and Electrical Engineering Departments, and has attracted students from Mechanical Engineering as well.

III. CAPSTONE COURSE

In this section we will describe the implementation of the capstone course, and the demographics of the students who registered. Throughout we will try to illustrate plans for improvement.

In the spring of 2011, the capstone course entitled "Introduction to Microfabrication" was offered for the first time. The syllabus description of the course is given in Figure 1.

Essentially, this course is a microfabrication course which *makes a particular effort to span multiple disciplines*. The projects it encompasses involve microfluidics, electronic devices, and optoelectronic devices. In addition to covering most major clean room tools and theory, it also introduces experimental techniques through device characterization, and

an exposure to the utility of microfabrication in a variety of different disciplines.

Catalog Data:

(Various) Multidisciplinary Introduction to Microfabrication: Introduction to clean room tools, procedures, and theory through the fabrication and characterization of various devices from the fields of electrical engineering, mechanical engineering, physics and chemistry. Fabrication of the devices will cover most clean room tools and techniques, including lithography based patterning methodologies; chemical vapor deposition; sputtering; thermal and e-beam evaporation; thermal oxidation; reactive ion etching; ion implantation; and wet chemical processing. The accompanying lecture will cover the theory of the tools used. 4 credits, one lab hour and 3 lecture hours/week

FIGURE 1

BRIEF SYLLABUS DESCRIPTION OF THE CAPSTONE MICROFABRICATION COURSE

The course included three laboratory modules; fabrication of transistors, OLEDs, and microfluidic devices. A fourth laboratory module on fabrication of optical gratings was developed this summer. In addition, it included a major project using the simulation capabilities of the Nanohub (<http://www.nanohub.org>), an excellent facility supported by the National Science Foundation.

IV. COURSE DEMOGRAPHICS

This initial runs of the course had the following demographic of students, broken down by major, gender, and academic year (and final grade awarded).

TABLE 1: DEMOGRAPHICS OF CAPSTONE COURSE ‘INTRODUCTION TO MICROFABRICATION’, 2011 AND 2012

| 2011: 17 students total | Breakdown |
|--------------------------------------|---|
| | 6% Junior, 18% Senior, 88% graduate student |
| By Year in School | |
| By Major | 52% EE, 35% ME, 12%PHYS |
| By Gender | 12% Female, 88% Male |
| By Awarded grade | 47% A, 18% A-, 18% B+, 12% B, 6% B- |
| 2012: 10 students total (2 auditing) | Breakdown |
| By Year in School | 20% Senior, 80% graduate student |
| By Major | 30% EE, 20% ME, 50%PHYS |
| By Gender | 20% Female, 80% Male |
| By Awarded grade | 25% A, 63% A-, 14% B+ |

The capstone course is limited by lab capacity to no more than 18, and the first year it was offered, it was filled to capacity (a single student dropped the course, which is why the course had only 17 students graded).

One concern, illustrated by the demographics in both years, is finding a way to attract more undergraduate students.

There is a similar course in physics which does attract some of the ‘market’ in physics students. We attribute this largely to this being the first two years that this elective was offered. It is not yet a required course in any minor or category, and is not well known in among the undergraduates.

The course is popular among graduate students. It is one of the first attempts to formalize the education that many of them need to complete their research in clean room techniques.

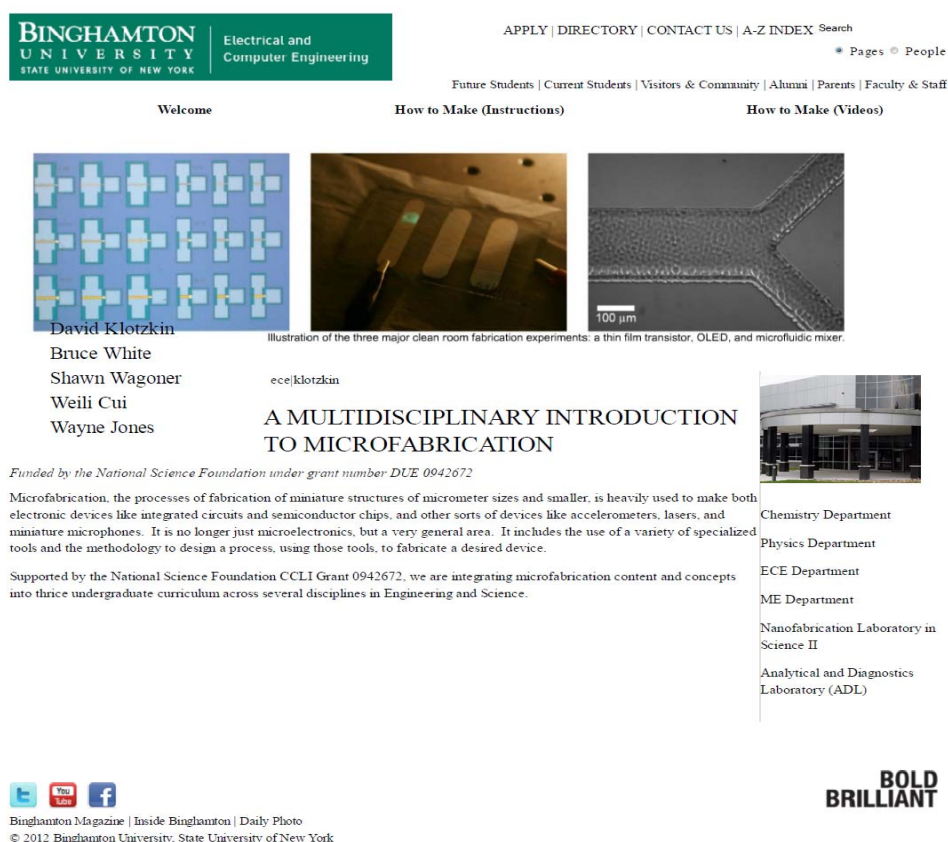

One of our goals is to increase the fraction of undergraduates in the class, as well as attract more majors from outside electrical and mechanical engineering. On the positive side, the students in this course were quite committed, and motivated. The grading was not inflated – most of the students in the course were invested in the material and learned it very effectively.

V. REACTION TO THE CAPSTONE COURSE

Reaction to the course has been quite positive. Positive comments mentioned the relevance of the course to engineering, and that it piqued the students’ interest in the subject.

For balance, most of the suggestions for improvement requested an even-more hands-on fabrication lab experience. All of the students reported medium or high interest in the subject matter after the class, and 80% reported that the labs were useful.

possible, a level above a demonstration, but at the same time

FIGURE 2

MULTIDISCIPLINARY INTRODUCTION TO MICROFABRICATION WEB PAGE (AT [HTTP://WWW2.BINGHAMTON.EDU/ECE/KLOTZKIN/](http://www2.binghamton.edu/ece/klotzkin/))

VI. WEBPAGE

Many of the activities and results from this pedagogical development activity were collected into a 'Microfabrication' web page, shown in Figure 2. This is intended to be an online resource at Binghamton University or elsewhere for students and faculty in educational aspects of microfabrication. The webpage contains links to videos describing the fabrication process, as well as detailed instructions for the fabrication of each of the various modules.

VII. MICROFABRICATION PIPELINE MODULES

One of the most important aspects of this project was the development of pipeline modules, which are experimental activities that are introduced in lower level classes to expose students to microfabrication [7]. The pipeline modules are designed to attract students from each department into the capstone microfabrication class. These modules fulfill the dual role of complementing the class they are associated with while exposing undergraduates to microfabrication technology. The ambition is to make them as 'hands-on' as

taking into account the time constraint of the existing course and the reality that the students are not qualified to safely do much in the clean room.

The original idea of the project was to make the pipeline modules the characterization part of the microfabrication lab, but that proved largely impractical due to class sizes and lab capacities. In this first year of the project, development of pipeline modules took the form of developing several videos which portrayed device fabrication and characterization. Scenes from a typical video are shown in Figure 3 and links to these videos are also on the microfabrication web page. Two videos have been completed so far, one on fabrication of

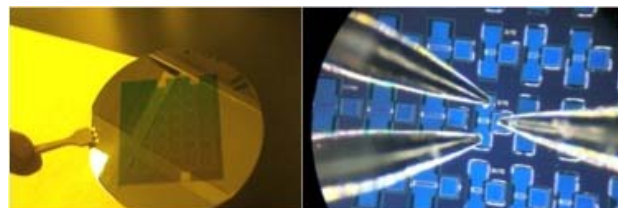

FIGURE 3

FRAMES FROM THIN FILM TRANSISTOR PROCESS DEVELOPMENT VIDEO

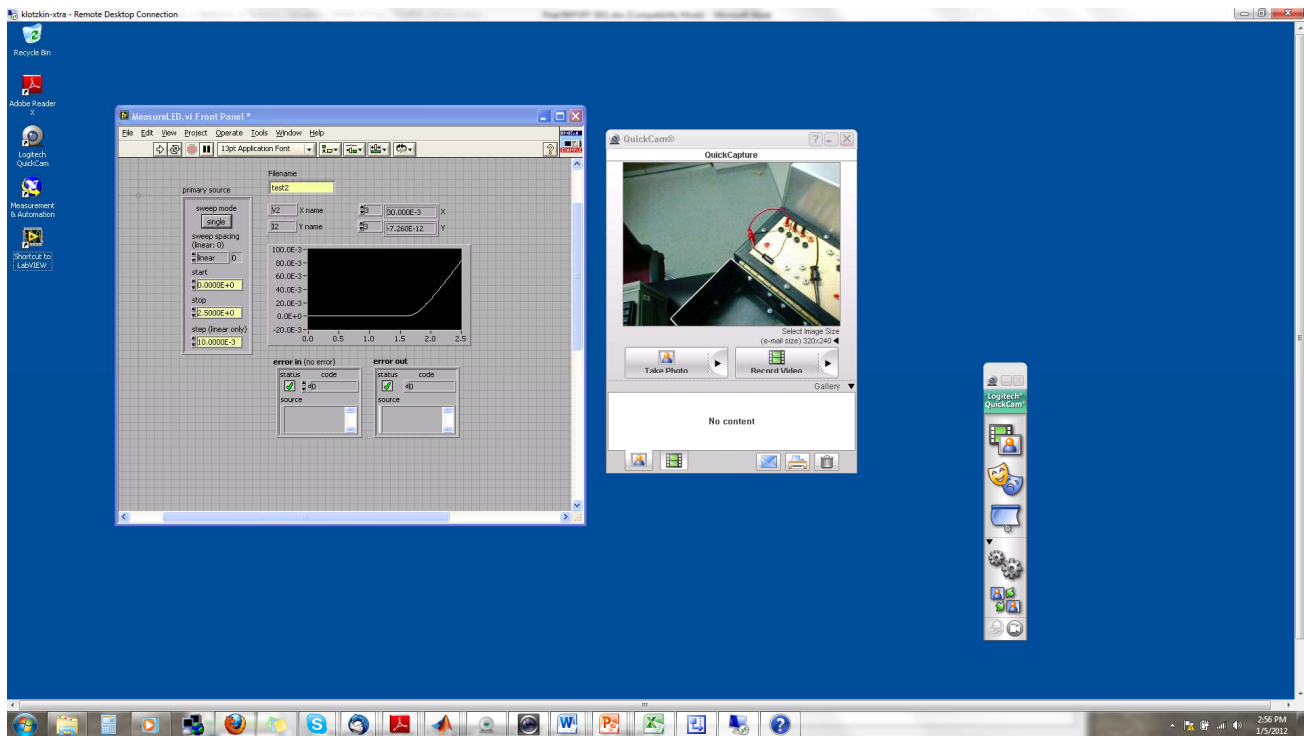

FIGURE 4

WINDOW FOR REMOTE LED EXPERIMENT IN WHICH THE STUDENTS CAN DO EVERYTHING BUT TOUCH THE SETUP: THEY CAN GATHER DATA, RUN THE INSTRUMENTS, AND SEE THE DEVICE BEING TESTED. WHILE OF COURSE THIS IS NOT AS GOOD AS FULL LABORATORY EXPERIENCE, IT IS MUCH BETTER THAN EXPERIENCING ELECTRONIC DEVICES JUST AS DESCRIPTIONS AND GRAPHS IN TEXTBOOKS, AND PRACTICAL FOR LARGE CLASSES. IN THIS EXPERIMENT, THE STUDENTS CAN ADJUST THE START AND STOP VOLTAGE APPLIED TO THE LED AND GET AND SAVE L-I-V CURVE, WHILE WATCHING FOR THE OPTICAL TURN ON.

organic light emitting devices and one on fabrication of thin film transistors. Another video, on fabrication of a microfluidic device, has had the footage shot and is in the midst of the editing process. These videos are used in relevant classes to expose students to the fabrication processes of the devices.

Another idea which we applied particularly for large classes was the remote experiment [8,9]. Instructional lab work typically involves a great deal of hands-on setup and manipulation followed by a brief experimental phase (taking the data) and an analysis phase. What we have done is implemented the first phase for the student for some simple experiments. This gives a very important opportunity for students to relate to a physical device. To illustrate it by example in Figure 4, a remote experiment on light emitting diode characterization was set up using a camera, Labview software and Remote Desktop. This combination allows the student to ‘log on’ to the lab from anywhere and run the experiment. In the experiment, the students were requested to remotely connect to the host computer, collect data, and analyze it. Other hands-on pipeline module activities are under development. We hope the remote experiments described here will be some of the many that we can gradually incorporate into classes such as semiconductor electronics, or solar cells.

The modules developed were incorporated into a variety of courses, as listed in Table 2. The goal was to give students an appreciation for the role of microfabrication, apart from the

various materials used. Each activity was generally accompanied by an assessment to aid us in refining the activity and to measure how well the desired learning outcomes were being achieved.

TABLE 2: COURSES IN WHICH PIPELINE MODULES HAVE BEEN APPLIED

| Course | Pipeline Module Used | Assessment Results |
|--------------------------------------|---|--|
| WTSN 111 Introduction to Engineering | Slide overview of microfabrication process | Clicker-based questionnaire on microfabrication topics |
| EECE332 Semiconductor Devices | Remote LED experiment; transistor fabrication video | Before and after microfabrication survey |
| PHYS227 | Fabrication of diffraction grating | Microfabrication survey |
| Chem 445 | Fabrication of OLED module | Microfabrication survey |

VIII. ASSESSMENT

To continuously guide and improve the program, baseline measures of nanotechnology content mastery were implemented across several courses and departments. A 23-question survey on general microfabrication knowledge, the Microfabrication Knowledge Inventory, was developed and administered to many classes. In addition, a more specific 'Microfabrication Concept Inventory' was developed for use with the capstone course, to evaluate its effectiveness. Some of the flavor of the assessments is contained in the typical questions shown in Figure 5. The Concept Inventory is much more specific, designed to be used with classes specifically in Microfabrication; the Knowledge Inventory is general knowledge of micro- and nano-fabrication and is intended to gauge how much the students absorb of microfabrication knowledge through their undergraduate curriculum. These assessment instruments were developed by the PIs based on what students could reasonably be expected to know about microfabrication from a conventional suite of engineering, chemistry and physics classes.

A full analysis of this data is ongoing, but typical results are shown in Figure 6. A class in semiconductor devices (EECE 332) did a subset (constrained by the time allowed) of the Microfabrication Knowledge Inventory test before and after participating in a pipeline module consisting of the 'Making of a Transistor' video, and the online experiment. Below summarizes the results; the nanotechnology activity seems to have enhanced their knowledge of microfabrication. We note that this is the result of all the questions asked of the students; some showed no statistical change, but in the main, the

CONCEPT INVENTORY QUESTION

14. At pressures typical of e-beam evaporation, the mean free path of the evaporating material
- is very small relative to the size of the deposition chamber
 - is typically similar to the size the deposition chamber (56% of responses on the pre-test were correct; 64% of responses on post-test were correct).**
 - has a size similar to the smallest feature size on a substrate
 - none of the above, the mean free path is not well defined for evaporating material

KNOWLEDGE INVENTORY QUESTION (WITH % CORRECT ANSWERS FROM INTO TO ENGINEERING, 2011)

Rank these in order of size, from largest to smallest:

- 1) Diameter of a human hair
- 2) Influenza virus
- 3) State of the art memory transistor
- 4) Width of a strand of DNA

- A) 1, 2, 3, 4 46%
 B) 4, 3, 2, 1 10%
 C) 2, 3, 1, 4 8%
 D) 3, 1, 2, 4 35%

FIGURE 5

TYPICAL QUESTIONS FROM CONCEPT INVENTORY AND KNOWLEDGE INVENTORY

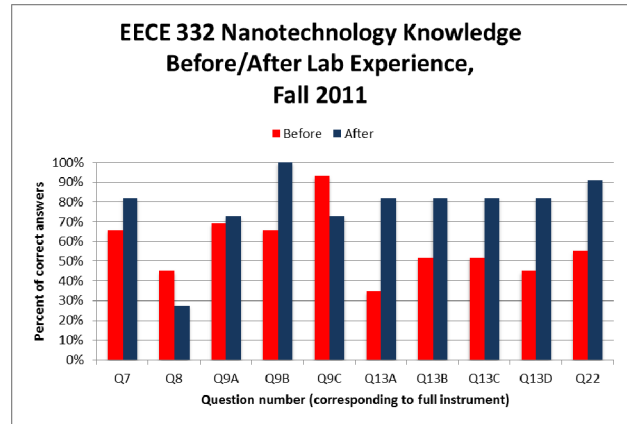

FIGURE 6

MICROFABRICATION KNOWLEDGE ASSESSMENT RESULTS IN EECE 332 BEFORE AND AFTER PARTICIPATION IN A PIPELINE MODULE.

module seemed effective.

A secondary goal of this project is to track the students' acquisition of microfabrication knowledge throughout the program, including both those exposed and not exposed to these pipeline modules and capstone course. A comprehensive list of all the assessments done is given in Table 3. We are also working towards refining the assessment instrument.

TABLE 3: ASSESSMENT ACTIVITIES

| Course | Assessment Used | # |
|--|---|------------------|
| WTSN 111 Introduction to Engineering Fall 2009 | Microfabrication Knowledge Inventory - subset | ~100 |
| WTSN 111 Introduction to Engineering Fall 2010 | Microfabrication Knowledge Inventory - subset | ~100 |
| EECE578, EECE431 PHYS 483A PHYS 583A Intro to Microfabrication Spring 2011 | Nanotechnology Concept Inventory | (9 pre/ 13 post) |
| Physics 132 Fall 2010 | Full Microfabrication Knowledge Inventory | 255 |
| ME362 | Full Microfabrication Knowledge Inventory | 121 |
| ME 480-590 | Full Microfabrication Knowledge Inventory | 18 |
| EECE260 Spring 2011 | Full Microfabrication Knowledge Assessment | ~80 |
| Physics 131 Spring 2011 | | |

Preliminary assessment results suggest that the pipeline modules, and capstone course, do effectively convey the desired information. The final piece of information we hope to obtain for this program is a short-term 'longitudinal study' indicating how many students who participated in this program up to the capstone course continued on to careers in microfabrication. This longitudinal survey will be done in the fall, but anecdotally, at least two students (out the 24 so far) who took the capstone course also took jobs directly involving microfabrication.

IX. SUMMARY

A plan for a comprehensive approach for integration of microfabrication activities into engineering and science curriculum is outlined. Assessments are used to continuously monitor the effectiveness and improve the approach. It is our hope that this multidisciplinary activity will not only expose students to the art of microfabrication, but will also enhance their appreciation for the need of interdisciplinary research early in their engineering and scientific career

ACKNOWLEDGMENT

This project is supported by the National Science Foundation under grant number DUE-0942672.

Work in Progress: Weekly Innovation Challenge

Changing the Mindset One Step at a Time Every Week

Abstract—While the value of the entrepreneurial mindset in engineering is now well recognized, faculty members are still struggling to find curricular and extracurricular activities to instill this mindset. This paper presents weekly innovation challenges as a relatively easy to implement set of activities that can be incorporated into:

- *Existing courses* as impromptu competitions and icebreakers that require no major curricular overhaul,
- *Extracurricular activities* to effectively engage students and faculty, and
- *Outreach activities* to promote STEM and entrepreneurship through summer camps, engineers week competitions, K-12 outreach, and open-house events.

The goal of the weekly innovation challenges is to instill the entrepreneurial mindset and foster interdisciplinary team to address a need under tight time constraints. In the long-term, the challenges have the potential to change the eco-system of the entire school. This paper provides insights into the organization of such challenges and logistics in conducting them.

Keywords—component; innovation; entrepreneurial mindset; multidisciplinary teamwork; challenges

I. INTRODUCTION

The Weekly Innovation Challenge (WIC) is an integral part of entrepreneurial education at Saint Louis University. It puts students in a real life situation involving collaborative and investigative learning, community exploration, and innovation. Participants exercise a frugal, flexible, and feisty approach to problem solving like MacGyver. Such an approach is a key to successful start-ups and innovation [1].

Companies are increasingly valuing creative, innovative, entrepreneurial employees. The experiential activities like the WIC help students hone these sought after skills. Experiential learning activities connect theory with practice and allow the participants to apply concepts and integrate experience with education [2]. Activities such as design challenges require students go beyond planning to prototyping and testing and serve to foster critical design skills such as problem solving, creative thinking, teamwork, and communication skills in an exciting, relevant way [3, 4]. Hence many programs are incorporating activity-based learning in the classroom and

curriculum. Some examples of activity-based learning that incorporate innovation are MIT's D-Lab, Harvard's public service classes, and "flipped classrooms" where the lectures are watched online as homework and the class time is for activities in an effort to create a more engaging learning experience [2,5,6].

Institutions often leverage competitions to motivate their students to exercise creativity and experience entrepreneurial skills. While business plan/pitch competitions are common, several competitions are focused more on engineering innovation. Lawrence Tech's Innovation Encounter, ASME IShow, the National Collegiate Innovators and Inventors Alliance OPENMinds competition, I2P (Idea to Product) competition, and Georgia Tech's Inventure Prize are examples of competitions focused on engineering innovation [7, 8, 9, 10, 11]. While these competitions foster innovation in a similar way to the WIC, they require a significant effort for a short time. Participants often move on after the competition. On the other hand, WIC requires consistent effort for a specified duration regularly. It can easily be incorporated into the participant's weekly routine.

At Saint Louis University, the WIC is hosted every week of the school year for continuous engagement to all students and faculty. While other competitions encourage interdisciplinary teams and restrict the number of teams, the WIC mandates interdisciplinary teams and puts no cap on the number of participants. Further, participants can just show-up at the start time to compete in the challenge.

Currently, Gonzaga University and Kettering University have embraced this idea. While Kettering University conducts similar challenges as a part of the speaker series, Gonzaga University conducts them on a monthly basis.

II. STRUCTURE OF WEEKLY INNOVATION CHALLENGES

A. Goal

The goal of the WIC program is to promote the entrepreneurial mindset through multiple exposures to innovation challenges in a competitive, multidisciplinary, team-based, creative environment where the students take on one challenge and one team is chosen as the winner. Just as people are encouraged to exercise everyday to keep the body fit, the WIC is designed to keep the mind fit. It's a mind

workout. The impact of the WIC is that participants entering the challenge are able to exercise their creative side, work in interdisciplinary teams, and experience the team dynamics. They tackle a novel situation under intense competitive time pressure, while networking with other students outside their disciplines, and most importantly, fine-tuning their entrepreneurial skills.

Each WIC is aimed at nurturing creativity, innovation or entrepreneurial mindset. For the purpose of WICs, creativity is defined as the ability to transcend traditional thought patterns and break through hidden assumptions. Theodore Levitt's quote "Creativity is thinking up new things. Innovation is doing new things." best summarizes our view of innovation. In the WIC, innovation is bringing the idea to life [12]. Entrepreneurial mindset takes innovation to the next step by adding value perspective. It is bringing a product or service with a unique value proposition that can provide a sustaining value to all stakeholders. In the WICs, the three concepts are distinguished using the judging criteria shown in Fig. 1.

Creativity = Ideas

Judged by novelty

Innovation = Ideas + Action

Judged by both novelty and usefulness

Entrepreneurial mindset = Ideas + Action + Value

Judged by novelty, usefulness, and value proposition

Fig. 1. Three concepts - Creativity, innovation and entrepreneurial mindset

B. Team Formation

The WIC is open to all students of Saint Louis University. The teams are restricted to exactly three members. To encourage multidisciplinary collaboration, the team members must be from different majors. At least one participant should be an engineering major.

Some participants form their teams ahead of the challenge time and come to the challenges. Several participants come to the challenge without forming their teams. The organizers help them to form teams. The team members get to know each other briefly before the challenge.

Due to significant interest from faculty and staff and requests from students, the challenge rules were modified to allow a maximum of one faculty or staff member per team. The multi-disciplinary requirement is enforced even for these teams. Normally, students select the faculty or staff member that they want to work with.

C. Time, Location, and Incentives

The challenge is held each week (except during the mid-term and finals week) on Tuesdays in the Engineering School Rotunda (shown in Fig. 1) from Noon to 1:00 pm. As it is held at the same location and time, the challenge can easily be integrated into the student's weekly routine.

The features of an ideal location are:

- *Central Space* which can attract a number of participants and readily accessible.
- *Open Space* that can accommodate the participants. Anticipate growth in the numbers as the challenges become popular.
- *Public Space* where a number of people will pass through. As people pass through the challenge location (while leaving or entering the building during lunchtime), it attracts attention. Passers-by may participate in future challenges.

The teams work on the challenge for about 50 minutes. The judges announce the winner at the end of the challenge. The winning team takes the entire prize money (\$225). Within 24 hours of the completion of the challenge, participants or viewers can submit written reflections on their learning. The best reflection wins \$75.

Fig. 2. The challenge space

III. OVERVIEW OF WEEKLY INNOVATION CHALLENGES

22 challenges were conducted during academic year 2011-12. Table I summarizes these challenges. The headings for columns 4, 5, and 6 in Table 1, C, I, and E denote creativity, innovation, and entrepreneurial mindset (refer Fig. 1). Detailed information on running the individual challenges and the learning outcomes is provided in the free iBook [12]. A brief description of each challenge is given below:

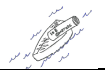

A. The Marshmallow Challenge

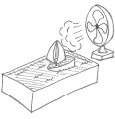

Participants were asked to build the tallest freestanding structure with a marshmallow on top. The best of two trials determined the winner. The time limit for each trial is 18 minutes [13].

B. The Toaster Challenge

Participants were informed that the design department created five unique toasters. Teams selected a toaster that they perceived as most sustainable and designed the packaging for that toaster to make it visually appealing to a "green" shopper.

TABLE I. INNOVATION CHALLENGES CONDUCTED

| Challenge | Description | C | I | E |
|---|--|---|---|---|
| Marshmallow Challenge  | Build the tallest freestanding structure that can support a marshmallow. | | X | |
| Toaster Challenge  | Design an appealing packaging for a toaster to a "green" shopper. | | | X |
| Puzzle Challenge  | Complete a given set of puzzles – the fastest team wins. | X | | |
| Foil Challenge  | Create a boat to float most quarters. | | X | |
| Scavenger Hunt Challenge  | Hunt the locations of close-up pictures. | X | | |
| Elevator Pitch Challenge  | Pitch an idea to add a healthy breakfast on campuses. | | | X |
| Newspaper Table Challenge  | Build the tallest table using newspaper to support a ream of paper. | | X | |
| Rubberband Car Challenge  | Build a car powered by a rubberband to travel the farthest distance. | | X | |
| Gmail Challenge  | Pitch improvements to Gmail. | | | X |
| Balloon Plane Launch Challenge  | Launch a paper plane using a helium balloon and the longest hovering plane wins. | | X | |
| Aesthetic Bridge Challenge  | Build an aesthetic bridge to support a certain weight and span a given gap. | | | X |
| Game Theory Challenge  | Play a series of game theory games and earn points. | X | | |

| Challenge | Description | C | I | E |
|--|---|---|---|---|
| Raft Challenge  | Build the cheapest raft to float a certain weight and travel a given distance using wind power. | | | X |
| Queen Bee Challenge  | Build the tallest tower – worker bees who are blindfolded build while queen bees can only instruct. | | X | |
| Electric Outlet Marketing Challenge  | Create the product presentation for a surge protector. | | | X |
| Reuse Bird Feeder Challenge  | Build an aesthetic bird feeder from trash materials. | | X | |
| Think Globally - Act Locally Challenge  | Bring a global best sustainability practice to a local level. | | | X |
| Outsourcing – Planner/Builder Challenge  | Recreate a Lego creation – planners create assembly instructions and a builder assembles. | | X | |
| Supply Drop Challenge  | Protect two glass candle holders from a two-story drop. | | | X |
| Space Launcher Challenge  | Build a device to launch ping-pong balls through a suspended ring. | | X | |
| Student desk challenge  | Prototype a student desk for a dorm room | | | X |
| Code Transmission Challenge  | Develop a code that can securely relay a message across a 20 ft. gap. | X | | |

C. The Puzzle Challenge

Participants solved a series of 10 puzzles and were timed. The first team to complete all 10 puzzles was the winner. Puzzles ranged in difficulty from relatively simple (laying dominos on a modified chessboard) to complex (balancing 10 nails on top of one nail fixed in place) [14].

D. The Foil Challenge

Teams created a boat capable of floating the most quarters possible using a 3×3 inch piece of aluminum foil. They had 30 minutes to prototype the boat. Teams could test the boat in the water during prototyping. The winner is determined on one final run.

E. The Scavenger Hunt Challenge

This challenge helps participants to be aware of their surroundings. Teams were given close-up pictures of sixteen locations around campus. They identified the items using only their knowledge of the campus and problem solving skills. The second part of the challenge included four tasks such as obtaining a signature from the director of the Intellectual Property Office. The first team to come back with the most correct responses won.

F. The Elevator Pitch Challenge

Participants were challenged to promote a healthy campus by adding a healthy breakfast to the students' diets. They were to create a plan and sell that idea to the community. They had 40 minutes to work on their ideas and then, pitch for 90 seconds to a rotating set of judges.

G. The Newspaper Table Challenge

This challenge was modified from the PBS Design Squad challenge [15]. Participants were given the following challenge: Design and build a table out of newspaper to support a paper ream. Participants could not open or damage the paper ream. The winner was determined based on the height from the base of the table.

H. The Rubberband Car Challenge

Participants were challenged to build a car that travels the farthest distance. Rubber bands can be the only power source.

I. The Gmail Challenge

Much of our communication heavily relies on email. Participants conceived and developed their concepts to improve Gmail in 40 minutes and then, presented them to judges.

J. The Balloon Plane Launch Challenge

The challenge is to use the helium balloon to launch a paper airplane. The airplane that stays in the air (launch to landing) the longest time wins.

K. The Aesthetic Bridge Challenge

The challenge is to design and build a bridge that supports 1 lb. and spans a two-foot gap. The most aesthetically pleasing (or best looking) bridge won.

L. The Game Theory Challenge

The challenge pitted teams against each other in a series of game theory games where the outcome of the games

determined the number of points a team had. The team with the most points won.

M. The Raft Challenge

The challenge is to build a raft that can float the Billiken and travel 2.5 feet on water using wind power. The participants used fake money to pay for materials, the lowest costing raft that performed the functions won.

N. The Queen Bee Challenge

The challenge is to build the tallest tower with several cups of different sizes. A maximum of two team members can be the worker bees and can touch or move the cups. The worker bees are blindfolded. The other member(s) act as the queen bee(s) and can provide only oral instructions.

O. The Electric Outlet Marketing Challenge

The challenge is to create a prototype model of the product presentation. Several innovative electrical outlet designs are provided to the participants. Participants can choose to create just the package or the product and package.

P. The Reuse Bird Feeder Challenge

The challenge is build an aesthetic bird feeder from trash. The teams have to upcycle material such as soda cans, plastic bottles, paper, and foam.

Q. Think Globally – Act Locally Challenge

The challenge is come-up with a concept from the global best practices. The team should bring the best practice to a local grass-root level innovation (product/service/campaign/...). The presentation is judged based on the innovation, potential impact, and feasibility.

R. Outsourcing – Planner/Builder Challenge

The challenge is to effectively communicate between planners and builder without face-to-face, verbal interaction. The planners reverse engineer a Lego Friends creation and write assembly instructions to aid the builder recreate the creation accurately.

S. Supply Drop Challenge

Participants created the inside packing for container that can keep two glass candleholders safe from a two-story drop. They purchased supplies using fake money. The cheapest design that kept the candleholders intact won.

T. Space Launcher Challenge

Participants built a device that could launch Ping-Pong balls into a suspended ring from a certain distance away. The team that got the most ping pong balls through the ring won.

U. Student Desk Challenge

Participants were asked to design and create a prototype of a student desk for a dorm room. The participants could not pitch or demonstrate the prototype to the judges.

V. Code Transmission Challenge

Participants developed an encryption code to transmit a secure message across a twenty-foot gap. The first team that transmitted the message securely and correctly won.

Fig. 3. A collage of the challenge pictures

IV. INNOVATIONS IN THE WIC

The first WIC was the marshmallow challenge where the teams must build a freestanding tower to support a marshmallow. As the challenges progressed during the academic year, several changes were introduced to make the challenges more open, better the learning experience, and be more unique. These innovations include:

- *Open-endedness*: The supplies in the later challenges are more open-ended where the teams select or buy their supplies. The criteria for winning were expanded beyond pure technical merit. For instance, the aesthetic bridge challenge is judged based on the ability to carry the predetermined weight (a technical criteria) and aesthetics (a qualitative non-technical criteria).
- *Learning Experience*: Initially, after the experiential activity of the challenge, all participants were given a debrief statement to help them to consolidate their learning experience. However, their learning experience could be quite different and can never be completely formulated before the challenge. Therefore, the format is changed to incorporate individual participant reflections. The reflections are posted in the reflection blog [12].
- *Uniqueness*: The challenges were altered to place a significantly higher emphasis on the teamwork. Both the queen bee and outsourcing – planner and builder challenges force the teams to collaborative and

communicate at a much higher level. The uniqueness of these challenges lies in the technical, business, and societal aspects to solve customer needs. Think globally – act locally challenge helps the participants to come-up with implementable green design solutions which will be embraced by an average customer.

V. ASSESSMENTS

The purpose of this paper is to discuss how to emulate these challenges and use them as good tools for teaching the entrepreneurial mindset. Currently, we are using reflections from participants, surveys, and focus groups to assess their learning. During the spring semester, an external moderator was used to conduct a focus group study. 12 student participants were randomly selected to provide feedback. The goal of the focus study is to determine the impact of the challenge and characteristics of winning teams. Preliminary results indicate a positive learning experience. The discussion of the results of assessment is beyond the scope of this paper.

Participant's written reflection on what their learning and/or their unique perspective on the challenge. Reflections are incentivized with cash prizes for the best reflection. Here is a sample reflection for the electrical outlet marketing challenge:

Most of our focus is usually on inventing and designing a product, it was difficult to switch gears and think about what would get the product sold in a store. By thinking about the products we personally like to buy, we decided that packaging must be simple and efficient but also appealing to the eye. We realized that the name and directions should clearly explain the product's purpose. Through working in this challenge, we discovered that our own experiences as consumers can be a great resource when trying to figure out what the public is looking for in products [12].

The participants believe that the WIC is changing their mindset. The WIC best summarized in participants' own words:

The WICs are changing the mindset one step at a time every week.

Innovation Challenge is the best opportunity to realize your full potential as a human being as well as an engineering student.

I enjoy participating in the innovation challenges because they provide problems that are different than those that I face in the classroom and require me to work with a group of students from diverse backgrounds to come up with unique and creative solutions.

The participants and winners come from a variety of backgrounds and is summarized in Table II.

TABLE II. LIST OF PARTICIPANTS MAJORS AND TIMES WON

| Majors | Total | Times Won |
|---|----------|-----------|
| Mechanical Engineering | 42 | 8 |
| Aerospace Engineering | 35 | 14 |
| General Engineering | 29 | 0 |
| Business | 24 | 2 |
| Biomedical Engineering | 18 | 2 |
| Electrical Engineering | 13 | 7 |
| Civil Engineering | 12 | 4 |
| Undecided | 12 | 0 |
| Aviation Science | 6 | 2 |
| Biology | 6 | 1 |
| Faculty/Staff | 5 | 1 |
| Computer Engineering | 4 | 1 |
| Physics | 4 | 1 |
| Computer Engineering, Entrepreneurship | 4 (each) | 0 |
| Computer Science | 3 | 3 |
| Political Science | 3 | 2 |
| Mathematics | 2 | 3 |
| Accounting, Biochemistry, Education, Engineering Physics, Finance, Leadership, Philosophy, | 2 (each) | 0 |
| Investigative Medicine | 1 | 2 |
| Music | 1 | 2 |
| Public Health | 1 | 1 |
| Bioelectric Engineering, Chemistry, Communication Science, Dietetics, Economics, French, Geology, Graphic Design, Health Mgmt., Information Tech Mgmt., Marketing, Neuroscience, Nursing, Physical Therapy, Psychology, English | 1 (each) | 0 |

VI. CONCLUSIONS

A recent article states “To encourage more play on the job, colleges and universities could emulate nonacademic institutions like Google, Bell Labs, and IDEO by establishing playrooms and allocating time specifically for the purpose of fostering creativity. Another idea is to create an innovation hothouse, like Stanford University's Hasso Plattner Institute of Design, where the goals are teaching imagination, choosing risky, out-of-the-box solutions, and working through repeated failures as part of the creative process” [16].

The WIC is designed to both foster the playful creative mindset and set a specific time every week for exercising the mind. The nature of each challenge is playful and is further accentuated with the materials used in the challenges. Challenges use water, colorful balloons, popsicle sticks, Legos, crayons, markers, tape, glue, construction paper and many more things that naturally bring out the “kid” in everyone.

While all engineers face challenging situations similar to the WICs where they have to come-up with creative ideas under tight time constraints, what differentiates leaders is how they deal with them. Eugene “Gene” Kranz, NASA Flight Director for the Apollo 13 mission, is known for the quote “Failure is not an option” [17]. During Apollo 13 mission, he successfully led NASA mission control to bring back the crew.

They solved a series of challenges such as jury-rigging a life saving carbon-dioxide filter from available materials. The NASA team demonstrated the critical improvisation skill, which is also a hallmark of the WICs.

The WIC cultivates an action-oriented culture in participants. A lack of action is a major obstacle to most entrepreneurs; they get caught up in the planning and the data gathering and focus less on the execution [18]. Entrepreneurs who take small, yet concrete action consistently, bring their ideas alive faster and better understand the business potential [18]. The WIC stresses continuous quick action - prototyping and refining. Thus, the WIC transforms participants into action-oriented, entrepreneurial-minded engineers.

ACKNOWLEDGMENT

The authors would like to thank the Kern Family Foundation and the Coleman Foundation for their support.

Constructing a Collegiate Motorsports Engineering Program

Pete Hylton, Scott Raymond, Wendy Otoupal-Hylton

School of Engineering & Technology

Indiana University Purdue University Indianapolis

Indianapolis, USA

phylton@iupui.edu, sdraymon@iupui.edu, wotoupal@iupui.edu

Abstract—A handful of universities around the country have capitalized on the increased visibility of the sport of auto racing, the financial growth in the motorsports industry, and the increased need for technically trained individuals to work in that industry. The motorsports industry has some unique challenges based on the extreme conditions in which products must operate, the rapid pace at which changes must be designed and implemented, and the necessity for engineers to operate in hands-on mode with the vehicles they oversee which requires a strong applied aspect to engineering education. This paper will examine the creation of the first four year Bachelor of Science degree in Motorsports Engineering offered in the United States. This paper will include a discussion of how new classes were selected and developed in conjunction with the program's industry advisory board. The design of applicable student projects will be examined, including how these various projects were utilized in the design and construction of actual vehicles used both in competition and as teaching tools. Developing any new program requires attention to not only curriculum construction but to student and program assessment as well. The efforts to develop unique assessment tools for this unusual program will be discussed as will the ongoing commitment of the program to work closely with industry advisors to produce graduates with the correct skills needed for the motorsports industry. The lessons learned from creation of this new program can prove useful to those involved in the creation of other unique engineering and technology programs.

Keywords—Motorsports, Program Development, Innovative Practice

I. INTRODUCTION

In 2006, the dean of the Indiana University Purdue University Indianapolis (IUPUI) School of Engineering and Technology (E&T), Dr. Oner Yurtseven, suggested that with the school located in the self-proclaimed "World Capital of Auto Racing" it would be appropriate for IUPUI to develop a motorsports program. [1] With that objective, the faculty members who had motorsports experience discussed what classes might be pertinent to add to the program in order to offer students some technical elective courses with a motorsports flavor. It was decided to create a new Introduction to Motorsports course and a Vehicle Dynamics course and offer them out of the Engineering Technology Department, which oversaw the more application based programs within the school. Additionally, a dormant course on Internal Combustion

Engines was resurrected and reinvigorated, adding a performance slant consistent with the motorsports theme.

Additionally, a motorsports project was initiated to take a donated production sports car and turn it into a competition race car. This car was to be used as a teaching tool in the new classes and also was advertised as a student project which volunteers from within the school could work on. All three of the classes filled in their first offering and were considered a great success by both faculty and students. This success soon led to the idea of creating a Motorsports Certificate Program which could be offered independently, or similar to a minor, as an accompaniment to a BS degree. In the end, an additional new class was created, in Motorsports Data Acquisition, and two versions of the certificate were offered, one with a mechanical slant and one with an electrical slant. These certificates required a minimum of three of the motorsports specific classes along with several existing classes from the School of E&T's curriculum. Additionally, it was required that the student participate in one of the projects being offered on the school's racecar design and construction. In two years of offering these options, the classes continued to fill and the race car (Figure 1) was successfully completed and began to compete in the Sports Car Club of America's (SCCA) autocross and club racing divisions, winning championships in both. Students graduating with the Motorsports Certificate have been successful in gain internships with both race teams and the sanctioning body for IndyCar racing.

In 2008 Dean Yurtseven instructed the Motorsports Program Director to draft a proposal for creation of a new BS degree in Motorsports Engineering, which would be similar to degrees existing in Europe, but would be the first of its kind in the United States. This program was approved in May of 2009, [2] accepted students for the fall semester of 2009, and had its first graduates in May of 2012. The model used to create this program and ensure its success is worthy of study, not just for those interested in motorsports, but by anyone considering developing a new university engineering or technology program.

II. DESIGN OF THE NEW PROGRAM

The proposal which was created capitalized upon the fact that Indiana's governor had recently made a point of acknowledging motorsports as one of the key economic drivers

for the state. The objective of the program, as stated by the proposal was as follows:

The Motorsports Industry offers a thriving and expanding career field requiring employees with specific engineering skills. This degree program would train engineering graduates for these industries which have recently become recognized by the State of Indiana as a major contributor to the state's continued economic growth.

Figure 1. The IUPUI Motorsports Director and the school's first race car project. (IUPUI Media Gallery)

Recognition of the economic impact of a new program, and how it fits with the state's economic and growth goals should be a key element in the decision process to create any new university program.

Using his own experience from motorsports, the program director created a list of twelve new classes that would have a specific motorsports angle. [3] These were then melded with existing classes from the Mechanical Engineering (ME), Electrical Engineering (ECE), Math and Science departments. By doing this, it was not necessary to create as many new classes. The math and science courses were chosen to be the same as they would be for a typical ME program. Additionally, fundamental classes which apply to multiple programs of study, such as Materials, Thermodynamics, Electrical Circuits, etc. were shared with the existing ME and ECE programs. The draft plan of study included the following courses:

Engineering

ENGR 195 (Intro to Engineering)
MSTE 272 (Intro to Motorsports)
ENGR 197 (Programming)
ME 200 (Thermodynamics)
MSTE 210 (Statics & Dynamics)
ECE 204 (Electrical Circuits)

ME 272 (Mechanics of Materials)
MSTE 320 (Motorsports Design)
MSTE 330 (Motorsports Data Acquisition I)
MSTE 340 (Dynamic Signals & Systems)
MSTE 350 (Computer Aided Engineering)
ME 310 (Fluid Mechanics)
MSTE 331 (Motorsports Data Acquisition II)
ME 344 (Materials)
MSTE 472 (Vehicle Dynamics)
MSTE 426 (Internal Combustion Engines)
MSTE 360 (Control Sys. Anal. & Design)
ME 401 (Engineering Ethics)
MSTE 414 (Motorsports Capstone)
MSTE 420 (Automotive Controls)
Technical Electives

Humanities/Social Science

ENGL W131 (Writing)
COMM R110 (Speech)
TCM 360 (Technical Writing)
IET 350 (Economics)
General Electives

Math and Science

MATH 165 (Calculus I)
CHEM C105 (Chemistry)
MATH 166 (Calculus II)
PHYS 152 (Physics I)
MATH 171 (Multi-Dimensional Math)
PHYS 251 (Physics II)
MATH 26 (Multivariate Math)
MATH 266 (Differential Equations)
IET 150 (Statistics)

As can be seen, this list maximized what the faculty believed were the necessary and pertinent supporting and foundational courses already being offered in other departments, as well as adding new motorsports related courses to the curriculum (all new courses are designated MSTE for Motorsports Engineering)

This list of courses was then sent out for review by a list of industry reviewers. The Executive Director of the Indiana Motorsports Association was asked to assist in the selection of the reviewers to ensure a broad cross section of representation. Three IndyCar race teams, three stock car race teams, three drag racing teams, and six businesses that support the motorsports industry were selected. After review by this group, the following classes were added to the list:

MSTE 297 (Motorsports Modeling)
MSTE 410 (Motorsports Internship)
MSTE 310 (Business of Motorsports I)
MSTE 311 (Business of Motorsports II)

The internship course was suggested by the reviewers because they wanted to ensure that hands-on experiential learning was a

required part of the curriculum since it plays such a large role in motorsports success. Additionally, they urged that experiential opportunities be included in as many of the design and analysis classes as possible. The modeling class was recommended because it would include the skills most likely to be used by students in internships. The business of motorsports classes were added because every member of a motorsports team is likely to be involved in decisions relating to the marketing and management of the team, and because more race teams fail due to poor management than due to poor race cars.

These activities demonstrate how review by, and feedback from, members of industry were used to develop the plan of study. This is pertinent because these are the businesses that will serve as internship homes for students, employers for program graduates, and potential collaborators for both faculty and student projects.

This program has served as a model for collaborations within the School of E&T. The decision was made to locate the new engineering program in the engineering technology side of the school so that it could make use of the more applied nature of that side of the school, as well as its hands-on laboratory facilities. This was consistent with the industry recommendation to keep the program tied to real world applications and experiential learning opportunities which are a strong point of the IUPUI technology programs. So while the program uses engineering classes as its foundation, and develops its own specialized engineering classes on motorsports topics, it maintains a strong tie to the hands-on nature of the technology side of the school. Additionally, the certificates are now offered as technology certificates to accommodate a motorsports option for all students in the School of E&T, regardless of program. This is an example of how programs with differing backgrounds and aspects can work together to create successful new programs.

Motorsports Engineering has proven to be the fastest growing program on the IUPUI campus, and a successful one in other ways, too. IUPUI's racing karts, both gas and electric, have proven the dominant entries in both the Purdue Grand Prix and the Electric Vehicle Grand Prix with the winning team shown in Figure 2. The school's initial entry into the Society of Automotive Engineers (SAE) annual Formula SAE competition, shown in Figure 3, proved to be the highest placed rookie team. All of the vehicles within the program were designed and built as projects associated with classes in the program, thus turning every one of these competition vehicles into a teaching tool. Additionally, a collaborative research project with a major drag racing team resulted in a new chassis design which set a new world record. [3,4]

III. ASSESSMENT OF PROGRAM

This curriculum was then compared against the guidelines set by the Engineering Accreditation Commission (EAC) of the Accreditation Board for Engineering and Technology (ABET). The desired outcomes of the program were then established by the motorsports engineering faculty at IUPUI are:

- a. Demonstrate and apply knowledge of mathematics, science, and engineering with:
 - a1. Knowledge in chemistry and calculus-based physics in depth
 - a2. Mathematics through multivariate calculus, differential equations, and linear algebra
 - a3. Probability and statistics
 - a4. Mechanical engineering sciences: solid mechanics, fluid-thermal science, material science

Figure 2 IUPUI's winning kart team at the Electric Vehicle Grand Prix. (IUPUI Media Gallery photo)

Figure 3 IUPUI's entry in the Formula SAE competition (Andrew Borme photo)

- b. Design and conduct experiments methodically, analyze and interpret data
- c. Design a system, component, or process,

meet desired needs with applications to:

- c1.** Mechanical systems
- c2.** Thermal systems
- d.** Function in teams to carry out multidisciplinary projects
- e.** Identify, formulate, and solve engineering problems
- f.** Understand professional and ethical responsibilities
- g.** Communicate effectively, in writing and orally
- h.** Understand the impact of engineering solutions in a global and societal context through broad education
- i.** Recognize the need to engage in lifelong learning
- j.** Demonstrate knowledge of contemporary issues
- k.** Use the techniques, skills, and modern tools of engineering effectively and correctly in engineering practice with:
 - k1.** Engineering analysis tools
 - k2.** Engineering design and manufacturing tools
 - k3.** Internet and library resources
 - k4.** Mathematical computing and analysis tools

Additionally, the program was assessed against the schools Principles of Undergraduate Learning (PULs) which are given here:

- 1(a) - Express ideas and facts effectively in written formats
- 1(b) - Comprehend, interpret, and analyze texts
- 1(c) - Communicate orally in one-on-one and group settings
- 1(d) - Solve problems that are quantitative in nature
- 1(e) - Make efficient use of information resources and technology for personal and professional needs
- 2(a) - Analyze complex issues and make informed decisions
- 2(b) - Synthesize information in order to arrive at reasoned conclusions
- 2(c) - Evaluate the logic, validity, and relevance of data
- 2(d) - Solve challenging problems
- 2(e) - Use knowledge and understanding to generate and explore new questions
- 3(a) - Apply knowledge to enhance personal lives
- 3(b) - Apply knowledge to meet professional standards and competencies
- 3(c) - Apply knowledge to further the goals of society
- 4(a) - Display substantial knowledge and understanding of at least one field of study

- 4(b) - Compare and contrast approaches to knowledge in different disciplines
- 4(c) - Modify their approach to an issue or problem based on contexts and requirements of particular situations
- 5(a) - Compare and contrast the range of diversity and universality in human history, societies, and ways of life
- 5(b) - Analyze and understand the interconnectedness of global and local concerns
- 5(c) - Operate with civility in a complex social world
- 6(a) - Make informed and principled choices regarding conflicting situations in their personal and public lives and to foresee the consequences these choices
- 6(b) - Recognize the importance of aesthetics in their personal lives and to society

Table I gives the outcomes for the MSTE degree, how they map to Bloom's taxonomy of learning, the IUPUI PULs, and ABET criteria a-k. This shows how a proposed program should be compared against relevant criteria prior to implementation, to ensure that all pertinent goals, objectives and projected outcomes are aligned.

IV. COLABORATIVE RELATIONS

The Motorsports Engineering program at IUPUI has grown, and the Industry Advisory Board (IAB) has continued to be a strong part of program development, meeting twice per year with the faculty and administrators to discuss possible improvements to the program. The BS program has reached its fourth year, with all classes having been taught at least once, and the first graduates nearing their walk across the stage at commencement. At this stage in the program, the program director was sent for a sabbatical in the field to spend time with over fifty race teams, sanctioning bodies, and motorsports manufacturing firms. The objective was to once more examine the needs of the industry and to audit whether or not the program was accomplishing the desired goals and creating the graduates that the industry needed.

One of the questions asked of those organizations visited was, "what course or courses are the most important for a graduate to have in order to have maximum potential in your organization?" The results are shown in Table II.

This is indicative of the fact that it is necessary to continually align the program to the needs of industry to produce the best graduate for the market. In this case, there were obvious additions needed to the program, as items 8-15 were not part of the original plan of study, yet clearly scored well on the list of priorities. An Aerodynamics and Computational Fluid Dynamics course and a Motorsports Project Management class have subsequently been created. Courses from the IUPUI Energy Engineering program and Mechanical Engineering Technology program will be made available to meet the needs relative to the green engineering and machining topics.

Table I Program Outcome Mapping

| Upon completion of the BS degree, students will be able to: | Bloom's Taxonomy | ABET a-k criteria | IUPUI PULs |
|---|------------------------------------|-------------------|----------------------------|
| 1. Demonstrate knowledge and skills in the use of the design and analysis of mechanical systems. Demonstrate a working vocabulary and knowledge of industry requirements and regulations. | Knowledge & Comprehension | a | 1d,1e, 3b,4a |
| 2. Use current knowledge of mathematics, science and emerging tools to solve problems and demonstrate solutions. | Application | b | 2a,2b, 2d,3c, 4a,4c |
| 3. Identify, analyze and integrate technical requirements with the needs of the industry as required in the degree program's courses. | Analysis | f | 1b,1d, 2a,2b, 2c,2d, 4a,4c |
| 4. Apply and design solutions for issues identified in industry. | Synthesis | d | 2b,2d, 3c,4a, 4c,6b |
| 5. Conduct, analyze and interpret experiments, gather data, and assess results. | Application, Analysis & Evaluation | c | 1b,2a, 2c,2e |
| 6. Function as a member of a team to complete a task in a timely manner. Demonstrate ability to organize work done by team members. | | e | 1c, 5c |
| 7. Write technical reports; present data and results coherently in varying formats. | | g | 1a,1c, 3a,5c |
| 8. Demonstrate skills for life-long learning by locating, evaluating and applying relevant information using external resources. | | h | 3a, 5c |
| 9. Demonstrate ethical conduct. Demonstrate knowledge of professional code of ethics. | | i | 2a,3b, 5b,6a |

V. CONCLUSIONS

The IUPUI Motorsports Engineering program serves as an example of how new university programs can be developed, and demonstrates some aspects of program design and development that can aid in success, such as the following:

1. Ensure that the new program aligns with industry needs and has economic merit for the graduates and the university

2. The program plan of study should maximize synergy with existing programs and courses on the campus so as to minimize the new work required to create the program.
3. Use industry feedback to ensure that the plan of study is designed to produce a graduate with the skills needed for a career in the industry.
4. Use new programs to diminish barriers between programs and departments by fostering collaboration and cross disciplinary cooperation.
5. Build and maintain a strong ongoing relationship with the industry to ensure that the program stays abreast of new technologies and new issues.

Designing Technology for Resource-Constrained Environments:

Three Approaches to a Multidisciplinary Capstone Sequence

Abstract—In this paper we describe three different offerings of a multi-quarter multidisciplinary capstone experience where students engaged in designing and building technology to address problems faced by populations in local and remote resource-constrained environments. We define resource-constrained environments broadly (e.g., low-income communities, low bandwidth environments). These environments provide unique constraints (e.g., cultures where people are unfamiliar with or afraid of technology, environments where power and network connectivity are scarce and expensive). Students are partnered with organizations interested in piloting a solution they devise. The course brings together multidisciplinary teams of students to conduct fieldwork with potential user populations, design a technology to solve a problem inspired by a community-based organization, implement a solution, and evaluate that solution. Students work on projects with real-world impact and gain valuable experience with multidisciplinary design and multidisciplinary team work. In this paper we describe the three class formats we have attempted, sample student projects, and course outcomes based on student projects and survey responses. We also address the various ways projects have continued past the course, and we analyze the structural course and project elements that have contributed to student and research successes.

Keywords - capstone, multidisciplinary, resource-constrained environments, ICTD

I. INTRODUCTION

Highlighting the ways engineering contributes to the larger social good is increasingly seen as a way to attract students to the field – and retain them through the duration of their degree program [1]. At the same time, ABET guidelines specifically ask that we provide students with “the broad education necessary to understand the impact of engineering solutions in a global, economic, environmental, and societal context.” [2] As we have discussed elsewhere [3, 4], we have spent the last several years building on an approach that exposes students to ways technology has an impact in low-income regions as one mechanism for making engineering relevant and showing its power to impact the world positively. For three years we have conducted a multi-quarter multidisciplinary capstone experience where students engage in designing and building technology to address problems faced by populations in local

and remote low resource environments. While this class did not emerge specifically in response to ABET guidelines, the overlap is certainly beneficial.

ABET, for example, asks that we provide students with “an ability to function on multidisciplinary teams” [2]. The multidisciplinary approach discussed in this paper grew out of a capstone experience that was originally grounded in one discipline and sought to provide additional disciplinary perspectives through guest speakers. We shifted that approach over time to more deeply explore how a multidisciplinary approach would enhance the educational experience. One of the strengths of that new approach, which is described in this paper, is the deep collaboration required by student teams. Throughout this multi-quarter course, students from different departments enroll for different credit levels which creates a layer of complexity within the class, but they also have to acknowledge varying disciplinary contributions and distribute workload effectively, in addition to performing traditional project management tasks such as managing expectations and ensuring that deadlines are met. The projects also provide students with the opportunity to experience project lifecycles: the class begins with open-ended ideation, includes engaging real world populations, and ends with implementation and evaluation. This deep experience with multidisciplinary teams is unique in the curriculum in our departments.

In the pages that follow, we describe this multi-term cross-departmental course on designing technology for resource-constrained environments. We define resource-constrained environments to refer to a range of conditions, including material issues such as limited electricity as well as societal conditions such low literacy rates. Resource-constrained environments provide unique infrastructure, technical, and social constraints that demand innovative design approaches. In this course, student teams implement a variety of projects that make them consider design challenges not encountered in their previous engineering courses; the course sequence also forces them to work in teams that challenge their conception of expertise and relevant skill sets. The strength of our approach is that students work on projects that (1) contribute to the social good (2) explore local and global impacts of technology, (3) give them experience working on multidisciplinary teams, (4)

interact with eventual users of their design, and (5) work under unique design constraints [4].

We have offered this course sequence three times since 2009. Each offering has differed slightly in structure and instructional staff. In all three instances, students were organized into project teams organized around student interests and drawing on local and international partnerships. Each team was multidisciplinary, consisting of students from Human Centered Design and Engineering (HCDE), Computer Science and Engineering (CSE), and at times also from departments of Psychology, Public Policy and Informatics. All three offerings have followed a somewhat similar pattern across quarters. This course is based on an earlier CSE capstone course on Information and Communication Technologies for Development (ICTD) [3].

In one quarter, HCDE students were responsible for doing needs analysis through fieldwork, literature searches, and social impact analyses to lay project groundwork. They conducted fieldwork through interviews, observations, web surveys, and user testing. CSE students generated initial prototypes and discussed technical specifications with the team. In the next quarter, CSE students (enrolled in a CSE capstone course) were partnered with HCDE students and the team built prototype implementations of the designs that had been developed in the prior quarter; HCDE students led the evaluation of the prototypes.

In the remainder of the paper we describe the three course offerings in detail, including sample projects, and discuss the trade-offs of various course structure and project elements. Our primary goal in the paper is to discuss how we iterated the course, seeking to improve the educational experience. However, since instructional staff changed slightly for each offering, what we learned from the evaluations was implemented within the constraints of how different instructors approach a classroom setting. While from a pure research perspective this introduces confounding variables, it is also a realistic presentation of how curricular innovations evolve and take root.

II. RELATED WORK

Service learning has long provided a way to incorporate engineering projects that have a positive impact on society [5-8]. Benefits of a service learning approach include building stronger relationships between the university and the community and attracting students to the field through the context of the projects. While we do not employ all aspects of the service learning approach in our course, we saw students engaged by the potential to use their design and implementation skills for social benefit. Other projects have motivated students by the incorporation of open-source humanitarian projects [9] and assistive technologies [10] into capstone courses or as independent study projects. Colorado School of Mines offers a Humanitarian Engineering minor [11]. Socially relevant projects are seen as a good fit for the altruistic leanings of this generation of students [12], and some studies have found that female students in particular are more likely to select humanitarian engineering capstone projects [13].

Our course is based on earlier offerings of a CSE capstone course on ICTD [3]. ICTD is an area of research that studies the opportunities and impacts of applying information and communication technologies in developing economies [14, 15]. ICTD projects are currently being pursued in many engineering departments and emphasize the importance of collaboration with fields such as public health, education, agriculture, and business. Examples of projects in this area include tracking adherence to HIV/AIDS regimens, making crop prices available to farmers, and collecting records of microfinance transactions. A few universities integrate ICTD into their undergraduate curricula [16, 17]. Having students work on ICTD-related projects forces them to consider design challenges not encountered in other computer science courses, such as creating low-cost technology solutions suitable for environments with intermittent power and low Internet connectivity, and designing interfaces appropriate for users who are illiterate or lack deep experience with technology. We differ from these approaches in that we define resource-constrained environments more generally than ICTD, encompassing geographic areas in both the developed and the developing world. Expanding our scope allows us to more easily connect students with accessible user populations and clients.

Much work has been done on multidisciplinary engineering projects in undergraduate education [18-21]. Our work differs in that it focuses on collaborations composed of students from two disciplines – human centered design and engineering (HCDE) and computer science and engineering (CSE) – one focused on understanding and designing around the human aspect of the problem, the other focused on the technical implementation of those human-centered designs. Students in the HCDE department learn to research, design, and engineer interactions between humans and technology. Although the HCDE department is unique to our university, students from human-computer interaction, design or psychology programs could play a similar role.

III. DESCRIPTION OF COURSE SEQUENCE

Since 2009, we have had three offerings of a variable-credit, multi-quarter course coordinated by the CSE and HCDE departments at the University of Washington (UW). Each offering has differed slightly in structure; the overall structure of the course across all offerings is shown below in Table I.

TABLE I. COURSE STRUCTURE

| | Autumn Quarter | Winter Quarter | Spring Quarter |
|-----------|--------------------------|--|---|
| 2009-2010 | 1 credit reading seminar | 2 credits for CSE 5 credits for HCDE (HCI Course) | 5 credits for CSE (capstone course) 2 credits for HCDE |
| 2010-2011 | | 2 credits for CSE 5 credits for HCDE (HCI Course) | 5 credits for CSE (capstone course) 2 credits for HCDE |
| 2011-2012 | | 2 credits for CSE 2 credits for HCDE | 5 credits for CSE (capstone course) 2 credits for HCDE |

A. Autumn 2009- Spring 2010

During the 2009-2010 academic year (consisting of three ten-week quarters), we offered a variable-credit, three-quarter

course. The sequence was co-taught by two instructors, one from HCDE and one from CSE. In autumn 2009, 17 students enrolled in a one-credit seminar to read and discuss research papers about projects in developing countries and resource-constrained communities within developed countries (i.e., low-income communities, homeless populations, low bandwidth environments). The purpose of this seminar was to familiarize students with some of the unique constraints encountered when designing for resource constrained environments (e.g. How do you design for cultures where people are unfamiliar with or afraid of technology, or for environments where power and network connectivity are scarce and expensive?). The course met one hour a week, and a different application area or design constraint was discussed at each meeting. Sample topics include education, transportation, non-literate user interfaces, designing technology for homeless populations, healthcare, and agriculture (full reading list on the course web page [22]).

Winter 2010 was a project design studio. 22 students enrolled in a five credit HCI course offered by HCDE partnered with 13 CSE students registered for two credits. Students were divided into project teams and each team consisted of both CSE and HCDE students¹. On Tuesdays, all students met together (CSE and HCDE students), and topics relevant to the project were discussed (reading related to resource-constrained communities, selection of project topics, team work skills), and project presentations were given to the class. On Thursdays, only the HCDE students met; during these sessions they discussed fieldwork and HCI topics. In addition, the instructors met regularly with each project team for a half hour to discuss progress and issues specific to that team.

There were seven project teams with about two CSE students and four HCDE students per team. Within the project teams, HCDE students were responsible for doing needs analysis through fieldwork, literature reviews, and social impact analyses to lay project groundwork. HCDE students did fieldwork in a variety of domains and scenarios including: interviews with doctors and medical students at local medical clinics, observations of food bank operations and elementary school classrooms, web surveys of potential carpoolers, and email surveys of Ugandan midwives. CSE students were responsible for coming up with initial prototypes for the technology and discussing technical specifications with the team. Throughout the course, teams gave presentations to the class, and at the end of the quarter a poster fair and demo session was held for the general public.

In spring quarter, 12 CSE students enrolled in a five credit capstone course were partnered with 10 HCDE students signed up for two credits of directed research. CSE students built prototype implementations of the designs developed in winter, and HCDE students helped evaluate the prototype through user testing. Throughout the quarter, teams presented their ideas to the class and to panels of experts in formal presentations, poster sessions, and written reports. There were a limited number of full class meetings; instead the instructors met with

each team for a half hour each week to discuss progress and issues specific to that team. The class as a whole met three times during the ten week quarter to select project teams and to give presentations.

Each team was assigned about four CSE students. Three of the projects from winter quarter were selected to continue into spring; they were chosen based on student interest and progress made in winter. Some teams had most members carry over from winter; others had several new members join the project at the beginning of spring quarter. All project teams were comprised of students from multiple departments.

B. Winter 2011- Spring 2011

During the 2010-2011 academic year, the course sequence was shortened to remove the autumn reading seminar. However, there is a multidisciplinary weekly discussion group focused on this subject area [23], and students from that discussion are now recruited into the class; for many of the students that weekly discussion serves as a substitute for the background introduction gained previously through the reading seminar. We also added some of the more critical readings to winter quarter. The 2010-2011 sequence was co-taught by two instructors, one from each department. An additional CSE instructor joined for spring quarter. Winter 2011 followed a format similar to the previous year. 27 students enrolled in a five credit HCI course were partnered with 15 CSE students registered for a two credit design studio. A similar structure of course and team meetings was used. There were eight project teams with approximately two CSE students and two to six HCDE students per team. Spring 2011 was also similar to the previous year in format. 15 CSE students enrolled in a five credit capstone course were partnered with 7 HCDE students signed up for two credits of directed research. The class as a whole met six times during the ten week quarter to select project teams, discuss challenges and evaluation strategies, and to give presentations. As in the previous year, instructors met with teams each week for half an hour to discuss progress. Six teams continued from winter and consisted of two to three CSE students and one to three HCDE students. Due to student interest and the nature of their particular projects, two teams consisted only of CSE students.

C. Winter 2012- Spring 2012

During 2011-2012, the pairing with the HCI course was dropped due to scheduling issues. Instead, in winter quarter 8 HCDE students registered for two credits of research, and 10 CSE students registered for a two credit design studio. The course sequence was co-taught by three instructors, two from CSE and one from HCDE. In winter 2012, without the pairing with the HCI course, all students registered for the two credits and attended the same number of meetings. The course met once a week for two hours. Approximately six of the meetings were used for organization, class discussion of readings, and presentations. On the remaining days the class met together for a few announcements before breaking up into teams the instructors then visited to discuss progress and give feedback. Instructors held a few other meetings with teams. There were six teams with one to three CSE students and one to two HCDE students per team. Spring 2012 was similar to the previous two

¹ Students enrolled in the HCI course were predominantly HCDE undergraduates but also included students from a variety of majors (Informatics, Psychology, Art, CSE). For simplicity we refer to all non-CSE students as HCDE students.

years in format. 16 CSE students enrolled in a five credit capstone course were partnered with 9 HCDE students signed up for two credits of directed research. All of the HCDE students who signed up for spring quarter were Masters-level students. The class as a whole met three times during the ten week quarter to select project teams and give presentations. All six teams continued from winter and most consisted of one to four CSE students and one to two HCDE students. One team consisted only of CSE students and one consisted of only HCDE students.

IV. COURSE PROJECTS

Over the three course offerings students have tackled a variety of projects ranging from relatively cleanly-scoped local projects (design intake and inventory software for a local food bank) to open-ended international collaborations (help an existing medical school program train midwives in Uganda to use ultrasound more effectively). Examples of projects include:

- Tailor a system that allows sharing of a single computer by multiple students to local schools
- Coordinate translation services for immigrant populations
- Diabetes screening application for a local health organization
- Device to measure the time water carrying cans move each day to determine the time cost of water gathering
- Smart phone application for converting paper forms to digital format using the camera on the phone
- Smart phone application for registering vaccinations
- Text-messaging system for encouraging pregnant mothers
- Visual modeling tool for vaccine cold chain management

Below we discuss two projects in more detail to give the reader a better sense of these student collaborations.

A. Midwives' Ultrasound

The Midwives' Ultrasound project was a collaboration with a Radiology professor who was working on a project to train midwives in Uganda to use ultrasound technology. They were having some issues with commercial portable ultrasounds (cost, difficulty of user interface, etc.), and so the problem posed to the students was: how can you make ultrasound more usable by midwives with limited training? And can you make it cheaper? In winter 2010 there were two CSE students and three HCDE students on the team. Students surveyed local area midwives, created surveys to send to Ugandan midwives, investigated other developing world based maternal ultrasound projects, conducted a literature review for maternal ultrasound, met with local radiologists and ultrasound technicians to learn about ultrasound technology, and contacted ultrasound manufacturers to find a less expensive technology that would be viable for the purposes of the project. The students took significant initiative in contacting both NGOs conducting ultrasound-related work, and ultrasound manufacturers, eventually finding an ultrasound probe on campus they could use for their project. In addition, the students applied for and won a capstone award from the College of Engineering.

In spring 2010, two more CSE students and one HCDE student were added to the team. The team obtained an ultrasound probe and sample control software, and

implemented a prototype interface designed for use by Ugandan midwives. They continued to design a help system and did user evaluations with local ultrasound technicians and radiologists. This team was characterized by a highly motivating problem, great team dynamics, an unfamiliar and remote user population, and an interesting technical challenge. There have been multiple positive outcomes moving forward from this project. Four of the original students continued their work on the project outside of the course. In March and July 2011, three of these students went to Uganda to do a preliminary evaluation of the project with midwives. Several other students and doctors joined the team, they published multiple academic papers (all with student authors, e.g. [24]), and in October 2010 was awarded a Bill and Melinda Gates Foundation Grand Challenges Exploration grant.

B. Milk Bank

The Milk Bank project was a collaboration with a non-governmental organization (NGO) working in South Africa and a faculty member and graduate student in the CSE department. In sub-Saharan Africa approximately 40% of HIV positive children are infected with HIV through their mother's breast milk. One approach to addressing the problem is to provide pasteurized breast milk from milk banks. Since pasteurization techniques used in the developed world are expensive, a low cost method of flash heating has been proposed, although the process is non-trivial to implement. The students were given the task of designing the user interface for a low cost breast milk flash-heating system that provides feedback for each step of the process and sends the temperature curve of the process to quality assurance (QA) personnel. The QA person then evaluates the curve, determining if the milk is safe for consumption by infants, and sends a response to the user.

In winter 2011 there was one CSE student and four HCDE students on the team. The students worked with the CSE graduate student and interviewed staff at the local and South African offices of the NGO to determine the background and training of potential users and details about the environment where the device would be used. The students created a survey to investigate what combinations of lights, sounds, and text would work best as feedback to users. They used hot plates, gas and electric stoves, to explore the range of temperature curves users might obtain. Finally they tested their own prototype and a higher fidelity prototype provided by the graduate student.

In spring 2011, the team consisted of two CSE and three HCDE students. Using the framework provided by the graduate student, students implemented a handheld device to provide feedback to a user heating milk. The device uses SMS to send temperature curves to a server that forwards them to quality assurance personnel. The students also created a smart phone application that allows viewing and approval/disapproval of temperature curves. Students tested the prototype and created user instructions based on a persona they created. One of the original HCDE students has continued work on the project, testing the system as it prepared for a pilot deployment in South Africa in May 2012 sponsored by the NGO. There has been a publication with five student authors from the class [25] and recently the project was awarded a Bill and Melinda Gates Foundation Grand Challenges Exploration grant.

V. LESSONS LEARNED

In this section we discuss structural aspects of the three course offerings and their impact on overall course outcomes. Across all three offerings, in addition to official end of course evaluations, we administered an end of course (and often mid-quarter) anonymous web survey (full results not presented here, some described elsewhere [4]). While not all lessons learned have been fully implemented, we have iterated on the course structure based on the constraints of a public university, especially as this course is an unfunded initiative. It has been especially informative to see what kinds of instructional changes are viable with instructor change-over and variations in scheduling. We are particularly interested in sharing these findings with the community because we believe this is a realistic attempt at curricular reform that responds to institutional limitations.

A. One-credit Reading Seminar in Autumn 2009

One problem with the three-quarter structure used in 2009-10 is that few students enrolled in the entire sequence. Of the 17 students enrolled in the autumn 2009 reading seminar, only 3 continued with the winter 2010 course. Attrition was due to a variety of factors including that we did not advertise it as a required pre-requisite for the remainder of the course sequence. Scheduling constraints also played a role. To accommodate the other 32 students enrolled in winter 2010, at the start of the winter quarter we repeated a few of the autumn readings.

With the availability of a separate multidisciplinary seminar on ICTD [23], and because of the low numbers of students continuing previously from autumn to winter, we have not offered the reading seminar since autumn 2009. Instead we start the winter quarter course with several key readings. While in our context we have found this approach to work well, other universities without as strong of an ICTD research presence would likely find the reading seminar valuable. We would also encourage other schools to consider offering this one credit reading seminar as a multidisciplinary introduction to designing technology for resource-constrained environments even without offering the full project course sequence.

B. Pairing with an HCI Course in Winter 2010 and 2011

The major difference between the 2011 and 2012 offerings of the course was that in 2012 there was no pairing with an HCI course in winter quarter. Some differences due to this change were:

- *Equal number of credits and “buy-in” for both cohorts in winter 2012.* In both of our previous winter end of course surveys we observed some complaints and confusion about the amount of work each cohort was responsible for. Some students enrolled in the 5 credit HCI course felt that if the CSE students on their team were not fully dedicated to the project it was easier for them to slack off since they were only signed up for 2 ungraded credits. Some CSE students observed that some non-CSE students on their team only cared about course deadlines and not the overall project.

- *Equal number of meetings for both cohorts in winter 2012.* In previous surveys some students expressed concern about the difference in number of meetings. Although CSE

students were welcome to attend both days of the HCI course, few did. Some CSE students felt that they were missing out on things that went on in the other meetings of the HCI course.

- *More graduate HCDE students in winter 2012.* In the 2010 and 2011 offerings, students in the HCI course were putting skills they learned in the course to use in their team projects. Without the pairing with an HCI course, in winter 2012 it was necessary to recruit more experienced HCDE students who already had those skills. This led to the majority of the HCDE students in winter 2012 being graduate students.

C. Course Deliverables

All three courses had similar deliverables for spring quarter: a final paper, a poster, and team presentations. In 2010 and 2011 the winter deliverables were similar, while in winter 2012 a briefer implementation plan was required instead of a paper. We feel these deliverables have worked well, but future offerings may collect these artifacts on a web site. When the winter course was tied to the HCI course we needed to specify which parts of the final paper the CSE students could help with. Similarly for all offerings of the spring course we have had to specify which parts of the final paper HCDE students should help with. We found that having students give presentations to audiences outside of class drives home the importance and relevance of their projects.

D. Course and Team Meetings

In both winter and spring quarters the courses were composed of a mix of entire class meetings and team meetings with instructors. Over the three course offerings we have experimented with different numbers of these meetings. In all of our course surveys, students have never expressed a desire for less individual team meeting time with the instructors. Many have cited these meetings as a crucial part of their learning, and some have expressed a desire for more meeting time. Students seem to have more mixed opinions about the number of times the class should meet as a whole. Some felt that the time could be better spent meeting with their team members, while some expressed a desire to at least see the entire class more often. We came up with somewhat of a compromise in winter 2012. Even on days the instructors met with teams individually, we first convened the entire class together for a few announcements before breaking up into teams. The instructors then moved around among the teams checking in with their progress and offering feedback. In this way, students had at least one 2-hour slot each week when they knew everyone in their team could meet together. It also allowed students to see their entire class at least briefly to provide some feeling of a unified cohort.

Scheduling team meetings so that all members can attend is difficult. This can be a challenge in any team project course, but scheduling meetings with students from multiple majors only throws more diverse course schedules into the mix. It is additionally challenging to accommodate schedules of a diverse set of students from one quarter to the next. In some quarters we were able to solicit student input on meeting times for the subsequent quarter. In other cases, we had to pick times knowing that it would not work for all students. The challenges of scheduling team meeting time outside of class and a lack of

team member continuity from quarter to quarter were both factors that detracted from true multidisciplinary collaboration and in some cases overall project success.

E. The Importance of Project Selection

Picking appropriate projects for students is probably the single most important step in course planning. Excitement about their particular project and dedication to their fellow team members were the two most common factors students cited for continuing from winter to spring. For our multidisciplinary course we have found it was important to select projects that provided challenges and rewards for both the CSE and HCDE cohorts. Selecting projects with accessible end user populations (or a reasonable surrogate) was critical for allowing the HCDE students to do fieldwork. In addition, we have found it useful to identify projects falling within a technological “sweet spot” – where the technical challenges are significant enough to be interesting yet not paralyzing.

We have found it to be incredibly motivating for students to have projects connected to organizations on the ground that are looking to pilot their solution. In their evaluations, students often mention their excitement about the opportunity to serve a real need as opposed to “doing the same project over again” as a design exercise. These interactions provide realism often lacking in courses where students devise their own projects and gives them valuable experience with “customer relations” and satisfying real needs. Finding a client or outside expert who was responsive was critical for all cohorts in terms of keeping them motivated and providing details about functionality.

F. Projects Continuing Beyond the Course

Of the nine student projects from the first two offerings of the course, six have lived on beyond the course in significant ways. Many of these have turned into long-term research projects and pilot deployments, involving students from the original course. Five have produced publications with student authors and three have received significant research funding. We have found that pairing teams with a graduate student mentor has helped students make progress during the course and has facilitated continuing the project beyond the course.

VI. CONCLUSIONS

Overall, all three offerings of the course have resulted in successful student project experiences. Our particular multidisciplinary approach is somewhat unique in combining two student populations that may be more likely to not understand the depth of each other’s skill sets, coming from disciplines that tend to attract different types of students with differing methodologies. We have found that the domain of resource-constrained environments is well suited to this kind of experimental multidisciplinary learning experience. The design challenges are complex, and the human-centered challenges are as complicated and rich as the computing-centered challenges. When we can unite both of these types of challenges with a motivating real-world problem, we can create opportunities that allow diverse teams of students to pull it all together and create great things. Students gain a multitude of skills, as well as unique preparation for the workplace where they will often

have to interact with people from varying backgrounds and with skill sets far from their own.

Using Domain General Learning Models to Guide Engineering Education Research

Jonathan C. Hilpert

Georgia Southern University, jhilpert@georgiasouthern.edu

Abstract - The goal of this session is to help attendees understand the difference between domain general and domain specific theories of learning, and how to apply domain general models of learning to engineering classroom research. The participants will work with the presenter to develop new ways of thinking about their own research through the use of examples and group work.

Index Terms - AboEngineering Education Research, Learning, Modeling

DESCRIPTION OF TOPIC

The study of learning and cognitive processing generally falls into two camps: domain general vs. domain specific. The domain general approach argues for broad principles applied to any context. The domain specific approach argues for narrow principles unique to context. For example, information processing models are domain general whereas models of expertise are domain specific. However, rather than a dichotomy, researchers argue for understanding domain general and domain specific processes as complementary during learning and strategy use [1]-[3].

A domain general model of learning should be broad enough to cover a wide range of learning tasks. Hirschfield and Gelman [4] define it as a body of knowledge that organizes a set of phenomena with shared characteristics, essentially offering a simplified framework for understanding a large amount of complicated information [5]. A domain general learning model should include a streamlined set of components that can explain learning across a broad range of contexts.

The components of domain general models also provide causal mechanisms, generally grounded in information processing theory [6], for understanding learning and cognitive processing [3]. Aspects of information processing related to working memory, including knowledge activation, executive functioning, and novel problem solving are most often considered domain general and common across all learning tasks [2][5][7].

Providing engineering education researchers with background knowledge of domain general theories, and how they can be applied to specified to engineering education contexts, can help them to organize future classroom studies around casual learning mechanisms central to any learning task. This can improve the external validity of future research projects and provide insight into how to choose

variables for classroom research and specify learning models based on theory and data.

SESSION AGENDA

FullIn this session, participants will be encouraged to work along with the presenter to learn about domain general models in education research. The participants will engage in activities designed to help them meaningfully interact with the new information and examples, with the goal of applying the learning objectives of the session to their own research interests.

The session will be organized around short activities that are followed by the presentation of new information and examples. The short activities are designed to help participants activate relevant prior knowledge and experiences, and share these experiences in informal groups. Below is a brief outline of these activities and approximate times for pacing instruction.

- **Introductory Activity:** Participants will write about and discuss example learning tasks from their classrooms and research studies that may be interesting for research. Participants will share their responses. (10 min)
- **Domain General vs. Domain Specific Theories:** Instructor will present on the differences between domain general and domain specific learning theories. The instructor will present a common domain general model of learning based on information processing theory. (20 min)
- **Collaborative Activity:** Participants will attempt to fit one of the learning tasks they described in writing at the beginning of the session into a domain general model. Participants will work together in informal groups to develop a simulated research topic (15 min). This activity will be guided by a handout that will guide basic steps of the process.
- **Application and Specification of Domain General Models:** Instructor will present on how to apply common learning variables to domain general approaches to research. Instructor will present on common methods for specifying the relationships among variables chosen for the model using both theoretical and empirical approaches. (20 min)
- **Collaborative Activity:** Participants will chose pertinent variables for the model they developed in the previous activity, discuss potential measurement

instruments, and brain storm methodological techniques for researching and specifying their models. Participants will share their responses (20 min). This activity will be guided by a second handout which will require answering specific open ended questions about research methods than can be applied to the simulated research topic.

- **Example Study:** Instructor will present an example study from his own work in engineering education research that demonstrates each step of the process: choosing a model, applying the model, specifying the model. Results will be discussed with the audience at a high level to emphasize conceptual guidance.

ANTICIPATED AUDIENCE

Because of the domain general nature of the learning theory that will be discussed, and the broad range of applicability, the participants can be any conference attendee interested in classroom engineering education research.

EXPECTED OUTCOMES

The session is designed to help participants rethink classroom research in the context of domain general and domain specific cognitive processes. The session is intended to help them design learning models for engineering education contexts, and to apply and specify theses models according to their research questions and data.

This session is important to me because it is part of a larger methodological interest of mine related to how to study the interaction of domain general processes with domain specific variables. Insights into how to apply and specify domain general learning mechanisms to specific learning tasks can help researchers to understand the nature of the complex network of relationships at play during learning in engineering classrooms.

JUSTIFICATION

This session should be considered because it has broad applicability to engineering education (i.e. it is generalizable across classroom research), it is grounded in contemporary cognitive psychology central to knowledge construction, and it will provide researchers the informal opportunity to design models which explain learning in engineering classrooms.

Presumably, these benefits, along with the example provided in the presentation, will help participants learn to organize research questions around domain general learning mechanisms.

ACKNOWLEDGMENT

The Funding for the data presented in the session was provided by National Science Foundation: REC-0960551, RAPID: Collaborative Research: Examining the impact of the Freshman Teaching Academy on Engineering Student Future Time Perspective awarded to Jonathan C. Hilpert and Jenefer Husman and Strategic Learning REC-0546856, CAREER: Connecting with the Future: Supporting Career and Identity Development in Post-Secondary Science and Engineering awarded to Jenefer Husman.

Panel: Ethics in Engineering Case Study

Deborah L. Limb
The Boeing Company
Renton, WA, USA
deborah.l.limb@boeing.com

Abstract— This panel session is designed to guide faculty members as they work to create a dialogue introducing students in Engineering, Computer Science, and Technology to ethical dilemmas faced by engineers in the fast-paced, budget-constrained, competitive workplace where on time, on budget performance is required. Industry panelists will explore engineering decision-making protocols that can be utilized to help students gain real-life perspective and make better decisions under pressure. The moderator/leader will introduce a set of questions/criteria engineers can routinely employ as a means of ensuring the highest ethical standards of decision-making.

Keywords- ethics, engineering education, computing education.

I. DESCRIPTION OF THE PANEL

Panelists representing multiple perspectives of aviation design and manufacturing will give specific examples. Audiences will leave the sessions with knowledge of specific industry examples of ethical dilemmas facing engineers/business

people and new perspectives on making decisions under pressure.

The introductory presentation will cover: personal accountability, character development, culture of accountability in business, ethical pitfalls in everyday life, ethics and integrity as the foundation of the future, framework of ethical decision-making, understanding and conveying one's values, defining boundaries, personal responsibility, working through ethical dilemmas and tough decisions, following values under pressure, and core questions to guide ethical decision making. Following the introduction, panelists will give examples of dilemmas faced by engineers in industry and demonstrate patterns of decision-making that follow a prescribed set of pre-determined questions to be employed time and time again to guide ethical problem solving.

The goal of the session is to increase awareness and provide educators with a detailed, ethics-based, decision-making strategy to impart to students. Attendees will learn about a step-by-step decision-making process model and multiple examples of industry-related case studies.

Panel: Engineering and Development: Facilitating Successful Project Work in Diverse Global Contexts

Abstract—Over the last decade, a growing number of initiatives have emerged to provide engineering students, faculty, and professionals with opportunities to work on service-oriented projects in developing contexts. And while these courses and programs provide needed resources and services to communities in far-flung locations, they also pose unique challenges and difficulties. For example, projects of this type often require knowledge, skills, and attitudes that are not typically covered in traditional engineering courses nor possessed by many faculty. Additionally, there is growing recognition regarding the need to predict and evaluate the full range of impacts that student projects have on partner communities – both positive and negative. This panel engages these kinds of challenges by bringing together a group of individuals with extensive experience preparing engineering students for project work in developing contexts. In addition to representing programs at four institutions (Colorado School of Mines, Michigan Technological University, Purdue University, and Worcester Polytechnic Institute), the presenters are involved with a host of related national and international initiatives. Each panelist will give an overview of their efforts, with particular emphasis on observed successes and failures, conceptual hurdles faced by students and professionals, pedagogical approaches employed, and most useful resources. The primary audience for this panel includes faculty, staff, and students who lead, support, and/or study global service learning. To enable a more engaging, interactive, and productive session, ample time will be provided to allow attendees to describe their own experiences, share resources, and pose questions. The primary intent of the panel is to help university students, faculty, and staff be more effective when undertaking engineering work in developing contexts, including by promoting scholarly community and collaboration, sharing resources, and seeding new research initiatives.

Keywords—community development; engineering education; global engineering; PBL; project-based learning; service learning

I. INTRODUCTION

Engineers have for centuries served as key agents of nation building. Early on, countless engineers assumed roles serving national development needs “at home,” while others fanned out to support colonial empires. During the 20th century, and

especially during and after WWII, many engineers from the West became involved in a new wave of development-oriented projects and initiatives abroad, often under the aegis of government or corporate interests [1]. Even more recently, globalization trends, the rising prominence of global “grand challenges,” and intensified calls for engineering education reform have led to an expanded array of curricular and extracurricular initiatives that provide engineering students, faculty, and professionals with opportunities to work on service-oriented projects in developing global contexts [2].

While these courses and programs often provide sorely needed resources and services to communities in far-flung locales – while at the same time building competence among participants – they can pose unique challenges and difficulties, [3]. For example, there is growing need to more systematically evaluate and predict the full range of impacts that projects have on partner communities – including positive and negative outcomes. At the forefront of this movement are organizations like Engineers Without Borders (EWB) Canada, which has published its annual *Failure Report* since 2008 and developed an accompanying web site and database [4].

This panel poses a series of provocative questions for participants and attendees. Are we brave enough to look at our programs and initiatives in the mirror? To boldly and critically evaluate their true impacts – both good and bad? To strive for continuous improvement in how we prepare students and faculty for service work abroad? As summarized below, our panelists respond with brief descriptions of their own efforts, placing particular emphasis on strategies that help enable positive outcomes for all participating stakeholders.

II. LEARNING FROM ENGINEERING AND DEVELOPMENT

A. Faculty-led Interdisciplinary Research Projects in the Developing World (Vaz)

Increasingly, engineering students are being exposed to challenges in the developing world, both through classroom activities and experiential work. When designed well, these interactions can benefit communities, while helping students

understand sustainability, grapple with appropriate technology, and reflect on their future roles as practitioners. Worcester Polytechnic Institute's approach involves faculty-led project work in Costa Rica, Namibia, South Africa, and Thailand. Since 1989, about 1,200 WPI students have completed over 300 interdisciplinary research projects in the developing world, focusing on topics such as energy sustainability, water resource management, community development, and sustainable agriculture. The overriding educational goal of these projects is for students to understand the social and cultural contexts in which technology comes to bear. WPI's experience is that these projects can benefit both local communities and students, but only if considerable attention is paid to program design and delivery. Five lessons that have emerged will be discussed and illustrated: (1) it is beneficial to develop strong, long-term relationships with local community organizations; (2) problems should be locally defined, and solutions locally endorsed; (3) students benefit from intensive preparation, including culture, history, and language, but also focusing on previous research and methods; (4) participatory methods and action research approaches often result in more lasting impacts, particularly when local partners can team with the students; and (5) capacity building and increased mutual understanding, rather than physical infrastructure or process improvement, are the most important long-term goals of student programs in the developing world.

B. Engineering Global Engagement: Strategies and Outcomes at Michigan Tech (Paterson)

A small group of visionary faculty started a grassroots effort for global community engagement at Michigan Tech beginning in 1995. Since then, nearly 20 distinct programs have been crafted, offering opportunities for students in most disciplines and levels. This presentation will focus on three of these programs, especially targeting engineering students: (1) a graduate level program, Peace Corps Master's International in Civil and Environmental Engineering, (2) an international senior design program, *idesign*, and (3) a graduate level course, *Discover Design Delight*. Objectives, design, activities, resources, and outcomes of each program will be summarized. Despite their unique features, recent efforts have focused on providing program integration through the creation of the D80 Center for Global Good. Among other developments, a baseline assessment program and an annual conference are key assets to this campus culture; both will be shared in brief.

C. Bridging Sustainable Community Development and Social Justice (Lucena)

This presentation briefly traces the history of engineers' involvement in international development to community development, and highlights when and how "sustainability" and "humanitarianism" became important dimensions of engineering work and education. Yet throughout this trajectory, a number of engineering mindsets have come to shape how engineers engage communities and contributed to making social justice invisible to most engineers, especially their ability to contribute to a fair distribution of rights, opportunities, and resources when working in community development and humanitarian endeavors. This presentation outlines these mindsets, and proposes a number of possibilities to overcome them so engineers can meaningfully and

effectively address social justice within their practices and projects in community development.

D. Integration of Global and Local Service-Learning Design Experiences (Oakes and Huff)

Engineering Projects in Community Service (EPICS), a vertically-integrated, engineering-centered service-learning design program, currently distributes over 350 students per semester from over 70 majors across 30 divisions with more than 80 active community-based design projects. Since its inception in 1995, the program has collaborated with local community partners. In recent years it has also expanded to include international partnerships with service organizations working in Haiti, Columbia, and Ghana. The majority of partnerships intentionally remain local, but the international partnerships have added an exciting dimension to the program. Some of these global partnerships began as new partnerships while others have grown out of local partnerships. The methods of interacting with community partners have evolved to better accommodate collaboration with trans-national communities. Some student have been able to travel to some of the partners with others having only remote access. In this presentation, we discuss the strengths and limitations of this approach and discuss EPICS as a model for immersive service-learning experiences that span local and global engineering designs. We also discuss how students develop cross-cultural competency and how partnerships are intentionally framed to ethically and appropriately benefit students and communities.

E. Building Global Design Teams (Dare and Jesiek)

Purdue University's Global Engineering Program (GEP) launched the Global Design Team (GDT) service-learning program in 2008. GDTs are designed to provide high-impact, multi-disciplinary, collaborative experiences that allow students to participate in real-world, full-cycle design projects, while raising global awareness amongst team members, faculty, and partners. The program strives for positive, sustainable interactions with partner communities through application of technical, global, and professional competencies to identify and address specific local needs. The goal is mutual benefits for all stakeholders, including through exchanges of knowledge and solutions that positively impact enrolled students, collaborating communities, NGOs, and partner universities. In this presentation we review the GDT curricular model, assessment results of design experiences since 2009, and content and outcomes from our inaugural Global Engineering Design Symposium (GEDS) held in early 2012.

A Sophomore Capstone Solid Modeling Experience: Virtual Dissection and Reassembly of Legacy Drawings

Edwin Odom, Steven Beyerlein, Jay McCormack, and Clarence Porter

Mechanical Engineering
University of Idaho
Moscow, Idaho
eodom@uidaho.edu

Abstract—A sophomore computer aided design course is investigated with respect to its ability to prepare students for an authentic team-based design experience surrounding solid modeling of a set of legacy drawings by a master draftsman from an earlier age. Work products include an electronic archive stored on a shared drive, part and subassembly renderings, a shop-ready drawing package, accurate animation of part assembly as well as normal operation, and reflective writing about the project. Preparation for the final project includes just-in-time use of locally authored videos supplied via the course website, deployment of peer mentors within the computer lab, and scaffolding provided by four different mini-projects. Intermediate milestones given on the course website, impromptu instructor/team/mentor meetings next to computer monitors as well as an overhead projector screen, and exemplary portfolios of student work are considered essential for guiding team-based work on the final project. Significant personal growth in engineering graphics skills leading up to the final project and throughout the final project has been observed in an end-of-course surveys that explore many attributes of pre-cad sketching, part modeling, assembly modeling, and creation of engineering drawing packages. Some refinements to the survey are needed to capture more of the wisdom embedded in many legacy drawings and the wisdom typically gained through the final project.

Keywords—solid modeling, virtual dissection, legacy drawings, drawing package formulation, rendering, animation

I. INTRODUCTION

A recent article in the Chronicle of Higher Education listed three practices to improve retention: 1) improve student's spatial-visualization, 2) use everyday examples to engage the students, and 3) improve faculty student interactions [1]. Educational researchers and professional task forces underscore the importance of these same steps in learning engineering [2,3,4,5]. Many engineering programs assume linear dependence between these three steps and tackle them sequentially over several years of study. Engineering graphics is part of the pre-engineering experience where students often learn model building and simple design analysis techniques through a tutorial-driven approach [6,7]. Theory in mid-program engineering science courses is connected generic examples that are anchored in disciplinary examples as part of junior-level courses within the major. Spatial visualization and engagement between students and faculty is often most intense surrounding senior design projects and electives at the end of the program [3,5]. This approach puts a large burden on

students to connect and internalize experiences in separate environments at different times in their academic career. Energetic and creative faculty often try to shoulder some of this burden by infusing compelling examples in introductory math, science, and engineering courses that involves some attention to spatial visualization. However, without an active learning design that promotes knowledge construction, socialization, and self-assessment, this approach is not guaranteed to yield significantly better results [8]. A more robust relationship between the three practices would be simultaneous immersion in which students and faculty alike take the plunge together in tackling spatial design problems in an engineering context that is new to both parties. All would face unknowns that require personal and collective inquiry as well as humility to overcome. This article describes how the University of Idaho uses the virtual dissection of legacy drawings of a rediscovered historical engine each semester to engage students, staff, and faculty in a meaningful learning experience at the end of an introductory solid modeling course.

II. COURSE DESIGN

Our introductory CAD course introduces sophomores to concepts and tools for producing solid models and engineering drawing packages that can be efficiently manufactured in an engineering shop. The knowledge, skills, and perspectives that students develop are intended to enhance upper-level design experiences and to be highly marketable in the engineering workplace, including summer internships. The first two-thirds of the course entails structured and interactive lab exercises surrounding a number of physical prototypes that have been previously produced in the University of Idaho mechanical engineering shop. Undergraduate mentors are used to assist faculty in coaching daily exercises at the keyboard. Prior to class, students view 4-6 minute videos created by previous undergraduate mentors on specialized topics in CAD sketching, part modeling, assembly modeling, and generative drawing. Each day, these are reinforced with short quizzes and large group show & tell sessions before the start of individualized lab exercises. Four different mini-projects are used to synthesize sketching skills, part modeling skills, engineering drawing skills, and assembly modeling skills. The final one-third of the course engages teams of 5-8 in a large-scale, team-based reverse engineering project involving legacy drawings that are 50 to 100 years old. Teams create extensive, shop-ready drawing packages along with renderings and animations of

their completed assembly. Examples of course materials and finished products from past projects can be seen on the course website [9].

The course supports the following learning outcomes that are typical of many first courses in engineering graphics with solid modeling [6,7].

- Describe drawing intent based on details shown in an existing engineering drawing and interpretations based on drawing standards/conventions.
- Use hand sketching to communicate design intent and reference geometry that is a value-added starting point for a CAD model.
- Accurately model parts using fully defined sketch entities, reference geometry, extrusions, lofts, sweeps, revolved features, and patterns.
- Accurately combine parts into assemblies that are constrained to display correct kinematic behavior.
- Make comprehensive part and assembly drawings that follow standard practices for dimensions, through holes, threaded connections, radii, and bill of materials. These drawings should provide all information necessary to manufacture and assemble the components.
- Identify key tolerances associated with part assembly and explain how to inspect parts to determine the degree to which parts match their corresponding drawings.
- Create and thoughtfully maintain an electronic drawing package with assembly, sub-assembly, and part drawings following a departmental template.
- Explode, animate, and render assemblies to illustrate part assembly as well as normal operation.

The course also supports the following design synthesis and professional growth outcomes desired by industry [4]. These build on the traditional outcomes listed above and ensure readiness for upper division design and manufacturing work.

- Document solid modeling work and resulting design products in a manner that others can use to identify underlying assumptions and replicate design intent, including the ability to edit specific features of the model.
- Make meaningful self-, peer-, and instructor-recognized contributions to an engineering design team tasked with creating a shop ready drawing package from a set of hand drawn prints for a mechanical system from a former technological age.

Quizzes, mini-projects, and the final project each account for approximately 1/3 of the course grade. Items that are scored are done so on the four point scale shown in Table 1. Work that meets performance expectations outlined in various

assignment check sheets is awarded a 3.0. Instructors often keep copies of work that is awarded a 4.0 as exemplars for future students. Students must earn an average of at least 3.2 to receive an ‘A’ in the course. The cutoff for a ‘B’ is 2.7 and the cutoff for a ‘C’ is 2.2. This system inspires students to invest time striving for excellence rather than just meeting the grade.

Table 1. Scoring scale used in course assignments.

| Score | Attributes |
|-------|--|
| 4 | Exemplary, insightful, worthy of sharing with entire class |
| 3 | Complete, correct, long-term reference value to self |
| 2 | Largely complete, numerous errors, limited reference value to self |
| 1 | Incomplete, major errors, no supporting documentation |
| 0 | Submitted late, missing major components |

III. ROLE OF MINI-PROJECTS

Four individualized mini-projects help students cultivate engineering graphics skills associated with the competency outcomes. Each of these mini-projects is scored separately in three different dimensions: (1) pre-CAD planning, (2) documentation of the modeling process, including lessons learned, and (3) finished products. Four to five key attributes unique to each mini-project and mapped to each of the three dimensions are given in a check sheet that students use to guide their work and self-assess their submissions. The first mini-project challenges students to sketch their initials with Solidworks using minimum dimensions and maximum relations. They are encouraged to implement ‘powerful’ sketches that are fully defined. Next they are challenged to investigate new and personally interesting feature tools, making their initials ‘cool and 3D’. An assortment of font styles, basic shapes, creative orientations, and surface textures result. The effectiveness of this assignment in capturing student’s imagination while underscoring proper sketch definition can be seen in the example of student work shown in Figure 1.

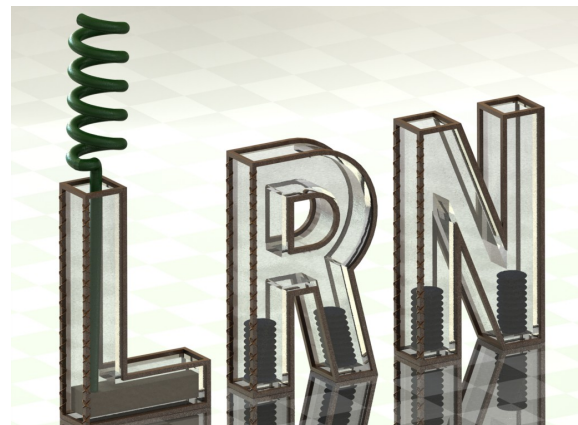

Figure 1. Exemplary submission associated with initials mini-project.

The second mini-project asks students to recreate a complex, patterned object created in our machine shop from a fully-dimensioned, fully-annotated engineering drawing. This requires students to combine and properly sequence many of the CAD tools they learned in various tutorials within a single object. Parts and accompanying drawings associated with previous capstone design projects have been a popular focus of this mini-project.

The third mini-project asks students to generate a solid model and shop ready part drawing from a parameterized part with complex geometry, usually derived from one of several mechanical drawing books published over a half century ago. Unique parts are selected each semester and these come from a rich array of valves, brackets, bearing mounts, and frames. Thoughtful origin selection, calculation of dimensions, use of reference geometry, and implementation of primary versus secondary features is necessary for a tractable model and sensible engineering drawing that uses the University of Idaho sheet format. One of the aims of this mini-project is to familiarize students with the look and feel of drawings from a past era. Extensive use of design tree annotations along with a design journal that describes part realization is expected with the finished product. Figure 2 illustrates a legacy drawing used for a recent part mini-project along with an exemplary render of the resulting part model.

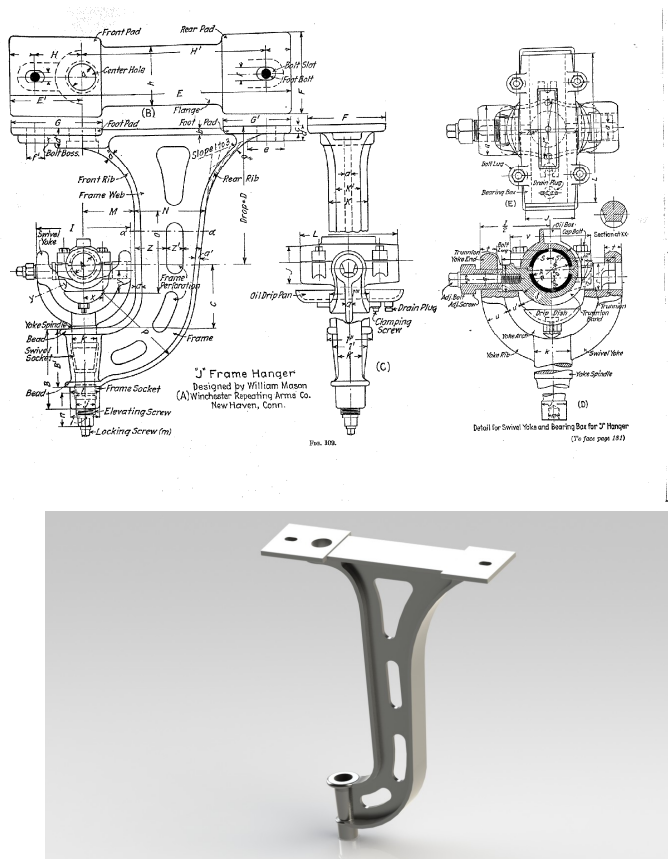

Figure 2. Legacy drawing of hanger for pre-electrification power take-off shaft (above) and example of rendered part submission (below).

The fourth mini-project presents students with a set of ready-made parts for a simple assembly. They are expected to organize these into sub-assemblies, assign part numbers and part property data, and combine the sub-assemblies into a working main assembly which is both rendered and animated. Sub-assembly level and assembly level drawings should use the University of Idaho drawing template that applies a standard sheet format for the title block and that is populated with part property data. Figure 3 illustrates typical work products from this mini-project.

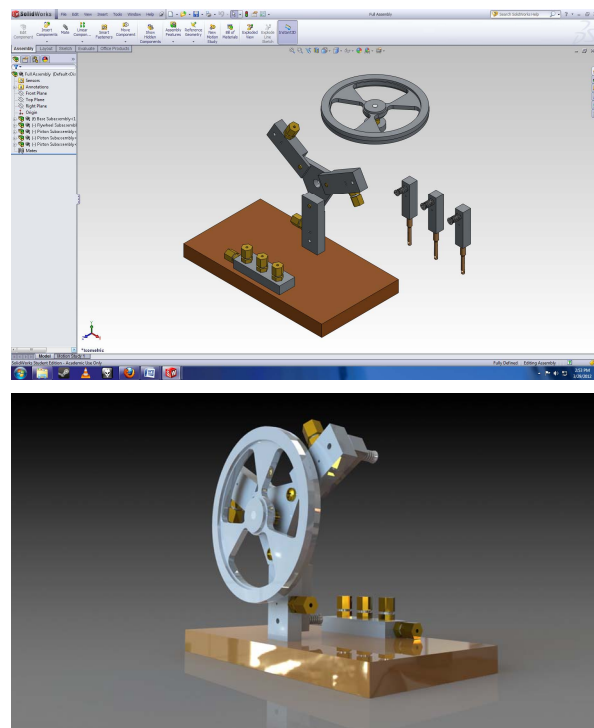

Figure 3. Air motor sub-assemblies before positioning and mating (above) and rendering image after assembly (below).

IV. FINAL PROJECT

The final project begins with a set of drawings taken from a similar source to that used in the third mini-project, avoiding copyright issues. Final projects and the problems that they raise are authentic to all involved—students, mentors, faculty, and machine shop staff. Projects are intentionally not repeated but are shared liberally to communicate and elevate project expectations. The project is team-based (5-10 person teams selected by the instructors, depending on the complexity of the design) and the goal is to recreate an accurate 3-D solid model of all the components, sub-assemblies, and assemblies. Deliverables include an electronic file management system on a shared drive at the University of Idaho, a complete set of engineering drawings that could be fabricated in our machine shop, animations showing assembly steps and operating principles of the engines, and reflections on lessons learned about the design, about the CAD tool, and about engineering teamwork.

Teams decide who is assigned to each component, part numbering protocols, and sub-assembly content. A team recorder is identified who keeps track of project completion using a spreadsheet template perfected by a former team. Complex prints are often enlarged to full size to facilitate visualization and validation of assumptions surrounding part placement and dimensions. Often there is some background information available on the internet, but this invariably is for similar but not identical machines that are defined by the legacy drawings. Figure 4 shows students interpreting a full-sized drawing for a 3 ½ x 5 vertical steam engine [10]. This is a vertical steam engine which has a characteristic ‘bottle’ shape typical of small single cylinder engines at the turn of the 20th Century, a Stephenson valve train, and a reversing linkage.

Figure 4. Students deciphering features and dimensions shown in fullsize assembly drawing for a 3 ½ x 5 Marine Engine.

Project outcomes include student, faculty, and staff respect for craftsmanship from another era, insights about intriguing mechanisms that have a place in the history of technology, and error discovery/correction opportunities not possible with modern 3D design materials. We have also found that these projects create a class wide identity tied with a particular semester project and heightened awareness of pre-course and post-course engineering graphics skills as well as software tool limitations. Figures 5 and 6 show fully-functional sub-assembly and assembly models associated with the Marine Engine.

Figure 5. Rendered Marine Engine Crankshaft.

Figure 6. Rendered Marine Engine Full Assembly.

Project portfolios are a source of pride amongst nearly all design teams. We select some of the best ones each term as a tool for orienting future students about our engineering graphics course and expectations associated with the final project. The portfolios include attractive renders and complete shop-ready drawing packages that have removed some apparent errors in the original legacy drawing. All involved in the project are surprised how few errors students actually find.

V. EDUCATIONAL IMPACT

A. Feedback from Students

Prior to the start of the final project, and again at the end of the final project, students are surveyed about their perceived efficacy in traditional engineering graphics skills [6]. These skills are divided into four areas (a) pre-CAD sketching, (b) part modeling, (c) assembly modeling, and (d) engineering drawing. In the first survey, students provide data on where they believe they were at the start of the semester as well as at the start of the final project. In the second survey, students update data on where they believe they were at the start of the final project as well as where they believe they are at the end of this project. The five point scoring scale below was used to query past and current states of development.

- 0 = not familiar with this skill
- 1 = awareness of what this skill means
- 2 = could perform this skill with coaching
- 3 = could perform this skill using the help system
- 4 = could perform this skill without other resources
- 5 = could effectively and efficiently teach this skill to others

At each stage of development, averages and standard deviations for each skill are computed across the class. Figures 7-10 present longitudinal findings for forty students

pre-CAD sketching attribute

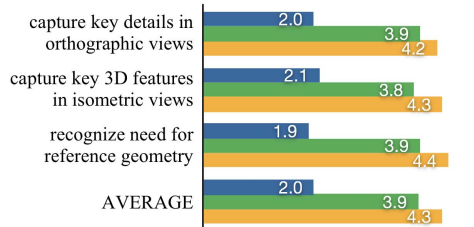

Figure 7. Student self-assessment of pre-CAD sketching efficacy

part modeling attribute

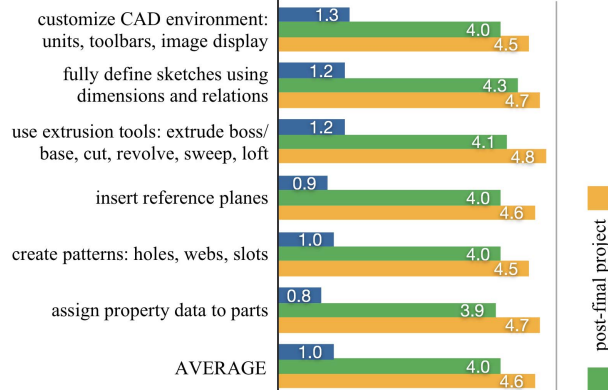

Figure 8. Student self-assessment of part modeling efficacy

assembly modeling attribute

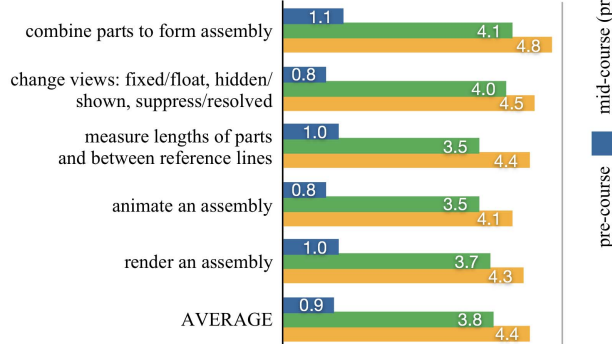

Figure 9. Student self-assessment of assembly modeling efficacy

engineering drawing attribute

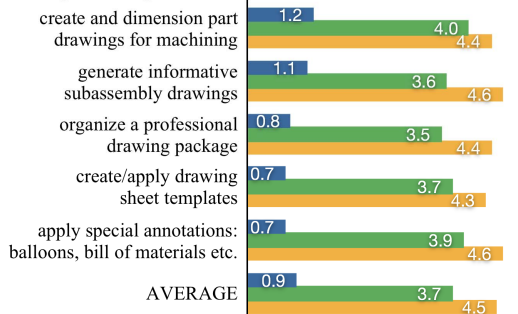

Figure 10. Student self-assessment of engineering drawing efficacy

enrolled in two different sections of the Spring 2012 course. The blue bars indicate perceived skill levels upon course entry. The green bars indicate perceived skill levels after the air motor mini-project but prior to the final project. The orange bars indicate perceived skill levels during the last week of the final project.

Figures 7-10 show the same general trend and improvement for all engineering graphics skills from the beginning of the course, through the mini-projects, and concluding with the final project. Students self-assessed that their familiarity with hand sketching generally exceeds their familiarity with solid modeling. There is wide variation in pre-course scores because this is the first engineering graphics course in our program. At this point, standard deviations in specific skills are as high as 1.5. By the start of the final project, the typical students report growth in perceived ability by nearly two levels. Class wide standard deviation in reported scores is now roughly half that reported for the beginning of the course. Additional growth in engineering graphics skills by one-half to one full level typically occurs throughout the final project.

Design teams write 2-4 pages of lessons learned through the final project. Overall, these comments demonstrate a level of maturity that would be appreciated by employers who hire mid-program students as interns. The wisdom contained in many of these exceeds the skill set queried by the engineering graphics survey. For many teams, the importance of pre-CAD sketching was expanded to include pre-CAD planning that accounted for features on adjacent parts as well as pre-thinking about the organization/naming of files and folders. In the area of part modeling, some teams shared best practices such as documenting assumptions in the comment fields associated with the part properties menu, labeling elements in the design tree to facilitate part debugging, and outlining how to obtain high quality renders. In the area of assembly modeling, thoughtful part numbering schemes, intra-team communication protocols, and spreadsheet designs for tracking project progress were frequently cited. In the area of engineering drawings there was heightened awareness about the use of drawing templates, error elimination through use of part property fields in the sheet format, and recommendations for improving drawing readability.

All design teams were aware of opportunities for additional growth in engineering graphics skills in future design projects. This is evident in representative comments such as:

We should have anticipated some of the adverse consequences of changing names of our directories after assembly began.

It was difficult to dimension sweeps and lofts and we wish we had avoided these more.

It would have been more efficient and effective if we had a clearer story line mapped out before we started our animation.

We assigned someone to lead each sub-assembly, but we underestimated the level of team communication required to make a fully-functioning main assembly.

Some of our drawings would have been improved by using additional sheets to capture multiple layers of detail.

B. Feedback from Instructional Staff

Based on input from the faculty, technical staff, and graduate student mentors who work with capstone design students on drawing package realization, class-wide performance in each of the skills areas queried in the engineering graphics survey should be at a post-course proficiency level of 3-4. This means that students have sufficient CAD efficacy to teach themselves what they have forgotten or don't know about part modeling, assembly modeling, and engineering drawing creation. At the end of each semester, a focus group consisting of CAD course instructors, undergraduate mentors, and senior design staff reviews the entire set of design portfolios that are created. It is their conclusion that actual student proficiency in the areas explored in the student survey exceeds the targeted proficiency.

When faculty started using legacy drawings, they provided novel mechanisms, components and assemblies that both students and faculty had not encountered before. In the end, students, machine shop staff, and faculty had to have a rich conversation that included hand gestures and simple sketches. To be successful, both students and faculty needed to have deep engagement in the project, adding to its value as an authentic engineering learning experience.

As we went deeper into these legacy drawings and the sources they came from, a tremendous respect for former engineers and their era developed. We also found that instructors in the past had pedagogical concerns similar to own. For example, design faculty today worry about students mindlessly clicking through the steps of excellent tutorials that come with the software. Faculty know first-hand how well-written tutorials leave users with the impression that they know the software as well as how to use it in subsequent design work. Faculty also know how easy it is for this impression to unravel in detailed design work surrounding original designs in subsequent projects. A hundred years ago, students learning the trade would make tracings of previous drawings. The following quote from Henry Spooner sums up the worries of that time (1908), *but only very exceptional workers could survive a long course of tracing, for it tends to blunt the perceptions and stifle the powers which are required to make good draftsmen and clever designers. Indeed, tracing has been defined as 'a diabolical invention for destroying draftsmen during their process of incubation [11].*

It is also human nature to worry about what we might not be doing that was part of routine practice in a bygone era. This is also found in the writings of Henry Spooner, *for in ordinary practice mechanical draftsmen are no longer called upon to*

produce drawings with delicate, beautifully joined lines, soft and rich shadows true to geometry, when describing a drawing created in the 1860's [11]. The economy imposed by the cost of vellum and the drawing effort to required maintain these has given way to the ease with which engineering drawings can be electronically propagated from part and assembly models. However, there is no reason that the finished products can't be as insightful and aesthetically pleasing. Outstanding designs still require a special eye and no less critical thinking than the original author. Between semesters, faculty and student mentors invest time updating quick references and video resources to better capture how drafting know-how of old is best translated into solid modeling practice with modern CAD software.

VI. CONCLUSION

Almost all of us have a fond memory of that one class period or that one project where there was special learning happening. It was challenging, engaging and time seemed to stand still. Mihaly Csikszentmihaly wrote about this phenomenon in his book about flow experiences [12]. Once you have had such an experience, you want to experience it again. For the past four years, the virtual dissection and electronic re-assembly of legacy drawings has predictably recreated one of these learning experiences. This is as true for faculty and staff involved in the project as it is for students. In the future, we plan to elaborate on some of the skill descriptions in the current engineering graphics survey in a way that captures more of the special wisdom gained through the use of legacy drawings in the final project.

Physical Modeling in Design Projects: Development and Testing of a New Design Method

Vimal Viswanathan¹ & Julie Linsey²

Mechanical Engineering Department

Texas A&M University

College Station, TX, USA

vimkucv@neo.tamu.edu¹, jlinsey@tamu.edu²

Abstract— Physical models are widely used as idea generation tools by industrial designers, engineers, engineering educators and government agencies. Many schools promote the use of physical models in their engineering curricula. Despite the apparent popularity of physical models, little is known about their cognitive impacts and when they should be implemented in the design process. A few studies have explored physical models and their use as idea generation tools; however the guidelines from them are conflicting. Based upon these conflicting guidelines, a series of controlled and qualitative studies are conducted by the authors to understand the cognitive impacts of physical models in engineering idea generation. In addition to the insights from these studies, data are collected from a project-based graduate design course. The reports from design teams prototyping their ideas as a part of a class project are studied. These reports provide insights about the conceptual errors that student designers make as they build and test physical models of their designs. To reduce the two most critical errors, a design method (Model Error Reduction Method) is formulated. This design method forces the designers to think about two potential conceptual errors in their designs and provides guidance to rectify the issues. The two conceptual errors that the method addresses are: failure to account for critical loads and failure to design connections. This paper presents a controlled experiment evaluating the effectiveness of the method. The preliminary results show that novice designers find the design method extremely useful; moreover, the method seems to help eliminate, to a large extent, said conceptual errors. These findings suggest that the method might augment existing engineering design curricula.

Keywords— *Physical Models; Design Method; Prototyping Guidelines; Design Cognition*

I. INTRODUCTION

Physical modeling plays an essential part in the design curricula of the world's top engineering schools [1]. Using Lidwell's, et al.'s definition, this paper defines a physical model as a prototype of any scale created as a part of the design task [2]. Physical models vary greatly in their complexity level, from very simple mock-ups to fully functional models [3]. They help designers identify flaws in their designs before the production stage of a project [4]. Consequently, physical models help reduce the risk associated with innovation [5]. Since physical models reduce risk, industry tends to encourage their use [4, 6].

Though existing literature fails to provide clear guidelines regarding physical model creation, many design teams, including student design teams, build physical models during their projects [7-9]. By building prototypes, designers aim to communicate their design to third parties, prove the feasibility of their design (proof-of-concept models) and estimate dimensions otherwise indeterminable. Still, recent research demonstrates that, if designers spend more time, money or effort building a physical model of an idea, they fixate to that idea [10]. Fixation can negatively influence the functionality of the overall system if the fixated idea happens to possess undesirable attributes [11, 12]. In the end, the disparate prototyping effects necessitate the formulation of clear guidelines and methods to increase the efficiency of the physical modeling process.

The study presented in this paper applies content analysis [13] to design reports from graduate design teams to identify conceptual errors in physical modeling. Based upon the results from this analysis, the authors develop a set of guidelines to make physical modeling more effective. Additionally, the formulation and testing of a Model Error Reduction Method solving two critical prototyping issues occurs. Subsequent sections include results from the testing of the method along with details regarding the development of both the design method and the guidelines.

II. BACKGROUND

A little empirical work exists about the role physical models in engineering design. The following subsections summarize the few important works in the literature and the authors' prior studies leading to the present work.

A. Physical Models in Engineering Design

Many researchers advocate using physical models as a part of design projects. Kelley, of the famous product design firm IDEO, describes physical modeling as the short hand of innovation [6]. Building physical models at early design stages can help designers visualize and solve problems in complex systems [14]. A verbal protocol study shows that physical models help students tackle ambiguities while solving ill-structured problems [15]. Physical models help students comprehend the difference between the behavior of actual and ideal systems. Building physical models early in the design process stimulates concrete discussion between designers, improving the quality of the final product [16]. Prototypes help designers detect and fix flaws in their designs before significant

effort is put into production [8, 17, 18]. Models also facilitate the communication of ideas across various disciplines [19].

Some researchers warn about the use of physical models in engineering design. Baxter [20] cautions about the resources involved in building a physical model. In order to optimize resource utilization, Burr and Andreasen [21] suggest building of physical models with optimum numbers of features. Kiriya and Yamamoto's observational study shows that building physical models lead graduate design teams to fixate [8]. Fixation involves blindly adhering to presented examples or initial ideas [11]. Similarly, the observational study by Christensen and Schunn [7] finds that physical models suppress distant domain analogies in professional engineers. Still, a study by Youmans [22] fails to detect fixation effects from the use of a physical model.

B. Insights from prior Studies on Physical Models

In light of the conflicting recommendations described previously, the authors conducted a series of controlled and qualitative studies to explore the role of physical models in design [10, 17, 23, 24]. These studies investigate the cognitive effects of building physical models during engineering idea generation. The results from these studies show that physical models help designers identify the flaws in their own internal representations, leading them to higher quality ideas [10, 17]. Physical models also help designers identify the drawbacks of certain undesirable example features present in their ideas, providing avenues to learn through their own mistakes [25]. In the end, physical modeling needs to be promoted as an essential part of engineering design process.

These studies also show that design fixation is not an inherent aspect of physical modeling; instead, it results from the Sunk Cost Effect [10]. The Sunk Cost Effect refers to a person's tendency to adhere to a selected course of action after investing significantly in that path [26, 27]. According to the Sunk Cost Effect, if a particular physical model costs significantly more to construct (where cost can be money, time or effort), designers might hesitate to consider alternate design solutions. Therefore, when building a physical model, one must reduce the associated cost. This reduction mitigates potential design fixation and maximizes the positive uses of the physical model.

Building upon the prior studies, the current work explores the conceptual errors by graduate design teams in building physical models as part of their coursework. Out of these errors, the authors formulate a set of guidelines. Furthermore, to solve two of the most critical issues, the authors test and create a novel design method. The guidelines and the method attempt to reduce the cost associated with the building process, potentially improving the benefits of utilizing physical models.

III. UNDERSTANDING CONCEPTUAL ERRORS IN BUILDING PHYSICAL MODELS

In order to understand the conceptual errors by designers during physical modeling, the data collected from graduate design teams were qualitatively analyzed. Next, content analysis technique was used to categorize the various errors. Based upon the identified categories, guidelines were formulated to facilitate the mitigation of these errors. Since a

majority of the errors led designers to an increased building time, it was essential to eliminate these conceptual errors to maximize the benefits of future physical modeling.

A. Design Teams and Data

The data were collected during two different semesters of a graduate design course taught by one of the authors. In this one semester course, the students completed a team project by applying engineering design theory based on Otto and Wood [3]. In this course, the teams went from gathering customer needs to proof of concept models with more focus on idea generation. The teams typically consisted of 3 or 4 students, but one student chose to work alone. Project topics ranged from industry-sponsored issues to projects solving design problems from developing countries. By the end of the course, each group had built a working proof-of-concept model and had presented it to the instructor. They were allowed to create either physical or virtual proof-of-concept models. There were five teams in the first semester and seven teams in the second semester. Two teams from each semester utilized only virtual models as proof-of-concepts; hence, their data were not included in the analysis.

To collect the data from the design teams, the authors utilized each team's final report and two specialized templates designed to study the cognitive impacts of physical modeling on graduate design teams [24]. The templates captured changes made to the ideas during the physical modeling stage of the project. Additionally, the template asked the teams to report the motivation for the change. Considering the data, the authors observed that design teams identified many difficulties with their ideas during construction; moreover, as reported in the templates, these problems led to changes in the original design. Consequently, one might conclude that the templates provided rich and relevant information regarding the difficulties faced by designers during physical modeling. More details concerning the templates and the primary results obtained from them are available in [24].

B. Procedure

A content analysis [13] was performed on the data obtained from the reports and the templates. During content analysis, the authors concatenated the textual information relevant to physical models or physical modeling. Next, the texts were divided into stand-alone sentences that convey a concept. Based upon the judgment of one of the authors, these sentences were sorted into groups. One of the groups contained information pertaining to the conceptual errors committed by the teams during the physical model construction process (For more information about the other categories from content analysis, refer [28]). In the next step, the textual information from this group was further categorized to identify similar conceptual errors. Following categorization, the categories were reanalyzed and combined to eliminate dependencies and increase categorical differences. The final set of categories represented the conceptual errors by the designers during the building of their physical models. The major errors identified are given below:

- Failure to consider one or more critical load, leading to the failure of the part/parts of the system

- Failure to design junctions of two or more parts (connections) leading to the failure of the assembly
- Improper planning of available time or budget, leading to inefficient utilization of resources
- Hesitancy to significantly modify parts after failure (Fixation to existing parts)
- Use of a complicated measurement system when a simpler one is available
- Building new parts when standardized parts are available for purchase at a lower cost
- Building physical models that provide no novel details
- Failing to properly scale loads when the parts are scaled
- Selection of materials (especially to reduce material cost) that require costly machining which leads to a higher overall cost

C. Formulation of Guidelines for Physical Modeling

Based upon the conceptual errors discussed in the previous section and various observations concerning the effective practices utilized by the design teams, the authors formulated a set of guidelines. TABLE I. lists the guidelines. These guidelines aimed to reduce the observed conceptual errors and decrease the total cost associated with the building process.

TABLE I. GUIDELINES FOR BUILDING PHYSICAL MODELS FORMULATED FROM THE ANALYSIS

| | |
|----|--|
| 1 | Support building with analytical calculations - use basic strength equations for calculations |
| 2 | Design the connections (interfaces of parts) before commencing construction |
| 3 | Plan the building process – in terms of time and budget |
| 4 | Combine superior features from multiple solutions |
| 5 | While scaling the model, scale loads accordingly |
| 6 | Be aware of unexpected phenomena during building |
| 7 | Wherever possible, use commonly available parts |
| 8 | Wherever possible, avoid complicated machining |
| 9 | Wherever possible, select materials that can be easily machined, |
| 10 | If standardized parts are available, use them instead of building new ones |
| 11 | When using parts of standardized length (e.g. Legos), make sure that other dimensions change accordingly |
| 12 | Use visual measurements if complicated measurement techniques are not necessary |

IV. DEVELOPMENT AND TESTING OF THE MODEL ERROR REDUCTION METHOD

From the list of conceptual errors mentioned in the previous section, the two critical ones are: failure to include critical forces in design and failure to design connections of parts. If present in the design, these two conceptual errors can lead to the failure of part(s) in the system or the failure of the entire design. Since the rectification of these two conceptual errors might involve redesigning the system, these issues typically involve comparatively higher costs (in terms of money, time and effort).

To develop a design method which rectifies the two most critical issues, the authors assume that, if designers are forced to think about each force and connection in their design, the quantity of complete designs will increase. Consequently, the method involves two templates as shown in Figure 1. and Figure 2. These templates are to be filled out by the designers once the design is complete but before the beginning of the building process. Template 1 forces designers to draw complete free body diagrams of each part and list the forces drawn on the free body diagrams in a table. Also, designers note down whether they considered the forces in their designs before using the template. Template 2 attempts to encourage the design of the connections involved in the system. It asks the participants to draw the free body diagram of each connection, marking the

forces on the parts. Later, participants are asked to note down the forces in the table below. Following this, participants are asked whether they considered the contact forces in their design before using the template. Both templates instruct designers to go back and incorporate any missing forces in their design.

The following subsections detail the controlled experiment and involve a discussion of the results.

A. Experiment Method

The controlled experiment testing the effectiveness of the Model Error Reduction Method templates follows a within-subject design. In the experiment, novice designers design a familiar mechanical system without the help of the templates. Later, they are instructed to fill out the templates and make the necessary changes in their designs. The scope of the changes made to the designs as participants complete the templates is studied to infer the effectiveness of the method. A more detailed description of the experiment follows.

Participants

The participants in this experiment were senior undergraduate students in the Mechanical Engineering Department of Texas A&M University. They were recruited through class announcements. Twelve students volunteered for the experiment. Three of them were female. The participants

were screened before the experiment to ensure that they had completed their courses on mechanical design of machine elements. This ascertained that each participant possessed the same level of expertise in mechanical design. None of the participants possessed more than 6 months of industrial experience. For participating, each person received either monetary compensation or extra credit in one of their classes.

Part name/number:
Free body diagram: (You may annotate your forces and use these annotations in the table below)

List the forces that you drew on the free body diagram in the following table:

| Force acting on the part | Type of force (tension, compression, bending, shear etc.) | I considered this force in my original design (Y/N) |
|--------------------------|---|---|
| | | |
| | | |

Figure 1. Template 1 of the Model Error Reduction Method (motivates designers to think about missing forces)

In order to ensure the effectiveness of these templates, a controlled experiment is designed and conducted. The controlled experiment tests the following hypothesis:

The use of the two templates motivates designers to rethink about their design calculations, helping them identify forces missing from said calculations.

Part name/number:
Part name/number:
Free body diagram: (of the two parts showing the forces between them - You may annotate your forces and use these annotations in the table below)

List the forces that you drew on the free body diagram in the following table:

| Force acting on interface | Type of force (tension, compression, bending, shear etc.) | Part on which the force acts | I considered this force in my original design (Y/N) |
|---------------------------|---|------------------------------|---|
| | | | |
| | | | |

Figure 2. Template 2 of the Model Error Reduction Method (for missing connection designs)

Design Problem

Each participant was asked to develop a detailed mechanical design for a bicycle. They were given a concept

sketch for a bicycle design (Figure 3.). The problem instructed them to develop a detailed design for the system as a whole and the components involved. Participants were allowed to make any necessary assumptions. No specific constraints were provided to them, but they were asked to list the steps they followed with the help of diagrams and descriptions. They were also instructed to state their assumptions and list the equations they utilized. They were told not to consider the seat, spokes and wheels in their design. They were also instructed to treat each member of the frame as a separate part. Since the final numerical values were not of interest in this experiment (the interest was on the design procedure), estimates of the dimensions of each part were available to the participants.

The bicycle design problem was selected for this experiment due to its sufficient complexity and the likelihood of participant experience with the device itself. If the design problem was too simple or contained too few parts, measuring the effect of the templates would be difficult. The bicycle problem was difficult to finish within the allotted time of the experiment, but participants were asked to only fill the templates out for the parts finished. Such a tactic avoided any bias due to an incomplete design.

Experiment Materials

The experiment involved three different activities, and in each activity the participants received a different set of materials. In the first activity, the participants were provided with the problem statement, instructions and a few blank sheets of paper. The participants were allowed to use as many sheets as they desired and were instructed to number the sheets in the order of their use. In this activity, the participants also received a copy of “Shigley’s Mechanical Engineering Design” textbook [29] and a calculator. In the second activity, the participants received copies of Template 1 and a different color pen to write with. The different color pen enabled easy tracking of any changes they made to their original design from the first activity. In the last activity, they were provided with copies of Template 2 and a pen with a third color. The problem statement and the original design were available to the participants throughout the experiment, and they were encouraged to make changes to the original design.

Procedure

As the participants entered the experiment room, they were guided to their seats. Up to two participants underwent the experiment at the same time, but their seats were separated by curtains. As the experiment began, participants received the design problem and the instructions. They were given 90 minutes to work on the design. Since completely designing the bicycle in 90 minutes was nearly impossible, they were instructed to complete as much of the design as possible in the time provided. They were given 5 minute breaks 50 minutes into the design and at the end of the design. After the second break, the participants were given copies of Template 1. They were instructed to fill the templates out for each part completed during the first activity. They were also told to mention whether they had considered all the forces in their free body diagram during the original design stage. If they did not, and if they thought that force was important, they were allowed to go back and make changes to the original design. This activity

lasted for 30 minutes. In the third activity, participants filled out Template 2. They were required to complete template 2 for each connection in their design. Also in this activity too, they were allowed to go back and make changes to their original design. This activity too lasted for 30 minutes. Participants were allowed to move on if they finished any activity before the time limit was reached. At the end of the experiment, they were asked about any previous industry experience.

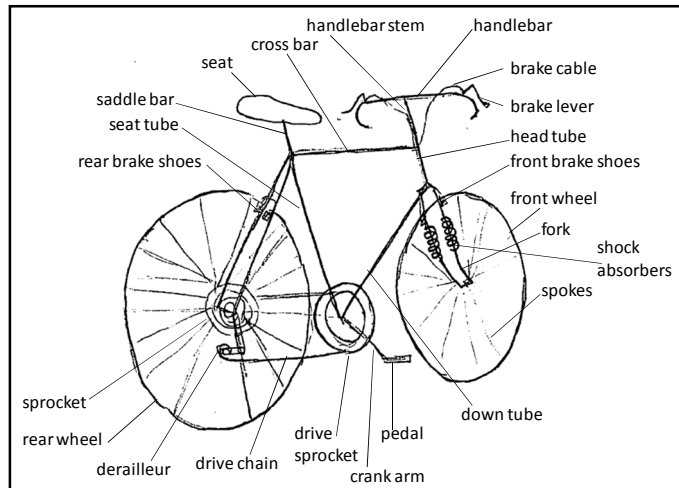

Figure 3. Bicycle concept provided to the participants in the experiment

Metrics for Evaluation

Two different metrics are employed to evaluate the effectiveness of the design templates: Number of extraneous template forces and number of design modifications. The method templates help designers in identification of forces not considered in their original design and prompt them to modify their designs including those extraneous forces. Number of extraneous template forces is defined as the number of forces listed by the participants in their design templates minus the ones already considered in their original design. This metric is calculated separately for the two templates. Number of design modifications measures the number of changes that the participants make to their original design as they use the templates. This metric also measures how many of the extraneous forces identified by the templates are perceived to be important by the participants. These forces are likely to be missed by the participants during their original design. These two metrics together provide valuable insights about the usefulness of the design method developed.

B. Experiment Results and Discussion

The results obtained for the metrics show that the newly developed design templates provide effective means in design calculations. A more detailed description of the results for each individual metrics is provided in the following sections.

Number of Extraneous Template Forces

It is observed that as participants use the method templates, they list many forces that they have not considered in their original design. For example, some participants considered only the forces from hands of the operator in the design of the handle bar. In reality, in addition to the forces from hands, the

handlebar takes the loads from handle bar stem also. Figure 4. shows the mean number of extraneous forces identified by the participants from each template. It is observed that majority of the participants fail to produce complete free body diagrams of the parts or connections they design, which leads them to missing forces in the calculations. As the design templates force them to draw a free body diagram for each part, they identify those missing forces.

A paired-sample t-test [30] is conducted to analyze the data statistically. This test confirms if the number of extraneous forces identified is statistically different from zero. The results show statistical significance for both the templates (for Template 1: $t = 2.98$, $p = 0.01$; for Template 2: $t = 3.91$, $p < 0.01$). This result confirms that in significant number of cases, the templates help designers in detecting extraneous forces in their designs. It also confirms that the templates satisfy their intended purpose of helping designers in identification of missing critical loads in their designs.

Number of Design Modifications

From the data, it is observed that the participants make many changes to their original design based on the extra information gained from the method templates. Though the templates provide them the extraneous forces, the participants do not include all those forces in their design. They include only those forces they perceive to be important for their design. Figure 4. shows the number of modification resulted from the individual templates and from the whole method. Only the changes that contribute significantly to the design are counted (for example: addition or deletion of the forces, modification of points of action of forces etc.).

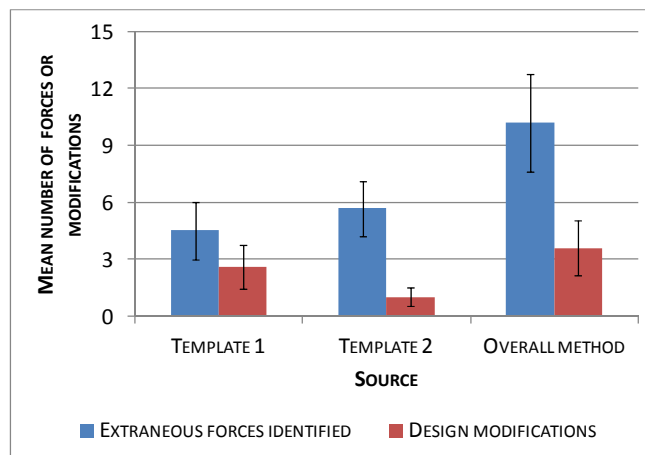

Figure 4. Mean number of design modifications due to the method

A paired-sample t-test is used for the statistical analysis of these data too. The results show that the number of design modifications is statistically significant (From Template 1: $t = 2.27$, $p = 0.04$; From Template 2: $t = 2.09$, $p = 0.06$; Overall: $t = 2.51$, $p = 0.03$). This shows that the method templates prompt designers to make significant number of changes in their design. This result provides strong support for the presented hypothesis and shows that the new method is effective in helping designers with their calculations for building physical models.

It is observed that though the participants identify more extraneous forces from Template 2 compared to Template 1, majority of the design modifications result from Template 1. This shows that the participants perceive the contact forces to be less critical compared to the forces on the parts. This may not be true in all design calculations. Forcing the participants to calculate the values of these forces and make the decisions based on the values may eliminate this difference.

V. LIMITATION OF THE DESIGN METHOD

The Model Error Reduction Method introduced here is shown to be very effective by the experiment results; however it possesses a limitation. This method is useful only for structural calculations as it mainly deals with forces on the parts and systems. However, in many cases design of systems include calculations from other disciplines like thermodynamics, fluid mechanics, chemical and material science etc. The current method cannot deal with such calculations; however, it can be easily modified to include these too. This needs to be completed in future work.

VI. CONCLUSIONS

Physical modeling is considered to be an efficient tool in engineering design as it helps to reveal the flaws in the ideas. This paper discusses the conceptual errors that novice designers face as they build physical models of their design concepts. These conceptual errors lead them to a higher building time and thus affect the effectiveness of physical modeling. To rectify this, a set of guidelines for physical modeling is proposed. A Model Error Reduction Method solving two critical errors (failure to consider critical loads in their design and failure to design connections) that novice designers make is formulated and tested. The test results show that the newly formulated design method is effective in rectifying the said two conceptual errors. However, the method needs to be expanded to include more problem domains.

Abstract— This paper presents a template for conducting rigorous reviews in design projects that set high standards for design excellence, thereby teaching and assessing students' design capabilities in the context of authentic design experiences. In engineering professional practice, the design performances of practitioners are tested in design reviews conducted at critical milestones of each project. For projects requiring approval by the US Food and Drug Administration (FDA) or other high stakes projects, design reviews evaluate the rigor and documentation of design processes as well as the quality of products delivered. The proposed design review structure draws from these rigorous design reviews to provide context, questions, and scoring rubrics that guide and probe design team achievements, documentation, and understanding.

Keywords: design assessment; design reviews

I. INTRODUCTION

Engineering is vital for advancing the economic well-being of the nation and for solving great engineering challenges [1, 2]. Although ability to design is a required student outcome of every ABET accredited engineering program, students' design competencies will vary greatly, depending on the authenticity of their design project experiences and the instructor's instructional methods and performance expectations [3].

In the world of engineering professional practice, the design performances of practitioners are tested in design reviews conducted at critical milestones of each project. For projects requiring approval by the US Food and Drug Administration (FDA) or other high stakes projects, design reviews evaluate the rigor and documentation of design processes as well as the quality of products delivered [4]. Engineering education programs should similarly utilize formal design reviews to (a) prepare graduates for professional work expectations, (b) ensure the quality of students' design solutions, and (c) examine and document the rigor of design activities supporting a solution.

II. DESIGN REVIEWS

The proposed design review structure draws from the rigorous practitioner design reviews to provide context, questions, and scoring rubrics for guiding and probing design

team achievements, documentation, and understanding of design. Design reviews are supported by high quality, organized design records:

- *Design History File:* Records of design activities
 - Answer questions of “why” design decisions were made (e.g., why a concept was chosen, why a need was ignored, why a solution was thought adequate).
 - Typically include meeting minutes, sketches of ideas, calculations, Pugh charts, interview notes, data, research summaries, etc.
- *Design Master File:* Archive of design solution stages
 - Define the “what” of the design at a distinct stage
 - Show a time-stamped problem definition (including specifications) and solution (including descriptions, explanations, drawings, etc.)

Design reviews are used to identify weaknesses in design processes and to guide design development toward better and more defensible design solutions. A design review will typically address the following categories of questions:

- How adequate is the **process** used to conduct this stage of development?
- How adequate are the **criteria** defined for acceptability of design products for this stage of development?
- How adequately did the **evaluation process** judge the design product's acceptability?
- How well do **records** defend the design process and outcomes?
- What are **plans** for advancing the design to the next stage?

Three design reviews are proposed for student projects – one at each of three decision points in solution development:

- 1) *Preliminary **Problem Scoping Review*** – problem definition, solution specifications and constraints

- 2) *Interim Concept Selection Review* – concept generation and selection, and defense of chosen concept
- 3) *Critical Solution Realization Review* – detailed design and evidence of its satisfying user needs

A. Problem Scoping

The first design review examines the design team's definition of the design problem and the set of requirements a solution must satisfy. The review probes the team's processes and achievements to understand stakeholder needs and to translate these needs into specifications (specs) for the functionality, technical feasibility, financial contributions, and social impacts of the solution.

B. Concept Selection

The second design review focuses on the design team's selection of a solution concept that best meets the solution specifications. This review probes the team's sources of concepts and their processes for selecting and evaluating plausible concepts, as well as their documentation of processes and solution concepts.

C. Solution Realization

The third design review focuses on the final solution presented by the team and its justification. This review probes (1) processes used in component design, component integration, prototype development, and solution evaluation, (2) value of final solution to stakeholders, and (3) quality of documentation of design processes and stages of the solution.

III. EXAMPLE DESIGN REVIEW

Design reviews should be conducted with all important stakeholders present to ensure that the review is thorough. Let's use the problem scoping review as an example. For this review, schedule approximately an hour and invite key individuals who may use, manufacture, maintain, dispose, or market the product. You also may invite any community or special interest groups concerned about the product. Request from the design team an organized set of design documentation for the project.

Alert the design team and invited audience members to the types of questions that need to be answered in a successful review. For a problem scoping review, these include:

- A. *How adequate is the problem scoping process?*
 - 1) What stakeholder groups were included? Adequate?
 - 2) How were "needs" converted into specifications?
- B. *How adequate are criteria for "good" specifications?*
 - 1) How well do criteria address clarity, measurability?
 - 2) How do criteria enable creativity? Revision needed?
- C. *How well do problem definitions meet "good" criteria?*
 - 1) How does project scope fit time and resource limits?

- 2) Which specs meet criteria for "good"? Need revising?
- D. *How well are processes and results documented?*
 - 1) How well are decisions explained? Revision needed?
 - 2) How well are stages of development documented?
- E. *How well are next steps defined?*
 - 1) How well do steps support solution excellence?
 - 2) What resources are required to be successful?

IV. DESIGN REVIEW FEEDBACK

The design review should produce feedback on the quality of the design process and products, as well as specific items that need attention. A suggested format for design review feedback is illustrated below.

PROBLEM SCOPING DESIGN REVIEW FEEDBACK

1. *Problem Scoping Process*
 - a. Adequacy: 5 4 3 2 1
 - b. Comments/required actions:
2. *Criteria for Specifications*
 - a. Adequacy: 5 4 3 2 1
 - b. Comments/required actions:
3. *Solution Specifications and Constraints*
 - a. Adequacy: 5 4 3 2 1
 - b. Comments/required actions:
- ...

V. NEXT STEPS

Design reviews have potential to rigorously assess design team progress and provide teams feedback that will improve their design learning and performance. The three design reviews presented here identify critical junctures in design development where reviews can add significant value to design activity. Questions posed probe vital issues that will determine quality of the final design solution.

These design reviews have not yet been classroom tested, so let's test and refine them together. Design educators interested in collaboration are encouraged to contact the first author.

Work in Progress: How Engineering Students Define Innovation

Nicholas D. Fila, William P. Myers, and Şenay Purzer

School of Engineering Education

Purdue University

West Lafayette, IN

nfila@purdue.edu, billy@purdue.edu, spurzer@purdue.edu

Abstract— Innovation is defined in diverse ways in the literature and often assessed in ways synonymous with creativity. As these arguments continue it is also important to identify student perspectives. In this pilot study, we examine how engineering students define innovation. Fifty-four first-year engineering students were asked to define innovation in an open response survey. Their answers were first reviewed to identify emerging patterns and then a detailed coding method was used to categorize students' responses. The analysis examined students' focus on feasibility, desirability, and viability as well as other important aspects of innovative design. The findings from this open-ended survey will be used to develop an assessment tool that is easy to administer and score.

Innovation; Creativity; First-Year Engineering

I. INTRODUCTION

Innovation is everywhere. The preceding statement refers not only to the cornucopia of innovative products, systems, processes, and individuals we encounter daily, but also to the proliferation of literature on innovation in engineering design, organizational settings, and STEM education. We want our students to be innovative so that they can eventually solve critical technological, social, and environmental problems, contribute to new and unforeseen knowledge, and build connections where none previously existed [1]. But what does it mean to be innovative?

II. LITERATURE REVIEW

The term “innovation” has been defined broadly in the literature and has been conflated with both creativity and entrepreneurship [2, 3]. Definitions commonly include aspects of novelty and usefulness [2, 4, 5], but it is also important to acknowledge the importance of business, users, and society in the development, production, and acceptance of innovations. Innovations, therefore, must also be feasible, viable, and desirable [6].

Previous studies have investigated the innovative capabilities of engineering students [7], compare novices and experts [8], and how context and processes affect innovation and engineering design outcomes [9]. Engineering education literature, however, lacks an investigation of students' definitions of innovation. Before we can help students

understand critical aspects of innovation and develop innovative skills, we must understand how they conceptualize innovation. Thus, the purpose of this pilot study was to investigate how students define innovation in the context of engineering.

III. RESEARCH DESIGN

Participants & Data Collection. We examined how students define innovation in the context of a introductory engineering course. During the last regular course meeting, 54 FYE students (36 male and 18 female) out of a class of 115 volunteered to complete an extra credit activity. As part of this activity, students were asked to respond to the questions: “What is your definition of innovation? What makes something more innovative than another?”

Data Analysis. We performed a content analysis of student responses [10]. The analysis was iterative, moving from inductive to deductive stages so that themes would emerge from the data [10]. First, two researchers individually open coded a selection of ten student responses, producing a list of 51 unique codes. Among these codes, students defined innovation in terms of how innovation occurs, the types of problems requiring innovative solutions, characteristics of innovators and innovative products, and general definitions of innovation and innovativeness. Based on the original 51 codes that emerged from open coding, we developed an eight-item codebook (Table 1) to use during a second round of coding. Two additional codes— *synthesis/adaptation of existing designs* and *aesthetics*—emerged during the second round of coding. Both original coders made a third pass through the data to identify instances of both of these codes. During the second and third rounds of coding, it was occasionally difficult to distinguish *transcendence*, *synthesis/adaptation*, and *aesthetics* from *creativity* and additionally to distinguish *improves upon existing design* and *solves unsolved problem* from *usefulness*, so we combined these codes to develop a final five-item codebook (Table 1). After a final round of coding, in which codes were accepted only if both coders agreed on instances of a code, we calculated the number of students who identified innovation as any of the five remaining codes: *creativity*, *usefulness*, *feasibility*, *viability*, *desirability*.

TABLE I. INITIAL & FINAL CODES

| Code | Initial Codes | Final Codes |
|------|-----------------------------|--------------------|
| CRE | Creativity/Novelty | Creativity/Novelty |
| TRA | Transcendence | - |
| USE | Usefulness | Usefulness |
| IMP | Improves on existing design | - |
| SUP | Solves unsolved problem | - |
| DES | Desirability | Desirability |
| VIA | Viability | Viability |
| FEA | Feasibility | Feasibility |

IV. STUDENT DEFINITIONS OF INNOVATION

Almost all students identified innovative solutions as creative/novel (96%) and useful (85%). However, students were less likely to identify innovative solutions as desirable, feasible, and viable. Figure 1 displays the number of students who identified innovative solutions in each of the five categories.

Most student definitions coded as *creative* featured words like “new,” “different,” and “original.” However, innovative outcomes could simply be new to some context or adaptations or syntheses of existing solutions. Other student definitions categorized as creative included “revolutionary,” “push[ing] boundaries,” or “chang[ing] perceptions surrounding an established medium or field.”

Within *usefulness*, students often defined innovations in general terms, e.g. “effective,” “an improvement,” or “solves a problem.” Others were more specific using the terms “efficient,” “helpful,” “sustainable,” and “easy to use.” Other students specified that innovative solutions had to address “big” or “important” problems such as the “Grand Challenges.”

Among the remaining categories (*feasibility*, *viability*, *desirability*), students demonstrated less variation, listing these terms verbatim. Alternatively, feasible was listed as “practical,” “could be implemented,” or “reasonable.” Viability was often listed as “cost-effective” or “profitable.” Desirability was often listed as addressing “user needs” or “attract[ing] people’s attention.”

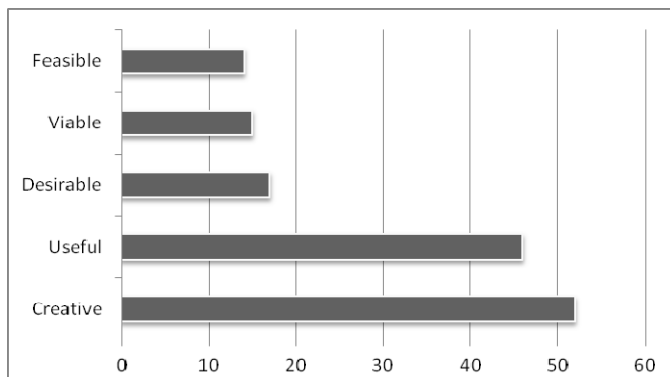

Figure 1. Number of Students Who Identified Each Construct Related to Innovation

V. PRELIMINARY CONCLUSIONS AND FUTURE WORK

By favoring creativity and usefulness in their definitions and demonstrating both variety and thoroughness in their conceptions of these constructs, students presented nuanced views consistent with literature on innovation [2, 4, 5]. However, students tended to overlook other critical aspects. Innovation requires creative thought to dream beyond existing solutions and useful solutions that fulfill some purpose, but additional barriers to innovation include whether a solution can be implemented, whether an organization has cause to implement potentially innovative solutions, and whether solutions will be accepted by potential users. Less than one third of students considered innovation in terms of feasibility, viability, and desirability, and when mentioned, these terms were accompanied with little elaboration.

Overall, these results reflect a strong consideration for the “big picture” of innovation, but little consideration of how innovation occurs from an industrial, economic, and societal standpoint. Thus, while continuing to inspire and discuss the importance of creative thought, instructors should encourage students to consider feasibility, viability, and desirability and promote a more complete interpretation of innovation. Our future goal is to conduct more in-depth interviews and develop a Likert-scale survey that can be used to compare different approaches used to support innovative design.

Work in Progress: Creativity, *Mindset*, and Implications for Engineering Design Instruction

Susan K. Donohue, Whitney G.S. Hunter, and Larry G. Richards
University of Virginia, susand, wgh3p, lgr@virginia.edu

Abstract - As a design-based profession, advances in engineering rely, in part, on the creativity of its practitioners. Therefore, it is important to explore means by which creativity, along with other critical skills, can be nurtured. As part of our research on the teachable nature of creativity, we are investigating the relationship between a person's belief that intelligence and talent are either fixed or can be developed and his/her assessment of changes in his/her creative skills. Preliminary findings indicate that, as may be expected, students with a fixed mindset report no changes. Possible pedagogical implications are discussed.

Index Terms – creativity, engineering design, *Mindset*.

“...(E)ngineers create the world that has never been.”
Theodore von Karman [1]

INTRODUCTION

Creativity is vital to the process of innovation, and innovation is vital to meaningful and significant outcomes in virtually every profession and, eventually, to the ability of a society to be competitive locally, nationally, and globally. It is certainly central to the study and practice of engineering, a design-centric profession. [2] However, perceptions as to the nature of “creativity” – as either an innate talent or a skill that can be learned and/or improved – may affect the degree to which truly innovative solutions are developed and implemented.

The goals for this research phase are to investigate student perceptions and definitions of creativity and its nature. Our primary research goal is the investigation of the teachable nature of creativity, with the development of a methodology and curriculum for doing so. The benefits of explicitly addressing key skills critical to success in the engineering curriculum, such as spatial skills, are well documented; we would add creativity to that list.

This paper is organized as follows. Background information on the research population, environment, and methodology is provided. Next, the theory upon which this research is based, Dweck's (Achievement) Goal Orientation Theory, is reviewed. We end with a discussion of preliminary results, conclusions, and direction of future work.

BACKGROUND

Fourth-year students in the School of Engineering and Applied Science at the University of Virginia (UVa SEAS)

must write a thesis to meet school requirements for graduation. Another requirement is the completion of a year-long capstone design course. Many students base the former on their experiences in the latter.

The capstone design course in which this research is conducted is MAE 4670/4680, Creativity and New Product Development I and II. Enrollment in MAE 4670 in Fall 2011 is 46 students (15 females and 31 males), and 43 students in MAE 4680 in Spring 2012 (15 females and 28 males). One female and three males enrolled in the fall semester did not continue their enrollment in the sequence in the spring.

In this course sequence, students (re)learn¹ the engineering design process through the development of two products, an Engineering Teaching Kit (ETK; see, for example, [3]) and a patentable product. An ETK is a self-contained set of lesson plans based on national and state educational standards. Participants are engaged in a series of age-appropriate engineering design challenges that reinforce appropriate math and science concepts. The patentable product is typically a redesign of an existing product; the goal is to add or change functionality and increase usability and appeal while filling a defined unmet need. In both projects, students must determine the problem to address and the appropriate solution brainstormed, selected, prototyped, and evaluated according to the engineering design process.

Students completed three sets of surveys during the 2011-12 academic year. The first survey gathered data on their perceptions on creativity in general and the self-assessed level of their creative skills in particular, and was administered in October, 2011. The second survey is based on Dweck's *Mindset* [4 and 5], and collected data on their perception of the nature – malleable or fixed – of intelligence and talent. It was administered in December, 2011. The third re-surveyed the students on their self-assessed perceptions regarding creativity levels and whether they feel as though any gains came from participation in MAE 4670/4680, and was administered in April, 2012.

ACHIEVEMENT GOAL ORIENTATION THEORY/MINDSETS

Dweck proposes a social-cognitive approach to the analysis of motivation, (Achievement) Goal Orientation Theory in

¹ “Relearn” is used advisedly. Anecdotal data indicate that many SEAS students have little to no formal exposure to the engineering design process after ENGR 1620, Introduction to Engineering course in the fall of their first year and thus have not retained that knowledge. Students from the College of Arts and Sciences are also enrolled in the course sequence.

[6]. According to this theory, a person's motivation to achieve is driven initially by his/her perception of intelligence as either fixed or malleable; this perception in turn affects goal orientation, which is either learning/mastery (goal is to increase competence) or performance (goal is to gain/avoid judgment of competence) in earlier models; and expanded to learning, performance, work-avoidance (goal is to minimize effort), or a combination thereof in later ones. [7] The combined effects of goal orientation and level of confidence in present abilities lead to either an adaptive or maladaptive pattern of behavior with respect to (non)attainment of goals.

Following research and the maturation and generalization of these findings has culminated in the concept of "mindsets." A mindset is a belief about your skills and abilities. If you believe that a certain skill or ability is an innate talent and no amount of work will alter what you've been given, then you have a "fixed" mindset. If you believe that you can develop a skill or ability through practice and dedication, then you have a "growth" mindset. A growth mindset supports resilience and perseverance, qualities necessary for long-term success. [4 and 5]

Implications of this body of work are far-reaching. For example, a student's performance orientation that's rooted in the perception that intelligence is fixed can ultimately be a demotivating factor resulting in fewer opportunities for intellectual growth. Also, emphasis on either achievement or innate talent in praise can affect the recipient's perception of intelligence and goal orientation. The former supports a growth mindset and the latter a fixed one. [8]

PRELIMINARY RESULTS AND CONCLUSIONS

Thirty male students and fifteen female students responded to the first survey. Both genders had a modal response of 5 in their self-assessment of their creativity in comparison to others in general on a scale of 1 (not creative) to 7 (extremely creative). The top two categories of coded responses to the open-ended question "What does it mean to be creative? Please list three or more characteristics of a creative person." for both males and females are the abilities to think "outside the box" and to be inventive (new or novel product). Third place for males is the ability to be innovative (adapt or improve existing product); for the female respondents, the third most frequent response is an unconventional, "free spirited" nature. Collectively, both genders define creativity primarily as divergent thinking.

Nine females and seventeen males took the *Mindset* survey. With respect to intelligence, more females and males perceive intelligence as being malleable (growth mindset; 4 F and 6 M) than fixed (3 F and 0 M), with the rest as neutral on the subject. With respect to talent, the majority of respondents are neutral as to its nature (5 F and 9 M).

Five females and six males who took the *Mindset* survey responded to the third survey. As might be expected, respondents of both genders who have a fixed mindset with respect to intelligence report that they have not changed their perception of their creative abilities from the first survey (2

F and 1 M); respondents of both genders with a neutral or growth mindset report that they have changed their perception for the better, with participation in the class cited as having an impact on the development of their creative abilities from "somewhat" (2 F and 1 M), "half" (1 F and 1 M) to "a good deal" (3 M).

CONCLUSIONS AND DIRECTIONS FOR FURTHER WORK

An understandable reaction to these results would be to review the syllabus to ensure that all activities meaningfully support convergent, divergent, and logical thinking, which are the primary components of scientific creativity. [9] However, it is not enough to provide opportunities for growth; as indicated above, students with a fixed mindset are likely not to perceive improvement even if it occurs. Therefore, we must consider how to structure both language and activities to encourage adoption of a growth mindset, and identify an assessment instrument that measures creativity independent of mindsets so we can truly determine the efficacy of course activities. Finally, we need to determine how we will roll these findings into our design courses and "K-grey" outreach. Interventions regarding teaching and supporting creativity and fostering a growth mindset may be helpful in remediating the frequently reported shortage of students and professionals in STEM.

Abstract— In this paper, we discuss an educational program approach to device fabrication and analysis for an advanced course curriculum for technical training at the Okinawa National College of Technology (ONCT). Letting students have the opportunity to learn technical skills in engineering fields through engineering experiments is a key subject. We deal with two topics related to device fabrication and analysis: MOSFET and SAW transversal filter. In this paper, we describe that we carried out device fabrication and analysis as the subjects of the engineering experiments in a course. The students learned several techniques for device fabrication and analysis through these experiments.

Keywords— Enginireeing Experiment; Device Fabrication Process; Decice Analysis; MOSFET; SAW Transversal Filter

I. INTRODUCTION

Each national college in Japan offers two courses: one as a regular course for 5th year students and one as an advanced course for 2nd second year students. The advanced course at the Okinawa National College of Technology (ONCT) began in 2010 for bachelor degrees. The aim of this course is to educate and train students learning technical skills for engineering fields. In designing the course curriculum, it was decided that the purpose of the subjects of the engineering experiments is to teach measurement and design skills. Usually, the main purpose of the engineering experiments in a curriculum is to get empirical results by having students test various methods, tools, or technologies. Many universities tried various approaches to manage their students in their curriculums [1-4]. Recently in Japan, how best to teach technical skills in university and/or college educational curriculums has been focused on [5].

To meet these aims, most engineering experiments have been carried out as a part of the courses or the subjects. Also, the purpose of “project (or problem) based learning” is to acquire engineering skills, and to learn how to accomplish goals by oneself as well as through teamwork [6,7]. It is necessary for students to learn and obtain more practical and more technical skills as engineers.

In this paper, we discuss an educational program approach to engineering experiment subjects for technical training in an advanced course curriculum. We report the implementation and execution of device fabrication and analysis as themes of the engineering experiments. Students were motivated to put their efforts towards experiments to improve their own knowledge and skills through group work.

II. CONCEPTS OF THE ENGINEERING EXPERIMENTS IN AN ADVANCED COURSE CURRICURUM

A. Implementation of Device Fabrication and Analysis

The subjects of the engineering experiments in our advanced course are focused on training and acquiring technical skills. The subjects were designed to allow students to perform both device fabrication and analysis for practical engineering training in the experiment program. It is difficult for students to acquire technical skills with a single experience in class since operating the necessary equipment is complicated in device fabrication and analysis.

To give students the opportunity to operate the equipment used in the device fabrication process and the device measurement, we deal with two topics used as the engineering experiment subjects for advanced course students: MOSFET fabrication and SAW transversal filter fabrication. Figure 1 shows the experimental flow used in the device process and analysis program. The context of the experiments is explained to students in an introductory talk. Before performing the device process and analysis, teachers explain the experiment procedures and the principal properties of the devices. In practical experiments, teachers and students need to crosscheck the key points of the process and analysis procedures.

B. Subjects and Contents of the Experiment Program

In device fabrication, students repeat process procedures by performing two different kinds of device fabrication, such as MOSFET and SAW transversal filter fabrication. In addition, students reconfirm the process techniques used in the device

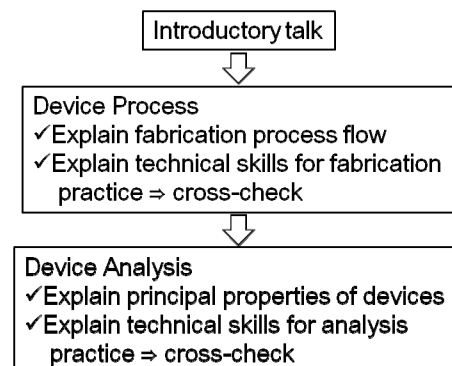

Figure 1. Experimental flow used in the device fabrication and analysis program

fabrication. However, the priority of the teaching points for each subject is different as follows.

The focus of MOSFET fabrication is to teach device fabrication processes. The device fabrication process for MOSFET consists of key device fabrication components, such as oxide formation, metal deposition, the diffusion process, and the photolithography process [8]. Therefore, the subject of MOSFET fabrication is a precise and suitable one for the engineering experiments of educational course curriculums.

The focus of SAW transversal filter fabrication is to teach how to analyze device properties. In particular, it is significantly important to learn how to use network analyzer equipment in order to obtain the frequency characteristics of devices. The calibration technique is one of the key techniques in device analysis. Also, a technique for probing a fabricated device is required to measure device properties.

III. EXECUTION OF EXPERIMENT PROGRAM

We spent 16 hours teaching the subjects of device fabrication and analysis of MOSFETs and SAW transversal filters. We made small groups of 4-5 persons. One student who had experience with fabricating devices in their graduate study was a supporter in each group and conducted the process procedures.

For the MOSFET, we focused on the device fabrication process. We spent 12 hours on device fabrication and 4 hours on device analysis. There were nine simply designed MOSFETs and four inverter circuits in a chip 10×10 mm in size. Students fabricated n-ch MOSFETs and measured the characteristics of the fabricated devices. During photolithography, students had a lot of trouble with the alignment process. The fabricated devices showed the principal characteristic of MOSFETs.

For the SAW transversal filter, we focused on the device analysis. We spent 8 hours on device fabrication and 8 hours on the theory and analysis of fabricated devices. Six pairs of interdigital transducers were formed by sputtering evaporation on a chip 13×15 mm in size. The fabricated transversal filters showed the well-known frequency characteristics based on the theory of surface acoustic wave propagation.

Most of students succeeded in fabricating and measuring the designed devices. However, some of them could not fabricate their devices due to not operating the equipment correctly. We carried out a class evaluation after the class in order to improve the educational methods.

IV. DISCUSSION

A class evaluation was carried out with the students to check the achievement level of the technical skills. Table I is a summary of a part of the class evaluations. The results of the class evaluation indicated that the students were satisfied with how much they had learned by fabricating and analyzing the electronic devices.

Device Process: Most of the students satisfied their achievement level for the device fabrication process. However,

the time originally allotted for the experiment program was exceeded since the students did not become accustomed to operating the process equipment for the device fabrication. Time-control was the one of the problems for MOSFET fabrication.

Device Analysis: Half of the students evaluated their achievement level for their knowledge of device properties with terms such as standard and average. Though the students had already learned device properties in their class, it was revealed that the students could not connect the measurement elements to the function of the measurement equipment.

TABLE I. PROGRAM EVALUATIONS

| Questions and achievement level |
|---|
| ✓ Do you think you achieved technical skill in the device process?: Good (62.5%), Standard (37.5%) |
| ✓ Do you think you achieved technical skill in the analysis technique?: Excellent (6.2%), Good (31.3%), Standard(56.3%),Poor (6.2%) |

V. SUMMARY

The device fabrication and analysis processes were carried out as the subjects of engineering experiments. In device fabrication, the key goals are to operate the process equipment of semiconductor devices and to learn device fabrication procedures. In device analysis, the key goals are to operate the measurement system and perform the probing technique. Most students felt that they had a good opportunity to acquire technical skills through learning the device fabrication process and device analysis. The main motivation for students was to prove their own skills and to put effort into the experiments. However, it was clear that they had some misunderstanding of the relation between the basic learning material in the textbook and operating real technical equipment. Therefore, we should improve the educational approach to teaching the technical skills used in electronic engineering.

Abstract—Longitudinal data from ten U.S. institutions are used to characterize outcomes of three matriculation models: Direct Matriculation to a specific major (DM), First-Year Engineering programs (FYE), and Post-General Education Programs (PGE). Both DM and FYE programs show high persistence rates, but FYE programs are less likely to attract transfer students and switchers. FYE graduates are the most likely to stick with their first choice of major (after completing FYE requirements), followed by DM graduates who begin in undesignated engineering (taking extra time to decide), then DM graduates who choose their major as part of the matriculation process, and then PGE graduates. FYE students also have the shortest time to graduation. We conclude that encouraging students to associate with engineering or an engineering discipline from the start, yet maintaining the curricular flexibility to allow alternate entry points onto the engineering path improves persistence, accessibility, effectiveness of major choice, and time to graduation.

I. INTRODUCTION AND BACKGROUND

This study describes some of the advantages and disadvantages of different matriculation pathways into engineering, considering both first-time-in-college (FTIC) and transfer students. How FTIC students are admitted into engineering and subsequently matriculate into their engineering major varies by institution [1]. While the U.S. engineering education system has a multiplicity of practices, we limit our discussion to the matriculation practices of the institutions

included in this study. At institutions participating in the Multiple-Institution Database for Investigating Engineering Longitudinal Development (MIDFIELD, described in the Methods section), FTIC students may follow one of six pathways into a specific engineering major. They are admitted:

1. to a formal First-Year Engineering (FYE) program that they must complete before declaring a major;
2. directly to a specific engineering major;
3. after a period as an undesignated engineering student;
4. after completing as many as two years of general education at their institution;
5. to institutions with a Mostly Common First-Year (MCFY) where they may declare a major preference, but they cannot advance until they have met common first-year requirements; or
6. to a university-level general studies program from which they may migrate into engineering.

In a formal first-year engineering program, students are admitted to the College of Engineering and take common first-year classes, including calculus, physics, chemistry, and an introduction to engineering sequence. Students in MIDFIELD FYE programs are advised by professional FYE advisors. Although a formal FYE program is not the predominant matriculation model, recent adoptions and planned adoptions of the FYE model provide evidence that their prevalence is growing [e.g., 2, 3, 4, 5]. During the years and cohorts in this

study, three MIDFIELD institutions had formal FYE programs, another began one in 2005 and a fifth will begin one in fall 2012. FYE programs provide early engineering experiences, inform disciplinary choice, and enable engineering faculty and staff to oversee the transition to engineering. Results of two national surveys of FYE programs describe the status of such programs across the country [6]. Upon completing the FYE requirements, students enroll in a specific engineering major such as electrical or mechanical. A summary of research and practice related to first-year engineering programs was created by the Foundation Coalition [7].

Four other MIDFIELD institutions admit qualified students directly to their choice of engineering major. Students majoring in engineering who are not sure which discipline they wish to pursue may be admitted as undesignated engineering students. The first-year curriculum at these institutions is nearly identical to that offered in FYE programs with respect to the basic math and science courses. All of the schools offer an introduction to engineering course or sequence although not all require students to take it. Students are already identified with their departments and generally are advised there. Undesignated students are generally advised by engineering student affairs but may be advised elsewhere in the university. These programs are defined as direct matriculation (DM) programs.

Although no MIDFIELD engineering college currently waits to admit students until after they have completed two years of general education, three colleges did so until the mid-1990's and thus their cohorts are included here for analysis. The comparison is useful even now because other universities around the country continue to use this matriculation model for their engineering students. In this model, students declare their major preference upon enrollment, but complete their first two years of general education in the arts and sciences college of the university before formally selecting an engineering major of their choice. In the first two years, these students are advised by arts and sciences advisors. To be eligible to select an engineering major, these students must take the engineering math and science courses as part of their general education core. These programs are defined as post-general education (PGE) programs.

We have termed a hybrid between an FYE program and direct admission as a "mostly common first-year" (MCFY). In these institutions, students identify with a preferred department and may be advised there, but they may not formally matriculate into their preferred major until they have successfully completed required first-year math, science and introduction to engineering courses. Of the three schools with the MCFY model in MIDFIELD, all have migrated or will migrate to a formal FYE program.

Clifford Adelman's metaphor of "paths" is used as a framework [8], because it captures the fact that there are many ways for students to navigate the process of getting an engineering degree. Note that this is somewhat in contrast to "pipeline" metaphors, which suggest only one entry point with many "leaks" or exit points [9]. In keeping with this paths metaphor, we discuss persistence (do students stay on the path?), accessibility (do students enter the path from other institutions and majors?), term of major declaration and

effectiveness of choice (when do students commit to a particular disciplinary path and how likely are they to stay on it through graduation?) as well as time to graduation (how long does it take them to reach their destination?).

II. RESEARCH QUESTIONS

The overarching research question for this study is "What are the advantages and disadvantages of these three matriculation models: first-year engineering (FYE) programs, direct matriculation into a specific major (DM), and post-general education programs (PGE)?" Key outcomes to be examined include persistence patterns of those who matriculate in engineering, i.e., those who start out on the engineering path; accessibility to those who matriculate outside of engineering (switchers) or outside of the institution (transfer students); the time at which students commit to a disciplinary path by declaring a major and the effectiveness of their choice; as well as time to graduation.

III. METHODS

These four matriculation models (FYE, DM, PGE, or MCFY) are mutually exclusive. Each cohort from each institution was categorized into one model group; MCFY were excluded from further study because the number of cohorts was not sufficient to protect institutional identity. These models represent the most highly-trodden paths, but individual students may follow alternate paths, which are still influenced by institutional structures and guides, some of which are described next.

Four schools admit students who do not meet college of engineering admissions requirements to a university general studies program. Students admitted to these programs who express an interest in engineering are advised to take the engineering math and science courses and may take the introduction to engineering sequence on a delayed basis. Upon successful completion of the engineering requirements, they are allowed to enroll in an engineering major. One FYE school, two DM schools, and one MCFY school offer students this option. Students who enter via general studies are included as "switchers," discussed in section IV.B. Another institution requires students who are only conditionally admitted to engineering to enter as "Freshman Engineering", which is classified as undesignated engineering in this study because they are not allowed to declare a specific major at matriculation.

The Multiple-Institution Database for Investigating Engineering Longitudinal Development (MIDFIELD) contains records for 977,950 unique students at eleven public institutions in the U.S. For reasons mentioned above, only ten are included in this study. This paper focuses on the subset of students in the included cohorts who ever declared a major in engineering and for whom we have six years of data (110,896). Of these, 72,728 matriculated in engineering as first-time in college (FTIC) students. The rest were transfer students.

While many institutions are not represented in MIDFIELD, the experience of MIDFIELD students is representative of the experience of a large fraction of U.S. engineering students attending large public institutions. A detailed description of the MIDFIELD dataset is available elsewhere [10].

Any semester or quarter in which a student is enrolled is counted as a term, including summer semesters. Since not all students enroll in every term, term counts do not necessarily correspond to calendar time. Consistent with previous literature, graduation is measured at six calendar years from matriculation [11]. For transfer students, this timeline is reduced by one year for every 30 semester credit hours the institution accepts as transfer credit.

Persistence rates are calculated based on FTIC students who matriculated in engineering (including first-year engineering and engineering undesignated); a student who graduates in engineering is automatically considered to have persisted through all terms. Accessibility is based on the number of engineering graduates who did not matriculate in engineering. Graduation was chosen over enrollment because it captures the product of access and retention.

IV. FINDINGS

Differences were observed between FYE, DM, and PGE programs on all outcomes examined.

A. Persistence on the Engineering Path

In comparing persistence, only FTIC students are included so that everyone has the same starting point. Although persistence rates are similar for FYE and DM, PGE programs lag behind as early as the fourth term and the gap grows over time (Figure 1). While 51% of FYE (N=38,062) and 50% of DM (N=28,173) engineering matriculants graduate in engineering in six years or fewer, only 32% of PGE (N= 6,493) students do so. Students may exit the engineering path early from the PGE programs because without engineering experiences they lose interest or discover other opportunities. Others may leave later because once they finally start their engineering classes they realize it was not a good match.

Comparing FYE and DM, the FYE programs lose a slightly larger percentage of their students in the first four terms than do the direct matriculation programs. We speculate that much of this is due the fact that requiring a change of major from FYE to *something* adds a gate to the pathway. That is, students must successfully complete a set of courses before they are

allowed to matriculate into a particular major while those who were admitted directly to a major who have not successfully completed prerequisite courses may still register without making satisfactory progress.

Losses between the twelfth term and graduation could represent students dropping out of engineering, leaving the institution, or taking more than six years to graduate. Some variation by race and gender is expected as there is with comparing outcomes at semester 8 versus six-year graduation [12] and this will be an area of future research.

B. Accessibility from Other Paths

To study the accessibility of engineering programs to students who start on other paths, all students who graduate in engineering within six years of matriculation are considered. While the structure and early engineering experiences of direct matriculation and first-year engineering programs may contribute to their higher persistence rates, it also appears that these “fenced” paths are not easily entered by those who do not matriculate in engineering at the institution. On average, 47% of engineering graduates in PGE programs are transfer students, compared to only 14% and 29% in FYE and DM, respectively. It should be noted however, that all of the PGE programs have strong transfer agreements with two-year colleges in their states. Figure 2 shows that two of the three FYE programs have proportionally fewer graduates who entered as transfer students than average. This is also important from a diversity standpoint because other work has shown that underrepresented minorities who transfer into a four-year institution are more likely to persist in engineering and outperform similar students who enrolled as freshmen [13].

Further, proportionately fewer “switchers,” or students who migrate into engineering from other majors within the institution (including undecided), are found at FYE schools (Figure 3). Overall, PGE programs have double the proportion of graduates (26%) who switched to engineering from another major as the other programs (FYE = 10%, DM = 12%). Here, all FYE programs fall below the average for all institutions indicated by the vertical line in Figure 3.

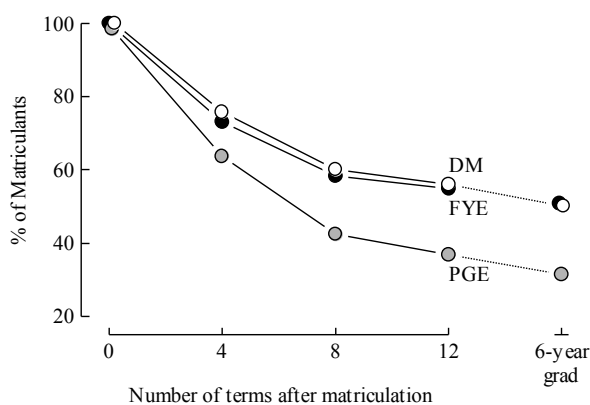

Figure 1. Engineering persistence patterns of engineering matriculants for direct matriculation (DM), first-year engineering (FYE), and post-general education (PGE) models.

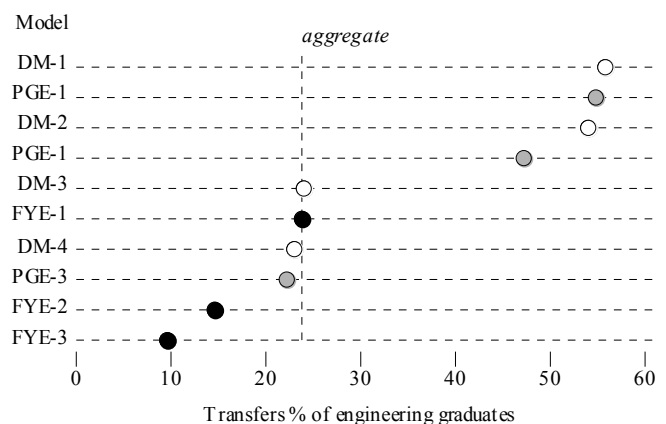

Figure 2. Engineering persistence patterns of engineering matriculants. To maintain institutional anonymity, model label numbers are not consistent across figures.

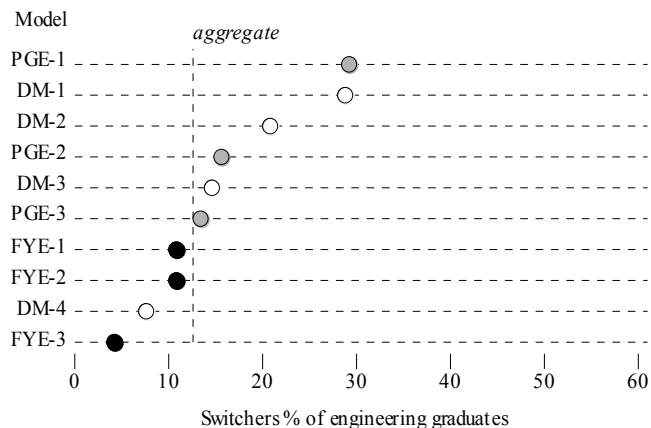

Figure 3. Engineering persistence patterns of engineering matriculants. To maintain institutional anonymity, model label numbers are not consistent across figures.

C. Term of Major Declaration and Effectiveness of Choice

As mentioned, one purpose of FYE programs is to inform disciplinary choice. While direct matriculation models do not require students to choose a discipline right away (they have the option to start as “engineering undesignated”), FYE students are not permitted to declare a major until they have learned about all of their options. This leads to the question: do students make more effective major choices when they after completing a FYE coursework than they would have at matriculation? We consider a major choice effective if the student graduates in the discipline. Note that different groups identify with a specific major at different points in the academic process. For FYE students this is the first major after FYE. For most DM and PGE students, this happens at matriculation. For students at DM and PGE institutions who matriculate as undesignated, we use the first major after they leave their undesignated status.

One potential drawback of giving students extra time to decide is that their connection with their future discipline is delayed, so we also examine the term when students declare their first major. When a student submits a change of major form, the major change does not take effect until the following term. Therefore, if a student selects a major during their second term (as expected in FYE programs), they are categorized as declaring their major in term 3. For this portion of the study we consider only FTIC students who matriculated and graduated in engineering in six years or less.

We first examine the timeline for FYE students declaring a major (Figure 4). Although FYE students are encouraged to declare their major by term 3 and most do, some spend more than one year in “first-year” engineering, possibly retaking courses or improving their grade-point average (GPA) to meet the standards of their chosen degree program. While the majority of students enter their discipline in term 3, cumulatively only 70% of the students have entered the discipline by term 3, then 90% by term 4, and 95% by term 5. Ninety-eight percent of graduates were in their discipline by the end of their sixth term (recall that this count includes any summer terms in which the student was enrolled). Whether a student is allowed to take courses in the discipline before

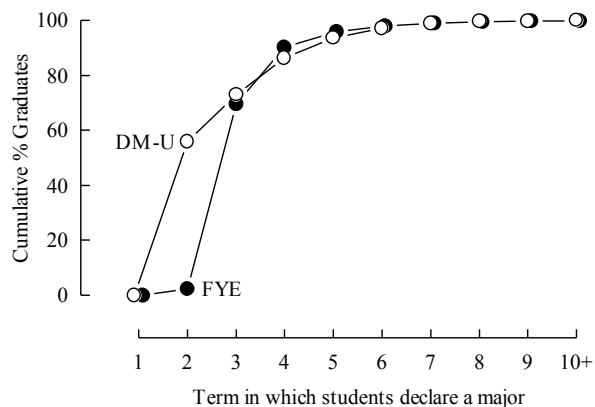

Figure 4. Term of major declaration for first-year engineering (FYE) graduates and direct matriculation graduates who entered as undesignated engineering (DM-U).

officially declaring a major varies by department. Once FYE students declared a major, 89% of those who graduated in engineering did so in the first engineering major they chose after FYE.

In the DM model, 22% of FTIC students who completed an engineering degree in six years started as undesignated engineering. Eighty-five percent of graduates who began as undesignated engineering students in DM programs graduated in the first major they chose. As was the case for FYE students, the selection of a specific major by undesignated DM students is distributed in time (see Figure 4), however the majority of students (55%) choose in their second term. Overall, only 78% of DM graduates stayed with their first major choice.

The record-keeping practices at the institutions with the PGE model make it difficult to identify students who indicated an interest in engineering but had not decided on a specific discipline. Future work will explore ways to identify these students and define their entry point into a specific discipline. We do know however, that only 60% of FTIC PGE engineering graduates remained in their matriculation major.

D. Time to graduation

Finally, we compare the average time-to-graduation for FTIC students graduating in each matriculation model (Table I). These estimates represent the number of regular semesters the student was actually enrolled. An academic quarter is 0.75 of a semester. A full summer term is 0.66 of a regular semester, and a half summer is 0.33 of a semester. The total credit hours earned for all academic work is also included in Table I.

TABLE I. AVERAGE ENROLLED TIME TO GRADUATION AND CREDIT HOURS EARNED

| Matriculation Model | Enrolled time to Graduation (semesters) | Credit Hours Earned |
|---------------------|---|---------------------|
| FYE | 9.0 | 128.8 |
| DM | 9.3 | 128.9 |
| PGE | 11.0 | 141.6 |

Although graduates of FYE and DM models earn the same number of credits, DM students typically require an extra 0.3 semesters to do so. PGE graduates are enrolled for 1.7 more semesters and earn more credits than both other models. This could indicate several things. The most likely possibility is that since more students change majors, some of their credits do not count towards their final major, and thus they must take more coursework overall. However, other possibilities include students taking more credits as part of a double major, a minor, or for personal interest, as well as differences in engineering curriculum requirements.

V. IMPLICATIONS AND CONCLUSIONS

Different matriculation paths appear to have advantages and disadvantages. FYE programs seem to be successful in helping students make informed choices about specific engineering majors, as evidenced by the high (89%) percentage of students graduating in their first choice. These programs also foster persistence within engineering as a whole. It is well known that advising is a key element in student retention, particularly of first-year students [14-16], so perhaps the professional advisors act as guides along the path to an engineering degree at least until a student is ready to pass through the gate to a specific major. FYE programs are also the quickest path to graduation in engineering. The drawback of these programs is that the common courses and experiences that tend to keep students on this path also seem to keep transfers and switchers out.

An advantage of direct matriculation is that students can identify with the major and its culture early in their academic careers through advising and possibly early introduction to the discipline. On the other hand, given the overall lack of familiarity with engineering in K-12 and the general public, students may be making their major selection based on limited information about the disciplines and what they have to offer. If there is a poor initial match, it may be difficult to switch to another engineering major because they may not have taken the appropriate courses for the new major. On a positive note, persistence is very high in these programs and students who enter as undesignated engineering are almost as successful at finding a good disciplinary fit as those in FYE programs. Also, transfer students are less likely to encounter the barriers created by institution-specific introduction to engineering courses.

The engineering persistence rates in Post-General Education matriculation models are troubling, but there are some positive aspects from which to learn, primarily that the common first and second year are more accommodating to transfers and switchers. Although the additional time to degree may be a hindrance to completion, the additional coursework and higher likelihood of changing majors may be enriching to the students. The additional time to degree and lower persistence rates could also be a result of the potential of being advised by people less familiar with engineering requirements and career paths. This may explain why all three schools in this study have moved away from a PGE model to either FYE or DM.

It seems that the ideal matriculation model allows students to associate with engineering or an engineering discipline from matriculation, yet maintains the curricular flexibility to allow alternate entry points onto the engineering path. Note that this work only examined a few of many possible outcomes. It is important to understand a broad spectrum of outcomes related to matriculation pathways, because if we understand what outcomes result and how they come about, it may be possible to design pathways that improve all outcomes rather than improve some at the expense of others.

Abstract— Building on the work of others, we propose a different approach to studying the influence of letter grades on engineering students' major choice and migration patterns. As this work progresses, we will improve understanding of the effects of course performance, grading distributions, and early major intentions on the likelihood that students will persist in a given field.

Keywords- major choice; persistence; migration; grades

I. INTRODUCTION

Concerns regarding the retention rate of undergraduate engineering majors abound, particularly in light of the growing demand for a highly-skilled and diverse scientific and technological workforce. The Bureau of Labor Statistics estimates that between 2008 and 2018 engineering occupations will increase by 11.3%, versus all occupations, which will increase by only 10.1%. The combined science and engineering occupations, moreover, are projected to grow by 20.6% [1]. To meet this growing need for engineering professionals, it is critical for higher education institutions to find ways to improve the retention of engineering majors. While the graduation rate of undergraduate engineers is now similar to that of undergraduates in other disciplines [2], migration of engineering matriculants into other fields is relatively high. Among students who matriculated in a 4-year college or university in 2003 and declared engineering as an initial major, only 55.9% graduated in engineering as of 2009. Meanwhile, 22.3% migrated into non-science and non-engineering fields, 10.1% into physical, math, and computer sciences, 2.7% into agricultural and biological sciences, and 3.5% in social and behavioral sciences [1]. On the other hand, students who initially matriculate in non-engineering disciplines are unlikely to transfer into an engineering program due to factors such as stringent course requirements and sequences. The outflow of students from engineering with limited inflow of students from other fields contributes to the lower number of students completing engineering degrees. The migration patterns of science and engineering students have therefore inspired a body of research on precipitating factors such as poor academic preparation, "chilly engineering climate," difficult course material, poor instruction and

advising, and variations in student self-confidence [3-6]. Since course letter grades are an integral component of evaluation and assessment in undergraduate studies, here we investigate the complexity of its influence on student major choice.

The prevailing concern regarding course letter grades arises from the differential grading distributions that may exist between science and non-science majors at higher education institutions [7]. As Rask [8] puts forward, "if STEM [Science, Technology, Engineering, and Mathematics] departments grade lower than non-STEM departments, and the grade received is an important factor in the major decision, grading practices could be an important factor in the high attrition rates experienced in STEM majors." Rask shows that the absolute grade received is an important predictor of the likelihood of taking another course in the major the subsequent semester. Further, Ost [9] suggests that students are "'pulled away' by their high grades in non-science courses and 'pushed out' by their low grades in their [science courses]." Yet, the relationship between grading distributions, student letter grades, and major choice is complex. For example, when student effort and motivation are taken into account by proxy, letter grades are not necessarily predictive of student major persistence and the effects can vary by student gender [10, 11].

Thus, to further understand student major choice and migration patterns, we propose a unique approach that incorporates multiple sources of observable data on students' major intentions and actual letter grades, as well as calculations of students' expected performance. Our view is that students' decisions are based on the context of grade-related factors, including their own predictions of their likely performance in future discipline-specific courses. Our research findings will shed light on whether engineering programs can retain students through system-wide changes in grading practices, such as providing students with more information regarding course-specific and/or discipline-specific grading distributions so that students are able to more accurately assess their performance and aptitude. Additionally, our findings will contribute to the debate on whether standardizing grading distributions between science and non-science majors could reduce the number of students migrating out of engineering.

II. DATA

Empirical data come from the Multiple-Institution Database for Investigating Engineering Longitudinal Development (MIDFIELD), and include individual-level demographic characteristics and detailed transcript records. The dataset is composed of 14 entering cohorts from 1990 through 2003 across 9 public four-year institutions allowing for a comprehensive examination of patterns in student major choice. We limit our study to first-time undergraduate students who complete a degree in the same institution where they matriculate. Therefore, students who transfer from another institution and students who leave the undergraduate program are not included.

The demographic variables comprise student gender, race/ethnicity, Citizenship, age at enrollment, year of entry, SAT scores, and initial and early major intentions. Course-related variables of interest include students' letter grades in introductory engineering courses and in gateway courses (first discipline-specific course often taken as an introduction to the field), as well as the proportion of "A's" and "C-'s" and below awarded in upper division courses for each engineering discipline by year.

III. RESEARCH QUESTIONS AND METHODS

A. *Are students more likely to select a major if they expect to receive relatively higher grades in the major's upper-division courses?*

Previous research has tended to focus on the actual letter grade received in determining student major choice. We take a decidedly different approach and examine whether students select majors based on their predicted future grades while taking into account students' initial or early major intentions. Since students are more likely to select leniently graded courses when grade information is provided [11], are students also more likely to select a major when they expect that they will receive relatively higher grades in that major? Conditional on major intentions and assuming that students gather data on grade distributions from various informal sources, we estimate the impact of expected performance and previous discipline-specific grade distributions on student major selection using logit and multinomial logit regression.

Expected performance is calculated using exact matching on gender and propensity score matching on race/ethnicity, SAT scores, high school grade point average, percentage of students enrolled in the free lunch program at the student's high school, college institution, year of college matriculation, and letter grades earned in general undergraduate introductory courses in mathematics, chemistry, and physics. The expected performance variable predicts, given a student's background and introductory grades, how a student will perform in a major's upper division courses based on how other students with similar characteristics have performed in that particular major. For each student, we calculate expected performance for each of the following majors: Chemical, Civil, Electrical,

Industrial, and Mechanical Engineering. Previous discipline-specific grade distributions include lagged variables for the proportion of "A's" and "C-'s" and lower awarded in upper-division courses. Findings from these analyses will help clarify the extent to which students consider future performance when selecting a major in light of initial major intentions.

B. *Do students' relative performance in gateway courses predict major choice?*

Among undergraduates who take at least two gateway courses in engineering, we compare their relative performance in the gateway courses to determine whether higher relative grades attract students to a major. That is, do students respond to grades as signals of their relative strengths and weaknesses? We use logit regression to estimate the effect of relative performance in gateway courses on migration patterns, taking into account early major intentions and background characteristics. Like previous research, we are unable to fully account for student effort or motivation when assessing the impact of actual grades on major selection. We argue, however, that students may be more likely to have similar levels of motivation across gateway courses since they are likely taking these courses with intentions to explore or to major in that particular engineering field. This is in contrast to potentially different levels of motivation that engineering students may exert between their STEM and non-STEM courses [8]. Likewise, engineering students may also exert similar levels of effort across gateway courses compared to the effort they may give non-STEM courses. Therefore, limiting the analysis to engineering gateway courses may constrain the range of motivation and effort and lead to new understanding of major choice. Research findings will help clarify whether relative grades influence students' persistence and major decisions.

IV. SUMMARY

We propose a different approach to examining the influence of letter grades on engineering students' major choice and migration patterns. Research findings will bring new understanding to the effects of course performance, grading distributions, and early major intentions on the likelihood that students will persist in a given field. These contributions will be useful to engineering faculty and programs in assessing grading practices and policies and in attracting and retaining larger numbers of undergraduates.

A First Look at Student Motivation Resulting from a Pass/Fail Program for First-Semester Engineering Students

Ken C. Stanton, Tom Siller
Colorado State University
Fort Collins, Colorado, USA

Abstract – In 2010, administrators at Colorado State University implemented an experimental program allowing first-semester engineering students to take their entire course load for pass/fail grades, instead of the traditional A-F grades. Engineering educators were interested in the impact that this program had, and initially looked to GPA and grades. Realizing that those were insufficient to understand impact of the program, this study expands on previous work by obtaining a preliminary measure of students' motivation and correlating it with GPA and other variables of interest. Results indicate that the pass/fail students and traditionally graded students were very similar in terms of motivational qualities on average, but that motivational qualities showed relationships with semester GPA uniquely for pass/fail versus traditionally graded students. Also, student comments suggested that at the least they felt no harm was done by the program being offered and their enrollment or non-enrollment.

Index Terms – pass/fail, grades, motivation, student stress

INTRODUCTION

This paper explores the motivational impact of an experimental program implemented in the first-year engineering program at Colorado State University. During the Fall 2010 semester, the College of Engineering started an optional, experimental program for first-year students that would allow them to take their entire first semester's academic load as pass/fail (P/F). This was motivated by a growing concern that first-year engineering students were suffering emotionally from the rigor of the engineering curriculum. The premise was that relieving some of the pressure to perform, in terms of GPA (grade point average), while also providing more contact and support with engineering faculty and staff, could enhance student performance and relieve some related stress while they adapted to the college environment. The P/F experiment was continued with the entering first-year engineering students of Fall 2011, constituting the second cohort, who are the subjects of the research presented herein.

The authors of this work previously explored their differing opinions of the program as well as the difference in grades that students attained between those in the P/F and those who elected traditional A-F grading [1]. This previous work found that students who took their classes P/F earned significantly lower GPAs (scored before being converted to pass/fail grades) than those who took their classes for a traditional A-F grade. However, when broken out by course to see more detail, only certain courses showed significant differences in grades, suggesting that there was still more to the picture than grades alone could show. Therefore, the previous work concluded with future research questions, including the one for this paper:

How do student motivations for learning and motivations for grades affect both their choice to enroll in the pass/fail program and their academic performance?

Therefore, the goals of this paper were to:

- Attain a preliminary motivational evaluation of the first-semester engineering students
- Analyze data for relationships between the motivational variables and academic variables to explain enrollment in the program
- Analyze data for relationships between the motivational variables and academic variables to explain academic performance

BACKGROUND

1. The Pass-Fail Program at CSU

Colorado State University (CSU) is a public land-grant university with approximately 1,800 undergraduate engineering students and 500 graduate engineering students. High school students may apply directly into any of the majors in the college, or enter as undecided engineering students. A typical first-semester course load includes a department-specific introduction to engineering course or a college-wide engineering course based on the NAE's Grand Challenges, calculus, and a science course – often physics or chemistry.

The decision was made during the summer of 2010 to implement the new P/F program for the Fall 2010 semester, under the supervision of the second author of this paper. Administrative-level support for this effort was attained based on the knowledge that similar systems are in place at other successful engineering schools, such as MIT and CalTech. At CalTech, a no-grade policy was first implemented in 1964, and was quite successful [2]. More recently, P/F systems have been successfully implemented in medical schools [3] with the intent of reducing student stress. With this as a background, the CSU College of Engineering was given permission to move forward with an experiment during the Fall 2010 semester, despite the fact that this would violate several established university policies. As this was considered an experiment, exceptions to the pertinent policies were given by upper administration with the proviso that a comprehensive assessment plan would be implemented and results shared with the administration. During the first week of classes, first-semester engineering students were recruited into the program on a purely volunteer basis. The program included the following elements:

- A new, required, 1-credit seminar course was implemented to increase student-faculty contact. A senior faculty member coordinated multiple sections of this seminar and developed curricula that focused on connecting engineering concepts with math and sciences courses being taken by the students.
- Passing was defined by the university as S for a grade of D and above, and failing as a U for a grade of F.
- Students could choose to either take all courses P/F or all courses with traditional A-F grading. This decision had to be made by the university-established deadline.
- Faculty members were unaware of students' choice to participate. Faculty graded using typical A-F grading, submitted the grades, and the Registrar's Office converted the grades to S/U for students in the program.
- Students were allowed to recover grades with certain restrictions, including: a student must recover all grades and the decision was then irreversible.
- The program was only available for first-time, entering freshman in their first semester.
- Students who chose to participate in this program were allowed to maintain all University and College of Engineering sponsored scholarships and Honors standing.

II. Motivation Theories

Two motivation theories were used in this work to evaluate student motivation: self-determination theory and expectancy-value theory. These two were selected, of the many motivation theories in the literature, as they were most directly able to explain students' intentions and source of motivation for their actions, to best answer the research question for this work.

Self-determination theory

The first was self-determination theory, founded on the principle that motivation lies on a continuum from amotivation to extrinsic motivation to intrinsic motivation. Intrinsic has the most internalized source of motivation (e.g., passion, deep personal interest), whereas extrinsic has the most externalized source of motivation (e.g., parental pressures, financial pressures); amotivation is a lack of enough drive to act at all. Internalized motivation has been shown to produce the deepest levels of affective, behavioral, and cognitive engagement in tasks, including learning, and consequently the best productivity. Externalized motivation, on the other hand, not only attains lower quality engagement and shallow learning, but also moves more easily into amotivation when the external motivator is removed or temporarily not present [4].

There are three underlying motivational needs that affect the process of internalizing motivation: autonomy, competence, and relatedness. Autonomy requires not only choice but that the options align with internal values of the person. Competence is similar to self-efficacy in that it requires the perception of ability as well as opportunities to demonstrate that ability. Relatedness is a need to feel connected to others or something bigger than the self. Satisfaction of these needs, as perceived by the individual, leads to increasingly-internalized motivation, which obtains the aforementioned benefits [4].

Expectancy-Value Theory

Expectancy-Value Theory evaluates individuals' motivations based on their anticipation of positive outcomes (expectancy) and their desire to obtain such outcome (value). The evaluation of expectancy involves one's perception of their competence, at the time when the task will be undertaken. The evaluation of task value depends on the task's quality, which leads to an increase or decrease in probability that the individual will prioritize the task in comparison to others [5, 6].

The task value may depend on four variables: attainment value, intrinsic value, utility value, and cost. Attainment value is the importance associated with the outcome based on internalized value. Intrinsic value is that which stems purely from interest in and enjoyment from the engagement in the task. Utility value is the value associated with the outcome toward other future goals and interests. Finally, cost, in the sense of motivation, is associated with how the decision to engage one task may limit the ability to engage others and the effort required to do so [5, 6].

MOTIVATION INSTRUMENT

A survey instrument was created to measure a few basic aspects of first-semester students' motivation, containing 21 questions assembled from the principles of self-determination theory and expectancy-value theory. The survey was distributed to all 488 first-semester engineering

freshmen via email near the end of the semester, after attaining IRB approval. Ninety-eight (98) students responded (20%), and out of those, 82 were complete enough for use, providing an effective response rate of 17%. No demographic information was collected, but students entered their names, allowing us to connect their survey responses to their actual course grades and other enrollment information.

The instrument had questions in two categories and for both motivation theories. The categories of interest were motivation for getting good grades and motivation for learning and understanding engineering. Therefore, each was measured using both self-determination theory and expectancy-value theory.

For self-determination theory, questions were taken from the Self-Regulation Questionnaires for both Academic (SRQ-A) and Learning (SRQ-L) [7] and their wording was altered for use in our context. Responses were on a 1 to 5 scale, with 1 labeled as “not very true” and 5 labeled as “very true,” scored by combining questions for each category into the Relative Autonomy Index (RAI):

$$\text{RAI} = (-3) * \text{Amotivation} + (-2) * \text{Extrinsic} + (-1) * \text{Introjected} + (1) * \text{Identified} + (2) * \text{Intrinsic}$$

A negative RAI, therefore, indicates the individual has an overall external source of motivation relating to the category in question, whereas a positive RAI indicates that their motivation is largely intrinsic and from internalized sources.

For expectancy-value theory, questions were derived from the key variables of the theory, worded for use in our context. Responses were on a 1 to 5 scale, with 1 labeled as “not very true” and 5 labeled as “very true,” scored by combining questions for each category by adding them (with no weighting). A high score indicates the individual is likely to prioritize this task category over others, whereas a low score suggests the category is less important compared to others.

The instrument also contained questions about students’ views on how enrolling or not enrolling in the P/F program affected them. This information was used to measure students’ evaluation of the program and to ensure that with this experiment we were adhering to *primum non nocere* (first, do no harm).

RESULTS AND DISCUSSION

I. Fall 2011 Enrollment

In Fall of 2011, the term whence this study was conducted, there were 488 first-semester engineering students at Colorado State University. Of those, 51.2% (250) stayed in traditional A-F grading format but the other 48.8% (238) enrolled in the pass-fail (P/F) program.

II. Overall GPA Comparisons

As per our previous work, we compared the overall GPAs of both groups of students. We found a significant ($p < 0.001$) difference in the A-F students’ GPA at 2.80 and the P/F students’ GPA at 2.67. Again, and as discussed in our previous work [1], we felt that GPA did not provide sufficient explanation of students’ performance or experience in the program and hence collected data on motivation and individual course grades to supplement.

III. Engineering Courses

When individual course grades (for all 18 courses) were compared, rather than the collective, overall GPA, only 7 courses showed significant differences, partially due to the lower number of samples to compare (lower statistical N-value). The courses that had significant ($p < 0.05$) differences in grades between A-F and P/F students, always with the A-F grades higher than the P/F were: Chemistry 111 & 112, Math 124 & 126 (College Algebra), Math 160 & 161 (Calculus I & II), and Psychology 100.

IV. Motivation Scores

Across the board, the motivation scores were, on average, in the middle of their respective scales. That is, for students’ motivation for getting good grades and for learning engineering, both the self-determination theory questions and expectancy-value theory questions were ‘neutral’ in terms of motivation, indicating no strong biases toward intrinsic or extrinsic motivations nor toward high or low expectancy or value. Further, no significant differences were found between motivation scores for P/F and A-F students nor between motivation for grades and motivation for learning. However, this was merely a comparison of means, which collectivized the individual scores; to disaggregate and see deeper patterns, we performed correlations, which are discussed below.

V. Student Opinions of Their Choice

The survey also asked students for their opinions of how the pass-fail program affected them. That is, for students in the P/F program, we asked them if it benefitted them; for students not in the program, we asked if they felt they missed out or felt slighted by the program being offered. The results showed that, for students in the program, they did not feel it hurt them or their academic futures, and for students not in the program, they did not feel they missed out or would be hurt by their choice. This allowed us to conclude that, at least from the students’ perspectives, our experimental program was not harmful to the students nor their academic progress, which of course was our first and foremost concern during the experiment.

Additionally, we looked at correlations between these opinion scores and other variables measured. Table 1 below presents informative relationships observed between students’ opinions that their choice between P/F and A-F was a good choice (variable 1) and the second variable.

The relationships with GPA suggest that students had some reactions to their choice of P/F versus A-F in hindsight according to their academic performance. That is, students who chose the P/F program and ended up getting good grades were less satisfied (negative r) with their choice than those who got lower grades; the converse applies for A-F students in that the higher their GPA, the more satisfied they were with their choice of grading schemes.

Table 1. Correlations with Student Opinions

| Variable 2 | For which students | r (Pearson) |
|---|--------------------------------|----------------------|
| GPA | A-F students: P/F students: | 0.515*** -0.318** |
| Self-determined motivation for getting good grades | A-F students: P/F students: | N/S 0.368** |
| Expectancy-value motivation for getting good grades | A-F students: P/F students: | N/S N/S |
| Self-determined motivation for learning engineering | A-F students: P/F students: | N/S 0.383*** |
| Expectancy-value motivation for learning engineering | A-F students: P/F students: | N/S 0.316** |

$p < 0.10$ level (*), $p < 0.05$ level (**), and $p < 0.01$ level (***), N/S = not significant

The relationships between GPA and the motivational variables provide a deeper explanation of their experiences. First, the relationships between students' opinions and the 3 significant motivational variables for P/F students suggests that the more internalized their motivation and the higher priority that grades/learning were, the better the students' experiences were in the P/F program. However, since none of the motivation variables correlated significantly for the A-F students, it is reasonable to conclude that their opinions of A-F grading were already set when they entered college and that their motivational qualities had no effect on this opinion.

VI. Research Question

To answer the primary research question for this study, we performed statistical analyses including correlations between variables such as GPA, motivation scores, credit hours taken in the semester, and the specific course section taken. In order to process these data, however, survey results had to be combined with student academic data, which led to only 70 students' data being useful. Due to the high variances in the data and the split of these 70 data points into P/F and A-F categories, statistical comparisons became difficult. Therefore, for this data, statistical significance was considered up to the $p < 0.10$ level, instead of the common $p < 0.05$ level, meaning that we tolerated a slightly larger chance that the correlation was actually zero.

First, relationships were analyzed for variables that could explain why students chose to enroll in the pass-fail program. This meant that any variable that significantly correlated with enrollment in the program was of interest. Unfortunately, none of the other 11 variables had significant correlations, even at the $p < 0.10$ level. Therefore, we gained no significant insight as to why students chose to enroll or not enroll in the P/F program from this data. However, recall that the GPAs of P/F versus A-F students has already been compared, and that A-F students had significantly higher GPAs. Therefore, we added to the data the Colorado Commission on Higher Education's (CCHE's) Admission Eligibility Index, to see if enrollment in the program correlated with this college preparedness score. It did not correlate, suggesting that student readiness was also not a factor in students' decisions to take their classes P/F. Overall, this lack of correlation with P/F program enrollment suggests that students may have taken the program for deeper reasons than we studied, but at least that they didn't enroll just because they were less motivated to learn or get good grades nor were they less prepared for college.

Second, relationships were analyzed for variables that could explain the lower GPA for P/F students versus the A-F students. Informative correlations between GPA (variable 1) and the other variables are shown in Table 2 below.

Table 2. Correlations with GPA

| Variable 2 | For which students | r (Pearson) |
|--|--------------------------------|---------------|
| Self-determined motivation for getting good grades | A-F students: P/F students: | 0.344* N/S |
| Expectancy-value motivation for getting good grades | A-F students: P/F students: | N/S 0.331* |
| Self-determined motivation to learn engineering | A-F students: P/F students: | N/S N/S |
| Expectancy-value motivation to learn engineering | A-F students: P/F students: | N/S N/S |

$p < 0.10$ level (*), $p < 0.05$ level (**), and $p < 0.01$ level (***), N/S = not significant

These results show that only the students' motivations to get good grades actually have a relationship with their GPA. For the A-F students, the more internalized their motivation for grades, the higher their GPA; also, the more external their source of motivation, the lower their GPA. This correlates well with self-determination theory, which says that internalized motivation will always produce better quality results for the individual. For the P/F students, the higher their motivational priority was for grades, the higher their GPA. This is interesting as it shows that students in the P/F program didn't have to prioritize good grades like A-F students all did (since they could get a D and still pass), so the P/F students who did actually prioritize grades did better.

The follow-up to that was to see if motivation for learning was greater for the P/F students, perhaps showing that lowering the priority for grades increased the motivation for learning; however, none of the data analysis revealed any such results.

VII. Other Relationships

Other relationships were observed in the correlations that are worth noting, briefly, as shown in Table 3; note that values are only listed for “all students” instead of being split by P/F and A-F. First, a correlation was observed, in the population studied, between GPA and the number of credits students took. Of course, as this was a correlation, we cannot tell which way any causation would exist, but both cases are of interest. In one direction, this may suggest that students who took more credits got better grades, perhaps meaning that more responsibility led to more focus and effort, and better results. In the other direction, it may suggest that students who are stronger academically felt comfortable or compelled to take more credits. To supplement this point, it is noted that the correlation between credits taken and CCHE Index scores is also significant and positive, suggesting that this latter direction is a likely explanation.

Table 3. Other Correlations of Interest

| Variable 1 | Variable 2 | r (Pearson) |
|--|--|-------------|
| GPA | Number of credits taken | 0.201* |
| CCHE Index | Number of credits taken | 0.376*** |
| Self-determined motivation to get good grades | Expectancy-value motivation to get good grades | 0.501*** |
| Self-determined motivation to get good grades | Expectancy-value motivation to learn engineering | 0.332*** |
| Self-determined motivation to get good grades | Self-determined motivation to learn engineering | 0.518*** |
| Self-determined motivation to learn engineering | Expectancy-value motivation to learn engineering | 0.355*** |
| Self-determined motivation to learn engineering | Expectancy-value motivation to get good grades | N/S |
| Expectancy-value motivation to learn engineering | Expectancy-value motivation to get good grades | 0.485*** |

p<0.10 level (*), p<0.05 level (**), and p<0.01 level (***), N/S = not significant

As well, the correlations between the 4 motivational variables were observed. Data showed strong relationships between both theories in both categories, except for one, providing some evidence of validity for the motivational measures developed for this instrument. As well, seeing that

students’ motivations for learning and motivation for grades are highly correlated suggests that students may not distinguish highly between grades and learning. While this may seem like a logical relationship to many people, the authors of this work find this concerning, as the composition of a grade is often based on performance measures rather than learning measures. This could lead students to believe that they aren’t learning when they get bad grades, as well as other messages that professors might not intend to relay to students through their academic performance measures.

CONCLUSIONS

Overall, our findings suggest that students who chose to enroll in the P/F program were not very different from those who elected to get regular A-F grades. Their experiences at the end of the semester differed, and interestingly these opinions of their choice of grading schemes were in relation to how their actual grades came out.

More specifically, and most importantly, our study found that students’ motivations to get good grades had a significant relationship with their actual GPA performance. For the A-F students, they had no choice but to prioritize grades or risk hurting their GPA, so not surprisingly, the only relationship between their motivation and their semester GPA was in how internalized their motivation was for getting good grades. However, for the P/F students, their motivational prioritization of their grades was found to directly correlate with their GPA, suggesting that there was some freedom for P/F students to lower their priority of getting good grades and raise the priority of other things; we were unable to determine what other things that may entail.

Another interesting finding was that none of our data were able to explain why students enrolled or didn’t enroll in the P/F program. We expected that students who enrolled in the P/F program might have a lower level of motivation for getting good grades, or a higher level of motivation for learning about engineering (in contrast to focusing on grades alone); however, neither of these relationships panned out. Since some of the past research on P/F programs suggested that reducing focus on grades was good for students, we hoped to see more evidence of this in our study. Therefore, the concluding assumption is that students’ reasons for choosing one grading scheme over the other were other than what we observed, but at least they weren’t taking the P/F option simply because they were less academically motivated, overall.

We also found that many of the motivational variables correlated with each other, including between motivation for grades and motivation for learning, indicating that students didn’t have a lot of separation between grades and learning. Since we feel there is a significant and underappreciated difference in the two, we found this concerning. However, noting that our survey instrument was brief and preliminary, we suggest that a more thorough research investigation may

reveal better results for these observations, as well as the others.

Nonetheless, we were able to discern that, at least in the students' opinions, this experiment has not hurt them. While only a very few P/F students asked to restore their actual grades and GPA, thereby reverting their choice to take the P/F option, this was the exception and not the norm. Overall, however, we feel that the program has been beneficial, and plan to research it more deeply with the Fall 2012 cohort, as the experiment has been extended for one more year.

Abstract—Changes in students' personal epistemology are especially important for engineering educators to examine because they may affect the way students learn and their ability to adapt to engineering education learning environments and culture. Despite the large amount of theoretical research that has been done concerning students' conceptual change, little research has been done concerning their epistemological change. This study is a preliminary effort in identifying students' beliefs about knowledge and their effect on learning and successful comprehension of engineering concepts. The cohort consisted of 10 Civil Engineering students in a sophomore level Statics class, and each student participated in a 90-minute interview. The questions were based around an epistemological framework currently in development, which includes six separate dimensions but allows for examination of the ties between the dimensions. Analysis was completed in multiple stages, and involved two researchers co-coding for inter-rater reliability. Most students viewed knowledge as very simple, certain and objective. However, many students felt that different people had different knowledge of statics because of their different backgrounds and learning. These beliefs may be leveraged to support pedagogical practices of proven effectiveness such as peer-tutoring or other active learning methods.

Keywords- Civil Engineering, personal epistemology, Statics

I. INTRODUCTION

In order for engineering educators to understand how students develop into successful practicing engineers, researchers must understand the conceptual and epistemological changes that they go through in that process. Personal epistemology may have a strong influence on the way students learn and adapt to the learning environments and culture of engineering education, which makes it especially important to study. It could also be part of students' development as critical and reflective thinkers because it impacts the ways in which students evaluate their engineering knowledge.

II. PURPOSE

This study is a preliminary effort in identifying students' beliefs about engineering knowledge. The purpose of this study is not to build causal arguments, but to present data and preliminary conclusions exploring how students' epistemological beliefs, or personal epistemologies, manifest

This research was funded by NSF IEECI Grant #1025205.

near the beginning of their pursuit of Civil Engineering education. The research presented here is part of a larger, longitudinal study designed to continue to explore students' beliefs about engineering knowledge as they pursue Civil Engineering into practice.

III. BACKGROUND

When researchers think about epistemology it is often in terms of the way it informs their research practices. Epistemology can inform the types of research questions researchers ask, the methods used to explore the answers to those questions and the answers that researchers consider valid [1]. Researchers have also begun to explore the ways that individuals incorporate these processes into their daily lives and information consumption through the concept of personal epistemology. Personal epistemology has also been linked to students' ability to experience conceptual change [2]. It is important for researchers to examine students' personal epistemologies and the ways in which they interact with student learning [3].

Several researchers have developed methods of evaluating students' personal epistemologies. For example, Schommer [4] developed the Epistemology Questionnaire (EQ) to explore personal epistemology. Several other researchers have since evaluated and refined the EQ and it encouraged the development of other questionnaires designed to examine personal epistemology. King and Kitchener [5] also developed a method to examine personal epistemology, which they call epistemic cognition. Their Reflective Judgment Model examined how people evaluated issues that are considered ill-structured, or problems about which "reasonable people reasonably disagree" [5, p. 37], through a structured qualitative interview process. Greene, Torney-Purta and Azevedo have also developed their own model of epistemic cognition, which utilizes three dimensions "Simple and Certain Knowledge, Justification by Authority, and Personal Justification," and developed a questionnaire to evaluate it [3].

Though many researchers have worked to develop frameworks of personal epistemology, there is much debate as to the reliability and validity of many of the frameworks as a whole [5]. Many of the personal epistemology frameworks and questionnaires have only been shown to be valid and reliable for a few of the dimensions that they consist of [3, 6, 7]. As a

result, continued work to develop valid and reliable methods of exploring personal epistemology is needed.

IV. THEORETICAL FRAMEWORK

Based on evaluations of the available frameworks of personal epistemology, our research group began to develop a framework which included many of the dimensions of personal epistemology other researchers have supported and validated through their research. In particular the work of Fitzgerald and Cunningham [8, 9], Mason et al. [10-12] and Hofer et al. [13-15] were influential. This framework was designed to incorporate the dimensions that other researchers have developed into a viable and, potentially, more complete personal epistemology framework that allows us to explore the many potential aspects of students' personal epistemologies without setting unnecessary limitations. Of the dimensions included in the framework, all but one (Social Processes of Knowing) were based primarily on the expert work that has already been done in the field of personal epistemology (see Montfort et al.'s Work in Progress titled "Theoretical Approach to Characterizing Changes in Students' and Engineers' Conceptual Understanding and Personal Epistemologies" in these conference proceedings for a more complete description of the foundations of the framework). It is this framework that the current study has been grounded in and the current study is part of the research process to test if the framework is a valid approach to explore engineering students' personal epistemologies. We consider a valid approach to be a framework that justifiably provides complete and accurate data about students' personal epistemologies in a way that allows it to be applied and tested by other researchers.

This personal epistemology framework consists of five dimensions. Each of these dimensions explores one aspect of personal epistemology that we have identified as defining the way that students understand and evaluate knowledge and knowing. The dimensions are Structure of Knowledge, Certainty of Knowing, Source of Knowledge, Justification of Knowledge and Social Processes of Knowing. Explanations of the dimensions are outlined in Table 1.

TABLE I. PERSONAL EPISTEMOLOGY DIMENSIONS

| Dimension | Explanation |
|-----------------------------|---|
| Structure of Knowledge | The ways in which students think about how knowledge is related and organized in a domain. |
| Certainty of Knowing | The ways in which students think about what knowledge in the domain is certain and how they attribute "truth" to knowledge. |
| Source of Knowledge | Where students think knowledge in the domain can come from. |
| Justification of Knowledge | The ways in which students think knowledge in the domain should be evaluated and the criteria for acceptable knowledge. |
| Social Processes of Knowing | The ways in which students think that different people know and how collective understanding affects knowledge. |

V. METHODS

This study employed a qualitative methods approach through the use of individual interviews.

A. Participants and Sample Selection

The cohort of students involved in this study consisted of ten Civil Engineering students. All of the students were sophomores enrolled in a combined Civil Engineering/Mechanical Engineering Statics class. Student participants were selected through preliminary interviews examining their personal epistemologies through a modification of Greene, Torney-Purta and Azevedo's Epistemic and Ontological Cognition Questionnaire [3] and conceptual understanding of Statics in combination with their performance on the Statics Concept Inventory [16]. A summary of these results are outlined in Table 2 and show a wide diversity among participants based on their conceptual understanding and personal epistemology. There are many different combinations of personal epistemology stances and conceptual understanding levels and Statics achievement. Students who a) agreed that Statics knowledge was simple and certain and b) had weak personal justification (meaning that they did not feel that they personally played an important role in the justification of Statics knowledge) represented radically different personal epistemologies than students who disagreed that Statics knowledge was simple and certain and who had strong personal justification. There was also a wide range of scores on the Statics Concept Inventory [16] and on Statics academic achievement. All of the students who were selected had at least a "C" grade in Statics to ensure that they could continue to participate in the longitudinal portion of the study. At the same time, we still selected students that ranged from the top 25% of the class to the bottom 25%. We also selected students that showed a wide range of conceptual understanding of statics from one student who scored close to a 92% on the concept inventory to one student who scored slightly over 4%.

B. Research Instrument

The interview protocol was developed based on the theoretical framework. It involved five sections of questions based on the five personal epistemology dimensions identified. Each section consisted of three to six statements reflecting an epistemological stance within that dimension. Students were asked to explain if they agreed or disagreed with that statement and why. Students were asked follow-up questions to clarify or expand on answers given in each section, as well as explore any relationships between the epistemological dimensions. All of the questions were asked with reference to Statics in order to provide domain specificity for the students' personal epistemologies, which is important to ensure the validity of student responses [3, 17, 18].

C. Implementation

Students participated in 90-minute interviews at the end of the term in which they participated in Statics. The interviews consisted of three sections, one being the previously mentioned direct personal epistemology section while the other two focused on student epistemologies in reference to other contexts. The interviews were conducted in the style of a

clinical interview [19]. The clinical interview was determined to be the most effective way to explore students' personal epistemologies because the individual understandings of knowledge and ways of knowing are "elusive" [20, p. 9]. Good clinical interviews are semi-structured and open-ended which allow participants to construct their own thoughts and pursue them while still maintaining comparable data. They also allow researchers to interpret meaning from statements made in the interview to construct an understanding of the participant's thinking as a whole [19]. In order to match the aspects of a clinical interview, these interviews were designed to have one interview protocol that was used with all participants. The questions in the protocol were developed to elicit a reaction to a statement about knowledge and knowing in each of the five personal epistemology dimensions. Participants were then asked probing questions to encourage them to explore in depth

the thoughts about knowledge and knowing that they were presenting.

D. Analysis

The interviews were coded using qualitative data analysis techniques. First, one researcher descriptively coded the interviews based on the responses the participants gave to each question. The researcher then went through the descriptive codes and developed a classification for each personal epistemology dimension for each student based on thematic analysis of the descriptive codes [21]. Another researcher completed the same process for four of the interviews and the results were compared for inter-rater reliability. After discussing the separate results and clarifying and the questions that arose, the researchers reached full agreement on the classifications of the students.

TABLE II. STUDENT RESULTS FROM SAMPLE INTERVIEWS

| Student | Gender | Previous Degree | Simple and Certain Statics Knowledge | Personal Justification ^a | Statics CI | Ranking Task on Beams | Statics Grade ^b |
|---------|--------|-----------------|--------------------------------------|-------------------------------------|------------|-----------------------|----------------------------|
| 101 | Male | Bachelor's | Agree | Weak | 33.3% | Correct | 4 |
| 102 | Female | None | Agree | Moderate | 25.0% | Correct | 3 |
| 103 | Male | Bachelor's | Disagree | Moderate | 41.7 % | Correct | 1 |
| 104 | Male | None | Disagree | Strong | 91.7% | Correct | 1 |
| 105 | Male | None | Agree | Moderate | 25.0% | Incorrect | 2 |
| 106 | Female | None | Agree | Weak | 37.5% | Correct | 2 |
| 107 | Male | None | Agree | Strong | 33.3% | Correct | 2 |
| 108 | Male | Associate's | Agree | Weak | 16.7% | Correct | 4 |
| 109 | Male | Associate's | Agree | Strong | 41.7% | Incorrect | 2 |
| 110 | Male | None | Agree | Weak | 4.2% | Incorrect | 3 |

a. Weak = no personal justification, Moderate = some personal justification, Strong = a lot of personal justification

b. Based on quartiles, 1 = top quartile, 4 = bottom quartile

VI. RESULTS

Based on the data analysis, three themes emerged that will be elaborated on in this paper. These themes were in the personal epistemology dimensions of Certainty of Knowledge, Source of Knowledge and Social Processes of Knowing.

A. Certainty of Knowledge

All of the participants felt that statics problems all had one correct answer and most felt that statics knowledge is certain. A typical answer was "...it always comes down to one number, one unit" given by student 102. This response shows that student 102 felt that Statics knowledge is simple and certain because it can always be simplified to a single, concrete answer. Several students introduced a caveat to this response though. One student (104) mentioned that there is a small range of correct answers available because of the slight errors introduced by things like rounding. His response shows that he still thinks that Statics knowledge is certain, by indicating that there are always correct answers, but he does imply that Statics knowledge is less simple by introducing the concept of error. Less than half of the students also mentioned that understanding of the subject was required for certainty in Statics.

B. Source of Knowledge

Most participants also responded that statics knowledge comes from observing the world, and most participants concluded that knowledge exists in the world, external to the knower. A typical response was:

104: "Maybe in a few years I'll make some observations that'll create knowledge... It's already there."

Interviewer: "Knowledge is already there?"

104: "Well, it's out there, we just haven't discovered it yet...Because it's not like we're changing any of the rules by knowing."

In this response, 104 shows that even though he thinks that it is possible to create knowledge in some way, Statics knowledge and the laws that make it up exist in the natural world and people's knowledge of them has no affect on what they are or how they work. In other words, whether people know Statics knowledge or not, it will exist in the world absolutely and immutably. He also shows that his version of knowledge creation is actually discovering knowledge that already exists in the world and is simply unknown to humans.

C. Social Processes of Knowing

Almost all of the participants felt that, though statics knowledge is universal in nature, different people could have different knowledge and/or understanding of statics. Over half of the students responded in ways that indicated that understanding is different between people. Student 109 gave a typical response for this stance:

I guess knowledge is the conceptual understanding--well no, just the understanding as a whole of a particular thing. So to have a different conceptual understanding that could happen because it could be that I figured it out differently and I see it differently. I know my math teacher, he looks at integrals and he sees it through paper, and I look at an integral and I understand it conceptually. So yeah, people could have different knowledge, if knowledge was defined as understanding of something.

Here, student 109 defines knowledge as understanding and asserts that different people can have different understanding of a topic, citing a personal experience to support that assertion.

Less than half of the participants felt that different people did have different knowledge of statics, without defining knowledge as understanding. Participant 103 responded with: "I think some people have more knowledge and I think some people think of things differently and sometimes one way of thinking is more beneficial than another." Here student 103 sets up his case that knowledge is different for different people by saying that people can have different amounts of knowledge and that people have different processes of thinking about things. He then goes on to further support that idea by saying that different people act differently and come to different conclusions based on their knowledge: "Different people are going to come to different conclusions and they're going to do things differently. Sure." He then concludes his point by asserting that even if people come to the same conclusion, they may reach it differently and they can never know if the conclusion is actually true:

103: "I think you can come to the same conclusions, but maybe the means that you take to get to those conclusions might not necessarily be done exactly the same. So yeah, I think different people might arrive-- I mean if it's a fact, it's kind of like you never know the truth, but people can arrive at something and if that actually turns out to be the truth, we just never know. But they both arrive there. They could do it differently."

Only one participant felt that correct knowledge was absolutely the same for everyone.

Interviewer: "Okay. If the people who studied statics in the past were different, our understanding would be different today."

104: "Well, if they weren't curious enough to go after that knowledge, we wouldn't have the same amount of knowledge. But as long as they were

doing their experiments correctly, they should've-- if it was completely different people doing it, they should've came up with the same knowledge. We've tested it often enough to prove it."

Interviewer: "Okay. So how would they have decided to do the same experiments? ...so let's say Einstein didn't come up with the Theory of Relativity, ...so you think that somebody else would've come up with it?"

104: "Eventually."

Interviewer: "Okay, would they have done it in the same way that Einstein did?"

104: "Maybe not-- okay, so maybe not quite exactly the same experiments but valid experiments, without any errors or anything like that. So reproducible experiments."

Interviewer: "And in the end we would still have gotten the Theory of Relativity?"

104: "Eventually, yeah <laughs>. At some point."

This participant's responses clearly indicate that he believes that as long as scientists were motivated and performing valid and reproducible experiments, they would absolutely have found the same knowledge that we have today eventually, whether or not the original scientists that developed that knowledge had done so.

As we will further explore in the discussion, this student's response about social processes of knowing directly matches with his beliefs about the source of knowledge and the certainty of knowledge, while most of the other participants had responses about social processes of knowing that did not align with their beliefs on the source or certainty of knowledge. Beliefs that knowledge is certain, external to the knower and the same for all knowers align with classifications of personal epistemology like Perry's dualism [22] or Greene, Torney-Purta and Azevedo's realism [3]. On the other hand, the idea that knowledge is different for different knowers is reflective of Perry's contextual relativism [22] or Greene, Torney-Purta and Azevedo's skeptic or rationalist [3] -- both of which are considered to be paradigmatically different ways of viewing the world from dualism or realism, respectively.

VII. DISCUSSION

Before beginning the discussion section we should note that this study asked students about their personal epistemologies in the context of Statics, not engineering in general. It is possible that the views represented here are specific to the domain of Statics. In that case, students may have more reflective or rationalist views about engineering in general. It is also possible that their views of Statics as simple, certain and objective are closer to being accurate than they would be of engineering in general. Statics is not currently a dynamic field, which may contribute to the represented personal epistemologies in that domain. Regardless of the relative stability of Statics as a field of study, however, it seems

unlikely to us that every issue in the field can be boiled down to a simple, singular and certain answer. Another result of these questions being asked about the domain of Statics, specifically the Statics course that the participants were taking at the time, is that there could be more complexity within the domain than we anticipated. It is possible that there are other sub-domains within Statics that the participants' personal epistemologies could vary over that were not captured by the generalization of the domain to their Statics course.

These concerns aside, the epistemological beliefs represented above could impact how well students are able to learn engineering. Both their ability to develop critical or reflective thinking skills and their ability to learn from traditional or constructivist engineering classrooms could be hampered by realist or dualist beliefs represented by belief in simple, certain and objective knowledge, which the majority of these students seemed to have.

One of the implications of their beliefs is that they may be lacking when it comes to reflective judgment and critical thinking skills. King and Kitchener define reflective judgment as using critical thinking and assessment of available information to inform decisions about knowledge [5]. If students are not thinking reflectively, it is likely that they are also not developing critical thinking skills and applying them to problems that they come across in engineering. King and Kitchener assert that reflective judgment occurs when students recognize that knowledge is not simple, certain and objective [5]. This implies that students are not developing the tools necessary to make critical evaluative judgments about ill-structured problems that will develop later in their academic and professional careers if they continue to view knowledge as simple, certain and objective.

It may be that students' epistemological stances on the certainty and objectivity of Statics could have a negative impact on their ability to be successful learners in traditional or constructivist classrooms. In traditional classes, there is limited epistemological training and basically no reason for students to question the simplicity, certainty or objectivity of the knowledge they are receiving because of the format of the class. As a result, this epistemological stance could limit students' desire to seek out new knowledge or be part of the knowledge creation process because they may not see any possibility for their involvement in knowledge creation in engineering. When they venture out into the workplace, these new engineers may have difficulty transitioning epistemologically to engineering practice where they would now be responsible for their own learning and for making critical decisions about difficult problems with no clear cut solution (e.g. how do you make a design decision when the process or acceptable results are not clearly stated in the code?). A constructivist classroom recognizes that students have previous knowledge that combines with what they are learning in class, that learning is a process of reorganization of knowledge and its placement within a context and that it is necessary for students to use their own metacognitive abilities to facilitate learning [23]. In this setting students are required to take part in making meaning of knowledge and building their own knowledge frameworks, but viewing knowledge as simple, certain and objective could limit their ability to do that.

The two students that gave responses that implied that either Statics or engineering knowledge might not be entirely certain, simple or objective both had previously obtained bachelor's degrees in other fields. This seems to support the assertion that students' epistemologies may change to a more relativist perspective simply through the college experience, which may mean that students' current beliefs about statics knowledge may change on their own with little negative effect on their ability to learn or become critical thinkers [20]. Because many of the students also mentioned that different people could learn or know statics differently, they may already be developing a more constructivist view of the world.

Most of the students interviewed believed that knowledge was simple, certain and objective while also believing that different knowers could know differently about the same topic. When trying to classify these students based on any of the common personal epistemology scales, this would put these students at both ends of a linear spectrum. Their beliefs represent extremely different viewpoints, both dualist or realist and contextual relativist or rationalist [3, 22]. These results imply that there is something more happening with students' epistemologies than just a linear transition from naïve to mature epistemological beliefs. As a result, one way to continue to improve upon the theories and frameworks of personal epistemology that have already been established would be to explore the nonlinearity of the spectrum of student epistemological beliefs.

VIII. CONCLUSIONS

The results of this study support two interesting conclusions. First, it appears that students have personal epistemology beliefs that may interfere with or limit their ability to be successful learners. These potential limitations are the result of student views of knowledge as simple, certain and objective and could affect their abilities to develop critical thinking skills and be fully successful in either a traditional or constructivist classroom. Conceptual change research has shown that simply refuting misconceptions is not enough to change student beliefs [24] and it is likely that there is a similar situation with beliefs about knowledge. Simply contradicting their epistemological beliefs may not be enough to change them. It may be important for faculty to work with students and train them to have more relativist or rationalist ways of thinking about engineering knowledge as they progress through their courses.

The second conclusion implied by these results is that a linear view of epistemology, from naïve to mature beliefs, may not encompass all of the potential combinations of epistemological beliefs students may have. Our data shows that students are able to have beliefs about the simplicity and certainty of their engineering knowledge as well as maintaining beliefs that engineering knowledge has social processes, which implies that their personal epistemologies have concurrent naïve and mature aspects. If we continue to classify personal epistemology based on a linear spectrum, it could limit the richness of our understanding. This conclusion opens up a new avenue of research into the multi-dimensionality of personal epistemology.

IX. FUTURE WORK

This study has highlighted some important questions that should be explored through future research.

- How do student epistemologies change over time?
- How are student epistemologies of engineering in general different than their epistemologies of Statics?
- How do student epistemologies and changes in personal epistemology relate to those of new engineers?
- Are student epistemologies of Statics detrimental to their ability to develop as critical and reflective thinkers in other areas of engineering?
- How do student epistemologies relate to their ability to successfully experience conceptual change?

We are beginning to explore these questions through a longitudinal study examining the personal epistemology and conceptual change of Civil engineering students from their sophomore year through their senior year and that of beginning engineers through their first two years in practice.

In the future, it would also be relevant to link these findings, as well as future findings about the development of personal epistemology through undergraduate engineering education, to other work that has explored student development in both their pre-college and collegiate experiences (e.g. [25] and [26]).

Understanding Engineering Transfer Students:

Demographic Characteristics and Educational Outcomes

Abstract—Transfer students make up a significant share of engineering college graduates, yet their persistence is seldom studied, largely because of the lack of longitudinal data. This analysis used longitudinal data from 11 universities enrolling large numbers of engineering students to investigate the demographic characteristics and educational outcomes of transfer students in engineering relative to non-transfers. We find that students who transfer to four-year engineering programs are more likely to come from under-represented minority groups (URMs) and less likely to be women, although both groups are over-represented at two-year colleges. The findings confirm existing research indicating that, on average, non-transfers outperform transfer students, and non-URMs outperform URMs. But we also find that URM transfers, and especially Black transfers, are no less successful than non-transfer students—indicating that the transfer pathway is an effective bridge to a four-year degree. This is partly true for women transfers who do as well as men but are outperformed by women non-transfers. Finally, we find significant variation in outcomes between full- and part-time students, which may be driving the observed differences by transfer status. Our results should inform debates regarding the efficacy of the transfer pathway in engineering, particularly for women and URMs.

Keywords—engineering; transfer students; persistence; student retention; STEM; higher education

I. INTRODUCTION

The need to increase the number of Americans joining the science, technology, engineering, and mathematics (STEM) workforce continues to draw national attention, most recently from the President's Council of Advisors on Science and Technology (PCAST). In the opening sentence of its latest report, the PCAST underscored the “need for approximately 1 million more STEM professionals than the U.S. will produce at the current rate over the next decade if the country is to retain its historical preeminence in science and technology” [1]. All five of the PCAST recommendations center on institutions of higher education, and one focuses in particular on partnerships between two- and four-year institutions to “diversify pathways to STEM careers.” In this paper, we explore one such pathway by focusing on students who transfer to four-year colleges with the intent to complete a degree in engineering.

Transfer students are a sizable, yet understudied, population that has the potential to increase the engineering workforce. Many of these students transfer from community and other two-year colleges in which women, minorities, and economically disadvantaged students are over-represented. For example, community colleges enroll nearly half of the nation's undergraduates and large shares of women (58 percent of community college students), minority (45 percent), first-generation (42 percent), and low-income (46 percent) students [2]. These are the very groups that are under-represented among engineers in the United States—and they constitute a potential pool of recruits for engineering and other scientific fields. Research on the effectiveness of the transfer pathway to an engineering degree is mixed, however. Some researchers argue that attending a two-year college lowers not only the probability of completing a bachelor's degree but also achievement through “transfer shock”, which they argue is commonly experienced when students transfer [3-7]. Some researchers add that transfer students are not as well prepared as non-transfer students to tackle college demands, particularly in STEM, and are therefore more likely to drop out. Others challenge these findings, particularly the effect of transfer shock (as student grades quickly rebound and even exceed those of non-transfers) and on the lower average achievement (they suggest that transfer students achieve higher academic performance and retention than do non-transfer students) [8-11].

Much existing research on transfer students is based on cross-sectional data and/or small data sets. We avoid both of these limitations by relying on a longitudinal data set that contains records for close to one million students in 11 institutions of higher education. By analyzing data on the large subset of engineering students, we are able to expand the existing literature by describing the characteristics and educational outcomes of transfer students compared to their non-transfer peers. In so doing, we contribute to the national dialogue on the effectiveness of this pathway to a degree in engineering and its potential to help address the need for more students, particularly women and under-represented minorities (URMs), completing degrees in engineering.

II. ANALYSIS SAMPLE AND METHODOLOGY

Our analysis used records for 94,732 undergraduate students from the Multiple-Institution Database for Investigating Engineering Longitudinal Development (MIDFIELD). MIDFIELD comprises a census of undergraduate students who attended 11 public institutions between 1988 and 2008. MIDFIELD institutions represent public universities that educate large numbers of engineering students (such as the Georgia Institute of Technology and the University of Colorado). The MIDFIELD database and sampling strategy are described in detail at <https://engineering.purdue.edu/MIDFIELD/p1.htm>.

From the 977,950 records available, we restricted our sample to those who (1) were domestic students (927,350), (2) were in the data set early enough for us to observe the possibility of graduation within six years (677,691), and (3) declared a major in engineering or otherwise expressed the intent to study engineering in the fifth semester of their programs (94,732). For transfer students, we estimated placement using transfer hours, assuming that 15 credit hours equals one semester; we also used the fifth semester as the reference point to capture most transfer students at the point of matriculation to ensure a valid comparison of transfers to non-transfers. This approach resulted in a sample of 21,542 transfer and 73,190 non-transfer engineering students included in this analysis.

We used standard *t*- and chi-square tests to establish whether any observed differences were significant, calculated Cohen's *d* and Cramer's *V* to estimate the magnitude of differences between groups irrespective of sample size, and used the Bonferroni adjustment to reduce the probability of false discovery due to the number of significance tests that were run. To facilitate replication of our work, we present unweighted and unadjusted results but replicated the comparisons of transfers to non-transfers by (1) weighing the data to account for different population sizes across institutions and (2) adjusting for clustering that might have led to underestimated standard errors. Results (available from the

authors) thus far indicate only one noteworthy change to the gender distribution by transfer status presented here (see Section III), and in a few other instances, slightly different point estimates.

Although our goal was to study the characteristics of and outcomes for transfer versus non-transfer students in engineering, it is important to note that transfer students are more likely to enroll in school part time than are their non-transfer peers. In fact, the proportion of students enrolled part time in the transfer population is four times that of the non-transfer population (30.7 percent versus 7.7 percent). Realizing that differences in outcomes between transfer and non-transfer students could be correlated with enrollment status, we also studied—and highlight here—meaningful differences that may be explained by enrollment status.

Last, it is also important to mention that, in studying student retention and graduation outcomes, we refer to students who neither graduated nor continued to be enrolled as dropping out or leaving the institution. We recognize, however, that some of these students (particularly transfer and part-time students) may, at a later time, resume their studies at the same or different institutions. Since we do not have enough years of data to observe these future outcomes, we restricted our findings to those that can be measured within the MIDFIELD institutions during the six years of available data.

III. WHO ARE THE ENGINEERING TRANSFERS?

Table I presents characteristics of engineering students by transfer and enrollment status. Results indicate that, on average, engineering transfer students are more likely to be male, older, and black, Hispanic, or Native American than are their non-transfer peers. Asians are equally represented across the two groups. This finding suggests that the transfer and non-transfer student populations differ in two key ways: the non-transfer population includes a larger share of Whites (77.9 versus 70.2 percent) and a slightly larger share of women (21.5 versus 19.3 percent) than does the subset of engineering transfers. Given that women and minorities account for large

Note: Symbols flag Bonferroni-adjusted significant differences between transfers and non-transfers (*), within transfers comparing full- to part-time enrollment status (^), and within non-transfers comparing full- to part-time enrollment status (†) at alpha = .0002. We also report (M) medium and (L) large effect sizes (Cohen's *d* and Cramer's *V*).

^a For Age, we dropped three institutions due to missing data; although we are missing values for the remaining institutions, the percent missing does not significantly vary by transfer status, suggesting we can report these results without biasing our analysis.

shares of two-year college students, it would be reasonable to expect these groups to be disproportionately represented among engineering transfer students. Our results, however, challenge findings from the existing literature, which suggest that the students who succeed in transferring are not more likely to come from under-represented minority groups. These findings suggest that, at present, the transfer mechanism is more effective in facilitating access to four-year engineering programs for under-represented minorities than for women.

An analysis by enrollment status suggests that URMs, particularly Blacks, are less likely to enroll full time than are their White peers (results available from the authors). Among all engineering students, Black students are twice as likely to enroll part time as White students (22 versus 11 percent, after rounding). If we look at transfer students, the gap is similar—38.2 percent of Black transfers are enrolled part time compared with 29.0 percent of White transfers (a 9.2 percentage point difference). The literature suggests that enrollment status is often driven by financial considerations, which can have significant implications for academic performance and persistence. In the sections that follow, we explore these outcomes by transfer and enrollment status as well as gender and ethnicity.

IV. DO ENGINEERING TRANSFERS PERSIST AND PERFORM AS WELL AS THEIR NON-TRANSFER PEERS?

Table II presents retention and academic performance outcomes of engineering students by transfer and enrollment status. Overall, engineering transfers are less likely to persist in college (in engineering or in other fields) than their non-transfer peers: compared with 11.5 percent of non-transfers, 17.3 percent of engineering transfers drop out or leave within the six-year observation period without completing their studies. Indeed, results show that transfer students, on average, are less likely than non-transfers to graduate or continue studying engineering (75.5 versus 78.1 percent) or to graduate in engineering in six years including time spent at prior institutions (71.6 versus 73.3 percent).

Although these average differences in persistence are nominal in terms of effect size, they conceal meaningful variation in persistence by enrollment status. Full-time transfer students are more likely than part-time transfer students to graduate in engineering within six years (a 25.4 percentage

point difference), and the gap is slightly wider for non-transfer students (a 37.4 percentage point difference). In addition, students who drop out or leave the institution are disproportionately part-time students in both the transfer and non-transfer groups. As expected, this finding suggests that enrollment status is a key factor in explaining retention outcomes for both transfer and non-transfer students.

Although non-transfer students significantly outperform transfers in engineering and overall GPA, the performance gap between these two groups is negligible in engineering and small overall (a .05 and .07 grade point difference respectively). But once again, enrollment status appears to be driving the results. Full-time non-transfer students outperform part-time non-transfer students by almost one-fourth of a letter grade in both engineering and overall cumulative GPA based on a four-point scale (moderate effect sizes); the gap between full- and part-time transfer students is smaller but still significant and meaningful. There are no significant differences in academic performance by transfer status within the full- and part-time enrollment groups. These findings suggest that, on average, full-time engineering students outperform part-time engineering students irrespective of transfer status, thus challenging the research cited earlier, which suggests that transfer students are less prepared to tackle college-level engineering coursework.

V. DO OUTCOMES DIFFER BY GENDER AND ETHNICITY?

Given the observed differences in both demographic characteristics and persistence by transfer and enrollment status, we compared outcomes by gender and under-represented minority status to assess retention and academic performance within these groups. Table III presents the results overall and by transfer status.

Overall, women appear to have higher retention in engineering than men, though the difference is negligible. In fact, there are no significant differences in persistence by gender within the engineering transfer population. This finding is particularly important, considering that women are under-represented in engineering generally and within the transfer engineering population. This finding is also congruent with national research showing that the under-representation of women in engineering is a function of recruitment, not retention [12, 13]. Although women who do transfer to a four-

^a“Left the Institution” describes students who are no longer found in the database. Such students may have transferred to another institution (possibly continuing in engineering), dropped out, or stopped out without having returned yet.

year engineering program persist as well as their male peers, they still lag behind non-transfer women. Results show that women transfers are more likely than women non-transfers to drop out or leave the institution (a 6.9 percentage point difference). Similarly, women transfers are outperformed by women non-transfers in terms of average GPA, although the effect size is small. Women overall, however, appear to outperform their male counterparts, though the gap is small. These findings indicate that women transfers do as well as men, but not as well as women who are not transfers.

More startling are the differences in outcomes by under-represented minority status. Non-URMs “out-persist” URMs on all measures, though effect sizes are small. About 66.5 percent of URMs persist in engineering compared with 79.0 percent of their non-URM peers. URMs are less likely than non-URMs to graduate with an engineering degree in six years (a 12.0 percentage point difference). And almost one-fourth of URM engineering students leave before obtaining a degree, irrespective of transfer status—double the proportion of non-URM engineering students. We find even larger performance differences in engineering and overall GPA by URM status. URM students do not perform as well as their non-URM peers, particularly in engineering, whereas on average, non-URMs perform one-third of a letter grade above URMs based on a four-point scale (large effect size). As discussed below, these findings are primarily driven by Black students.

Although URM persistence and academic performance lag behind that of non-URMs overall, URM transfers appear to

succeed in four-year engineering programs. They are as likely, if not more likely, to persist in engineering and to graduate with a degree in engineering in six years than are URM non-transfers (a 5.4 and 6.9 percentage point significant difference, respectively, though effect sizes are negligible). URM transfers also perform as well as non-transfers in both engineering and overall GPA. These findings are particularly important, as they suggest that the success of URM students in engineering programs is not dependent on direct entry into a four-year engineering program (transfer versus enrollment straight from high school). These findings are also relevant in light of previously cited research suggesting that, once students transfer, they suffer from “transfer shock”. URM students who transfer into four-year engineering programs perform as well as their non-transfer peers on average, despite taking fewer courses that would have been likely to boost their GPA. Future research will explore whether they experience transfer shock and recover, or whether they do experience transfer shock at all.

Given the significant differences in retention and academic performance by URM status, we disaggregated the analysis by ethnicity to better understand outcomes for specific ethnic minorities. Table IV presents these results overall and by transfer status. We find that Blacks are primarily driving the difference in persistence—25.6 percent of Blacks drop out or leave the institution compared with 14.1 percent of Hispanics, whose drop-out rate trails closely behind that of their White peers and is indistinguishable from that of Asian students. Blacks also lag significantly behind their peers in academic

Note: Symbols flag Bonferroni-adjusted significant differences between transfers and non-transfers (*), between given ethnic group and White students ([^]), and between Hispanics and Blacks ([†]) at alpha = .0002. We also report (s) small, (M) medium, and (L) large effect sizes (Cohen's d and Cramer's V).

^a "Left the Institution" describes students who are no longer found in the database. Such students may have transferred to another institution (possibly continuing in engineering), dropped out, or stopped out without having returned yet.

performance. Black students earn an overall GPA of 2.70 on average, one-quarter of a letter grade behind Hispanics and one-third of a letter grade behind Whites based on a four-point scale. The gap widens considerably if we focus only on engineering GPA (and it results in large effect sizes). It therefore appears that Blacks are driving the gap between URM and non-URM students in both persistence and academic performance.

While the persistence and academic performance of Black students is of great concern, outcomes for Black transfers suggest that their success in engineering programs is not dependent on direct entry into a four-year engineering program. In fact, Black transfer students are more likely to persist in engineering than are Black non-transfers (a 7.9 percentage point difference). And 65.1 percent of Black transfers graduate with a degree in engineering in six years compared with only 56.2 percent of Black non-transfers. Last, there are no significant differences in academic performance between Black transfers and non-transfers. These findings suggest that the transfer pathway may be an effective mechanism for fostering the completion of college degrees in engineering among Black students.

VI. CONCLUSION

This analysis provides valuable information for policymakers, educators, and professionals seeking to expand the pool of highly trained engineers to meet the needs of the modern workforce. Although one of the functions of community and other two-year colleges is to act as a stepping stone to a four-year degree, the transfer mechanism appears to be more effective in facilitating access to and completion of

four-year engineering programs for under-represented minorities than for women even though both groups are over-represented at two-year colleges. Women transfers fail to enroll in and complete engineering programs at the same rate as those who enroll in college directly out of high school. Therefore, the transfer pathway does not appear to increase the supply of female engineers as much as it could.

Yet the transfer pathway does seem to be an effective means to an engineering degree for under-represented minorities. Not only are URMs well represented among transfer students, but URM transfers are more likely than non-transfer URMs to graduate in engineering in six years and perform as well in the same courses. These results suggest that, for under-represented minorities, success in engineering programs is not dependent on direct entry into a four-year engineering program. Still, despite the success of URM transfers, the broader problem of low academic performance and persistence among Black students merits further study to both uncover its causes and devise solutions [15].

Moving forward, we intend to develop models to test the effectiveness, efficiency, quality, and equity of the transfer pathway to a baccalaureate engineering degree, taking into account the factors and relationships revealed in this paper. Understanding the outcomes associated with the transfer population, both overall and for under-represented groups, is an essential first step towards understanding a population that holds promise with respect to augmenting and diversifying the engineering workforce.

Abstract—Our paper presents preliminary results of interviews of 28 transfer students in engineering at two institutions and is part of a larger mixed-methods study on engineering transfer students. The two institutions differ on a key dimension: one has many formal articulation agreements and the other does not. We discuss the reasons students begin their studies at the sending institution and describe their experiences with the applications and admissions process at the receiving institution. We describe the “culture shock” students experience when adjusting to the academic requirements and social culture of the new institution; we also highlight the transfer student capital and strategies students use to adjust to the receiving institution.

Keywords—transfer student; articulation agreement; transfer shock; persistence; STEM

I. INTRODUCTION

Transfer students comprise a significant share of engineering graduates, yet the context of the transfer process and motivations for transferring are rarely studied. Research indicates that both institutional- and individual-level factors should be considered when investigating how to improve transfer student retention and completion [1, 2].

We present initial findings from the qualitative portion of a mixed-method study of the pathways, persistence and outcomes of transfer students in engineering using the Multiple Institution Database for Investigating Engineering Longitudinal Development (MIDFIELD). The quantitative portion of our study uses the MIDFIELD database, which includes records for 174,075 undergraduate students who matriculated into engineering, 35,152 of whom were transfers, at eleven public institutions between 1988 and 2008. The qualitative portion will ultimately comprise 80-100 interviews of engineering transfer students. Unlike prior work that focuses mainly on students who begin their studies at four-year colleges, this project extends MIDFIELD analyses in a new direction by examining the experiences of transfer students in engineering.

II. RESEARCH QUESTIONS

To more fully understand the experiences and motivations of transfer students in engineering, our analysis explores the following questions: (1) When and why do students choose to transfer? Why do they choose engineering?; (2) How do students describe the climate for transfer students at the receiving institutions? What challenges do they face?; (3) Do transfer students participate in special transfer programs?; Do

such programs help with the acculturation process?; and (4) What processes and structures help or hinder the transfer process? In this paper, we report the results of our interviews at two of the eleven MIDFIELD institutions.

III. RESEARCH METHODS

Campus representatives at two MIDFIELD institutions sent an invitation to all engineering students who had transferred into the institution in the two semesters preceding the semester of the interview. Interested students completed a survey to provide demographic and scheduling information. Participants were chosen from six engineering majors - civil, chemical, computer, electrical, industrial, and mechanical - and were diverse with respect to gender and ethnicity. Selected students were interviewed in Fall 2011 and in Spring 2012. We used a semi-structured interview protocol to learn more about student experiences with the transfer process. Interviews ranged from 19 to 65 minutes in length; the average interview lasted approximately 37 minutes. Participants were paid \$20 upon completion of the interview. Interviews were audio-taped and then transcribed verbatim and verified. We used a constant comparative coding method, whereby emerging concepts were constantly compared to data that had already been coded [3].

IV. INITIAL FINDINGS

A. Reasons Students Initiated Studies at Sending Institution

Students reported a variety of reasons for initiating their studies at another institution, including: (1) participation in a dual-degree program with the MIDFIELD institution; (2) scholarship restrictions leading to selection of the first institution (e.g., sports scholarship); (3) saving money; and (4) as a “backdoor” route to the MIDFIELD institution for students who were initially denied admission.

B. Assistance Provided by the Sending Institution

One institution has formal transfer agreements, such as 2+2 and 3+2 programs, with a large number of schools. Several students, particularly those enrolled in such programs, reported that staff, advisors, and professors at the sending institution were helpful with the transfer process. Many students who initially enrolled in a school without a formal transfer arrangement with either institution received little help with the process from the sending institution. Several students reported feeling pressured by the sending institution’s staff to remain at the school, rather than transfer.

The authors gratefully acknowledge the support of a NSF STEP Type 2 Research Grant (0969474).

C. Experiences with the Transfer Process

Nearly all respondents described the application and admissions processes as smooth. This was especially true for students in formal transfer programs or those who had been accepted to the MIDFIELD institution as first year students, but opted to begin at another institution. Many benefitted from information posted on the university website, such as course descriptions and curriculum maps; several students relied solely on this information to ensure they met the transfer requirements. However, many said the credit evaluation and course selection processes were difficult to navigate. Those who visited the campus and talked to someone reported more positive experiences with the transfer process.

Students expressed mixed opinions about formal transfer orientation activities. Although the majority of students found the information about the basics to be useful (e.g., location of buildings, parking rules, etc.), many reported they could have benefitted from more information about their major and an opportunity to meet faculty and students from their department.

D. Culture Shock: The Academic Transition

Nearly all students, especially those further along in their coursework at the time of transfer, reported experiencing an “academic culture shock.” Students felt ill-prepared for the difficult courses and overwhelmed by professors’ expectations at the new institution. Some students were very pleased with the higher-order learning at the receiving institution. They were able to become involved in real-world problem solving that enabled them to extend their learning beyond the rote memorization emphasized at their sending institutions.

Several felt that native students at the destination institution had a “GPA advantage” over transfer students because their grades in general education courses boosted their overall GPA, whereas transfer students arrive with no GPA and must begin taking difficult courses right away. Thus, they do not benefit from the GPA “buffer” offered by what they perceived to be easier courses than those offered in engineering.

E. Adjusting to the New Institution

Several students reported feeling like they did not fit into the “student culture” in which the native students had been participating since their freshman year. Few students said they participated in programs designed specifically for transfer students, other than the regular orientation. For example, one student participated in a general minority transfer student program; another minority student participated in a transfer program in his major. Students used several strategies to acclimate to the new institution, including joining social organizations (such as fraternities), finding paid employment (both on-campus and off-campus), living on campus, and interacting with friends from high school or the sending institution. These strategies reinforce themes from Tinto’s research on the importance of social and academic integration for student retention [4]. Others expressed feeling isolated upon their arrival, especially those who did not have time to join social groups or to find employment. Many respondents joined professional engineering groups. Some said they joined mainly

for “resume building” while others gained more concrete benefits from joining the professional groups.

F. Strategies for Succeeding at the MIDFIELD Institution

Nearly all students reported forming study groups, either informally through friendship networks, or formally through engineering classes. One student said she didn’t know such groups were a part of the “engineering culture” at her institution. Thus, she floundered on her own during the first semester. Students who were involved with an independent study or research project with a professor reported smoother transitions as did students who found employment on campus.

G. Suggestions for Improving the Transfer Process

The interviews suggest that transfer students have unique experiences and needs that personnel who assist students during the transition process often do not consider. Students would benefit from opportunities to network with other students who have been through the transfer process. For example, a formal transfer mentoring program and a “transfer panel” of students could be useful. Students described the need for a more extensive orientation session. Students should be allowed to contact departmental advisors earlier in the transfer process, prior to transferring. And, the receiving institution could provide more information to transfer students prior to their arrival, much like the university does for native students.

V. FUTURE RESEARCH

Our study aims to understand the retention and success of engineering transfer students who comprise a significant share of engineering majors. While the study results reported here support the existence of “culture shock” among some students, the findings also highlight how students accumulate transfer student capital (TSC) to ensure successful transitions [5]. TSC is evidenced in students’ ability to access knowledge required to negotiate the transfer process, such as information about course prerequisites and about transfer agreements. In 2012-13, we will interview students at three additional MIDFIELD institutions, including those with strong and weak transfer agreements, and relatively high percentages (>25%) of transfers into their engineering programs. These data will allow us to compare across institutions, based on a number of factors, including major, presence of transfer agreements, participation in research or study groups and in programs for transfer students.

Work in Progress: Development of a Metacognition Scaffold in STEM / P-6 Engineering Context: MCinEDP

Ronald L. Carr & Johannes Strobel
Institute for P-12 Engineering Research and Learning
Purdue University
West Lafayette, Indiana, USA

Abstract— A new model of metacognition scaffolding, *Metacognition in the Engineering Design Process (MCinEDP)*, which parallels instruction in engineering design processes (EDP), has been designed for use in pre-college, particularly 2-6, engineering classrooms. MCinEDP utilizes engineering as the context for implementation of metacognitive activities that are designed to aid students in building mastery of metacognition and to improve specific abilities in engineering design. This paper outlines the design process in order to reveal the intersection of instructional design theory, instructional design models, cognitive theory and learning theory that supported this project.

Keywords—metacognition, engineering design, K-6, scaffolding

I. INTRODUCTION

Schoenfeld (1992) wrote, “problem solving and metacognition ... are perhaps the two most overworked -- and least understood -- buzz words of the 1980's,” because, as he further noted, the definitions of metacognition were varied and disjointed to the point that the concept was difficult to use. Since that time, many models of metacognition have been devised and the construct has been studied in various subjects. While definitions varied, metacognition as monitor and regulator of cognitive processes has been a central theme [2] through most. The model of this paper, *Metacognition in the Engineering Design Process (MCinEDP)*, borrowed from that notion and teaches children a simpler version, stating that metacognition is “thinking about thinking.”

MCinEDP utilizes engineering design as the context for implementing activities designed to aid students in building mastery of metacognition. Students learn that metacognition is knowledge of one's own cognitive processes, strategies, implementation and regulation. Specific questioning and instruction in cognitive strategies is scaffold in MCinEDP. Metacognition instruction, teacher questions, student metacognition sheets and social interactions are outlined in the Teacher Guide that serves as an implementation resource.

Not only are we interested to find if the model is effective, we also want to learn more about metacognition in elementary design contexts. This study starts at the beginning design stages and has progressed through field testing and revisions. Further research will investigate metacognition in elementary students in general, using a comparison group while evaluating the model with a treatment group in a pilot study

that will determine effectiveness and further opportunities for improvement.

II. BACKGROUND

A. Instructional Design

The design process used for MCinEDP is based on the ADDIE model (Analysis, Design, Development, Implementation and Evaluation), an iterative and cyclical process of ID that is common in the instructional design (ID) field today [3]. Experience teaching elementary school students in design processes and attempts at implementing metacognition instruction informed the analysis stage of development. Further, literature review extended into the design stage. The development and implementation stages have included formative evaluation that included field testing in grades 3-5 engineering classrooms with an expert K-6 engineering teacher.

B. Metacognition

John Flavell is cited in most metacognition literature and, despite the many studies that have come since, his work in the 1970's still influences many, including this model. He wrote that cognitive monitoring and regulation are areas that children are limited in but can be taught through metacognition experiences focused on person, task and strategy [4].

Model development evolved through consideration of many existing models of metacognition, including Flavell's, from which all were based on regulated learning, strategic questioning, critical thinking, reflective judgment, iterative learning, purposeful strategy selection, and social metacognition. The MCinEDP model intersects with scaffolding of self-regulated learning, the LEGACY learning cycle of adaptive instruction [5] and EDP instruction utilizing ill-structured design problems [6]. This scaffolding intends to facilitate metacognition without overtaxing cognitive load [7].

III. MCINEDP

A. Contribution

While a considerable amount of literature and research investigates the use of metacognition skills in reading and mathematics [7-8], science and engineering are largely ignored by the conversation. Situating the scaffold in an engineering context builds on the National Research Council's

guiding principles for engineering education by promoting engineering “habits of mind” in reflective, technology design applications [9].

There are a few research studies involving the use of metacognition and measurement of cognition with college level engineering students [9-11], yet thus far, none specifically deals with elementary level engineering. Improving metacognition in other domains has been found to improve learning abilities [4, 7-8]. The importance for scaffolding of metacognitive skills increases even more in the advancement of online and self-regulated learning, and domain-specific instruction supports metacognitive skills that are generalizable to other content areas [12]. MCinEDP differs from other models and studies of the target age group, in that scaffolding and in-time prompts are present throughout. Contrarily, another study uses software for design logs which are later used for post hoc reflection [13].

B. Model

MCinEDP involves student reflections at three stages of the five-stage EDP [14]. These Steps are labeled Plan, Monitor, and Evaluate (Figure 1). The students are instructed to consider the Aspects of Person, Task or Strategy in terms of thinking and not physical actions, or the next step of the EDP.

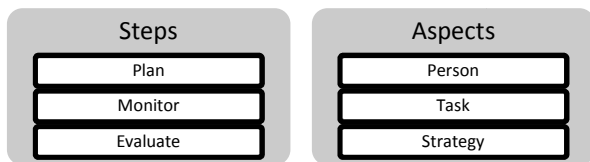

Figure 1 Students examine the three aspects of their progress throughout all three steps of the MCinEDP, individually, by responding to written prompts.

The prompts for metacognition are also influenced by Jonassen’s seven steps of solving an ill-structured problem based on framing a problem, monitoring strategies and adapting the solution [15], or in this case, adapting the metacognitive knowledge. In planning (Figure 2), students reflect on prior knowledge (person), goals, framing the problem (task) and what they need to do or learn to solve the

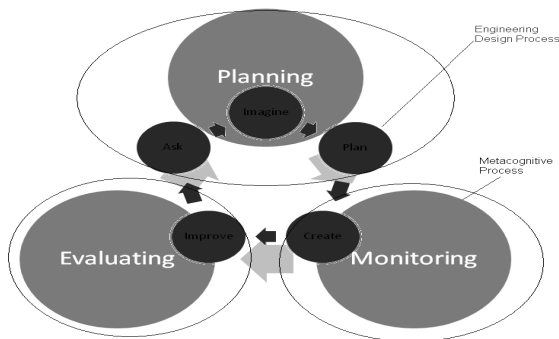

Figure 2 The three phases of MCinEDP align with the five stage engineering design process[16] (Ask, Imagine, Plan, Create, Improve), as well as others, that are used in elementary schools.

problem (strategy). Monitoring occurs when building a testable model in the EDP, and students evaluate their planning before modifying strategies or reframing the

problem. During evaluation, students reflect on their thinking and metacognition throughout the project and identify opportunities for improvement. At each stage, and particularly in evaluation, the students discuss their metacognition responses such as strategies, goals, and prior knowledge. In addition to the socially constructed metacognition in each project, the classroom will occasionally write and improve a letter to future classes to teach them about their metacognition experiences.

IV. CONCLUSION AND NEXT STEPS

The implementation and evaluation phases of the project will include mixed methods to determine the effectiveness of the model. Pre and post student reports, observations, teacher and student interviews, and in-depth content analysis of student products will be used for the evaluation that will also be used for further refinement of materials prior to an additional round of evaluation.

Animated Engineering Tutors: Middle School Students' Preferences and Rationales on Multiple Dimensions

Gamze Ozogul, Amy Johnson, and Martin Reisslein
School of Electrical, Computer and Energy Engineering
Arizona State University
Tempe, USA

Gamze.Ozogul@asu.edu, amjohn43@asu.edu, reisslein@asu.edu

Abstract— The goal of the study was to explore middle school students' preferences for an animated engineering tutor, and investigate their rationales for their choices. 77 middle school students participated in the study, and provided their preferences and rationales on various dimensions of an animated engineering tutor such as gender, age, personality, and clothing. Results showed that for teaching engineering in a computer-based instructional module, students preferred an animated engineering tutor that was similar to their age, matching their own gender, with a fun personality, and that speaks slowly.

Keywords: *animated pedagogical agents; engineering education; preferences; engineering tutor*

I. INTRODUCTION

How can we help middle school students learn about engineering, focus their attention on relevant parts of a computer-based engineering instructional module, and keep them motivated to learn throughout the program? One technique used in multimedia research that could be applied to engineering education is to use visual presence of animated pedagogical tutors within the instructional module to facilitate students' engineering learning and influence perceptions of the learning experience.

An animated pedagogical agent (APA) is a human-like or otherwise animated on-screen character appearing in a computer-based instructional module [1][2][3]. Common objectives of pedagogical assistance provided by an APA are to keep students focused on important elements of the learning material, to keep them motivated, and to provide context-specific learning strategies [4]. By establishing a social interaction between learner and agent, APAs may maintain learners' engagement in a learning task, ultimately fostering student learning [5][6][7][8]. According to the persona hypothesis, the visual presence of an APA in computer-based learning environments can increase learning outcomes and positively affect learners' perceptions of the learning experience [9][10].

While designing an engineering instructional module for middle-school students, the animated engineering tutor that is present in the module may be a role model for students. Students perform in a certain way because either their behaviors are prompted, modeled, or valued by significant others to whom they feel or want to feel attached or similar [11]. In science and engineering this may suggest that relatedness, the need to feel belongingness, similarity, and connectedness with others, is centrally important for internalization, and improving learning. Sorge, Newsom, and Hegarty [12] examined the attitudes of Hispanic middle school students towards science and scientists, concluding that most of the middle school students in the study had difficulties perceiving themselves as scientists mainly due to a lack of exposure to role models and negative media stereotypes. Students develop a stereotypical image of a scientist as they get older and scientists drawn are predominantly male [13]. In order to increase minority involvement in science, students need early exposure to role models and after-school programs [14].

A. Agent Similarity Hypothesis

APAs have both internal and external properties which influence student learning [15]. The internal properties of APAs are related to the instructional methods used by the agent in facilitating learning. Instructional methods applied through APAs may include directing learner attention through gestures [16][17], visual signaling, coaching, delivering feedback messages, verbal guidance, and modeling [18][19][6]. External properties of APAs relate to the image and voice of the agent, and include agent characteristics, such as gender, age, ethnicity, clothing, appearance and tone of voice.

According to the similarity attraction hypothesis, humans are more attracted to others who appear and behave similarly to themselves [20]. The similarity attraction hypothesis in the

context of learning with animated pedagogical agents would predict increased learning and more positive perceptions the greater the similarity between the learner and the agent.

Previous research has explored various agent similarity effects. Kim and Wei [21] conducted a research study with high-school students to examine learners attributes (gender and ethnicity) and their preferences for a pedagogical agent. The results indicated, first, that students preferentially chose a same-gender agent, and Caucasian students chose a Caucasian agent and Hispanic students chose a Hispanic agent significantly more frequently than a different-ethnicity agent. In studies [22][23] it was found that animated agents who match the observer in race and gender can have greater impact on women in increasing their interest in and reducing their stereotypes about gender in engineering fields.

Capobianco, Diefes-Dux, Mena and Weller [24] found in draw-an-engineer tests that 58 % of elementary school students drew the engineer as a male, whereas 18 % drew a female, and 24 % drew a group or a person without discernible gender. A study conducted with college students [25] stated that a majority of students reported a preference for agents that were similar to them, at least in terms of gender, a majority reported a preference for avatars that were “like” them, suggesting that students may also want to match other characteristics, such as hair color and race, perhaps sexual orientation, or even hobbies. As humans often treat computers as social entities, social accounts of interaction such as the similarity attraction hypothesis may be relevant to computer-based instructional environments. How people perceive agents may influence both the self-perception and perception of others using a particular agent as well as message perception and retention [25].

A study conducted by Moreno and Flowerday [26] randomly assigned learners to a choice condition, in which learners selected an agent from 10 options, differing in gender and ethnicity, or a non-choice condition, in which learners were assigned to an agent. Results first indicated that overall learners did not more often select an agent that matched their gender or ethnicity, but students of color were more likely to select an agent with the same ethnicity than their Caucasian counterparts. Next, the results did not indicate positive effects of gender similarity or ethnicity similarity on retention, or transfer learning measures, nor on program ratings. Furthermore, the students who were able to choose had lower scores, lower transfer scores, and lower program ratings when the agent matched their ethnicity.

Behrend and Thompson [27] did not find positive effects of gender similarity and surprisingly found a negative effect of ethnicity similarity on utility ratings of the agent. However, these two effects were shown to be additive for engagement of students; the highest engagement ratings were obtained in the group where both gender and ethnicity was matched to the

learners gender and ethnicity. But, the learning outcomes were not significantly influenced by gender or ethnicity similarity. Kim and Baylor [6] found that Caucasian students rated Caucasian agents as more engaging and affable, whereas African American students rated these characteristics higher for African American agents. Kim and Baylor did not find better learning, self-reported self-regulation or self-reported satisfaction for agents who matched the learners in gender or ethnicity.

Rosenberg-Kima, Baylor, Plant and Doerr [22] in experiment 2 explored participant perceptions of engineering (self-efficacy, interest, stereotypes, and utility) after learning with one of eight agents differing on three factors (age, gender, and ‘coolness’). Rosenberg-Kima, Baylor, Plant and Doerr [22] expected that participant perceptions would be most impacted after viewing an agent they considered that was similar or aspired to (i.e., young and ‘cool’). Results supported this hypothesis; the two conditions (male and female) with young and ‘cool’ agents led to higher self-efficacy and interest ratings than the remaining six conditions. Lee, Liao, and Ryu [28] explored gender similarity by using computerized voice only. The authors showed that male participants rated a male agent’s voice more likeable than a female agent, whereas no difference in voice likeability was found for female participants. A similar pattern was found in participants’ ratings of voice credibility, content quality, and self-confidence in the topic discussed (e.g., skin care and makeup or dinosaurs). In these studies, learning outcomes were not measured [22] or [28].

Our current study examines middle school students’ preferences for an engineering animated tutor on multiple dimensions and their rationale for attractions to those dimensions for an engineering tutor. If we were to teach middle school students about engineering, who would they be more motivated to learn engineering with and why? Stereotypes and preconceived notions may be crucial to interpreting a character’s purpose in a computer-based learning module. Engineering is mainly viewed as a male-dominated field. So what would be the middle school students’ choice for animated engineering tutors? Who would they feel more comfortable with, and be more eager to learn from? Who would capture and keep their attention? This current study focuses on furthering the research by targeting middle-school students’ preferences for an engineering tutor, and contributing to the body of research not only by investigating gender and gender match-no match preferences, but also by investigating further characteristics of an animated engineering agent, such as teaching style, age, outfit, talking style, and preferences for a cartoon or a realistic looks, as well as the rationale that leads to these preferences.

B. Research Questions

1. What are students’ preferences for an animated engineering tutor?

2. What are the rationales for students' choices for specific tutors?
3. What are the preferred attributes of an animated engineering tutor for middle school students?
4. What are the rationales for the preferences for specific attributes of an animated engineering tutor?

II. METHOD

A. Participants

The participants were a total of 77 middle-school students at a public school in the Southwestern U.S with the mean age of 12.83 years ($SD = 0.84$). There were 35 (45.5%) males, and 42 (54.5%) females.

B. Materials and Procedure

Each student was provided with a survey form that included pictures for three agents that were of various age and gender. Students were asked who they would prefer to learn about engineering from (Which of the below would you want to teach you about electric circuits in the computer?) and asked to list three reasons for their choice. The survey had an image of old male agent, a young female agent, and a young male agent displayed side-by-side (see Fig. 1). Additionally, the survey form had six forced-choice items and each of these items had an open-ended portion for students to explain their choices in detail. These six survey items asked students their preferences for an animated engineering tutor on various dimensions, (e.g., I learn better from my engineer teacher if s/he is girl/boy, young/old, dresses serious/dresses cool, talks fast/talks slow, fun/serious, cartoon human/real human). Also, students' own gender and their choices for the agent gender were captured to conduct further statistical analysis.

Figure 1. Agent choices in the survey

C. Data Coding

Quantitative and qualitative data analysis techniques were used to analyze the collected data. Frequencies were obtained from student choices for each agent and analyzed quantitatively for significant differences between choices. Qualitative data that were obtained from the students open ended-responses analyzed by two researchers. During the analysis, researchers identified characteristics of the agents noted by the students. Any characteristic that was noted only once and did not fit into any already existing category was collected in the "other" category. As soon as a particular characteristic was noted twice or more frequently, a category was established. From the initial investigation seven superordinate and 30 subordinate categories emerged, and the data were coded into the seven superordinate categories that are displayed in Table 1.

Under each of these superordinate categories listed in the Table I, each superordinate category included various numbers of subordinate categories. For example under the "personality" superordinate category; personality_cool, personality_comfortable, personality_fun, personality_interesting, personality_nice, personality_interested, personality_relatable, personality_smart, personality_trustworthy, personality_good subordinate categories emerged.

TABLE I. AGENT PREFERENCE SUPERORDINATE CATEGORIES

| Superordinate Categories | Subordinate Categories | Example Statements |
|--------------------------|--|--|
| Age | Young Old | He looks younger He is older he may know more She seems more of my age |
| Appearance | Dress Pretty Professional Real | She has cool shoes He dresses like us He knows how to dress |
| Personality | Comfortable Cool Fun Good Interesting Interested Nice Relatable Smart Trustworthy | He looks like someone to trust She looks like she is interested Because he looks like someone I would get along |
| Gender | Male Female Opposite | She is a girl He is the opposite sex Women know a lot of thing |
| Speech | Boring Clear Slow | It looks he doesn't talk fast She talks at the right speed Talk clear |
| Teaching | Comprehensive Effective Examples Friend Gesturing Patient Understands | He is smarter as a teacher He looks like a person who explains things to you He might teach me a lot |
| Other | All other characteristics | Feels more better Because I don't know her, and I would like to know what she likes The others do not influence me |

III. RESULTS

A. Preferences for a Specific Agent:

Twenty-eight (36%) of the students chose a young male agent to be their engineering tutor. Thirty-six (47%) of the students preferred a young-female agent. Thirteen (17%) of the students preferred an old-male agent as tutor.

B. Rationales for Preferences for Each Agent

Young-male agent: When the open ended responses were analyzed the following categories were frequently cited for students' rationales for choosing the young-male agent (each student was able to list three categories); "teaching_effective" (13 students), "personality_cool" (11), age_young (9), "appearance_dress" (9), "personality_smart" (7), "appearance_real" (6), "personality_nice" (4), personality_relatable (3), "personality_fun" (3), "gender_male" (3), "personality_trustworthy" (2), "personality_interesting" (2), "teaching_comprehensive" (2). There were students who noted less frequent traits for young-male agent choice, such as having "personality_good" (1), "gender_opposite" (1).

Young-female agent: When students' responses to open-ended questions were analyzed, the following categories emerged as most frequently cited for preferring the young-female agent; "gender_female" (16 students), "teaching_effective" (14), "appearance_real" (13), "personality_smart" (11), "appearance_dress" (5), "speech_clear" (5), "age_young" (4), "personality_cool" (3), "appearance_pretty" (2), "personality_nice" (2), "teaching_friend" (2), "personality_trustworthy" (2), "personality_interested" (2). There were students who noted less frequent traits for young-female agent choice such as; "personality_comfortable", "teaching_patient" (1), "personality_fun" (1).

Old-male agent: When students' responses to open-ended questions were analyzed, the following categories emerged as most frequently indicated as a reason for their choice for the old-male agent; "teaching_effective" (13 students), "personality_smart" (8), "appearance_professional" (4), "teaching_examples" (3), "age_old" (2), "personality_cool" (2), "personality_fun" (2). Some students who indicated less frequent traits for old-male agent choice, such as "speech_clear" (1), "speech_slow" (1), "personality_good" (1) and "personality_nice" (1).

C. Overall Preferences and Comparisons

Agent gender preference: Forty participants (52%) preferred a female engineering agent, and thirty-seven participants (48%) preferred a male engineering agent. Overall, male and female students demonstrated a significant preference toward a pedagogical engineering tutor that matched their own gender, $\chi^2(1) = 21.75, p < .001$. Thirty-two of the female students (76%) chose a female agent; twenty-seven of the male students (77%) chose a male agent for their animated engineering tutor. The learners were more likely to choose either a young female or young male agent for their

learning interactions, $\chi^2(2) = 10.62, p = .005$. Thirty-six (47%) of all students reported preferring a young female agent and twenty-eight (36%) of the students reported preferring a young male agent. Example student rationales for choosing matching gender were "I am a girl too", "boys are better than girls", "they [boys] are easy to understand", "I would feel more comfortable", "I am a boy too", and "they [boys] would be cooler."

Agent age: Overall, students preferred a young agent over an old agent for their learning interactions, $\chi^2(1) = 17.78, p < .001$. Fifty-seven (74%) of all students reported preference for a young agent. Thirty-six (86%) of the females chose a young agent, whereas twenty-one (60.0%) of the male students chose a young agent. The preference for a young agent among female students was significant, $\chi^2(1) = 21.43, p < .001$, while there was no significant preference among male learners. Students had various rationales for preferring a young agent such as "[young] up to date", "I can relate to them", "they don't need to stop and think", "he understands us because he is young," "it would be like a friend teaching me," and "old people don't get my attention."

Agent personality: Overall, learners are more likely to choose an agent with a 'fun' personality, compared to a more 'serious' personality, $\chi^2(1) = 12.48, p < .001$. Seventy percent (70%) of all learners reported preference for an agent with a fun personality. Thirty-four (81%) of females preferred a 'fun' agent, whereas twenty (57%) of male students preferred a 'fun' agent. When broken down by the learner gender, the difference in number of males preferring a fun agent over a serious agent was not significant, $\chi^2(1) = 0.71, p = .40$. However, female learners did demonstrate a significant inclination toward a 'fun' pedagogical agent, $\chi^2(1) = 16.10, p < .001$. Example student rationales for choosing a fun personality agent were as follows; "serious is boring", "fun is good", "I learn more", "make you laugh", "make subject fun", "to make the learning process fun", and "it will make learning easier."

Speech pace: All learners are more likely to choose an agent with slow speech pace for their engineering domain learning interactions instead of fast speech pace, $\chi^2(1) = 31.18, p < .001$. Sixty-three (82%) of the learners reported preference for an agent with slow speech pace, and fourteen (18%) of the students reported preference for an agent with fast speech pace. Rationales for choosing a slower speech pace over a faster speech pace were as follows; "so I could understand it", "that is good that he talks slow", "slow is better", "so I can hear everything they are saying", "explains more clearly", "so he explains it step-by-step", and "it lets me memorize."

Clothing: There was a marginally significant preference, across all participants, for animated agents with dress described as 'cool', compared to agents with 'serious' dress, $\chi^2(1) = 3.75, p = .053$. Forty-seven (61%) of all learners

reported a preference for an agent with ‘cool’ wardrobe, whereas thirty (39%) of the students preferred an agent with a “serious” wardrobe. Example student quotations for reasons for choosing an agent with cool clothing instead of serious clothing were as follows; “I dress cool”, “she looks great”, “makes me want to pay attention”, “class would go easy”, “more fashion the better”, “they look pretty”, and “so you could learn fast.”

Cartoon image or real human image: Overall no significant differences were found for the choices for a cartoon or real human image. Forty-two (55%) of the students preferred a cartoonlike image for the engineering animated agent. Rationales for choosing a cartoon-like image over a real human image were as follows “cartoon humans grab my attention”, “it would be fun and educational”, “funny” and “engineer teachers look like a cartoon”, “I would focus more on the problems”, and “it’s cool and funny”. Thirty-five (45%) of the students preferred a real-humanlike image for the engineering tutor, and the rationales for choosing that were as follows; “serious”, “helps us understand more”, “so I can ask questions back at her”, “they explain better”, “to explain easier and no distraction”, “it would look better”, and “it would be more realistic.”

IV. CONCLUSION

The present study showed support for the similarity hypothesis, concluding that middle school students tend to choose animated engineering tutors that are similar to them in age and gender. Students may feel more comfortable learning a perceivable difficult topic such as engineering, from a peer like agent that is similar to them. It is clear from students’ responses to open-ended questions that they feel close to same-age and same gender agents. As engineering is perceived as a difficult topic [29][30][31], middle school students tend to choose a fun personality engineering tutor compared to a serious one, primarily to keep the topic interesting and enjoyable, as well as a slow rate of speech to help them to follow easier and understand better.

Our results indicate that for middle school students, the use of a peer-animated engineering tutor agent that is similar to the students may improve interest and students motivation for learning. More research is needed to determine the effects of cool, young, same-gender, and fun-personality animated engineering agents on actual learning outcomes for this population.

The findings of this exploratory study shed light on future instructional modules that focus on teaching pre-college students about engineering fields and the design of recruitment materials. Computer-based and print-based, engineering outreach materials should be designed in a motivational manner by including suitable animated engineering tutors to capture students’ attention and continuing motivation to learn from those agents.

V. FUTURE RESEARCH

We will build on this study to develop a computer-based preference survey to investigate students’ preferences for animated engineering tutors in more detail. The proposed computerized survey will aim to reach to a broader audience, including elementary, middle, and high school students. The categories that most frequently emerged in this study for choosing a particular agent, will be used as a base for the computerized version of the survey, while categories that occurred with low frequencies will be excluded. Specifically only one participant noted agents’ personality as being “comfortable” as a reason which will be excluded.

Based on the present study, frequently stated categories will be used to prompt student responses in the computerized survey. Specifically, after students watch an introductory module on engineering disciplines that includes the different agents, students will be asked for their preference for an animated engineering tutor. Also they will be asked what they most and least liked about the displayed agents. The following options will be given for most liked categories for the agent: smart, young/old, male/female, realistic, professional, slow speech, fast speech, helpful, cool, dress, clear voice, nice, fun, interesting, trustworthy. The following choices will be given for the least liked attributes for the displayed agent: smart, young/old, male/female, realistic, professional, slow speech, unhelpful, boring voice. An old-female animated engineering tutor will be added. Students’ preferences and opinions towards this old-female agent will be investigated.

Additional future research directions are to employ these agents in computer-based engineering instructional modules [1-3, 32] and study their effectiveness in specific pedagogical functions, such as signaling [17], prompting [33], and practice guidance [34].

Abstract— Current society is characterized by an increasing interest in the provision of high-quality Early Childhood Education and Care (ECEC) services. In this area, we developed a platform aimed to create an effortless communication channel among parents and educational professionals. Parents and educators are provided with technological tools to increase the performance of the educational process in a holistic manner by means of automatic alert mechanisms and recommendations according to personalized information within the system. The next phase in the progression of our platform has been reusing information freely available on Internet to enrich the local Knowledge Base of the platform. This paper discusses the approaches used to complement the platform initial local data with information available on different Internet sources in order to improve the performance of the developed platform services.

Keywords - Early Childhood Education and Care; Knowledge Based Systems; Linked Open Data; Semantic Enrichment

I. INTRODUCTION

Over the last years, the use of new technologies in the education field has improved the democratization and the universality of the educational environments. Even during the childhood stage, focused on Early Childhood Education and Care (ECEC), the application of software tools is causing a growing interest. In this context, we developed an ECEC platform [1][2] which allows parents and educators to collaborate and to cooperate in order to create a high quality learning environment for the child. With our solution, parents and educators have a natural communication channel and smart assistants being able to generate automatic alerts and recommendations according to child's evolution. With this purpose, the information of the system has been semantically modeled in such a way that, according to the predefined semantic rules, it is possible to apply reasoners to extract conclusions about the child's condition and current evolution.

In our platform, software assistants infer (similar to human reasoning) complex and intelligent recommendations based on the context of the child. Initially, the information treated by these assistants consists of community-generated data, i.e., data introduced by the users of the system (families, caregivers, teachers, etc.). The platform has been specially designed to early childhood schools and to parents with children enrolled in these centers. It provides services for both the care and education of the child. Among these services, we can highlight:

the blogging service, allowing centers to publish multimedia information about the daily activities; the educational resources recommender service, which allows retrieving resources tailored to the capabilities and progress of each child; and alerts and monitoring services focused on major factors in this stage, such as health and food issues.

The next step in the evolution of our platform is reusing information freely shared on Internet to enrich the Knowledge Base (hereafter KB) of the intelligent assistants. To this end, we propose the use of the available data under the precepts of the Linked Open Data Initiative (LOD) [3], which seeks to create an interconnected space of “machine-understandable” information from different sources. Using this approach, local data are complemented, increased and linked with data from different repositories and contexts. This enrichment can improve the performance of the developed services and get new features and functionality not previously envisaged.

Since currently the LOD network does not yet have many data nodes (it is in its early stages), we have also considered the possibility of extracting relevant information from different traditional web portals on the Internet.

This paper presents the strategies used to enrich the local data managed by our ICT platform smart services through the use of data available in external sources. Particularly, the paper focuses on the enhancing of the following services: a) educational resources recommender, b) nutritional monitoring service and c) health monitoring service. Previously, section 2 discusses the LOD network as a global knowledge base and briefly describes its previous uses for the enrichment of semantic data, and section 3 briefly describes the key issues of the original ECEC platform. Sections 4 and 5 describe how the platform was enhanced and the steps taken to enrich our data with the various external sources and the effects of the achieved enrichment. Finally, Section 6 outlines the main conclusions of this work.

II. LINKED OPEN DATA AS AN ENRICHMENT RESOURCE

The World Wide Web is a universe of information that, since its inception, has been specifically designed to be friendly and readable for a human being but, in consequence, it is illogical and meaningless for a software agent, which makes it difficult to automate the processing of web pages. In order to solve this problem, Tim Berners Lee has initiated and

promoted a social movement oriented to the global freely-available publishing data on the Web in a standard and machine-processable format. This initiative is known as Linked Open Data (LOD) and seeks to turn the Web into a vast interconnected information space, known as the Web of Data. The chosen publication format is based on the RDF metamodel, which allows to represent statements in the form of triples (subject, relation, object). The LOD initiative is constantly growing. In September 2011, it had 295 nodes linked together and more than 31 billion of RDF triples [4]. Among these nodes we can distinguish two types: area specific nodes, focused on a specific topic (such as music, books, health, statistics, etc.) and multidisciplinary repositories, whose most outstanding element is the DBpedia [5], a pivotal centralizing node that maintains information extracted from Wikipedia.

In this ocean of inter-connected information, an intelligent application (or Knowledge-Based System) has at its disposal a huge supporting KB, which can be interpreted and used in the most convenient way for providing rich and accurate user services. These applications are known as Linked Data applications. A simple example of these is the DBpedia Mobile [6], an agent for mobile devices that provides the user with a map of his position including information, extracted from the DBpedia node, on nearby locations. Moreover, there are applications that combine and supplement their own semantic data establishing connections with web-based open data. This is known as “enrichment”. In this area there are several successful projects among which we mention two. The first one, promoted by the BBC, it is aimed to create a website about music, BBC Music [7], which includes ad-hoc generated data enriched with information of albums, discographies, biographies of singers, etc., from LOD nodes as DBpedia, Music Brainz [8] or Echo Nest [9]. The other notable example is the Linked Movie DataBase semantic repository [10], specialized on the cinematographic area, in which adding a new record (film, actor, director, etc.) it is automatically generated a link to an equivalent record, one that refers to the same object, in other LOD repositories such as DBpedia.

Currently, in the field of education (especially in higher education), there are many semantic tools that try to personalize and customize in an intelligent way each course based on the user profile. These are the applications known as Semantic Web-based Educational Systems (SWBES) [11]. The use of semantic technologies in this field to create, query and manipulate knowledge in a standardized way helps to reach the goal of enhancing and improving the student's educational experience. Under this approach we can find projects such as MAPLE (Mobile, Adaptive & Personalized Learning Experiences) [12], that allows to customize the learning environment by local exposure of information following the precepts of the Linked Data initiative. Also noteworthy is the development of new Intelligent Tutoring Systems (ITS) based on semantic technologies. These ITS individually infer what (and/or how) resources must be presented to the user. This is the case of projects such as [13].

It must be noted that this kind of educational platforms base their operation just on the information generated by their user's communities. Thus, the automatic use of information from

external sources such as Linked Data nodes is a very novel approach. However, as above mentioned, its application allows to have global, detailed and virtually unlimited information which can be used to enhance and improve processes and outcomes. For this reason, in this paper we describe the process used to enrich the educational platform, which we have previously created for the field of early childhood education, with data from different sources, particularly from Linked Data nodes.

III. THE ORIGINAL PLATFORM

The provision of a holistic platform oriented towards the childhood education and care has led us to generate a natural way of communication linking the families and the educators. By means of the tools provided by the platform, they can collaborate and cooperate to improve the quality of the attention and the education received by the children. The key supporting feature of our platform is the capacity to generate results (alerts, recommendations, observations, etc.) in an automatic manner.

To achieve this goal, it was developed a semantic model to express all the relevant pieces of information in the system, i. e., the KB. To complete this task, several modules were developed using the support of OWL. This RDF-based language guarantees the syntactic interoperability and enables the use of certain searching mechanism such as SPARQL to conduct systematic searches. Also, it was developed a set of semantic rules that make possible for inference engines, such as Pellet, Jess, or RacerPro, to extract complex conclusions about the evolution of the children (e.g., alerts about inappropriate menus for celiac child and suggestion about an alternative dish) according to the information stored in the KB.

In order to facilitate and boost the use of the platform a multichannel web-based interface specially designed for “connected TV” (through Wii or GoogleTv) and for mobile devices (smartphones and tablets) was developed. For that purpose, the platform is composed of two logic layers: the business logic layer (BLL) and the presentation layer. In the BLL, a number of services are installed to support further services offered by the platform. Each application processes the relevant information for its purposes by means of inference engines and a Linked Data explorer. The latter recovers information from the KB using SPARQL queries. In the presentation layer, the information is adapted to an output data flow tailored for the specific target device in use.

IV. ENHANCING THE PLATFORM

The initial platform included a closed KB composed by the data provided by the system users. The primary task of this contribution is oriented to complement this initial set of knowledge with the freely available information on the Web. Therefore, the authors developed a module for the enhancement and enrichment of the original system capable of discovering, and processing knowledge from the Internet and adding it to the KB under the form of RDF sentences. These features are implemented by means of three agents that tackle information from different sources.

The main mechanism to enrich the platform is the use of Linked Open Data repositories. The applied philosophy is based on searching and linking records related to the same concept from different repositories, including ours. This is also known as Record Linkage [14]. To carry out this task, it was developed an agent, called LOD Enrichment Agent, in charge for gathering new knowledge by means of launching periodically a semi-automatic tool based on SILK [15]. Using SILK, this agent creates new links among records using the relation `owl:sameAs` according to the level of similarity of the checked properties. This is achieved with a proper definition of concepts and properties to be compared using a specific declarative language (LSL) inherent to the frame of SILK. This configuration must be conducted by an expert in the domain well aware of the needs of the system and the involved repositories. As a result of the use of this tool properly configured, new RDF triples are created and inserted into the KB resulting in a better base for inference processes.

Another mechanism to enrich the information within the system is based on processing information from APIs of pre-selected web platforms. The information recovered from a query to a specific API is compliant with the ad-hoc provider model. Therefore, for each one is required to make a custom parsing of the response to get the requested information. To server as a proof of concept, it was developed the software to make use of a particular API, the Smart Indexer. This agent performs requests using a HTTP channel and processes the response from the server to get the new knowledge.

Finally, it was developed a Web Parser. This agent behaves as a crawler that explores a set of pre-configured pages expressed in HTML. Upon its examination, it is created the appropriate set of new RDF triples with the new knowledge to be added on the KB. This process, usually referred to as Web Scrapping [16], is based on a pre-configuration of the HTML entities with the relevant information for the custom purposes.

As shown on the Fig. 1, the presented architecture enables the provision of a set of complex and add-value services in a seamlessly manner to the rest of the modules as the only impact is on the KB that is eventually enriched.

V. ENRICHING THE KNOWLEDGE BASE OF AN EARLY CHILDHOOD EDUCATION PLATFORM

In this section we will focus on describing as we have enriched the local data, especially with information from the Linked Data network, and what improvements this means for our platform services. Particularly, we will focus on three basic user applications offered by the platform: the resources educational recommender, the monitoring food service and the monitoring health service. These three applications manage key factors in the education of children and the effects of enrichment have been a marked improvement on their performance and functionality.

A. Educational resources recommender

This application seeks to get, from the large collection of educational resources of the platform, a list of individual recommendations based on the child's evolution. To do that, the application is based on the child's profile to select the resources to work with, in order to achieve new competences. In the short time, from the history of already fulfilled activities, a specific smart agent selects those resources allowing a thematic continuation, thus favouring the consolidation of concepts (e.g. if the child has made a farm animal activity, the following recommended resource could be focused on wild animals, but always tailored to his educational needs). This ensures that the chosen activity gives the child the essentials and the concepts needed in his current state of development.

Initially, for each educational resource, it is stored a group of basic data (name, description, type, etc.) and a set of tags to identify them (source tags). These tags can be introduced by any platform user. This is known as social indexing or collaborative folksonomy [17]. To enrich this initial data, we have followed three different approaches:

- In order to complement the collaborative folksonomy tags, we made use of the well-known WordNet lexical database [18]. This database provides an API to query those terms (synonyms, hypernyms and hyponyms) related to a particular concept. On this basis, the system periodically runs an automated process to get

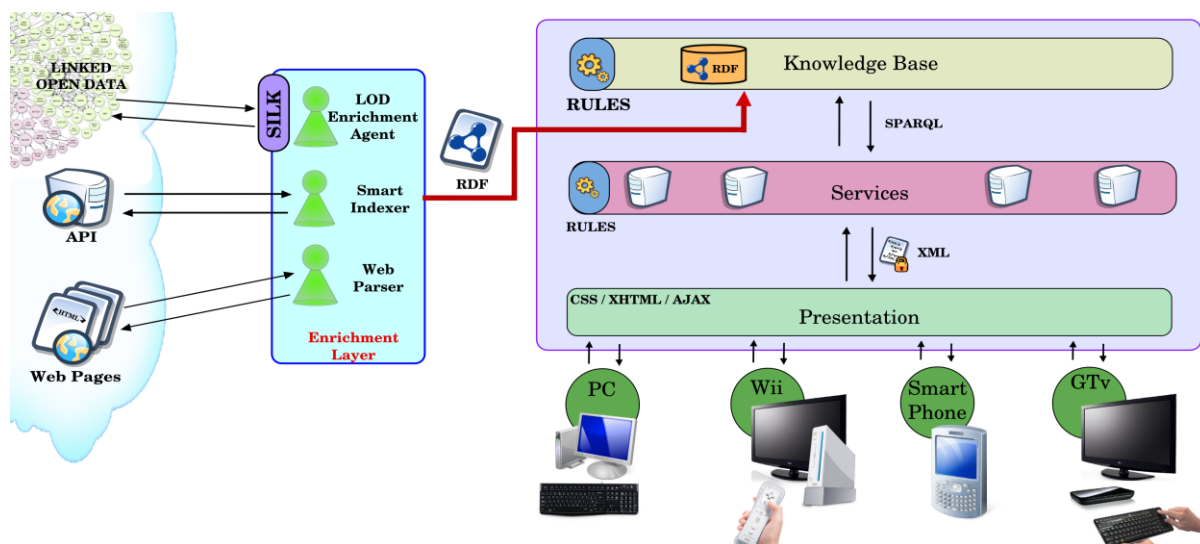

Figure 1. High level platform architecture after enrichment modules

new lexical terms related to each source tag. Thus, it is possible to get derived tags that complement the existing ones. This is what we call a “smart folksonomy”. Thus, the agent controlling the recommendations can list educational resources sharing at least one tag with the already viewed resources. Furthermore, these recommendations are sorted by the number of tags matching the source resource. An example of this process is showed in Fig. 2. It can be noted that two Learning Objects initially labeled by the community with different tags ("pet" and "fish" respectively) are not in any kind of relationship. Then, using the Smart Agent Indexer new tags can be obtained from the tags introduced by the community. For this, the agent gets terms derived from the original tags through WordNet API queries. With these new tags, the system gets more information on resources and can detect new relationships (in this case the Learning Objects share the "animal" tag).

- Using the DBpedia Linked Data node, we have obtained additional information (descriptions, images, etc.) related to the source tags of each educational resource. To this end, the SILK application has been configured to link the local tags with the analogous DBpedia records, particularly, to link local tags with those DBpedia records with a equal or similar textual name (`rdfs:label`, `skos:prefLabel`, etc.). On Fig. 3, it is shown a snippet of the configuration SILK file for this purpose. Reader can note: a) on line 12, the definition of the property to link similar records under the `owl:sameAs` property; b) on lines from 13 to 22, the concepts to be compared, namely any from DBpedia and `brc:TagConcept` from our KB; c) on lines from 29 to 32, the properties for each concept to be checked and the heuristic for the comparison (`rdfs:label` from DBpedia and our KB using the Jaro distance in our

case); d) on line 51, it is set the threshold to accept the match as correct (97% in our case).

- Currently, there are a number of web pages, as PBSKids (c.f. <http://pbskids.org/>) or BestKidsApps (c.f. <http://www.bestkidsapps.com/>), that list and meticulously describe different digital applications, particularly applications for mobile devices (games, interactive stories, music videos, etc.). These pages are organized as paged catalogue of entries, in this case, applications. Each page contains a limited set of result with fixed fields of information and links to navigate among results. Taking advantage of this information, it was developed an ad-hoc HTML parser. Thus, with the information gathered with this technique, a ser of RDF records inserted into our KB has been created. Therefore, it is possible to launch it periodically to update our KB with the description of hundreds of up-to-date digital applications. In this way, we increase our resource library with new external applications available at Android Market and iTunes. On experimental tryouts, it was launched on several web portals related to mobile applications for kids and the KB grew by 127% more with the new records.

The enrichment process has allowed the intelligent agent to have more available information (more tags per resource), therefore, its recommendations can be more accurate. Additionally, the user has more detailed information about each resource. Thus, the educator or the parent can better understand the nature and objectives of each resource and, consequently, accomplish a better choice, which ultimately results in an improved educational experience for the child.

B. Monitoring food application

The food monitoring and control application provides assistance services to the educational centres, helping them to create and configure the school menus; at the same time, the system helps the families giving them some advices and information about how to improve their children's diet. The application focuses on three key factors: the recommendation of complementary food, the nutritional information on menus and the monitoring and conflict detection in the diet of children with some kind of intolerance (diabetes, allergies, etc.).

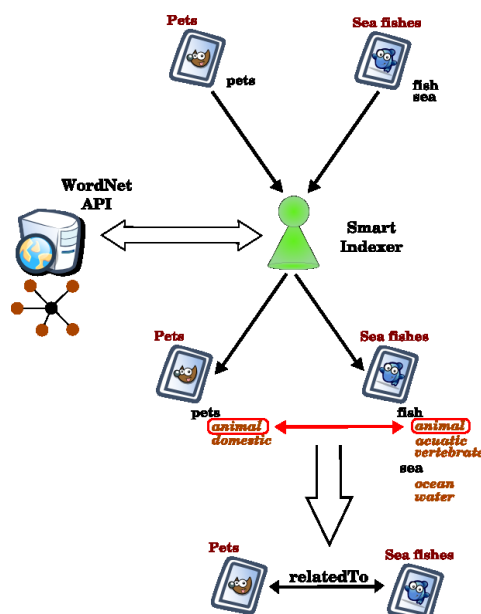

Figure 2. Functional diagram of the intelligent folksonomy. Here, the Smart Indexer agent gets (from Wordnet) derived tags from the source tags.

```

13: <SourceDataset dataSource="dbpedia" var="a">
14:   <RestrictTo>
15:     ?a rdf:type owl:Thing
16:   </RestrictTo>
17: </SourceDataset>
18: <SourceDataset dataSource="local" var="b">
19:   <RestrictTo>
20:     ?b rdf:type brc:TagConcept
21:   </RestrictTo>
22: </SourceDataset>
...
29: <Compare metric="jaroSimilarity" optional="1">
30:   <Param name="tag1" path="?a/rdfs:label" />
31:   <Param name="tag2" path="?b/rdfs:label" />
32: </Compare>
...
51: <Thresholds accept="0.97" />

```

Figure 3. Extract from SILK configuration file for comparison of two different datasets based on their properties.

To enrich the initial data generated by the community we have used the information available in the U.S. Department of Agriculture Database for Nutrition Information (USDA-DB). The USDA-DB is a well-known and reputable source of nutritional information. Once obtained, this information was transformed to RDF statements using the terminology defined by an ontology specially designed for this purpose. Finally, a local LOD-like node was created and linked to external repositories DBpedia and Agrovoc [19] (this last one is the largest agricultural thesaurus in the world). The methodology used to link the information is based on the location of the food and nutrient records published on these repositories that had their equal in our node. To automate this process, we use the SILK tool properly configured to meet the particulars of this context in a similar manner to the previous case. In this way, we can obtain, for each food registered in our platform, their nutrients and the number and proportion it comprises. Additionally, it is gained access to the virtually unlimited information provided by the connections to the DBpedia and Agrovoc (descriptions, images, links to other registries and repositories, etc.). The interested reader can find a more detailed description of this enrichment process in [20].

The enrichment process has meant a qualitative step in the functionality of this application by making it possible for new, more detailed, information that would be unthinkable to recover from data introduced by the user community. Particularly interesting is the information about the nutrients, and their proportion, of each of the menu and recipes foods.

With these data, an agent can generate a detailed report with the approximate amount of calories, proteins, fats and lipids present in each of the dishes and on the menu as a whole. In our platform, this new information is showed to the user in an intuitive color scale (Fig. 4). Furthermore, with this knowledge and the information about the nutrients to which the child is intolerant, the agent can infer whether a menu food is incompatible and then alert parents and educators. This is done using a set of explicit logical rules expressed in SWRL [21], which is used by the inference engine of the agent. Here is an example of the defined rules:

$$\text{Ingredient}(?i) \wedge \text{component}(?i,?cm) \wedge \text{Child}(?ch) \wedge \text{componentIntolerance}(?ch,?cm) \rightarrow \text{ingredientIntolerance}(?ch,?i)$$

$$\text{Food}(?f) \wedge \text{ingredient}(?f,?i) \wedge \text{Child}(?ch) \wedge \text{ingredientIntolerance}(?ch,?i) \rightarrow \text{foodIntolerance}(?ch,?f)$$

Another feature offered by the platform is the configuration of alternative menus in case of conflict: it is possible, from a complementary food ontology, to propose the user the substitution of one conflicting menu food by another one tolerated by the child (e.g. change milk cream by soy cream in case of lactose intolerance). For this, SPARQL CONSTRUCT statements with specific rules are used.

With all these mechanisms, the system also generates recommendations for home menus. It configures a list of menus that has a composition tolerated by the child and supplements the daily recommended amount of nutrients to food received in school.

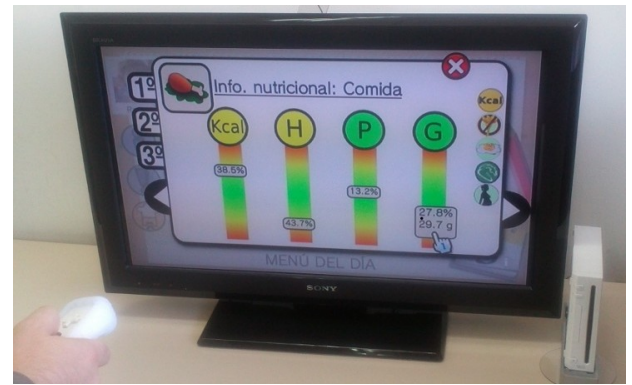

Figure 4. Screenshot of the platform user interface for Nintendo Wii where the basic nutritional values of a particular menu are shown.

C. Monitoring health application

This application is aimed to help both families and centers on the communication and management of the health of children by providing an environment where it is possible to register and obtain information from different medical events. The application is focused on three key factors: healthy history log (diseases, allergies, immunizations, etc.), agenda of medical treatment scheduling and dosage, and complementary navigable information about these questions (diseases descriptions, medical prospects, diseases symptoms, etc.).

To enrich the initial data generated by the community, we have identified three Linked Data nodes including reusable information of medical/health nature. These are the DBpedia and Freebase [22] multidisciplinary nodes, where we can find information on both diseases and drugs, and the DailyMed repository [23] of medical nature, which keeps detailed information about an extensive list of medications. Having identified those useful nodes, the SILK tool is configured so that, each time a new disease or drug is recorded on the platform, an automated process is launched in order to search for disease registries (on DBpedia and Freebase) and drugs registries (on the three repositories). Particularly, searches try to localize registries that have as name (property: *rdfs:label*, *DailyMe:name*, etc.) a word syntactically similar to the name of the locally registered disease or drug.

In the Knowledge Base of the original platform, it was recorded information provided by families and educators about the diseases and the period of time during which the child experiences them. Also it was stored information about the drugs (just the name), doses and times to be administered. This allows setting up an agenda that provides educators and families information and access to health events that should be conducted and the results thereof (Fig. 5).

Nowadays, after the enrichment process, we have achieved to add new significant information on these events and data elements, providing users with accurate descriptions of diseases and their symptoms, adding digital versions of prospects and allowing the browsing of related information (similar diseases, images, etc.). This allows the background support for health education of users, resulting in better care and attention to children. An example of this improvement can be seen in the episode that a child is diagnosed with a rare

Figure 5. Screenshots of the platform user interfaces for Nintendo Wii and tablets where the health management tool is showed.

disease. In this situation, both the educators and the parents can be learned with the contextual information provided by the platform, where they can find a description of the disease, symptoms, possible adverse effects, etc.

VI. CONCLUSIONS

Most of the educational platforms developed to date seek to provide the user with an improved educational experience through automated services that use and interpret the information generated by the user community (mainly, teachers and families). This data generation process is slow and tedious, and usually very low verbose. Thus, the approach described in this paper proposes and focuses on the use the free information available on the web to supplement and extend the knowledge base on the system in order to get an effective and useful enrichment of the information. This external data is generated both by typical web users and by subject experts. Particularly interesting are the data published in an easily processable format, such as the information published under the requirements of the Linked Open Data initiative.

Once the knowledge base is enriched, the smart services have much more information that allows to: improve performance, get new features not originally provided, and provide more and better information to the user. In short, the enrichment processes applied in educational ICT-based platforms can be an outstanding way to enhance the educational experience of the end user.

Currently, the enhanced KB is being used in a local scenario by real families and teachers. This is possible due to the support of a pilot project conducted on local schools that are collaborating with this project.

ACKNOWLEDGMENT

Work in Progress: Analysis of Change in Engineering Construct Knowledge

Ronald L. Carr, Heidi A. Diefes-Dux, Benjamin J. Horstman

Purdue University
Institute for P-12 Engineering Research and Learning
West Lafayette, Indiana, U.S.A.

Abstract— Interview transcripts from students (grades 2-4) were examined to measure change in understanding of engineering constructs using a coding scheme that is in development. The participants were students of teachers from a large, urban school-district that participated in two summer teacher professional development (TPD) engineering education academies and received continued support from a university center devoted to P-12 engineering education. To analyze the interviews, the overarching themes were broken into eight constructs that were points of focus during the TPD. Sample results show change in all mean scores. The inter-coder reliability for this iteration of scheme development was 91.3%. Scored level of understanding of the constructs (on a scale of 0-3) produced 75% agreement. The coding scheme continues to be refined in an effort to provide a form of evaluation of TPD and teacher effectiveness that identifies weaknesses in curriculum design and implementation.

Keywords- *engineering constructs, interview analysis, teacher professional development, pre-college engineering, K-6*

I. PURPOSE OF STUDY

Engineering continues to find a place in national curricula through policy and funding movements as well as through a growing presence in state and national standards [1]. Meanwhile, the National Research Council (NRC) suggested careful integration driven by empirical evidence [2]. This study is integral to the empirical framework used to examine student engineering construct knowledge (ECK). The primary purpose of this study is to understand the impact of two summer teacher professional development (TPD) academies (over consecutive years) and ongoing support from a university research center devoted to P-12 engineering.

This interview analysis of ECK extends previous research on K-6 engineering by providing insight into initial levels and change of ECK. Rating the level of change and identifying how the change is present informs TPD practices, redesign of existing curriculum and design of new curriculum.

Previous research has looked at conceptualization of engineers by students [3-5] and change in knowledge in broad general areas related to engineers and engineering [6, 7]. More specifically, this coding expands on the evaluation of student context maps. These maps showed elementary students most often used general engineering and engineering design frameworks of expression [8]. This qualitative analysis of student reflections helps to “capture richer descriptions and experiential narratives to depict more fully and to help

understand” [9 p.42] what is being learned in K-6 engineering classrooms and to improve epistemic developments as called for by the NRC [2].

II. METHOD

A. Participants

Three cohorts of elementary school teachers in grades 2-4 (2008-9: N=32; 2009-10: N=36; 2010-11: N=30) from a large, urban school-district participated in a week-long TPD academy during one summer and a three-day follow-up academy the following summer. Four or more students were randomly chosen from select teachers’ classrooms to participate in pre-post interviews. Pairs of interview transcripts, pre-post, were purposefully chosen from this collection of interviews for preliminary analysis and inter-coder agreement so that the students included in this study were in engineering classrooms for the first time.

B. Intervention

The curriculum used in the teacher academies stressed the roles of engineers, engineering design, problem solving and technological literacy. Activities were designed so teachers could actively participate in learning, as their students would, when the classroom-ready activities were integrated into their science and math curricula. Model-Eliciting Activities (MEA) [10], *Engineering is Elementary (EiE)* units [11] and a modified version of the *EiE* engineering design process were used across grade levels to provide consistent engineering curricula. Other design challenges and technology-defining activities were provided to grant a variety of activities supporting the emphasis on problem solving [12]. Teachers were instructed to use a minimum of one design challenge, one *EiE* unit, one MEA and the provided technology-defining activities in their classrooms over the course of the school year.

C. Defining Constructs

The primary objectives of the TPD were to: 1) Convey a broad perspective of engineering; 2) Examine differences between engineering and science; 3) Develop comfort in discussing engineering with elementary students; 4) Engage students in complex open-ended problem solving [13]. These objectives align with curricular suggestions from reports from the National Academy of Engineering, national technology standards, and engineering standards from states such as Massachusetts and Indiana [1].

These objectives yielded the overarching themes of the academies that focused on roles of engineers, engineering design process (EDP) and technological literacy. To analyze the interviews in this study, the overarching themes were broken into eight constructs that were points of focus during the TPD: 1) What engineers do; 2) Types of engineers; 3) Purpose of EDP; 4) Parts of EDP; 5) Teamwork; 6) Use of math; 7) Use of science; and 8) Technological literacy.

D. Coding and Analysis

The transcripts were analyzed using mixed methods. Using Nvivo qualitative analysis software [14], words or phrases fitting one or more of the eight constructs were manually coded into one or multiple constructs. Coders then assigned scores on a four-point scale to quantify the level of understanding. The scale ranged from 0-3 with the following criteria: 0) no mention of construct; 1) awareness of constructs minimal or incorrect; 2) some understanding of construct; 3) understanding construct evident.

The independent coding between two coders was then compared using the software to compute inter-coder agreement for both construct identification and for assigning scores to the level of understanding. The coders were selected based on experience in engineering education: an undergraduate research assistant majoring in engineering and a graduate student that works in engineering education. Both had instructed multiple TPD academies and were familiar with the subject matter that informed coding decisions.

In the preliminary analysis, pre and post interviews from ten students were coded and rated. The inter-coder agreement for the rating of the understanding was 75% agreement. However, the inter-coder agreement for the coding of the constructs was 91.3%.

III. RESULTS AND DISCUSSION

The coding scheme was able to identify levels of change in all eight constructs when comparing pre and post interviews. However, due to the iterative nature of the coding design process, those results are too preliminary to report and only help guide the refinement of the criteria for both measures. The sample results did show the largest change in the constructs related to EDP Parts, EDP Purpose (Change = 1) and What Engineers Do (Change = 1). There is a decrease in mean scores for Types of Engineers and Teamwork.

IV. CONCLUSION & NEXT STEPS

The inter-coder agreement for construct coding was promising, yet improvements to the coding criteria are being made and additional coders will then perform similar analyses. The agreement level for rating the understanding indicates more than desired subjectivity and scoring levels will be better defined for the next step. Additional data from knowledge tests will be used to compare the construct knowledge to the overall knowledge for further validity. A larger sample size (15-20% of the total 338 interviews conducted over the three years of the study) will be used to ensure coding reliability.

It appears that this study will be beneficial in identifying the strength of the TPD and the teacher implementation and

will help identify strengths and weaknesses in specific construct areas. The final results of the study should be beneficial in helping to revise interview protocols in order to gain a better understanding of construct knowledge.

Work in Progress: Serving Rural Communities: A K-8 LEGO Robotics Case Study

Tanja Karp

Electrical and Computer Engineering Department
Texas Tech University
Lubbock, TX, 79409-3102
tanja.karp@ttu.edu

Abstract— In this paper we describe approaches to better assist teachers in rural areas to participate in an annual LEGO robotics competition offered at Texas Tech University. While local schools have a student mentor visiting the robotics teams on a weekly basis, schools that are more than 20 miles away from Texas Tech University do not benefit from this service. Although there is a significant amount of literature available on LEGO robotics, teachers and students seem to prefer personal interaction. We propose daylong fieldtrips and webinars to partly overcome distance and still provide direct interaction.

Keywords—component; K-12 Engineering Education, LEGO Robotics, teacher professional development

I. INTRODUCTION

Since 2006, the Whitacre College of Engineering at Texas Tech University (TTU) in Lubbock, TX, serves as a local hub for the Get Excited About Robotics (GEAR) [1] LEGO robotics challenge. In this annual 8 week competition students from elementary and middle schools design, build, and program a robot based on the LEGO MINDSTORMS NXT kit [2]. Each year, the robots have to perform a series of pre-defined tasks described in the annually changing challenge. The theme of the challenge motivates the use of robots in areas such as farming or an energy corporation. Over the last 6 years the challenge has grown from one local participating elementary school to over 500 students from about 40 school from all over the Texas High Plains, and beyond, see Figure 1. Over the last two years the number of participating schools which are over 50 miles away from Lubbock has continuously grown. While local schools are served by an engineering student who mentors the GEAR team and meets with the students at the school once a week as part of a service learning project associated with a college wide Introduction to Engineering course [3], this approach is not feasible with schools further than 20 miles away due to travel cost and time constraints. Apart from a group of schools in the Midland/Odessa area these schools are mostly located in scattered small rural communities and have a large percentage of socio-economically disadvantaged and Hispanic students.

The challenge of disseminating STEM content into after school informal learning activities in 4-H Clubs in rural areas was described in [4], where the major challenge faced was training of the 4-H staff interacting with the participants.

Successful teacher professional development via video-conferencing was reported in [5], where the benefits of a feedback channel and a learning environment close to traditional face-to-face instruction were emphasized.

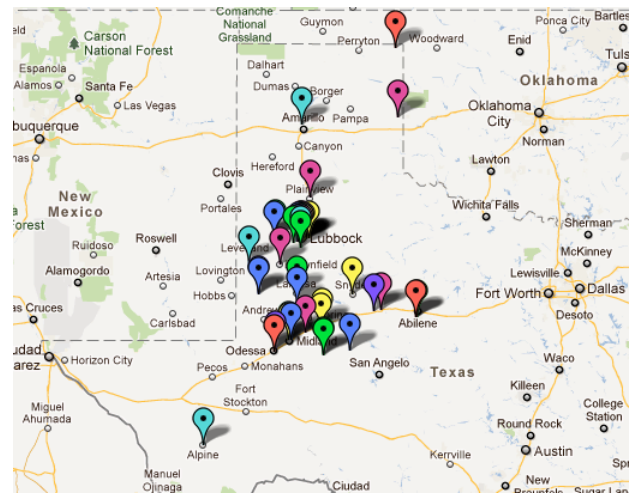

Figure 1. Schools participating in Lubbock GEAR competition.

In this paper we describe approaches taken to better serve rural communities that alleviate the burden of travel but still promote the interaction with engineering faculty and students who are content experts and serve as role models for participants.

II. LEGO ROBOTICS FIELD TRIPS

Day-long LEGO robotics field trips hosted on the TTU campus have been proven a successful recruiting tool to expand participation in robotics competitions such as GEAR. Students together with a teacher participate in a day-long hands-on robotics workshop held at the Whitacre College of Engineering (WCOE). The workshop starts with participants familiarizing themselves with the LEGO MINDSTORMS NXT kit through the building of a standard robot according to instructions. They next learn the basic steps of the NXT-G programming concepts in order to rotate the wheels or an arm, collect sensor inputs (light, sound, ultrasonic, touch), and play sounds. The field trip instructors are TTU engineering professors assisted by engineering undergraduate students. The instructors first

explain the usage of the software for a given example and students copy this example and try it. They are then asked to apply the learned concepts to a slightly different / more complicated problem.

After a lunch break participants visit a robotics research lab in the Computer Sciences Department on campus and then spend the afternoon accomplishing various tasks with their LEGO robot such as navigating through a maze using the touch sensor, building a burglary alarm system based on the ultrasonic sensor input, tossing tennis balls into a goal. These tasks are organized in a set of stations each mentored by a student.

Teachers easily commit to this field trip format since no prior training is required on their side. In addition, it promises to be a fun hands-on learning activity. They are generally surprised about the accomplishments of their students throughout a single day and leave the campus inspired and confident that they could organize a robotics team at their school. The field trip thus not only provides an educational hands-on experience for the students but also for the teachers. During the field trip teachers also learn about professional workshop opportunities and useful resources available online.

While students still have to travel to campus, the block format provides a better value for the travel expense and fits into the format of fundable activities at the schools. Field trips have also been arranged for schools participating in our GEAR competition.

III. MENTORING THROUGH VIDEO CONFERENCING

We offered on-demand video conferencing through Skype [6] during the 8 weeks of the GEAR challenge last year. Every afternoon, experienced engineering students were signed-in on Skype during the afternoon and available to answer questions. However, participants did not take advantage of this opportunity. Partly, this was due to internet access restrictions at the schools, partly participants did not feel the need of having a mentor and preferred to independently work on their problem until it was solved. Some students/teachers did request help by email and were provided answers.

IV. WEBINAR BASED TEACHER WORKSHOPS

During our GEAR robotics competition we offer a series of teacher workshops. These workshops are hands-on in nature and start with a New Teacher Workshop which explains the format of the GEAR competition at TTU, showcases some of the challenges that the robot had to accomplish in a previous year, and then has a hands-on component where teachers program a pre-built LEGO MINDSTORMS NXT robot to perform specified motion and to react to sensor input. Finally,

teachers typically accomplish to solve 1-2 tasks of the previous year competition. In collaboration with National Instruments [7] we also offer hands-on workshops customized to specific questions solicited from teachers. This workshop mostly consists of hands-on programming and problem solving accompanied by explanations from the instructors. While these workshops were originally offered as on-campus workshops only, we have also offered them in mixed format (participants on campus and at home watching streamed content) as well as webinar format only. In the mixed format, a problem was explained and then participants in the classroom and at home had time to solve the challenge. At the end of a given time period, the challenge was wrapped up and explanations to a solution were presented.

A first webinar-only new teacher workshop was offered this year for teachers who were not able to participate in the on-campus workshop. Participants could voice their questions either using their built-in microphone or by entering them in a chat window and took advantage of it.

V. CONCLUSIONS

Our first experiences with offering webinars were encouraging. The bidirectional interaction offered seems to provide a substitute for face-to-face communication and teachers can easily participate in evening webinars from their homes thus circumventing IT restrictions existing at their schools. We plan to hold a webinar-only LEGO robotics teacher training workshop in the fall for teachers new to the LEGO MINDSTORMS NXT kits. They will be accompanied by the offer to bring students to the Texas Tech Campus for hands-on field trips.

Work in Progress: Exploring Programming Anti-patterns as Emphasis on Creativity in the Teaching of Computer Programming

Programming Anti-patterns as Emphasis on Creativity

Deller James Ferreira
Informatics Institute
Federal University of Goiás
Goiânia, Brazil
deller@inf.ufg.br

Abstract—Computer programming is a creative activity. However, while computer scientists have devoted their work to solving complex problems and developing new technology, few have written on the creative process behind their innovations. This work explores programming anti-patterns as beneficial detour to the creation of good programming designs. Examples of programming anti-patterns are: failure to combine linear traversal and a flag variable to search a given value in a uni-dimensional array; to draw wrong analogies from natural language; not consider uncommon cases in a solution; to overlook minor parts of the problem; to assume that a program construct will work in the same manner in all situations; not be flexible in understanding new code, not being aware that there are many different right solutions to a problem. In this research, the teacher of introductory programming course promotes discussions among students involving the bad and good features of program anti-patterns, when there are programming anti-patterns code examples and discussions based on situations having the potential to prevent programming anti-patterns, when programming anti-patterns describe a lack of programming skill. An initial experiment showed improvements in creation of good program designs by students, when the teacher boosts discussions exploring program anti-patterns.

Keywords—programming anti-pattern; creative programmer; collaborative programming

I. SCIENTIFIC AND EDUCATIONAL FEASIBILITY OF THE PROJECT, EXPECTED OUTCOMES AND EVALUATION PLAN

Computer science is a creative field to work, innovation is a necessary condition to create new products and technology and creativity is evident in software design processes. Although in computer programming creativity is required, pedagogic methods applying tasks that address creative aspects of programming are scarcely reflected in computer science education. Students should be fostered to develop and apply

their creativity and computer science education researchers and teachers should approach creativity more often.

Our approach is under a creative perspective for programming. In this research, the teacher anticipates programming anti-patterns in order to encourage better critical analysis and creation of programs by means of explorations of good and bad features of a program anti-pattern. Sax and Dix [1] has investigated the exploration of bad ideas as a way to support creativity in human-computer interaction. They advocate that bad ideas encourage both divergent thinking and a more structured analysis of the problem, pulling the designer to a new and unpredictable place within the design space.

In this research, students are motivated to discuss about what is bad concerning a programming anti-pattern, why this feature is illogical, inadequate, and ill-crafted, if there is a good design possessing this feature, if so what is the difference, and if there is a situation where it could be considered well-crafted. Students also discuss about what is good concerning a programming anti-pattern, why this feature is logical, adequate, and well-crafted, if there is a bad design possessing this feature, if so what is the difference, and if there is a situation where it could be considered ill-crafted.

Here we apply collaborative programming. In collaborative programming, a group of students jointly perform the same task. Computer programming has traditionally been taught and practiced individually. Nevertheless, computer science educators have recently adopted different collaborative learning practices such as programming in pairs and team projects. By means of these collaborative activities, students can produce better programs and improve their performance and programming skills [2]. However, the teacher must help the students to develop the collective ability to use dialogs for learning, fostering productive interactions during argumentation in instructional settings. Discourse must be

This work is supported by FAPEG – Fundação de Amparo à Pesquisa – Goiás.

facilitated aiming creative and innovative processes and products.

Collaborative programming combined with programming anti-patterns examination, constitutes a potentially powerful learning method for computer programming that provides profitable exploration of possibilities among the participants and provide a framework for social interaction that favors fruitful idea generation and program design discussion.

In this research, we expect students to produce program codes correctly in a greater percentage. Also, we aim student's better programs understanding as a result of discussions concerning a great repertoire of not perfect program solutions. We expect to prevent students misunderstandings as well, going further in discussions based on situations having the potential to prevent programming anti-patterns, scrutinizing previous recurrent students bottlenecks.

For at least four semesters of computer science introductory courses, there will be one class taught by traditional method (control group) and another one taught by the proposed method (treatment group). Students performance will be confronted by questionnaires measuring their understanding of program codes, their grades, the percentage of the occurrence of correct and incorrect code generated by the students, as well as the percentage of the occurrence of programming anti-patterns classified by different types.

II. IMPORTANCE TO THE EDUCATION COMMUNITY

Traditional teaching proceeds by generating programs that meet problem constraints and best fit good design constraints. An usual approach is to guide students toward effective strategies for programming. However, understanding such strategies and program design demands a high level of comprehension and abstraction [3]. Novices are supposed to make connections beyond the scope of question, be able to transfer knowledge to a new situation, make a lot of interconnections among program components, and to integrate language constructs in a logical way in order to provide a computational solution to a problem.

Our motivation for the application of programming anti-patterns is that novice programmers usually cannot find their way out confronting a programming problem. They sometimes say "I don't even know how to fail." On the other hand, there are better students able to produce fully correct or almost right solutions. Recurrent and almost right solutions are then used to help students that the answer is blank or totally wrong.

To overpass student's cognitive load and lack of programming knowledge and skills, instead of considering bad designs as problems to be overcome, students are encouraged to analyze and discuss them. Student's bad program design is related to the student prior knowledge, contains correct parts, and is a naive solution. So, programming anti-patterns are easier to be understood and their exploration serve as springboards for the understanding and creation of good programming designs.

III. PROJECT STATUS AND PRELIMINARY RESULTS

During one semester of an introductory programming course, two classes containing forty under graduate students from food engineering course were analyzed considering students' generation of language-based anti-patterns, such as wrong program sequence. Second, we analyzed design problems, i. e., students' inability to properly combine, specialize, optimize, and students' incapacity to visualize details during correct code adaptations. Third, we checked students' skills to develop solutions to new problems, measured by means of the quantity of innovative program code generated.

The programming anti-patterns considered in this research were: inability to combine language features generating new programs; incapacity to improve programs; difficulties in identifying particular cases of known problems; bad usage of previous knowledge during programs interpretation; difficulties in delimiting control structures; inability to predict unexpected cases in a problem; incapacity to understand the sequence of a program; difficulties in decompose a problem in sub-problems; incapacity to identify and correct errors in programs; incapacity to understand step-by-step the program code; false belief that programming constructs have the same form in every program; false belief that there is only one correct solution for a computational problem; failure to combine correct program code; failure to adapt correct program code; failure to generalize examples to conceive a correct program code; failure to detect details during correct program code adaptation; inability to understand the program code considering correct program code combinations.

The experiment results showed that in the second class, where the teacher facilitated discussions involving programming anti-patterns, the occurrence of programming anti-patterns and code adaptation problems was smaller and the occurrence of innovative program code generated was bigger as shown in Table I.

TABLE I. STATISTICAL OVERVIEW OF THE RESULTS OBTAINED

| Data Considering Programming Anti-patterns Application | Percentage of Occurrence |
|--|--------------------------|
| Programming Anti-patterns and Code Adaptation Problem | 40.00% smaller |
| Innovative Program Code Generated | 20.00% bigger |

Instilling a Software Engineering Mindset through Freshman Seminar

Michael J. Lutz, James R. Vallino, Kenn Martínez, Daniel E. Krutz

Department of Software Engineering
Rochester Institute of Technology
Rochester, NY, USA

Abstract—Student retention is a challenge faced by all engineering programs. Our first year software engineering students have schedules filled with computer science, mathematics, science and humanities. The lack of any exposure to engineering meant some students, expressing a dislike for software engineering, left the program before they had any exposure to the discipline.

To address this issue, we created a one credit Software Engineering Freshman Seminar, which all entering students take in their first term at RIT. This lets us insure student/faculty contact early in the program, as well as providing an opportunity to introduce engineering concepts and practices early in each student's program of study.

This paper discusses the seminar's current incarnation. In particular, we focus on those aspects of the course which help students identify with software engineering as a profession. The challenge we face is achieving this goal with students whose technical knowledge and skills are modest. We have settled on an approach that provides experience with teamwork, requirements elicitation, and the effects of change, and addressing professional ethics. These in-class activities are complemented by an assignment to interview a practicing software engineer and to write an interview summary for discussion.

This activity ensemble serves to disabuse students of the notion that software engineering is little more than programming, or that the discipline is identical to computer science. Should a student exit the program at this point, at least he or she knows a bit about what they are leaving behind.

Keywords—*first-year seminar; software engineering; teamwork*

I. INTRODUCTION

In 1996, the Rochester Institute of Technology (RIT) launched the first undergraduate software engineering program in the United States [1][2]. From an initial class of 15, the undergraduate program has expanded to a current enrollment of approximately 375 students. While the Department of Software Engineering has grown to encompass a masters program, the undergraduate program remains the focal point of the department's identity.

Engineering programs seek to prepare engineers who can define, design, develop and deploy useful, cost-effective, and maintainable systems; this is no less true of software engineering than of more traditional disciplines. Traditional

engineering builds upon (but is distinct from) natural sciences such as physics and chemistry. Similarly, in our view software engineering has its foundations in computer science, but it is no more the case that computer science encompasses software engineering than it is that chemistry encompasses chemical engineering.

The proof of our philosophy is in its results. First, software engineering is recognized as an engineering discipline by ABET, and the first graduates of an ABET-accredited baccalaureate software engineering program came from RIT. In addition, software engineering students have great success both on co-op and after graduation. Across the broad range of undergraduate computing programs at RIT, our students have the highest median co-op wages and the highest median salary upon graduation. Students and graduates work for firms large and small, and in domains spanning embedded systems, as at Goodrich Aerospace and Harris RF Communications, through end-user focused firms such as Microsoft, Apple and Google. All in all, our program provides a solid foundation for entry into and continual growth within the world of professional software development.

II. THE FIRST YEAR CHALLENGE

While our program is successful overall, we face the challenge of instilling a sense of engineering practice and professionalism, along with the distinctive perspective of software engineering, in our first year students. The challenge is made more difficult by the fact that entering students are often confused as to where software engineering fits within the larger framework of computational studies. Software engineering's recent emergence as a discipline distinct from computer science, combined with a first year program of study that is heavy in math, natural science, computer science, and the liberal arts, serves to exacerbate this confusion. In the end, first year students who leave software engineering often did so as a result of this confusion – they had little knowledge of or appreciation for the distinctive nature of software engineering.

To address the challenges and confusion outlined above, our program includes a one credit hour course providing a broad perspective on the discipline for entering students; over time, this Software Engineering Freshman Seminar[3] has evolved into the one we present in this paper. While tuning and tweaking is regularly taking place, the general structure, topics, and flow of material has stabilized. As a consequence, students completing the course have a grasp of some key software

engineering concepts and practices, and can appreciate the role of their foundation studies as preparation for the software engineering courses that follow.

III. COURSE GOALS

The overriding course goal is reducing first year attrition in our program. We know that attrition after the second year is less than 10%, especially after students complete our Engineering of Software Subsystems course, where software design principles and patterns are first discussed in detail. We decided a bridge was needed to see students through the first year of the program, where math, science and liberal arts courses predominate, into the second year where software engineering *per se* becomes the curriculum's focus. Our hope was to forestall student departures because "I don't like software engineering" or "I want to do something besides just programming." Certainly students should be free to pursue interests elsewhere, but we'd prefer they do so based on an accurate perception of the discipline. Misperceptions, whatever their cause, should be eliminated.

Our bridge comprises two courses, the seminar described in this paper and a Personal Software Engineering [4] course taken at the beginning of the second year. Both serve to forge bonds between software engineering majors and the faculty in the department, and to provide distinctive engineering experiences in conjunction with foundational studies. In this our program is in line with many similar efforts in other engineering programs [5][6][7].

For the seminar, we decided to focus on three elements of software engineering practice that undergird our program and that can be imparted to students with modest technical background: product requirements and design, teamwork, and professional communications. We also saw this as an opportunity to introduce students to ethics and ethical professional behavior. Activities throughout the course illustrate and reinforce these concepts.

With one exception, requirements and design activities do not involve software. In part this is a concession to the fact that many students are software development naïfs, and requiring them to do development in both the seminar and introductory computer science would create an unreasonable load. As important, we wanted students to realize that many engineering problems they will encounter (as well as their resolution) require more than the creation of executable code. Thus the requirements and design activities involve paper mockups and Lego based exercises rather than executable programs. Even the one exception, requiring teams to provide enhancements to Java classes, is small enough so as not to obscure the concepts being taught.

Our program, in contrast to many computing programs, is heavily team-based. Indeed, with only two exceptions, all courses in the program have at least one (and usually several) team-based projects. In light of this, an early exposure to both the benefits and costs of working in teams gives first year students a leg-up on what they will be doing later on in their studies. It also serves to counter the "lone hacker in a cubicle" perception of software development so prevalent in the culture at large. In any event, by the end of the seminar most students

are comfortable working on teams, solving problems larger than they could address on their own.

The ability to clearly and concisely communicate ideas is as critical to a software engineer's career as his or her technical skills. Indeed, one impetus for developing the curriculum was recognition of the divergence between the preparation of graduates from previous computing programs and the needs of industrial software development firms; poor communication skills were at the core of the problem. Thus our courses require significant written documentation and frequent oral presentations. It is natural to reflect these demands in the seminar course, though at somewhat reduced formality. Once again, such activities serve to distinguish software engineering from other computing disciplines.

Finally, as we are educating future professional engineers, it is incumbent on us to reinforce the professional responsibilities and ethical demands of the discipline; there is no reason why this education cannot begin at the outset of each student's studies. Of course professional ethics is an area that is notoriously difficult (and dull) to teach via lecture; such approaches often come off as special pleading. In our approach, we try to balance the need for teaching specific ethical principles with experiences in which students explore the ethical ramifications of specific technical decisions. Unintended consequences, such as epileptic seizures due to rapidly flashing game screens, provide a rich environment in which to discuss professionalism.

To provide this view of the breadth of software engineering, we defined the following learning outcomes for the Software Engineering Freshman Seminar.

A student will be able to:

1. Identify the principles of the Software Engineering ethics (e.g. Code of Ethics as recommended by the IEEE Computer Society and ACM)
2. Identify the major activities of Software Engineering
3. Identify strategies to address issues that can arise in a team project.
4. Identify the difference between Software Engineering and other computing disciplines.
5. Apply general concepts to a specific process step, namely execute a project test plan and, acting as the quality assurance group, assess the effectiveness of the test plan for the development team.
6. Explore and describe the responsibilities, working environment, skills and technologies of a software engineering professional.

With this background information on our course goals, it is appropriate to turn next to the specific topics and activities – the tactics, if you will – by which we strive to achieve these goals.

IV. TOPICS AND ACTIVITIES

The seminar is heavily oriented towards active learning, as we've found that this engages students in the material for each

session. This engagement leads to insight and interest in software engineering, with the consequence that students acquire a broad perspective on the discipline.

Given the team-based nature of the curriculum, it is no surprise that most of the work in the seminar requires working in teams of 3-5 students; to help students become acquainted, we usually vary the teams from one exercise to another. While most exercises are completed during class, a few span multiple meetings, and require the team to meet outside the class period. Once again, this reflects a situation they will encounter throughout their software engineering studies.

One issue we frequently have to address is the lack of (graded) group work in high school. Even in situations where collaboration is encouraged, at the end of the day most assignments entering students are familiar with had to be completed individually. To counter this mindset, we purposefully focus on the degree of collaboration within teams, and downplay individual assessments based on project outcomes. It is true, of course, that peers and instructors evaluate individual contributions when grading projects in later team-based courses, but in the seminar it is more important to have students feel comfortable being assessed as a group. We seek to encourage open, collaborative approaches to problem solving as the norm across all the exercises.

The learning outcomes from the previous section are addressed across the 10-week course, with the emphasis varying among the activities pursued in any given week. Initially the focus is on perceptions of the software engineering discipline, followed by activities related to various phases in a software development process (e.g., lifecycle activities), capped by interview sessions with students returning from co-op and a sample of software engineers from local industry. For convenience, we classify activities as non-software (applicable in any engineering context), software (focusing on issues of particular importance in software engineering), and the "real world" (via interaction with practicing professionals). The following subsections expand on activities in each of these classes.

A. Non-Software Activities

1) *Planning and Team Collaboration*: In this activity, while we stress the importance of team collaboration and communication, we also want the students to recognize the importance of careful planning. Such planning can mitigate the unexpected consequences that often prove costly at later stages of development.

The stated objective is the construction of the tallest Lego tower, using the kit provided. Often teams immediately begin assembly, following the first idea from an outspoken team member, and paying little attention to the future. As the towers grow, a rule change is introduced: Team members are only allowed to use their left hands. Students quickly realize that they can no longer function autonomously; rules and protocols are required for the team's work to continue.

Finally, the requirements are changed - each team is given a set of wheels and told their tower must move across a table prior to its height being measured. Naturally, those with flimsy,

unstable towers must rush to reinforce their constructions - this is a valuable lesson on premature optimization in the face of continuing changes.

At the conclusion of this activity, all students observe the performance of each tower - whether it passes the acceptance test and only then whether it is the tallest. We often hear comments such as "we did not think of doing it that way" or "we probably should have spent more time planning what we were going to do". Once the tests are completed we have a class discussion in which the students are asked to reflect on the activity as it relates to software products with which they are familiar.

2) *Disruptive Teamwork*: In this activity, teams of 4-5 students are set to the task of preparing a short presentation on a software engineering topic. Unbeknownst to most of them, one member of each team is a "mole," selected by the instructor. The moles are pulled aside on some pretext, and told to be disruptive during their team's meeting. Typically instructors give a variety of disruptive roles from which to choose. The goal is to introduce common team problems and see how the team as a whole reacts.

We are continually impressed by the thespian abilities of our moles and the energy they put into their roles. In the past, we've had moles who demand to be in charge of the team, who tried to get their colleagues to watch YouTube videos with them, who challenged each and every idea other team members proposed, and who even entered the team space, put their head on the table, and went to sleep. As one might expect, by the end of the 30 minute team session the other team members are annoyed (to put it mildly).

At the conclusion of the exercise, the teams reassemble in their classroom. The instructor then exposes the mole on each team, as well as the particular disruptive behavior each mole was assigned. Groups then work on the *real* presentation: How they handled their "problem" member and what they might do in a similar situation in the future. Presentations are followed by a class-wide discussion of the advantages and disadvantages offered by teams.

3) *Professional and Ethical Responsibilities*: The session on professional and ethical issues is preceded by an out-of-class assignment to read and comment upon the Software Engineering Code of Ethics developed by the ACM and the IEEE Computer Society [8]. In the class session, this is expanded upon via a short lecture on related topics, including health and safety, moral and government guidelines, and ethical behavior in the workplace.

Students then form teams and develop a short skit on one of the specific topics covered in the Code of Ethics or in class. Students generally have fun with this assignment and their skits usually illustrate their topic effectively (and often humorously). Following each skit, a focused discussion takes place related to the skit's topic. In particular, students are asked to reflect on real world situations related to the topic and how they might deal with the resulting situations.

B. Software Activities

1) *Defining and Describing Software Engineering*: One of the earliest activities centers on the meaning of software engineering as a discipline. Students are asked to work in teams to create a short presentation or brochure to be delivered to their former high school. Teams are given an example presentation (one used during open houses, and familiar to many of the students), along with an outline of topics to consider for inclusion. The topics include the differences between software engineering and other computing disciplines, the relationship between software and our rapidly changing world, and the range of career opportunities within the field.

We know that students are largely ignorant of the ethical issues involved in plagiarism [9]. The presentation provides an excellent venue, early in their studies, to present these issues, along with advice on how to avoid plagiarism. As part of the activity, students are required to provide proper citations, and we also offer guidance on abiding by rules of ethical academic behavior.

Given the proliferation of internet resources of widely varying quality, we also introduce students to ways of identifying credible, trustworthy, and informative sources. Key points include verifying the original source of a work, determining the work's publisher, and finding the last revision date.

Having spent a week on this activity, several are selected to make a formal presentation. A resulting class discussion on the merits of the content, style and sources increases student appreciation of the software engineering profession's place in the context of an expanding and ever changing technical world.

2) *Challenges of Requirements Elicitation*: At the midpoint of the term, students participate in a second Lego project, this one to build a house to a customer's specification. The goal is to expose students to the difficulties of both eliciting and conforming to customer expectations.

At the outset, each team is provided with the basic requirement that the team must build a Lego house satisfying a customer's requirements. Instructors and course assistants prepare by identifying a simple set of requirements such as a minimum of two rooms, a window in each room, a roof, etc. Elicitation spans three iterations; during an iteration, each team has the opportunity to ask three specific questions (queries like "what do you want the house to look like?" receive short, direct and ambiguous replies).

Teams soon realize that they must carefully consider which questions to ask and how to frame them in order to maximize the useful information received. Course assistants enjoy acting as customers during this activity, and revel in truthfully answering questions so as to reveal as little information as possible. Question: "Does the house have windows?" Answer: "Yes, the house has windows."

At the end of the 30 minutes devoted to the activity, each team shows the house they built and how it meets the requirements as they understood them. Normally, no two houses are even vaguely similar, reinforcing the problems of

obtaining accurate and useful information from customers. Students see firsthand how requirements can be interpreted in radically different ways. Overall, the exercise reinforces the importance of maintaining a continuing conversation with the customer, while working to ensure the real requirements are understood and the customer's desires are satisfied.

3) *Software Process Methodology*: We introduce the notion of a development process via a version of the Extreme Programming (XP) game, using a variant of Joe Bergin's coffee machine planning game[10]. XP is used because it allows teams to make headway in the face of changing requirements; in particular, it emphasizes evolutionary development with small, incremental releases.

Each student team designs a vending machine on paper, where the machine must conform to prioritized, predefined user stories. Students in each team assume one of three distinct roles: customer, developer, or monitor. Customers establish machine feature priorities using their own opinions combined with an estimate from developers as to the effort needed to include the feature. Developers add features to the vending machine from most to least important; in the second and later iterations, this includes integration and refactoring of what was done previously. Moderators are part coach, part referee, monitoring communications between customers and developers, and ensuring the process stages are properly time boxed.

At the conclusion of the exercise, student teams compare the resulting systems, recognizing that they all started with the same user story set. The class ends with discussion of the process, what went well and what caused problems, and the effect of the different roles on estimation and prioritization.

4) *Team Design and Implementation*: The longest activity, spanning two weeks, is the Robocode[11] project. Robocode itself provides a framework for simulated battles between programmable, robotic tanks. In addition to the battlefield, automated scoring, and various graphic and sound effects, Robocode provides an API for creating new tanks.

In this activity, we introduce pair-programming, and have pairs of students develop their own unique robot from a skeleton we provide. In the first class, each team sketches the behavior they want to implement, and then works on its tank for the remaining time. Near the end of class, all the teams' tanks (as well as a few from the Robocode library) are placed in the arena and the battle begins. After all the flashes, sounds, and mayhem subside, students see where their robot ranks.

Between class sessions, and at the start of the second week, each pair hones its robot based on the first week's results. At the end of the second week, another section-wide battle is waged, with each section's winning robot submitted to the final battle royale at the end of the term. The team that emerges victorious from the final battle has its robot memorialized by a small trophy with a toy tank on top.

The goal of this activity is less about improving student programming skills than it is about working in pairs to develop a software system over several iterations. In addition, planning an adaptive strategy to exploit other tanks' weaknesses reinforces the need for a well-considered and flexible design.

5) *Cross-Team Testing*: Near the end of the term, teams of students from the seminar pair with teams from our second year Introduction to Software Engineering course in a cross-team testing exercise. Each seminar team acts as an independent test team, performing acceptance tests from a test plan prepared by their paired second year development team. We encourage the test teams to take initiative, and expand testing of functionality and usability beyond the boundaries of the test plan.

Both the first year and second year students gain valuable lessons from this exercise. The first year students gain testing experience, and see for themselves the significance of usability design and the importance of validation. In particular, the acceptance test drives home the connection between requirements and black box testing; students realize effective testing does not require access to the source code. The second year teams, in addition to the obvious benefit of having their test plan exercised, see actual users struggle with or delight in the systems they produce.

C. Exposure to the Real World of Software Engineering

Near the end of the term, we turn our attention to software engineering in the world outside of RIT. The primary vehicles for this are a panel discussion with upper-division students and local software developers, as well as a paper summarizing an in-depth interview with a software engineer in industry. These activities are designed to expose students to the real life activities of software professionals, to foster increased interest in and curiosity about the profession, and to clarify any remaining misconceptions regarding work in the field.

As preparation for the panel session, each student submits a set of questions they would like answered. They know that the panel will consist of upper-division students who have completed several co-op blocks, as well as practicing professionals, many of whom are alumni of the program. As a consequence, the questions range from the mundane (“how do I find housing while on co-op?”) to the profound (“what non-technical skills do you find most useful?”). On the whole, our experience has been that students appreciate the opportunity to learn from those with experience, and as a result have a better idea as to whether or not software engineering is the career for them.

The interview paper requires students to find a software developer to interview, to arrange an interview by email or (preferably) over the phone, and to summarize the interview and their analysis of it in a written document. We place a few restrictions on the selection of an interviewee: the person must be engaged in software development or management, may not be a close relative of the student, and may not be selected by more than one student. Occasionally students are unable to find anyone; if the instructor is persuaded that the student made an honest effort, the instructor may tap into his or her professional network for a colleague who will agree to be interviewed.

To overcome student inertia, we provide an initial set of generic questions to help frame the discussion. However, students must supplement what is provided by specific questions of their own. In the best of all worlds, the students have a conversation with the person they select, and such

conversations frequently lead to wide ranging discussions that enhance the student’s understanding of software engineering.

Each student submits a transcript of the conversation and a document reflecting on what he or she learned. Students often describe their preparation, thoughts, and expectations prior to the interview, along with unexpected discoveries as a result of the interview.

The “final exam” is actually a class-wide, collaborative reflection on the course as a whole and the interviews in particular. Once again, students are divided into groups, where they compare experiences and compile a list of observations as to what they have learned during the term. When the class gets together again, teams share these observations. Occasionally instructors impose some structure on the proceedings, such as having teams create mind maps for the course; other instructors take a more freewheeling approach in the interest of spontaneity. Whatever the approach, the class usually ends on a high note with students able to articulate what makes software engineering different.

V. EVALUATION

Part of our curriculum internal assessment is based on student feedback. The opportunity to provide course-specific feedback is afforded to students at the end of each school term via an online anonymous survey. Table I contains student course evaluation data from the last two years when we ran the version of Software Engineering Freshman Seminar discussed in this paper. The columns range from Strongly Agree (SA) to Strongly Disagree (SD) from left to right.

The feedback received in the course’s latest incarnation helps validate both the individual class activities as well as overall student learning. Recurring themes are an appreciation for hands on team activities in a software engineering context, the understanding of how software development benefits from process, and the importance of communication between teams and customers.

TABLE I. STUDENT COURSE EVALUATION DATA

| Question | SA | A | N | D | SD |
|---|------|------|------|-----|-----|
| I learned a lot in this course. | 17.7 | 54.4 | 19.7 | 7.5 | 0.7 |
| In general, the out-of-class assignments were relevant to the course. | 38.8 | 49.0 | 8.8 | 2.7 | 0.7 |
| In general, the in-class activities were relevant to the course. | 53.1 | 37.4 | 5.4 | 4.1 | 0.0 |
| Overall, I would recommend this course. | 43.7 | 33.8 | 16.9 | 3.5 | 2.1 |

Following are representative samples of written feedback we have received:

As I understand it, what I just took in this course was already a rework. Keep it!!! This "intro" course to software engineering was fantastic! It was really great, my favorite course by far!

I enjoyed Software Engineering Seminar and I think it made me feel certain that I'm in the right major, and that I have a thorough understanding of

what Software Engineering is like outside of the classroom.

This course was very informative, and fun. This is a great course and it gives you a great idea about what Software Engineering is like and starts to prepare you for what lies ahead.

We continually struggle with how to impress upon our entering students that software engineering is much broader than the programming they may have done through high school, and even the material they will see in introductory computer science courses. This is a reprise of the concern expressed at the start of the paper that students leave the program before they have seen any engineering. In particular, they need to see that software engineering will not relegate them to a lifetime of low-level coding.

For most of our students, this realization does not really set in until after they have been out on co-op. Our hope is that Software Engineering Freshman Seminar helps students move towards that realization at the outset of their college studies. Based on the following comment, our hope for the course was met, at least for one student:

I felt this interview was very useful. It opened my eyes to how great SE-101 [Software Engineering Freshman Seminar] was. I'll admit I didn't feel like some of the projects were that useful. Until this interview I was a little disappointed we didn't do more coding in class. However, I found that we actually covered the most important topics, like communication, and working with others. It really opened my eyes to what software engineering is really like.

For many students, this first introductory experience reaffirms their desire to pursue a career in software engineering.

VI. FUTURE EVOLUTION

We expect the seminar course to continue evolving in the future. In particular, RIT's impending switch from academic quarters to semesters has forced us to reconsider some of the pedagogy. Our present 10-week course with one two hour meeting per week will expand to a 15 week course with one or two meetings per week. Activities which currently require a full two hours to complete will have to be rewritten or replaced in light of these constraints.

A particular challenge will be process activities, such as the XP game, that require extended time to be effective. One possibility, inspired by field trips in biology and zoology, is to schedule one or two long activities for a weekend, with, of course, sufficient food and refreshments to entice students to participate. The feasibility of such an approach is up for discussion.

We also see a role for expanded coverage of intellectual property issues. Currently we only address these in the context

of proper citation of other's work, but much more could be included that is accessible to first year students. Certainly software engineers need be cognizant of the role played and restrictions imposed by copyrights, trade secrets, and patents.

VII. CONCLUSION

When the term software engineering was first coined, it was mostly an aspiration and a metaphor. Over the past 45 years the term has come to signify a new and exciting engineering discipline. The seminar course we've described is one way in which that excitement can be communicated to the next generation of professional software developers.

ACKNOWLEDGMENTS

We would like to acknowledge the many student course assistants who have helped run this course. They have not only engaged students during class time, but also were responsible for creating content for two of the class sessions. Another invaluable service that they provide is to aid our freshmen students in their adjustment to college life. We regularly note interactions between the course assistants and students in the seminar that are more about how to navigate the ins and outs of the RIT campus and systems than how to set the color of the team's Robocode tank turret using Java.

Abstract - The difficulty in learning and teaching the algorithms and programming subjects is a major concern for managers and teachers of Computer Science (CS) undergraduate courses. These are foundational subjects for CS professionals, yet continue to present a high degree of difficulty in learning for students. This paper presents two experiences we conducted with Computer Science beginner students related to the teaching of computer programming. Results obtained were positive and encouraging in a way that continues to be used with new students in CS courses. We are convinced that other actions like this one are vital for interdisciplinary work, preventing student evasion resulting from the learning environment, casting them as process actors. Algorithms and computer programming are becoming evermore necessary tools for academic and professional development.

Keywords – *programming teaching; algorithms teaching; introductory computing courses; Greenfoot; Python.*

I. INTRODUCTION

Teaching algorithms and programming concepts for first year students of Computer Science courses has always been a great challenge for universities. It is common for students to feel different level of difficulties and several of them abdicate from their courses. The difficulty in learning and teaching algorithms and programming is making managers and teachers of CS undergraduate courses concerned. These subjects deal with key contents for the formation of the CS professional and present a high degree of difficulty in learning for students.

Study habits focused on memorizing and trouble in understanding the wording of problems are some of the factors pointed out as responsible for a high failure rate and consequent withdrawals from algorithms and programming courses.

One of the obstacles for programming teaching is the concept of problem complexity, which must be given a computerized solution. After understanding such a problem, students must design an algorithm through a step-by-step procedure for solving the problem in a finite number of steps. The algorithm does not depend on the adopted programming language during this design phase.

New Computer Science students usually have difficulties in understanding and abstracting the problem logics and transforming it into a step-by-step sequence in order to develop the algorithm later [1].

The primary target of initial programming courses is algorithm design. As these are considered core courses for the CS undergraduate, it is extremely important that students can clearly understand all the concepts covered. However, these courses have the highest failure rates in Computer Science courses.

This fact is due to two factors: a) the paradigm created inside and outside classrooms makes students come to first classes with the fixed opinion that this course will be a great obstacle, extremely difficult to be overcome; and b) some teaching methods used by teachers to present the concepts, because understanding how the computer executes its tasks requires much abstraction ability from the students [2].

Several reasons for student failures in learning algorithms and programming concepts have been described [3]:

- Undisciplined study habits focused on memorizing;
- Unstructured previous knowledge, especially for mathematics and logics domain;
- Non-motivating teaching approaches;
- Taught contents are irrelevant to students' day-by-day lives;
- Difficulties in understanding problem wording;
- High levels of abstraction.

Algorithms learning difficulties faced by first year Computer Science students are many and very well known by researchers. It is especially important that students can clearly understand the problem and the kind of solution required by this problem. After that, student must devise a set of steps to solve the problem. To achieve this goal, it is necessary to rearrange thoughts, which requires much attention and concentration from the student. In the first semester of the course, most beginner students have no prior programming knowledge. Every new concept is a new fright that is really new and requires a different dynamic and logic reasoning.

This is certainly a challenge for teachers of programming everywhere. Some problems may have higher complexity level that makes it difficult for students to think about their solution, and applying programming concepts which are not completely clear for beginner students is not an easy task for them, as for most students they have their first contact to those concepts in the university.

As pointed by [4], students are not motivated or challenged to solve problems with wording like this: “enter five names and grades of students and show the room average, the lowest and the highest grade”. This wording just increases the difficulties listed before, because the problem does not call students’ attention to go into its solution.

About the lack of motivation of students due to complexity and non-attractive problems, even a case with more involvement of the teacher with his students can not improve the situation, because teachers are not able to give attention to all the students and some of them will be set aside, increasing the discouragement environment, very properly to evasion and failures.

In order to arousing more interest from students, it is necessary to suggest other situations which are more usual to their daily activities, and that also challenge them to give a solution to the problem.

According to [5], all students have their own learning potential, different skills, they can learn but in different levels. Even so, algorithm classes are taught as if every student would learn in the same way. It would be extremely important to give students the possibility for each one of them to work those contents in accordance to their own learning rate, in an individualized way.

A proposal for helping the solution of this problem is the adoption of teaching support tools, which use animation and interaction to allow beginner students a better understanding of the contents. Examples of these tools are Greenfoot and Python.

II. GREENFOOT

Greenfoot is a tool developed to allow Computer Science students to get knowledge about Object-oriented Programming (OOP). Greenfoot was a joint production between Kent University researchers, in England, and La Trobe University, in Australia, and it has a differential characteristic related to the development of graphical applications like games creation in 2D environment.

Using the animation and interaction of objects, it is possible to create mini-worlds and represent their objects graphically. Greenfoot makes the objects’ graphical view easier and controls the execution of several tasks. All these can be viewed in a two-dimensional environment, making the understanding and interaction between the objects easier.

Greenfoot has a typical software development environment, with several functions like “edit”, “compile”, “run” the source-code created by the student. The most differential characteristic from other environments is the direct interaction, for example: when an object is instantiated, it is possible to put it anywhere in the “world”, and when a method is called, this action is immediately viewed.

According to [6], this tool can be used for initial and advanced programming courses in universities. Its design and use simplicity draws the attention of those students who are not yet familiar to programming, making the task for teachers easier.

III. PYTHON

Python is an open source high level computer programming language, developed in the end of the 80’s in the Netherlands, by Guido Van Rossum, and was published for the first time in 1991. As any other language, Python aims for software quality, though it was designed to facilitate computer programming learning.

In accordance to [7], Python has some characteristics that make it a good language for programming learning: its syntax is clear and objective; its dynamic typing makes variables automatically determined on execution time; its interpreter returns immediate feedback due to potential errors.

IV. BACKGROUND AND RELATED WORKS

Some authors have discussed about teaching algorithms and programming courses in the first year of Computer Science, emphasizing the high level of difficulty students address [8]. This problem is the reason for the development of this project. We have to conduct this research and carefully analyze the results looking for effective solutions, because learning algorithms and programming is of paramount importance for undergraduate courses with focus on software development. It is common for students to really learn computer programming during the second or third year of Computer Science course, which brings to a great concern about students’ learning rates on those courses whose core is teaching algorithms and programming concepts.

Over the last decades, universities have started their programming courses using algorithms development, as they are the basis for computer programming. It is necessary to change this traditional way of teaching programming, turning into other approaches that can arise more interest from students, working with their daily examples which make them feel challenged to solve the problems [4].

The use of computer graphical tools is a good approach to reach this. Besides drawing students’ attention for being different from pencil and paper, a computer environment can provide challenging situations like in a game, allowing interaction of student to the program under development and presenting its result instantly.

An important research related to our work [9] was conducted at Denver University. They used Greenfoot and other tools with the objective of stimulating students in the

courses of Sciences, Technology, Engineering and Mathematics. That project had an interdisciplinary learning basis approaching drawing to arts, design and computer programming. They described that Greenfoot was chosen because of its functionality and easiness of teaching introductory programming and games design. The research consisted in providing a set of classes to students so that they could develop their own games. At the end, students had to answer a questionnaire and report how important that experience was to them. Most students answered that they could understand better the concepts of classes and objects using Greenfoot. They also answered that, after the experience, they were feeling more comfortable with programming and technology. As a final result, the researchers concluded that it was a very successful experience in teaching programming elementary concepts to young programmers.

On his studies, [10] also reports an experiment to improve Object-Oriented Programming learning, creating groups of students and introducing Greenfoot to them. The learning process was divided into units: on every unit a new concept was introduced and students had a new project to be developed. Each project had a wording and some resources (classes, images) so that students could develop the project using Greenfoot. As projects progressed, fewer resources were given to students; sometimes projects had only the wording problem. In the end of the process, they applied two tests to evaluate students. The results were not as good as they were expecting, but the author emphasizes that there is something very difficult to be represented on numbers of an assessment: the quality of source codes presented by students was much better than the quality of source codes presented by students years before. This happened because when students solve a problem using Greenfoot environment, they have an immediate return about success or failure and then they are motivated to implement the next program.

A research with high school students was conducted in Finland [7], which aimed to give the students: the understanding of data structures and programming basic concepts, writing and testing programs, and producing documents about their work. Authors emphasize that they used Python to introduce programming concepts and the results were very motivating: students reported success feelings when writing and reusing structured programs and when they worked with interfaces.

On the same research line, another project was conducted by [11] in which they taught object-oriented programming to CS students using Python. The language was adopted to strengthen OO concepts, and in the next semester students were presented to other OO programming languages: C++ and Java. Although they are very different languages, if compared to Python, authors reported that students did not bring difficulties in recognizing OO concepts on those last two languages.

V. OBJECTIVES

We consider that all students have their own learning potential, different skills, all they can learn, but not on the same way and the same speed. However, algorithm classes are

mistakenly taught as if every student would learn in the same way. It would be very important to provide students the possibility for each one of them to work those contents in accordance to their own learning rate, in an individualized way, using a contrutivist pedagogic model where students construct their own knowledge instead of passively absorbing it in a classroom [12]. In accordance to Constructivism theory, students are motivated to construct their knowledge rather than merely receiving and storing knowledge transmitted by the teacher.

On this work we present an experience for helping the solution of this problem with the adoption of teaching support tools for programming contents. We will present the results of two experiences we have conducted for getting better results with computer programming teaching: the first one, in 2010, was undertaken with first year students of Computer Science course using Greenfoot tool; the second one, in 2011, targeted last year high-school students using Python programming language. It is important to emphasize that our main focus on this work is introducing programming concepts for CS students, using Greenfoot and Python, but not on the tools adopted. The two experiences will be related on the next two case studies.

VI. CASE STUDY 1

In order to know better the effectiveness of Greenfoot for teaching object-oriented basic concepts, we conducted this first case study with 30 students in the first year of Computer Science at FEMA. This study was divided into four steps: identifying the students' OO knowledge, OO introductory course, Greenfoot course and assessment.

1st Step: Identification of Student's OO Knowledge

Before introducing the OO basic concepts, we applied a questionnaire to identify the students' OO knowledge level. The questionnaire form had 25 questions and, for each one, students should give an answer in a scale from 0 to 5, where 0 meant no knowledge about that topic and 5 meant deeply knowledge about that topic. About the topics, 21 of them were directly linked to object-oriented and 4 of them were about algorithm basic concepts. With that, we could extract some important information.

About the 21 topics related to object-oriented:

- 54.54% answered 0, what means that they knew absolutely nothing about those concepts.
- 28.57% answered between 1 and 2, what means that they knew very little about those concepts.
- 13.7% answered between 3 and 4, what means that they already knew those concepts.
- Only 3.17% answered 5, meaning that they knew those concepts very well.

After identifying and analyzing students' knowledge, we elaborated the strategies for the next steps.

2nd Step: Object-Oriented Introductory Course

As we concluded from the first step results, most students didn't have any knowledge about OO concepts. So that they could have a productive experience with Greenfoot, then we provided them with introductory lessons about OO. On those lessons, students were taught with OO main concepts: classes, objects, attributes, methods, polymorphism, inheritance, aggregation and composition. During the lessons, students were also asked to solve exercises for practicing the contents.

This was an important step for giving students the basic knowledge about object-oriented and they can transform their theoretical knowledge into practical ability on next step.

3rd Step: Greenfoot Course

After getting in contact with object-oriented concepts in the previous step, students were introduced to the most interesting part of this case study: Greenfoot classes and the development of a game.

In this step students had Greenfoot practical classes and were introduced to examples so that they could understand the OO concepts application. Such examples were introduced in a sequence to facilitate the learning.

The first example aimed to reinforce some OO concepts and students were also introduced to software interface, how to invoke methods from Greenfoot objects, methods return types, and methods parameters. Students were familiarized to software interface and remembered the contents of second step.

In the second example, a very important concept was practiced: inheritance. They could also work more with method parameters, learning how to edit classes' source code using Greenfoot Classes Editor.

In the third example students had more contact with the source code, increasing their knowledge. At this moment new concepts were introduced: method signature, indenting and class compilation.

In the end of all examples students needed to solve some problems, using the concepts learned. While they worked on the solution of the problems, it was remarkable students' excitement and how easily they used Greenfoot. Most students could successfully solve the purposed problems, and some of them could create new functionalities.

4th Step: Assessment

In the end of this case study, we conducted an assessment to evaluate what and how much students learned about object-oriented concepts. This assessment was not about Greenfoot, but it was about OO concepts. The grades obtained by students on this assessment process were:

- 16.67% got 2.0 to 3.9 points
- 23.33% got 4.0 to 5.9 points
- 36.67% got 6.0 to 7.9 points

- 23.33% got 8.0 to 10.0 points

- The average was 7.50 points

- The standard deviation was 2.084.

This assessment showed us that most students had more than 60% of success in learning the contents taught. Results set out the growth of students' knowledge about OO concepts.

VII. CASE STUDY 2

With the objective of verifying the contribution of Python language in algorithms and programming teaching and learning, we conducted a case study with 35 High-School students at Centro Paula Souza School.

These students were having the first classes of algorithms and programming, so they were getting into contact with those concepts for the first time in their lives. Teacher had taught these contents: variable types, conditional structure and looping structure. The teaching methodology adopted was teaching theoretical classes and presenting problems with mathematical and day-by-day wording to the students.

The same strategy adopted on case study 1 was also adopted for this case. The study was divided into four steps: identifying the students' OO knowledge, Python language course, assessment about students' capacity in solving problems and final assessment to verify students' learning.

1st Step: Identification of student's knowledge about algorithms construction

Students were asked to respond a questionnaire which aimed to identify their knowledge about algorithms contents and the use of pseudocode for problem solution. The questionnaire form had 25 questions and, for each one, students should give an answer in a scale from 0 to 5, where 0 meant no knowledge about that topic and 5 meant deeply knowledge about that topic. We extracted the following information from their answers:

- 73.70% answered 0, what means that they knew absolutely nothing about those concepts.

- 18.40% answered between 1 and 2, what means that they knew very little about those concepts.

- 6.3% answered between 3 and 4, what means that they already knew those concepts.

- Only 1.60% answered 5, meaning that they knew those concepts very well.

Starting from that scenario, we conducted the next three steps of this case study.

2nd Step: Python Language Course

The first step emphasized that most students answered they had no knowledge about algorithms construction. This was an important information for the teacher to adequate the Python material for students. On this course, the focus was: variables,

logical and relational operators, condition structures, looping structures and Python language characteristics.

3rd Step: Assessment about students' capacity in solving problems

After the second step, students had an assessment with 13 questions, aimed to evaluate how much they learned about computer programming concepts. This assessment was not exclusively about Python language but about students' capacity in solving specific problems. Students' grades were:

- 11.43% got 2.0 to 3.9 points
- 22.86% got 4.0 to 5.9 points
- 28.57% got 6.0 to 7.9 points
- 37.14% got 8.0 to 10 points
- The average was 6.51 points
- The standard deviation was 2.23.

4th Step: Final Assessment

This final assessment applied to those 35 High-School students had 20 questions about their satisfaction degree about Python course and the assessment at third step.

The data gathered from this final assessment were used to find evidences about the perception of success or failure pointed by students. Likert scale was calculated for every question in the final assessment to getting students' general satisfaction with the methodology we had adopted.

We considered Likert scale from 1 to 7 for this assessment. We considered as negative perception for answers with levels 1-3, as positive perception for answers with levels 5-7 and as neutral perception for answer with level 4.

The results obtained with data gathered from students' answers were:

- 17.1% answered in the scale 1-3, meaning a negative perception about their satisfaction;
- 14.3% answered in the scale 4, meaning a neutral perception about their satisfaction;
- 68.6% answered in the scale 5-7, meaning a positive perception about their satisfaction;
- The standard deviation was 1.706.

We got very encouraging results, as they showed an important value related to motivation and beliefs of students. Even considering that this was a subjective assessment, this scenario converged to the assessment we had on third step.

VIII. CONCLUSIONS

This work aimed to present the experiences in using two methodologies for computer programming teaching in CS introductory courses. Computer tools were used as pedagogical

basis, with the objective of providing practical activities fomenting the study assessment process.

We conducted two case studies. The first one was taken with 30 undergraduate students in the first year of Computer Science, in which we worked with object-oriented teaching and Greenfoot software. The second case study was taken with 35 High-School students, in which we worked with algorithms and programming teaching and Python language.

In the first case study we could compare students' knowledge level about Object-Oriented concepts before and after our project. It was evident in the answers gathered on first and fourth steps. In the first step we concluded that 54.54% of students had no knowledge about object-oriented concepts and the fourth step showed us that most students had more than 60% of success in learning the contents taught. Results set out the growth of students' knowledge about OO concepts. Furthermore, it is important to highlight the students behavior when using Greenfoot, they felt motivated and had fun solving the proposed problems, and these are essential factors for facilitating the learning.

In the second case study we concluded that most students (92.1%) had no knowledge for constructing algorithms. In the end of this case, we could verify that 59.71% of students had more than 60% of success in the assessment. In this case it was clear that students could construct programs only after understanding the concepts of algorithms. Python language has an important role for having a clear presentation and is coherent with the initial strategies for computer programming teaching. Due to Python having a simple syntax, if compared to other languages, it was easier to introduce programming concepts to High-School students, emphasizing programming and problem solution.

Abstract — Building written feedback, pedagogically sound, standardized and flexible enough to accommodate students who may be in different stages and learning curves is a complex and laborious task. In this paper, we describe a multinational case study involving diverse types of pedagogical feedback provided to Portuguese and Brazilian novice programming students. Programming errors, especially logical ones, can be used as a consistent metric for assessing learning. The research done looks for an innovative form to define content of several types of feedback. It also aims to create an efficient method for the discovery and mapping of students' logical programming errors. The results obtained so far using this approach are presented and analyzed.

Keywords - feedback; programming learning; logical errors; software testing; pedagogical rubric

I. INTRODUCTION

Students' difficulties in introductory programming learning are a well-known problem that motivated many researchers to propose methodologies and tools to help students [1].

Good feedback is essential to improve students' learning in Higher Education (HE) [2, 3]. They can learn more effectively if they receive quick and appropriate feedback about their actions in a short amount of time. However, creating written feedback, pedagogically sound, standardized and flexible is a complex and very time-consuming task.

When classes have many students, as it is common in introductory programming courses, feedback creation can be a huge task for teaching staff. In this context, developing methods and tools that may automate feedback creation, even partially, may be a good help for teachers' work and improve the support available for students during the course. That is the main objective of our work.

Ihantola et. al. [4] made a systematic literature review about systems for automatic assessment of programming assignments. They also discussed strategies to design good assignments from a pedagogical perspective. They concluded that not all programming exercises could be automatically assessed and also that many research projects do not offer guidance on how to overcome automatic assessment limitations.

One of the limitations of current automatic assessment tools, such as Mooshak [5] or Boss [6], is the limited quality of

automatic feedback they generate. The feedback text is fixed and little detailed. For example, in Mooshak the feedback is limited to small expressions, such as: "accept" (passed all tests), "presentation error" (mistake in input or output formatting) or "wrong answer" (failed in some tests). This is not surprising as Mooshak main objective is to support programming competitions, although it has been also used to support pedagogical activities.

There are also tools for automatic grading of programming assignments [7], but in many aspects they still require a direct inference of the teaching staff [8].

We decided to propose a semi-automatic solution that combines some types of pedagogical feedback with software testing techniques adapted to common introductory programming assignments. To define the assessment criteria consistently we used rubrics.

As we want to automatize the process as much as possible, separate steps have to be considered: logical error detection in students' assignments (programs), definition of the best feedback model to use, and adequate feedback creation and delivery to the student.

In section II we propose a method for error discovery and for students' assignment evaluation (considering common assignments in introductory programming courses). In section III we discuss several types of feedback and present a methodology for feedback creation in the context of introductory programming courses. In section IV we describe and discuss the first application of our proposals, in the context of a multinational case study that involved non-majors introductory programming courses in Portugal and Brazil.

II. DISCOVERY AND PEDAGOGICAL MAPPING OF PROGRAMMING ERRORS

To provide proper feedback to students it is necessary to detect logical errors in their assignments. Teachers know very well the logic of the assignments they suggest to students. Even without an explicit method, they can inspect students' source code and verify if it works or in which cases that doesn't happen. They intuitively use a set of test cases to verify if a solution is correct.

However, manually correcting a high number of assignments is a hard and time-consuming task. It would be

useful to have a system that helps teachers, namely analyzing students' assignments and producing the corresponding feedback. This would also allow that the testing and feedback is consistent for all assignments and for all students.

A general idea about the proposed method is presented in Fig. 1. For a particular assignment, its proponents (teaching staff normally) need to produce several pieces of information:

- The assignment description, including input examples and corresponding output (test automation needs a rigid formatting of the inputs and outputs, so it is important that students follow that formatting).
- A rubric that includes the programming aspects to verify in the students' solutions, and classification criteria to each of them. Rubrics are effective if we can enumerate exactly the qualities and the assessment criteria that the students are expected to achieve in each grading category [9].
- A correct solution for the problem.
- Set of test cases necessary to fully evaluate students' solutions and feedback sentences corresponding to the possible results of those tests (supported in the rubric defined for the particular assignment).

On their side, students have to interpret the assignment and propose a solution. Taking in consideration the test cases and the rubric defined for the assignment, the system tests each solution and produces feedback in function of the results.

In this section we focus on the method to discover and map students' logical errors.

To test a solution properly, it must be ensured that each line of code is run at least once. Therefore it is necessary to find the smallest number of test cases that guarantees this requirement. This number should be as small as possible to simplify the mapping of the set of test cases into feedback content, although some extra test cases might be pedagogically useful, for example to identify common errors novices make in that particular assignment. Mathematically, this problem can be solved using the cyclomatic complexity metric defined by McCabe [10]. This set of test cases should completely test the control flow graph (CFG) of a solution. A CFG is a representation, using graph notation, of all the paths that might be traversed through a program during its execution [10].

There are several free tools available to calculate the cyclomatic complexity of a solution. We used cyclo 2.0 [11]. It analyzes the cyclomatic complexity of ANSI C or C++ code. It calculates the minimum number of test cases necessary for a particular solution. After that it is necessary to identify those test cases and see which lines of code they cover in the solution. This can be done during code execution. We used the GCC (GNU Compiler Collection) compiler and the tools developed for it to verify the test coverage of source code (Gcov). We also used another free tool, called LCOV [12], for the dynamic visualization of the source code. It is a graphical front-end for coverage testing using Gcov. LCOV supports statement, function and branch coverage measurement.

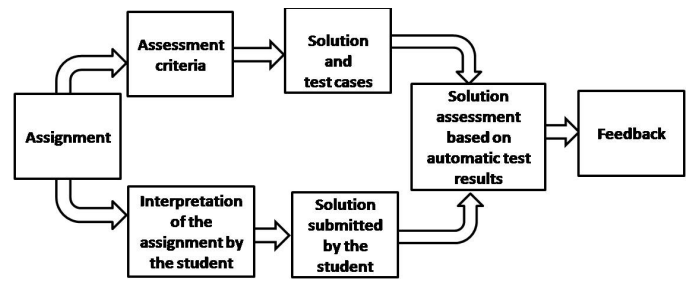

Figure 1. General working schema

The method proposed will be illustrated with a small example. Consider that the aim of an assignment is to read an integer between 100 and 999. If the sum of its digits is even, a zero should be added to the right of the number, and if the sum is odd, a 1 should be added.

In this case the cyclomatic complexity is 2 because there are only two possible linearly independent paths in the CFG of the solution. It is necessary to use a decision point, implemented in C by an if-else statement, that verifies if the sum of the digits of the number read is even or odd. It is necessary to define which are the two test cases necessary and sufficient to traverse these paths.

Looking at the decision point of the CFG, with the help of Gcov and LCOV, two inputs were chosen to test the solution: one number with an even sum of its digits and another number with an odd sum of its digits. As expected, after running the two test cases LCOV indicates 100% coverage, guaranteeing that all code lines were executed at least during one of the runs. It is possible to determine interactively which lines are executed in each test case.

Of course, having only test cases that test the expected solution is not enough, as some students' will likely submit solutions that are far from expected. So there is the need to define a set of test cases that are able to test logically equivalent solutions. A solution is logically equivalent to another if they have the same results when submitted to the same set of test cases (that tests all the program logic).

The information about each test success or failure can be used to map and simulate experimentally possible students' logical errors. Moreover, it is also desirable to create new test cases to facilitate the mapping of logical errors in students' incomplete or partially correct solutions. Also test cases can be created to identify common errors made by novices in that particular assignment (normally teaching staff has a good knowledge about this from past experiences).

The definition of test cases can be time-consuming (although Gcov and LCOV can give a good support). However, it is important to note that the time spent will allow a stronger learning support that done manually would mean much more time. Also, it is worth noting that this work is done once for assignment, but can be used many times, including in different courses and years.

III. BUILDING PEDAGOGICAL FEEDBACK

Feedback used in educational contexts is often seen as very important to improve knowledge and skill acquisition. In

addition to its influence on achievement, feedback is also seen as a significant factor in motivating learning. It is possible to find in literature a large number of research reports on feedback and its influence on learning. Many types of feedback have been proposed and different strategies for its implementation in pedagogical contexts have been suggested [2, 3, 13]. Reports are often divergent on the best type of feedback for a particular situation. It is also possible to find divergent views about what to include in feedback messages, and even in the amount of information that is more effective to reach the pedagogical objectives.

For the purpose of this study we chose three models of pedagogical feedback. Two of them are classic and very well known: formative and summative feedback, while the third is less known and used: ipsative feedback.

Formative feedback can be seen as information that is communicated to the learner to modify his/her thinking or behavior for the purpose of improving learning. Information may address the accuracy of a response to a particular problem or task and may additionally touch on particular errors or misconceptions [13].

Summative feedback is connected to summative assessment that usually is made for the purpose of assigning grades to students. So, the main aim is to find errors and judge them consistently and coherently [14]. The result of that assessment is then communicated to students in summative feedback.

Ipsative feedback is based on a comparison with the learners' previous performance and linked to long-term progress. The idea is to inform the learner about his/her performance in a specific skill developed in the long term. This type of feedback may have a higher impact on motivation, as it may stress the improvements shown by the student in a particular topic during the time. This is particularly interesting in programming learning, as students often get discouraged when they don't recognize progresses in their learning. After all it is expected that the student makes progresses and ipsative feedback may help the student to recognize them [15]. When compared with formative and summative feedback, ipsative is much less known and used, as we couldn't find any other research project that uses ipsative feedback in computer science education.

Although contextualized feedback is important to learning, it is difficult to implement in the form of an automatic pedagogically consistent assessment and feedback system [7].

In the next sections we describe the feedback creation process we propose for the context of introductory programming learning. It is based on the information about the assignment described in section II and in the student solution proposal to that assignment.

A. First stage - Creating basic pedagogical feedback

In our context, feedback content depends essentially on the programming errors made by the students and the model of pedagogical feedback in use.

As mentioned in section II, we use rubrics to consistently define the assessment criteria to be used. Rubrics should include the logical parts to verify, but also the quality criteria

for each of them (for example expressed in a qualitative scale of four levels: excellent, good, fair and poor). The number of parts to consider in an assignment and their weight in assessment depends on what is considered pedagogically important by the teachers involved. Normally, in the context of introductory programming learning, teachers are more concerned with the logical errors students make when devising a solution for a particular problem. So, in this case, rubrics will be focused (or contextualized) in the logical aspects of the proposed solutions.

The rubric criteria are associated with the test cases defined for the assignment, allowing the system to make an evaluation of which criteria were successfully met and which weren't by a particular student solution.

Our research approach supports the definition of rules connecting feedback text with combinations of test cases results. It is possible to have direct associations, for example some text that should be included in the feedback if a particular test case fails. It is also possible to have multiple associations, connecting a feedback text with a more complex situation, for example test cases 1 and 2 are successful, but test case 3 fails.

Hence, at the end of this first stage the results of test cases run on the student solution originate feedback contents that will help the student to understand the tests' results. With this information it is expected that the student reflect on the mistakes made. Hopefully this reflection may lead to learning, and, if necessary, the student will be able to improve the proposed solution.

B. Second stage – Model dependent feedback content

It is possible to enrich the feedback created in the first stage, so that it can be more useful for students. In the second stage the software test results are interpreted under the perspective of summative, formative and ipsative feedback theories [2, 3, 14]. The information given to students depends on the type of feedback the teacher feels more adequate in a particular situation.

In summative feedback it is necessary to include information about test cases where the student solution failed, and possibly also some grading information that comes from the mapping between the successful test cases and the rubric for the assignment.

The aim of adding formative information is to stimulate learning and motivation. This can be achieved including also positive aspects in the feedback, namely the test cases the solution passed successfully. Formative feedback can include also study indications, such as suggestions to read some material and indications to solve some other problem that might help the student to get insights on how to solve the current assignment.

In the ipsative feedback approach it is important to give not only feedback about the current assignment, but also some information about the student evolution in the course or the current module. Of course this past information must have been collected in previous assignments, facilitating its reuse in the current assignment.

To facilitate the understanding about the three types of feedback considered in our work, we will exemplify what could be sent to students that made a common error in the same assignment already used above: instead of calculating the sum of the digits and then check if it is even or odd, the student simply verifies if the number is even or odd. In such a case the solution would pass the test cases where both the sum of the digits and the number itself are even or odd, but it would fail otherwise.

Summative feedback would care about the test cases that failed and include the corresponding information. It would also include explicit grading information about the submitted solution. For example: “Your solution failed in all tests where the sum of digits is even and the number is odd and conversely. So your solution is not correct and was graded with 30%”.

In the same situation, formative feedback would include the result of all test cases and the corresponding information. It would also include some extra suggestions and hints for study and improvement. For example: “Your solution verifies if a number is even or odd and adds a 0 or a 1 to it. However, the assignment asked you to verify if the sum of the digits of a three-digit number is even or odd. So, your solution does not answer what was asked. Please check exercise 3 available in our course LMS, since there are some similarities to what you should have done in this exercise. Next time you should read the assignment description more carefully.”

If ipsative feedback were used, it would include information about the failed test cases and associated information. It would also include some contextual information, both about the assignment objectives, the student performance in previous assignments and other information about the student participation in the course (e.g. previous assignments not submitted, missing lab classes, results of previous assessments and others. It could be: “This assignment objective was to see if students were able to decompose a number in its digits and verify if the sum of the digits was even or odd. Your solution doesn’t solve the problem completely, since it fails in all tests where the sum of digits is even and the number is odd and conversely. This is the 3rd out of 4 assignments that you cannot solve as expected. You should commit more in the course. Remember the first test is three weeks from now. It might be a good idea if you ask some guidance from your teacher.”

Of course, it would also be possible to use mixed approaches where feedback would have characteristics from more than one type. However, it is important to keep feedback messages simple and direct, so that there are no misunderstandings from the student (the student might be tempted to skip long or complex messages).

C. Third stage – Personalized pedagogical feedback

In some cases it can be necessary to introduce some individualized information in the feedback, e.g., some remark about code quality or presentation issues. This appreciation cannot be done automatically. So, this possibility should be used exceptionally, as it may add a significant load to the teacher work.

IV. EXPERIMENTAL STUDY

A. Brief description

To make a first test to our approach and to gather information that might help us to improve it, we organized a multinational case study in the context of non-majors introductory programming courses. It includes novice students from Industrial Management Engineering of the Faculty of Sciences and Technology (FCTUC) of the University of Coimbra (UC) in Portugal and students of Civil Engineering and Food Engineering from the Institute of Informatics (INF) of the Federal University of Goiás (UFG) in Brazil. In total, these courses included 114 students (30 in Portugal and 84 in Brazil), 4 teachers and 4 monitors. In all courses the C programming language was used.

In order to compare the effects of the three feedback models considered, students’ solutions were classified using the same metric (mainly logical programming errors) and the same rubrics. Also the error discovery methods and the sets of test cases were common in all cases. Test coverage of 100% was guaranteed in the test cases used in all assignments. This was confirmed experimentally using LCOV.

The students involved in the three courses made a total of 1256 submissions that were tested using the semi-automatic method of discovery and mapping of programming errors described in the previous sections. However, for our study purposes we only considered the submissions that corresponded to a set of 10 assignments that were common to the three courses. This set was agreed with all the teachers and involved the key issues of the course syllabus (each teacher proposed other assignments only to their students). There were a total of 919 submissions to the 10 common assignments. As some students submitted a low number of solutions, we decided to consider only as participants students who submitted at least 50% of the set of common assignments, which corresponded to 795 submissions (Table I).

It was also defined that assignments would be solved in groups of two students, but only one of them would submit their solution. However, the feedback would be sent in individual e-mails to ensure that all students would have access to the same information.

In Civil Engineering and Food Engineering students were allowed to resubmit solutions after they received feedback about their first attempt. The same didn’t happen in the Industrial Management Engineering course.

TABLE I. NUMBER OF SUBMISSIONS AND TYPES OF FEEDBACK USED IN THE COMMON ASSIGNMENTS

| Feedback Model | Engineering course | | | | |
|----------------------|---------------------------|------------|-----|-----------|-----|
| | Industrial Management Eng | Civil Eng. | | Food Eng. | |
| | | 1st | 2nd | 1st | 2nd |
| Summative | 60 | - | - | - | - |
| Formative | 38 | 227 | 120 | - | - |
| Ipsative | - | - | - | 222 | 128 |
| Total of submissions | 98 | 347 | | 350 | |

Mooshak was used for automatically run the set of test cases defined for an assignment on each solution proposed for that assignment. Each test case consisted of an input to the solution and the expected output that was compared with the solution-generated output. As a result, teachers and/or monitors had access to which test cases a particular solution passed or failed. With that information and the mapping between test cases results (alone or in combination) and feedback texts, it was possible to easily compose the feedback messages to send to each student after a submission.

In the next two sections we will present the results obtained in each of the experiments.

B. First experiment - Portugal

The first experiment was done in Portugal, in the first semester of the 2011/12 academic year, with students of Industrial Management Engineering. Students were divided in three lab classes. Students from two of them received summative feedback for their solutions, while students from the third class received formative feedback.

With a few exceptions students received one assignment per week during the course. Feedback was sent to the students in a short notice (2-3 days normally).

It was decided that students' participation would be voluntary, meaning that this activity would not count for the final grading. Maybe because of this decision, only 30 out of the 90 students could be considered participants in the study (33.33%), accordingly to the rule defined.

Considering the average results of all assignments submitted, students who received formative feedback had a performance that was 26.26% higher when compared with students who received summative feedback. Of course we can question if this difference was influenced by the difference in feedback. We verified also that on average the formative feedback students submitted more assignments than their colleagues (the difference was 12,5%). Although we suspect that other variables in the learning process might have contributed to these differences, we believe that the different feedback received had also some influence. This was also supported by informal feedback during classes, making us believe that formative feedback was more appreciated than summative feedback.

C. Second experiment - Brazil

The second experiment was done in Brazil, in the second semester of the 2011/12 academic year, involving 96 students of Civil Engineering and Food Engineering, divided in 4 lab classes. As we used the same rule to define who were the participants, only 84 students (87,5% of the total) were considered participants of the study.

In this experiment we decided to use formative feedback and ipsative feedback. The former was used with Civil Engineering students and the later with Food Engineering students. In this experiment, students were allowed to make a second submission of the assignment after they had received feedback about their first attempt. Table II shows the summary of results obtained in this second experiment.

TABLE II. SUMMARY OF SECOND EXPERIMENT SUBMISSION RESULTS (BRAZIL)

| | Civil Eng. | Food Eng. |
|--|---------------------------|--------------------------|
| | <i>Formative Feedback</i> | <i>Ipsative Feedback</i> |
| Correct solution in 1 st submission | 32.92% | 20.21% |
| Partial improvements in 2 nd submission | 12.26% | 23.82% |
| Correct solution in 2 nd submission | 27.91% | 20.38% |
| No improvements in 2 nd submission | 12.86% | 13.20% |
| No 2 nd submission | 14.05% | 22.39% |
| Total | 100% | 100% |

All students that solved the assignment correctly in the first submission were not considered for the comparison of the feedback models. Comparing both submissions allowed accessing the evolution students had after receiving the feedback.

Consulting table II, it is possible to say that formative feedback had slightly better results, as there was a higher percentage of completely correct 2nd submission solutions. Also the percentage of formative feedback students who made second submissions was higher. On the contrary, it is possible to conclude that a higher percentage of students who received ipsative feedback showed partial improvements in their second submissions, without reaching the completely correct solutions.

V. CONCLUSIONS

The construction of consistent and pedagogically contextualized feedback for introductory programming students requires a methodology focusing on helping them overcome their learning difficulties.

The feedback models must be based on consistent assessment models, because otherwise feedback content can be, at best, useless and, at worst, dangerous, as it simply would not effectively measure and detect students flaws or produce useful information in pedagogical terms.

We created and experimentally tested a semi-automatic method based on software testing and rubrics for programming errors discovery and mapping in feedback texts. The results of software testing and rubrics can contain information that allows judging learning from the point of view of the correct application of the programming logic and also of good practices (comments, coding style, etc.).

This method is able to discover and pedagogically map students programming errors in information used by three different feedback models, namely formative, summative and ipsative. There are, however, some restrictions for applying any method based on automatic software testing, such as solutions with syntax errors, plagiarism, or solutions that use logic explicitly prohibited in the assignment.

In the experimental study, students who received formative feedback showed a higher percentage of completely correct solutions when compared to their colleagues.

In some cases, we observed that students who received ipsative feedback had the perception of being monitored closely, as feedback received included information about their evolution and commitment in the course. This may be positive to some students who have better performance when they feel closely monitored.

After analyzing the experimental results we can conclude that pedagogically well-constructed feedback helps students to reduce the number of logical errors in some extent. This influence depends on the model used. In general, we think feedback has a positive influence on the learning process in introductory programming courses.

It is important that feedback generation can be done without representing a significant increase in the teachers' workload. Although we already used some available tools to support the different steps in our work, our aim is to increase the automation of the full process, giving to the teachers a web-based tool that automatizes feedback generation and management as much as possible (possibly integrating some of the already used tools). This tool should allow the generation of feedback based on different models. This will be the next step in our work.

Abstract—This paper focuses on understanding and developing learning environments for computer science education. We present two models that we have successfully used in European and African contexts. The first model, Computer Science Learning Environments (CSLE), presents seven dimensions of computer science courses, which should be considered in learning environment design for computer science. The second model, Investigative Learning Environment (ILE), presents an action plan model, inspired by action research, for combining educational research and computer science teaching. In the empirical section we outline two case studies where these models were used to design and implement computer science learning environments in two different learning contexts. In the first case in University of Helsinki, Finland, we developed and studied a method of learning-by-inventing in a robotics programming course. That course was designed around problem discovery and inventing, and it employed LEGO® Mindstorms robots. In the second case in Tumaini University, Tanzania, we designed an environment for studying and improving introductory programming courses. Both models showed to be useful for designing, implementing, developing, and analyzing the courses in both learning contexts.

I. INTRODUCTION

Computer science education is a widely studied and intensely discussed topic. The literature proposes a variety of pedagogical viewpoints, practical approaches, learning theories, motivational vehicles, and other elements related to the learning situation. Recent pedagogical trends include, for example, problem-based-learning (PBL), inquiry learning (IL), and other student-centered learning practices, which are argued to increase motivation [1] and to support deep-level learning [2]. There is also contrasting evidence, speaking in the favor of more traditional, teacher-driven learning practices [3]. Evidence on cultural or contextual factors for the learning environment is also inconclusive. There is no coherent understanding on how pedagogical approaches work in different courses and in different contexts in computing education.

This paper presents a conceptual framework for classifying and analyzing learning environments in computer science. That framework consists of seven groups of variables. The model has developed as a part of an action-research ap-

proach of developing computer programming courses in two universities—one in Finland and one in Tanzania.

In the Finnish university we designed and studied *learning-by-inventing* by using LEGO® Mindstorms as a vehicle for learning. The experiment was iterated three times. In the Tanzanian university we designed and studied various pedagogical approaches to support deep-level learning and intrinsic motivation in computer programming courses. That experiment was iterated twice.

II. CS LEARNING ENVIRONMENTS: A CONCEPTUAL FRAMEWORK

A *learning environment* is a combination of teaching practices, physical surroundings, students' learning processes, and assessment. Learning environment provides scaffolding for a desired learning trajectory, which is a path that a learner takes to accomplish the learning goals [4, 61–70]. A learning environment generates destructive friction if it is too strictly or too loosely structured in relation to a student's self-regulation skills, while constructive friction emerges from a proper amount of shared control between the teacher and the student [5]. A learning environment should also activate the student's zone of proximal development (ZPD) [6].

In the context of computer science education we propose a combination of variables that should be determined in order to configure the learning environment efficiently: *tradition of computing, objectives and assessment, problem types, problem management, teaching style and social interaction, motivation and sociocultural context, and control*.

1. Tradition of Computing: Computer science consists of three intertwined traditions [7]. The theoretical tradition deals with verifiable theoretical structures, such as algorithms, data structures, and their properties. The engineering tradition aims at working implementations, products, and inventions. The scientific tradition aims at finding causalities and generalizations based on models, theories, and laws. The traditions upon which different curricula and courses are rooted bring great variation to each curriculum's problem types and to

suitable pedagogical approaches [8]. Although the traditions are deeply interwoven, most learning situations emphasize one of the traditions over the others. The traditions are often tacit within a department's ethos, and thus invisible to the teacher and/or the learners. As each tradition of computing determines techniques, theories, and working modalities in computing practice, it is a root determinant of the learning environment, and should not remain a tacit, invisible, or subliminal component of teaching.

2. Learning Objectives and Assessment: Learning objectives and their assessment usually derive from the traditions of computing. How easy it is to evaluate whether students reached the learning objectives depends on the objective. While it is relatively simple to evaluate learning of factual information or the ability to solve a first degree equation, it is certainly not straightforward to evaluate the acquisition of new learning skills or problem-solving skills, such as deep-level or active learning skills. The manifold learning objectives makes evaluation of learning environments a complex task that requires methodological and pedagogical competence. In one related study [9], it took researchers several years to be able to measure the acquisition of activating learning styles. Also, the learning environment and assessment tasks should be in proper *constructive alignment* [10, pp. 95].

3. Problem Types: A variety of problem types can be found in education. Those include, for instance, logical problems, algorithmic problems, story-problems, rule-using problems, decision-making problems, troubleshooting problems, diagnosis-solution problems, strategic performance problems, case-analysis problems, and design problems [11]. Problems are subject-relative, and context-dependent [12, pp. 76], and also problems can be classified according to their openness. In closed, or well-structured problems the starting point, solving technique, and goal state are known [13]. In open or ill-structured problems the starting point, technique, and goal can all vary from closed to open. Other classifications include the dimension between pseudo-problems, authentic problems, and ethical problems. The selection of problem types is usually related to the computing tradition and learning objectives.

4. Problem Management: Solving a problem is often only one stage in a process of solving multiple problems. Many problems raise more new problems than they solve, and thus the process of managing the solving of multiple problems is important. In computer science problem management can be closed (the teacher gives students certain problems, such as weekly theoretical exercises), or it can be done according to an industry-standard software engineering model (in software development courses of the engineering tradition), or it can be more open (a science-like research project or a design-oriented software course).

5. Motivation and Sociocultural Context: Emotions affect motivation and performance [14]. Task involvement is fostered by many emotions, and solving a challenging task often requires a range of emotions. The learning environment should promote a balance between feelings of competence and feelings of challenge [15]. Imbalance leads to a decrease in

concentration and involvement. As a rule of thumb, a too high challenge is better for concentration than a too low challenge [15]. Another theory argues that intrinsic motivation is a favorable state for learning, and it can be supported by a proper combination of autonomy, relatedness, and competence [16]. There again, emotional and motivational support requires understanding of the broader sociocultural context of the learning environment, such as power distance between teachers and students, cultural norms for classroom interaction, and individualistic versus collectivistic study habits.

6. Teaching Styles and Social Interaction: A common distinction between teaching styles is that between teacher-driven, or instructivistic teaching styles and student-centered, constructivistic teaching styles. In instructivistic teaching, the teacher is in full control and feeds students with information, while in constructivistic teaching, the teacher works more as a coach, who directs and helps students to find their own learning paths. A professional teacher can select his or her teaching style and classroom interaction types based on the selected tradition of computing, objectives and assessment, problem-, and problem management types, and context of education. Another important aspect concerning social interaction in coursework is the choice between individual work and groupwork.

7. Control: An open environment grants full control to a student, while a closed environment gives the teacher full control of the learning situation. The level of openness has triggered heated conversations between pedagogues, and it has given rise to pedagogical approaches such as PBL and IL, which stress the benefits of openness in the knowledge construction process. There again, some argue that for some learner groups, such as novice learners, too much openness is detrimental to learning [3].

The seven variables above constitute our conceptual framework for analyzing, designing, and evaluating learning environments. Theoretically speaking, teacher can configure a learning environment by freely adjusting the variables above. In practice, the configuration options depend on the skills of the teacher and the characteristics of the surrounding context. To develop new learning environments and to develop one's teaching, risk-taking, new experiments, and research is needed. Those are not always promoted by the traditional models of teaching. The following chapter presents an action-research based approach to teaching, which has, in our work, shown to be a powerful vehicle for designing and studying new learning environments.

III. INVESTIGATIVE LEARNING ENVIRONMENT

Traditional teaching consists mainly of teaching acts. But as such, teaching acts do not support research very well. Our proposed approach extends teaching to contain both teaching acts and research acts. Thus, in our approach, a number of research-oriented activities are explicitly included in teaching. Our approach includes, in a cyclical process, a background study; a literature study; a detailed plan for teaching, designing and conducting research; teaching and researching in collaboration

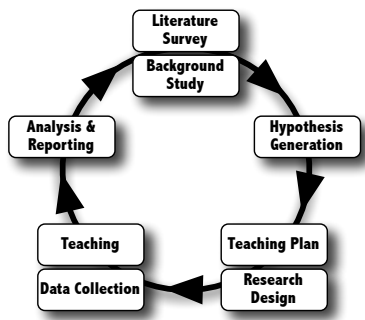

Fig. 1. Cycle of Activities in Investigative Learning Environment

with students and other staff (by observing, interviewing, and surveying); systematically combining the results; and then iterating the cycle (Fig. 1). Improving teaching through action research has been considered as a good idea by a number of studies (example: [10, pp. 284]).

Concerning teaching plan and research design, one can intertwine curriculum development principles [17], action research principles [18], and other educational and educational technology research principles [19]. The *plan* stage in action research [18, 13] is found in the first three steps in our cycle; the *act* stage is found in our teaching step; the *observe* stage is inherent in our data collection step; and the *reflect* stage is found in our analysis and reporting step. In addition, action research brings forth a number of ethical issues which need to be acknowledged [20].

In our model, teaching and researching can be done in small collaborative teams including teachers, researchers, students, and other staff. All pedagogical choices are grounded in educational theory, teaching skills and research skills are learned-while-doing, and the research parts can be conducted lightweight or more thoroughly, depending on the available resources. In the following sections we describe and analyze our experiences of investigative learning environment design in two different contexts: in a Finnish university and in a Tanzanian university.

IV. LEARNING BY INVENTING: CASE HELSINKI

The project started from amorphous thoughts and visions about a learning environment in which students would be motivated by topics and projects of their own interests, and where students could engage in their own learning without restrictions by working with various platforms, gadgets, mobile phones, game consoles, and robotics kits of their choice. An important theme was to promote deep learning and hard work through positive emotions, play, inventing, and a sense of freedom from restrictions.

We selected a very open environment by granting the learner a lot of control. We controlled the skill-level and phase of studies of students entering the course, since openness is not considered to suit novice learners well [3]. Also, solid domain-relevant skills, which the novice CS students do not yet have, are required in inventing, and in creative problem solving [21].

TABLE I
CONCEPTUAL FRAMEWORK FOR LEARNING BY INVENTING [21]

| Component | Method of Support |
|---------------------------------------|---|
| Competence | Use of creativity-enhancing methods, providing effectance-promoting feedback. |
| Autonomy | Providing choice for self-direction. |
| Relatedness | Encouraging teamwork, promoting social interaction and creative working methods. |
| Domain-relevant skills | Advanced computing skills required from all attendees. |
| Creative processes and working styles | Use of creativity-enhancing methods: brainstorming, 3+, and open-space workshops. |
| Constructionism | Use of LEGO Mindstorms robots. Each student was provided a robotics kit. |

We chose to promote all the traditions of computing (see section II). Thus, we encouraged the discovery of problems from all three computing traditions. We wanted to give the students an environment where they can practice and develop their computing skills, and we wanted to promote a new, inventive working approach for project work, and software development [21].

We did not want to specify the problem types in detail, but instead wanted to promote a problem discovery process. In the problem solving process we wanted to promote deep-level, creative problem solving where risk-taking and inventing would be preferred over risk-free textbook solutions. We also made problem management open because we did not want to promote a production-oriented working model, but instead aimed at supporting a process of inventing. To promote motivation and constructionist learning [22], we selected a flexible technical tool (LEGO®Mindstorms robotics kit) as the learning platform. On the dimension of motivation and sociocultural context we wanted to provide emotional support accordingly, especially to promote a state of intrinsic motivation and creative “flow” experiences [23].

We started by conducting a literature study (see Fig. 1), and chose the theories of creativity [23], intrinsic motivation [24], constructionism [22], and deep-level learning [25] to support the learning environment we aimed to create. Amended with the three components of intrinsic motivation—competence, autonomy, and relatedness—we ended with a total of six components for the conceptual framework, upon which the practical guidelines for the course were built (see Table I [21]).

After having developed the teaching plan and research plan we started the course, having weekly learning sessions. The learning sessions were not teaching in the traditional sense, but those sessions provided a psychologically relaxed atmosphere for discussions and idea-generation related to students’ problems. This meant sitting down together and engaging in creativity enhancing games, practices, and plays (for details, see: [21]). The data was collected using the mixed-methods approach [26].

We worked in a team of three teacher-researchers. The first iteration cycle of this action research resulted with a large set of research data and a wealth of practical information for improving the learning environment in the next iteration.

Based on the analysis (Fig. 1) we decided to add a few scaffolds for the second cycle: workshops for building robot structures, and ideas for robot designs for students who felt insecure in the open environment.

The results showed that most of the problems which students discovered in the first round of course implementation, belonged to the engineering tradition of computing. On the second round, also problems from other traditions increased. An example problem from the theoretical tradition was designing new signal processing algorithms for fixing a bad color sensor signal. An example problem from the scientific tradition was a small study for measuring the efficiency of motors and CPU under different conditions. From the engineering tradition, students introduced multiple projects with various programming problems, including game consoles, GPS devices, model cars, factories, chess-playing robots, sorting robots, ant-shooting laser robots, guarding robots, beer bottle opening robots, weather forecasting science robots, and robots communicating and being controlled by mobile phones.

The results showed that students used various types of problem management processes in their work. Some students worked in a linear, production oriented fashion, while other students adopted a more experimental approach, trying out different techniques, building prototypes, and flexibly changing their plans when necessary. Some students felt very comfortable working in this kind of open, creative environment, while others did not acquire a new active working style, but felt a need for clearer structures and guidelines.

The creative group games were received with surprise, but generally with various positive emotions [21]. Students were not used to bringing in their own problems, discussing them, and commenting and ideating on each other's problems. Breaking the usual classroom traditions might have caused some discomfort, but was generally received with joy. In learning sessions predetermined problem sets were typically discussed, students presented their solutions one at a time, and the teacher(s) then promoted and directed the discussion by using various creativity-enhancing plays and methods [21]. The final demonstration sessions were a success, with many people outside the course also joining in, including journalists.

Through the investigative learning environment we learned to support a new, inventive kinds of problem discovery, problem solving, and problem management processes related to learning computing, computer programming, and software development. We call this approach *learning-by-inventing*. The utilization of the action research process was a necessary part of the experiment. Before this activity, we did not have any knowledge or experience in arranging such courses, and the development and research of this course was an important learning experience for us as computing educators and educational researchers.

V. GUIDED ENVIRONMENT: CASE IRINGA

Our second experiment with investigative learning environments took us to a very different context: to a developing

country in East Africa. Teachers from Spain, Uganda, Tanzania, USA, and Finland have, over the past 4 years, introduced a variety of approaches for developing programming education at Tumaini University, Tanzania. The pedagogical approaches have included a traditional lectures-exercises-exams-pattern, with several attempts to employ different pedagogical extensions. Those extensions have included program visualization and animation tools, the coding-while-lecturing technique, contextual learning material and course contents, and e-learning resources as a support tool for learning [27], [28].

In 2009 we started to combine teachers' views about issues that affect the learning environment in programming courses, as well as teachers' ideas for improving teaching. That work resulted in a list of challenges related to, for example, students' educational background, hardware and software, study material, learning strategies, students' previous skills, assumptions about programming, fear of programming, time management, groupwork dynamics, and language [27]. Concerning what worked well, teachers named easy interaction in the classroom and positive experiences with e-learning materials. For suggestions for further improvements several aspects came up: addition of individualized exercises, increased amount of time to work with programming tasks, and inclusion of varying types of programming problems, such as completion of documented but unfinished example problems. Teachers also suggested increased emotional support for easing students' negative emotions towards programming [27].

After we started to have initial ideas about the challenges and possible remedies of programming education, we considered inclusion of research activities into teaching to be of top priority. By combining teachers' ideas together we came up with a five-factor model of challenges in programming in our context (Table II) [27]. The literature survey (Fig. 1) pointed out several theory-based practical ideas on how to address those challenges. We decided to add iterative action-research based activities to teaching, which would start from exploring and continue with describing, developing, and evaluating. The research and teaching activities included collaborative co-operation with teachers, researchers, students, and faculty staff.

Based on the theoretical background we made plans for providing a new kind of learning environment for basic programming courses in Iringa, Tanzania. Since the learning objectives are concerned with basic programming skills, the tradition choice (see Section II) followed mostly the engineering tradition. The learning objectives were based on a traditional CS1 course. However, in this environment learning objectives spanned beyond learning the basics of programming. Those additional learning objectives included problem-solving skills and deep-level learning skills—which have been identified as a major challenge in the whole undergraduate program—and other skills, such as groupwork dynamics, and cognitive and metacognitive learning skills. Multiple interrelated learning objectives made the design of the learning environment very challenging. Many of those learning objectives were impossible to be met within one course, but would require extensive coordination within the full curriculum.

TABLE II
FIVE-FACTOR MODEL OF CHALLENGES IN PROGRAMMING COURSES [27]

| Component | Explanation |
|---|--|
| Educational Background | Due to the multidimensional nature of the Tanzanian education system, the background skills in science topics, language, and problem solving vary a lot. |
| Learning Strategies (Deep/Surface Learning) | The mainstream learning strategy is rote memorizing and surface learning, aimed at solving well-defined, closed problems. |
| Motivational Orientations | Students risk generating extrinsic motivations when their learning strategies fail. |
| Groupwork Tendencies | Communal groupwork tradition, inherent in many African cultures, has both positive and negative effects for learning. |
| Study Environment and Habits | Language problems, copying, and plagiarizing of coursework is a common challenge. Internet, availability of computers for training, and other teaching facilities are often lacking. |

Concerning problem types we favored closed problems since most of the learners were novice learners. Also problem management was left mostly for the teacher. For quickly advancing students, we also provided more open-ended problems and small problem management tasks of building up solutions from smaller tasks. Thus, one cornerstone of the pedagogical approach was the provision of large amount of contextual multi-level exercises starting from extremely simple, but providing enough challenge for advancing students, too.

In terms of *teaching styles and social interaction* in classroom sessions we designed several roles for the teacher. As a rule of thumb, every learning session contained an instructive part, which introduced some general theme and then proceeded with a method we call *coding-while-lecturing* (similar to think-aloud modeling, e.g. [10, pp. 144]), where the teacher wrote programs while interacting with the class. The teacher and students discussed and debugged the program, taking multiple viewpoints into account. That method aimed at making explicit the implicit problem solving processes required for writing programs, and at helping students to unlearn their rote-memorizing learning styles, and thus, to support deep-level learning [28].

For western teachers, the social interaction in the class posed some cultural challenges. Students were not used to questioning a teacher's authority, which sometimes limited classroom interaction. To overcome these kinds of communication barriers, students were constantly encouraged to ask questions and to discuss the topics from multiple viewpoints.

In the dimension of motivation and sociocultural context it became evident that understanding the cultural context posed challenges for western teachers. While emotional support is needed in universities worldwide, the means of supporting it may vary a lot between sociocultural contexts. For example, in Tanzania expressing emotional support seemed to require a closer and more personal contact than it does in Finland. The intricacies of this aspect included a social code of manners and politeness, with elaborate greetings concerning matters of family, life, and health. The power distance between a teacher and student seemed to remain high, which sometimes seemed

unnatural from outsiders' perspective. Our affective support was based on the three components of intrinsic motivation: autonomy, competence, and relatedness [16]. We aimed for a relaxed, trusting, close, and safe interaction and environment, though it is hard to evaluate how those worked out.

Students at Tumaini University are mostly used to closed learning environments, and during classroom sessions we sometimes utilized methods of open learning environments by utilizing PBL-style activities, and by granting the learners more autonomy. Thus, we promoted the feelings of autonomy by shifting control between the learner and the teacher.

In this environment, a traditional mode of teaching does not work well because the learning environment is poorly understood. Hence, we employed the investigative learning environment design approach (see Section III) and worked in a team of three teacher-researchers, working in multiple and changing roles in the learning environment. We shifted roles between teachers, researchers, observers, and interviewers. The first iteration of this research was investigated by group interviews and survey studies accordingly [27], [28].

The first iteration (2010–2011) with the initial teaching plan (see Fig. 1) and case-study research design yielded a lot of practical guidelines and important understanding about the challenges of learning in this context of education [27]. Still, although a number of students made impressive developmental leaps during those activities, the overall learning outcomes remained unsatisfactory. Rather than answers, the analysis of the first iteration resulted with a number of open hypotheses for further research. The most important question that arose concerned students' work when they practice on their own time. Probably the most important learning environment for learning—one's work on one's own time, especially doing homework—would need careful inspection. The home environment is, however, typically highly unguided, and unguided learning has, in educational psychology, been considered negative for novice learners [3]. Pedagogical approaches for promoting guidance in programming have been successfully used in other contexts [29].

In the second iteration we aimed at firstly testing the impact of guided learning sessions on the learning outcomes, and secondly, at studying students' problem solving processes during homework practice more thoroughly. To do the first, we changed the research design into an experimental research setup. We kept all the previous pedagogical approaches constant, but added guided exercise sessions as a pedagogical intervention. We conducted a pretest-posttest experimental research setup, recorded observations utilizing a thinking-aloud-protocol [30], and conducted a survey study (for detailed results, see [31]). While the outcomes in the classroom looked very promising, there was no statistically significant difference between the control group and experimental group in the learning outcomes (see [31]). The difference between qualitative results and quantitative learning outcomes led us to consider additional hypotheses: for example, maybe we test the students' learning wrong. If we want the students to learn-by-doing, perhaps we should test-by-doing also [31].

VI. CONCLUSIONS AND DISCUSSION

Our two example cases extended teaching activities with research activities. The educational contexts were very different from each other, the other being a top-100 university in a hi-tech society, and the other being a new educational program in a small private university in a developing country. In both cases we wanted to extend current computing education by promoting deep-level learning and problem solving through a number of pedagogical tools and vehicles and through iterative development activities inspired by action research.

A learning environment is a complex construction of multiple factors. This research was based on our initial draft of a conceptual framework for classifying and analyzing learning environments of computer science (see Section II). Although the two learning environments had notable differences, both of them could be defined with our model.

Our proposed model of investigative learning environment, following the action research tradition, has several gains in computing education. Teaching in a collaborative team brings multiple viewpoints and ideas to action, and the planning sessions force the staff to articulate their reasoning behind the pedagogical routines. This discourse can be aided with a framework that focuses on the cornerstones of a learning environment. In this study we found the framework presented in Section II useful in both of our educational contexts.

By bringing rigorous research into teaching we reminded that teaching is not only an art but also an activity where teachers should be able to justify their selections by reasoning and intellectual traditions. We have found action research activities to fit well in both developing and developed country contexts. Investigative learning environment design can be conducted lightweight or in a comprehensive manner, depending on the available resources.

mrizvi@nsu.edu, thumphries@nsu.edu

Abstract—This paper presents the results of a CS0 course based on the Scratch programming language that was designed to improve the retention of at-risk computer science majors. At the authors' university, prior to the introduction of the CS0 course, students who selected the computer science major but entered the university with weak mathematics preparation from high school left the major at a high rate. The Scratch-based CS0 course was developed to keep the students who had a desire to major in computer science engaged in the department, as well as prepare them for success in future computer science courses. This paper discusses the formal study that was conducted on the CS0 course offerings in Fall 2009 and Fall 2010, which reached about 120 students total, and over 60 in the target group of freshman CS majors with low mathematics placement scores. The study examined the course's effectiveness at improving the retention, performance and attitudes of these at-risk majors.

Keywords—CS0; retention; Scratch

I. INTRODUCTION

This paper presents the results of a CS0 course based on the Scratch programming language that was designed to improve the retention of at-risk computer science majors. At the authors' university, prior to the introduction of the CS0 course, students who selected the computer science major but entered the university with weak mathematics preparation from high school left the major at a high rate. These students left the major for several reasons, such as the following: if the students were not allowed to take CS1 until they had completed one or two semesters of mathematics, they were likely to leave the major because they were not taking any computer science (CS) courses; if they were allowed to take CS1 in their first semester at the university, then they had a high failure rate, and thus also tended to change majors. The Scratch-based CS0 course was developed to keep the students who had a desire to major in computer science engaged in the department, as well as prepare them for success in CS1 and CS2.

The course is a hands-on oriented introduction to programming, covering core programming concepts including sequence, iteration, selection, variables and arrays. The Scratch language and development environment, created at MIT, allows students to focus on programming concepts without the distraction of syntax errors. It also allows the students to create much more creative and interesting projects, like games and animations, than might be possible for

beginning students in languages like C++ and Java. The Scratch language also allows for early introduction of more advanced programming concepts, such as event-driven programming and concurrency.

The CS0 course was piloted in January 2009. This paper discusses the formal study that was conducted on the course offerings in Fall 2009 and Fall 2010, which reached about 120 students total, and over 60 in the target group of freshman CS majors with low mathematics placement scores. The study examined the course's effectiveness at improving the retention, performance and attitudes of these at-risk majors. Results of the study indicate that students of the target group who programmed using Scratch had a high degree of perceived self-efficacy with respect to their programming abilities, both in Scratch and later, in C++. Furthermore, the target group's performance in CS1 was better than that of freshman CS majors who were not considered at-risk, and their performance in CS2 was equivalent to that of all other CS majors. Finally, retention of the target group improved significantly over historical rates for at-risk majors, and also exceeded the rates for majors not considered at-risk.

The rest of the paper is organized as follows: Section II explains the details of the motivation for the new course. Section III provides some background and discussion of related work. Section IV gives some details about the course itself. Section V discusses the results of the study, and section VI concludes with a discussion of the meaning of the results and some directions for further work

II. MOTIVATION

The CS0 course was created as an intervention to improve retention. In the years leading up to the course's creation, the authors had noted that the attrition of computer science students with weak mathematics backgrounds was excessively high. The definition of a weak mathematics background for this study is placement in elementary or intermediate algebra upon entering the university. Students whose placement test scores indicate that their level of mathematics understanding is at the college algebra or college algebra and trigonometry level are considered to have acceptable mathematics proficiency. Students who place into calculus may take an honors section of CS1, and these students are not considered in any of the statistics presented here.

In the years 2005-2007, 38 students who were declared CS majors placed into elementary or intermediate algebra. Of these students, only 13 went on to take the CS2 course, and of those, only 5, or 13%, passed on the first attempt. This is in contrast to 39% of the CS majors with acceptable math proficiency. In Fall 2008, there were 18 freshman CS majors with weak mathematics backgrounds who took CS1. Four semesters later, in Spring 2010, only 3 of those students (17%) were still active CS majors and had passed CS2.

Obviously, failure of the core CS courses is a good reason to leave the major, and almost none of the students with weak mathematics backgrounds were being retained. To solve this problem, the CS0 intervention addressed two objectives: to improve the success rates of students in the core CS courses (CS1 and CS2), and to improve the attitudes of the students towards computer science and programming (the normal content of CS1 and CS2) in particular.

The new course was offered using an existing course, CSC169 Fundamentals of Computer Science, which was intended for non-majors. Some students take it as a free elective, but it is required for certain majors, including the natural sciences, mathematics, and some education tracks. Those departments agreed to the new content, so about half the students in the new CS0 course are non-majors. However, unlike some of the efforts with Scratch described in the next section, this course is not intended for recruitment, and neither does it succeed in recruiting students from other majors. Most of the non-majors take the course in their junior or senior years. However, one student did change his major to CS, and a few others expressed interest in a CS minor, as a result of taking the course.

III. BACKGROUND

A. Related Work

In the past decade, several approaches have been proposed by researchers to reduce attrition through the development of visual programming tools. The objective of these tools is to provide some level of abstraction with respect to the syntax of the programming language and to provide media-enriched programming environments that support computational thinking and creativity to gain the interest of students who have little prior experience. Examples of these languages and environments are Alice [3] and Greenfoot [8].

Several studies have been conducted on the effectiveness of media-rich languages in attracting and retaining students in the CS major. Most notable is the study conducted by Cooper, Dann and Moskal [2, 12] on the use of Alice as a programming language for CS0 courses. Guzdial [6, 7] has also successfully incorporated several media-rich computational courses using Python as the programming language into the curriculum at the Georgia Institute of Technology.

Recently, Malan and Leitner [10] and Wolz [18] used yet another media-rich language that was originally designed for use with K-12 students, Scratch, during the first week of their introductory computer science courses. Malan and Leitner were the first to perform a preliminary study on the use of Scratch as a precursor to Java in a course that was offered at

the Harvard Summer School. At the end of the course, they surveyed the students with respect to the impact that Scratch had on their experience programming in Java and found that 76% rated the effect as positive, 8% rated the effect as negative, and 16% indicated that there was no effect [10]. Wolz at The College of New Jersey also used Scratch at the beginning of a CS1/CS2 course before transitioning into Java [18].

The positive results of Malan and Leitner influenced several researchers to experiment with Scratch as an introductory programming language for the first few weeks of a programming course. In the second semester of 2007, Kereki at ORT Uruguay University initiated a study to determine the effect of using Scratch for three weeks in a CS1 course as the initial programming environment before transitioning into either Java or Visual Basic [9]. Although Kereki saw no significant differences in grades, she reports that students' description of their learning process and programming experiences differed between the target group, who programmed in Scratch first and then went on to use the main programming language of the course, and the control group, who did not program in Scratch. Those who started with Scratch used words such as "interesting" and "easy" to describe their learning process and programming experiences whereas the control group described them as "difficult" and "not easy" [9].

Malan and Leitner's work also influenced another team at the University of California - Berkeley [4, 5] to develop a CS0 course in Fall 2009. In this course, students were taught computational thinking. Programming assignments were implemented using Scratch and in a new programming language based on Scratch, Snap! (formerly known as BYOB (Build Your Own Blocks)), that was developed at UC Berkeley [1]. In Snap!, additional functionality, including procedures and multi-dimensional arrays, was incorporated into the Scratch environment. Therefore, using Snap!, more advanced programming topics such as recursion could be introduced. Berkeley's new CS0 course also covered diverse computer science topics such as the social implications of computing and video games.

Unlike the CS0 course that was developed at Norfolk State University, only about half of the CS0 course at UC Berkeley was focused on programming [5]. Additionally, the two CS0 courses have different objectives. The objective of the CS0 course at Norfolk State University is to retain freshman computer science majors, while the CS0 course at the UC Berkeley has a recruitment objective.

The idea of developing new courses to better orient at-risk students, women or all students to computer science or to programming before they start the traditional CS1/CS2 programming series is not a new concept. There have recently been some approaches that use multimedia. For example, in a study that was conducted at the University of Illinois at Chicago [17], a CS0.5 course was created using the Python media materials developed by Guzdial at the Georgia Institute of Technology [7]. According to [17], Sloan and Troy were able to increase retention by 21%. They also indicated that the number of students who rated themselves as having good

programming skills increased by 61% by the end of the course. Cooper and Dann created an Alice-based course that aimed to improve the performance and retention of at-risk students [2]. Their findings indicated that targeted students' retention rates were raised dramatically [12].

B. Scratch

Scratch is a media-rich programming language and environment developed by the Lifelong Kindergarten group at the MIT Media Lab, which was officially launched in May 2007 [11, 13, 16]. In addition to helping students develop or enhance their problem-solving skills, Scratch provides an environment conducive to learning about problem decomposition and the design process. The following are the major design goals and features of Scratch: a simple and intuitive snap-together block style that prevents syntax errors, media-richness, the support of common programming constructs, a *failsoft* programming environment, and the large online community of Scratch programmers that provide an enormous repository of programming examples [11]. A sample Scratch program, developed by a student in the CS0 course, which implements a game, is shown in Fig. 1.

Although Scratch is not object-oriented, it supports the notion of objects through its sprites and the scripts associated with the sprites. Thus, a student is exposed to objects in a natural manner. Additionally, Scratch provides an environment which makes it easy for students to express their creativity while programming.

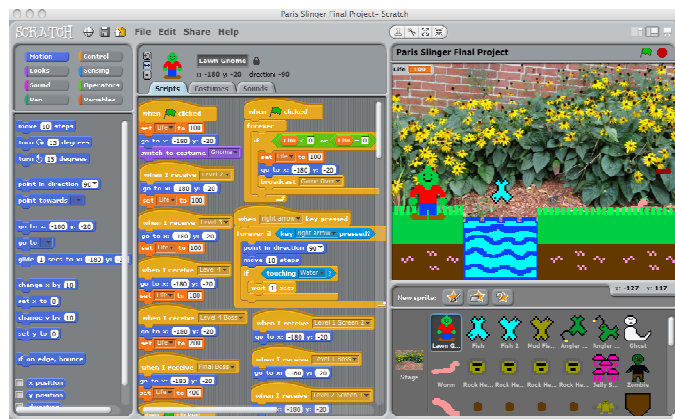

Figure 1. Sample of the Scratch Programming Environment

Although the designers of Scratch do not encourage the use of Scratch at the upper high school level or at the college level, the programming environment supports programming concepts like variables and arrays, which are not typically used by the primary target group for Scratch, children aged 8 - 16. In fact, statistics available on the Scratch website show that variables are used in less than 25% and arrays are used in less than 2% of all Scratch projects shared on the website [16]. Variables and arrays, along with more advanced features in Scratch, such as concurrency and event-driven programming, combined with the simplicity of the programming environment, make Scratch a very suitable choice for freshman college students with no prior programming experience.

IV. THE CS0 COURSE

Beginning in Fall 2009, the CS0 course was offered to students who placed into lower-level mathematics courses. Before Fall 2009, these students had been allowed to take CS1 directly. Currently, all students that do not have the mathematics prerequisite for CS1 cannot take CS1. Thus, students who do not have the mathematics prerequisite are encouraged to take CS0 by their academic advisors and 100% of them elect to do so, even though it is not a required course. In the second year of the course offering, a few students whose mathematics levels were at the level of proficiency elected to take the CS0 on the advice of other students who had found the course enjoyable and/or valuable.

Details of the course content have been published in [14]. The CS0 course is structured like most introductory programming courses, consisting of lab work and some lectures on general topics, such as program design, variables, and 2D graphics. Most lectures introduce a concept and demonstrate it with examples. Each concept is reinforced with a hands-on lab exercise, an in-class review of the lab, and then a homework exercise that includes the new concept as well as concepts previously covered.

Lab exercises focus on one concept by having the students solve problems (e.g. evaluate Boolean expressions), create individual Scratch scripts to perform specific tasks, or modify existing projects by adding new features or revising the techniques used in the project. Homework assignments usually require that a full Scratch project be developed. Sometimes the students are permitted to choose their own project topic as long as it fulfills certain criteria; in other cases, the project to be built is fully specified.

The focus of this course is the core programming concepts up to and including arrays. Students grasp the ideas of sequence, iteration and selection quite easily. Scratch currently has no procedure construct, but it will be available in Scratch 2.0 (expected 2012). Scratch has the broadcast mechanism, where signals can be broadcast to initiate actions. Students also grasp this concept quite easily, as well as the simple sound and animation concepts.

However, the concept of a variable, which is introduced around midterm, is difficult for some students, and the concept of arrays, introduced in the last month of class, is difficult for most students. This is despite Scratch's very visual and intuitive interface for both programming constructs, and numerous class exercises on reading code and tracking the contents of variables and arrays. The authors' personal experience with other introductory programming courses suggests that this issue occurs regardless of the language used.

Students are assigned exercises and homework that is geared toward mastering the concepts of variables and arrays. The final exam has two parts – programming and written. The programming exam requires the use of variables, but not arrays. The written exam contains questions that address both these concepts. Many of the students' final projects contain variables, but almost none of their projects contain lists. The authors believe that this initial introduction to variables and arrays, although most of the students only partially master

them in CS0, makes the concepts more familiar when they are introduced in CS1 (in C++).

V. RESULTS

In Fall 2009, 35 freshman CS majors took CS0 and 42 freshman CS majors took CS1. In Fall 2010, 29 freshman CS majors took CS0 and just 15 freshman CS majors took CS1. These differences are based simply on the changing number and level of students entering the university from year to year. In Fall 2009, the instructor for the CS0 was one of the authors of this paper, so she was highly invested in the success of the project. In 2010, a different instructor, unconnected to the project, taught one of the CS0 sections, using exactly the same materials and structure. There was no difference between any of the results for that section and the other section.

The students who took CS0 in Fall 2009 and Fall 2010 are considered the target groups of this study. The students who took CS1 during their first freshman semester in 2009 and 2010 are the control groups. Only freshman CS majors were considered in both the target and control groups, even though students from other majors take both the CS0 and the CS1 courses.

A. Student Attitudes

As reported in [15], the data for the Fall 2009 students showed that the target group's self-perceived programming proficiency improved continuously throughout CS0 and up to the end of CS1. Additionally, a focus group was conducted with the 2009 target group in Fall 2010 to determine their impressions of the CS0 course while they were taking CS2. Students were asked to respond to the following question:

"In what ways has learning how to program in Scratch helped you in your programming classes?"

Some unedited anecdotal data in response to the above question is presented below:

- "Using loops, it helps in C++"
- "Helps to learn how to trouble shoot problems"
- "Gave us a programming mindset, doing things step-by-step"
- "Good foundation to start with"
- "Teaches you how to plan instead of just jumping into it"
- "Steps and logic are similar in Scratch and C++"

In Fall 2010, some problems with the survey mechanism occurred and, although the results were similar, not enough data were collected to be statistically significant.

B. Performance in Future Programming Courses

The performance of the target group in future programming courses was compared against the performance of the control group. The results are shown in Table I. It should be noted that the low pass rate for freshman CS majors in CS1 in Fall 2009 was consistent with the overall pass rate for all students in CS1, and was similar across different instructors. The instructors who taught CS1 in the spring were the same ones who taught it in the fall.

TABLE I. CS1 PASS RATES

| CS1 Pass Rate | Academic year: 2009-2010 | Academic year: 2010-2011 | Overall |
|-----------------------------|-----------------------------|-----------------------------|---------|
| Target group (CS0 & CS1) | 74% (17/23) | 67% (14/21) | 70% |
| Control group (CS1 only) | 39% (15/38) | 60% (9/15) | 45% |

Due to students from both groups retaking CS1 and CS2, it was not easy to isolate the control group for CS2; therefore, in looking at performance in CS2, only students from the target group who took CS2 on schedule were considered. The pass rate in CS2, collected in Fall 2010 for the Fall 2009 target group, and in Fall 2011 for the 2010 target group, was exactly the same as the pass rate for the course as a whole. Only CS majors take CS2, so this shows that the target group is performing at the same level as all other students when they reach CS2.

C. Retention

In considering retention, the Fall 2009 target group was compared with the Fall 2008 students who placed at the same level in mathematics (similarly 'at-risk' students). The 2008 students took CS1 in their first semester (there was no CS0 intervention). The one-year retention rate is defined as the number of students who are still actively taking classes and still CS majors in the fall of the following year. The Fall 2010 target group's similar retention rate indicates that the increase gained by the initial introduction of the CS0 course is consistent. The rates are shown in Table II.

TABLE II. ONE-YEAR RETENTION RATE

| | One year retention rate | |
|----------------------------|-------------------------|---------|
| Fall 2008 at-risk students | 33% | (6/18) |
| Fall 2009 target group | 57% | (20/35) |
| Fall 2010 target group | 59% | (17/29) |

A long-term retention rate for the Fall 2009 target group as compared to the 2009 control group was also collected, representing the number of students who started in Fall 2009 and were still active CS majors six semesters later in Spring 2012. Of the 35 students in the 2009 target group, 14 (40%) remained active in 2012, and of the 42 students in the 2009 control group, 13 (31%) remained active in 2012. The long-term rates show that the CS0 intervention produced retention rates for at-risk students that are slightly better than those for students who were not at-risk.

D. Other results

Anecdotal data indicates that the CS0 course, and Scratch, is enjoyable for non-majors as well as CS majors. Generally non-majors get the highest grades in the class, but they are usually junior and senior science or mathematics majors, so it is not surprising, due to the maturity level of these students. Invariably, non-major female students get the top grades in the class, and seem to enjoy the class more than their male counterparts, but this is not the case among the CS majors. In fact, there is no indication that the CS0 course has any special effect on women CS majors, of whom there are very few.

VI. CONCLUSION

The Scratch-based CS0 course as an intervention to improve the retention of at-risk CS majors has been successful by meeting the objectives of the study through improving the students' attitudes towards programming in general and their perceptions of their own abilities with respect to the programming process, as well as improving the students' success in future programming courses. With Scratch, students always get some level of success in the programming process; they are never faced with a screen full of syntax errors. They are able to see the outcome of their programs visually and learn how to modify their programs to get the desired behavior. The CS0 course provides the students with rewarding programming experiences, such as presenting their final projects to their classmates who provide positive feedback about their programming abilities. Additionally, students are provided with an extra semester to learn about algorithm development and core programming constructs such as control structures, variables and arrays. The authors believe that it is a combination of all these factors that have allowed the targeted 'at-risk' students to exceed the performance of the students who were not at-risk.

The authors expect that further improvements in the overall success of the target group will occur after the release of Scratch 2.0, which contains the concept of a procedure with arguments. They are considering expanding the group of students directed into CS1 to include the students who place into college algebra, and only have students who place into college algebra and trigonometry take CS1 directly. An extra semester spent in CS0 is preferable to an extra semester retaking CS1 or CS2. A further improvement being considered is to make a smooth transition between CS0 and CS1, using the last few weeks of CS0 and the first few weeks of CS1.

The materials for this course are available at <https://sites.google.com/site/upccssite/>.

Abstract - Recently, academic institutions have started to explore the potential of commercially available multi-player computer game engines for the development of virtual environments for instructional purposes. This trend is motivated by the fact that many students are highly accustomed to and knowledgeable about playing electronic and computer games. Computer games share a number of potential characteristics with effective instructional tools and therefore have a great potential for positively affecting learning. Achieving a sense of immersion by the students and interactive collaboration among them are two of the main goals being pursued in exploring new types of educational laboratories as alternatives or complements to traditional hands-on experiments.

A scripted scenario for a game-based gear train laboratory exercise was implemented in 'ME 358 Mechanisms and Machine Dynamics', a junior-level course for mechanical engineering majors at Stevens Institute of Technology (SIT). This paper discusses the learning assessment conducted in that implementation. The results are presented for two assessment studies comparing versions of game-based gear train experiments to workbook-based gear train experiments with a 'hands-on' laboratory experience. The results suggest that the students learned the concepts addressed by the laboratory content better in the game-based condition and that they had a realistic understanding and appreciation of the practical advantages of game-based gear train experiments over more traditional learning experiences. In addition, a questionnaire was administered to the students and then analyzed in order to obtain further insights into the students' opinions about and attitudes toward the game-based laboratory approach.

Index Terms - Game-based laboratory, Gear design, Virtual experiment, Assessment, Game engine.

INTRODUCTION

Today's students habitually use digital electronic technology for communication, entertainment and education on their own, and often they have a more positive attitude toward games and simulations than they have toward traditional instruction [1]. Several studies [2,3] concluded

that computer/video games are characterized by rules, goals, objectives, outcomes, feedback, conflict, competition, challenge, opposition, interaction and representation of the story. These capabilities will lead computer games to become recommended practice and preferred tools for solving problems. They are proving to be effective as learning devices for people of all ages [4]. As a result of the widespread availability and popularity of gaming technology [5], computer games have drawn significant attention in a number of businesses to help users/workers in developing skills through hands-on navigation of simulated scenarios in virtual environments. By now, they have been adopted for use in many fields, including education, medicine, architecture, city planning, disaster response and military training [6,7]. The report of the Summit on Educational Games released by the Federation of American Scientists [8] indicated that computer games and simulations can serve as powerful 'hands-on' tools for teaching practical and technical skills, from automotive repair to heart surgery. It is for these reasons that computer games have strong potential for providing the basis of powerful learning environments.

As computer processing speeds continue to increase, computer hard drives grow in capacity and available network bandwidth expands, computer games continue to become more sophisticated and complex [9]. Upon examination of modern computer game architectures and their features that are essential to build an interactive collaborative laboratory environment [10,11], Figure 1 illustrates the core components of a generic game and its engine, which can be divided into three distinct layers:

- **System Layer:** This layer represents the hardware of both the computer and the network. Modern computer games are usually structured as client-server applications. The client machine communicates with a centralized game server via data packets in order to evaluate the moves made by the users within the game. This layer defines the low-level performance of a game engine, determining the quality of graphics, the quality of sound and the network capabilities.
- **Engine Layer:** This layer consists of the software that abstracts the lower layer and implements functionalities such as the artificial intelligence (AI) of the characters,

the physics of the environment, etc. For example, the physics engine uses advanced mathematical models for calculating rigid body motions of arbitrarily shaped and articulated objects (e.g. vehicles, machines, etc.). The graphics engine displays and manages the data related to graphical content and visual effects. All audible content such as sound effects, ambient noise and music is handled by the audio engine. Artificial intelligence, provided by the AI engine, is needed for controlling non-player characters (NPCs). The AI engine deals with giving emotions to the NPCs, path finding, decision making, scripting and the finite state machine. The term NPC is used in computer role-playing games to describe entities not under the direct control of the players. The NPC behavior in computer games is usually scripted and automatically triggered by certain actions or dialogue with the player characters.

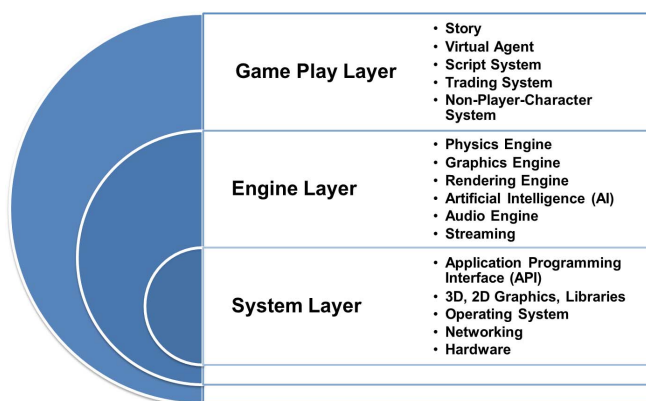

FIGURE 1
COMPUTER GAME TECHNOLOGY CORE

- **Game Play Layer:** In this layer, all of the game rules are defined. It is about creating the game play and defining how it works before the software developers put any substantial time or effort into decorating the game environment. It also includes the actions that the players can take. For example, almost every game has some sort of a story, the ‘embedded’ story (created by the designer) and the ‘emergent’ story (created by the players). This layer depends on the complexity of the game and integrates challenges into a larger task or a problem. Also, progress in a game is rewarded with positive feedback and rewards. There are three categories of rules: setup (things the players do once at the beginning of the game), progression of play (what happens during the game) and resolution (what conditions cause the game to end and how an outcome is determined based on the game state). In accordance with the goals of engineering education, all these rules can be educational.

Several observations can be derived from the above examination. Computer games can provide familiar and engaging interactions and increase the appeal of an

educational experience [12 , 13]. They have many characteristics of problem solving activities, for instance the construction of a problem context, multiple paths to a specific goal, learning by doing, discovery learning and guided discovery, task-based learning, role playing, etc. Therefore, computer games and problem-based learning are experiential, collaborative, active and learner-centric approaches [14, 15]. Taking advantage of the favorable characteristics of computer games [16], existing multiplayer computer game engines [17] can be utilized as a means for creating educational tools that have the potential for enabling students to learn in an engaging manner.

COMPUTER GAMES AS AN EDUCATIONAL TOOL

By utilizing one of the commercial game engines with its vast set of built-in functions as the framework for creating an interactive virtual laboratory environment, the continued advances in gaming technology are leveraged and the system development efforts can thus be focused more on implementing effective pedagogies. Recently, a virtual laboratory environment has been created for the laboratory component of a junior-level undergraduate mechanical engineering course on mechanisms and machine dynamics at SIT as shown in Figure 2.

Detailed Level

FIGURE 2
MODELING OF A REALISTIC VISUALIZATION OF A PHYSICAL
LABORATORY SPACE

This immersive interactive laboratory environment is based on ‘Source’ [18], a commercial multi-player computer game engine that is widely distributed and commonly used to develop massively multiplayer online role playing games. It provides all the functions needed to develop a virtual laboratory environment. Furthermore, it has extensive

support included in the form of the associated Software Development Kit (SDK) [19], e.g. the ‘Hammer’ editor and the game engine’s source code. All physics simulations are handled by the ‘Havok’ physics engine [20], which allows for realistic interactions between the objects in the virtual world. The experimental equipment was implemented using custom models, and the custom model primitives were made by third-party 3-D modeling software such as 3ds Max or SolidWorks. These custom models were extremely useful in implementing the virtual laboratory, as scripts can be written to define their behavior. So far, two predefined scenarios for laboratory exercises have been scripted and implemented [21]. They both allow teams of students to assemble an experimental setup within the game environment and subsequently carry out an experimental procedure using this setup.

GOALS OF THE PRESENT PROJECT

The goals of this project are to evaluate the educational effectiveness of a game-based gear train experiment relative to a workbook-based gear train experiment with a ‘hands-on’ experience within the context of a course on mechanisms and machine dynamics. This course involves three 50-minute lectures and one 2-hour laboratory per week for a total of three academic credits. It is designed to provide mechanical engineering students with the background and necessary tools for the kinematic analysis and synthesis of mechanisms and machines as well as the skills required for considering the role of dynamics in the design of machines. Our assessment of the educational effectiveness includes learning outcomes, student ratings of satisfaction, effectiveness and teamwork across the two different laboratory formats.

GEAR TRAIN LABORATORY

During the course of this laboratory exercise, the students study some basic elements of power transmission. The transmission (also called gear train) consists of several mating gear pairs. It represents a vital system used in many tools/machines to transfer mechanical energy and to change the type and direction of motion, increase/reduce the output rotational speed(s) relative to the input speed and reduce/increase the output torque(s) relative to the input torque. This laboratory exercise is intended to give the students an understanding of the overall function of a gear train system. The experimental capabilities of this laboratory system include:

- Introduction to gear trains, transmission ratios, speeds, etc.
- Assembly of a variety of gear train arrangements that include spur gears, helical gears, worm gears, bevel gears, rack and pinions and compound gear trains
- Demonstration of the working principles of gear train systems
- Calculation and experimental observation of the angular velocity ratios of gear trains

- Experimental determination of the torque ratios in gear trains
- Calculation of the gear train system efficiency

Two specific laboratory experiments were designed for this evaluation: a workbook-based planetary gear train experiment with a hands-on experience and a game-based simple gear train experiment. In each laboratory session, the students were divided into teams of three members each. Each laboratory session consisted of four phases. First, the students were asked to complete a pre-experiment test designed to gauge their prior knowledge of the gear train system. Following completion of the pre-experiment test, the hands-on or game-based experiment phase began with a brief introduction. The workbook-based planetary gear train experiment with a hands-on experience was conducted at a particular time and place and required face-to-face interaction. During the game-based experiment, the students moved their respective characters (avatars) through the virtual laboratory and interacted with other characters to achieve various goals. The teaching assistant (TA) observed how the students interacted with the game interface, how much difficulty they had in assembling the gear train and in performing various calculations, and how long they took to finish the different steps. After the hands-on or game-based experiment, the students were asked to complete a post-experiment test with the same number and format of questions as on the pre-experiment test to measure their learning outcomes. At the end of each session, the students’ feedback about the laboratory’s usability was solicited.

GAME-BASED GEAR TRAIN LABORATORY SCENARIO

The scripted scenario for the game-based experiment was implemented in the Fall 2011 semester in ‘ME 358 Mechanisms and Machine Dynamics’, to perform several experiments related to the fundamental law of gearing and the fundamental concepts of planetary motions of gears [22]. This virtual environment offers experiments dealing with simple, compound, reverted and planetary gear trains. Each experiment was designed to teach the students how the gear ratio of a gear train alters the output speed and torque of a machine. The apparatus in the virtual gear train laboratory consists of spur gears, helical gears, bevel gears, base, axle shafts and holders as shown in Figure 3. In addition, several spacers and washers are included to allow alignment of the gears and to ensure tight meshing.

Setting and Procedure

The study took place in three separate rooms. The groups consisted of three students who were each placed in one of the three rooms. Before conducting the game-based experiment, the students were provided with an experiment scenario in the form of a tutorial in order to introduce them to the capabilities of the laboratory environment and to inform them about how to log into the experiment webpage, how to customize their game avatars (i.e. gender, outfit, physical appearance, etc.), how to distribute the work load amongst the team members, how to select and use the built-

in features of the laboratory system and how to get feedback from the instructor. Note that the developers and a TA were present during the laboratory sessions as well. While most of the laboratory sessions for the student groups lasted approximately half an hour, some students who had additional questions and needed extra help with the tutorial stayed longer for further assistance. After introducing them to the general concept of the game-based laboratory environment and to the specific experimental setup, the students first had to sign in on the attendance sheet, familiarize themselves with the laboratory manual and then enter the virtual laboratory environment for performing the selected experiment.

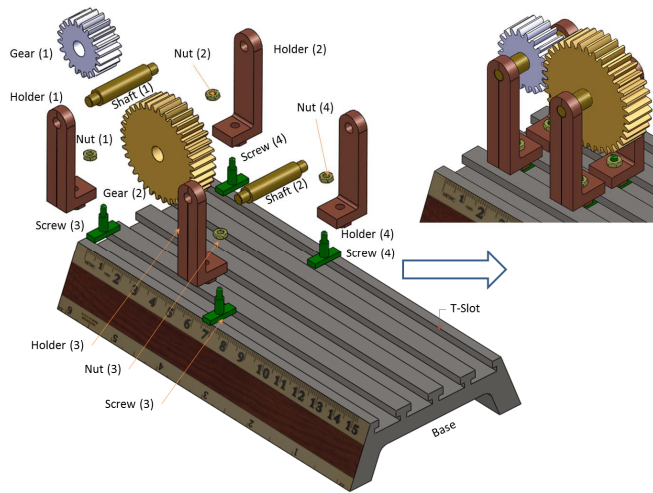

FIGURE 3
SIMPLE GEAR TRAIN EXPERIMENT ASSEMBLY

Usability of the Game-based Gear Design Laboratory

After the brief introduction at the beginning of the laboratory session, the game-based laboratory system [23] administers a simple pre-experiment test to the students to gauge their knowledge of the gearing system and the fundamental concepts of planetary motions of gears (see Figure 4). Then, the laboratory system offers input options related to the experiment, the students select a particular input configuration (gears, shafts, holders, base, etc.) and proceed to performing the experimental procedure. After the experimental results (gear ratio, angular speeds, torques, etc.) have been displayed, the students may repeat the experiment with a different set of input parameters if they wish, thus enabling them to compare the results of the different configurations with each other. At the end of the virtual experiment, the system administers a post-experiment test to the students. Finally, the system provides the students with a questionnaire, offering an opportunity to give feedback regarding the game-based laboratory environment in general, its control and navigation, ease of use, the students' learning and feel of immersion, and other aspects. This user feedback is considered very important for future improvements in the existing virtual laboratory environment.

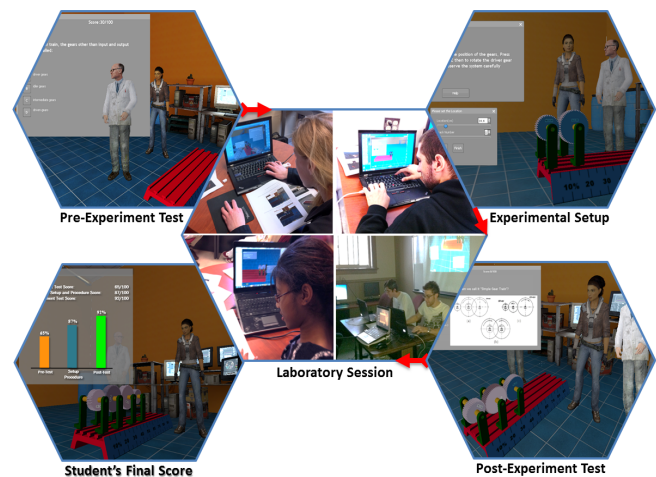

FIGURE 4
GAME-BASED GEAR DESIGN LABORATORY SCENARIO

PRE- AND POST-EXPERIMENT KNOWLEDGE TEST

The pre- and post-experiment knowledge tests used exactly the same format. Each test consisted of ten multiple-choice questions. Table 1 describes the content of the pre- and post-experimental test questions for the simple gear train laboratory. The purpose of the pre- and post-experiment knowledge tests was to determine whether or not the game-based gear design laboratory had helped the students to improve their understanding and knowledge of the concepts taught in the lecture component of the course and to see whether they had improved in the areas where they had problems in the pre-experiment test. The results of the pre-experiment test highlighted the areas where the students had the most difficulties and also informed the instructor about the subject areas where they needed additional or remedial instruction.

TABLE 1
SIMPLE GEAR TRAIN PRE- AND POST-EXPERIMENT TEST QUESTIONS

| No. | Pre-Experiment Test | Post-Experiment Test |
|-----|--|--|
| 1 | Gear train arrangements | Distinction between different gear trains |
| 2 | Motion transfer between two meshing gears | Purpose of simple gear trains |
| 3 | Examination of simple gear train output speed | Gear ratio in simple gear trains |
| 4 | Train value | |
| 5 | Identification of an idler gear in a simple gear train | Function of an idler gear in a simple gear train |
| 6 | Effect of an idler gear on the gear ratio | |
| 7 | Effect of an idler gear on the rotational direction | |
| 8 | Effect of the number of idler gears on the rotational direction and output speed | |
| 9 | Problem-solving | |
| 10 | Real applications of simple gear trains | Limitations of simple gear trains |

STUDENT EVALUATION QUESTIONNAIRE

The purpose of the questionnaire was to obtain student evaluations of the game-based gear design laboratory and to identify issues for further investigation in future work. The questionnaire consisted of two main parts. The first part concerned the evaluation of the laboratory experience regarding the laboratory's educational effectiveness, student satisfaction and team communication. The second part contained four additional questions about the gear assembly and an additional opportunity for students to comment on other aspects.

EVALUATION RESULTS

Student Evaluation Questionnaire: In the first set of questions, the students had to evaluate the educational effectiveness of the simulation-based laboratory experience. Specifically, the students were asked to rate, on a five-point scale (from 1 = 'strongly disagree' to 5 = 'strongly agree'), how effective they thought the laboratory exercise had been in 'teaching specific concepts relevant to the laboratory topic', 'increasing the general knowledge of the field', and 'providing skills that will make one a better engineer'. Another group of questions addressed student satisfaction (again rated on a 5-point scale) with the following specific aspects of the laboratory: overall satisfaction, feeling of immersion, ease of use, total time required, clarity of instructions, ability to control assembly, ability to set parameters and ease of collecting data. Descriptive statistics for the respondents who completed the questionnaire (N=22) are given in Table 2.

TABLE 2
DESCRIPTIVE STATISTICS ON EFFECTIVENESS AND SATISFACTION RATINGS

| Question | | M | s.d. |
|--------------------|-------------------------------|------|------|
| Effective in: | Teaching specific concepts | 3.82 | 1.01 |
| | Increasing knowledge of field | 3.55 | 0.86 |
| | Better skills as engineer | 3.45 | 1.01 |
| Satisfaction with: | Overall satisfaction | 3.95 | 0.72 |
| | Feeling of immersion | 4.09 | 0.81 |
| | Ease of use | 3.50 | 1.06 |
| | Total time required | 3.59 | 1.14 |
| | Clarity of instructions | 3.77 | 0.81 |
| | Ability to control assembly | 3.50 | 1.14 |
| | Ability to set parameters | 3.77 | 0.75 |
| | Ease of collecting data | 3.91 | 0.97 |

The results in Table 2 show that the effectiveness and satisfaction ratings of the simulated laboratory experience were generally quite high. For effectiveness, the students judged the virtual laboratory best at teaching laboratory-related concepts and somewhat less effective at providing general knowledge and skills needed by engineers. Satisfaction was highest with the feeling of immersion and overall satisfaction as well as with the ease of collecting data. The students were least satisfied with the ability to

control the physical assembly of the gears and the overall ease of use.

Four questions addressed the nature of the immersion experience, i.e. to what extent the simulated laboratory really promoted a feeling of 'being there'. These questions, answered using a 5-point scale, were: 'During gear assembly and data collection, to what extent did you: ... feel engaged in/absorbed by the experiment?' (M = 3.41, s.d. = 0.85), '... feel you had active control over the experiment?' (M = 3.45, s.d. = 1.01), '... feel you could choose freely what you wanted to see?' (M = 3.76, s.d. = 1.09), '... experience a sense of 'being there' inside the environment you saw/heard?' (M = 3.55, s.d. = 0.96). Again, the answers were generally positive (i.e., above the scale midpoint) but the pattern suggests that the visual aspects of the simulation were more compelling than the physical-control aspects.

The teams seemed to function well in the simulated laboratory environment. Three questions that dealt with team cooperation and effectiveness elicited very positive agreement ratings (where 1 = agree not at all, and 5 = agree completely): 'You and your team mates communicated effectively' (M = 3.73, s.d. = 0.98), 'You and your team mates worked cooperatively on this lab' (M = 4.14, s.d. = 0.83), 'You could depend on your team mates for help' (M = 4.36, s.d. = 0.49).

Another section of the questionnaire asked the students to indicate information sources that helped augment their learning, choosing from the textbook, conversation with the instructor, online resources, conversation with the TA, conversation with teammates, and conversation with other students. Generally, the social sources of information were most often mentioned as augmenting laboratory learning: 68% of the students cited conversations with the instructor and 59% conversations with team mates and other students. Also frequently mentioned were the TA (55%) and the textbook (50%). Only 18% of students cited online resources as being helpful.

Learning outcomes: As described above, the students took both pre- and post-tests of their laboratory-related knowledge, for both the simulation-based simple gear laboratory and the workbook-based planetary gear train laboratory with a 'hands-on' experience. Descriptive statistics summarizing performance on the pre- and post-knowledge tests (both measured on a 10-point scale) are shown in Table 3. The students did well on the tests, though less so on the planetary gear post-test.

TABLE 3
DESCRIPTIVE STATISTICS ON LEARNING OUTCOMES.

| Knowledge Tests | M | s.d. | N |
|------------------------------------|------|------|----|
| Pre-test - VR simple gear lab | 7.52 | 1.26 | 25 |
| Post-test - VR simple gear lab | 7.40 | 0.91 | 25 |
| Pre-test - workbook planetary lab | 7.28 | 1.31 | 25 |
| Post-test - workbook planetary lab | 6.40 | 1.00 | 25 |

However, direct comparisons of the mean performance on these four tests should be interpreted cautiously. In particular, the post-tests were purposefully made more difficult than the pre-tests so that they would be more appropriate course experiences. Thus, the decline in scores from pretest to posttest presumably means that the post-tests were more difficult and not that student understanding declined. In contrast, attempts were made to equate the two pre-tests (for the simple and planetary gear train experiments) for difficulty, and the near-equality of the mean values ($M = 7.52$ versus $M = 7.28$) seems to confirm success in this equating. Similar attempts to equate difficulty for the two post-tests were also made; thus, the difference in post-test mean values for the two laboratory formats may be interpreted (cautiously) as showing an advantage for the VR game-based laboratory.

The observed differences in knowledge test mean values were confirmed in a repeated-measures ANOVA, which revealed a significant main effect for laboratory format due to higher scores in the VR game-based condition, $F(1,24) = 9.55$, $p = 0.005$, and a marginally significant laboratory format \times time interaction, $F(1,24) = 3.610$, $p = 0.087$. The direction of the results is consistent with the idea that VR simulation-based laboratories are equivalent to or better than the workbook-based laboratory in promoting the learning of course concepts.

However, the confounding of laboratory content (simple vs. planetary gears) with laboratory format makes assessment and comparison of learning effects difficult. More carefully controlled evaluations of the effectiveness in teaching course concepts of simulation-based laboratories would be desirable in future studies. Specifically, such studies should unconfound content and laboratory format and better control test difficulty.

CONCLUSIONS

A virtual laboratory environment was used to implement and pilot laboratory exercises on both simple and planetary gear train systems. It was found that game-based laboratories can excite and motivate students, foster experimental, design, problem-solving and analysis skills, allow real-time feedback and remedial instruction based on the integrated learning assessment, promote student collaboration, and facilitate 24-7 laboratory access. Thus, virtual laboratories can help students to achieve many of the learning goals for educational laboratories listed by the Accreditation Board for Engineering and Technology (ABET) in 2005. However, more rigorous assessment of the learning effectiveness of game-based laboratories will require large-scale studies that control for laboratory content and test difficulty. We plan for such studies in future work.

ACKNOWLEDGMENT

This work was supported by NSF Grant No. 0326309. This support is gratefully acknowledged. Our thanks also go to Diana Kolesnikova for contributing to the data analysis.

What Are We Teaching In Cyber Competitions?

Abstract— *Student competitions are widespread across all academic disciplines, and are often touted as a means to motivate and educate students. Competitions may be internal within a single class or course, or vie school against school as regional, national, or international competitions and exist at all levels including 9-12 grades. These competitions have different formats and focuses such as vulnerability assessments, forensic challenges, offensive, and defensive competitions (or a combination of these). Some competitions require simple scripts and are considered ideal for script kitties while others require in-depth understanding of computer security and networking techniques to successfully compete in the competition. While the number of competitions and students participating in them have increased, it is unclear whether the stated academic goals of the competition are being met. In some cases, it appears that the focus of the student and institutional effort is more on the competition itself than on learning underlying concepts and developing skills. At our institution, students participate in several cyber-competitions, some of which we have initiated. The purpose of this paper is to survey existing cyber-competitions to understand the purpose of the competition, review underlying stated educational goals, and explore how the competition meets these goals. We compare the role of cyber competitions with the role of other computer-related competitions such as robotics, programming, unmanned aerial vehicles, and artificial intelligence comparing and contrasting the educational impact of the competitions on the participants.*

Keywords: Cyber, Competitions, Security Education

I. INTRODUCTION

In the past few years, competitions have become more and more a part of Cyber Security educational programs. Organizations are creating new competitions focusing on offensive, defensive, and computer forensics exercises. At our institution, we have created a student cyber competition team that we support by providing funds to travel to competitions as well as excused absences from classes and other required school events to prepare and attend formal competitions. When one of our classes needed a way to assess how well students can identify and correct vulnerabilities in a computer system, we created our own competition and opened it to a number of universities in our geographical area. It has even become popular with local high school students as an opportunity to develop computer security skills. Our competition was created with a strong mission statement, clear

goals, and identified educational outcomes directly supporting classes taught in our curriculum. This competition caused us to wonder what goals and outcomes were being addressed by other cyber competitions. This focus on what we are teaching in cyber competitions is the impetus for this paper.

II. BACKGROUND

Competitions have long been used as a motivational mechanism for students across a wide variety of academic disciplines and age groups. Spelling bees, science fairs, science Olympiads, writing contests, discipline-specific competitions, and quiz bowls are but some of the many competitions that have been created to attempt to enhance student learning and development.

Historically, student competitions were used to identify talent and develop gifted students for advanced study. Some of the earliest examples of competitions in academia came from Russia who started the academic Olympics in 1934 [1]. These competitions focused on mathematics and were used as a means to identify talent for further development. Students scoring well in the competitions were given automatic admission into top universities. Competitions grew throughout Europe with Germany having the most elaborate nationwide system of competitions with over 100,000 students participating annually in more than 20 federal competitions across many disciplines [1]. In the United States, interest in academic competitions increased significantly after the Russians launched Sputnik and President Eisenhower's science advisor, Edwin Teller, urged the use of competitions to get students interested in technical fields at an early age (www.osti.gov/accomplishments/teller.html).

Today, academic competitions are prolific throughout the educational process. Individual, team, inter-classroom, local, regional, national, and international competitions can be found in almost every discipline at all grade levels. Many studies have been conducted to attempt to evaluate the impact of competitions with both advocates and critics pointing to results supporting their positions.

Proponents of competitions in academia point to the additional motivation for self-learning and peer-learning provided by the natural competitiveness of many students. Competitions are

typically well-structured events with clearly-defined goals. Individuals or teams compete within the competition framework for some extrinsic award or recognition. Proponents claim such competitions encourage participants to excel on a mental level much the way they do on a physical level in competitive sports. In an evaluation of 44 student competitions for engineering and technology students, Wankat [2] discovered that student advisors were unanimous in their opinion that the contests provided a good learning experience, and students learned more by participating in the competition. Wankat [2] also drew a correlation between success in the competition and alignment of the competition with an institution's curriculum.

Another positive aspect of competitions is that they can direct career choices and provide participants with a broader view of possible life choices motivating further education. In a discipline-specific study, Bishop found 39% of competition participants claimed their participation influenced their choice of college major [3].

Team competitions that engender a cooperative learning environment within a team are more effective than individual competitions [4]. In an analysis of 46 studies on cooperative versus competitive competitions, Qin showed cooperative learning significantly outperformed a competitive approach. Effective teams generate a sense of belonging to individual participants, encourage peer mentorship, and provide the cohesiveness of a common goal. Hammer [5] noted the additional benefit gained from using peer-assessed competitions as opposed to expert judging.

Critics of competitions point to misplaced participant motivations, a focus on winning versus learning, negative impacts on self-concept, and self and peer pressure to perform resulting in negative learning experiences. In evaluating motivations for student participation in science fairs, Abernathy and Vineyard [6] found the majority participated through teacher coercion, as a requirement, or because of credit given. In a study of student motivation for participation in quiz bowls, Dalton found that reasons such as being able to claim participation on college applications far outweighed student interest or desire to learn [7]. External motivations for participation are not in and of themselves a detriment. In an evaluation of over 30 years of science fair participant surveys, Bellipanni [8] found the vast majority (96.2%) rated the value of participation as high.

Another criticism of competitions is the potential negative impact they have on student self-concept. Students who perceive themselves as less-able than their peers and perform worse than their counterparts in competitions have their low self-image reinforced and can become discouraged and frustrated [9]. Cheng proposes an "equal opportunity tactic" to allow students of similar ability to compete with each other and reduce the perception of underachieving students.

Gay et al [10] suggest several negative messages that can result from grading based on individual competitions including:

1. Learning is an activity that is to be pursued individually.
2. What is to be learned is determined solely by the teacher.
3. Learning consists of memorization and translation on what authorities agree is true.
4. The measure of how well one has learned can be determined by examining one's scores on objective tests in comparison to one's peers.
5. School learning has nothing to do with real life.

If the emphasis is on winning and the extrinsic reward is great enough, competition can be viewed as mutually exclusive goal attainment. That is, the success of one requires the failure of another. The article also points out that competition can foster cheating.

III. EXISTING COMPETITIONS

One of the earliest identified academic competitions is the science fair competition sponsored by the Society for Science and the Public. Beginning in 1950, and expanding to an international competition in 1958 by bringing in Canadian, Japanese and German students, this competition has set the standard for many others to follow (<http://www.societyforscience.org/iseef/about>). The science fair offers a vision of "promot[ing] the understanding and appreciation of science and the vital role it plays in human advancement: to inform, educate, and inspire." Focusing on high school aged students, this competition offers a strong set of rules which emphasizes the design of the research project ensuring that it not only meets rigorous standards but also matches up students with mentors (high school faculty or even college faculty members) to ensure a strict set of criteria is followed. Human research requires a formal Independent Research Board approval and strict criteria is provided to students as part of the registration process. Judging of the competition is well designed and consistent across competitions clearly outlined in writing.

Another well-known and defined competition is the Scripts Spelling Bee. The national spelling bee, a uniquely American experience, has been run since the 1920's and is set on a series of well-defined rules for both contestants and judges. The spelling bee has a strict mission focusing students on the study of "help[ing] students improve their spelling, increase their vocabularies, learn concepts, and develop correct English usage that will help them all their lives." (<http://www.spellingbee.com/about-the-bee>).

Both the science fair and the spelling bee are well defined competitions which have clear missions, goals and clear educational outcomes.

As the popularity of competitions continued to grow, competitions have been created which include such themes as Robotics, Computer Programming, and Artificial Intelligence. Technology subjects lend themselves to multiple team-based competitions which are often sponsored by well-known organizations such as the Institute of Electrical and Electronics Engineers (IEEE) and the Association for Computing Machinery (ACM). Some of these competitions are well designed and are defined with formal missions and structure. An analysis of well-known technical competitions at the high school and collegiate levels, in an attempt to understand what drove the individual competitions, is outlined in Table 1.

Table 1 - Non-Cyber High School and Collegiate Technology Competitions

Each of the identified competitions was analyzed based on three criteria: a well-defined mission statement, clear goals outlining the competition, and clearly defined educational outcomes or expectations. In addition to the science fair and the spelling bee, eight competitions were identified. Out of these eight, five had well defined mission statements and clear goals. Only two (the First Lego League and the BattlebotIQ) had well defined educational outcomes.

IV. CYBER COMPETITIONS

To fully discuss cyber competitions, we must define the word cyber. For the purpose of this paper, we refer to cyber as a reference to both networked infrastructure components

(computers, routers, hubs, switches, and firewalls) as well as the assets which go with it (critical data for a given organization) [11]. In the case of cyber competitions, any competition which focuses on the above definition was identified. Cyber Competitions are focused on three specific areas: computer forensics, capture the flag (offensive) competitions, or cyber security (defensive) competitions. All three were included in this analysis.

A review of the literature as well as competition web pages found a total of fourteen formal competitions open to the public and one formal competition (CDX) which was not open to the public but available only to US military organizations. An overview of these competitions is outlined in Table 2: High School and Collegiate Cyber Competitions along with a notation as to whether clear goals, well defined mission statements, and clear education outcomes associated with the competition were located on the competition's web site or in the advertised literature.

Of note from this analysis is that only one of the cyber competitions had clear educational outcomes identified and associated in the competition description. This is true even though six of the competitions (NYU Poly, US Cyber Patriot, Pacific Rim CCDC, UCB CTF, San Diego Mayor's Cyber Cup and CDX) were all focused on high school or college student participants. The CyberPatriot competition provided materials for use in preparing teams to participate in the event. This could be due to the fact that CyberPatriot is attempting to recruit members from high schools, a population that is not commonly thought of when developing cyber competitions. In fact, out of the fifteen formal competitions and four information competitions reviewed, only two (CyberPatriot and the San Diego Mayor's Cyber Cup) were focused on high school students while others focused on either college undergraduates, graduate school students, or industry experts. Understanding its population, the CyberPatriot developers realize that high school teachers may not have a background in cyber security and compensate for this by providing formal training modules as well as coordinating an industry-based mentor to work with each team during the training process. This compensation requires the competition to identify associated educational outcomes as well as clear competition goals to ensure that participants develop skills needed to succeed.

Table 2- High School and Collegiate Cyber Competitions

V. CONCLUSIONS: WHAT ARE WE TEACHING WITH OUR CYBER COMPETITIONS?

Over the years, in the non-technical realm (Science Fairs, Spelling Bees, etc.), competitions developed clear mission statements and goals as well as educational outcomes. Most technical competitions, however, do not seem to be as well focused. Looking specifically at cyber competitions, there are even fewer organizations which identify their own competition mission and goals much less specify associated educational outcomes. In fact, in our analysis there was only one competition (specifically focused on high school students) that has educational outcomes identified on their web pages and those outcomes come from the fact that the program provides

an educational piece to help teachers and mentors to prepare the students for the competition.

A lack of identified educational outcomes leads to the question of what purpose cyber competitions are trying to attain. Is the goal to motivate students to learn by focusing them on the opportunity to 'win' against other schools or even against other teams within the same school? Without clear educational outcomes associated with the project, how are students expected to prepare for a competition? Some even suggest that schools should focus on creating a curriculum to support competition [12] or even identifying learning objectives through competition [13] instead of developing competitions to support existing learning objectives. While supporting the concepts identified by Wankat [2] that a strong alignment of competition with an institution's curriculum is a sign of a winning institution, the fact that competitions are being used to drive curriculum suggests that overarching educational outcomes are not being sufficiently identified prior to developing and implementing formal cyber competitions.

Work in Progress: Evaluating the Use of Mobile Game Development in Introductory CS Courses

Abstract—Computer games have been accepted as an engaging and motivating tool in the CS curriculum. However, designing and implementing a playable game is challenging and is best done in advanced courses. Games for mobile devices offer the advantage of being simpler and, thus, easier to program for lower-level students. By exposing these students to a wide range of advanced topics, we can demonstrate to them that CS can be much more than coding. Here, we discuss our evaluation of a set of learning modules for introductory CS courses that use mobile game development as a motivational learning context.

Keywords—Games, mobile computing, introductory courses, motivation, engagement

I. INTRODUCTION

Computer games have been successfully applied to improve recruitment and retention in Computer Science (CS) courses and degree programs [10]. They have been shown to be a successful learning tool by leveraging students' enthusiasm towards computer games and their social relevance. Designing and implementing a playable game is a very challenging task, especially for lower-level students. Thus, this is best done in advanced CS courses where students already have sufficient experience in software development and exposure to other CS topics. Games for mobile devices, on the other hand, are simpler by nature and are thus easier to program [6]. This makes it more feasible for lower-level students to develop playable games as part of their classroom experience [4]. Mobile applications are often easy for students to relate to since mobile technology plays an increasingly important role in the lives of today's students. Thus, leveraging mobile game development as a motivational learning context has strong potential to improve student success in introductory CS courses and increase student motivation to stay in the major [8].

Creating engaging and feature-rich games requires a skillful integration of a wide range of techniques from many areas of CS; thus, computer games can be used at different points in the CS curriculum including in introductory courses. Using mobile devices as a learning context in these courses aims to provide a simple and elegant means to motivate students and communicate the diversity and power of many advanced CS areas in a manner that engages students in experiential education [9]. Moreover, research also shows that participatory learning methods such as those used in mobile game development can level the playing field for different types of students [1]. Research literature and our own experience

demonstrate that most CS students seem to be very interested in computer game development, and introducing students to this topic early in the curriculum could serve as a good tool to increase student retention [1]. More broadly, current research literature indicates that students perform better when they find their course material relevant and motivating [2].

II. DEVELOPMENT OF LEARNING MODULES

Supported by an NSF TUES/CCLI grant, we are working on a comprehensive set of eight learning modules consisting of laboratory projects and accompanying instructional materials for introductory CS courses taught using Java. Each learning module serves as a platform to introduce students to an advanced CS topic, such as algorithms, artificial intelligence, computer networking, computer security, computer systems, database management, human-computer interaction, or software engineering, as well as to practice a fundamental topic, such as arrays or inheritance. By demonstrating these and other non-programming and diverse aspects of the discipline to the students early, this approach may help dissolve a widely popular misconception that "CS is all about coding" [1].

Each learning module consists of a small laboratory project suitable for CS I and beyond. Each project focuses on a single mobile game, introduces one advanced topic, and reinforces one core concept. In addition to the project, deliverables for each module include a set of instructional and supplementary materials. These include an instructor's manual that provides a sample syllabus to go with each project and guidelines for the adoption and adaptation of the curricular material. Instructional materials consist of lecture notes, illustrations, references, and sample solutions, as well as supporting materials such as project source code and documentation.

III. EVALUATION OF OUR APPROACH

We tested a few of the developed modules at Central Connecticut State University (CCSU) and Rose-Hulman Institute of Technology (RHIT) with a total of 161 students. In testing the modules highlighted above, we employed three assessment strategies: 1) student course grades and course completion, 2) the Classroom Survey of Student Engagement (CLASSE) administered at the end of the term, and 3) the Motivated Strategies for Learning Questionnaire (MSLQ) administered at the beginning and end of the term. The modules were used relatively late in the courses, during the last few weeks of the term.

This work was supported in part with NSF awards DUE-0941348 and DUE-0941658.

During the first year of the project, 161 students enrolled across eight sections of introductory CS courses at CCSU and RHIT, although the total number of students who completed each assessment varied. A total of 84 students were enrolled in a test section in which one or more curricular modules using mobile game development were used to convey basic concepts, and 77 students were enrolled in paired control sections of the same course. Not all students completed the courses, however; nor did all of those students who completed the courses participate in both administrations of MSLQ and the one administration of CLASSE. At both CCSU and RHIT, the courses were open to students of any major, as long as they met the courses' prerequisites.

According to the interim report [7], results from the first year of the assessment of the project yielded findings in various areas of interest. We highlight a few of these areas.

A. Student Persistence

Persistence rates appear independent of administration of mobile game development curricular modules but were significantly different between the two institutions, with students at CCSU persisting at lower rates. The differences between universities in persistence rates very likely reflect the selectivity of the institutions, composition of the class population, and academic inputs of students taking the courses, with students at the less selective CCSU exhibiting lower persistence rates and lower levels of academic performances.

B. Course grades

Student course grades were independent of the use of the curricular modules. This suggests that the mobile game development modules as administered at both institutions did not affect student performance on the assessments used by these instructors.

C. Student engagement with course

Findings about student engagement in the course present a mixed bag of results that suggest limited positive effects of using the mobile game development modules in increased note taking, making connections across courses, and for the students at CCSU, whose academic preparation for college was not as strong as those at RHIT, perceptions of course difficulty decreased. Use of the mobile game development modules with the better prepared RHIT students, however, exhibited some negative effects in the area of instructor comfort and communication as well as student interest in the material. It is possible that these negative findings were a result of students who expected a more traditional classroom experience with these concepts or that the curricular modules did not fit seamlessly into the rest of the course taught at RHIT.

D. Student motivation

Generally, motivation among students in CCSU computer science classes declined, but this decline was less pronounced in test sections than control sections. By contrast, RHIT student motivation stayed level or increased slightly over the course of the term for both the test group and the control group, with motivation gains among the control group slightly outpacing those in the test group.

IV. SUMMARY AND FUTURE WORK

Evaluation results indicate that in each of the areas discussed above, the test groups did no worse than the control groups. As a matter of fact, students in the test groups were more engaged with the course in which the modules were presented and their motivation did not decline as much as the control groups. We will continue to refine the modules and adjust the points in the courses in which we use them. Allowing students more time to work with the modules and to apply what they learn to other topics may produce more positive results.

This project has a lot of potential. We believe that using mobile game development projects in introductory CS curricula will promote teaching and learning, help improve student experience in the critical introductory CS courses when student attrition is at its highest, and ultimately will help train outstanding computer scientists. We are currently in the process of making changes and finalizing the modules to address the concerns raised as a result of ongoing project assessment. We shared one of the modules with instructors at the 2011 ACM Special Interest Group on Computer Science Education (SIGCSE 2011) symposium and at several Consortium for Computing Sciences in Colleges (CCSC) conferences [5] and it was very well received. We are also working toward developing a web portal where we can share this and other modules with the wider community.

Work in Progress: Teaching Game Design and Robotics Together:

A Natural Marriage of Computing and Engineering Design in a First-Year Engineering Course

Adam R. Carberry and Ashish Amresh

College of Technology & Innovation

Arizona State University

Mesa, AZ, USA

adam.carberry@asu.edu; ashish.amresh@asu.edu

Abstract—The increased dependence on computer programming in engineering has made it essential for engineering students to learn about programming throughout their undergraduate education. In the same vein, computing students benefit when given an opportunity to learn more about engineering design and systematic thinking. This paper discusses how one college embedded computing and engineering into a combined first-year introductory course. The course fuses computing and engineering using game design and robotics as an offering for both cohorts of students to work together in a multidisciplinary environment. Over the course of the semester, students learn introductory computing and engineering design concepts by designing games and robots using informatics tools to solve design challenges. Interdisciplinary teams consisting of computing and engineering students work together to prototype a game design idea and then bring that idea to life using robots as part of their final project.

Keywords – game design, robotics, project-based learning, problem solving, common engineering core, computing for engineers

I. INTRODUCTION

Understanding of and an ability to program has become an essential skill for engineers to learn since the creation of the computer. The increased reliance on computing to address engineering needs has rapidly increased the number of programming-based courses required to receive an engineering degree. A parallel need also exists for computing students to understand the principles of engineering as it relates to design, problem solving, and applied learning [1]. The ability to think in a design-centered way and approach problems systematically are skills that assist engineering and computing students in problem solving. The intended goal of these two learning objectives suggests a mutual give and take that lends itself ideally to a multidisciplinary approach. Yet, common offerings to address the learning of these skills have taken on a “siloe” or separate disciplinary structure where engineering and computing students learn these skills separately [2]. This has several pitfalls; the most severe being that underclassmen lack the maturity or the far-sightedness to understand why they have to learn the basics of other disciplines if it is not their intended major [3, 4].

The following work-in-progress discusses the creation of a

fused multidisciplinary computing and engineering course, similar to that of Xu *et al.* [5], that relies heavily on the principles of game design [6] and LEGO® Mindstorms® robotics [7, 8]. The course was designed and taught by a computing and engineering faculty team – one instructor from each discipline. Students in both engineering and computing enrolled in the course together during their first-year to create a multidisciplinary experience.

II. COURSE DESIGN

In 2009, the computing department merged with the engineering department allowing for an opportunity to fuse each disciplines separate introductory courses. Teams of computing and engineering faculty began offering these fused introductory classes. The fused computing and engineering course is taught as part of a required first-year project spine.

Anecdotally, the faculty found that the courses were not preparing students well enough for the subsequent second-year courses in both engineering and computing, especially in computing. The courses were technically fused, but in practice became essentially two courses taught during one insufficient time block.

A new approach was piloted during the Spring 2012 semester to explore how a combination of game design and robotics would impact the computing-engineering fusion. The course was designed to utilize the strengths of the department, to make use of the flexibility of both media to address computing and engineering content, and to learn how the benefits of learning robotics and game design separately could be applied to one another.

As shown in Figure 1, students started out by learning the principles of programming using a drag and drop tool (GameMaker™) to design games. They then transitioned into another drag and drop tool (ROBOLAB™) to learn the principles of engineering design. The two skills were then combined via a final project. The final project placed the emphasis on game design to prototype the solution for an engineering design problem (i.e. iterate, test and refine the solution). Robotics was then applied to finish the real-world

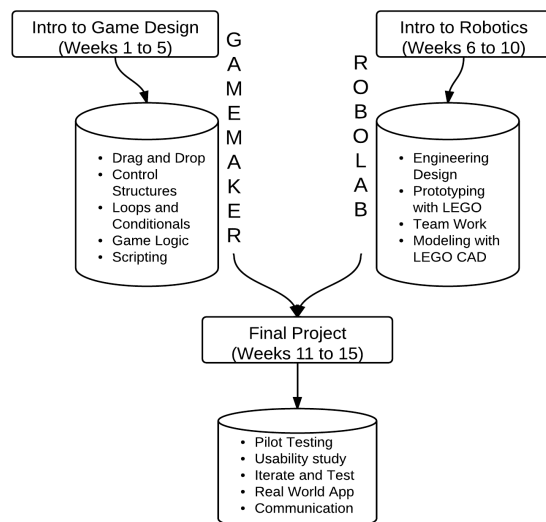

Figure 1. Design of a 15 week fused course

implementation of the solution. Multiple projects for each of the first two sections were used to ensure students had opportunities to display their competency and to work in many different groups. A flipped classroom approach (reverse teaching-homework paradigm) was also used to save class time for hands-on assignments and troubleshooting [9-11]. The overall curriculum design aimed to extract the benefits of gaming and robotics in harmony with one another in a way that showcases the importance of learning both computing and engineering design fundamentals.

III. COURSES ASSESSMENT

During the Spring 2012 semester, one of four sections consisting of twenty-one students, used the combined game design and robotics curriculum. The cohort of students consisted of eleven declared computing students and ten declared engineering students. The course was assessed throughout the semester using student reflections to determine the effectiveness of this approach. Students provided feedback on the content and identified the “muddiest point”, i.e. what was most confusing, each week (source of quotes seen below).

A. Game Design

Game design was received well by the students. The drag and drop style programming of GameMaker made it straightforward and easy for students to learn through the online video tutorials. The majority of students found “*GameMaker [to] definitely [be] an interesting learning experience.*” The flipped classroom approach made it easy for the instructors to help students learn the basic skills necessary to program in GameMaker. Individual and group assignments were then completed in class in an environment that allowed students to consult one another. Students generally “*...enjoyed working on assignments in class in collaboration with other students.*”

The most common “muddiest point” was the conversion from drag and drop to written script. The instructors agreed

that all of the students, particularly the computing students, needed practice with written code, including an ability to identify what a drag and drop function would look like if written. This proved to be a difficult transition for many of the students with the limited time given to learn the skill.

B. Robotics

The easy assembly and familiarity with the LEGO products made it easy for students to design and construct their ideas. Students found the robotics section to “*Overall [be] a pretty enlightening experience*” that gave students “*... a great concept on how to be an engineer.*”

The programming was a natural extension of the game design section. ROBOLAB is also a drag and drop program that runs within LabVIEW™ Software; the chosen programming language used in the second-year engineering project courses.

As opposed to the game design section, the robotics section utilized teams of students to complete a series of tasks. The explicit team projects were enjoyed by all of the students.

C. Final Project

The biggest challenge of the game design—robotics curriculum was determining how to combine the two media into a natural final project. While both utilize a drag and drop approach to programming, the two programs do not naturally interact with one another. To temper the compatibility issue, it was decided that students would design a two-player game. First, the students would draw up multiple ideas for their game in written form. Second, the students would create a video game version of the game using GameMaker. The video game would act as a simulation of a physical game. Finally, the teams were tasked with creating a physical version of the video game using robotics.

IV. CONCLUSIONS & FUTURE WORK

Our preliminary results suggest the use of game design and robotics as natural media to include in a fused computing and engineering introductory course. The skills required to complete game design and robotic activities complement and enhance each other. The two media are also viewed as fun to the first-year students.

Future assessment of this course will involve an in depth analysis of how this approach impacts student learning. A comparison will be made between traditional offerings and the fused course. Additional quantitative analysis of computing and engineering design self-efficacy, anxiety, and the perceived values associated with a computing-engineering fused course will expand our understanding of this new approach. Research will also identify how best to use a flipped model classroom by iteratively changing the curriculum to improve proficiency with programming.

ACKNOWLEDGMENT

The authors would like to thank the Arizona State University College of Technology and Innovation’s Scholarship Support and Enhancement program for funding this research.

Work in Progress: Who Answered First? – A Trivia Game utilizing Timed Electronic Classroom Response Systems

Jonathan Riehl, Brett Hamlin
Engineering Fundamentals
Michigan Technological University
Houghton, Michigan, United States
riehlj@mtu.edu, bhhamlin@mtu.edu

Abstract—Currently, classroom response systems (CRS) are being integrated into an increasing number of university courses. One of the least pursued usages of CRS is the ability to capture speed of student responses. Many of these systems produce a dynamic comma-separated value (CSV) file that presents all of this information in a database that can then be tapped for various uses. The system described in this paper combines the i>Clicker CRS, Mathworks MATLAB, and Microsoft PowerPoint to create an interactive trivia game for use in the classroom. The current implementation is used as an exam review in two first-year fundamentals of engineering courses at the university level.

Keywords—classroom technology, clickers, trivia, classroom games, classroom response systems, classroom applications.

I. INTRODUCTION

The quiz show Jeopardy!® is one example of a timed response trivia game. The greatest challenge in implementing such a trivia game in the classroom is the ability to measure who “buzzes in” first. Generally, only two dichotomous methods have been utilized: hand- raising and remote timed response systems. Both of these methods sacrifice some aspect of the quality of experience. Hand-raising, although cost effective, is an imperfect system and cannot be scaled well to a classroom-sized group. Hand-raising often involves time spent arguing about who has raised their hand first and causes instructors or TAs to make somewhat arbitrary decisions based on what they saw at the time. On the other hand, remote timed response systems are expensive, situation specific, likely difficult to set up, and not scalable.

The system described in this paper offers an alternative method utilizing already widely operating CRS. Specifically, this system combines Mathworks MATLAB [1], Microsoft PowerPoint [2], and the i>Clicker system [3] to create an interactive trivia game for use in the classroom. The current implementation is used as an exam review in two first-year fundamentals of engineering courses at the university level. To the authors’ knowledge, there are no other published works on interactive quiz-style systems using CRS.

The development and implementation of this interactive game includes three major steps. The first step was the development of the software interface between the i>Clicker database and the programming environment, MATLAB. The

second step was the development of fully-functional PowerPoint slides that provide parallel operation between the slides and the MATLAB program. The third step was conducting a case study involving a first year engineering course at the university level with approximately 60 students using this system as an exam review session. Finally, future developments are presented with the goal of attaining a smoother, more user-friendly system which will be adaptable to many different classroom situations. This work is significant because it shows an inexpensive and scalable timed electronic CRS for use in an academic setting.

II. SOFTWARE

A. MATLAB/i>Clicker Interface – Quicker Clicker

A MATLAB program, Quicker Clicker, was developed to display the name of the student who clicked in first in response to an i>Clicker question asked by the instructor. The i>Clicker system is set up to record student responses in a comma-separated value (CSV) file. After asking a question with the i>Clicker software, the file is immediately updated with information on the question, including the students response and the time of their first click. The program works by polling the CSV file and running whenever the file is updated. The file is searched and the student’s name is displayed in a large yet unobtrusive format on the screen. At this point, the instructor can call on the student to answer the current question. The student’s name drops off the screen after about five seconds, allowing for subsequent responses.

B. PowerPoint Slides

A PowerPoint Jeopardy-style system was developed in order to efficiently ask questions and allow seamless interaction between slides. Each round begins with a display board with six categories and five squares per category with increasing point values. When a student or team selects the category and point value desired, the instructor can click on the square and the question will appear. The question is then asked by the instructor and the Quicker Clicker program is activated. Once the question is answered, the instructor can click the back button and return to the display board.

The slides are set up in such a way that an instructor can change category titles and individual questions, with the

functionality remaining intact. This allows for this software to be expandable to any class with any type of questions.

III. FIRST-YEAR ENGINEERING CASE STUDY

This system has been developed for use in a first year engineering course at the university level with approximately 60 students using this system as an exam review session. Over the past three years, the software has been developed and improved based on trials in this setting.

The course is already broken-up into teams of four students, and these teams are used for the game scoring. Students use their i>Clickers to click in for each question and control of the board goes to the team that most recently recorded a correct answer. The game can either progress until all questions on the board are answered or the game can be timed. In a 90 minute class session, two full rounds and a final round can be run, which gives students access to 61 questions. Generally instructors can also provide insight after a student response to each question.

There are many benefits that have been noted based on these trial sessions. First, student engagement in the review process is much higher than a standard review class period due to the competitive nature of the game. Second, the questions are set up in a very organized manner covering all of the topics students need to review, which allows students to go back after the class and review effectively. Third, students can choose to participate actively or passively based on their learning preferences. Some students try and click in for every question whereas others decide they would rather pay attention to the questions and answers and they do not click in. Fourth, the process to students appears seamless and non-intrusive, thus allowing them to focus completely on the questions and reviewing.

IV. NEXT STEPS

Although the software currently works as written, there are a few areas that are being improved to make for a more manageable, scalable system. Ultimately, the package will be released online for general academic use. The following is a list of improvements in development:

- *Question elimination* – The current system relies on the instructor and students to remember which questions have been answered. A beta version of a MATLAB implementation of question elimination is currently in use, but is still not very user friendly. The goal is to make a system that either dynamically updates the PowerPoint slide as questions are selected or automatically records these clicks in the MATLAB program.

- *Team responses* – The current system only allows for individual student names to appear as a response for fasted click. An improvement would allow for the instructor to choose between individual and team operation.
- *Automated scoring* – The current system does not integrate scoring and this is currently done by the instructor or teaching assistant. This manual process is very time intensive and does not allow for students to have a consistent, quickly updated score available. The improved system will automatically record and display scores based on who has clicked in and an instructor's click on "right" or "wrong" after the question is answered.
- *Automatic roster updates* – The current system requires the instructor to modify the remote identification file to put in full student names. The improved system will cross-link the names from other files already created, so that the instructor does not need to do any preprocessing before running the session.
- *Automated Timer* – Currently the instructor needs to be careful to time the game appropriately. The improved system will include a timing system in order to make sure that the game will end by the end of class.
- *Enhanced MATLAB/i>Clicker Interface* – Currently the interface neglects many technical issues with wireless communication and may not accurately select the quickest clicker in all cases. The improved system will look at a more fair and accurate method to obtain the quickest clicker.
- *Help request mode* – A feature is planned that will allow the system to be utilized as a team request for help. Identifying which team requested help first during work sessions in an active classroom environment can be challenging. In our experience it is often the closest team requesting help which receives it first. In "Help Request Mode," teams would click in when they have a question and the team number would be displayed on the screen. Instructors would then have a time based order to follow in which to give aid to the different student teams.

A study on the influence of rich versus traditional classroom response system (CRS) questions on concept retention

Smitesh Bakrania
Mechanical Engineering
Rowan University
Glassboro, NJ, USA
bakrania@rowan.edu

Abstract—Clickers in classrooms have been shown to increase student engagement. With the emergence of touch-based smart devices, such as iPhones and iPads, there is a move towards migrating the functionality offered by the clickers to these advanced response systems. Apart from being a convenient alternative, do these advanced touch-based devices offer anything new with respect to student learning? For a start, beyond the traditional multiple-choice and true/false responses, these advanced clickers provide several new question modalities that the traditional button-based clickers do not offer. It can be hypothesized that the rich interactions offered by touch-based devices can enhance student engagement even further than the traditional clickers currently do and contribute towards improvements in student learning. To explore this hypothesis, a study was designed to investigate the difference in concept retention among students who use the traditional versus rich classroom response systems (CRS). The study was conducted using a custom-designed iPhone app during an engineering lecture. While no significant difference in retention was evident, several insights were gained in favor of the rich interactions offered by the new CRS. This work highlights the distinct features that make advanced clickers conducive to student engagement and guides future developments in such next generation classroom technologies.

Keywords—component; clickers; iPhone; iPod; iPad; classroom response system; CRS; rapid feedback; student feedback; smartphones

I. INTRODUCTION

Research has indicated that classroom response systems (CRS) make classrooms more engaging for students [1]–[7]. For instance, extensive work with traditional clickers has demonstrated improved student participation [6],[8],[9], interaction [10]–[13], engagement [14][15], retention [16] and sometimes even grades [1],[17]–[19]. Such studies make CRS very attractive for our classrooms. However the current CRS technology exhibits limitations in terms of the types of interactions offered. Typically when using commonly available button-based devices, only multiple-choice answers (A, B, C or D) or true/false answers (e.g., A for True or B for False) are available as response alternatives. Figure 1(a) provides an image of a traditional clicker that is currently available as one

of the least expensive CRS option. Also depicted in Fig. 1(a) is a touch-based smart device by Apple, iPod Touch that can at minimum provide response options similar to the traditional clickers.

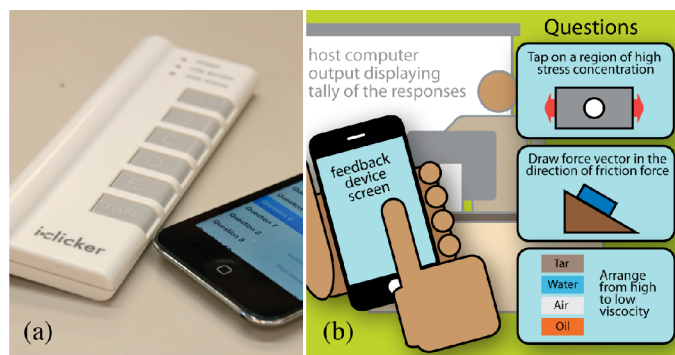

Figure 1. (a) A photo of a traditional i>Clicker response device, currently a widely used clicker system, along side Apple's iPod Touch unit. (b) An illustration depicting possible rich interactions via a touch-based platform.

A touch-based system, however, can dramatically expand the available forms of interactions considering it is not limited to the four buttons (or more) that are available on the traditional clicker. Though the examples provided are specific to engineering, the illustration in Fig. 1(b) demonstrates the potentially new and improved interactions available via a touch-based platform. Instructors will be able to solicit responses by asking every student in the class to, for instance, tap on the region of an image where the correct answer exists, draw the response with their fingers, and sort items in an ascending or descending order. Previously, such deep interactions were limited to instructors individually asking a student for response. Considering the touch-enabled devices such as iPod Touch and iPhone are ubiquitous, these rich question types can be easily adapted to develop an advanced CRS platform.

While we can anticipate rich questions providing deeper engagement with the questions, it is yet to be seen if the rich questions improve learning. Specifically, do rich questions

enhance concept retention because of their ability to better engage compared to traditional questions using a classroom response system? The study described here attempts to investigate this research question using a custom-designed app that runs on an iOS device (iPod Touch, iPhone or an iPad). This paper describes the details of the preliminary study and how concept retention was tested. Even though the study did not provide conclusive result, the outcomes are promising for future investigations into advanced CRS; which will inevitably become part of future classrooms.

II. DESCRIPTION OF THE TECHNOLOGY

CRS typically involve two critical response stages: the *student response* stage where students respond to pre-designed questions and the *instructor feedback* stage where the instructor reviews and discusses the student responses. The customized touch-based CRS was developed as a two-component system:

- **ClikMe.** An iPhone/iPod app called ClikMe was developed by engineering students at Rowan. ClikMe allowed a) remote downloading of question packs prepared by the instructors, b) displaying the questions for student interaction, and c) students to send their responses to a remote location for analysis.
- **Server.** The server was designed to accept student responses from the various iPhone and iPod Touch devices over the campus WiFi network. The responses would then be aggregated and analyzed for correctness. The server also provides simple analyzed output of the student responses.

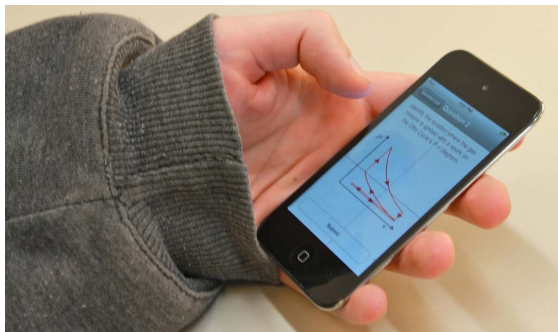

Figure 2. A photo of ClikMe app running on an iPod Touch. Student interacting with Region of Interest question.

ClikMe offered the following question modes: a) Multiple-choice - select from a list of choices, b) True/False - select whether the statement is true or false, c) Short Answer - provide a short response to the statement, d) Sorting - arrange in ascending or descending order, e) Region of Interest - identify a region on the image, f) Drawing - draw an arrow over the image provided. All question types were able to embed an image to provide a more visual experience. The question packs were remotely downloaded from a cloud storage location (dropbox.com) to the iOS devices. The responses were sent to a designated web-server for subsequent analysis. At this stage of the app development, the *student response* stage of CRS was fully functional however the

instructor feedback was only partially complete. For instructor feedback to take place the server required the ability to analyze the data and visually present the results. Therefore, the student responses were aggregated but their responses were not instantly available for analysis by the instructor. Also, for the preliminary study, the drawing question was not included due to the incomplete nature of the server component. However, the rest of the question-types were included in the study. Figure 2 provides a photo of a student interacting with ClikMe's Region of Interest question.

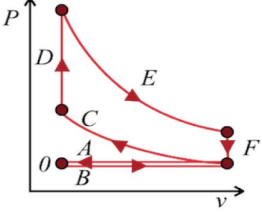

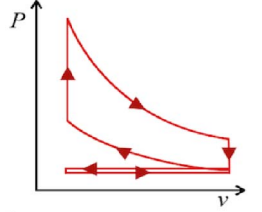

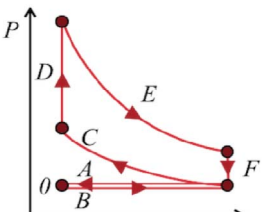

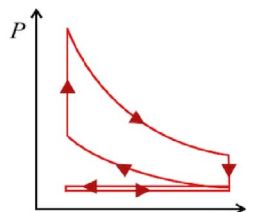

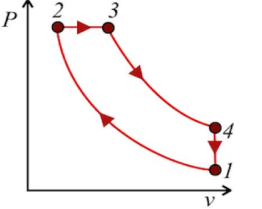

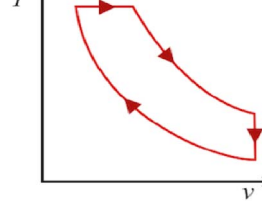

III. METHODOLOGY

An undergraduate Thermodynamics course was selected for the study. Internal combustion (IC) engine cycles topic was chosen as a lecture-topic for the ClikMe CRS session. Both rich and traditional questions were prepared beforehand and the study was conducted at the end of a lecture on Otto and Diesel cycles. Half of the students in the class received iOS devices loaded with traditional questions ('control') while the second half received devices loaded with rich questions ('treatment'). The students were randomly assigned to receive traditional or rich devices. ClikMe was used to present both rich and traditional mode questions to the participants. Traditional clickers (the button-based devices) were avoided to limit any unintentional biases between the rich and traditional responders (eliminating the 'coolness' factor of using iPods). The only difference between the rich and traditional question responders was the question mode - the traditional responders were limited to multiple-choice and true/false question types. The study proceeded in two stages: the clicker test (treatment stage) and the concept retention test (assessment stage). For the clicker test, a touch-based CRS session was conducted at the end of a lecture. The concept retention test was administered during the next class period (4 days later and over the weekend) to assess the influence of rich or traditional question types on concept retention.

A. Clicker Test

Six equivalent questions were prepared for rich and traditional responders. Each question was designed such that it fit the respective definitions of rich versus traditional question types. The list of questions for both question types is provided in Table I. As an example, the first question (Q1) tests the same concept however the traditional format asks the student to select a single step that follows the BDC location of the piston, while the rich question-type asks to arrange the three steps in order. It is anticipated that the rich question responder is forced to understand the relationship between each of the steps compared to understanding the sequence with respect to BDC alone when considering traditional question type. As another example, the second question asks students to indicate where the gas mixture is ignited on the plot, providing six choices for the traditional question format. Here the rich question format affords numerous potential responses, including the end points for the steps. Again, the rich responder is forced to consider a multitude of choices and select a single response. It is this more open-ended process, that provides an avenue for deeper engagement and thus retention of concepts being tested.

TABLE I. CLICKER TEST QUESTIONS DIVIDED INTO TRADITIONAL AND RICH QUESTION TYPES.

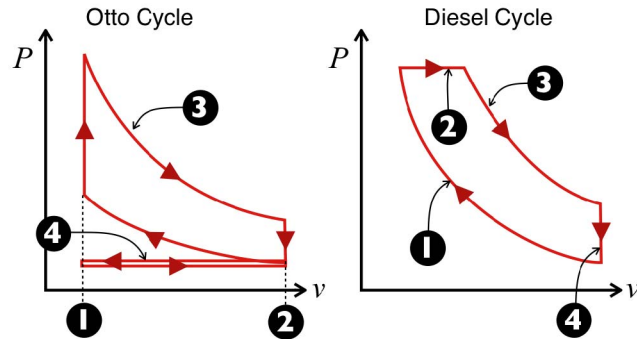

| Traditional | Rich |
|--|---|
| Multiple-choice 1. Which step of the Otto Cycle follows the piston at the Bottom Dead Center (BDC)? A. Piston at the Top Dead Center B. Isentropic Compression C. Isentropic Expansion D. None of the above | Sorting 1. Arrange the Otto Cycle steps in sequential order starting with the piston at the Bottom Dead Center (BDC). 1. Isentropic Expansion 2. Piston at the Top Dead Center 3. Isentropic Compression |
| Multiple-choice 2. Identify the location where the gas mixture is ignited with a spark on the Otto Cycle's P-v diagram.  | Region of Interest 2. Identify the location where the gas mixture is ignited with a spark on the Otto Cycle's P-v diagram.  |
| True/False 3. Thermal Efficiency of the Otto Cycle is a direct function of the compression ratio. Spark knock is observed when the recommended limit for compression ratio is exceeded. | Short Answer 3. Thermal Efficiency of the Otto Cycle is a direct function of the compression ratio. What phenomenon is observed with exceeding recommended compression ratio for an Otto Cycle? |
| Multiple-choice 4. Indicate where the combustion products are exhausted in the Otto Cycle P-v diagram.  | Region of Interest 4. Indicate where the combustion products are exhausted in the Otto Cycle P-v diagram.  |
| Multiple-choice 5. The difference between an Otto Cycle and a Diesel Cycle, respectively is A. Constant volume versus constant pressure heat addition B. Spark versus compression ignition C. Lower compression ratio versus higher compression ratios D. All of the above | Short Answer 5. A major difference between an Otto Cycle and a Diesel Cycle is ... |
| True/False 6. The step 1-2 is unique to a Diesel Cycle compared to an Otto Cycle.  | Region of Interest 6. The following step is unique to Diesel compared to Otto Cycle.  |

For the clicker test, the class was equally divided into rich and traditional participants, who were randomly assigned question types. The questions were revealed sequentially and students answered each question simultaneously before moving to the next. Once all the responses were registered, the instructor briefly explained the concept without differentiating between rich or traditional question explanations.

B. Concept Retention Test

Following the clicker test, the next class session involved a paper-based quiz to assess the retention of the IC engine concepts covered in the previous week. Individual students were tracked using their ID numbers (which were subsequently eliminated once the two intervention results were evaluated). The three concept questions were common for both the rich and traditional responders students and are summarized in Table II.

TABLE II. CONCEPT RETENTION TEST QUESTIONS.

| |
|--|
| True or False. 1. Engine knock or auto-ignition is a problem common in a Diesel Cycle. |
| Short Answer. 2. List (one or more) ways in which the Otto and Diesel cycles differ? |
| Short Answer 3. Label the diagrams (to the right) according to the numbers provided.  |

IV. RESULTS

A total of 28 students participated in the study using a variety of devices: iPod Touch, iPad, iPhone and iPhone simulators on an iMac (N=28). All the responses were simultaneously collected over WiFi on a local server. The clicker responses were analyzed for correctness and the students tagged with an ID for the follow-up concept retention tests. Once administered, the concept retention tests were manually evaluated and assigned to the respective students with their clicker performance. The grader was blind to the rich or traditional assignment. Figure 3 provides a comparison of the final results. The plot provides the average scores for the two interventions (the clicker test and the concept retention test) separated into rich and traditional student responders.

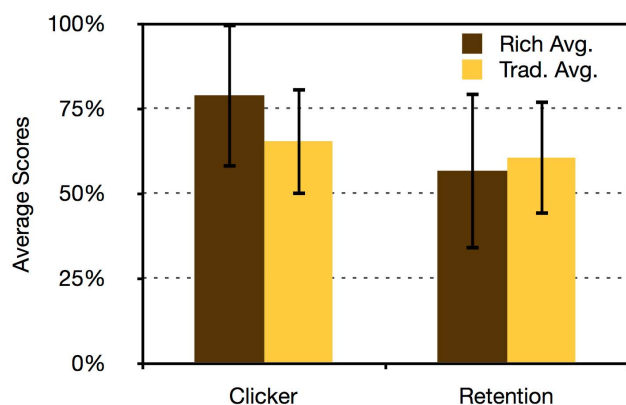

Figure 3. Average scores for the clicker test and the concept retention test for rich and traditional question responders. The error bars represent one standard deviation in the test scores.

Figure 3 shows that the students with the rich question types performed better on average than the students with traditional question types during the clicker test stage. For the concept retention test, there was a noticeable drop in the average scores for rich responders with performance at 50-60%. Interestingly, there was no discernible difference between the average scores for the rich and traditional question responders, especially considering the large error bars. In other words, the study yielded no observable influence of question type during CRS session on concept retention. However, to make such a conclusions would be premature considering the small sample size and several other factors that can obscure the causality.

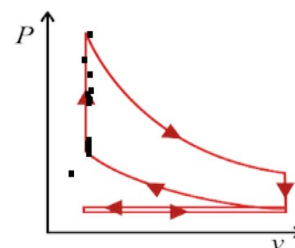

V. DISCUSSION

The described study is one of its kind using touch-based portable devices to explore new question modalities for student engagement. Even though, laptops and tablet PC's have been used to expand the CRS medium [20],[21], their bulky form factor and high costs are considerable limitations for mass implementation. The transition to such 'post-PC' devices is a more natural evolution of CRS technology. Therefore, the demonstration of an advanced CRS on an iOS platform is an equally important endeavor from the educational technology standpoint, as is the research question to investigate the influence of question types on student learning. The combination of these efforts are necessary to build a robust next generation CRS.

An added benefit of using the advanced CRS, which could not be captured with the described concept retention study, became clear while analyzing the student responses. Considering the rich question types are more open-ended and do not present pre-defined misconception to the students, the CRS session created an opportunity for instructors to discover unanticipated misconceptions. This is in contrast to the construction of multiple-choice and true/false question types where misconceptions are designed from instructor's perspective. For instance, question two (Q2) for the rich responders asked students to indicate where the gas mixture is ignited. The correct answer lies towards the bottom of the left-

most vertical rise in pressure. As seen on the server-analyzed output of rich Q2 in Fig. 4, several students indicated their response as an area close to the top of the pressure increase. This option was noticeably unavailable in the traditional question format and would prompt further discussion as an incorrect choice after employing a rich questioning mode. This example demonstrates additional benefits beyond engagement

Q2. Identify the location where the gas mixture is ignited with a spark on the Otto Cycle's P-v diagram.

offered by an advanced CRS.

Figure 4. Server analyzed response showing student submissions to the rich Question 2 during the clicker session. Black dots indicate student inputs.

The inconclusive nature of the results can be attributed to the preliminary nature of the study. As identified earlier, the CRS platform was incomplete with respect to the *Instructor Feedback* stage. It is entirely possible the differences in question types manifest themselves during the question review by prompting instructors to elaborate on all the incorrect responses and misconceptions rather than at the *Student Response* stage where the deeper engagement was anticipated. Since this stage was replaced with a more general discussion of the correct answer after the CRS session, it is conceivable no influence on concept retention was registered. It is also unclear what yielded the overall better performance with the rich question types during the clicker test over traditional question types. One can hypothesize that the intentional ambiguity introduced with multiple-choice alternatives when constructing the traditional question could have made some questions particularly more difficult. Nevertheless, this was an unexpected outcome of the study that requires further investigation to make sure no biases were introduced during question preparation and construction.

Current efforts are underway to develop a more rigorous research study involving all the features of the advanced CRS platform once complete. The following is a list of potential study aspects that will be addressed to strengthen the methodology.

- Involve a third party with expertise on the topic concepts to verify equivalency in questions among rich and traditional question types.
- A number of lecturers and a variety of topics need to be considered.
- A more open-ended concept retention test holds a better chance to amplify the differences in retention, as

opposed to some of the multiple-choice and true/false question types used [22],[23].

- The study needs to involve varying sample size with both large and small class sizes.
- An additional control group can be incorporated to highlight the benefits of using clickers in general: those who did not participate in a clicker study.
- Involve a crossover approach where rich and traditional students switch for a second round of the CRS session.
- Include the drawing question-type for further differentiation between rich and traditional.

VI. STUDENT FEEDBACK

In order to gain a student perspective regarding the touch-based CRS, the participants were solicited for their feedback at the end of the clicker session. The students used the same advanced CRS devices to provide responses to the survey questions. The first two questions were multiple-choice questions while the last two were open-comment questions. Table III provides the list of question and the corresponding summary of results for the multiple-choice questions. No differentiation between the rich and the traditional question responders was made. The students had an opportunity to provide additional open-ended feedback during the concept retention test.

TABLE III. STUDENT FEEDBACK QUESTIONS AND RESPONSE RESULTS TO THE MULTIPLE-CHOICE QUESTIONS

| Questions | Response Alternatives | Results |
|---|---|-------------------------|
| 1. How useful was the response experience | a. Hindered learning b. Not useful c. Somewhat useful d. Greatly helpful | 3% 11% 65% 21% |
| 2. What were the questions like? | a. Unfair b. Difficult c. Appropriate d. Ideal | 0% 0% 79% 21% |
| 3. Comment on the responses to the questions above. | (open-ended) | |
| 4. What did you like most or least about the response experience? | (open-ended) | |

Considering every student provided responses to the survey questions (100% response rate), the study gathered invaluable feedback from the student on the methodology and the technology. The results from Table III indicate 100% of the students felt the questions were appropriate and the majority of the students (>85%) perceived the response experience as useful. Among the most encouraging feedback was the overwhelming support for the advanced CRS through the open-ended questions. The statements below are a few that highlight these sentiments.

- “This was fun! And it helped me realize what I need to study after having a lecture and then a “quiz”.”
- “Good for increased class participation and understanding material.”

- “The questions were appropriate and they are useful for reinforcing major concepts.”
- “I thought it has the potential to be an effective education product...”
- “The visuals (example: Q3 on this questionnaire) are an especially good mental check of concepts learned in class. Visuals = Good!”
- “The questions were very ideal in determining whether you knew the material and I liked the variety of questions. I liked the graph questions the most because they really challenged how well you knew the material.”
- “I have been told that it is best to review material within an hour after you learn it. This helps prove that as long as the smart technology is used at the end of the class as a review it will likely stick in a student's mind better. I would have likely forgotten these answers otherwise.”

A. Student Feedback Conclusions

Overall, the students provided useful feedback on the study and the ClikMe app. A majority of the negative feedback was associated with the incomplete nature of the platform and not necessarily the concept. The feedback is summarized below into themes to provide a general sentiment shared by the students on specific aspects of these efforts.

The Technology. Several students commented how typing long sentences was challenging, especially when providing feedback. This is understandable considering not all the students were familiar with the specific devices they were using. The short answer question was designed to limit the length of input from students for this reason. A number students felt there should be an indication of whether their answer was submitted or not and that the app should proceed to the next screen once submission was complete. As noted, these were mostly interface concerns and that can be easily addressed.

The Questions. A number of students acknowledged the novelty and uniqueness of the “graphical” or “coordinate-based questions”. Of course, the region of interest questions were specific to the rich responders but the comments clearly demonstrated the advantage of such advanced clickers and their ability to visualize questions. None of the traditional question responders commented on the question types other than sharing their appreciation for the visual nature of the multiple choice questions.

The CRS exercise. There was a general consensus that this was a very helpful exercise. Whether the students felt this was a good mental check for their understanding or that they thought it helped everyone participate, the student viewed the app as a positive influence in a lecture. Other students commented more generally on how the app was a good idea or that the exercise was simply “fun,” suggesting potential for better engagement. These were all positive indications, in

addition to the fact that over 80% of the students felt the experience positively influenced their topic knowledge.

VII. CONCLUSION

The emergence of touch-based smart portable devices have invigorated the development of social and professional apps that are readily available for deployment where laptops previously proved impractical to carry. It is foreseeable that these devices will make a transformational impact in the classrooms where a single device offers multiple functionalities. This work was designed to highlight how such a technology can influence student learning. Specifically, does the more natural mode of interaction afforded by a touch-based CRS improve student learning. While the results were inconclusive, the feedback and outcomes suggest a strong need for further research using advanced CRS. The students especially appreciate the highly visual aspects of interactions offered. Suggesting an advanced CRS can, in turn, engage a wider spectrum of learning styles. Therefore, from a broader sense, these efforts are aimed at inspiring the next generation of classroom technologies that will directly benefit the students.

ACKNOWLEDGMENT

The author would like to acknowledge the tremendous hard work and dedication of the undergraduate engineering students who developed the advanced CRS platform over the course of a year. The initial development was lead by Jeremy Zee, Joe Ridgeway and Daniel Houwen. Frank Kemper, Ryan Hogan and Josh Negley implemented the subsequent platform development and the study reported here. The author would also like to thank Dr. Jennifer Kadowec for her input in guiding the survey question construction and her overall support.

Work in Progress: Examination of Student Experiences in Immersive vs. Traditional Group Projects

Irena Bojanova

University of Maryland University College, Adelphi, USA, ibojanova@umuc.edu

Abstract—Group projects are essential for graduate level programs. This paper presents a study on student experiences from immersive and traditional online group projects. The study revealed that student engagement in group projects is a distinguishable construct worth to be studied further. Review of conducted research on student engagement revealed also that there is a need of a reliable and valid measure of student engagement in group projects.

Keywords: *student engagement; immersive group projects; virtual worlds; reliability and internal consistency of test scores.*

I. INTRODUCTION AND BACKGROUND

Graduate programs have to emphasize on group projects, as they bring social, psychological, and learning benefits to students; and because team-work is increasingly essential in the new era of globalization and information technology (IT). So, the question is not: Should we have graduate level group projects? The question is rather: How should we optimize students' learning experiences from group projects, as well as the projects' outcomes?

Since Spring 2010, immersive group projects have been conducted at the Information Technology Systems (ITS) department at the University of Maryland University College (UMUC) in parallel with traditional online group projects. The approach is applied to the most challenging core IT course, ITEC620 Information Technology Infrastructure, which each semester has 4 face-to-face and 20 online sections. Students from several sections, taught by the same professor, are able to choose to work on an immersive or on a traditional group project with the same required deliverables: project outline and schedule, project status, peer evaluations, project presentation, presentations' evaluations, and time-sheets. The immersive group project experiences are based on virtual team-building and research activities, enabled by the futures of a virtual world. Students conduct avatar-based meetings and presentations, and participate in virtual learning tours, simulation games, and scavenger hunts [1, 2]. The focus is on enhancing course objectives through utilization of free educational resources in Second Life.

II. PURPOSE OF THE STUDY

The purpose of the presented study was to analyze student experiences from immersive and traditional online group projects, focusing on the following objectives: (1) Identify a distinguishable construct, worth to be studied further via a focused on group projects, reliable, valid, multi-dimensional

measure. (2) Review conducted research on identified construct and the availability of corresponding measurement instruments.

III. DATA

All students from seven ITEC 620 sections, taught by the same professor in 2010 and 2011, were invited to participate. Data was gathered from 107 students: 33 of which worked on an immersive group project and 74 – on a traditional group project. The participants' demographics highlights are as follows. More students with expert technical level worked on immersive projects (33% vs. 3%); but, also more newbies worked on immersive projects (6% vs. 3%). More not-working students (12% vs. 3 %) and none part-time working students were involved in immersive projects. Almost same percentages by gender worked on both kinds of projects (30% vs. 27% female; 70% vs. 73% male). More students of age over 35 worked on the immersive group projects (60 vs. 47%).

IV. METHOD

A multiple-item instrument with Likert-type scaling [10] (Table I) was developed to examine student experiences in the two types of group projects. Calculated Cronbach's α coefficients of reliability (all above 0.9) and Pearson's r correlation coefficients (all positive, average 0.5 [4]) indicate a high degree of reliability and internal consistency of the administered measurement instrument.

TABLE I. STUDY'S MULTIPLE-ITEM INSTRUMENT.

Please answer the following questions about your experiences from the Group Project. Rate each of them on the following scale:

1 = Definitely Not, 2 = No, 3 = Maybe, 4 = Yes, 5 = Definitely Yes

The group project helped me:

Q1: Develop my communication/presentation skills

Q2: Develop my technical skills

Q3: Develop my team-building skills

Q4: Develop my leadership skills

Q5: Understand better course material

The group project activities:

Q6: Challenged me academically

Q7: Developed my critical thinking and problem solving

Q8: Provoked my curiosity and sense of discovery

Q9: Were engaging and fun experience

Q10: I would like to have similar in other classes

A. Main Results

Analysis of survey's results shows that: Students working on both kinds of projects equally agreed that project activities helped them develop team-building skills (80% for traditional vs. 79% – for immersive projects). Students working on the immersive group projects were much more engaged and had fun experience (**100%** vs. 58%). The project activities helped them more to develop their communication/ presentation skills (73% vs. 69%), and technical skills (79% vs. 65%). They also would like to a much larger degree to have similar projects in other classes (82% vs. 50%). Students working on traditional online group projects were slightly more academically challenged (77% vs. 70%). The project activities helped them more to understand the course material (78% vs. 64%) and to develop their critical thinking and problem solving skills (85% vs. 79%), as well as leadership skills (68% vs. 58%).

B. Intriguing Correlations

The strong correlations ($r > 0.7$) of the survey results are as follows. For immersive projects: "Technical skills" & "Team-building skills", "Engaging and fun experience" & "Provoke curiosity and sense of discovery". For traditional projects: None. For both kinds of projects: "Academically challenging" & "Develop critical thinking and problem solving", "Communication/presentation skills" & "Technical skills", "Communication/presentation" & "Team-building skills", "Leadership skills" & "Team-building skills", "Would like similar in other classes" & "Engaging and fun experience".

Further examination of correlations reveals that students working on immersive projects would like to have similar projects in other classes mainly because of the engaging and fun experience, which is strongly correlated to provoking curiosity and sense of discovery.

Some intriguing facts based on correlations' examinations are as follows. For immersive projects: "Time spent on research" does not correlate to "Academically challenging" (0.024), but negatively correlates to "Team-building skills" (-0.371), "Leadership skills" (-0.316) and "Engaging and fun experience" (-0.306). "Time spent on presentations" correlates negatively to student "Technical level". "Time spent on all research, collaboration, and presentations" correlates negatively to "Develop critical thinking and problem solving" (-0.436) and "Engaging and fun experience" (-0.312). For traditional projects: "Time spent on research, collaboration, and presentations" correlates to "Would like similar in other classes" (0.302). Interestingly, 44% of students, who worked on traditional projects, had the technology to work on immersive projects; and 34% of them did not even check if they had the technology.

C. Distinguishable Construct

The study identified student engagement in group projects (100% for traditional vs. 58% – for immersive projects) as a distinguishable construct that deserves further reliable, valid, and detailed examination.

A. Measuring Student Engagement

"Student engagement is generally considered to be among the better predictors of learning" [3] and research on this construct date to the mid-1980s [14]. Search on student engagement research revealed there are higher education studies that assess student engagement at institutional and program level. For example: the Higher Education Research Institute (HERI) [6]; the National Survey of Student Engagement (NSSE) [13]; the Community College Survey of Student Engagement (CCSSE) [5]. There are also studies that assess student engagement at course level and specifically in online courses. For example: Handelsman et al. developed a reliable and valid measure of in class college student engagement [8]; Molinari & Huonker developed an instrument to diagnose student engagement in business school classes [12]; Robinson & Hullinger, researched student engagement in online classes [15]. However, no reliable and valid measure of student engagement in group projects was identified.

B. Developing a New Measure

Research on constructs that are relative to attitudes, emotions, and opinions involve the use of Likert-type scales. To quantify a not directly measurable construct such as "engagement", a summated ratings scale should be developed. The scale should have multiple items – each measuring something with a quantitative measurement continuum, having no right answer, and being a statement that can be rated [16]. To capture the many potential dimensions of "student engagement in group projects", an inductive approach should be applied. Focusing on student engagement definitions, students and faculty should be asked to describe what engaged in group projects students *do*, *feel*, and *think*. The responses should be used to generate items that reflect the construct and to develop a preliminary scale with potentially indicative of engagement behaviors and attitudes. The preliminary scale should be further discussed and refined by a focus group.

C. Explanatory Factor Analysis and Reliability Estimates

A study on the scale's initial data reliability and validity should be conducted in accordance with established psychometric principles for use in survey research [9]. Initial item reduction should be performed through exploratory factor analysis and examination of reliability estimates [11]. The validity of the measure should be further verified through a study on the relationship between the scale factors and, for example, students' self-reported engagement, endorsement of self-theories, and goal orientation [7].

VII. CONCLUSION

This paper presents an examination of student experiences in group projects, focusing on immersive and traditional online group projects. Main findings of the research are that students' engagement in group projects is a distinguishable construct, worth to be studied further and that there is a need of a reliable and valid measure of student engagement in group projects. The paper discusses further steps for developing a new measure of student engagement in group projects and refining its scale.

Collaborative Learning Frameworks to Promote a Positive Learning Culture

Keith Willey

anne.gardner@uts.edu.au

Abstract — Engineers are often required to make critical judgments involving decisions that extend beyond traditional discipline boundaries. This requires professional engineers to undertake ongoing learning. Much of this learning is informal, learnt on the job from peers. Hence, to prepare students for professional practice they require opportunities to experience, practise, reflect and improve their ability to work in collaborative learning environments.

While few would argue the benefits of collaborative learning these benefits are not automatic. Thoughtful design including scaffolding to motivate desired approaches and behavior is required. In this paper we report the results of several studies investigating the components of successful collaborative learning activities. We found that assessment scaffolding directed at promoting a culture of learning rather than a focus on passing a series of assessments was effective in engaging students, that formative activities allowed students to focus on learning and that learning from collaborative activities improved if the activities included variation for learning and a confirmation task. Using the results of these studies we developed two frameworks characterizing the elements of collaborative learning activities. In this paper we report investigating the capacity of these frameworks to develop an effective and integrated learning experience for students.

Keywords—collaborative learning; learning oriented assessment; formative; summative; assessment scaffolding.

I. INTRODUCTION

Stump et al [1] report criticism of traditional engineering educational strategies such as lecture, laboratories and homework because of their inadequacy in preparing students to engage in the collaborative partnerships that are expected of practicing engineers [2]. Others have reported that these traditional teaching methods often promote passive learning and compartmentalize the curriculum and run the risk of being ineffective in preparing students for the roles expected by industry [3-6]. Workplace learning is often collaborative [7]. Hence, to prepare students for professional practice they require opportunities to experience, practise, reflect and improve their ability to work in collaborative learning environments. Dana [7] reports that compared to traditional competitive or individualistic learning environments, benefits of collaborative tasks such as small group or team based learning include higher student achievement, greater use of

higher level reasoning and critical thinking skills, more positive attitudes toward the subject matter and satisfaction with the class, and better interpersonal relationships among students and between students and instructor. Furthermore, others including Prince, Springer et al and Bowen report collaborative learning's potential to positively influence students' achievement, persistence, and attitudes about learning [3, 8, 9].

In an educational context, collaboration is generally described as an approach involving joint intellectual efforts between students, or between students and the instructor [10]. While few would argue the benefits of collaborative learning these benefits are not automatic. Kirschner et al [11] suggest that group learning could be more effective than individual learning if the complexity of the material to be learnt is high. Based on cognitive load theory the collective working-memory effect predicts sharing the load of processing complex material among group participants enables more effective processing and easier comprehension of the material to be learned. Groups in effect form a distributed working memory which had greater capacity than the working memory of an individual. However, one must be careful to avoid the issue of “collective ability” reported by Willey and Gardner [12, 13]. They found that some students as part of a collaborative team were strong contributors who appeared to understand the subject learning outcomes. However, they could only demonstrate this understanding in a collaborative environment. Individually, without the support of their peers, gaps in their understanding became evident.

Thus planning a successful collaborative learning activity is a nontrivial task. Thoughtful design including scaffolding to motivate desired approaches and behavior is required. In this paper we report the results of several studies investigating the components of successful collaborative learning activities. We found that assessment scaffolding directed at promoting a culture of learning rather than a focus on passing a series of assessments was effective in engaging students, that formative activities allowed students to focus on learning and that learning from collaborative activities improved if the activities included variation for learning and a confirmation task. Using the results of these studies we developed two frameworks characterizing the elements of collaborative learning activities. In this paper we report investigating the capacity of these frameworks to develop an effective and integrated learning experience for students.

II. RESEARCH STUDIES

For several years the authors have been researching the impact of learning oriented collaborative activities on students' learning [12-15]. These activities have been both formative and summative but in each case were specifically designed to provide opportunities to learn.

In these studies, we found that:

- When activities are summative students, with some justification, tend to strategically focus on how to achieve the best mark.
- Formative collaborative activities provide a low-risk environment [16] allowing students to push their learning boundaries, make mistakes, identify gaps in their learning and have these addressed by their peers and if necessary the teaching academic.
- To assist students to make the most of the opportunities provided by formative learning activities their design should include scaffolding to promote a learning focus as opposed to a task-focused disposition in students. For example, we constantly remind students that "mistakes compress learning" and to benefit most from formative activities they should be pushing their learning boundaries until they make mistakes and / or discover what they do not know [17]. Furthermore, the formative activities should be one of the best opportunities for students to assess and receive feedback on their learning in preparation for their eventual summative assessment.
- Collaborative activities should include several cycles with increasing complexity
- Collaborative activities should include variation for learning to check understanding [18].
- Collaborative activities should be followed by an individual confirmation task allowing students to confirm their learning to address the issue of "collective ability"[12, 13].
- When activities are open-ended (have more than one answer), context dependant and have no specific endpoint for example a design problem, students learning is difficult unless it is supported by a

discourse and feedback that allows students to discover the strengths and weaknesses of their thinking.

III. FRAMEWORKS

The results of these studies informed the development of the following two frameworks to assist in the design of effective collaborative learning activities.

A. Framework 1: Collaborative Learning Activity Cycle

This framework was designed to assist in the development of collaborative learning opportunities. The first step in every collaborative learning cycle should be an individual activity that allows participants to identify gaps in their learning/ understanding. Often these individual activities are undertaken out of class. Fink reports that "*The key to getting students to do the necessary work and reading before class seems to lie in devising the right kind of in-class activities. Students need to know that the reading done beforehand will be absolutely necessary to do the in-class work and that the in-class work is an important and valuable kind of work*"[19]. The individual activity is followed by a collaborative task where participants have their learning gaps addressed by their peers while completing the activity collaboratively. Groups are then brought back together and an instructor clarifies any outstanding issues. In order to discern a difference, one must have experienced a variation from their previous experience [20]. Consequently, variation is needed for discernment, which is an important step in learning [18]. Hence, to verify understanding the instructor should subsequently vary an aspect of the activity changing the outcome and have students complete this first individually then collaboratively to check their understanding. Finally, a confirmation task that applies the learning in a new context and/or a more complex situation should be undertaken individually to confirm understanding after which the cycle is repeated.

We also recommend that a review be undertaken after any summative activity including a final exam. While completing summative activities students are often able to identify gaps in their learning through finding they were not able to answer a question or demonstrate a skill. The authors hold reviews where students can come and look at their papers, discuss their presentation, etc. These are not an opportunity for a remark but purely for students to continue learning by addressing any learning gaps identified during the summative activity.

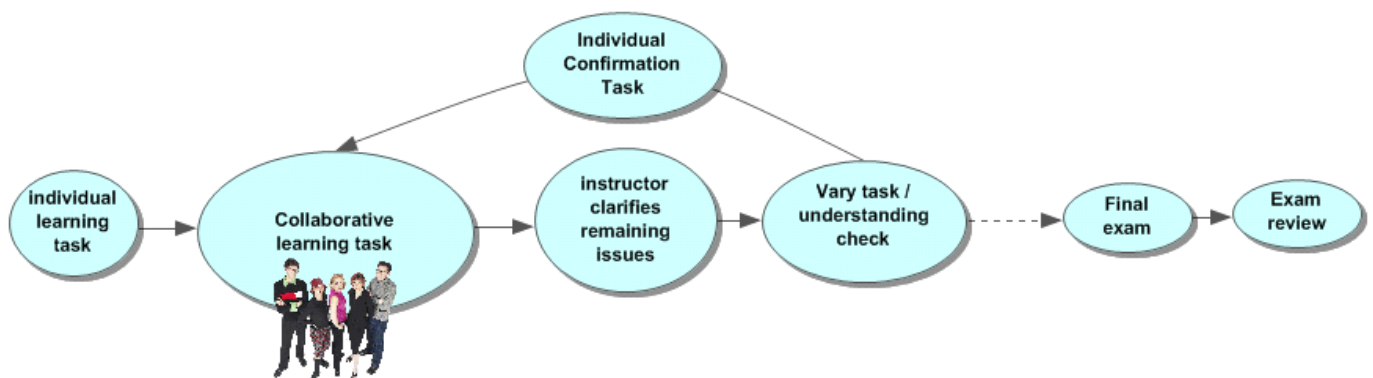

Figure 1. Collaborative Learning Activity Cycle Framework

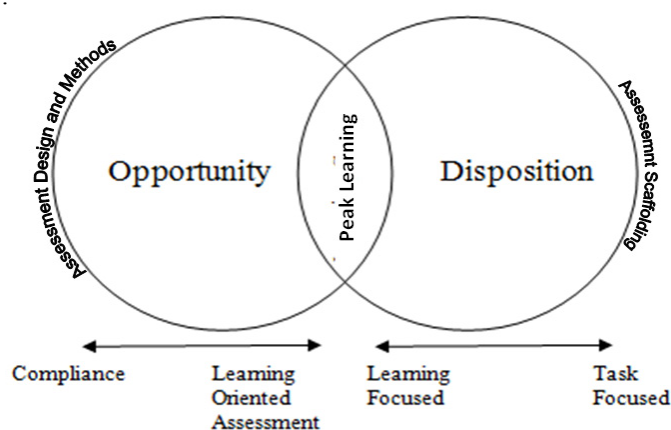

Figure 2. Opportunity and Disposition Framework

B. Framework 2: Opportunity and Disposition Framework

In this framework we suggest that learning is maximized when an assessment activity provides a well-designed learning opportunity and participants (students) approach the activity with a learning focus. Carless [21] describes learning oriented assessment as assessment designed to meet both certification and learning purposes. He characterizes learning oriented assessment as having three major components:

1. Assessment tasks as learning tasks
2. Students involvement in the assessment process (self and peer assessment) and
3. Feedback as feed forward

In the case of formative activities the certification purpose could be considered an evaluation purpose. That is, certification implies meeting the requirements of the third-party whereas evaluation can solely be for the purpose of the students evaluating their learning and identifying any gaps and/or areas that need to be addressed. Through discussions with academics examining their assessment tasks we identified a tendency to include compliance measures to encourage students to engage with these tasks. For example academic comments included, “*if I didn't give the students marks then no one would complete the exercise*” and “*if I didn't have a quiz each week students wouldn't come to the lecture*”.

Furthermore, as discussed by Sadler [22] we regularly found instances of instructors giving marks for activities that were not related to learning outcome achievement. Even when they were, they were often below the level required to demonstrate satisfactory achievement for the subject. For example:

- attendance (not participation) at tutorials
- revision of pre-requisite material
- frequency of contributions to a discussion forum (without regard to the quality of these contributions)
- quizzes containing simple questions that assessed material at a level lower than required to satisfactorily meet the course learning outcomes

- spelling and grammar
- participating in an activity for example self and peer assessment or peer-review (without regard to the quality of their contributions)

From our research we theorize that the effectiveness of assessment opportunities is often undermined by the addition of compliance measures [22]. Through structured discussions with students we found evidence that compliance measures may result in over assessing or at least over stressing conscientious students who strive to obtain the maximum grade in all activities. They sometimes describe their semester learning experience as going from “*assessment to assessment*”, “*revising material I already know to prepare for assessments*” (summative) and being so focused on so many summative assessments that there is “*no time to really learn*” by engaging deeply with the material. While poorer students conceded such measures did force them to at least participate more with such activities, we suggest that often this engagement may only be at a surface level.

We would argue that instructors should focus on developing a good learning opportunity and then design scaffolding aimed at moving students towards approaching the activity with a learning focus. Scaffolding measures could be described as being persuasive rather than punitive in that there is no summative penalty for non-compliance. Subsequently we recommend that for all assessment activities (both summative and formative) academics should explain to students:

- 1) why they designed the assessment activity the way they did.
- 2) what learning opportunities the activity provides the students
- 3) how students can evaluate their learning from the activity
- 4) how it is going to impact on their reality (enable them to see the world differently)

C. Integrating the two frameworks into a single collaborative learning activity.

The following is an example of how these two frameworks could be integrated in designing a collaborative learning activity:

- 1) **Opportunity** undertake a formative activity/assessment individually (often out of class) keeping in mind Finks [19] recommendation reported earlier in this paper.
Scaffolding Students are instructed to use the exercise as a means of identifying gaps in their understanding /learning.
- 2) **Opportunity** Students work in groups to repeat the activity/assessment collaboratively.
Scaffolding Groups are reminded to not only answer the question but to particularly focus on helping team member's address their learning gaps and through their discourse identify new ones.
- 3) **Opportunity** Course instructor leads a discussion to resolve any outstanding issues.

Scaffolding Explain to students that this is their opportunity to address any outstanding questions.

- 4) **Opportunity** The instructor varies an aspect of the problem (introducing variation) and asks students to reattempt the problem first individually and then collaboratively to evaluate their understanding.

Scaffolding Explain to students that this is their opportunity to check their understanding

- 5) **Opportunity** Students are given a new problem in a different context (and often slightly more complex) to attempt individually to confirm their understanding and identify any learning gaps.

Scaffolding Explain to students that this is their opportunity to confirm their understanding and check that they have addressed their previously identified learning gaps and / or identify new gaps in their learning.

Steps 2 to 5 are repeated. That is, in each subsequent cycle the confirmation task in step 5 became the individual task (that was originally completed in step 1).

IV. METHOD

The subject Design Fundamentals taught in English for the University of Technology, Sydney in Hong Kong was chosen as the vehicle to investigate the effectiveness of the two collaborative learning frameworks. Students had previously had difficulty with the subject material that required them to apply critical thinking and judgment. The activities designed using the frameworks are as follows:

A. Out of Class Preparation

Students were asked to complete pre-readings for each

subject topic. To both guide their reading and help them evaluate their understanding against the subject learning outcomes students were also provided an opportunity to complete a series of online formative multiple choice questions (out of class preparation). The software tool SPARK^{PLUS} [23] allows students to log on and compare their answers with their peers. That is, students are able to compare their answer (indicated by the yellow (lightest) bar in the histogram Fig 3) to the range and frequency of answers provided by their peers. Furthermore, students are able to click on the slider to view the reasons de-identified peers gave for each answer choice. Fig 3 shows that for question 2 this student chose answer D, one of their peers chose answer B, while the rest and by far the majority chose answer E. The sub window shows the reasons given by peers for those who chose answer B. The instructor deliberately chose not to provide the correct answer to the questions before the lecture sessions to encourage students to reflect when comparing their answers and reasons with those provided by their peers. In contrast to instructor feedback that often provides closure discouraging reflection, (as students accept the instructors opinion) students must use judgment in interpreting feedback provided by peers.

Before each topic was presented in class students were asked to discuss what they already knew from their pre-readings. After a general discussion and answering any questions the instructor proceeded with presenting the topic lecture. The fact that students had already completed pre-reading and partially evaluated their learning by both attempting and viewing their peers' answers to the multiple-choice questions meant that the instructor could move quickly through the fundamentals in each topic allowing the majority of time to be focused on the higher-level learning outcomes.

Figure 3. SPARK^{PLUS} results screen. The histogram shows the range of answered provided by students in the class (the logged on student's answer is identified by the yellow histogram bar). The sub window shows the reasons given by students who chose answer B. Similarly, these answers can be displayed for any individual choice (A, B, C, D or E) or for all answers simultaneously.

Furthermore, as the instructor had viewed the summary histograms reporting the range and frequency of answers to the multiple-choice questions prior to each topic they were able to identify aspects of each topic that were less understood and subsequently place more emphasis on these aspects during the lecture.

B. In Class Collaborative Learning

After each topic was presented students undertook a series of in-class formative assessments first individually and then collaboratively. These assessments took the form of a series of problems (at least 3) that increased in complexity until they were typically harder than students would encounter in their final examination. The process combined the two frameworks in line with the opportunity/scaffolding process described in Section 2 Part C summarized below.

Students first undertook each problem individually then formed into groups to repeat the exercises collaboratively. The course instructor then led a discussion to resolve any outstanding issues, then varied an aspect of the problem and asked students to reattempt the problem first individually and then collaboratively to evaluate their understanding. Finally, students were given a new more complex problem in a different context to attempt individually to confirm their understanding and identify any remaining knowledge gaps.

This process was repeated at least three times for each topic. Each stage was accompanied by associated scaffolding including the instructor explaining the assessment design (by articulating the 4 points described in Section 2 Part C) to focus students on using the collaborative activities to first identify and then resolve gaps in their understanding/learning.

These activities were evaluated using a combination of survey instruments, focus group, observations and video analysis.

V. RESULTS / DISCUSSION

All students (n =16) in the class agree to be part of this research under the condition of the usual ethical practices. Each student kept a learning diary, completed two survey instruments and participated in a focus group.

A. Pre-work Activities

In regard to the pre-work activities students reported that it helped them to get more out of the lectures as they already had some understanding of the subject material. Some students expressed a reluctance to reflect and consider the explanations provided by other students to their pre-work multiple-choice answers. In particular, they were uncomfortable when they could not decide on the correct answer and would have preferred to be told by the instructor. We expect this discomfort to dissipate as we gain more experience with running these type of activities and provide better scaffolding to support students in their endeavors. As stated earlier in this paper, in our experience if an instructor prematurely provides the correct answer to the questions than this provides a form of

closure and students tend to commit the answer to memory without reflecting on or challenging their understanding.

Overall students were positive about the opportunity the pre-work provided as demonstrated by the following free response comment:

“more easy to remember the material learned than with traditional reading learning”(sic)

B. Individual in Class Activity

In regard to the in-class individual activities students reported that it helped them identify their learning gaps and gave them the opportunity to independently reflect on their learning/understanding before commencing the group activity as articulated in the following free response comments:

“I can think myself about the whole picture first before getting into a group discussion or idea”

It was good *“to know my degree of understanding during the individual part then addressing my gaps with my team”*

C. Collaborative Activities

Many students reported that the discussions in the collaborative activities were not only useful in addressing the learning gaps identified in the individual activity *“my group members helped me fill my knowledge gaps”* but typically uncovered even more and often higher-level gaps in their learning. In the individual activities on average student's identified 2.3 gaps in their learning, while in the collaborative activities this increase to an additional 4.8 (Table 1).

They described the collaborative activities as making it *“easier to learn the content through discussion”*, that they could *“share our idea of how to solve the problem”* and *“get to know the opinions of others”* and they *“improved our problem-solving methods”(sic)*.

Students commented that the process assisted them to identify and understand what they did not know allowing them to more clearly articulate what they wanted feedback on to assist their learning.

Students also reported that the collaborative activities improve their confidence in what they had learnt commenting that: *“I can confirm my answer, increase my confidence”* it was good *“to understand what you got wrong”* and the *“group discussions gave me confidence that I could pass”*

One unanticipated result is that students commented that the collaborative activities gave them the opportunity to *“communicate in our primary language Chinese to explain ... ideas”*. This assisted greatly with overcoming the comprehension problems associated with not being instructed in your primary language.

TABLE 1: NUMBER OF LEARNING GAPS IDENTIFIED BY STUDENTS IN THEIR LEARNING JOURNALS

| Learning Gaps Identified | Average | Minimum | Maximum |
|--------------------------|---------|---------|---------|
| Individual Activities | 2.3 | 0 | 7 |
| Collaborative Activities | 4.8 | 1 | 13 |

While students were overwhelmingly positive about the format of the collaborative activities they did highlight some areas of concern including:

“sometimes you can be lazy and don't do anything” making “no contribution to the group”

and feeling apprehensive when we had “different answers in a group and no one person is sure what the correct answer is until the lecturer explains the answer in class”

D. Instructor Impact

The presented frameworks have assisted both the authors and other academics in developing collaborative learning activities. Breaking the activities down into a number of steps with specific impacts and outcomes enables one to focus on designing the opportunity, scaffolding and evaluation for each individual element, providing efficiencies for the instructor and when combined an effective and integrated learning experience for students. Furthermore, the frameworks provide a language for instructors to discuss, reflect and evaluate their design of and students their learning within collaborative activities.

The authors and a number of other projects have subsequently applied these frameworks to designing other collaborative learning activities including tutor and / or marker benchmarking [24], the development of academic standards [25] and improving research peer review [26].

VI. CONCLUSION / RECOMMENDATIONS

We found that the frameworks presented in this paper provided both efficiencies for the instructor and an effective and integrated learning experience for students. Furthermore, we recommend that all assessment activities include scaffolding directed at promoting a culture of learning in students, include variation for learning and a confirmation task. In addition, we encourage all instructors to explain to their students why they designed their assessment activity the way they did, what learning opportunities the activity provides them, how they can evaluate their learning from the activity and how it is going to impact on their reality (enable them to see the world differently).

Work in Progress: Choose Your Own Homework

Andrew Bennett and Rekha Natarajan

Department of Mathematics
Kansas State University
Manhattan, KS, USA
bennett@math.ksu.edu

Abstract—We are developing online interactive materials that allow students to adapt their text and homework to their own needs and interests. For example, students may specify topic areas of interest and then selected mathematics homework word problems are adapted to those areas. Using proper data management, their work can be hand-graded with feedback for the students and allowances for students to correct and resubmit their work after initial feedback in less time than is taken in grading traditional assignments. Such tools can support individualizing instruction even in large lecture classes.

Keywords—*component; differentiated instruction; online homework; open-ended problems*

I. INTRODUCTION

At Kansas State University, we are currently in our sixth year of running a version of college algebra called “Studio College Algebra,” which focuses on connecting real world phenomena to concepts taught during lecture (see [1] for a discussion of the specifics of this class). We have started building and maintaining an online “Choose Your Own Homework” (CYOH) system, in which students have the opportunity to learn about and apply college algebra concepts to various problems in a context of their interest, emphasizing categories such as student major, Hollywood, and entertainment. The system has a built in 2-step grading/feedback component in which students have the opportunity to modify their solutions based on grader comments (grading done by a human). This project aligns well with the objectives of differentiated instruction, mainly by giving students the option to customize their own assignment while addressing their interests simultaneously. The ultimate goal is to create a system with a large library of CYOH online assignments, serving as a permanent, stand-alone (textbook-independent) tool that can be incorporated into any college algebra curriculum.

II. THE MOTIVATION FOR CYOH: DIFFERENTIATED INSTRUCTION

The need for a student-centered curriculum in which students are given the chance to learn and demonstrate their knowledge lies at the heart of differentiated instruction. This instructional approach has been a key focus area in the movement to improve student learning and retention. This method of curriculum design recognizes that individual students are unique, possessing different learning styles,

interests, background knowledge and preparedness when coming into a new course. Flexibility in the approach and design of curriculum materials is a suggested method of accommodating this variance in the classroom. See [2] and [3] for more discussion of differentiated instruction.

III. DESIGN OF ASSIGNMENTS

With the CYOH system, the student chooses the context of each problem. A typical assignment is developed in the following manner. First, we begin with a particular topic of interest that all students need to master. We then select contexts in which we can explore the concept. Two examples of CYOH assignments already in place within the Studio College Algebra course at Kansas State University, for instance, cover the topics of power/exponential models and quadratic models.

The design of these initial versions of CYOH were based on

- the need for accommodating a large number of students;
- using real, relevant, and current data, and
- providing a variety of contexts

Future assignments will be modified to include questions based on contexts and settings relevant to student interests and undergraduate college life. These areas include sports, music, and various social issues. Within each context, we search through a variety of sources for real world data, and create downloadable spreadsheets containing the information we find. Examples of data sets that we have used in past assignments include the number of students taking AP tests each year, the number of apps available in Apple’s App store, and the weekly box office receipts for the movie Inception.

For each CYOH assignment, students work online, and are presented with a problem and 4 radio buttons, each corresponding to a different context. Students are welcome to click through all 4 buttons and decide which question they like. Students then download associated data/spreadsheets and carry out a mini-exploration/investigation. Typical investigations include finding a model that describes the data and deciding whether the model is appropriate, along with

using the model to predict future outcomes. Students may work on the selected problem and save their work at any time, and they may edit saved work until the deadline. Responses in the CYOH framework are allowed to be lengthy, frequently having a written component. Students may type out all their work and include written explanations (which is often necessary in application based problems, especially when asked to ‘interpret’ or ‘analyze’ an answer). See Fig. 1 for an example of how the system looks to the student.

IV. GRADING FEATURES

These new assignments are not graded automatically, but by a human. After students submit their answers for the first deadline, our departmental graders for the course are presented with a set of responses for one problem and one context on the assignments. Rather than grading several assignments one at a time, the graders are assigned to a specific problem/context. The graders are also presented with the correct answers for their question. The graders mark the number of points earned on each problem, along with providing certain comments, such as ‘error in units’ or ‘calculation error.’ The first round of grading is completed in two days, and students may log into the assignment to view their feedback. The student is shown the grader responses, and given one chance to correct their answers. Once the student submits corrected answers, the graders go to work once more, this time finalizing scores. Because grading online avoids the paper chase of collecting and returning paper homework and reading scribbled student answers, and because organizing the grading by problem is more efficient than having each grader grade all the problems for a particular section, grading the assignments twice in the new system is much quicker than grading them once in the traditional fashion. Thus this system allows additional opportunities to the students at a reduced cost in terms of grader time.

Section 5.4
Exp and Log Trend Data spreadsheet

4. After downloading the Exp and Log Trend Data spreadsheet, click on the tab at the bottom of the worksheet that corresponds to the type of problem you wish to complete (Agriculture, Hollywood, Life Expectancy, or Apps). Make sure the radio button you clicked corresponds with the spreadsheet you choose to work with.

Select the type of problem you would like to answer.

- ☐ Agriculture
- ☐ Hollywood
- ☐ Life Expectancy
- ☒ There's an App for that

Apple introduced the iTunes App store in July 2008. Since then the number of apps available has increased. The Apps worksheet has the number of active Apps available by month for the first two years of the App store. Graph the data on an x-y scatter plot.

(a) Using what you learned in studio, add an EXPONENTIAL trendline with the equation and the R^2 value displayed on the graph. What is the exponential equation that best models the data?

(b) Using your model, predict the number of apps available in June 2011. Is this value reasonable?

(c) Create a second trendline, this time a POWER function. Make sure to display the equation and the R^2 value on the graph. Enter the equation in the space provided. Does the exponential or the power function appear to be a better model of the data. Refer to the techniques in the studio to decide on which model, exponential or power, is better.

(a)

(b)

(c)

Figure 1

V. STUDENT REACTIONS

Initial student reaction to the assignments was mixed. The initial implementation only allowed for a single submission, as we had not yet discovered the increased efficiency in grading would support repeat submissions. Since the standard online assignments, which were computer graded, allowed for multiple submissions, students felt that any online assignment should allow for that. Changing the grading protocol to include an option to revise the answers has improved the student reaction.

A second issue was adapting problems to engage student interests. Only about a quarter of the students reported that they selected problems based on their interests the first time the system was used. Most students indicated they looked through the problems to find the one that looked easiest, with others just picking whatever was the first problem listed. After interviewing students, we decided we had erred in picking contexts based primarily upon common student majors. Many freshmen students do not yet have sufficient experience or engagement in their majors for that to be the most effective way of addressing their interests. After discussing ideas for engaging student interests with our office of New Student Services, we added contexts such as entertainment and technology and that increased the number of students selecting topics that they found personally engaging.

VI. FURTHER WORK

Now that we have refined our techniques so that they are succeeding in engaging student interests, we are expanding our approach in three ways. First, we are developing more assignments and contexts so that we have materials for a full semester and not just for selected assignments. Second, we are including ways for the grader to provide feedback beyond a score. Analyzing answers submitted in previous semesters has allowed us to identify about a half-dozen typical errors for each problem. We now allow graders to select from a short list of comments to help students identify their mistake. Note that the last choice in the list is always, “Non-standard error – get human help.” Finally, we are starting to experiment with use of techniques such as support vector machines to build a model for automated grading of the free response questions based on the database we have accumulated of student responses and grades they received.

When Students Choose Competencies: Insights from the Competency-specific Engineering Portfolio Studio

brooks2@uw.edu

Abstract— Recent work in engineering education has made it clear that for students to be prepared to function effectively as engineers, they will need to acquire a diverse set of competencies by the time they graduate. In this research, we explored students' experiences with an innovative pedagogy—a competency-specific, engineering-preparedness portfolio studio—as a means to support students in being prepared with respect to specific competencies. In this work, we showed that when given the opportunity to choose, students select a range of competencies for quite sophisticated reasons. Furthermore, when in this studio environment for multiple experiences, students engaged in deeper reflection and meaning making about prior experiences. Finally, through this environment students supported one another through formal and informal peer learning.

Keywords- competency, portfolio, studio

I. INTRODUCTION AND BACKGROUND LITERATURE

Current work in engineering education has emphasized the link between students' engineering preparedness and the fact that they must acquire a diverse set of competencies by the time they graduate. What is less clear is exactly which competencies are most important and how to support competency development. Consider that while there is overlap in the competencies identified in the Engineer of 2020 report [1] and those embedded in the ABET accreditation criteria [2], the competencies represented in these two sources, as well as the competencies represented in other sources [3-7] are not the same. Such disparate calls in needed competencies for engineering students suggest that one challenge is how to grapple with which competencies are most significant.

Understanding what competencies students are attaining, supporting them in attaining the competencies and gathering evidence of competency attainment are also challenges. In an intriguing piece of research, Walther and his colleagues [5] demonstrated the complexities of this space through their exploration of the notion of accidental competencies including what they are, how students acquire them and how to elicit them from students. Others focus on efforts to support competency development such as the purposeful integration of on-campus and workplace environments [6], and more generally the alignment of engineering curriculum with practice (e.g., [5]-[7]).

In this research, we are exploring student experiences with an innovative pedagogy—preparedness portfolios and portfolio

studios [8]—as a means to grapple with these challenges. The core of the pedagogy involves asking students to create a professional portfolio in which they make an argument about their preparedness to engage in engineering practice. The studio environment provides a supportive social environment for working on the portfolio. In five sessions, students in the studio share and provide feedback to one another on their portfolios. For example, in the second session participants share and provide feedback on initial drafts of their portfolio statements, while in the fourth session, students share and provide feedback on the first draft of their overall portfolios.

In prior research studies, we have linked student experience with this pedagogical activity to important educational issues such as professional identity development, goal setting and monitoring, epistemological awareness, and self-efficacy (see [8] for a summary). In addition, in our work with students, we have consistently heard about the benefits of the peer learning aspect of the studio—the learning opportunities that occur because of peer review activities and general opportunities for students to learn about and from each other.

For this research, we are interested in a variation of this pedagogy in which students create a competency-specific preparedness portfolio—an argument about their preparedness to engage in a competency in a manner relevant to engineering. So, for example, in a communication-specific, engineering-preparedness portfolio, a student would make an argument about his or her preparedness to engage in the type of communication relevant to engineering. In addition, we are interested in an implementation of such an idea that involves students *selecting* the competency that they will focus on in their portfolios, which results in a studio where multiple competencies are being addressed across students.

At this point, we have offered two competency-based portfolio studios, with fourteen students in one studio and seven in the second. While some students chose to work on relatively traditional competencies (e.g., communication), other students made more non-traditional choices (e.g., leadership, adaptability). Because of the nature of the larger project of which this work is a situated within, this portfolio was not the first portfolio studio for the students to participate in—all students had completed a prior portfolio studio in which they created a "core" engineering preparedness portfolio (see methods for portfolio descriptions). For some of the students, the "core" portfolio studio was the only other studio experience

that they had had; still other students had had an additional portfolio studio in which they focused on building a course-specific preparedness portfolio. Clearly, it is possible that their prior experience with building a preparedness portfolio in a studio is significant.

In this research, we sought to use analysis of the students' portfolios and their experiences in the studio as a means to explore the general challenges raised above. To this end, we captured the students' reactions to the experience (via surveys and an exit interview with each student) and collected the student portfolios. In our paper, we use these data sources to address the following questions:

1. Which competencies did students choose and why?
2. What were students' reactions to the experience of choosing and defending a competency?
3. How did the fact that this portfolio studio came as a second or third studio experience factor into the students' experiences?
4. What role did peer learning play in students' experience?

In the sections below, we focus on answering these research questions and then discussing how the answers link back to the overall issues of helping students develop competencies and grappling with which competencies are most significant.

II. METHODS

In this study, we investigated students' experiences with the competency-specific preparedness portfolio intervention. Over the course of two separate ten-week academic quarters, junior and senior engineering students ($n = 21$) from a range of engineering disciplines participated in a studio that consisted of five two hour sessions per quarter. Specifically, we analyzed the data to address the questions cited above.

In this section, we describe the portfolio intervention and environment, participants, and data collection and analysis.

A. Intervention – Portfolio construction in a studio setting

In a social environment, engineering undergraduate students who had completed previous preparedness portfolios (i.e., a core engineering preparedness portfolio and possibly a course-based engineering preparedness portfolio) constructed a competency-specific engineering preparedness portfolio. Fourteen students had constructed only a core portfolio; seven students had developed both a core portfolio and course-based portfolio.

The focus of each of these portfolios was to make an argument about one's preparedness for future activity. Across the portfolios, the emphasis of the content and/or the source of the evidence differed. In a core portfolio, students create an argument about their preparedness for engineering (i.e., across the broad array of competencies necessary for engineering) and support their preparedness argument using evidence gathered from their life experiences. In the course-based portfolio, students make arguments about engineering in general but draw evidence from a single course. In the competency-specific

preparedness portfolio that is the focus of this paper, students created an argument about their preparedness for a specific competency within engineering (e.g., communication, leadership, or programming) and then supported their preparedness argument using evidence gathered broadly.

The competency portfolio process was the same as developing a core or course-based portfolio. In the studio environment, students constructed the competency portfolio. The studio took place in five, two-hour sessions over the course of a ten-week academic quarter. The studio environment was characterized by a great deal of student interaction in the sessions, as students worked alongside their peers to develop their individual portfolios. The students were guided by a facilitator through activities (e.g., peer review, usability testing, think aloud) that were intended to scaffold the process of developing portfolio content.

B. Participants – Engineering undergraduates

With human subject's approval, we invited engineering undergraduate juniors and seniors who had completed prior portfolios (i.e., core and/or course-based) to develop a competency portfolio. In spring 2010, 14 students (5 men and 9 women) developed a competency portfolio; in fall 2011, 7 students (4 men and 3 women) completed a competency portfolio. Students received compensation for their participation in the study.

These students, from a research extensive institution, represented nine out of ten academic departments, specifically Aeronautics and Aerospace, BioEngineering, Chemical Engineering, Civil & Environment Engineering, Computer Science & Engineering, Electrical Engineering, Human Centered Design & Engineering, Industrial & Systems Engineering, Material Science & Engineering. Some of these students were also double majoring; second major departments included Spanish, Business, Math & Natural Sciences, and Digital Arts & Experimental Media.

C. Data collection – Survey and interviews

In order to understand students' experiences, we surveyed and interviewed them at the completion of portfolio development. The survey and interview consisted of a range of questions. Both opened with questions designed to elicit information about the students' experiences generally (e.g., take-aways, surprises, challenges). Both instruments also included more targeted questions, such as questions designed to address life-long learning and questions specific to the type of portfolio being designed.

The current data analysis focused on parts of the survey and interview that elicited answers to the research questions: which competencies did they choose and why, their overall reaction to the experience of choosing and defending a competency; how the fact that this portfolio studio came as a second or third studio experience factored into the students' experiences; and the role of peer learning in their experience.

D. Data analysis – Constant comparison, deductive coding

For this study, the post-surveys and interviews served as the primary data source. While the portfolio content was not

directly analyzed, it helped to confirm findings (i.e., validating findings from the post-surveys and interviews).

Using a deductive exploratory approach [9], the second author conducted a constant comparison thematic approach to the data [9]. First, the data was read to identify potential emerging themes and confirm the potential of the research questions. Once these areas had been identified, the data was filtered for survey and interview questions that directly addressed these areas or would be potentially fruitful areas in regards to these themes. Third, the second author conducted a constant comparison [9] of this data in order to understand the findings. Finally, the first author provided confirmation in these results by providing spot checking and confirmation of the emerging results. The results below represent these 20 students along the lines of precise qualitative language (i.e., some, few, and all).

III. RESULTS

In this section we provide results around the four questions: what students chose and why, students’ reactions to developing a competency portfolio; students’ opinions about developing a second or third portfolio; and students’ experiences in peer learning. The themes discussed below represent the students’ experiences building a competency portfolio in a studio setting.

A. What students chose and why

When asked to develop a competency portfolio and given the freedom to choose the competency, students chose a range of competencies for a variety of reasons. Table 1 represents students’ chosen competencies and their reason(s) for choosing the specific competency.

As indicated in the table, the most frequently chosen competency, selected by seven students, was communication (including technical communication). This choice represented the most direct connection to the ABET learning outcomes. Among the other competencies chosen, leadership played a role in five portfolios, research in two portfolios, and adaptability in two portfolios. The remaining portfolios featured competencies that were emphasized by only one student. While some of these remaining competencies were relatively standard within the engineering education community (e.g., community, design), other competency choices were more idiosyncratic (e.g., audio tech art/design and opportunity advantage optimization). These latter choices reflect a certain amount of creativity on the part of the students.

Students' reasons for choosing the competencies also varied. While some students chose a competency based on whether they had enough artifacts, other students had more nuanced reasons. Consider the following explanations from the students:

“I chose the leadership and management, and I chose that one 'cause I felt that I probably had the most like artifacts, experiences, to support it.” (004F)

“Um, I chose design because I feel like that's one of the most important things in engineering, because whenever you do projects, or big projects, you have to -- like it's not

just laid out for you, like, you know, like a freshman class where they just” (016M)

“[I chose experimental design] because I thought it encompassed a lot of what a chemical engineer needs to know how to do to be an effective chemical engineer, so to design an experiment, ...so like in regard to choosing artifacts, I had some available under the topic of designing experiments.” (056M)

“Oh, I choose leadership and management skill, because I knew that I had in my...in the future, I want to pursue my career in management, so I thought this would be a good way to actually find out what I've been doing.” (003F)

“I chose adaptability for a challenge because I had not ever considered this quality and think it's very beneficial in the field of engineering, but it's an aspect that's often overlooked.”...(001F)

“The reason I chose that [opportunity advantage optimization], like you said, was being unique, but I also felt like that was a huge personal way that I think and operate, whether it's in the engineering world or whether it's in classroom form, that's something that actually like I'm good at and something I use, and it defines like how I'm able to achieve different things, and the one skill that sets me apart from other people. That's what I really wanted to emphasize.” (073M)

TABLE 1. RANGE OF COMPETENCIES AND REASON FOR CHOOSING ASSOCIATED COMPETENCY.

| Student | Competency | Reason |
|---------|------------------------------------|-------------------------------|
| 002M | Leadership | Competent leader |
| 003F | Leadership & Management | Future, strong experiences |
| 004F | Leadership & Management | More experiences |
| 009F | Tech. Comm. & Leadership | Enjoys public speaking |
| 074M | Leadership | Growth |
| 007F | Communication | Importance |
| 008F | Communication | Importance |
| 011F | Communication | Broad |
| 031F | Communication | More experience |
| 033F | Communication | Related to future aspirations |
| 086M | Tech. Comm. | Unique, more experience |
| 103F | Communication | Importance, broad |
| 010M | Independent Researcher | Useful for interviews, broad |
| 038F | Research | More experiences |
| 056M | Experimental Design | Importance, more experience |
| 001F | Adaptability | Challenge, engr. relevance |
| 113F | Adaptability | Importance |
| 005M | Programming | n/a |
| 016M | Design | Importance |
| 030M | Audio Tech Art/Design | n/a |
| 073M | Opportunity advantage optimization | Unique |

*n/a: students did not provide reason.

B. Students' reaction to developing a competency portfolio

All students had a positive reaction to developing a competency portfolio. Several students reported generally learning about the definition of a competency. For example, one student (086M), when asked about his chief take-aways from the experience, described learning about competencies as “enlightening”:

Well, I guess the main one was especially just finding what a competency actually was, because for the—I don't know, I think it was the first session where we actually did spend a lot of time going over the definition of a competency, and so that was really enlightening.

More specifically, these students' reactions included enthusiasm for learning about competencies generally and about various competencies that are “essential to engineering” (007F) to appreciation for learning more about their chosen competency. Some students reported gaining a sense of awareness about “other” competencies (e.g., leadership and communication) besides technical ones (e.g., programming). Even further a few students reported learning about non-traditional competencies, such as adaptability.

Many students found the process of choosing a competency to be manageably challenging. Students struggled with choosing a single competency that was still broad enough to create an entire portfolio around. While many students found choosing the competency was an enjoyable part of portfolio development, some students struggled with the requirement to focus on one competency. For some students, the narrow nature of the task helped them. In order to deal with the challenges of choosing a competency and then writing the portfolio content, many students articulated sub-competencies within the main competency. This strategy helped the students balance an emphasis on single specific competency with a desire to include content from other areas. For example, one student (011F) described this process as

Choosing ONE competency that encompassed all the points that I wanted to cover was somewhat challenging. Sometimes it felt like a stretch, trying to tie certain things back into my competency. But perhaps this was part of the process as well.

C. Students' opinions about developing a second or third portfolio

Overall, students self-reported that developing a competency portfolio was a positive experience. More specifically, most students identified that constructing different types of portfolios (i.e., core, competency, and course-based) in the same format was positive. The same structure provided all students with a common portfolio language; as well as familiarity with the process and activities. Several students commented on this familiarity being a source of comfort during portfolio development.

Many students reported a positive experience with constructing a portfolio because this time was the second or

third time developing the portfolio. These students reported that they felt comfortable with the process, so they could dig deeper into more complicated areas of portfolio development, such as identity work. In becoming comfortable with the process, one student (103F) said she finally realized that there was no “right way” to build a portfolio:

I would say the portfolio studio in the spring, I felt like I was going into something that was supposed to be really formulaic, that there was a right way, you know. Even if [instructor's name] said, like, oh, there's no right way to do this, it's your portfolio, that's—I didn't really believe it, I guess, because, um—because I had never made a portfolio before, so I didn't really have any direction...

In this example, 103F recognizes that she thought the portfolio would have a right or wrong way; she attributes this mindset to the traditions of higher education, and school more generally. As she and a few other students experienced, through the process of developing multiple portfolios in the same way these students overcame this mindset, which made them less stressed and more focused on more important content issues, rather than just getting the portfolio “right.” 103F specifically attributed this mindset to the customs of school; therefore, it was difficult for her to overcome this mentality and truly embrace and trust the “liberating constraints” [10] characteristic of the portfolios.

A few students expected the competency portfolio to be a “wrap-up” portfolio, so they anticipated a different and/or new process that integrated the prior portfolio development experiences. For these students, they understood that this studio was the last portfolio in this series, so they reported expecting a wrap-up type of portfolio. In a wrap-up portfolio they anticipated to do something different or something broader that integrated prior portfolio work. More specifically, a couple students reported being “bored” of the same studio structure and activities applied to different content. In these instances a few students reported complaints about the similar structure for multiple studios. Even in the case in which students' expectations did not align with reality, the students still found the portfolio to be beneficial.

Finally, because this portfolio was constructed after the core and/or course-based portfolio, some students self-selected not to include an experience because it was part of a different portfolio. In these cases, this mindset might have contributed to a missed opportunity for students to think deeply or in a different way about an experience. However, for many students they reported thinking about these experiences in a new way (i.e., experiences they thought about in prior portfolio development, they reflected on for the competency portfolio).

D. Students' experiences in peer learning

Many of the comments about peer learning confirm prior results about students' experience developing a portfolio in a social environment. It is promising that students continued to experience the portfolio and the studio as an activity and space that supported peer learning. However, what is unique about

this experience is that students were developing a second or third portfolio. In this case, students had worked for multiple quarters alongside and with one another on portfolio development, as well as had the same facilitator.

In this environment, many students reported learning formally and informally from each other. The intentional structures of the studio environment (i.e., peer review, discussion) provided a certain level of scaffolding of peer interaction. For example, one student (103F) described learning through the structured peer review sessions—

Um, yeah, it does. I mean 'cause we are working together and doing the peer reviews, and it made you like look at other people's ideas, and also to like think of why they think that. So, yeah, it has prepared me to -- helped me to be more accepting of other people's ideas, I guess, and also to just -- just to look at their things, and, yeah...and also it helps me think about other people's ideas, be more accepting, because I feel like if I didn't do these experiences I might not be like as accepting of other people's ideas or I wouldn't be able to interact very well in the group setting, so it really prepared me, I guess, all these experiences have prepared me to be a better college student and as an individual, so that was really good.

In some cases students commented on learning from one specific person (e.g., learning programming from a CS student). Many students acknowledged one person's portfolio decisions becoming a benchmark for the rest of the group.

While most students felt comfortable with the peer review process, a couple of students reported feeling some angst about receiving peer review (something that has come up in prior studies). One particular student (103F) reported feeling quite a bit of anxiety with peer review in her first portfolio development, and through participating in a second portfolio she overcame this fear—

This quarter I felt a lot less awkward having someone else read my writing, and it -- I -- you know, maybe I'm coming out of my shell or something like that, but I just felt more okay with it, because I had had more -- I had had peer review experiences in the past, so, um, I felt like it was really helpful, and things were always -- every single time we had a peer review, there was something that was pointed out that I never -- that never even crossed my mind, so that did improve my portfolio. So, yeah, I think that I said in the last interview that I felt like peer reviews were awkward and maybe kind of, I don't know, self-conscious, and same with giving feedback, that I would have a hard time maybe being honest, because I didn't want to be too critical, but I felt a lot more okay with that this quarter, and it just seemed a lot more helpful.

In addition to these more formal structures that provided opportunities for peer learning (e.g., peer review, discussions), students commented on informally learning from each, and in a couple cases developed a friendship and/or business relationship. For example, a student who was starting a company invited another student to be part of the startup. The student was asked to join the company based on skills seen in the studio, as well as demonstrated by the portfolio.

Finally, even though the portfolio was not a team activity, students reported feeling as though the activity and structure helped prepare them to work more and better in groups. While prior portfolios might have contributed to such things as growth in collaboration ability, students recognized it more here. For example, students described being more aware of how to work with people generally. Furthermore, after portfolio development, students recognized their growth in openness to others' ideas. Finally, the entire process reminded students about the importance of giving and receiving feedback—recognizing peers as a powerful source of knowledge. One student (074M) described this learning as a surprise—

one aspect of how seeing other people's work is definitely helpful and fulfill the creating process, because at first I didn't really know how I should structure my portfolio, but seeing from the portfolios of my other classmates, it gave me, you know better ideas of what could work for me, what could not. And it was great, because each of the classmates or participants had a pretty unique portfolio, you know in a sense.

For a few students, they developed the competency portfolio in their last quarter as an undergraduate student, so they were able to relate to where peers currently were in their process, as well as to where their peers were heading. For these students, this peer involvement provided a sense relief for the upcoming finish line, as well as a source of pride. One student (056) described this comparison as an opportunity to see alternative undergraduate pathways, which resulted in personal satisfaction about his own choices and direction—

Um, I would say I learned, um -- I think it was learning about others' experiences, actually, like learning about what type of path I had taken in chemical engineering or in engineering in general, and then comparing it to others...it was interesting to hear other people's perspective on what they had been doing with their undergraduate studies, and then comparing it to what I did and where I ended up...

IV. DISCUSSION

To summarize the findings, we found that (a) students chose a variety of competencies, (b) students felt both enjoyment and challenge in the tasks of choosing and supporting the competencies; (c) the task of creating the competency-specific portfolio was perceived as slightly easier than their previous portfolio construction (i.e., core and possibly course-based) because of their prior knowledge; and

(d) students in this experience (as in their prior ones) had significant, positive things to say about the role of peer learning. Below we discuss each of these findings.

The findings concerning students' choices demonstrate that students are indeed capable of picking important competencies for powerful reasons. It is interesting also to see what students chose. For example, the fact that seven of the portfolios emphasized communication suggests that engineering students (at least these students) are clearly hearing the message that communication is an important competency for engineering. Also, students' identification of "independent research" and "adaptability," competencies that do not typically appear on competency lists, is worthy of discussion. Creating an entire portfolio around such competencies was an opportunity for creativity and a chance for the students to differentiate themselves. With more research, we could know even more about the kind of educational experiences made possible when students take such out-of-the-norm choices.

The additional findings concerning students' reactions to creating a portfolio around a self-selected competency provide further insight into what is entailed. For example, the results remind us that such a choice can be challenging for both the student and educator. Often, a pedagogy that supports individual choice involves a dramatic shift in power dynamics. Since our portfolio studio was not a graded activity, we likely did not have to contend with some of the power dynamics that might arise if the activity were to be graded.

Given the novelty and challenge of choosing a competency in order to develop it in a portfolio, it seems that it was helpful for students to have been familiar with the portfolio model and the studio approach (i.e., because of their prior experience). At the same time, the results about student confusion clearly indicate a need to improve the studio materials and the framing of the studio activity to the students. In terms of transferability, because our results are specific to the situation where students had built at least one portfolio prior to this experience, future research could help determine if our findings would accrue to students who are building a competency-specific preparedness portfolio as their first portfolio.

Unsurprisingly, the peer learning component continued to be perceived as a valuable part of the experience. It is interesting to read students' comments about learning to work with others as preparation more generally for teamwork or even team design experiences. While this area has not been a focus of our analyses, it is interesting to pursue in the future. While we did hear about peer learning in general, we did not hear as much as we had hoped about the participants learning about other competencies through the portfolios of their peers. Clearly there are many explanations for such an observation (i.e., we didn't ask the right questions, the participants are themselves uncertain what they learned from the other portfolios, or simply that the participants learned little about other competencies from other portfolios). Because such learning represents a valuable aspect of this type of portfolio experience, this area is something we plan to investigate further.

V. CONCLUSION

While recent work in engineering education has made it clear that students will need a diverse set of competencies to function effectively as engineers, open questions exist concerning: (1) how to help students develop specific competencies and (2) how to grapple with which competencies are most significant. In this paper, we have provided evidence concerning the potential contribution of an intervention that involves students advancing their preparation for a specific competency by explaining their preparation for a competency, of their choosing. More generally, we have opened up the question of the students' role in deciding which competencies to emphasize and also how to help students explain their own preparedness.

Abstract—The current study was part of activities in a Work in Progress paper presented at the 41st Frontiers in Education Conference that focused on activity Phase 2. This study evaluated students' metacognition using the Self-Regulated Learning (SRL) framework while learning electric circuit concepts. Two research questions guided this study: (1) Was there any improvement in metacognitive self-regulation skills while learning using the enhanced guided notes (EGN) throughout the semester?, and (2) To what degree were students' monitoring strategies reflected in regulating strategies at the beginning and end of the semester? The subjects for this study were engineering students enrolled in the Fundamental Electronics for Engineers course at Utah State University during the fall 2011. Thirteen sets of EGN were developed and used in the semester. A survey instrument developed using Butler and Cartier's SRL model was used to capture students' metacognitive self-regulated learning strategies. Participants were asked to complete the survey twice; at the beginning and end of semester. Descriptive statistics and mean differences of SRL features were used to analyze survey data. Mean differences were conducted in two ways: (1) comparing mean values of the same SRL items, and (2) comparing the level/quality between SRL features for two themes (i.e., knowledge acquisition and problem solving) at the beginning and end of the semester. The findings suggested that there were improvements in some aspects of monitoring and regulating strategies. Comparison of SRL item mean values revealed that there was increasing awareness on specific SRL items. Students did a good job in monitoring and regulating strategies for knowledge acquisition and problem solving. They successfully improved the quality of SRL feature in knowledge acquisition and maintained the quality level in problem solving. This article will also discuss the potential implications for electric circuit concepts instruction.

Keywords—*electric circuit; enhanced guided notes; metacognition; self-regulated learning*

I. INTRODUCTION

Education literature suggests that, in general, classroom activity does not stimulate students to actively engage in learning. Specifically in engineering education, many instructors still focus on writing engineering formulas and

solving problems on the whiteboard, and sometimes ask the students to check their understanding. During traditional lectures, students are generally passive [1]. Information received passively with no attendant action is not readily retained in long-term memory.

A wide body of literature suggests that students learn best when they take an active role in learning through discussing, practicing, and applying concepts and ideas [2]; however, these activities are often impractical to conduct, particularly in large classes. A major concern of most instructors is about the effectiveness of the lectures in facilitating students' learning. Studies have found that students' attention during lectures declines after 10-15 minutes [3]-[5]. According to Hartley and Davis, the amount of notes written declined over the course of a lecture [4]. Unless the students' attention is focused on what the instructor is saying, there is little chance that meaningful processing and note-taking will follow.

The use of guided notes has been perceived by students as a supportive tool that helps them concentrate on the lecture [6]. Guided notes, prepared by instructors, contain incomplete texts, diagrams, and graphs. Students need to listen to their instructor and think critically to answer the prompted questions and fill in missing parts of the information. According to Kobayashi, one of the benefits of note-taking is the development of higher-order thinking skills [7]. Although previous studies have been conducted to develop and evaluate guided notes, a limited study has been conducted by involving a variation of metacognitive prompts in electric-circuit concepts. The primary objective of this study is to develop a new type of note-taking activity that not only helps engineering students to actively engage in learning during lectures, but also help them become better at note-taking.

II. RELEVANT LITERATURE REVIEW

A. Standard Guided Notes vs. Enhanced Guided Notes

Guided notes contain incomplete information with blank spaces consisting of essential concepts, ideas, diagrams, graphs, problems, and conclusions. Standard guided notes, also

This material is based upon work supported by the National Science Foundation (NSF) under Grant No. 0942942. Any opinions, findings, and conclusions or recommendations expressed in this materials are those of the author(s) and do not necessarily reflect the views of the NSF.

called semi- or skeleton-notes, have been used in undergraduate teaching for quite some time. Unlike the guided notes introduced in many studies [6][8][9], the enhanced guided notes (EGN) developed by this study include questions that prompt students to assess their metacognitive self-regulated learning (SRL) strategies. This component is not present in the standard guided notes. The questions appear throughout the guided notes, including the introduction of each topic, elaboration of the theoretical concepts, and during problem solving.

Through EGN, students engage in the learning process along with their instructor during lectures. Besides conceptual theories, formulas, and problems to solve, the EGN include questions that prompt students to assess their understanding about theories, problem-solving strategies, and the principal concepts related to the topic of discussion. Compared to the traditional lecturing method in most colleges, these new learning materials and strategies may offer students an enhanced learning experience that more effectively utilize lecture time.

B. Metacognition in a Self-Regulated Learning Framework

The function of metacognition is to control other cognitive processes. Zimmerman argued that self-regulated learners are “metacognitively, motivationally, and behaviorally active participants in their own learning process” [10, p. 239]. It is clear that metacognition is a major component of one’s self-regulated learning (SRL) strategies. In this article we used metacognitive SRL strategies to represent the link between metacognition and SRL. Butler and Cartier’s SRL model described the dynamic and iterative interplay between metacognitive and cognitive activities [11]-[13] which characterize SRL as a complex, dynamic, and situated learning process [14]. The model consists of six major SRL features that interact with each other: layers of context, what individuals bring, mediating variables, task interpretation and personal objectives, SRL strategies, and cognitive strategies.

This article focused on monitoring and regulating strategies such as metacognitive SRL strategies in order to capture and understand students’ activities in knowledge acquisition and problem solving, both of which are core to learning representations. Knowledge acquisition is “the attainment of information due to instruction” [15, p. 17]. Commenting on the relationship between learning and knowledge acquisition, Chandrasekaran stated “learning is one means of knowledge acquisition” [16, p. 339]. Moreover, in discussing problem-solving activity, VanLehn summarized that different difficulty levels of problems require different amount of knowledge [17]. One of main parts of the EGN provided concepts in which students were prompted to fill in the blanks and link one concept with other concepts. Another part of EGN provided a list of problems need to be solved. Metacognitive SRL strategies represented by monitoring and regulating strategies are essential to succeed in those activities. Monitoring strategies refer to one’s ability to make sure their activities are conducted as expected. Regulating strategies, which are closely related to monitoring strategies, refer to one’s ability to execute necessary cognitive actions based on monitoring efforts. In general, the implementation of SRL strategies benefits students

in improving their learning performance. According to Zimmerman, SRL refers to students’ “self-generated thoughts, feelings, and actions which are systematically oriented toward attainment of their goals” [18, p. ix]. Applying learning strategies is important; Borkowski and Thorpe suggested that low-performing students may not understand how to relate learning strategic behavior with learning efforts [19].

C. Information Processing

According to Miller, there are three kinds of memory: sensory registers, short-term (or working), and long-term [20]. The enhanced guided notes in this study utilized the second concept of the information processing theory introduced by Miller. While the first concept is associated with the capacity of short-term memory, Miller’s second concept suggests that information processing involves gathering and representing information (i.e., encoding), holding information (i.e., retaining), and accessing the information (i.e., retrieving) when needed. Effective encoding occurs when information received is meaningful and activates one’s prior knowledge. When students pay attention to information received by the sensory registers, the information is transferred to their short-term memory.

Popularly called ‘guided notes,’ these may reduce students’ cognitive load, thereby helping engineering students to focus attention on and engage in cognitive processing of the lecture contents while developing notes for later review. Guided notes help students focus on the lecture content. During lectures, students are expected to develop understanding far beyond knowing the surface facts. Instead, when they learn something new about a discipline, they integrate that learning with prior knowledge, resulting in a growing complement of knowledge. Miller argued that once the information is processed for 5 to 20 seconds in the students’ short-term memory; it will then be transferred to their long-term memory.

III. THE STUDY

A. Study Participants

Students enrolled in Fundamental Electronics for Engineers (ETE 2210) during the fall 2011 semester at Utah State University (USU) were invited to participate. One hundred and fifteen engineering students participated in this study. Eighty-six percent of the students who completed the survey had a cumulative GPA of 3.00 or higher. Fourteen percent had a cumulative GPA range from 1.00 to 2.99. Sixty-one percent were sophomores, followed by juniors (34%), seniors (4%), and freshmen (1%).

B. The Context of the Study

The Fundamental Electronics for Engineers is a fundamental electric-circuit course required for engineering students at USU who are not enrolled in electrical engineering. Similar circuit courses are offered at universities across the country. At USU, the students are from the mechanical and aerospace engineering, civil and environmental engineering, biological and irrigation engineering, and engineering education. The 3 credit-hour course is conducted for 50

minutes three times a week. Typically, students are required to participate in 11 laboratory activities during the semester, each 3 hours long.

The course covers the study and application of direct current (DC)/alternating current (AC) and digital concepts which include circuit fundamentals, theorems, laws, analysis, components, digital design fundamentals, and combinational circuits design, equipment and measuring devices. The laboratory will include circuit design, construction and analysis of DC/AC circuits, and the use of measuring instruments, power supplies and signal generators. In one class meeting, the instructor distributed several pages of guided notes to the students. The notes were used to replace the one-way communication that was typical of class meetings. Students were asked to fill in the blank spaces found on the pages. On several parts of the guided notes, students were prompted with “what,” “why,” and “how” questions to exercise their metacognitive knowledge about the material covered. The questions were provided to trigger students’ thinking about the materials, and the instructor sometimes raised the questions in a discussion setting, for example, “What would the equivalent inductive value for two inductors in parallel be? Bigger? Smaller? Why?” At the end of the class meeting, students were asked to evaluate their learning process in a “self-reflection” section. Multiple-choice questions were provided to evaluate student understanding on some concepts in a particular EGN. In this section, students were prompted with principles and methods related to the questions. Last, a question prompts the students to check their answer, for example, “Should the lengths be in centimeters or meters? Does it matter?”

C. Data Collection and Analysis

The metacognitive SRL survey used in this study was adapted from the Inquiry Learning Questionnaire (ILQ) by Butler and Cartier based on their theoretical model (Butler & Cartier, 2004; Butler & Cartier, 2005; Butler & Winne, 1995; Cartier & Butler, 2004). Students were asked to rate themselves on a 4-point Likert scale (1 = *never*, 2 = *sometimes*, 3 = *often*, 4 = *always*). Five subscales were developed to capture students’ understanding of learning activities and

metacognitive knowledge at the beginning and end of the semester.

The subscales were task interpretation, planning, cognitive, monitoring, and regulating strategies. However, this article was focused on monitoring and regulating strategies for two reasons. First, monitoring and regulating strategies are the core components of metacognitive self-regulated learning strategies and are closely related. They represent the essence of metacognition, ‘thinking about thinking’ activity. Second, the internal reliability scores show that both monitoring and regulating strategies have relatively high Cronbach’s Alpha scores, .870 and .801, respectively.

At the beginning and end of the semester, surveys were conducted to evaluate students’ perception about the use of EGN that they had experienced in the ENGR 2210 class. One hundred and fifteen engineering students participated in this study, but only 97 valid data sets were analyzed. There were 18 suspiciously completed surveys that required us to further investigate the validity of the responses. We found those students responded to each survey item with the same answers (e.g., marked “3” for all items or block of items). A survey questionnaire was delivered two times through Qualtrics™, an online survey tool, to assess students’ understanding of learning activities and their metacognitive SRL strategies (see Tables 1a-b for the detail of the survey items). The mean values of all questionnaire items were then calculated and compared across SRL features (e.g., monitoring and regulating strategies). In addition, paired-sample *t*-tests and Chi-squared tests were applied in the analysis.

IV. FINDINGS

A. *Research Question 1: Was there any improvement in metacognitive self-regulation skills (monitoring and regulating strategies) while learning using the enhanced guided notes (EGN) throughout the semester?*

The data analysis to answer the first research question was conducted by calculating the mean values of questionnaire items between two phases, at the beginning and end of

the semester. Comparisons of SRL item mean values between two phases revealed increasing awareness of specific items between the beginning and end of the semester. Students' monitoring strategies significantly increased on "check whether I can describe the main topic of the subject" ($M_{early} = 2.72$, $M_{end} = 2.93$, $t = -2.032$, $p = .023$); "check whether I have found all the important concepts" ($M_{early} = 2.92$, $M_{end} = 3.11$, $t = -2.179$, $p = .016$); and "ask myself whether my methods for solving problems are good" ($M_{early} = 2.82$, $M_{end} = 3.02$, $t = -2.208$, $p = .015$). No significant increase was found in regulating strategies.

B. Research Question 2: *To what degree were students' monitoring strategies reflected in regulating strategies at the beginning and end of the semester?*

To address this question, drawing on findings from the EDQ, we first defined two themes regarding the use of EGN in the course: *knowledge acquisition* and *problem solving*. While knowledge acquisition (Theme 1) consisted of questionnaire items describing learning efforts to understand concepts, problem solving (Theme 2) consisted of items describing efforts to apply relevant concepts for solving problems.

Then, we calculated the mean value of each theme for monitoring and regulating strategies (see Figure 1). With most mean scores > 3.00 , there was an indication that the students had thought about both SRL strategies often during their learning. It was clear that students monitored and made necessary adjustments during their learning activity. It was also found that students scored a bit below 3.00 on monitoring efforts for knowledge acquisition at the beginning of the semester.

Based on those mean values, we then constructed a model that would help us better interpret students' metacognitive SRL profile. The model was constructed by plotting a pair of relevant SRL features on two different axes. To help us interpret the SRL profile, we used a mean score of 3.00, which indicated "often," as the cut-off score to differentiate between low and high SRL levels. Any mean scores < 3.00 were considered low level; scores > 3.00 were considered high level. Four different quadrants, A, B, C, and D, were then constructed from the model.

For example, students' monitoring and regulating strategies were plotted as shown in Figure 2. For these strategies pairs, we named Quadrants A, B, C, and D as an *ignorant*, *in-adaptive*, *adaptive*, and *chaotic quadrants*, respectively. From students' responses on one of the monitoring items, they scored 2.93 on a monitoring effort "When learning and solving math, science, or engineering problems involving new concepts, I check whether I can describe the main topic of the subject," and scored 3.26 on regulating strategy "When I have difficulties, learning and solving math, science, and engineering problems involving new concepts, I review the difficult concepts again." For problem solving in Phase 2, students scored high on monitoring strategy "When learning and solving math, science, or engineering problems involving new concepts, I ask myself whether my methods for solving problems are good" ($M = 3.02$, $SD = .78$), and they also scored high on regulating strategy "When I have difficulties, learning and solving math, science, and engineering problems involving new concepts, I try to use better methods for working" ($M = 3.08$, $SD = .73$). They seemed to be putting efforts toward making good monitoring and regulating strategies.

| Theme 1: <i>Knowledge Acquisition (KA)</i> | | | | | |
| SRL Features (Phase 1) | Mean | SD | SRL Features (Phase 2) | Mean | SD |
| Monitoring Strategies (KA) | 2.97 | .530 | Monitoring Strategies (KA) | 3.10 | .561 |
| Regulating Strategies (KA) | 3.09 | .525 | Regulating Strategies (KA) | 3.11 | .533 |
| Theme 2: <i>Problem Solving (PS)</i> | | | | | |
| SRL Features (Phase 1) | Mean | SD | SRL Features (Phase 2) | Mean | SD |
| Monitoring Strategies (PS) | 3.20 | .518 | Monitoring Strategies (PS) | 3.31 | .533 |
| Regulating Strategies (PS) | 3.16 | .548 | Regulating Strategies (PS) | 3.17 | .563 |

Figure 1. Mean values of the two themes across monitoring and regulating strategies

By following the mean values of the two themes across monitoring and regulating strategies in Figure 1, we focused on Quadrants C and D to describe changes on the number of participants between Phases 1 and 2 for both themes on: the same quadrant (i.e., changes on Quadrants C or D), and the different quadrant (i.e., changes from Quadrants D to C). Chi-squared tests were applied by using 80% and 20% as expected percentages of score increment and decrement in Phase 2, respectively. Our findings showed an increasing number of students, from 28_(Phase1) to 31_(Phase2) (3% of total participants; $\chi^2 = 27.801$, $df = 1$, $p = .00$) in Quadrant C and a decreasing number of students, from 13_(Phase1) to 7_(Phase2) in Quadrant D (6% of total participants; $\chi^2 = 2.813$, $df = 1$, $p = .04$) for knowledge acquisition. A similar pattern was found for problem solving; there was an increasing number of students, from 24_(Phase1) to 30_(Phase2) (6% of total participants; $\chi^2 = 20.167$, $df = 1$, $p = .00$) in Quadrant C, and a decreasing number of students, from 4_(Phase1) to 2_(Phase2) (2% of total participants; no significant difference was found) in Quadrant D.

Moreover, when investigating the transition from the *chaotic* to *adaptive* quadrants, the findings showed an increasing number of students, from 13_(Quadrant D) to 28_(Quadrant C) in Phase 1 and from 7_(Quadrant D) to 31_(Quadrant C) in Phase 2 for knowledge acquisition. The increasing number of gaps between Quadrants D and C on Phases 1 and 2 was 9% of total participants, from 15 to 24 ($\chi^2 = 8.308$, $df = 1$, $p = .00$); Chi-square tests used 80% as expected percentage of score increment. The problem-solving theme showed a similar finding; there was an increasing number of students, from 4_(Quadrant D) to 24_(Quadrant C) in Phase 1 and from 2_(Quadrant D) to 30_(Quadrant C) in Phase 2. The increasing number of gaps on Phases 1 and 2 was 8% of total participants, from 20 to 28 ($\chi^2 = 14.083$, $df = 1$, $p = .00$). These findings suggested an improvement in learning on both knowledge acquisition and problem-solving activities, in that the number of students in Quadrant C was higher than in Quadrant D, and the percentage of students increased in Quadrant C and decreased in Quadrant D, between Phases 1 and 2.

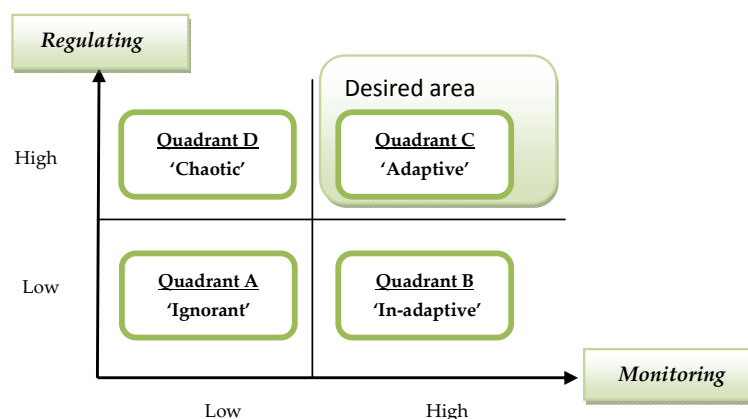

Figure 2. Level/quality categorization of SRL features

V. CONCLUSION

This study was conducted to evaluate undergraduate engineering students' metacognitive SRL strategies in an electric circuit course and identify the level/quality of the SRL features at the beginning and end of the semester. It was also the intent of this study to learn and develop a methodological framework for evaluating the extent to which students' monitoring strategies were reflected in their regulating strategies. From the findings, we found that students achieved significant improvements on some items of monitoring strategies. On the other hand, no significant improvement was found on regulating strategies. The findings indicated that the use of EGN benefits students more on their monitoring strategies. We suggested that improvements on metacognitive prompts must be conducted to trigger students to execute relevant cognition actions based on their monitoring efforts.

Furthermore, there was a transition on how students reflected their monitoring strategies on regulating strategies between the beginning and end of the semester. Positive changes were shown both in knowledge acquisition and problem solving during the semester, and more students were identified in the desired or *adaptive* area, Quadrant C, and fewer students were found in the *chaotic* area, Quadrant D. An increasing number of students in Quadrant C, problem solving, was relatively higher than on knowledge acquisition. Moreover, a relatively fewer number of students was found in Quadrant D on problem solving than on knowledge acquisition in both Phases 1 and 2. These findings may be explained by the different nature of knowledge acquisition and problem solving. Understanding concepts is a critical step in learning before students move to another activity such as problem solving. In this case, monitoring strategies were required at the same level of regulating strategies. Our findings showed that the numbers of students in Quadrant C were relatively stable on knowledge acquisition between Phases 1 and 2. However, the amount of learning resources may influence some students to focus more on executing cognitive strategies based on monitoring efforts at the beginning of the semester. During a problem-solving activity, students are triggered to find solutions. Every step in the activity should be checked to come up with a correct solution. Because problem-solving skills also rely on the understanding of concepts, it was found that the number of students in Quadrant C, problem solving, was relatively fewer than on knowledge acquisition at the beginning of the semester. It seemed that students may need more time to become acquainted with problem solving.

Lastly, from the current findings, we will use a multi-methods approach to gather more information related to students' metacognitive SRL strategies. Open-ended questions will be provided on the questionnaire to obtain more rigorous perspectives. In addition, investigating the correlation between students' metacognitive SRL strategies and learning achievement will be conducted.

The Adjustment Experience of First-Year International Undergraduate Students in Engineering

Whitney Barnes and Michael C. Loui
Department of Electrical and Computer Engineering
University of Illinois at Urbana-Champaign
Urbana, Illinois, USA

Abstract—To compare the challenges that domestic and international students experience in adjusting to college, we conducted a mixed-methods study of first-year undergraduate engineering students at a large public university in the Midwest. We administered a survey to all first-year engineering students. We conducted separate focus groups of domestic and international first-year students. While the domestic and international students identified similar adjustment issues, international students had more difficulty with making American friends, understanding cultural references, adapting to American food, and becoming acquainted with unfamiliar teaching methods and assignments.

Keywords—diversity; first-year students; international students

I. INTRODUCTION

In Mexico, Aarón Martínez (fictionalized name) was seen as the brightest student in his high school. He was one of the first in his area to be accepted to a top university in the United States to study engineering. When Aarón started his courses, however, he had to adjust to a new environment. He struggled to learn difficult mathematical material, and to read texts in English in history and humanities courses.

When courses in his second semester became harder, Aarón had no one on campus who really supported him. He tried communicating with other domestic and international students, but his thick Mexican accent made him feel insecure.

Eventually, he fell so far behind in assignments that he became depressed and stopped attending classes. Soon, he failed all of his courses and returned to Mexico. He concluded that college just wasn't for him, but his parents would not let him give up. His parents encouraged him to reapply, and in the fall, he returned to college with a new attitude.

Aarón studied harder, made a group of study friends, and graduated two and a half years later. Now he is pursuing a PhD in engineering. In retrospect, Aarón knows that he almost did not complete college because he never got the support that he needed. Since Aarón does not want other students to struggle as he did, he mentors Hispanic students to help them adjust to an unfamiliar learning and cultural environment.

Cases like Aarón's are common. While many domestic students also struggle through the first year, international students experience additional difficulties because they are unfamiliar with American culture and academic expectations. If

they do not receive the support that they need, they might become depressed, receive low grades, and drop out of college.

In this study, we addressed a fundamental research question: *What challenges do international students in engineering experience in adjusting to universities in the United States?* We found little previous research on the adjustment of international students. As the enrollment of internationals increases, particularly in engineering programs, it is vital to understand their adjustment experiences, so that universities can properly support them to help them succeed.

II. LITERATURE REVIEW

A. International Students in U.S. Colleges and Universities

International students are valuable to universities in the United States because they inspire intercultural learning, and they foster understanding of diversity and global issues. Upon graduation, international students can become business partners and political allies.

According to the Institute of International Education Open Doors [1], the United States hosts more international students in colleges and universities than any other country in the world. In the 2010–2011 academic year, the U.S. hosted 723,277 international students. Of the internationals studying in the U.S., 19% were in engineering. According to the American Society for Engineering Education [2], in 2010, internationals constituted 6.7% of 450,685 engineering undergraduates, 41.3% of 103,335 engineering master's students, and 54.9% of 67,369 engineering doctoral students in the U.S. Overall, internationals contributed approximately \$12 billion to the U.S. economy in 2005 [3].

B. The Adjustment of International Students

In adjusting to U.S. universities, international students experience challenges with academic expectations, language barriers, and cultural differences.

When international students first come to the U.S., they must learn how to adjust to a different classroom environment. For example, in Korea and Japan, the higher education classroom atmosphere is more competitive because students compete for a limited number of high salary jobs. On the contrary, in the U.S., the atmosphere is more cooperative, and students focus more on what interests them, rather than competing for jobs [4].

Language barriers can also hinder international students' adjustment. They may struggle to understand lectures and instructors who speak quickly and use advanced vocabulary [5]. According to Jacob [6], international students hesitate to participate in class discussions since they have difficulty understanding classroom lectures.

In general, culture can be considered the main factor in the adjustment to the U.S. Region of origin can affect cultural adjustment, and concerns vary from country to country. For example, according to Constantine et al. [7], African students value group survival, communalism, harmony, cooperation, etc., while domestic students tend to be individualistic and self-reliant. Since African students generally depend on a communal culture, they may be challenged by their absence from family when they have to rely on themselves. African students are less likely to utilize services such as professional counseling because of cultural beliefs about the treatment of mental health problems, commitment to their family values, or lack of familiarity with the services [7]. Klomegah [3] found that many international students rely on other internationals rather than on campus staff for social and emotional support.

C. Problems

Parents often push their children to study abroad, and U.S. universities vigorously advertise to pull them in. Although universities dedicate substantial efforts to attract the international students, most dedicate little effort to take care of these students once they arrive [8].

As observed by Reynolds [9] and Constantine et al. [7], when students lack support, their excitement and enthusiasm about academic life and career goals can quickly evolve into sadness and disappointment. When their experiences deviate from their initial expectations, they may have mixed feelings and confusion about how to adjust. They may experience psychological distress, physiological complaints, and mental health problems such as depression or anxiety [9].

Biases of faculty and staff can hinder the adjustment of international students. Many college counselors practice a theory based on a universal normal behavior that favors individualism, rather than collectivism. Biased counselors who favor individualism naturally conflict with international students who cannot always relate to individualism based on their own culture characteristics [10].

Like counselors, instructors may also misunderstand students' behaviors or needs. For example, an instructor might reject an international student's form of writing because it is expressed differently from academic norms in the U.S. Some instructors assume that students do not participate because they already understand the material, when in reality, the students may not be able to keep up with the pace of the lecture [5].

III. RESEARCH METHOD

To compare the contemporary challenges encountered by first-year domestic and international students in engineering, we conducted a mixed-methods study at a large public university in the Midwest, with the approval of the local Institutional Review Board (#11047). Nearly all undergraduate

students enroll full time and reside on campus. All 1,676 first-year students in engineering were invited by e-mail to participate in focus group interviews and in an anonymous online survey during the fall semester.

For the focus groups, separate recruitment e-mail messages were sent to all first-year domestic students; international students in the International Buddies in Engineering Program, which paired first-year international students with more advanced domestic student mentors; and all other first-year international students. Eighty-three students volunteered to participate in the focus group sessions. For each group, 8 to 10 participants were selected at random based on their gender and country of origin in order to ensure diversity. Not all chosen students actually participated, however.

We conducted three separate 90-minute, semi-structured focus group sessions: a session with seven domestic students, a session with four international students, and a session with seven international students in the International Buddies Program. Among the domestic students were three men and four women. Among the eleven international students were seven men and four women; there were students from Europe, Latin America, Southeast Asia, South Asia (2), East Asia (4), the Middle East, and the Caribbean. As compensation, each focus group participant received \$10 and free pizza.

The survey had 39 multiple-choice questions and two open-ended questions. It took about 20 minutes to complete. We received responses with consent from 312 domestic students and 108 international students, mirroring the actual proportions of each population of first-year engineering students.

The focus group interview protocol and the full survey appear in the first author's senior thesis [11].

IV. FOCUS GROUP RESULTS

The focus group transcripts were analyzed using a basic thematic analysis. Each of us first read through the transcripts individually, marking important ideas that were expressed by students. We then shared our notes and grouped the findings into themes. We considered a theme significant if it was raised by two or more students.

A. Communication

Past literature focused on the language barriers that international students must overcome in domestic universities. Andrade [5] and Lee [8] emphasized that international students often do not speak English fluently; therefore, they cannot communicate easily with other native speakers. However, the international focus group participants stated that they struggle less with their fluency in spoken English and more with understanding accents, American slang, cultural references, and different terminology. These particular barriers hinder conversations with the domestic students and communication with instructors and teaching assistants (TAs).

1) Accent

In the classroom, students must adjust to the accents of instructors from other countries. An accent can compound the challenge of keeping up in a fast-paced lecture. In the focus

group sessions, one international and five domestic students said that they had to adjust to an instructor's accent.

I have a professor whose accent is very difficult to understand. So I do a lot of extra studying in that class and I would say generally the classes are pretty fast. –Female, U.S.

International students have an added communication barrier when instructors cannot understand them because of their different accents.

If you take the TAs and stuff. The same thing happens if they are from another part of the world. Yeah, so sometimes you can't get your ideas across, through because maybe, you don't have good command of the language or you have a kind of accent slightly. You have to really keep repeating yourself, which can kind of be a bit annoying. –Male, South Asia

2) Cultural References

International students from countries dissimilar to the U.S. are unfamiliar with certain topics that may be interesting to Americans. Consequently, they find it arduous to join a conversation about an unknown subject.

I think, I just found it a little bit hard to make American friends. Because they have their same talkings and cultures and they become excited when they talk about some soap opera. But I know a little about that. I can't know why they are laughing or why they feel excited when they talk about some people or something. –Female, East Asia

Let's say, you have a group of Americans and you want to join in ... It can be a bit difficult because the topics they talk about aren't familiar to you ... Like for instance, "nerf wars." I had no idea about "nerf wars." So, things like that. People here, they know from like their childhood what these stuff are but you don't know these stuff. So, some conversations can be pretty one-sided. –Male, South Asia

Sometimes domestic students speak quickly and use slang without realizing that international students may not understand their conversation. International students quickly feel left out.

The most difficult problem that I face is to chatting with American people ... I find that they just talk really fast and a lot of American slang. I can't already know what they are talking about. Yeah, I can't get like all of their conversations. It's real bad. –Male, East Asia

In the classroom, some unfamiliar subjects are difficult for international students to understand. For example, domestic students take American history in high school, but international students do not always comprehend references to American history.

Maybe, some courses are easy for Americans or natives, but it's really hard for us. Like, the western history ... it's quite hard for the internationals because we really spend a lot of time on the readings of books and textbooks and extra stuff like that. Maybe the general of us can't understand what we've did so far. –Female, East Asia

3) Terminology

International students must become accustomed to the academic terminology used by instructors.

We say, 3 by 5 or something for fractions. And they say 3 over 5 and they don't get it when you say 3 by 5 or something, but it's like small things. I found that annoying when I first came. I'm trying to get used to the other way of saying it. –Female, Middle East

Internationals may also be unfamiliar with kinds of assignments and projects that are common in the U.S. Instructors often take common practices in the U.S. for granted and do not explain what they expect from their students.

In Italy usually in high school, we don't have any projects or study group. It's a very, I guess, it's more helpful and also interesting to get to know other people. Like how do they face different problems or assignments or whatever. –Female, Europe

B. Interpersonal Relationships

1) Friends

When students have difficulty with concepts or homework, they may ask a tutor or teaching assistant at office hours, use online lecture notes, or search for answers to their questions online. But most often, students ask their friends for help. Asking their friends for help is more convenient because friends are available more often and are easier to relate with.

My first step if I did have friends in those classes would be to go those friends and be like, "Hey, can you explain this to me?" cause that's a little more familiar and easier. But if I don't have friends in the classes that I've known previously or met, then I usually go to the TAs. Otherwise, I do use the online lecture notes, especially for my physics class. –Female, U.S.

Many domestic students may have the advantage of having a group of friends from high school at their same college. They can come to college feeling more comfortable with a group of people whom they already know.

I know people from high school who were in the engineering program and they're taking the same classes as me. So it's kinda like a built-in study group right there. –Female, U.S.

Unlike many domestic students, international students rarely have an immediate friend base. In fact, a disadvantage for some international students is integrating into pre-formed groups of domestic students.

Maybe just like knowing a lot of new people, and then especially my dorm, actually everybody comes from Chicago or suburb of Chicago. So, it's kinda hard to adapt with them, but actually it gets better and better. –Male, Southeast Asia

2) Working in Groups

Although domestic students are welcoming to international students, they find it easier to work with other domestic students in a study group. The domestic students mostly work with other domestic students by choice.

My [composition class] group is all domestic. It's not that I don't get along with international students, but uhm, it's whoever I can easily converse with and those are mostly domestic students. –Male, U.S.

C. Adjusting to Living

1) Roommates

Both domestic and international students had some concerns about mixing two different cultures. All students have to adjust to living with someone who may have different cultural views. Differences range from interests in music, daily schedule, religious views, or interest in American topics.

We had some, or well I had some problems adjusting 'cause we had some differences in our beliefs, our religion. By, I think by being more open-minded, I think I can deal with it. And sometimes it gets a bit too, too uncomfortable, I can just leave. –Male, U.S.

2) Food

In the focus group sessions, nine international students found it hard to adapt to Western meals. In the dining halls, there are few choices of food from their own countries, so they adapt to eating different types of food. Students complained about the high calories in meals and the lack of fresh fruits and vegetables. Also, American meal times were much earlier than meal times at home.

I would say the food is very American. And uh, if you eat too much, it will make you fat. –Male, East Asia

V. SURVEY RESULTS

Of the 422 participants who responded to the survey (25% response rate), 420 consented to allow their responses to be analyzed. Some students did not answer some questions; at a minimum, 336 responses were used, but mostly 415 to 420 responses were used. The two-sample t-test was used to check for significant differences between domestic and international students in the number of credit hours students took and the number of hours that students spent studying. The Mann-Whitney U test was used to check for significant differences for the remaining questions, where students were asked to rate a statement based on a discrete scale. When a test produced a p value of .05 or less, the difference was considered significant, and it is marked with an asterisk (*) in the tables below.

In the survey, students could respond to two open-ended questions:

- Do you have any comments you would like to share about your adjustment to the academic aspects of college?
- Do you have any additional comments you would like to share about your adjustment to the social aspects of college (for example, with regard to your interactions with peers or professors/TAs)?

Themes were created based on the students' comments and survey responses. With the exception of some noted comments, the quoted comments contain themes that were expressed by more than one student.

A. Time Management

Domestic and international students generally take the same number of credit hours of courses during their first semester, but they use their time differently for studying. International

students spend significantly more time with their humanities and social science courses ($p < .05$). See Table I.

TABLE I. TIME MANAGEMENT

| | Domestic | International |
|--|----------|---------------|
| <i>Reported to the nearest whole number 1, 2, ...</i> | | |
| How many semester hours of credit are you currently taking? | 15.20 | 15.22 |
| How many hours per week do you work outside of classes and labs for engineering, math, and science courses (homework, studying, attending office hours, etc.)? | 14.45 | 13.37 |
| How many hours per week do you work outside of classes and labs for humanities and social science courses (homework, studying, attending office hours, etc.)? | 4.14 | 5.19* |

B. Working with Others

Students occasionally do homework or study in groups, but domestic students are significantly more likely to do homework in groups, especially with students who are from their own country ($p < .05$). Both groups of students relate with their fellow classmates, yet domestic students feel that they have more in common with other classmates. See Table II.

TABLE II. WORKING WITH OTHERS

| | Domestic | International |
|---|--------------|---------------|
| <i>Rated on the scale 1 = Never, 2 = Rarely, 3 = Occasionally, 4 = Often, 5 = Very Often, 6 = Almost Always</i> | | |
| I study in groups. | 2.90 | 3.03 |
| When I study in groups, it is with people from my own country. | 4.39* | 3.47 |
| I do homework in groups. | 2.85* | 2.52 |
| When I do homework in groups, it is with people from my own country. | 4.42* | 3.20 |
| <i>Rated on the scale 1 = Don't Know, 2 = Strongly Disagree, 3 = Disagree, 4 = Neutral, 5 = Agree, 6 = Strongly Agree</i> | | |
| I can relate to the people around me in my classes. | 4.57 | 4.42 |
| I have a lot in common with other students in my classes. | 4.43* | 4.16 |

Many students were dissatisfied in different aspects with the integration of domestic and international students. Some domestic students said that they preferred not to work with international students because of the language barrier.

I hate people who can't speak English on par with a native speaker; they hinder a group's effectiveness. –Domestic

Many international students mentioned that it is difficult to integrate with domestic students who already have groups of friends. One international student from a less-represented country observed that other internationals from largely represented countries mostly associate with those from their own country instead of getting to know other students.

My comment is more for people from other countries (not the U.S.) who unlike me, came to the university with lots of others from their country and hence spend most of their time together sitting together in their huge groups and not really getting to know people out of their nationality. So maybe the larger non-U.S. groups could just gently advised to try break away from sticking together so much. –International

C. Abilities

Most students rated their self-confidence, leadership, public speaking, communication, and teamwork abilities as average to above-average. International students rated their math, science, and critical thinking skills as significantly above average ($p < .05$). See Table III.

TABLE III. ABILITIES

| | Domestic | International |
|--|----------|---------------|
| <i>Rated on the scale 1 = Lowest 10%, 2 = Below Average, 3 = Average, 4 = Above Average, 5 = Highest 10%</i> | | |
| Social self-confidence | 3.67 | 3.61 |
| Leadership ability | 3.78 | 3.63 |
| Public speaking | 3.32 | 3.31 |
| Math ability | 3.85 | 4.30* |
| Science ability | 3.76 | 4.19* |
| Verbal communication ability | 3.64 | 3.65 |
| Written communication ability | 3.62 | 3.56 |
| Ability to perform in teams | 3.92 | 3.92 |
| Critical thinking skill | 3.96 | 4.21* |

Many students commented on the importance of communication and their struggles to communicate with other students. International students mentioned that their accent and lack of familiarity of language and culture caused some problems with communicating with others.

Good verbal communication is needed in discussions, daily conversations, seeking jobs, problem solving, working in groups and almost everywhere if one wants to get involved. However, it is usually tough for international students who have disadvantages in language and culture to pick up everything in a short time. –International

Sometimes it takes a while for other students to understand what I'm trying to say but overall it has been a wonderful experience. –International

D. Course Load

Students generally agree that their classes are challenging, but not overwhelming. See Table IV.

I think the courses are challenging and require effort and time, but it is nothing that every student accepted into engineering cannot handle. –Domestic

TABLE IV. COURSE DIFFICULTY

| | Domestic | International |
|---|----------|---------------|
| <i>Rated on the scale 1 = Don't Know, 2 = Strongly Disagree, 3 = Disagree, 4 = Neutral, 5 = Agree, 6 = Strongly Agree</i> | | |
| I find my classes challenging. | 4.87 | 4.46 |
| I find my classes overwhelming. | 3.96 | 3.83 |

An international student had the difficulty of adjusting to the different academic level and the language barrier.

I have found adjusting to college academics very challenging, as my high school was a low-level school. Besides, I came from Europe two years ago, which made it even more difficult to catch up with other undergraduates (language barrier). –International

When students had difficulty with assignments or studying, they often asked their friends more than instructors or teaching assistants. International students asked questions in class and studied their notes before class significantly more often than domestic students ($p < .05$). See Table V.

TABLE V. COURSE HELP

| | Domestic | International |
|--|----------|---------------|
| <i>Rated on the scale: 1 = Never, 2 = Rarely, 3 = Occasionally, 4 = Often, 5 = Very Often, 6 = Almost Always</i> | | |
| My friends help me when I am having difficulty with the homework assignments or studying. | 4.09 | 4.10 |
| I attend the instructors' or teaching assistants' office hours when I need help. | 2.65 | 2.92 |
| I ask questions in class. | 2.85 | 3.02* |
| I study my notes before class. | 2.60 | 3.09* |

VI. DISCUSSION

A. Comparison with the Literature

1) Making Friends Is Important

According to Olivas and Li [10], international students who make friends with host students are able to reduce their stress and adapt to American culture differences. The focus group participants confirmed that making friends right away helped them feel comfortable on campus. With friends, they had people to do activities with, to eat meals with, and to help them with academics or living. One focus group participant said that he served as a “bridge” between East Asian international students and American students.

2) Homesickness

Andrade [5] cited previous research that found that international students feel more homesickness than domestic students because their families are farther away; thus, they have less support from their families. In the focus group sessions, however, international students did not mention homesickness as a major adjustment factor. With today's advanced

communication technologies, international students keep in contact regularly with their friends and families at home.

In addition, first-year domestic students also indicated that at times they missed their homes, but many were able to go home on the weekends to see friends and families. Because of travel expenses, many international students are not able to go home until winter or summer breaks. Despite these limitations, international students generally do not suffer from constant homesickness as previously believed.

3) Language Barriers

Andrade [5] stated that international students may have a more difficult time understanding lecturers because they speak quickly or use sophisticated vocabulary. As stated in section IV.A.1, however, international students agreed that they experience some difficulties in communicating with instructors, but the difficulty arises from understanding different accents. Domestic students struggle with the same communication barrier as well. In mathematics, science, and engineering, many instructors are internationals with accents, so all students need extra effort to understand and communicate with instructors.

As implied by Jacobs [6], international students are also more hesitant to participate in discussions in class because of their English proficiency level. The survey results show the opposite: internationals were more willing to ask questions in class. Recently, it seems that English proficiency may be less of an adjustment issue, because international students now have more opportunities to learn English in their home countries. Instead, as stated in section IV.A, international students have difficulty in communicating because they do not understand American cultural references and specific unfamiliar terms

B. Limitations

In the survey, some demographic information was not requested. Information such as gender and place of origin would have been useful in comparing the results. Without the demographic information, comparing the survey results with the focus group results based on location is not feasible.

Although the focus groups were diverse, many countries and regions of the world, such as Africa, were not represented. South Korea was not represented at all, even though the population of Korean students on this campus is very large.

VII. CONCLUSIONS

This study has found evidence that first-year international engineering students have more difficulties in adjusting than domestic students in communication, interpersonal relationships, and living at a university. Language poses many problems because international students are unfamiliar with American slang, cultural references, and technical terms. International students must also become familiar with American teaching methods and assignments. All students must adjust to living and working with different types of people in a new community. International students must also adjust to American food, but they do not seem to suffer homesickness.

According to the survey, in the first semester, international engineering students spend more time studying for humanities

courses than do domestic students. They study more because they require more time to read the texts and learn about subjects that are completely new to them. Domestic students are more likely to work with other students in groups. They may be friendly to other international students, but they mostly prefer working with other domestic students. The ease of communication between domestic students is a major reason to associate with each other.

All participants in the focus groups agreed that their friends were crucial in adjusting to campus. Those who had struggled at the beginning of the semester improved after making friends. International students who made friends with other internationals were able to survive the adjustment period. Those who became friends with other domestic students not only adjusted more quickly, but also understood American culture and customs better. Universities should help international students make friends with domestic students, so they can live comfortably and succeed academically.

ACKNOWLEDGMENTS

Russell Korte, Julie Misa, and Serena Wee suggested references for the literature review. Susan Larson, Haseeb Moten, Mark Persaud, Stephanie Seiler, and Jack Su helped prepare and administer the survey. Nick Fila assisted with the focus group sessions. "Aarón" let us use his story.

Work in Progress: A Holistic Approach to Re-Engineering the Freshmen Engineering Course

James Collofello, Amy Hall
Ira A. Fulton Schools of Engineering
Arizona State University

Abstract— Engineering schools must strive to evolve a new paradigm for undergraduate education that recognizes the evolution of the skills and learning styles of its incoming students and prepares them to tackle society's grand challenges of the future, while at the same time increases the probability of their success in their chosen engineering program. Most researchers and experts in the field agree on some basic tenants of retention [1-3], which include developing community amongst freshmen, creating connections for freshmen through meaningful interactions with returning students and faculty, engaging freshmen in active learning environments, helping freshmen understand and internalize the vision and mission of the school, and assisting freshmen to develop a personal identity as an Engineer. This paper describes the creation of new freshmen engineering courses, taught in a new learning environment with a new instructional model that addresses all of these important tenants of retention.

Keywords- *freshmen engineering; first-year experience; multi-disciplinary; project-based learning; engineering design*

I. BACKGROUND

The freshmen introduction to engineering course has been the focus of research and experimentation for decades. There are countless models of instruction that differ in ways such as whether or not the course is general for all majors or taught to a specific major, the extent of project based instruction, and the optimal size of the class.

Common introduction to engineering classes are usually embedded in curriculum in which the institution has made a decision to admit students into a pre-engineering program in which all engineering students proceed through a set of mostly common courses. In this approach, students select a specific engineering major after several semesters of common courses. The primary rationale for this approach is to provide students with more time to explore their options before committing to a major. The challenges, of course, lie in structuring a curriculum with enough major depth that can be completed after the selection has been made. Potential advantages of admitting students into a chosen major include helping the student identify with their chosen profession earlier with more targeted classroom experiences as well as interactions with faculty in their chosen discipline. Introduction to engineering approaches vary greatly across institutions with both common and discipline specific first year programs, with some institutions requiring discipline specific or common introduction to engineering courses, while other institutions

offer only elective engineering courses or no required engineering courses in the first year [4].

It has been considered best practice for some time to include “hands-on”, team based projects in introduction to engineering courses [5-8, 9]. The type and duration of these projects, however, varies considerably and is usually constrained by class size which also varies greatly among institutions [4, 5, 7, 10, 11]. Some common introduction to engineering courses include a series of short projects or laboratory exercises to introduce students to each engineering discipline [10-13]. Others use project-based learning, in which engineering concepts are taught using a just-in-time approach in the context of a semester-long team design project, which may be discipline-specific or multidisciplinary in nature [4, 6, 14, 15, 16]. Both approaches have shown positive results and the approach taken depends on the structure of the curriculum and class sizes. There is also great variability in the number of credit hours (typically between 1 and 4) as well as the type and number of contact hours (i.e. lecture, lab, recitation) available in the introduction to engineering course, which impacts the structure and content of the course.

Common learning outcomes for the introduction to engineering classes most often include:

- Learning to work in teams
- Gaining an understanding of the Engineering Profession and Disciplines
- Developing Effective Communication Skills
- Improving skills that support academic success
- Learning and practicing the engineering design process
- Developing a sense of community with peers
- Connecting with elder peers and faculty

The specific content of freshmen introduction to engineering classes also varies considerably across institutions, depending on the desired outcomes of the course. Typical topics covered in freshmen engineering courses include the engineering design process, engineering analysis (general or discipline specific), engineering problem solving, engineering careers, academic success topics (time management, study skills, etc.), ethics, and communication skills as indicated by the learning outcomes above. Most of these topics are taught in a single semester or two semester introduction to engineering course at many universities, while at other

institutions topics are split between an engineering design/analysis course and a general university success course (not engineering-specific). Depending on the specific objectives of the course, some classes focus mostly on technical skills necessary for future courses while others focus more on non-technical 'soft' skills including teamwork and communication.

Despite the advances made across the freshmen year via these courses, retention remains a concern. Many institutions have found that active learning, working in teams, hands-on projects, and community building with peers and faculty can help improve retention and student success [1-3, 5, 7]. We hope to address many of the important factors contributing to retention and provide first year engineering students with a fun and rewarding educational experience in our new freshmen engineering courses.

II. HOLISTIC APPROACH TO FRESHMEN ENGINEERING EXPERIENCE

Our institution is a large state university which grants degrees in almost all of the engineering disciplines. Our freshmen engineering class exceeds 1,500 students. Our freshmen are admitted directly into the engineering discipline of their choice. The engineering school itself is not organized around traditional departments but instead consists of 5 schools, each of which contains faculty and students working together on theme based research and curricula. For example the School of Computing Informatics and Decisions Systems Engineering integrates faculty and students in the computer science, computer systems engineering, industrial engineering, engineering management, and informatics degree programs. Prior to the introduction of these new courses, freshmen students in each of the academic programs took a discipline specific introduction to engineering course. The content and instruction of each of these courses varied greatly both by design as well as quality of instruction. As part of a renewed commitment to improve our freshmen engineering experience incorporating the latest best practices, all aspects of these courses were analyzed leading to the new approach described in this paper. In particular we analyzed retention rates among the programs, differences in course content and project experiences, interviews with students leaving engineering and faculty focus groups to identify areas for improvement.

The discipline specific 3 credit hour Introduction to Engineering course was changed to an experiential multidisciplinary 2 hour lab and lecture course (FSE 100) complemented with a 1 hour engineering success class (ASU 101) both of which are described in detail later in the paper. Rather than create a common course that all freshmen would take, the FSE 100 classes are theme based closely aligned to the schools with projects that are closely tied and very relevant to the students' majors. The instruction of the new FSE 100 courses is primarily performed by a core of lecturers specifically hired to work together in the instruction, evaluation, and continuous improvement of the courses. The classes are taught in a newly constructed classroom environment (eSpaces) in class sizes of 40 to maximize instructional effectiveness. The new innovative eSpaces provide a collaborative learning environment in which students

sit at work tables in teams of four to complete a variety of hands-on engineering activities and projects. In eSpace, student teams have the opportunity to use electronic equipment, sensors, computers with engineering software, and hand tools to visualize designs, complete analysis tasks, and build prototypes. Throughout eSpace there are whiteboards and writeable glass wall panels to encourage student collaboration. All furniture in the room is mobile, with wheeled tool cabinets and demonstration tables, to make eSpace modular allowing for a variety of activities and courses.

All of the classes also utilize Undergraduate Teaching Assistants (UGTAs) who are current engineering students that are selected to assist in problem based instruction and to serve as role models. Each UGTA works alongside a Graduate Teaching Assistant (TA) and the faculty instructor to instruct and assist students in the laboratory portion of the course. UGTAs interact with the students primarily in class, answering questions, and offering assistance and suggestions as needed as students complete various engineering lab activities and design projects. As a near peer, the UGTA is able to relate well to students and their difficulties and successes, and offer them valuable insight that may help improve student motivation and confidence.

Unlike the FSE 100 classes, the ASU 101 classes are discipline specific and are typically taught by tenure track faculty with a class size limited to 19 with the goal of achieving a high degree of faculty-student interaction. The ASU 101 class is where students in the same major will build a community and identify most closely with their chosen profession. In the remainder of this section, the courses will be described in detail.

A. FSE 100 Introduction to Engineering

FSE100 is a 2 credit multidisciplinary lab and lecture course, where the focus is on hands-on active learning and working in teams. Class size is limited to 40 students to maximize interaction. The course introduces students to the engineering design process and some basic engineering tools and software, culminating in a 7-8 week team design project. Students attend one 50 minute lecture and one 3 hour lab each week for the entire 15 week semester. Faculty lead the lectures, introduce the labs and project, and are present in lab to assist students along with a graduate TA and UGTA. The lectures involve group discussions and student participation whenever possible, and are used to introduce and reinforce new concepts that are explored in the lab activities and projects. With the help of the tools and equipment available in eSpace, freshmen students have the opportunity to actually 'do' engineering in the lab throughout the semester. Lab activities range from building circuits, programming, or testing gear ratios to building functional prototypes for their design projects. The hands-on lab is the focus of this course, and the lecture supports the lab by providing students with the knowledge required to obtain deeper understanding of the concepts explored. Topics are presented in the context of the design project whenever possible.

There are currently three different versions of the FSE100 course in the college, each theme based with a project related to

the disciplines of students taking the course. The students are grouped by discipline into one of the three theme based versions of the course as follows: (1) ME/AE/EE: Mechanical, Aerospace, and Electrical Engineering; (2) CS/CSE/IE: Computer Science, Computer Systems Engineering, and Industrial Engineering; (3) CEE/ConstE: Civil and Environmental Engineering and Construction Engineering. The overall course structure is consistent throughout each version of the course. The general course structure begins with 6-7 weeks of introducing design and engineering topics/tools, and ending with a 7-8 week team design project. The specific engineering tools and topics covered in each School's course (with the exception of the design process), however, is related to the course 'theme' which is evident in the course design projects.

1) *Learning outcomes:* The specific learning outcomes for the FSE100 course are the same across all themes, and are closely aligned with the outcomes of introduction to engineering and introduction to engineering design courses at other institutions as well as ABET [16]. As a result of completing the FSE100 course, students will:

1. Understand and practice using the engineering design process;
2. Become familiar with tools, software, and terminology used in engineering;
3. Learn to use engineering models, physical principles, measurements and data to solve problems;
4. Gain the ability to work effectively in teams and recognize the importance of teamwork;
5. Gain basic skills in technical communication (oral presentations, technical reports, presentation of data);
6. Gain experience using basic project management techniques (scheduling, budgeting) to complete projects successfully; and
7. Use creativity to solve an engineering problem related to challenges facing our world.

2) *Major topics:* The main topics covered in FSE100 include teamwork, technical communication skills, and the engineering design process. Teamwork is learned through practice, with students working in teams of four throughout the semester. Both oral and written communication skills are emphasized through presentations and technical reports. Students gain experience working through the stages of the engineering design process in an introductory design process lesson or mini-project, and in their team design projects.

In addition to the major topics discussed above, students also explore various engineering topics related to the project theme in that particular course and are introduced to topics, tools, and software that are most relevant and useful for their major. For ME/AE/EE students, these topics typically include mechanical concepts (e.g. gears, motors, drag, friction, etc.), electrical concepts (e.g. basic circuits, power, etc.), multidisciplinary project topics (e.g. solar cell characterization, renewable energy, etc.), and general

engineering concepts including engineering drawing, measurements, and energy conservation. Other tools and software introduced to ME/AE/EE students include MATLAB, LabVIEW, and various measurement and construction tools. The course topics for CS/CSE/IE students typically include programming, robotics, manufacturing, system modeling and analysis, and various programming languages and software tools are introduced. In the third version of the course, CE/ConstE students learn and practice AutoCAD, an important tool in their field, which they use to visualize their prototypes during the design project.

3) *Project Information:* In the team design projects, students work as engineers to design and build a functional prototype of a system related to their field of study. Students are provided with a project description which describes the customer needs and constraints. Student teams are then required to work through all stages of the engineering design process to design and build a small-scale functional model. They develop engineering requirements, generate multiple conceptual designs, select a design, build a prototype, and test prototype(s), repeating steps when necessary as they experience the iterative nature of design. Modeling and analysis are included in the projects in different forms and to differing degrees, but all projects require some quantitative analysis.

All projects are multidisciplinary in nature and require students to learn and apply skills relevant to their majors. Whenever possible, students are placed in multidisciplinary teams so that they can work with students in other disciplines as well as their own. Projects that were done in Fall 2011 (and the disciplines involved in each project) include the following: Renewable Energy Power plant (including wind, water, and/or solar power) (ME/AE/EE), Solar-powered car (ME/AE/EE), Autonomous maze-solving robot (CS/CSE/IE), Sumo Robot (CS/CSE/IE), hydroelectric power generation system (CEE/ConstE). In all projects, students must design and build functional prototypes that meet functional requirements and other various project constraints. For the Renewable Energy, Solar car, and Hydroelectric projects students acquire various construction materials including wood, plastics, motors, gears, and various other raw materials from an in-class 'store' and must stay within a specified 'budget'. For the two robotics projects, each team is provided with a Lego Mindstorms NXT robot kit and use Microsoft Visual Programming Language (VPL) to program the robots.

Throughout the project, the student teams complete a series of project deliverables to document their progress and receive feedback throughout the design process. Deliverables include preliminary design proposals, progress report memos and/or meeting minutes, a final design report, a final presentation, and prototype demonstration (or competition). All project deliverables are completed as a team, and follow technical communication guidelines discussed in class.

B. ASU101: Engineering Success

ASU101 is a 1 credit lecture course intended to help students gain the skills they need to be successful students and engineers. The class meets once a week in classes of 19

students in the same major and is taught by a faculty member in that school. The small class size provides an excellent environment for the students to interact with other students in their discipline, and to make connections to a faculty member in their school. Through discussions and other active learning, students explore career opportunities in their discipline, start to develop personal goals based on their interests, and learn about the resources available at the university to help them reach their goals. This course helps students to really understand the missions and values of the school and what they can do as engineers, and helps them start to see themselves as future engineers.

1) *Learning outcomes:* The specific learning outcomes for ASU101 are all related to students gaining the skills they need to be successful students and professional engineers. These outcomes are those typically covered in introduction to engineering courses at other institutions that are not covered explicitly in our introduction to engineering course (FSE100). As a result of completing ASU101, students will:

1. Set Personal, Academic, and Career Goals to guide their success at ASU;
2. Learn about the resources available through ASU and the Ira A. Fulton Schools of Engineering that will help them to be successful in their academic careers;
3. Enhance skills to support academic success (time management, academic/career planning, study skills);
4. Understand the ethical issues related to a career in engineering and the role of academic integrity in becoming an ethical and responsible professional engineer;
5. Gain an understanding of the exciting career options available in engineering and what they can do as engineers; and
6. Become a part of the engineering community and learn about ways to become more involved in the School's and University's culture

2) *Major topics:* In the discipline specific ASU101 classes, students learn about their engineering major and career options, practice skills that will help them to be successful students and professionals, and learn about the resources available at ASU to support them through their studies. Towards the beginning of the course, students learn about engineering careers and career planning through a three week career exploration module. In the career exploration module, they first explore the wide variety of career options available to them as engineers, and the difference between engineering disciplines (majors) and job functions. In the second week, students have the unique opportunity to talk to working engineers from all engineering disciplines at the 'Career Exploration Night' event held specifically for Freshmen engineering students. The third week of the module discusses career planning, tools, and resources they can use to help them achieve their career goals.

Specific academic success related topics covered in the course include time management, learning goals, and learning from feedback. Additional topics covered in the course include opportunities in the college and/or university (e.g. clubs, research experience, etc.), Academic Integrity and Engineering Ethics, and academic resources (e.g. advising, library, etc.).

The course culminates with an oral presentation assignment, in which students complete individual or group presentations on a selected topic (topic areas vary between instructors and disciplines). Topic areas for presentations have included Engineering Failures, Top Engineering Achievements, National Academy of Engineering (NAE) Grand Challenges for Engineering, and other topics related to their interests and engineering.

III. EXPERIENCE WITH THE NEW COURSES

The new freshmen engineering courses, FSE100 and ASU101, were successfully implemented on a large scale throughout all disciplines mentioned above in the Fall 2011 semester. There were approximately 1,100 freshmen enrolled in FSE100 across 28 sections of the course (16 ME/AE/EE, 8 CS/CSE/IE, 4 CEE/ConstE). The total number of ASU101 sections across all engineering disciplines was approximately double that of FSE100, since the class size is limited to 19.

A. *Lessons learned*

Under the new instructional model, the student experience in FSE100 was more consistent across all disciplines involved with each course using an experiential lecture and lab format. The transition from a lecture based course to lab based course had a positive impact on the students' experience, as expected due to the increase in hands-on learning. Students also appreciated the opportunity to interact with and receive assistance from the faculty, TAs, and UGTAs when necessary throughout the design project and other lab activities.

The design project was well received by most students, and they enjoyed the opportunity of learning challenging concepts while actually 'doing' engineering. The opportunity to design and build a complete system from the ground up excited and motivated the students; they embraced the opportunity to act as engineers. The open-ended nature of the problem caused some students to be apprehensive and/or uncomfortable at first, but once the teams started working together on the designs they all appeared more confident that they could be successful. The multidisciplinary nature of the projects and the related lab activities completed in preparation for the projects gave students an opportunity to see how all engineering disciplines work together to solve real world problems. All students were able to complete the projects successfully and produced functional prototypes of the system explored in their project. The design project was cited as the best part of the course by many students, and students clearly were motivated by this type of activity.

One of the challenges with theme based courses is choosing a 'theme' or project that the majority of students are interested in. This fall, most students were genuinely interested in the projects, but at times it was difficult to maintain student interest

in some of the other lab activities, particularly if it was outside a student's chosen discipline. During the early labs, some students would complain or question why they needed to learn certain topics, but once they started their design projects they no longer questioned the concepts covered. Through this, we learned the importance of providing a context for all topics and activities, and the necessity of emphasizing how each lab or lecture topic connected to the course design project. As the course continues in the future, we hope to continuously improve the projects and content of the course, based on student and faculty feedback and interests.

Another challenge encountered is choosing an appropriate level of workload for the students for a 2 credit course. Although many students enjoyed the course, there were still several complaints about the workload associated with this 2 credit course. The additional workload for students also increases the grading workload for TAs and faculty as well, as it is multiplied by the number of sections taught. We are currently exploring this issue and are planning to try different forms of work and assessment to remedy this problem.

In the ASU101 courses, the student experience varied, and appeared to be dependent on the faculty and their level of involvement in the course. Overall, students enjoyed the small class environment and were happy to have met other students in their discipline and make a connection to a faculty member in their school. Students appreciated when faculty members were willing to help and showed that they cared about their success. Students enjoyed the opportunity to learn about engineering careers in the career exploration module, and especially interacting with professional engineers at the Career Exploration Night event. Student responses to academic success skills related topics in the course were mixed, with some students appreciating the information and others feeling that they already have the skills presented and thus found the course material to be 'common sense'.

B. What the students had to say

The majority of student feedback for FSE100 was positive, and the recurring theme of what students liked most was usually the 'hands-on' projects and activities. As seen in the student comments below from course evaluations, students enjoyed the opportunities to learn by 'doing' engineering.

"What I liked most about this course was EVERYTHING! Everything seemed applicable to my degree and I enjoyed the final project. I learned the most in this class and I wish there was another class like this to take next semester!"

"I like how it gave the students a glimpse of engineering. It helps show us that team work and critical thinking are essential in this line of business."

"I got to test engineering concepts and I worked with a group to design a mini-powered city to supply energy. The design project was very interesting and challenging."

"The thing that I liked most about this course was the ability to think creatively and express those ideas and opinions to my group during lab."

Most of the negative student feedback for the FSE100 course was related to the course load and grading, or the speed at which topics were covered. The number of different topics covered in some of the courses due to the multidisciplinary nature of the project was overwhelming at first for some students.

As mentioned above, student feedback on the ASU101 course varied greatly across sections and instructors. The majority of positive feedback commented on learning about engineering and their disciplines, and resources available to them as students. Student comments also indicated that they enjoyed having an opportunity to meet other freshman students in their discipline and to meet and connect with a faculty member in their school. Negative feedback included students feeling that some topics were 'useless', or that the course included too much 'busy work'.

Freshmen retention data for our Fall 2011 cohort of engineering students within the university improved to 96% from 94% the previous year. Freshmen retention within the engineering school also improved to 88% up from 85% the previous year. Drilling down into the data, retention in the mechanical engineering program increased from 85% to almost 92%. and retention in aerospace engineering increased from 79% to over 83%.

IV. CONCLUSION

Overall the introduction of our new freshmen engineering courses was very successful. Our freshmen welcomed the opportunity to "be engineers from day one". We have seen significant increased participation of our freshmen in engineering student organizations, undergraduate research programs, outreach activities and service learning projects. The quality and consistency of our instruction has improved through the coordination and communication of our freshmen engineering instructional team. Active learning is fully integrated into our courses. We are confident that we have developed a sustainable instructional model that will continuously improve over time.

Work in Progress: A New Concept Mapping Approach in an Introductory Engineering Course: Correlation Between Students' Conceptual Understanding and Problem-Solving Skills

Ning Fang

Department of Engineering Education
Utah State University
Logan, Utah, USA
ning.fang@usu.edu

Abstract—This paper presents a new concept mapping approach, called “Tree of Dynamics,” to enhance students’ perception (intuitive cognition) of the relationships among fundamental concepts in an introductory engineering dynamics course. In this approach, the relationships among concepts are represented by tree structures including roots, trunks, branches, leaves, and fruits, rather than by using linking words or phrases. A total of 76 engineering undergraduates participated in this work-in-progress study. Statistical analysis showed that moderate correlation ($r = 0.309$, $p < 0.05$) existed between students’ “tree” scores and exam scores. This research finding implies that the new “Tree of Dynamics” approach not only helps identify students’ misconceptions, but also provides a useful tool to help assess students’ problem-solving skills in the introductory engineering course.

Keywords: *Concept mapping; conceptual understanding; correlation; problem-solving skills; Tree of Dynamics*

I. INTRODUCTION

Dynamics is a sophomore-level course that nearly all students in mechanical, aerospace, civil, biological, and biomedical engineering programs are required to take. The course is widely regarded as one of the most difficult undergraduate courses to succeed in because the course covers a broad spectrum of foundational concepts such as force, velocity, angular velocity, acceleration, angular acceleration, work, energy, impulse, momentum, and vibration. Many students fail this course because they lack a solid understanding of these foundational concepts and do not know when and why to apply what concepts and associated equations.

Concept mapping, developed upon constructivist learning theory, is a graphical representation (like a flow chart) that shows how individual concepts are related to and connected with one another to form large wholes [1]. Extensive educational research has confirmed the effectiveness of concept mapping in improving student learning [2, 3]. However, in the conventional concept mapping approach, the relationships among concepts are indicated by linking words and phrases [1-3]. Students must “read” those linking words and phrases to

learn the relationships among concepts. Cognitively, this “learning by reading texts” activity might not be most effective.

To enhance students’ perception (intuitive cognition) of the relationships among concepts and also add an element of fun to learning, the author of this paper has developed a new concept mapping approach called “Tree of Dynamics.” In the new approach, the relationships among concepts are represented by tree structures including roots, trunks, branches, leaves, and fruits, instead of by using linking words or phrases. For example, the foundation on which all concepts are built can be placed as the root of a tree. The main concept can be the trunk. Concepts that derive from the main concept can be the branches.

This work-in-progress paper reports preliminary results of the new Tree of Dynamics approach recently implemented in a dynamics course. The primary assessment question is: Is there a statistically significant correlation between students’ conceptual understanding (measured by the scores of student-constructed “trees”) and students’ problem-solving skills (measured by students’ dynamics exam scores)? The answer to this question helps determine whether the Tree of Dynamics can be used as a tool to assist in assessing students’ conceptual understanding and students’ problem-solving skills as well.

II. STUDENT PARTICIPANTS

A total of 76 engineering undergraduates who took the dynamics course from the author of this paper in a recent semester participated in the present study. Among these students, 45 students (59.2%) were mechanical and aerospace engineering majors, 19 students (25%) were civil and environmental engineering majors, and 12 students (15.8%) were other majors such as biological engineering and pre-engineering students. Sixty-seven students (88.2%) were males and nine students (11.8%) were females.

III. STUDENT-CONSTRUCTED TREES AND SCORING CRITERIA

Because many students in the dynamics class did not have

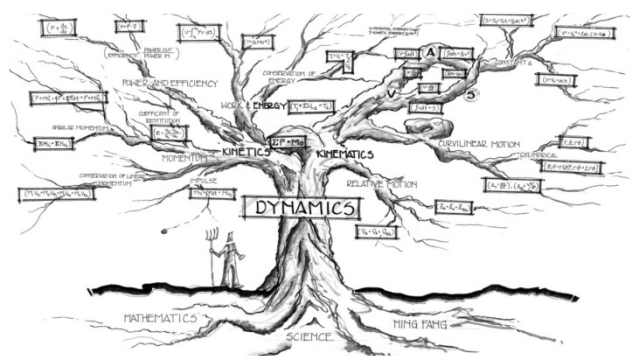

Figure 1. An example tree built by a two-student team.

prior experience with construing either concept maps or trees of dynamics, the instructor spent considerable time in teaching about concept maps and trees, and in demonstrating example maps and trees to the students. The students were then asked to construct “Trees of Dynamics” of their own by working either individually or collaboratively.

Among the 76 student participants, 35 students (46%) chose to work individually, and 41 students (54%) chose to work in teams of two to four students, forming 15 teams. Therefore, a total of 50 “trees” were generated, including 35 “trees” generated by individual students and 15 “trees” generated by student teams. As an example, Fig. 1 shows a “tree” constructed by a two-student team. Each tree was evaluated against the following criteria:

- The “tree” shows two main branches of “Kinematics” and “Kinetics,” or the “tree” shows that “kinematics” is the foundation (root) of “kinetics.” (+1).
- The “tree” correctly shows the relationships among displacement, velocity, and accelerations. (+1).
- The “tree” correctly shows that all six Dynamics principles stem from Newton’s Second Law. (+2).
- The “tree” correctly shows the hierarchal relationship between the “Principle of Work and Energy” and the “Principle of Conservation of Energy.” (+1).
- The “tree” correctly shows the hierarchal relationship between the “Principle of Linear Impulse and Momentum” and the “Principle of Conservation of Linear Momentum.” (+1).
- The “tree” correctly shows the hierarchal relationship between the “Principle of Linear Impulse and Momentum” and the “Principle of Angular Impulse and Momentum.” (+1).
- The “tree” correctly shows the hierarchal relationship between the “Principle of Angular Impulse and Momentum” and the “Principle of Conservation of Angular Momentum.” (+1).
- The “tree” shows only some (not all) hierarchal relationships among dynamics concepts (-1 point); or the “tree” does not clearly show the hierarchal relationships among dynamics concepts at all (-2).

- The number of technical errors (regarding the hierarchal relationships among dynamics concepts) contained in the “tree”: 1-2 errors (-1), 3-4 errors (-2), 5 or more errors (-3).

IV. MEASUREMENT OF STUDENTS’ PROBLEM-SOLVING SKILLS

All students took two dynamics exams to apply mathematics to get numerical answers to 31 technical problems (i.e., 31 assessment items). The coefficient of reliability (Cronbach’s alpha) of assessment instruments was 0.69.

Content validity, which was employed as a major measurement of construct validity in the present study, was measured by using Lawshe’s quantitative method [4]. Five veteran instructors were asked to respond to the following question for each assessment item: “Is the skill or knowledge measured by this item ‘essential,’ ‘useful, but not essential,’ or ‘not necessary’ to the performance of the construct?” The content validity ratio [4] was calculated based on the responses of the five veteran instructors. The results showed that the content validity ratio was nearly 1.0, which confirmed the content validity of the assessment instruments employed in the present study.

V. CORRELATION ANALYSIS

Statistical correlation analysis was performed between students’ “tree” scores and exam scores. For student teams, only team leaders’ exam and “tree” scores were used (team members had the same “tree” scores but different exam scores). The results showed that the Pearson correlation coefficient $r = 0.309$ with $p = 0.029$ (< 0.05). Therefore, moderate correlation (not causation) exists between student’s “tree” scores and exam scores, or in other words, between students’ conceptual understanding and problem-solving skills. This research finding implies that the new Tree of Dynamics approach also provides a useful tool to help evaluate students’ problem-solving skills in this important introductory engineering course.

VI. CONCLUSIONS

This paper has reported preliminary results of the new Tree of Dynamics approach implemented in a dynamics course. The results show that a statistically significant correlation ($r = 0.309$, $p < 0.05$) exists between students’ conceptual understanding (measured by “trees” scores) and problem-solving skills (measured by exam scores).

matushm@vt.edu

Abstract—Many engineering programs have a common first-year curriculum required for all students. The courses tend to be large in size requiring the use of Teaching Assistants (TAs) for implementation. The responsibilities of TAs vary including lecturer, lab instructor, and grader. Despite their significant presence and varied functions, little is known about the roles of TAs as a whole across institutions. This study fills a gap in the literature by describing the roles and responsibilities of TAs in multiple first-year engineering programs across the nation, providing a foundation for future work investigating TA experiences, motivation, and identity development.

Keywords—teaching assistants, first-year engineering, survey

I. INTRODUCTION

Many engineering programs have a common first-year engineering curriculum required for all engineering students. The courses tend to be large in size requiring the use of Teaching Assistants (TAs), both graduate (GTAs) and undergraduate (UTAs). The responsibilities of TAs at each institution vary from lecturers to lab instructors to graders [1, 2]. Despite their significant presence and varied functions, little is known about TAs experiences programs as a whole. Because TAs spend significant time in undergraduate classrooms and directly impact undergraduate experiences, understanding the roles of TAs is an important step in improving and enhancing undergraduate curricula. This study fills a gap in the literature by providing descriptions of the roles and responsibilities of TAs in multiple first-year engineering programs to answer the question: *What are the commonalities and differences between how TAs are employed in different first-year engineering programs?* This study is part of a larger sequential exploratory mixed methods [3] project that examines the experiences of TAs employed in first-year programs, specifically targeting motivation and identity development.

To date, the literature related to TAs in engineering focuses on TA development programs, TA responsibilities, and TA evaluations [e.g., 1, 2, 4, 5]. Such research typically reports on the perspectives of faculty or students with regard to their TAs, not on the TAs' perspective. Recently, research has focused on the TA perspective, e.g., a study by Winters and Matusovich [6] explored TA feelings of autonomy, but more research in this area is needed. The larger project for this research builds

on existing work by focusing on TA perspectives in first-year engineering courses which has not been extensively studied. This paper is a foundational piece for that future work, where details about first-year programs were collected from program directors and administrators so that a baseline could be established and future TA participants could be identified.

II. THEORETICAL FRAMEWORK

Ultimately this work will build into the analysis of motivation and identity development of GTAs in first-year engineering programs. The theoretical framework for the larger study combines self-determination theory (SDT) and possible-selves theory (PST). SDT is a motivational framework based on three psychological needs, competence, relatedness, and autonomy [7]. Autonomy refers to a sense of ownership and control, competence refers to self-assessments of knowledge while relatedness refers to a sense of connection or belonging to a community [7]. Each of these components relates to individual intrinsic motivation where the context in which the motivation occurs is essential. PST is an identity framework wherein one looks towards who they could become in the future, both good and bad [8]. This future possible self, along with connections to your current identity and tangible goals, leads to identity development [9]. By combining these two frameworks for our future work, we can create a more complete picture of TA motivation with regard to their current context and their identity development related to future aspirations. However, before we can explore TA motivation and identity development, we must first understand the nature of the work they do in first-year programs. This study provides that knowledge foundation.

III. METHODS

Currently, our dataset includes responses to an online survey sent to 23 universities identified as having common first-year engineering curricula or programs. Based first on the researchers' familiarity with programs, an initial list of schools with first-year programs was generated. Contacts for each university were identified through internet searches and were limited to program directors, course coordinators, and general administrators. After the initial surveys were administered,

additional programs were identified by snowball sampling, where survey participants were asked to identify other universities that had first-year engineering programs. These programs were verified through another internet search which also produced contacts. Survey invitations were managed such that only one response from each school was obtained.

The survey consisted of questions focused on identifying the general size and structure of first-year engineering programs, the current responsibilities of both GTAs and UTAs, and the perceived pathways of TAs after they leave first-year programs. The survey consisted of nine main questions some of which were broken down into GTA and UTA sub questions. The survey took approximately 10 minutes to complete and asked for participants for future studies related to the motivation and identity development component of this work. To date, the response rate is 65% for a total of 15 responses, but the dataset is still growing.

IV. PRELIMINARY FINDINGS

Based on the preliminary analysis of the surveys collected, TAs who teach in first-year engineering programs are usually masters and/or PhD level students studying engineering. On average, first-year engineering programs have just over 800 students who participate in programs with varying content and structures including honors tracks, multiple course sequences, discipline specific sections, etc. Out of the responses gathered, only one university indicated that they did not use TAs in any capacity. Most UTAs involved in these programs are employed as graders while most GTAs are employed as lab or workshop instructors. See Figures 1 and 2 for more information about the responsibilities of TAs in first-year engineering programs. Note that totals can be greater than 15 since each respondent could mark more than one responsibility.

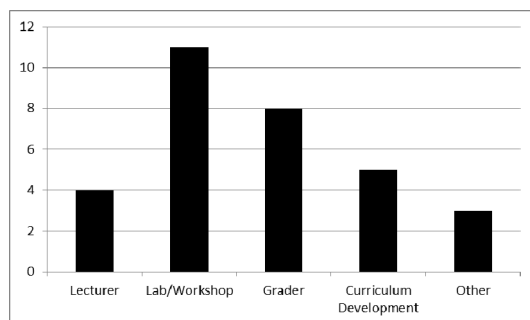

Figure 1: GTA Responsibilities in First-Year Programs

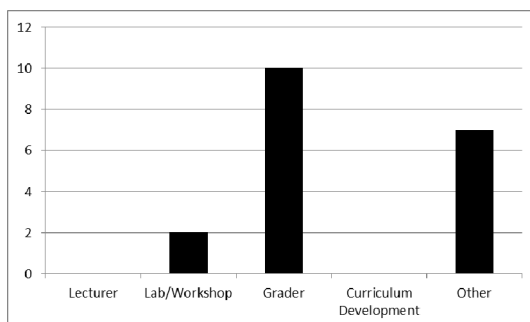

Figure 2: UTA Responsibilities in First-Year Programs

On average, from year to year administrators reported that approximately 50% of all TAs are new. They also indicated that they thought the most common reason for TA departure from teaching was simply graduating rather than pursuing other opportunities for teaching or even receiving funding to solely conduct research. As the database expands more results related to TAs roles and responsibilities in these programs will be explored.

V. CONCLUSIONS AND FUTURE WORK

The overall purpose of this survey was to gather information regarding TA involvement in first-year engineering courses. The results of this study provide a snapshot of the current state of TA involvement with these courses and set the stage for additional studies regarding TA motivation and identity development in first-year programs. We intend for the results of our future work to be used by program administrators, course coordinators, and even the GTAs themselves to help improve GTA instruction in first-year engineering programs. This baseline information on the type of work that TAs do is essential to be able to contextualize GTA experiences, motivation, and identity develop in our future studies. Future work will answer questions such as why do GTAs choose to teach in first-year programs? What causes them to leave after only a short time of teaching aside from graduating? How have their experiences affected their development as teachers? More work is needed to truly understand the impact that TAs have in first-year engineering programs, but this study is the first step in examining their importance to engineering education.

Work in Progress: First-Year Engineering Students Development of Test Cases for Model Development

Heidi A. Diefes-Dux & Monica E. Cardella

School of Engineering Education

Purdue University

West Lafayette, IN, U.S.A.

hdiefes@purdue.edu; cardella@purdue.edu

Abstract—When developing mathematical models for authentic problems that draw on basic descriptive statistics, many first-year engineering students do not address data distribution when it is appropriate to do so. An assignment was created in association with such a problem that asks students to develop their own test cases as a means of getting students to think more deeply about the data provided and the models they are developing. In this work in progress, these test cases are analyzed. The means and standard deviations of the test cases are quite different than those provided with the problem. However, there is evidence that students may not be attending to the original problem context. Next steps are briefly indicated.

Keywords—mathematical modeling; statistics; first-year engineering

I. INTRODUCTION

Model-Eliciting Activities (MEAs), a manifestation of the models and modeling perspective [1,2], are a special case of open-ended authentic mathematical modeling problems. They have been used to provide engineering students with opportunities to engage not only in complex and iterative authentic problem solving [3] but also guided problem formulation [4], peer feedback [5,6], and reflection on solution development processes [7] and progress. At the heart of a decision to use MEAs in an engineering classroom is the desire to promote the development of critical mathematical modeling skills and the appropriate use of math and science concepts in context [e.g. 8]. MEAs help expose students' misconceptions to instructors [1] who may then provide immediate remediation or redesign instruction for later use.

This work in progress contributes to the research being conducted on first-year engineering students' iterative mathematical solutions to an MEA involving decisions with univariate data. In prior work, students' use of basic descriptive statistical concepts revealed that when a high quality model requires some quantification of the distribution of the data, student teams have a difficult time moving past looking at only measures of central tendency and variance even with instructor written feedback [9,10]. While analyzing student team solutions to this MEA and other MEAs, researchers have noted that student teams often treat the embedded test cases (data sets) as "the" problem. These test cases are intended to prompt the development of generalizable models that can be used to interpret other similar data sets. Many teams are failing to

anticipate other potential and plausible scenarios that could be used to (re)think their models.

To better understand what students think about the test cases they are given and to encourage them to think beyond these test cases, a new activity was added to the MEA implementation sequence. In this activity, students are asked to individually create data sets to further test their team's mathematical model. A preliminary study of students' explanations of their data sets was conducted [11]. The overarching finding was that students provide vague qualitative descriptions of their created data sets and little to no discussion of how their data sets further test their models. This work in progress is guided by the question: What is the nature of the data sets that students create to further test their models?

II. METHODS

This study is set in a second semester, required first-year engineering course that continues to develop students' engineering problem solving, design, and teaming skills while introducing students to computational tools (i.e. MATLAB and Excel). Sections of 120 students meet in two 110-minute periods each week led by a faculty member and supported by one graduate teaching assistant (TA) and four undergraduate TAs. Participants (~200) were enrolled in Fall 2011 [11]. Typically an additional 1800 students enroll in Spring.

This work focuses on the first MEA implemented in Fall 2011, *Just-In-Time Manufacturing (JITM)*. More complete descriptions of this MEA are provided elsewhere [e.g. 8-10]. In essence, a manufacturing company (DDT) operates in a JIT manufacturing mode and requires a shipping service to move materials between two subsidiary companies in a timely fashion. DDT needs a procedure to rank potential shipping companies. Students are provided with a historical data set that includes late arrival times (in hours) between two locations for 4 or 8 (depending on the solution iteration) shipping companies. This MEA requires students to use their knowledge of mathematics and statistics to develop a procedure (mathematical model) to rank shipping companies from most likely to least likely able to meet DDT's delivery timing needs. Teams work with the historical data sets to iteratively develop their generalizable solution. Teams formally submit a Draft 1 (which enters a double-blind peer review [12]), a Draft 2 and a Final Response (each is evaluated by a TA [13, 14]).

From the data set provided (summarized in Table I), the student teams should conclude that the mean alone cannot be used to differentiate shipping companies. Further, no shipping company has the lowest mean and lowest standard deviation combination. The shipping company with the greatest number of on-time (0 hr) deliveries (IHE) also has one of the highest number of late deliveries. Teams need to find a way to balance findings with regards to central tendency, variation, and distribution of the data in the problem context to develop their model. Many student teams struggle to recognize this need, even with peer and teaching assistant feedback [9,10].

TABLE I. SUMMARY OF DATA SET FOR *JITM* MEA. NUMBER OF HOURS LATE FOR SHIPPING RUNS FROM LINCOLN, NE TO NOBLESVILLE, IN

| Statistics | IHE ^a | DS | SC | UE | BF | DFC | NPS | FSP |
|------------|------------------|------|------|------|------|------|------|------|
| Mean | 1.49 | 1.51 | 1.49 | 1.52 | 1.54 | 1.52 | 1.60 | 1.60 |
| St. Dev. | 2.54 | 2.19 | 2.25 | 2.56 | 1.34 | 1.55 | 1.61 | 1.74 |
| Min. | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Max. | 16.4 | 10.5 | 13.0 | 26.0 | 9.3 | 16.2 | 14.0 | 14.0 |
| Median | 0.74 | 0.62 | 0.65 | 0.95 | 1.13 | 1.13 | 1.06 | 1.12 |

| 0 hr | 100 | 36 | 79 | 14 | 14 | 17 | 1 | 16 |
| < 2 hrs | 193 | 199 | 196 | 203 | 193 | 197 | 198 | 206 |
| > 8 hrs | 9 | 9 | 6 | 4 | 1 | 1 | 2 | 6 |

a. IHE= Iron Horse Expeditors; DS = Delphi Shipping; SC = ShipCorp; UE = United Express; BF = Blue Freight; DFC = Direct Freight Company; NPS = National Package Service; FPS = Federal Parcel Service

Between submission of Draft 2 and the Final Response, students were assigned the new task of individually developing two data sets (each with 100 data points). Students were also asked to explain how their two data sets are different from that provided (Table I) and how they further test their model [11].

All student work on MEAs are collected through a web-based interface connected to a database [15]. Students entered both their data sets and their explanations through this interface. The work of only those students who were issued a final course grade (N = 171) were considered for analysis. Eleven student teams (or 36 students) were randomly selected to bring the number of students for inclusion in this preliminary analysis up to roughly 20%. All student data sets were analyzed using basic statistics similar to that shown in Table I.

III. PRELIMINARY RESULTS

There were 47 complete data sets from 24 students. Data sets from four students were eliminated from further study because they had too few or too many data points in their data sets. Six students did not submit their data sets.

Fig. 1 summarizes the mean and standard deviation combinations of the student generated data sets versus the MEA provided data sets. Five data sets (from 3 different students) included negative values; one student explained that early arrivals are just as problematic as late ones in the JIT context [11]. While most student data contained only positive values, the combinations of high and low means and standard deviations do vary considerably, a fact that was unclear from the students' explanations alone. Table II lists three special cases. Each case contains one or more extreme data point values that seem to indicate that the student was not considering the context of the original problem. Take the maximum value of 569 hours late (24 days late)!

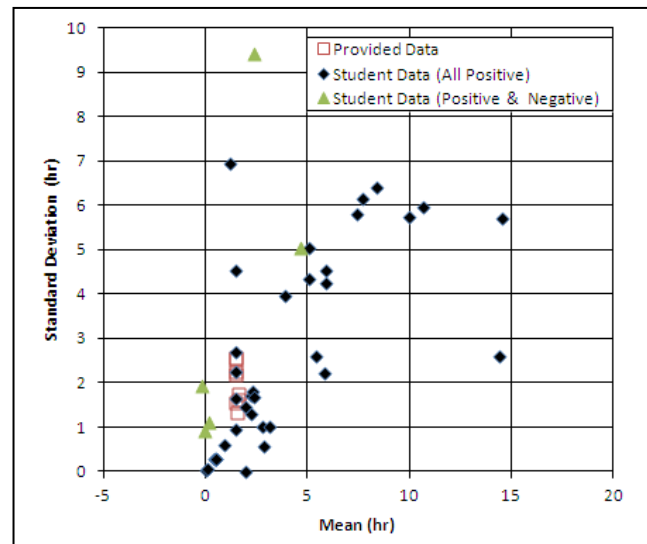

Figure 1. Mean and standard deviation combinations for provided and individually generated data sets.

TABLE II. SPECIAL CASES OF INDIVIDUALLY GENERATED DATA SETS

| Special Cases | No. of Data Sets / Different Students | Data left off Fig. 1 (mean, st. dev., max.) |
|--------------------------------|---------------------------------------|---|
| High Max. Value (70 - 569 hr) | 3 / 3 | (29.27, 49.10, 343) (17.81, 79.12, 569) |
| High Means (> 14 hr) | 3 / 3 | (24.50, 0.25, 24.99) |
| Two Extremes (All 0 or > 8 hr) | 2 / 2 | (8.98, 27.66, 134) |

IV. NEXT STEPS

A first next step is to expand the student work samples included in the analysis. This may move some seemingly odd cases into the main, such as the excessive high data point values. The second next step is to examine the distribution of the individually generated data sets. This may provide additional information about the nature of the students' data sets. For instance, a few students explained that they used a random number generator [11] but these students did not seem to acknowledge that a uniform distribution with values between 0 and 1 had been created. The degree to which uniform distributions were generated (even without explanation) can be detected from the data distributions. A third next step entails linking the nature of the data sets with students' explanations for their data sets. This may provide information about intentionality. For instance, excessively high values in a data set may have resulted from a student trying to achieve a certain mean or standard deviation. Finally, looking at which data sets the student teams carry into their Final Response (as a means of demonstrating how their model works) will reveal how teams vet the data sets for appropriateness in testing and demonstrating the functionality of their models.

The overall goal of this work is to understand how students think about data and testing their models. This work is beginning to reveal how students do and do not make sense of data they are provided to develop their models. Future findings will inform the design of the individually generated data assignment, content coverage of statistics, and classroom discussions about test cases and testing models.

Work in Progress: Constructing a Multidisciplinary Design Project for First-Year Engineering and Computing Students

Traffic Simulation Engineering Design Challenge

micah.lande@asu.edu

Abstract— Teaching first-year students is a balance between introducing technical content and providing perspective for students to forge connections to the context of what engineers do. Making the possible impact of engineers real and visible to introductory students in an authentic manner can be challenging. This paper describes the implementation and impact for a Traffic Simulation engineering design challenge in a freshman level “Introduction to Engineering Design” course comprised of both Engineering and Computing students at Arizona State University.

Keywords— first-year engineering, multidisciplinary, engineering design, programming, problem based learning, projects

I. INTRODUCTION

First-year engineering students are, no doubt, well aware of cars, roadways, traffic lights, etc. They may not have a perspective on the engineering efforts behind these systems however. Posing an engineering design challenge in a real world context can engage and motivate the learning of technical knowledge necessary to address this type of problem and to gain a broader context of understanding [1]. This paper describes a Traffic Simulation engineering design challenge given to freshmen multidisciplinary engineering students to introduce shared skills needed for their engineering success. The civil engineering context focuses on analysis of a transportation network and the optimization of transportation control systems after collecting data for a system involving randomness, decision making, and human users of the system in an environment with time pressure. The civil engineering nature of project theme was a guise under which a baseline of engineering skills and approaches was presented. These specific project goals are implemented within the context of a course with learning outcomes including the use of a design process, teaming skills, and communication skills. In addition, by using the Python object-oriented programming [2] language as a tool, students were introduced to engineering modeling,

incorporating computational modeling and algorithmic constructs, to complete the project-based learning course [3].

This first-year course was conceived and designed as a fusion of first-year engineering and computing students [4, 5]. Multidisciplinary teams of diverse students were tasked with applying their new-found computing skills to a scenario to model, prototype and test a system of stoplight traffic controls. The aim was to manage vehicle traffic in a simple, scaled-down road network. Students were asked to maximize the total throughput of traffic, measured as total trips between designated stations on a playing surface installed in a classroom space. The road network featured roadways, 4-way traffic lights and traffic sensors. A hardware interface with Arduino controlled the traffic lights and read optical traffic sensors. In addition to optimizing traffic throughput and controlling the traffic lights, teams of students remotely navigated a RC car through the road network with the goal of maximizing their car’s trips between a pair of designated stations.

II. PROJECT-BASED LEARNING AS CORE CURRICULA

In Arizona State University’s College of Technology and Innovation, the Department of Engineering houses both an undergraduate engineering program and multiple computing degree programs. In academic years 2010-2011 and 2011-2012, a common set of courses – Engineering 101/102 Introduction to Engineering Design I/II –with project-based learning experiences [3] was shared in the fall and spring semesters for both engineering and computing students. These courses built upon the pedagogical framework of a hands-on project spine in the undergraduate program in the Engineering Department. The programs have a core, project course each semester throughout the student’s tenure in the program from freshman to senior years. Within this multidisciplinary undergraduate engineering major there are opportunities for students to concentrate in civil and land development, electrical systems and mechanical

systems areas. Reference [4] and [5] describe the context of the undergraduate multidisciplinary engineering program, its origins, objectives and structure. Computing students can major in software engineering, applied computer science and computer systems. Reference [6] provide pedagogical descriptions of the software engineering program.

The freshman year provides some foundation in engineering process, an array of technical competencies, and practice in tackling engineering projects [7]. Table 1 lists the relevant Engineering Program learning outcomes connected to the Engineering 101 Introduction to Engineering Design course. Fig. 1 shows the matrix of core classes in the undergraduate program's first year mapped to specific learning outcomes.

TABLE I. ENGINEERING 101 COURSE LEARNING OBJECTIVES

| | |
|--------------------------------|--|
| Design (Level 1) | Recites the steps and information flow in the engineering design process and uses at least one organizational or technical tool in each step |
| Professionalism (Level 1) | Exhibits professionally appropriate behavior patterns, appreciates engineering as a learned profession and possesses daily success skills |
| Engineering Practice (Level 1) | Describes the essential elements of engineering practice including teaming |

Number indicated levels 1-4 within each outcome the associated course aims to meet. Some Engineering Program learning outcomes are listed in detail in Table 1.

III. TRAFFIC SIMULATION PROJECT

Traffic flow and optimization was selected as an interesting application area for first-year engineering and computing students. The variety of electro-mechanical elements in the system as well as the mapping of a traffic control algorithm to the concept of a finite state machine in computing made this scenario a useful context for teaching computing outcomes in a problem based environment. Additionally, traffic flow control is an aspect of civil engineering involving logic, experimental data collection, human-centered systems, and transportation network design. This project balances engineering and

computing content within an interdisciplinary problem scoped appropriately for first-year science, technology, engineering and math (STEM) students. The learning objectives of the Engineering 101 course state that students should: (1) be aware of how team member behaviors affect teaming, (2) use design process steps and tools, (3) perform engineering modeling, (4) design solutions to problems incorporating computational and algorithmic constructs, and (5) gain experience in the object-oriented programming paradigm.

Students were given the following design brief for the Traffic Simulation engineering design challenge:

Your team will design a traffic control computing system to manage vehicle traffic in a simple road network. You are asked to maximize the total throughput of traffic, measured as total trips between designated stations. The road network features roadways, 4-way traffic lights and traffic sensors. A hardware interface controls the traffic lights and can read optical traffic sensors. In addition to optimizing traffic throughput, your team will remotely navigate a RC car through the road network to maximize your trips between designated stations.

The project requires effective teamwork and application of the software and engineering design processes (course objectives 1 and 2: teaming and design process) to perform physical analysis of the system to set light timing and create a path-finding strategy to maximize your car's trips between stations (course objectives 3 and 4: engineering modeling and incorporating computational and algorithmic constructs) to create a user interface (UI) for the traffic light controls and program a finite state machine to manage the traffic lights (course objective 5: gain experience in the object-oriented programming paradigm).

The project's basic criteria and constraints were also outlined and detailed, along with basic documentation of the hardware and software interfaces that to be used, and an explanation of the deliverables, rubrics, and rules of the project.

A. Teaming

Each section was divided into 10 teams of four students each. The Comprehensive Assessment of Team Member Effectiveness (CATME) [8, 9] team formation and team feedback tool were used to create diverse teams (by discipline, experience, gender, etc.). Teams remained the same over the entire project, spanning a standard four-month semester.

B. Design Process

As part of the pre-project preparation in the course, students were given exercises and information about a general design process and design language to be used in the class and the project. As the class was made up of students who would be advancing towards either a multidisciplinary engineering major or computing major (software engineering, applied computer science or computer systems), effort was made to include and discuss both an engineering design process and a slightly differentiated software development process. The concepts and processes introduced were the same but the differentiated language used was disciplinary specific. Table 2 lists both the

engineering design process and software development process used.

TABLE II. ENGINEERING DESIGN PROCESS AND SOFTWARE DEVELOPMENT PROCESS

| Engineering Design Process | Software Development Process |
|--|---|
| Problem Definition Criteria & Constraints Specifications | Planning Requirements Specifications |
| Concept Generation Concept Selection Architectural Design | Analysis & Design |
| Prototype Implementation Prototype Evaluation Communicate Solution | Implementation Testing & Evaluation Documenting |

To help students practice their design process steps and introduce the application area of traffic light design, an initial assignment was given to students to explore the front end of the design process. Students were asked to:

Discuss why a traffic engineer might select a “4-way stop sign” concept over a “stoplight” concept for an intersection. Engineers use numbers; what are some numbers this engineer would consider?

For individual student responses, a grading metric was used to reward (1) multiple criteria for concept decisions described and (2) a quantitative example of numbers an engineer could use as supporting evidence for a decision..

As teams developed models of a finite state machine for one traffic intersection, teams were asked to write-up an initial report and then create a poster on how they would solve the larger project at hand. Teams were asked to include a problem statement, criteria and constraints, a Finite State Machine design, a reflection on their concept generation and selection, a storyboard of the interactions at a traffic light and information on how they would implement a finite state machine in code.

Formal formative feedback on student communication of their design process was given by faculty at each project “checkpoint”, and student teams communicated their final design and experimental results. This documentation also included their graphical user interface design and final Python language algorithm code.

C. Modeling:Automated Control with a Finite State Machine

Students were required to first develop a Finite State Machine that would control one four-way stoplight intersection, and then second control a five intersection system as pictured in Fig. 2 and Fig. 3. Sensor inputs to the algorithm included sensors at each approach to an intersection, and the algorithm’s outputs are the red-yellow-green lights for the traffic lights.

Students were asked to create a Finite State Machine that managed traffic flow in a single intersection to meet specified design criteria as determined by their RC Car modeling and GUI modeling. The Finite State Machine algorithm optimally managed a single intersection light using only sensor input and no human intervention. Ideally, this algorithm was capable of generating more trips than would be possible using a manually

controlled intersection light. The most successful algorithm for automatic control allowed the most total scoring trips by all four driving teams on the roadway, as averaged over multiple timed runs.

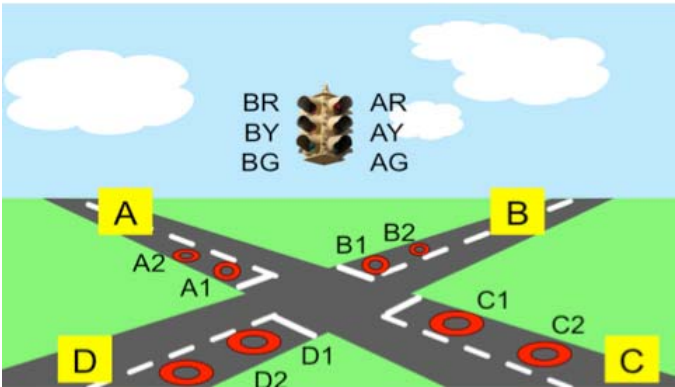

Figure 2. Representation of one intersection and its traffic lights

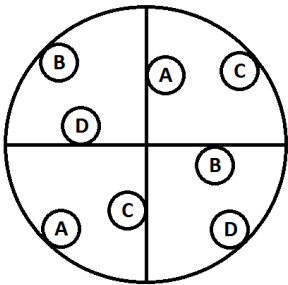

Figure 3. Schematic representation of the five-intersection traffic network designed for four teams (teams are A, B, C, D) to make “trips” traversing the network between a pair of “bases” assigned to their team.

D. Modeling: GUI for Human Operation of Lights

Student teams were also required to develop Graphical User Interface (GUI) control scheme to interface with their code and allow manual intersection control. A simplified example of the GUI is pictured in Fig. 4. During the running of the cars on “Race Days”, the expectation was that an operator could use manual control of a light mediated by a Finite State Machine that delivers traffic sensor and light states to the human intersection control operator in an easy-to-use manner and without reference to the actual traffic lights or RC car status.. The most successful GUI was the one whose human controllers allow the most total scoring trips by all four driving teams on the roadway, as averaged over multiple timed runs. In this test human operators were selected from among the members of the team that built the GUI. Also, the human operator is turned away from the roadway is to prevent the operator from obtaining visual information that is not provided by the GUI.

Figure 4. Simplified traffic light control GUI example coded in Python

Bonus points were given to the student teams that successfully integrated their Finite State Machine and user interface systems so that all five intersections were controlled from a single computer, using a single automatic algorithm, and which in separate runs a single GUI with which a single human controller runs all intersections. Students that were able to achieve this level of proficiency were then challenged with a stretch goal to demonstrate efficiency through integrated traffic management. By optimizing their automatic algorithm already implemented, students were asked to show that their integrated automatic algorithm produces better trip-scores for a network of traffic lights than the basic Finite State Machine that controls a single intersection independent of information about the other four intersections' states, using quantitative evidence that the integrated algorithm boosted trip counts.

E. Modeling: Human Operated RC Car Performance

Students were also required to conduct an engineering experiment to analyze the kinematic performance and reaction time of the human operated RC cars used for driving around the course and model that performance to choose optimal traffic light timing and sequence. A companion how-to video was produced by one of the course instructors to walk student through the necessary steps. This video can be viewed on YouTube at <http://bit.ly/egr101cars> [10]. Students captured video of the RC cars stopping and used Tracker Video Analysis and Modeling Tool, a physics-based freeware tracking software to do analysis [11].

Fig. 5 shows the general setup to capture video of the RC car. Lines with blue tape are spaced 12" apart next to the Traffic Simulation roadway as the test track. Three people are needed to do this experiment: a driver, starter and videographer. The car's driver begins driving at maximum speed when the starter provides a signal, and then brings the car to a complete stop when the starter provides a signal. The starter's signal and the entire path of the car must be visible in the video (a signal can be provided by lifting and dropping a foot, for example). It is important that the starter provide a "random" or surprising start and stop signal that cannot be anticipated by the driver, so that the driver's reaction time may be accurately interpreted from the video evidence. It is suggested that each member of the team understand and experience each role, and that several data collection runs be conducted with different members in different roles to generate a statistically meaningful sample of kinematic data.

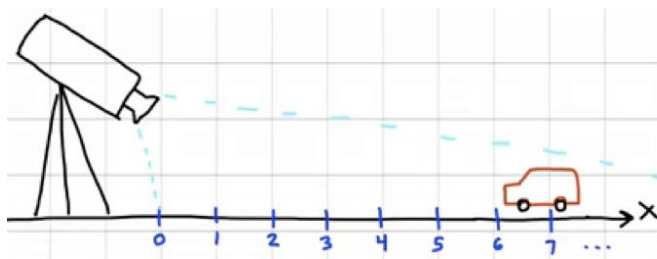

Figure 5. General setup to capture video of the RC car

The analysis tool used was Tracker Video Analysis and Modeling Tool version 3.10 [4]. It was the basis for recording the car's travel. Fig. 6 shows the Tracker software screenshot. Notice the blue tape lines and the red target marks capturing the RC car's travel trajectory at equal distances along the course.

Additional tools required in preparation were a custom Python code script to correct the effect of camera perspective on the car position data. Collected video was processed through Tracker. Axes were added and in clip settings set to advance 5 video frames at a time. Using the Point Mass Track feature of the Tracker software, students were able to map the travel of the RC car over time and create a track of pointed for its forward movement, stopping and reverse movement. This is shown in Fig. 6 by the red target marks. The collected data was then run through the Python code script to generate corrected data.

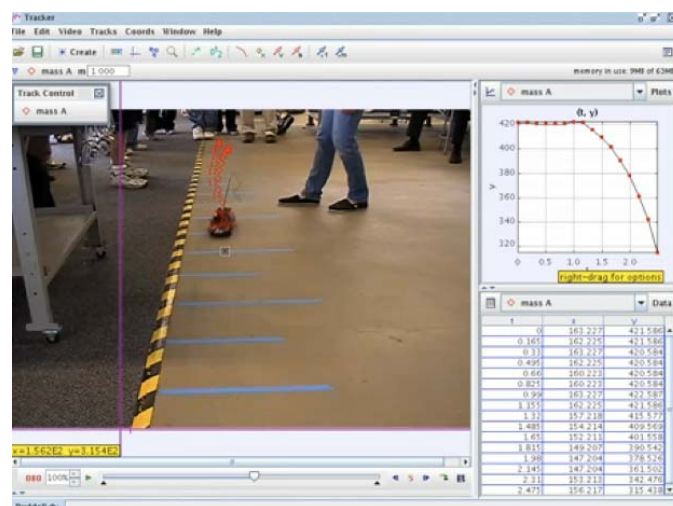

Figure 6. Tracker software screenshot

Student teams were asked to use Tracker and then generate plots in MS Excel of distance, velocity and acceleration over time. Braking time and reaction time may be calculated as the length in time between when the starter's visual signal is issued and when the car's acceleration changes. The results of all teams' analyses for rate of braking, acceleration, maximum velocity, and operator response time are shared with the class, providing a statistically meaningful sample of performance for the diversity of RC car operators in the class. Student teams then generated short reports analyzing the class's kinematic data, presenting estimates for acceleration and braking rates, peak velocities, and operator reaction times for the class. This information is utilized to choose optimal traffic light timings given the specific geometry of the traffic networks' roads and lights.

F. Learning Object-Oriented Programming

The programming basis for this class was Python 3.2. An online textbook, *How to Think Like a Computer Scientist* [2], was used in support of the programming content. A summary overview of concepts applied in this class are listed in Fig. 7.

| | |
|-----------------------|--|
| Python types/objects: | <ul style="list-style-type: none"> ▪ numbers (integers and floating point) ▪ characters ▪ lists/arrays/maps/dictionaries ▪ user defined |

Figure 7. Overview of course programming concepts

G. Design Solutions

Based on their finite state machine modeling and RC car kinematics analysis, students teams applied an array of strategies to optimize transit from one corner of the traffic simulation course to the other. Fig. 8 shows the name of the project as given to students to highlight the real-world application of the project. Fig. 9 shows the race course setup in the classroom.

Figure 8. Name of project as given to students. Attempt to highlight the application area of traffic simulation and to ground it in students' experience.

On "race days" at the culmination of the project, several pools containing four teams each took turns racing the RC cars using the automatic and GUI-driven manual FSM traffic control algorithms. Total trips between opposing "bases" completed by each of the four teams during the timed duration of each "race" was recorded. A "traffic cop" enforced timed penalties on any RC car driver who left the delineated lane boundaries, initiated collision with another driver's car, or ran a red light. Right turning on red lights was allowed in these races.

Following "race day", students analyzed the resulting trip data to generate empirical evidence that their automated and manual-GUI control algorithms performed optimally relative to the project's criteria. A modest number of "bonus" points were

allocated to the teams with the highest trip scores in the manual-GUI light control, automatic light control, and RC car driving categories, to incentivize effort toward efficiency and performance.

Following the project, student teams were asked to reflect on their design process and communicate project results in a written report. Students were asked to: (1) address each portion of the design process in some part of the report, (2) include schematics of their finite state machine and figures detailing results of analyses, (3) pre-competition testing and estimation of vehicle speed, stopping time, (4) pre-competition estimates of optimal light cycle times and light control algorithms, (5) pre-competition estimates of total trips and individual team trips, (6) pre-competition testing to validate estimates, (7) comparison of competition data with estimates based on pre-competition analysis and (8) suggestion of specific improvements to their control algorithms based on competition results.

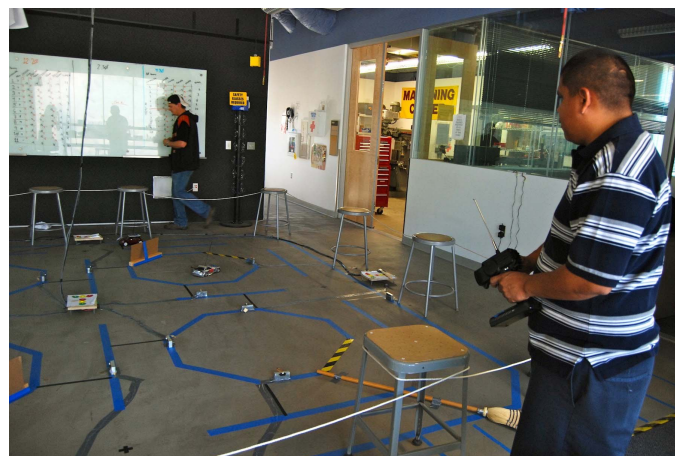

Figure 9. Race course setup in classroom; blue tape delineates lane boundaries, striped tape delineates entries to the "bases", and black tape delineates intersection stopping locations.

IV. DISCUSSION: INTEGRATED ENGINEERING SYSTEMS

Students were asked to reflect on their experience in a fused engineering and computing classroom experience. The analysis of their responses and emerging thematic analysis is still ongoing but there seems to be at least two surprising learning outcomes. The first is that even for those engineering students who were surprised at the amount of computing content, a confidence in thinking computationally seems to have emerged and fear of programming, debugging, and other computing activities has lessened. The other is a realization at how integrated computing and engineering disciplines are in embedded systems.

Another class project that is electro-mechanical in nature – to build an automatically functioning elevator – is being implemented in the spring semester freshman engineering project course. Future work may include comparison of this second project's added learning outcomes with those of the first project.

Developing a Simple and Effective Method of Assessing Civil Engineering Student Outcomes

Hudson Jackson, Kassim Tarhini, Sharon Zelmanowitz, Charles Hatfield

Department of Engineering
United States Coast Guard Academy
New London, Connecticut

Abstract— The assessment of student outcomes can be made easier if the proper plan and processes are put in place before starting data collection. The key to simplifying the process is to collect targeted data after developing performance indicators and mapping them to appropriate courses. The authors discuss the evolution of the Coast Guard Academy's Civil Engineering assessment process highlighting how the process has been streamlined and simplified through the development of assessment tools to measure achievement of performance indicators linked to each student outcome. The authors further discuss how the assessment data are analyzed holistically and used to guide improvements to courses and the curriculum.

Keywords—Accreditation, Assessment tools, Performance indicator, Student outcomes

I. INTRODUCTION

It is usually a challenge for undergraduate academic programs to determine with certainty the type and amount of data on student performance that should be collected to satisfy ABET (Accreditation Board for Engineering and Technology) requirements, ensure continued accreditation, and foster continuous program improvement. Academic institutions continue to struggle with the task of making data collection and the overall assessment process more manageable. This process becomes especially challenging with the dynamic nature of some of the ABET criteria. The importance of accreditation is valued by colleges and universities across the nation and overseas because it assures the quality of engineering and technology programs as well as facilitates the improvement of those programs. Furthermore, a degree from an ABET accredited institution is a requirement for licensure as a Professional Engineer.

In preparation for an ABET visit, academic institution must prepare a "self study" which can be considered a vital step for academic institutions to review the "health" of their engineering and technology programs and make improvements to enhance student learning. Cummings, Heng and Tsang, support the process of self critic before an ABET visit and wrote: "By providing a process to identify shortcomings with respect to student attainment of student learning outcomes, institutions or programs are better able to make necessary

improvements, as well as understand their institutional or program strengths" [1]. Some programs have used the weaknesses or concerns raised by ABET to foster support from the administration by requesting more financial support, more faculty and improvement of facilities and resources.

Since their establishment in 1932, ABET standards have evolved over the years and has resulted in nationwide curricular revision and the strengthening of engineering education [2]. However, the potential for this system to drive improvement of engineering programs at academic institutions continue to depend on how well the faculty understand, appreciate and support the changes to meet these standards [3]. To become ABET accredited, programs must have a set of Program Educational Objectives (PEOs) and Student Outcomes as well adequate facility, a certain number of faculty and institutional support [4]. In 2010, ABET reported that meeting the requirements on Program Educational Objectives and Student Outcomes continue to be the areas in which most institutions fall short [5]. Some of the shortcomings highlighted in the ABET report included:

- "Inadequate evidence that the process in which the objectives are determined and periodically evaluated is based on the needs of the constituents (Criterion 2)."
- "Confusion between the definition of program educational objectives (Criterion 2) and program outcomes (Criterion 3)."
- "Inadequate evidence of using the results of evaluation of objectives and/or assessment of outcomes for improvement."
- "Inadequate evidence demonstrating achievement of objectives or outcomes."

A key step in avoiding some of these shortcomings when assessing student outcomes is to develop specific and measurable performance indicators that students are expected to demonstrate in relation to the outcomes. The performance indicators can be mapped to appropriate courses and measured using assessment tools. Selecting appropriate assessment tools to adequately assess student performance on the outcomes is crucial since focusing on overall course grades may not provide important details. Performance threshold(s) for meeting the individual outcomes must be established before the assessment

data is collected and reviewed. Establishing a data collection cycle and looping findings to make improvements are also key components of the assessment process.

The authors discuss the evolution of the Coast Guard Academy's Civil Engineering assessment process highlighting how the process has been streamlined and simplified through the development of assessment tools to measure achievement of performance indicators linked to each student outcome. The authors further discuss how the assessment data are analyzed holistically and used to guide improvements to courses and the curriculum.

II. CIVIL ENGINEERING AT THE COAST GUARD ACADEMY

The United States Coast Guard Academy (USCGA) is a small undergraduate institution of approximately 1,000 cadets with eight majors. Approximately 10-15 percent of the cadet corps graduates with a Civil Engineering degree. Civil engineering graduates pursue a number of different career paths and many of them serve in the Coast Guard as practicing civil engineers, pursue professional licensure, and attend graduate programs in Civil Engineering. The Program Educational Objectives, listed below, are based on what civil engineering graduates are expected to have achieved within 4 to 6 years after graduation:

1. Graduates of the Civil Engineering Program perform effectively in a variety of career paths as Junior Officers in the Coast Guard.
2. Graduates of the Civil Engineering Program provide appropriate Civil Engineering expertise to the Coast Guard while serving in Civil Engineering related billets.
3. Graduates of the Civil Engineering Program demonstrate a commitment to intellectual and professional growth through activities and accomplishments such as graduate study, professional licensure, professional society activity, continuing education and promotion.

The Civil Engineering curriculum at USCGA includes a variety of required core courses in the humanities, science, engineering, mathematics, professional maritime studies, organizational behavior, management, leadership and law. The curriculum is broad and provides a solid background in the structures, environmental, geotechnical, and construction sub-fields of civil engineering. Similar to engineering programs at most academic institutions, the Civil Engineering Program at the USCGA is structured to meet ABET standards. It is a well known fact that these standards are dynamic-changing with technological advancement, societal and global trends, and advancement in educational instruction. The CE Program has made several changes to their assessment process since the last ABET visit in 2007. A brief description of the assessment process and highlights of the changes are presented in the following section.

III. COAST GUARD ACADEMY CIVIL ENGINEERING PROGRAM ASSESSMENT MODEL

The current assessment process used in the Civil Engineering Program consists of four main components:

1. End of Course Review (EOCR): An EOCR is conducted at the end of each semester for all required civil engineering courses offered that semester. Student success in meeting performance indicators is assessed and evaluated, and then recommendations for course improvements are made. Individual reports that documents details on how the course was conducted, assessment tools used, how issues were resolved, effectiveness in meeting the course objectives, students' performance and recommendations for future changes, are generated for each course. Results from the EOCR reports provide vital input for the Civil Engineering Program Review.
2. Civil Engineering Program Review (CE-PR): This is conducted every two years at the end of the spring semester. At this level, the achievements of all student outcomes for the entire program are evaluated holistically based on information from all end of course review reports. Achievement of the program educational objectives is assessed and evaluated using several surveys and other tools (alumni, senior exit, supervisor/employer, capstone surveys and interviews). The CE-PR is usually conducted in alternate years to a Departmental Review. Recommendations from the most recent Departmental Review are also discussed and implemented when practical. Results and recommendations from the CE-PR provide vital input for the upcoming Departmental Feedback the following year.
3. Department of Engineering Feedback: The Department of Engineering consists of four programs (Civil, Mechanical, Electrical, and Naval Architecture and Marine Engineering). At this level all four engineering programs are evaluated and changes for department-wide improvement recommended. A joint review with representatives from all four engineering programs is conducted every two year (in alternating years to the CE-PR) at the end of the spring semester. Other department level feedback is gathered and used in the assessment process.
4. Engineering Advisory Council (EAC): The EAC is a panel consisting of regular members from the Coast Guard and other federal agencies and episodic members from industry and academia. The EAC advises all four engineering programs in the Department of Engineering. The role of EAC is to distill input from students, industry, academia, and United States Coast Guard Engineering Commands. The purpose of a combined Engineering Advisory Council is to leverage the important professional, industry, and academic guidance within the framework of the needs of the United States Coast Guard engineering community. The EAC also reviews PEOs and comment on suggested changes to ensure that PEOs are in keeping with best practices in higher education. The Engineering Advisory Council meets annually in April

and the council's discussion and recommendations are summarized in the form of written meeting minutes.

These components and other assessment activities undertaken throughout the academic year are shown in Figure 1. Only details of the EOCR process are further discussed in this paper.

Figure 1. USCGA Annual Assessment Activities

A. End of Course Review

The end of course review plays a major role in the process used to assess individual student outcomes and to evaluate the effectiveness of the courses in preparing students to meet the outcomes. In preparing the EOCR for each engineering course, student assessments are conducted throughout the semester using both direct and indirect measures. The direct measures make use of a combination of specific homework assignments, projects, technical papers, oral presentations, specific exams questions and laboratory reports. Indirect measures include student self assessment using surveys and instructors' observations and evaluations.

In assessing the student outcomes, the Civil Engineering faculty has developed several performance indicators to serve as measurable criteria students must meet for successful demonstration of achievement of the outcomes. The performance indicators were developed through extensive discussions amongst faculty. They represent the Civil Engineering faculty's interpretation of the ABET outcomes and serve as measurable "skills, knowledge and behaviors" students are expected to demonstrate in regards to the outcomes. These performance indicators were then mapped to courses within the civil engineering curriculum. An example of the mapping for two specific civil engineering student outcomes (CE02 and CE03) is shown in Table I. An "X" in Table I indicates that the

course contributes to providing students' with the knowledge and experience required to be proficient in the particular performance indicator.

TABLE I. EXAMPLE OF MAPPING OF STUDENT OUTCOME PERFORMANCE INDICATORS TO COURSES

| | | Civil. Eng. Materials | Soil Mechanics | Environmental Eng I | Steel Design | Structural Analysis | Const. Proj. Management | Civil Eng. Design | Geotechnical Eng. Design | Environmental Eng. II | Reinforced Concrete Design |
|---|--|-----------------------|----------------|---------------------|--------------|---------------------|-------------------------|-------------------|--------------------------|-----------------------|----------------------------|
| Student Outcome | Performance Indicator | | | | | | | | | | |
| CE02: Can conduct fundamental civil engineering experiments, analyze and interpret data, and prepare engineering report. | CE02-1: Identify the important variables in laboratory or field experiments. | X | X | X | | | | | | | |
| | CE02-2: Use appropriate techniques and tools to collect laboratory/field data; follow standardized procedures to collect data. | X | X | X | | | | | | | |
| | CE02-3: Apply fundamental principles to analyze and interpret data including the identification of trends and range of expected results where applicable. Draw appropriate or reasonable conclusions by comparing test data with expected results. | X | X | X | | | | | | | |
| | CE02-4: Prepare written report in standard engineering format documenting details of the experiment. | X | X | X | | | | | | | |
| CE03: Can design a system, component, or process in the context of structural, environmental, and geotechnical engineering. | CE03-1: Analyze a practical civil engineering problem to identify need and requirements; list objectives and constraints. | | | | X | | | X | | X | |
| | CE03-2: Apply engineering principles and design concepts (including design codes and specifications) to solve a civil engineering problem. | | | | | | | X | | | X |
| | CE03-3: Identify and evaluate potential design solutions. | | | | | | | X | | | X |

For each performance indicator under each student outcome, at least one but usually two, assessment tools representing direct measures of student performance are used to assess outcome achievement. These direct measures are based on assessment tools that range from grades on particular exam questions or assignments to performance rubrics scores. Thresholds representing minimum student performance were also established for the successful achievement of the performance indicators as shown in Figure 2. As can be seen in Figure 2, different thresholds were set for exams and non-exam activities (projects, homework, reports, technical paper, oral

presentation, etc). At least two courses are mostly used to assess each performance indicator. The thresholds must be met for *all* the performance indicators (in *each course* mapped to that performance indicator) for an outcome to be successfully achieved. A table of student performance on the tools used to assess the performance indicators is included in the EOCR—an example is shown in Table II. The information in Table II is used to populate the percentage of students meeting the thresholds into a Program Outcome Achievement Matrix used for the Program Review.

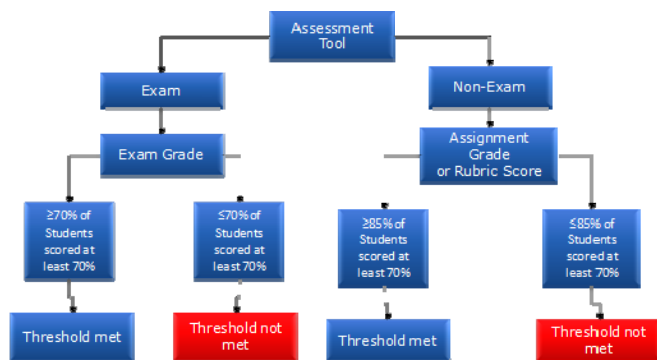

Figure 2. Assessment Tools Thresholds

Prior to the EOCR meeting, the course coordinator prepares a “read-ahead” document that includes a review of issues raised at the previous EOCR, an examination of assessment instruments used, the course’s contribution to the program in the context of the program outcomes achievement matrix and course changes (long and short range). The final EOCR report contains the read ahead material, issues discussed at the meeting, action items, and a number of attachments. The final reports are stored electronically for future use and historical records.

TABLE II. EXAMPLE OF STUDENT OUTCOME ASSESSMENT (SOILS)

| Outcome | Performance Indicator (PI) | Assessment Tool | Average score on PI (high, low) | % Students meeting PI threshold score | Achievement Threshold for PI met? | Achievement Threshold for Outcome met? |
|---------|----------------------------|--|---------------------------------|---------------------------------------|-----------------------------------|---|
| CE01 | CE01-1 | Final exam | 85.6% (93%, 75.4%) | 100% | Yes | Required information from other courses |
| CE02 | CE02-1 | Pre-lab Write & data sheet | 95.1% (100%, 70%) | 100% | Yes | No |
| | CE02-2 | Lab reports (procedure) /Instructor observation rubric score | 79.8% (100%, 50%) | 78% | No | |
| | CE02-3 | Lab reports | 86.1% (89.5%, 81.8%) | 100% | Yes | |
| | CE02-4 | Lab reports | 86.1% (89.5%, 81.8%) | 100% | Yes | |

The EOCR process has evolved such that linkages between courses and program outcome and performance indicators are strongly made. It is the general consensus that the process improves courses and the Civil Engineering Program by involving many stakeholders in meaningful discussion and evaluation.

IV. BENEFITS OF THE CURRENT PROCESS

The previous assessment model that was used prior to 2007 did not incorporate performance indicators. Student achievement of the outcomes was assessed somewhat directly based on the wording of the outcomes supported. Justification for using a particular course to assess specific outcomes was provided through a set of narratives. These narratives rated the level of development students were expected to achieve using a scale of 1 to 3. A lot of data were collected in each course but students understanding of the principles and concepts related to the outcomes were difficult to deduce from the data. For the most part, the overall course grade was used as the main tool to assess the achievement of the outcomes; this made it challenging to identify areas students had difficulties with for continuous improvement. Furthermore, thresholds for meeting the student outcomes were not clearly defined making it problematic to assess the level to which the student outcomes were achieved. The current assessment model is a result of several modifications made to address these shortcoming and to ensure more harmony with ABET expectations. A summary comparison of both assessment models is provided in Table III.

The revisions made to the assessment process have greatly improved and simplified our data collection efforts. Having developed suitable assessment tools, targeted data are now collected and this has resulted in a decrease in the overall quantity of data. It is also easier to identify areas where students are underperforming and recommend changes for improvements--leading to improved classroom instructions. This has been quite evident when the overall grade is broken down into categories based on the course objectives, by using performance rubrics that address specific performance indicators instead of using the overall grade. Examples of exam breakdown and the use of performance rubrics are shown in Figures 3 and 4. Both examples are from the senior year *Geotechnical Engineering Design* course. From Figure 3, it can be deduced that about 30% of the students scored less than 70% in dewatering design, retaining wall design and site investigation--areas that were identified for improvement during the next offering of the course. Similarly from Figure 4, student performance in each category of the rubric was good with 90% of students meeting or exceeding expectations--a direct indication that the course objective for this module was achieved. In most of the courses, new assessment tools had to be developed to ensure that relevant data are collected on the performance indicators. Instructors had to reevaluate the methods and tools used and this has led to an improvement of how student learning is assessed in our program. Additionally, faculty members have embraced the new assessment process because they were all fully engaged in making the changes.

TABLE III. SUMMARY COMPARISON OF CURRENT AND PREVIOUS ASSESSMENT MODELS

| Attribute | Current Model | Previous Model |
|--|---|--|
| Consists of a list of outcomes to address ABET Criterion 3 | Yes | Yes |
| Outcomes expressed in measurable terms using performance indicators. | Yes | No |
| Each outcome is described by at least two performance indicator | Yes | No |
| At which level is assessment data collected? | Assessment data is collected on the performance indicators for each student outcome. | Assessment data was collected directly on the student outcome based on the wording. |
| What tools are used for assessment? | Exams, lab reports, homework, technical papers, oral presentations, projects, instructor observation in labs, in-class student self assessment survey (mid & end of semester), performance rubrics. Particular exam question(s), rubric scores or individual components of the listed tools are used to assess specific performance indicators. | Exams, homework, projects, lab reports, technical papers, oral presentations. Course grade was widely used to assess student outcomes. |
| Performance threshold | Yes: At least 85% (70% for exams) of students should score 70% or better on the assessment tool. Detailed distribution of student performance. | No minimum threshold that should be met was established. |
| Outcome achievement criteria | Performance threshold should be met on ALL performance indicators for a student outcome to be considered achieved. | Final course grades were used somewhat subjectively. |
| Assessment coordinator | Yes: Full-time faculty responsible for ensuring that assessment processes are up to date and in line with current ABET requirements and advancement in pedagogy. Periodic updates and/or reviews twice a year. | No |
| Continuous improvement | Yes: Information from student performance on the performance indicators are evaluated and looped to improve courses and the Program. | Yes: Information from student performance on the outcomes are evaluated and looped to improve courses and the Program. |
| Student feedback | Yes: Newly developed mid-semester and end of semester in-class survey was introduced. Students assess their understanding of the principles and concepts, course objectives and provide general feedback on the courses. Particular emphasis is placed on the course objectives and assessment tools. Results readily available for use in End of Course Reviews. | Yes, but somewhat ineffective. No formal student feedback during the semester. A general standard online survey was conducted at the end of the semester, but the questions did not address specific aspects or uniqueness of each course. Results were not readily available to include in End of Course Reviews. |

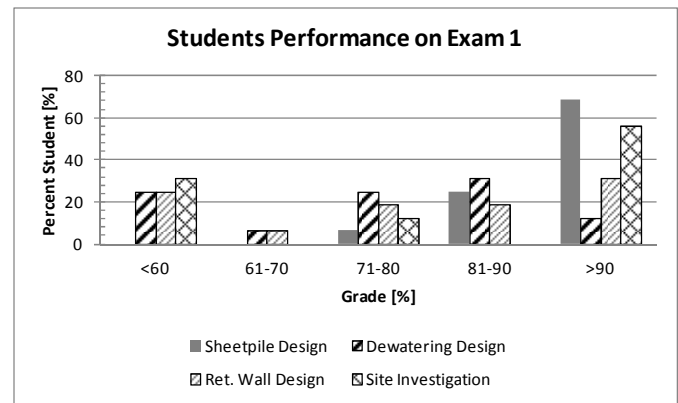

Figure 3. Performance distribution from Exam 1 (Geotechnical Engineering Design)

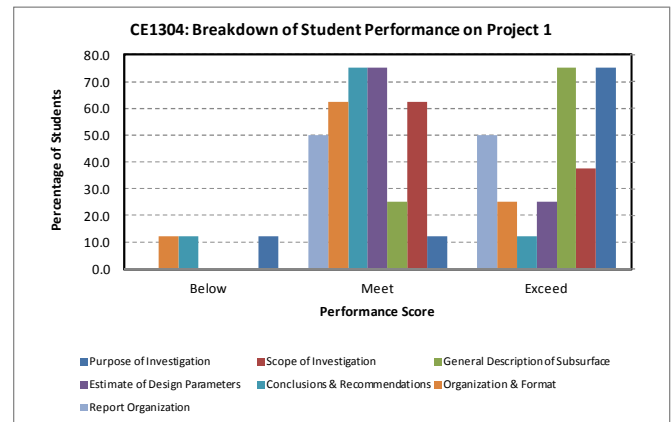

Figure 4. Performance distribution on performance rubric for Project 1 (Geotechnical Engineering Design)

V. CONCLUSIONS

The assessment of student outcome achievement at the United States Coast Guard Academy has been significantly improved and streamlined since 2007 resulting in a more effective and efficient assessment process. The major improvements over the previous system includes the development of specific and measurable performance indicators linked to each student outcome, the creation of multiple assessment tools for performance indicators, the development of consistent thresholds to gage whether student outcomes are achieved, and incorporation of the data into a holistic assessment process to ensure continuous improvement of the program. Our experience working together as a Civil Engineering Faculty to develop, refine, and use performance indicators and assessment tools demonstrates that it is feasible to craft an assessment system that is sustainable, consistent with ABET criteria, and embraced and used by an entire faculty for the improvement of an educational program.

University of Victoria

Victoria (BC), Canada

Canadian undergraduate and graduate programs in Engineering and Computer Science attract a large number of international students. This is a relatively recent phenomenon with social and academic implications that are not completely understood. We are aware that more can be done for the recruitment, retention, and more generally for increasing the quality of the learning experience of our international students. More efforts need to be made in order to foster and expand social and academic interactions between Canadian and international students, as well as student-faculty interactions. The research described in this paper aims to identify the first steps in creating an inclusive environment that fosters academic, social, and personal growth for both international and Canadian students. This study discusses data collected about the experience of international undergraduate students in the Faculty of Engineering our university. The purpose of the data collection was to determine their specific needs, and to solicit suggestions and recommendations about ways in which to address them.

Keywords: *internationalization, global education, qualitative analysis, focus groups.*

I. INTRODUCTION

The Faculty of Engineering at the University of Victoria attracts a large number of international students. This is a relatively recent phenomenon with social and academic implications that are not completely understood. We are aware that more could be done for the recruitment, retention, and more generally for increasing the quality of the learning experience of our international students. More efforts need to be made in order to foster and expand social and academic interactions between Canadian and international students, as well as student-faculty interactions. The long-term goal of this project is to provide international and local students with the best education possible by positioning our students to become global citizens and leaders. We are particularly interested in fostering an environment in which students from different cultural backgrounds work together effectively within both

class and social settings. The research objective of this project is to identify the first steps in creating an inclusive environment that allows for this academic, social, and personal growth.

The remainder of the paper is structured as follows. Section II provides details about previous studies that are similar to ours. Section III describes the methodology that has been used in the proposed study. Section IV presents the results, while Section V provides a discussion of new strategies and recommendations in light of the results. Section VI concludes the paper.

II. BACKGROUND

The literature on strategies for successful integration of international students in engineering and computer science is somewhat limited; however, previous work has identified areas that need to be addressed by universities. Although engineering and computer science programs are often thought to be culture-neutral and not strongly influenced by individual factors, some authors believe that learning patterns in these programs vary by culture [1]. The study in [1] examines the learning patterns and strategies employed by students from different backgrounds at a college in Finland; a large majority of international students reported that they were unsure of the college expectations of them and had difficulties completing assignments due to difficulties in understanding instructions. Moreover, these students reported that they were not able to communicate this lack of understanding to faculty and staff, further complicating this issue. Interestingly, these difficulties were not strongly correlated with English language proficiency, suggesting this was not a matter of a simple language deficit.

Student surveys also indicated that international students, particularly those from third-world countries, were more accustomed to teacher-led instruction emphasizing a strong hierarchical relationship between student and professor [1].

This may contribute to difficulties in international student engagement in class discussions or group work as these students may not know or understand that Western learning styles emphasize student initiative, asking questions in class, and independent knowledge acquisition. This was also apparent in a study examining Chinese students' perceptions of their supervisory relationship while completing a thesis [2]. The authors of [2] found that international students often felt great anxiety in the first six months of the supervisory relationship, primarily due to differences in supervisory practice due to insufficient closeness with, joint research with, and guidance from the supervisor. Student expectations of the nature of this relationship were often unmet due to differences in cultural norms surrounding the supervisor-supervisee relationship. Many of these students experienced adjustment to the local cultural and academic norms after one year in the program upon viewing their learning environment in a different way from which they were accustomed.

One issue identified in the literature is the discrepancy in the definition of plagiarism and cheating across international university systems [3]. The authors of [3] suggest that international students may be particularly at risk of accusations of plagiarism due to differences in attitudes towards plagiarisms in their countries of origin, which may not be in line with Western views on academic integrity. This study [3] implemented a program for making Western requirements for academic integrity explicit for students; the program included an orientation to Western norms, provision of online resources, academic scholarship workshops, and assignments. Over a period of two years, the authors found a significant reduction in the number of students committing plagiarism. This suggests that engineering programs may need to implement similar programs that link international students with faculty and support staff to clarify the University regulations regarding plagiarism.

International students often have to manage many issues related to moving to a new country and adapting to a new culture, and therefore often have non-academic issues to contend with that may affect their classroom performance. Interviews with Asian students at an American university revealed that these students often carried heavy burdens of responsibility for the economic success of their families back home, which could affect their career aspirations [4]. These students often felt greater financial strain and stress than their local peers due to increased international tuition, as well as to financial requirements to reside in the United States. Finally, Asian doctoral students reported feeling socially isolated from peers, faculty, and staff, possibly due to the tendency of people in these departments towards socializing in culturally homogeneous groups. This limited social support group may contribute to students' sense of alienation within the department or within the larger institutional context.

III. METHODOLOGY

The purpose of this study was to gather information about the experience of international and Canadian undergraduate students in the Faculty of Engineering at the University of

Victoria. We were primarily interested in collecting data regarding the specific needs of international undergraduate students and participants' suggestions for ways to address any unmet needs. Further, we were interested in gaining a deeper understanding of the level and quality of interactions between people of different cultural backgrounds, specifically among the undergraduate students, and between the undergraduates and graduate students, faculty, and staff. Of particular interest are the attitudinal beliefs that are shaping these interactions, and how these beliefs shape the way these groups work together.

A. Research Design

Qualitative data analysis methodology was used to address the research question and objectives. The purpose of using this methodology was to gain information that is descriptive of the experience of students, staff, and faculty in the Faculty of Engineering at our university. This type of analysis is not highly interpretive, as we did not choose to interpret the data within the context of a particular theory. Instead, we attempted to be as unbiased as possible in providing a description of the current situation at the University of Victoria based on participant responses. A major goal of this approach is to provide a summary of the information provided at the focus groups and interviews that is descriptive of the responses of most participants and stays close to the data collected. Descriptive summaries of focus groups and individual interviews were collated and an iterative process was used to determine major themes and sub-themes that emerged from the data. Group consensus on themes and sub-themes was obtained from all authors.

B. Participants

Undergraduate students, graduate students, staff, and faculty in the Faculty of Engineering participated in either individual interviews or focus groups.

1) *Participant Recruitment*: Three focus groups and seven individual interviews were conducted to glean information from key stakeholders: five staff, four faculty members, six graduate students, and three undergraduate students in the Faculty of Engineering. Participants were recruited through use of targeted group emails through the Faculty of Engineering. Participants were asked to contact the research assistant if they met eligibility criteria and were interested in participating. At this time, they were given further information about the study, and asked to participate. We also employed targeted participant selection by personally emailing or calling staff and faculty members who had a particular interest in this topic or who were in roles in which they frequently interacted with international undergraduate students. These staff and faculty members were asked to participate as they were likely to have a wealth of knowledge regarding specific needs of this population.

2) *Inclusion and Exclusion Criteria*: The participants for this study were staff, faculty, undergraduate students, and graduate students in the Faculty of Engineering. Eligible staff and faculty were required to have frequent contact with

international undergraduate students in the department, either through their role as a professor, director of a lab that included undergraduate students, or through their staff position within the Faculty. Undergraduate students were required to be in their fourth year of studies, as this group of students has been in the University system for several years, and would likely have the most information to contribute to the study. Further, these undergraduate students will have completed at least one co-op placement, and would be able to provide information on this process as well. Graduate students recruited for participation were required to have contact with undergraduate students in the Faculty through their role as a teaching assistant (i.e. lab instruction, tutorial instruction). Both international and local (Canadian) participants were encouraged to participate in the study.

3) *Description of Participants*: Participants were asked to complete a short demographics questionnaire. The sample consisted of ten females and eight males who ranged in age from 24 to 66 years old (mean age: 37.6 years). Three separate focus groups were run by the research assistant/first author: the first consisted of two staff and two faculty members, the second consisted of five graduate students, and the third consisted of one staff and one faculty member. Seven in-person and one Skype-assisted interviews were conducted individually with two staff members, one faculty member, one graduate student, and three undergraduate students respectively. Of the graduate students, two were at the Master's level and four were at the Doctoral level of training. Of the fifteen participants who provided information on cultural background, ten self-identified as being international and five self-identified as being local (Canadian).

C. Data Collection Procedure

The primary data collection strategy consisted of in-depth focus groups and individual interviews. The focus groups allowed participants to share ideas and group discussion was encouraged by the interviewer to facilitate collection of rich data regarding relevant experiences. Open-ended questions and prompts were used to elicit participants' perspectives. The interviews began with the following two questions:

- "What does being a student/staff member/faculty member in the Faculty of Engineering mean to you?"
- "What does internationalization mean to you?"

The first two questions were aimed at beginning the conversation and helping participants become more familiar with the process of sharing their thoughts and opinions. The following questions being asked were:

- "How does internationalization influence your research, teaching or work?"
- "What are your experiences with competitive (individual) versus cooperative learning styles with undergraduate styles?"
- "How does internationalization come into play in teamwork?"

- "Are you aware of factors outside the classroom that affect students' performance and learning at the University of Victoria?"
- "Do you think the Faculty of Engineering provides an adequate learning environment for international students?"
- "Do you think the expectations of the students typically align with the expectations of the program, instructors, and teaching assistants?"
- "What are some strategies that could promote successful interactions among students, faculty, and staff in the Faculty of Engineering?"
- "What are your experiences as a teaching assistant with respect to internationalization?" (only grad students)

All focus groups and six of the individual interviews took place in meeting rooms in the Engineering/Computer Science building at the University of Victoria and one individual interview took place via Skype. Individual interviews were approximately 25 to 45 minutes in length and focus groups were approximately 45 to 90 minutes in length. The research assistant reviewed the audio recordings of each focus group and interview to transcribe the dialogue from these sessions.

D. Data Analysis

Qualitative data analysis techniques were used for this study as these methods are often more effective than qualitative methods to describe social phenomena [5]. These techniques are often of particular benefit in the early phases of research where detailed information about a particular topic can be collected from a relatively small number of participants. Results from qualitative analyses can provide a detailed description of the current situation (i.e. internationalization in the Faculty of Engineering), which can then be used to guide future quantitative studies. Gathering information through focus groups and interviews provides a rich basis of data that convey meaningful information beyond numerical summaries used in quantitative analyses [6]. As participant responses were unstructured (i.e. in response to open-ended questions), the main goal of our analysis was to classify participant responses into overarching themes to elucidate the main issues regarding internationalization of the Faculty of Engineering at the University of Victoria.

Data from this study were analyzed using an iterative approach for determining common themes emerging from participant responses. In this process, the researchers/authors with a psychology background performed individually an analysis of the responses to each question in order to determine emerging themes. This method allows for the comparison of each piece of data to all other pieces of data in order to determine emerging relationships among the data. Following this individual analysis process, the researchers met to compare and contrast the themes they had previously identified for each question. This comparison allowed for refinements of themes identified for each question.

After this process, data were examined holistically, and major themes that were apparent across questions were identified. At this point, five major themes were identified:

motivation, interactions between students and faculty, relocation issues, infrastructure, and student expectations. Through discussion, the themes were restructured and re-conceptualized to determine the broadest categories for the major themes of the data within which several sub-themes would fit. These abstractions were then shared and discussed with the entire research team for validation.

IV. RESULTS

Based on responses from participants, two major themes emerged regarding the experiences of international undergraduate students in the Faculty of Engineering. The first theme encompassed aspects of *expectations*, and the second theme was about *integration*. Each theme comprised several sub-themes, which were then classified as being primarily within the Faculty of Engineering and/or the University of Victoria, outside the Faculty and University, or applicable to both settings (Table I). Further, several potential actions were suggested to address some of the difficulties expressed by participants (Table II).

A major theme that emerged from participants' responses was the issue of expectations, including both student expectations of the program/faculty/university, and the expectations the program/faculty/university has of its students. Participants expressed concerns about international students' expectations of the program and university, including policy and regulations within Canadian practice. A specific example of an inconsistency between students' expectations and those of the university include differences in perceptions of plagiarism and cheating and the acceptableness of these actions within the Canadian learning environment. There are "certain backgrounds where plagiarism is the normal way of proceeding, but that is not accepted here." One participant remarked that the faculty members "need to try to clarify the goal of the plagiarism policies and the subtleties of the policy ... It may be harder for international students to understand these subtleties."

Of particular interest to the Faculty of Engineering are the suggestions put forth to improve the learning environment for international students. Implementation of several of these strategies may provide the University of Victoria with an opportunity to further engage, increase retention of, and better support international students in Engineering. Most respondents suggested that the Faculty could be doing more to support their international students and that a good first step would be to engage the staff and faculty in the process of making the Faculty more sensitive to issues of cultural diversity. Several participants noted that the faculty and staff lack sufficient knowledge, understanding, and sensitivity regarding this issue, which might impede future progress in this area within the Faculty. Of primary importance is the education of all members of the Faculty, including faculty, staff, and students, about issues regarding diversity as a step towards better understanding of international students and the particular challenges they may face. "Without compartmentalizing everyone, there are basic pieces of information about different cultures and what we can

anticipate about behaviours of people from different cultures" that should be provided for professors and staff within the faculty. Suggestions for this type of education ranged from formal lectures and information sessions to more informal presentations and handouts. This may be a role for a cross-department committee committed to issues of diversity who will provide ongoing support for strategies to promote successful integration of international undergraduate students.

TABLE I. THEMES AND SUBTHEMES EMERGING FROM FOCUS GROUPS AND INTERVIEWS

| Theme | Subtheme | Location |
|--------------|--|--------------|
| Expectations | Expectations about programs, UVic policy, regulations - Canadian practice | Within UVic |
| | Plagiarism, cheating | Within UVic |
| | Outcome of Canadian/ Engineering degree - Citizenship | Within UVic |
| | International research collaborations | Within UVic |
| | Expectations about student-faculty relations - Hierarchical - Role of gender | Within UVic |
| | Learning and teaching styles/ motivation | Within UVic |
| | Life in Canada - Housing on or off campus - Banking - Distractions | Outside UVic |
| Integration | Language / communication | Outside UVic |
| | Culture | Outside UVic |
| | Social isolation | Outside UVic |
| | Personal values - Pressure | Outside UVic |
| | Gender issues | Outside UVic |

Further, international students may have very different expectations regarding student-teacher interactions than local students, especially in relation to the hierarchical nature of this relationship. "Some students just assume the professor is always right." Several participants reported that international students may be less likely to participate in class discussions, ask for help from a faculty member when they need it, and engage in debate with a professor. One faculty participant noted that, "I am looking for students to challenge me, but some are not used to doing this based on their past experience." It was suggested that this might be due to cultural differences; these types of behaviours may not be acceptable in other learning contexts. This issue may be exacerbated by cultural differences in perceptions of faculty members of different genders. This also seemed evident in certain student-teaching assistant relationships in which there have been situations of "male students wanting to change their lab group because the instructor is female." Some participants also expressed concerns about student motivations for coming to the University of Victoria, noting that "sometimes I feel more like an immigration officer than a professor."

Participants also expressed concerns about discrepant expectations regarding learning and teaching styles between international students and the Faculty of Engineering. One participant noted that, “we do not spoon feed students, but they [international students] may expect it.” This was further built upon by one staff member noting that “I am sensitive to the fact that international students receive and interpret information in different styles... I want to help the student in the way I like to be helped, but it’s not always the way the student receives, processes, or analyzes information best.” There may be additional differences in expectations regarding support materials used within a teaching setting. One participant remarked that, “we need to recognize that one size does not fit all in terms of advising, teaching, and giving information.”

The second overall theme dealt with issues of integration into the Canadian society in general, and within the local environment in the Faculty of Engineering at the University of Victoria specifically. The sub-themes that emerged in this area were quite broad, and were thought to affect international students both within the university setting as well as outside of it. It was suggested that international students may not engage in group work as readily as local students, possibly because they “may not feel safe yet because of language barriers.” It was also suggested that the language barrier, or perceived language barrier, could discourage local students from forming groups with international students: “Canadian students may not have even given the language issue a chance... may happen because there is such a time pressure on students that they don’t want to take a chance on someone they don’t know.” Additional issues that may affect international students’ performance include difficulties adjusting to a new culture, social isolation, and adjusting to new gender roles. It was noted that there may be “isolation of international students who have few or no other students of similar background ... success comes from feeling that you are part of a group.”

Several excellent suggestions were put forth to address the needs of international students that are not currently being fully met. These suggestions for future steps are described in Table II, and are explored in the Discussion section.

V. DISCUSSION

The primary purpose of this study was to gather information about the experience of international undergraduate students in the Faculty of Engineering at the University of Victoria through focus groups and individual interviews with key stakeholders. Following data collection, the authors reviewed the data pieces multiple times to elucidate common themes that emerged among participants’ responses. Following an iterative process, these themes were revisited and refined to produce themes that were consistent with all authors’ interpretations of the data. Through consensus, two major themes were identified as being critical to the experiences of international undergraduate students in the Faculty of Engineering at the University of Victoria: student expectations and student integration. Several subthemes within each area

were identified, as well as strategies suggested by participants to address any unmet needs of international students.

TABLE II. STRATEGIES SUGGESTED FOR ADDRESSING THE NEEDS OF INTERNATIONAL UNDERGRADUATE STUDENTS

| Theme | Suggestions | Location |
|--------------|---|-------------------------|
| Expectations | Staff or student liason with Engineering Student Society | Within UVic |
| | Faculty mentor for international students | Within UVic |
| | Cross-department committee to address international issues | Within UVic |
| | Make classroom materials more clear for non-English speakers | Within UVic |
| | International students’ orientation within the Faculty | Within UVic |
| | Peer volunteers to help new students understand expectations | Within and outside UVic |
| | Column on international engineering in Engineering Student Society newsletter | Within and outside UVic |
| Integration | Faculty-student modeling/mentoring <ul style="list-style-type: none"> - Group supervision - Face-to-face - Make explicit where to get help | Within UVic |
| | Peer mentoring | Within UVic |
| | Buddy system for exam studying | Within UVic |
| | Opportunities for individual projects | Within UVic |
| | International student buddy system | Within and outside UVic |
| | Liaisons outside Faculty | Outside UVic |
| | International Students Society links | Outside UVic |
| | Housing | Outside UVic |

A further step that could be taken by the Faculty of Engineering is to encourage engagement of international students both socially and academically within the environment at the University of Victoria. It was suggested that international students are more socially isolated than local students, and thus may encounter challenges in forming peer relationships. It was noted that, “international students [are] more comfortable in pairs with someone from a similar country,” suggesting they may be less likely to engage with local students both academically and socially. This could have a negative impact on the educational outcomes within the University setting, as well as on the integration into the Canadian society more broadly. One participant remarked that, “our job is to train them to work in the real world where you will have to work with people who are not like you... we need to nicely tell them to get over it.” It is of great benefit to the University of Victoria to put in place support for international students that will increase the likelihood of student success and continuation in the program, and thereby future graduation of strong, confident, successful engineers and computer scientists.

Several participants suggested the formation of a mentoring system within the Faculty of Engineering as a particularly useful method to address this issue. This mentoring was suggested at both the student-faculty level as well as the student-student level. The main goal of student-faculty

mentoring was to provide an opportunity for international students to better understand the structure of student-faculty relationships within Canada, as well as a forum to get information from faculty about classroom expectations within this country. Peer mentoring was seen as a step towards providing further support for international students entering their first year at the University of Victoria; these freshmen students are facing several challenges related to transition and integration within this system. A buddy system whereby senior students, either local or international, could be paired with incoming international students would provide a context in which the new students had an opportunity to learn about Canadian customs and norms. This would also provide an opportunity for the international students to form bonds with local students, which could be of great value both socially and academically in terms of study groups and group projects. This system is in line with previous recommendations in the literature aimed at improving students' learning experiences by clarifying expectations [2]. While the main focus of this system is to support the international students, this will also be of value to Canadian-born student buddies who will gain exposure and better understanding of different cultures, which is of particular importance given the current context of engineering as a profession that is greatly globalized.

Students, staff, and faculty noted that the Faculty of Engineering has an excellent opportunity to put support in place for international undergraduate students during orientation week at the University of Victoria. While international students currently take part in a general orientation with students from other faculties, it was suggested that an additional orientation should be made available. Specifically, participants suggested an orientation for international students that would address many of the misunderstandings they are currently experiencing, with an emphasis on knowledge translation about the structure of the university, the faculty, and the common classroom set-up. This would provide an opportunity for sharing information regarding common classroom etiquette and customs in Canada, including an emphasis on expectations regarding active learning and critical thinking. This would also be an excellent venue for an in-depth discussion about the customs and norms about plagiarism in this country, and the specific regulations at the University of Victoria. Beyond information presented at this session, this would also be a way in which international students can identify resources that can help them best succeed in the coming years, both in terms of persons they can later turn to for help as well as more general resources (i.e. Counseling Services, International Students Society, Faculty Advisor, etc).

While the responses garnered in this particular study were of particular relevance to international undergraduate students at the University of Victoria, it is believed that other universities may experience similar issues as those presented here. Many of the suggestions for improvements at the University of Victoria could be highly applicable to other Canadian/US/European postsecondary educational institutions. While some these suggestions may appear to be cumbersome

and difficult to initiate at first, we strongly believe that they are necessary steps for Engineering faculties and universities to take to promote successful completion of engineering and computer science programs by international undergraduate students. These suggestions may require resources from the faculty as an initial investment, but it is expected that the benefits gleaned from these steps will far outweigh the initial costs of setting up such programs. As greater numbers of international students are accepted into engineering and computer science programs, the faculties accepting these students will have an increased responsibility to provide an environment in which academic success is best promoted.

VI. CONCLUSIONS

Qualitative analysis of participant responses regarding international undergraduate students in the Faculty of Engineering at the University of Victoria suggests that some needs of international students are currently unmet. These needs fall into two major categories: expectations and integration issues. This study identifies areas in which our Faculty of Engineering can improve to create a better learning environment for international students. Specific strategies include dissemination of information regarding cultural diversity, peer mentoring, student-faculty mentorship, and a faculty-specific orientation for new students entering engineering and computer science. Implementation of these strategies is expected to have a significant positive impact on the social and academic experiences of international students in these departments.

Future work involves the design of a longitudinal study that will follow a cohort on international undergraduate students in Engineering from the moment they enter the program to graduation. This study will inform us on the challenges that international students encounter as they adjust to the new environment, as well as on how they address those challenges.

ACKNOWLEDGMENT

We are grateful to the Office of International Affairs (OIA) and to the Faculty of Engineering at the University of Victoria for providing the financial support for conducting this research.

Work in Progress: Out-of-Class Learning: Shaping Perception of Learning and Building Knowledge of IT Professions

Hwee-Joo Kam, D.Sc.
Information Security & Intelligence
Ferris State University
Big Rapids, MI, USA

Greg Gogolin, Ph.D.
Information Security & Intelligence
Ferris State University
Big Rapids, MI, USA

Abstract - Freshman and sophomore college students, who have just begun their academic careers in Computer Science, are challenged by difficult courses while having little insight about the job demands in the information technology (IT) industry. This study adopts an out-of-class learning approach to discover how out-of-class learning (1) shapes students' perception of learning computer science subjects, (2) promotes understanding related to the challenges in IT professions, and (3) closes the gap between computer science education and the required IT skills in industry. The preliminary findings of this study demonstrate that interviewing IT professionals sheds light on the challenges of working in IT. Subsequently, students realize the critical skills in support of future success. This study proposes that course work in project management is a useful mechanism to bridge between the critical skills and technical skills, thereby better preparing students for careers in IT

Index Terms – out-of-class learning, computer science education, computer science learning outcomes, project management education in computer science

INTRODUCTION

Extant literature shows that there are many studies exploring different learning approaches for enhancing computer science education. For instance, Lingard and Barkataki [5] suggested that team-based learning with Web-based tools improved students' participation through collaborative learning and promoted insights into team progress. To accommodate different learning styles, Carver et.al [1] used adapted hypermedia courseware to allow students the ability to customize the course materials according to their learning habits. For augmenting learning effectiveness in computer science education, McIntyre and Wolff [6] applied the World Wide Web (WWW) as an interactive learning tool to teach an Introduction to C Programming course.

However, there are not many studies examining the impact of out-of-class learning on student learning outcomes. Based on a college impact model [4], this study defines out-of-class learning as the interaction between students and the institution's environment. In this respect,

out-of-class learning encourages students to step out of the formal classroom, studio, or laboratory setting to participate in activities relevant to their course work. Additionally, out-of-class learning transcends the traditional classroom and closed laboratory boundaries so as to broaden the student's horizon, augment their knowledge base, and cultivate attitudes and values attributing to future success [4].

In the context of computer science education, this study employs the college impact model and intends to discover how out-of-class learning would enable students to (1) obtain knowledge about real-life IT professions and (2) form more accurate perceptions about learning computer science subjects and shape attitudes and values attributing to their future success. In addition, this study intends to examine how out-of-class learning closes the gap between the computer science education provided by universities and the demand of IT skills in the real world.

THEORETICAL FRAMEWORK

The college impact model stresses the external environment (e.g. the IT industry), sociological conditions (e.g. diversity workforce) and origins of change (e.g. innovation, paradigm shift etc.) [4]. The college impact model suggests that learning outcomes associated with out-of-class learning includes knowledge and subject matter competence, cognitive skills and intellectual growth, psychosocial changes, attitudes and values, moral development, educational attainment, career choice and development, economic benefits, and quality of life after college [4].

As stated, college impact model highlights the value of out-of-class learning [4]. While in-class learning tends to be symbol-based (e.g. programming concept), out-of-class learning openly links to events and objects in the physical worlds (e.g. the most sought-after IT skills in the industry). This thereby suggests that learning well in the classroom does not necessarily mean that one will perform well outside the classroom [7]. Hence, using the college impact approach, this study seeks to assess the learning outcomes produced by the interactions between students and their institution's environments and to discover how out-of-class learning close the gap between the computer science education provided by universities and the actual skills demand in the IT industry.

DATA COLLECTION

This study was conducted at a college in the Midwest region. Students enrolling in an Introduction to Computer Programming course were randomly placed into different groups. It was mandatory for each group to interview an IT professional. Each group was assigned a different interviewee (IT professional). Upon completing the interview, every student was required to provide written feedback regarding his or her experiences for out-of-class learning. In two semesters, this study collected data from 7 groups consisting of 21 individuals. Overall, this study collected approximately 70 pages of transcripts with students' written feedback.

RESEARCH METHODOLOGY

Since all human experiences can be interpreted and understood as text [2], the data collected in written text from this study depicts student perspectives for out-of-class learning. The hermeneutic circle approach was employed to analyze the written feedback gathered from students. Mainly, the hermeneutic circle approach [3] proposes that an understanding of a complex whole comes from the preconceptions about the meanings of its parts and their interrelationships. Given that, the sentences written in student feedback are aspects that serve to shape an overall understanding of student perspectives regarding the out-of-class learning. This provides insight into how the global understanding of student perspectives concerning the out-of-class learning improves the understanding on each part.

DATA ANALYSIS

At the preliminary stage of data analysis, this study discovered that out-class learning experience enabled students to realize the importance of communication. A student mentioned:

"Surprisingly, I learned that communication is very important in the computer science major because to work efficiently in groups you need to communicate".

Additionally, students learned that there are job opportunities in computer science field:

"Overall in the interview, I learned that I shouldn't ever have to worry about job opportunities because job market is growing and will continue to grow".

Through the interview, students gained reassurance that they have chosen the right field:

"At times I wonder if I made the right choice but after interviewing [the interviewee] I see more and more that I did make the right choice".

Most importantly, students began to understand the insights of the IT industry. A student stated that his/her interviewee shared his/her pearl of wisdom. The interviewee mentioned:

"I think one of the big things that you can do is just try to stand out in IT....to really get yourself established and to get yourself built up in IT."

Also, an interviewee voiced his/her view to dissolve the stereotype of IT workers, claiming that IT workers are not insulated from social interaction in the workplace:

"A lot of people think that IT people are a bunch of loners. NOT TRUE! It's one of the most team oriented jobs I have ever had. A project requires so many talents...the people who make it look good aren't the same people who do the coding. It's a huge team thing."

Another interviewee shared the challenges he/she faced: *"[My client] insisted on using the wrong technology. There are times that you don't have a choice. You're told what has to be done and you do it."*

DISCUSSION, CONCLUSION AND RESEARCH IMPLICATION

The preliminary findings reveal that out-of-class learning promotes (1) insights into the IT field; (2) criticality of communication skills and teamwork; (3) awareness of the current IT job market; and (4) reassurance of choosing IT as the right field. In conclusion, the preliminary findings infer that out-of-class learning enables a new learning channel in computer science education. Mainly, out-of-class learning sheds light on the challenges in the IT industry, allowing students to decide whether they have made the right decision in choosing their majors. The insights gained from the interview also help students to justify their investment of time and money in learning difficult subject matter.

The implication of this study proposes that out-of-class learning enables students to shape perception based on the importance of communication and teamwork. This gradually forms student perceived learning about computer science. To close the gap between computer science education offered by universities and the required IT skills in the real world, the computer science curriculum may want to incorporate project management course work to cultivate communication skills and teamwork among students. This can prepare students for attaining future success. Finally, this is a research-in-progress, and therefore, more research is required to yield meaning findings.

What Should I Do Next?

How Advanced Engineering Students Decide Their Post-Baccalaureate Plans

Anwen Jiang and Michael C. Loui
Department of Electrical and Computer Engineering
University of Illinois at Urbana-Champaign
Urbana, Illinois, USA

Abstract—To describe how advanced engineering students decide their post-baccalaureate plans, we conducted a mixed-methods study with engineering students at a large public university in the Midwest. According to the surveys, there were no statistically significant differences between men and women in their choices of post-baccalaureate plans. Students who had positive undergraduate research experiences and students who felt attached to their departments as undergraduates were more likely to enter graduate school immediately after graduation. Students who had industrial internships were more likely to enter professional practice immediately. From the interview data, we defined eight decision style archetypes that characterize how students make post-baccalaureate plans.

Keywords—decision-making; post-baccalaureate plans; careers; graduate study

I. INTRODUCTION

Having graduated from Harvard College in 1955 with a degree in mathematics, I was confronted with a decision as to what to do next. Working for a living had little appeal, so graduate school was the obvious choice. —Richard M. Karp [1]

When approaching the senior year, many undergraduate students start to seriously consider their post-baccalaureate plans. Seniors ask themselves, “What should I do next?” Some of them may already have specific post-baccalaureate plans, while others may just have some vague ideas about their lives after undergraduate studies. Picking a post-graduation plan can be difficult. For engineering students, the most common two post-baccalaureate choices are working in industry and entering graduate school in engineering. There is little previous research on how engineering students make this choice, however.

In this paper, we address a basic research question: *What factors influence the post-baccalaureate plans of engineering students?* Through surveys and individual interviews, we determined what factors have influenced students’ decision-making processes when they choose between work and graduate school. We described eight different decision styles. This study may also provide some insights to engineering educators and administrators when they advise engineering students who are making post-baccalaureate plans.

II. LITERATURE REVIEW

Research on enrollment in undergraduate engineering programs has generally concentrated on factors that motivate first-year students to choose engineering and factors that affect students’ persistence in engineering programs [2, 3]. In particular, professional identity can influence the level of commitment to an engineering program [4]. Students who demonstrate some personal identification with engineering tend to persist to complete an engineering degree. By contrast, students who demonstrate poor connection with engineering tend to switch to other majors. Previous engineering experiences do not necessarily affect a student’s professional identity [5].

Meanwhile, there is limited literature on seniors, who are struggling with a significant choice for their future. In one of the few studies to include engineering seniors, Amelink and Creamer [6] point out that since peers can influence students’ career aspirations, gender biased behavior and male-dominated culture may negatively affect female students in engineering.

Basically, engineering students have two common choices for post-baccalaureate plans. The first one is to enter graduate school immediately. The Academic Pathways Study [2] shows that forty percent students are considering engineering graduate school, and more than sixty percent of engineering graduates have a combination of plans. The other common post-baccalaureate choice for engineering students is to enter the workplace to begin their careers.

Students’ choices of careers are influenced by many factors. Social Cognitive Career Theory (SCCT) organizes the factors that influence how students choose their career paths, and why students choose certain careers instead of others [7]. SCCT does not seem to apply to choosing graduate school, however.

III. RESEARCH METHOD

To determine the factors that influence engineering students’ post-baccalaureate plans, we conducted a mixed-methods study at a large public research university in the Midwest, with the approval of the local Institutional Review Board (#12244). All 2,293 seniors and all 664 first-year graduate students in the College of Engineering were invited by e-mail to participate in an online survey and an optional

follow-up 60-minute interview. The full survey and interview protocol appear in the senior thesis of the first author [8].

The survey for seniors had 25 questions, including 9 open-ended questions. The survey for first-year graduate students had 27 questions, including 10 open-ended questions. Sixty-two seniors and 43 first-year graduate students responded.

Among students who responded to the interview invitation, we selected eight students to participate in a semi-structured interview, based on their genders, majors, domestic/international status, and academic standing. We selected only graduate student interviewees who had entered graduate study directly after they received their bachelor's degrees. We assigned a pseudonym to each interview participant. See Table I.

TABLE I. INDIVIDUAL INTERVIEW PARTICIPANTS

| Pseudonym | Gender | Major | Academic Standing | Domestic/International |
|-----------|--------|-----------------------------------|---------------------------------------|------------------------|
| Patricia | Female | Bioengineering | 5 th year | Domestic |
| Jason | Male | Engineering Physics | Senior | International |
| Elizabeth | Female | Civil & Environmental Engineering | Senior | Domestic |
| Brian | Male | Industrial Engineering | Senior | Domestic |
| Richard | Male | Computer Science | 1 st year Graduate Student | Domestic |
| Lisa | Female | Computer Engineering | 1 st year Graduate Student | International |
| Jennifer | Female | Physics | 1 st year Graduate Student | Domestic |
| Daniel | Male | Mechanical Engineering | 1 st year Graduate Student | International |

IV. SURVEY RESULTS

A. Respondents

Students who were unsure about their post-graduation plans or had other plans besides work and graduate school were removed from the analysis. In total, 100 responses were analyzed out of 105 responses. In Table II below, "Work" counts the number of advanced undergraduate engineering students who plan to work in the industry after graduation. The "Graduate School" category combines all first-year graduate students with those undergraduates who planned to continue to graduate school.

TABLE II. DISTRIBUTION ON POST-BACCALAUREATE PLANS

| Work | Graduate School | Not decided | Military Service |
|------|-----------------|-------------|------------------|
| 39 | 61 | 4 | 1 |

Some students did not answer some survey questions; at the very minimum, for each question, 77 responses were used, but mostly 95 to 100 responses were used. We used Fisher's exact test for two-way contingency tables to check for significantly differences between students who chose industrial jobs and students who chose graduate study. We used the Mann-Whitney U test to check the influence of participation in student organizations. We considered a difference significant if the statistical test produced a p

value of 0.05 or less; these cases are marked with an asterisk (*).

B. Genders

There was no significant difference between men and women in their decisions between industrial jobs and graduate schools. See Table III.

TABLE III. GENDERS

| | Female | Male |
|-----------------|--------|------|
| Work | 15 | 24 |
| Graduate School | 23 | 38 |
| p value | 1.00 | |

C. Research Experiences

In Table IV, "Have research experiences" counts the number of engineering students who conducted research when they were undergraduates. Research-based internships are also included.

TABLE IV. RESEARCH EXPERIENCES

| | Have Research Experiences | No Research Experience |
|-----------------|---------------------------|------------------------|
| Work | 15 | 24 |
| Graduate School | 43 | 18 |
| p value | 0.0019* | |

According to Table IV, there was a significant difference between students who had research experiences and those who had none in their choices between industrial jobs and graduate schools. We should not conclude that an undergraduate research experience predisposes the students to choose graduate school, however: the quality of that research experience matters. Survey responses also indicate that research experiences have both strong positive and negative influences on students' decisions to enter graduate school. Even a single negative research experience can discourage students from choosing graduate school.

They showed me that I excelled in and understood the laboratory research process. Since this is what a large part of grad school looks like, I thought I would extend and improve those skills by pursuing a PhD. —Mechanical Science & Engineering, First-year Graduate Student

Undergraduate Research Lab. Worked with a grad student, topic ended up being boring, which caused me to be less interested in research. —Computer Engineering, Senior

D. Internships

In Table V, "Have Internships" counts the number of advanced engineering students who worked in industrial positions, in a form of summer internship or co-op. Very few survey respondents had previously worked full time. Research-based internships are excluded from this count.

TABLE V. INDUSTRIAL INTERNSHIPS

| | Have Internships | No Internship |
|-----------------|------------------|---------------|
| Work | 32 | 7 |
| Graduate School | 21 | 17 |
| p value | 0.014* | |

According to Table V, there was significant difference between students who had industrial internship experiences and those who had none in their decisions between industrial jobs and graduate schools. Survey responses also indicate that students who were positively influenced by their internships planned to work after graduation. Very few students reported negative industrial experiences.

Multiple internships and co-ops. They have exposed me to the working industry and have likely influenced me to search for a job as opposed to continue my education. — Mechanical Engineering, Senior

E. People

There was no significant difference between students who are influenced by people, such as mentors and friends, and those who are not in their choices between industrial jobs and graduate schools. On the other hand, survey responses suggest that people such as family members and advisors are indispensable in students' decisions on their post-graduation plans. See Table VI.

TABLE VI. PEOPLE

| | Large Influence from People | Little Influence from People |
|-----------------|-----------------------------|------------------------------|
| Work | 26 | 3 |
| Graduate School | 42 | 8 |
| <i>p</i> value | 0.74 | |

Mom and grandparents convinced me that learning more was essential. [Name of professor] has been so nice to me and convinced me that I need more experience in research. —Agricultural & Biological Engineering, First-year Graduate Student

F. Attachment

In Table VII, "Attachment to My Department" counts the number of advanced engineering students who felt connected to their departments when they were undergraduates. Students who reported such attachment as somewhat connected to very closely connected are included. Moreover, "No Attachment to My Department" counts the number of advanced engineering students who reported little connection to their departments as undergraduates.

TABLE VII. ATTACHMENT

| | Attachment to My Department | No Attachment to My Department |
|-----------------|-----------------------------|--------------------------------|
| Work | 21 | 18 |
| Graduate School | 43 | 13 |
| <i>p</i> value | 0.026* | |

According to Table VII, there was a significant difference between students who felt connected with their engineering departments and those who have little in their decisions between industrial jobs and graduate schools. Specifically, a good connection to the department can attract undergraduate students to stay in the same program.

I feel really close to the MatSE department and am applying there for grad school because of it. —Materials Science & Engineering, Senior

G. Student Organizations

In Table VIII, "Participation in Student Organizations" counts the number of advanced engineering students who participated in student organizations during their undergraduate study. We use a 1 (Very active) to 5 (Not active at all) scale to describe how actively students participated in the student organizations when they were undergraduates.

TABLE VIII. STUDENT ORGANIZATIONS

| | Participation in Student Organizations | | | | |
|-----------------|--|----------|-----------|-------------------|---------------------|
| | 1-Very active | 2-Active | 3-Neutral | 4-Not that active | 5-Not active at all |
| Work | 23 | 9 | 3 | 2 | 2 |
| Graduate School | 27 | 16 | 6 | 6 | 6 |
| <i>p</i> value | 0.12 | | | | |

There was no significant difference between students who participated in student organizations and those who did not in their choices between industrial jobs and graduate schools. On the other hand, survey responses indicated that participation in student organizations can help students develop professional skills.

They have significantly improved my network of professionals in engineering, allowing me further insight into the field. They have also given me great amounts of interpersonal experience, a necessity for any engineer. — Material Science & Engineering, Senior

IV. INTERVIEW RESULTS

The eight interviewed participants described similar factors that influenced their post-graduation plans. Although they shared some similarities, the eight interviewees expressed different personalities and decision styles. Obviously, various styles and attitudes played important roles in participants' decision-making process. To fully represent different styles, we used a grounded theory process to define eight archetypes. A student might fit several archetypes. See Table IX.

TABLE IX. EIGHT ARCHETYPES

| | |
|---|---|
| Avoider Attributes: Eschews intimidating situations that cause insecurity and reduce confidence | Opportunist Attributes: Seizes opportunities when they arise; seeks personal benefits |
| Drifter Attributes: Follows trends; easily influenced by other people | Planner Attributes: organized; systematic; following goals step by step |
| Pragmatist Attributes: Practical in actions and decisions | Idealist Attributes: Enthusiastic; passionate; optimistic |
| Tortoise Attributes: Content with current conditions; resists change; avoids potential risks | Adventurer Attributes: Takes risks; embraces change; loves challenges |

Avoider

The Avoider feels anxious and fearful in risky situations. Usually, the Avoider identifies these situations and understands their potential risks. Lacking confidence and courage, the Avoider intentionally avoids encountering

these risky situations. As a consequence, when confronted with an uncomfortable situation, the Avoider often hesitates, and then chooses to escape that situation with rationalizations.

I don't feel prepared for a real job yet ... I haven't had any winter driving experience at all being that far from parents (like Chicago) and being that far from everyone I know and having to drive myself all over the place to work, to the store, to the gym, everywhere all the time is really intimidating for me. —Elizabeth

Opportunist

The Opportunist takes advantage of an opportunity because of its long term benefits, even when the opportunity itself does not interest the Opportunist personally. If an opportunity could guarantee better income or career promotion, the Opportunist would grasp that opportunity immediately. The Opportunist prioritizes income and career promotion over personal interests.

To become, say, a professor is a little stressful and maybe not completely something I should do but I might as well try in a sense. To get to that level where people would trust you with that kind of thing, especially at the undergraduate university level, you need to have a PhD ... if I manage to complete a PhD that opens an extra door of saying maybe I can be a professor, maybe I can be trusted to be a mentor for other students. —Richard

The biggest difference between the Avoider and the Opportunist is their motivations. The Avoider tries to avoid uncomfortable situations, whereas the Opportunist seeks opportunities that are most rewarding. For example, when the Avoider decides on post-baccalaureate plans, the Avoider might wish to avoid social interactions required in an industrial position. The Avoider would choose graduate school because it would require fewer social interactions, rather than because of an interest in research. By contrast, the Opportunist might apply for job openings and to graduate programs simultaneously. When offered admission to a graduate program but no suitable industrial job, the Opportunist would choose to enter graduate school.

Drifter

The Drifter is greatly influenced by the environment and adopts the values and goals of others. Because the Drifter listens to different opinions, the Drifter tends to be indecisive. Rather than think independently, the Drifter imitates and follows the actions of most others. The Drifter enters professional practice or graduate school without clear reasons or goals.

Back in my undergraduate, most of the people go to grad school. It's like the trend. In that time, I don't have very distinct, clear plan for my future life. I just follow the trend. —Daniel

Planner

The Planner is highly organized and composes explicit plans for achieving goals. The Planner loves to schedule and prepare everything ahead of time in order to meet deadlines.

The Planner considers not only the overall goal, but also the details of each step. Compared with others, the Planner takes a long-term perspective on life, and invests time and effort planning for life-long benefits.

I like to plan for long terms. I planned my post-graduation plan long time ago. Now I am planning for my post post-graduation's plan, what I am going to do after my post-doc. Do I want to start a family? What kind of house do I want to buy? What should I start investing now? ... I start planning and thinking about it, start taking actions. —Jason

The Drifter and the Planner have different sources of influences. The Drifter is dominated by the trends and others' opinions, whereas the Planner follows specific plans. The Planner takes others' suggestions only for reference, whereas the Drifter blindly accepts those suggestions. For example, although the Planner consults people such as advisors and friends, the Planner will not change the original plan due to what most people has chosen. In contrast, if most of the Drifter's acquaintances choose industrial jobs over graduate school, the Drifter will do the same.

Pragmatist

The Pragmatist is unemotional and prioritizes the practical aspects and consequences of decisions. The Pragmatist chooses a career goal that is logically related to his or her academic program. Then the Pragmatist chooses an industry job or graduate school that is an essential step toward that goal. When making short-term career plans, the Pragmatist emphasizes financial compensation. The Pragmatist understands that some jobs have the potential for regular career promotion and advancement into managerial positions. Targeting at a better career path, the Pragmatist actively pursues higher education, such as a PhD degree, even with little interest in and passion for the degree itself.

Starting salary for a PhD will be around 7000 or 8000 per month, that give you 80,000 to 90,000 a year. That's why I do a PhD and it give you a good income. If you lose a job, with a PhD, you can go anywhere that is willing to accept you. —Jason

It would be relatively easy for me to get a job in Korea ... but I want to stay in the states. So one way I can do that is to get a job in the United States or go to grad school, don't want to go back to Korea, so I go to grad school. —Lisa

Idealist

The Idealist is driven by emotions and feelings, and pursues the ideal over the practical. The Idealist naturally follows feelings and disregards many practical concerns. Instead of evaluating both advantages and drawbacks, the Idealist concentrates only on the advantages.

Well, I always wanted to go. I feel like the reason I really wanted to go was that graduate school really makes you an independent scientist. —Jennifer

The Pragmatist and the Idealist hold opposite attitudes. The Pragmatist makes decisions logically and practically, while the Idealist measures different situations depending on

feelings. When the Pragmatist plans to work after graduation, the Pragmatist first considers the job expectations, such as income and promotion opportunities. When the Pragmatist plans to enter graduate school, the Pragmatist concentrates on the affordability of graduate school. In contrast, the Idealist puts personal interests as the highest priority. If a job could bring feelings of happiness and accomplishment, the Idealist would take that job even if the income is lower than alternatives. Similarly, to the Idealist, research areas are more important than whether a graduate degree could bring better career advancement. Therefore, the Idealist's decisions can be impetuous and lack practical consideration.

Tortoise

The Tortoise is content with the current situation and feels secure with low risk choices. The Tortoise is usually afraid of changing. For instance, the Tortoise feels uncomfortable adapting to a new environment or trying a new food. Since changes can bring unnecessary troubles and uncertainties, the Tortoise avoids the potential risks.

I'm not really a big fan of change so I don't really feel like embracing the giant change from being a student to being an adult yet so I'm totally cool with sticking around and being a student some more. —Elizabeth

Adventurer

The Adventurer approaches difficulties with a positive attitude and is not afraid of failure. Even if the initial attempt fails, the Adventurer is still optimistic about other possible solutions. The Adventurer is passionate about challenges in the life. Besides, the Adventurer actively explores, analyzes, and solves challenges.

I wanted something that I found more challenging or that would engage my brain a little bit more than just interacting with people all of the time. —Elizabeth

Even though I want to get things done, I'm a perfectionist, I'm not seriously minded nor say afraid to fail than some of the other students I see. So this is why I'm like - it's okay to fail grad school - just go to it. —Richard

The Tortoise and the Adventurer hold opposite attitudes toward risk. The Tortoise hates risky changes, while the Adventurer prepares for encountering new challenges. When the Tortoise makes post-baccalaureate plans, the Tortoise finally chooses the one that requires fewest changes and involves least risk. Considering job offers, the Tortoise picks the one with a stable position and salary. On the contrary, the Adventurer strives to accomplish daring goals. The Adventurer might choose a position at a start-up company that involves interesting people and projects. Meanwhile, the Adventurer is willing to risk losing that job or receiving a lower income. The Tortoise and the Adventurer take the different approaches to graduate school. The Tortoise would be inclined to a program with a high ranking and sufficient resources for financial aid. However, the Adventurer would value a program with exciting research projects and faculty members.

A. Findings

1) Research Experiences

We usually assume that research experiences allow students to figure out their future concentration areas and prepare them for doing more research in the future. Meyers et al. [5] also point out that research experiences can help students identify and confirm their interests. Our study indicates that research experiences are correlated with interest in graduate school, but the direction of influence is unclear. A research experience could motivate an undergraduate to consider graduate study, or conversely, an undergraduate interested in graduate study might choose to obtain a research experience.

Our results also indicate that many students suffer negative research experiences. Such negative research experiences directly cause students to stop considering graduate school any longer. Specifically, a single negative research experience can lower undergraduate students' passion for research.

2) Industrial Internships

In the surveys, when undergraduate students recalled their industrial internships, nearly all of them described their experiences as positive. Specifically, among the survey respondents, many undergraduate students chose to directly enter engineering workplace due to their internship experiences. Very few undergraduate students reported their internships as negative. Those students chose graduate school over industrial jobs.

3) Attachment

In the surveys, around sixty percent of the first-year graduate respondents reported close attachment to their engineering departments when they were undergraduate students. Most important, because of close attachment to the department, through interaction with faculty members, those first-year graduate students chose to enter graduate school. Some of them even stayed in the same department because they had bonded with faculty and staff in their department. According to the surveys, for many first-year graduate students, when they were undergraduate students, faculty and staff not only provided them abundant resources and suggestions for graduate school, but also encouraged them throughout the decision processes on post-graduation plans.

Several undergraduate survey respondents reported that they felt attached to the department, but such attachment did not influence them to choose graduate school over industrial jobs, or vice versa. Moreover, most undergraduates have little connection to their departments and most of their post-graduation plans are barely influenced by the disconnection.

4) Decision Styles

By studying the interview participants, we developed eight archetypes of decision styles: Avoider, Opportunist, Drifter, Planner, Pragmatist, Idealist, Tortoise, and Adventurer. The Planner, Idealist, and Drifter archetypes

resemble the Rational, Intuitive, and Dependent styles of students' career decision-making defined by Harren [9].

The behaviors of interview participants who fit one archetype are dominated by that single decision style. Moreover, when the influence of one decision style becomes dominant, a student might not be influenced by the research and internship experiences. The decision style of one interviewee, Daniel, matches perfectly with the Drifter. In Daniel's undergraduate institution, most seniors entered graduate school immediately after graduation. Moreover, Daniel's parents believed that Daniel should stay in school as long as possible, and so did Daniel's peers. However, Daniel had little passion for research, even though he had one experience in a research lab in the United States. He mentioned that entering graduate school would help him postpone an industrial job, since he felt unprepared for real-world jobs. Otherwise, he had no particular reason for graduate study. Daniel just drifted into graduate school.

Meanwhile, when the interview participants fit into two or more archetypes, the influence of decisions styles and research/internship experiences can be important. For instance, Brian fit both the Adventurer and the Planner styles. Brian loves challenging problems and prepares himself to solve those problems throughout the undergraduate study. As an Adventurer, Brian is energetic, optimistic, and confident. He joyfully explored his talents and took advantage of them as he proceeded to enter professional practice. Moreover, Brian's aspired to become a future leader and impact his workplace. Through internships, he realized that an industrial job could help him pay off his college debts and prepare him financially for further education in the future. Thus, Brian targeted his post-graduation plan in industry. To become a future leader in engineering, he took leadership roles in the student organizations to further sharpen his interpersonal skills. Brian's decision process illustrates how two archetypes can co-exist in one person and guide him through choosing his post-graduation plans.

B. Limitations

This study was conducted at only one institution, a large public research university. Therefore, the results of this study might not apply to other colleges and universities, which have different institutional cultures.

Because of delays with approvals, both surveys were conducted around the time of final exams in the fall of 2011. The timing of the surveys may have reduced the response rate to below 10% of the entire population.

VI. CONCLUSIONS

To investigate how advanced engineering students decide their post-baccalaureate plans, we gathered data using surveys and individual interviews. In the survey, we investigated six factors that may influence students' post-baccalaureate plans: gender, research experiences, industrial internships, people (e.g., faculty and family members), attachment to the department, and student organizations. For three of the six factors, we found statistically significant differences in students' decisions between industrial jobs

and graduate school: research experiences, industrial internships, and attachment to the department. Students who had research experiences were more likely to choose graduate school, but even a single negative research experience can discourage students from further considering graduate school. Students who had no research experiences were inclined to choose industrial jobs. Students who had industrial experiences were more likely to work in industry after their undergraduate study. When students felt connected with their engineering departments when they were undergraduates, they were more likely to continue to graduate study.

In the interview results, we found that students' post-graduation plans are influenced by their decision styles. From the interview data, we described eight decision style archetypes: Avoider, Opportunist, Drifter, Planner, Pragmatist, Idealist, Tortoise, and Adventurer. By realizing how students fit into one or more archetypes, mentors and advisors can effectively guide students through their decision processes on post-graduation plans.

“Need to Know” in Engineering Programs; STEMing the Uncertainty around Graduate Education

Kenneth Gibbs¹, Erin Crede² and Maura Borrego²

1. National Science Foundation, 2. Virginia Tech

Abstract - A country's leadership in global technological and scientific development depends on its ability to recruit and retain students into engineering master's and doctoral programs. This qualitative study aims to develop a fuller understanding of the factors driving U.S. students' decision-making processes with respect to pursuing a graduate degree in engineering. During the fall of 2010, more than 1400 undergraduate engineering students and 800 graduate students at four universities across the United States completed surveys containing open-ended questions that allowed students to express their thoughts about and experiences in engineering graduate education. Thematic analysis of 256 undergraduate student responses focused on the barriers and supports underlying their decisions to pursue graduate education (including uncertainty in the application process, availability of funding, and concern about the grade point average requirement). The responses of 220 graduate students focused on the steps important for successful preparation for and navigation of graduate school (including strong theoretical and research preparation, clear goals for pursuing the degree, choice of advisor/research group, and selection of an engaging research topic). These results clarify the factors influencing undergraduate students' decision-making regarding graduate engineering education, and the qualitative training experiences of students in graduate school. These findings provide undergraduate students a starting point on questions to ask when considering graduate school while alleviating their potential misconceptions. The results also help engineering faculty and administrators improve recruitment of potential graduate students and improve their training experiences.

Index Terms – graduate, undergraduate, qualitative

INTRODUCTION

With expected growth in employment in engineering positions, long-term economic competitiveness and global leadership depends on a country's ability to cultivate a vibrant domestic engineering workforce [1, 2]. The masters and doctoral workforce is of particular importance due to their contributions to research, innovation, and teaching [3]. However, the percentage of US masters degrees earned by

Americans grew only slightly during the 2000s (56.2% from 2001-2004 v. 58.7% from 2005-2009), while the percentage of doctorate degrees earned by American citizens and permanent residents decreased throughout the decade (42.8% from 2001-2004 v. 38.7% from 2005-2009) [4]. Thus, there is a need to better understand the decision-making process of undergraduate students with respect to the pursuit of graduate engineering degrees.

In this study, we qualitatively explore the student decision making process using responses from both undergraduate and graduate engineering students. By integrating these perspectives, we are able to offer guidance to academic departments interested in recruiting undergraduate students, and to undergraduate students seeking guidance in their decision.

QUALITATIVE RESEARCH METHODS

This study analyzed the qualitative responses to a survey that included both quantitative and qualitative items [5]. The following sections present detailed information on the respondents, and the qualitative data collection and analysis methods. The survey was administered to undergraduate and graduate engineering students at four universities across the United States; shown in Table 1.

TABLE I
PARTICIPATING SURVEY INSTITUTIONS

| Institution | Engineering Departments | Engineering Graduate Students* | Engineering Undergraduate Students* |
|-------------|--|--------------------------------|-------------------------------------|
| EPUB 1 | Aerospace, Chemical, Civil, Electrical and Computer, Industrial and Systems, Materials Science, Mechanical | 2,000 | 5,800 |
| EPUB 2 | Chemical and Biochemical, Civil, Computer Science, Electrical, Mechanical, and Systems | 950 | 1,500 |
| MPUB | Aerospace, Chemical, Civil, Electrical and Computer, Industrial and Systems, Materials Science, Mechanical | 2,600 | 5,300 |
| WPRI | Aerospace, Chemical, Civil, Electrical and Computer, Mechanical | 4,100 | 2000 |

*Student populations are approximated to mask the particular institution

All institutions are considered Very High Research Universities (RU/VH) based on their Carnegie Classification [6]. The first two universities, EPUB 1 and EPUB 2 are public institutions on the east coast of the United States. Next is MPUB, a public university located in the Midwest, followed by WPRI, a private west coast university. Students from more than 14 engineering disciplines responded to the online survey, resulting in 256 undergraduate student responses and 220 graduate student responses to two open-ended survey items. Undergraduate students were asked the following question: “Is there any additional information you would like to provide regarding your decision to attend (or not attend) graduate school in engineering?” Graduate students responded to: “Knowing what you know now, what would you tell undergraduate students who are considering graduate school in engineering?” Demographic information on the participants is shown in Tables 2 and 3.

TABLE 2
UNDERGRADUATE PARTICIPANT DEMOGRAPHICS

| Gender | Year in Program | Ethnicity*/Nationality |
|-------------------|-------------------|-----------------------------------|
| Male – 173 (68%) | First – 31 (12%) | Caucasian – 176 (72%) |
| | Second – 43 (17%) | African American – 6 (2%) |
| | Third – 92 (36%) | Hispanic – 10 (4%) |
| Female – 83 (32%) | Fourth – 72 (28%) | Asian/Pacific Islander – 34 (14%) |
| | Fifth – 18 (7%) | International – 20 (8%) |

* 10 students declined to answer this item so the numbers do not add to 256. Percentages shown are relative to the adjusted number of respondents.

TABLE 3
GRADUATE PARTICIPANT DEMOGRAPHICS

| Gender | Year in Program | Ethnicity/Nationality* |
|-------------------|-------------------|----------------------------------|
| Male – 149 (68%) | First – 58 (26%) | Caucasian – 104 (49%) |
| | Second – 64 (29%) | African American – 5 (2%) |
| | Third – 32 (15%) | Hispanic – 5 (2%) |
| Female – 71 (32%) | Fourth – 27 (12%) | Asian/Pacific Islander – 17 (8%) |
| | Fifth – 40 (18%) | International – 89 (39%) |

* 6 students declined to answer this item so the numbers do not add up to 220. Percentages shown are relative to adjusted number of respondents. Ethnicity shown only for U.S. citizens.

Thematic analysis of open ended responses was used to generate individual codes, categories, and ultimately themes [7]. Two members of the research team independently coded the graduate and undergraduate responses. These codes were then integrated into larger categories, and ultimately into broad themes [8]. The findings were then discussed together, to better understand the commonalities between the data sets. Themes, categories and codes are shown in Table 4 for the undergraduate data set and in Table 5 for the graduate data set.

TABLE 4

QUALITATIVE FINDINGS

Undergraduate responses were divided into 18 different codes (the amount required to fully describe the responses), listed in Table 4. These codes were grouped into 7 broader categories. Finally, the categories were clustered into two main themes: barriers to attending graduate school and supports for the decision to attend. Barriers included: mismatch to career goals, issues with funding, poor grades, and administrative questions. Supports for attending graduate school included talking to professors or graduate students, creating career opportunities, and personal growth and development.

The graduate student responses were described by 15 codes, which clustered into 7 categories and two themes: preparation (the things one needs to do and consider prior to pursuing graduate education) & navigation (the things one must do and consider to successfully complete the degree once admitted). Regarding preparation, respondents indicated that students must have a solid base in research and theory, and have clear goals for pursuing the graduate degree. With respect to navigation, respondents indicated that students must carefully select their advisor/research group, select interesting research topic, cultivate independence, secure funding, and start research early.

In the following sections, the undergraduate findings are discussed using the two main themes: barriers and supports for attending graduate school. We then present detailed findings on graduate student advice to undergraduate students considering graduate school. Finally we will consider these findings together in the discussion section to highlight areas where improvements might be made to recruit undergraduate students into graduate engineering programs.

I. Undergraduate Barriers and Supports to Attending Graduate School in Engineering

Overall, 30 (11%) of the 256 respondents said they were considering graduate school in the future, most often after working a few years. However, it should also be noted that 28 (11%) were considering pursuing a graduate degree other than engineering. The most popular alternative degrees were an MBA (7%) and MD (2%). Other degree programs of interest included public health and law.

The largest barrier reported by undergraduate students surrounded issues of funding for graduate school (15%). This was manifested in several ways, including: the absence of disposable income while attending graduate school, not being able to afford the tuition, and needing to pay off student loans accumulated during their undergraduate years. As a fourth year male mechanical engineering student noted,

Even if I was well funded, I still wouldn't have any disposable income. That means no money to start a family, and no money for hobbies, such as working on my car. I don't live to go to school; I live for the outside activities. If I can't afford those, school isn't worth the torture.

Other notable barriers included the notion that graduate school was not required for the career students thought they wanted (8.2%). A female, third year chemical engineering student felt

...open to the idea of graduate school, especially since I am considering doing research. However, I do not plan on attending graduate school at this point in time because I do not think it is necessary if I want to work in industry.

Several respondents also felt that graduate school would over qualify them for jobs, as a fourth year Aerospace engineering student inferred: "PHD seems to over qualify people for a lot of jobs." Another 8% of students discussed issues with grades, most commonly that they did not think they were good enough to get into graduate school. Several students had comments similar to another fourth year aerospace student who said

I really want to attend my undergraduate institution; however my GPA is 0.2 points (on a 4.0 scale) below the benchmark of what the department wants masters applicants to have. The chair of the graduate board has discussed with me that it is highly unlikely I can get in and my application will not even be considered unless I have the minimum GPA that they require, even despite having a minor in mathematics, excellent research experience, taking graduate courses during my undergraduate years, and having a personality.

Finally there were 8% of students who mentioned confusion with the admissions process and the variety of questions they had about graduate school that they were unsure who to go to for help. Specifically students mentioned a lack of information about deadlines, how the admissions process worked and who to talk with if they were considering going to a school other than the one they attended for their undergraduate program.

Despite identifying several barriers to attending graduate school, students also described several factors that support(ed) their decision to apply to graduate school. These were organized into three categories: talking to professors or graduate students, creating career opportunities, and personal growth and development.

Four percent of the responses centered on students' desire to apply to graduate school as a means of personal development. Specifically students mentioned wanting to learn more, push personal limits, and learn to think independently. A second year male engineering mechanics student noted that "graduate school would provide a great learning experience because so much of your success depends on your ability to think independently."

Discussions with faculty or other graduate students were mentioned in 2.3% of the student comments. Specifically, students mentioned talking directly with a faculty member, participating in undergraduate research with faculty and graduate students, and discussing graduate school with other graduate student teaching assistants or classmates. A fourth year female systems engineering student replied that "I was not interested in attending graduate school in engineering until a professor approached me with his thoughts on it. It called my attention and now I am applying to get into [university's] engineering graduate program."

Finally, there were students (3.5%) who felt that graduate school would create more opportunities for them in

the future. A fourth year electrical engineering student explained

I want to go to graduate school to not only learn more, but also to enhance my academic record With a graduate degree, I will be able to have more employment opportunities in industry and a higher starting earning potential. So, I want to have many career options available to me after I graduate.

Based on our findings, undergraduate engineering students focused on a variety of issues relative to their decision process ranging from very practical (admissions process) to the impact of this decision on their future careers. To better understand the student decision process, we considered the reflections of current engineering graduate students.

II. Graduate Student Reflections on Graduate School in Engineering

On the other side of the decision process were students already in graduate engineering programs. Again, we asked them to reflect on information they would like undergraduate students to know when considering graduate school. The results clustered around the themes of preparation and navigation. With respect to preparation, 29% of respondents emphasized the need for undergraduates to develop a solid foundation in both theory and research prior to pursuing graduate education. Several students made comments similar to these from a third year biomedical engineering (BME) female student:

A degree in a basic engineering discipline, eg Electrical Eng [EE]... is the best way to really learn your fundamentals. Some other BMEs are having trouble with circuit analysis and complex mathematics, and I have a very strong background with these subjects due to my degree in EE.

Similarly, a fifth year computer science student said:

It is very helpful to get involved in research projects while pursuing an undergraduate degree. Being in a research group gets one into the habit of reading and critiquing papers as well as writing, presentation, and deliberation. It helps one think about new problems, different ways to question, and learn about methodology.

The other category regarding preparation (11%) was the need for students to clarify their goals in pursuing a graduate degree. In other words, how does pursuing a graduate degree fit into your long-term career goals? A female fifth year information systems student said

I'd tell undergraduates to think long and hard about why they truly want their PhD degree. It's a long and stressful road. Don't pursue the degree just to have "Dr." before your name. What benefits do you expect to

receive from having a PhD? How interested in, or even passionate about, your field are you? What will your life be like as you are pursuing your degree (e.g. do you really have the time, money, interest, motivation)?

The most commonly reported category with respect to successful navigation of a graduate program was the importance of selecting the appropriate adviser and research group (40%). Distinct from funding and prestige, respondents indicated the quality of interactions with and mentoring support from advisors would "make or break" their graduate school experience. As a fifth-year electrical engineering student indicated,

Find an advisor who is willing to actively participate and invest time in your work. Having an advisor who cares about you as a person and about your career and life aspirations is extremely important, and that kind of advisor will support you to finish your studies no matter what.

In addition to picking the appropriate research group, 23% of graduate respondents indicated the importance of selecting an engaging research topic to successfully navigate through graduate education. A second year engineering mechanics student noted that she warns undergraduates to only pursue graduate education, "if they have a[n] earnest interest in the topic" because "writing a thesis without passion or interest is very difficult."

There were a few other navigation-related categories of responses worth noting. First, students should cultivate a greater sense of agency/independence than in undergraduate education (9%) because "you are in charge of your own success and ability to complete the degree." Second, students should secure funding (7%), because without funding "it will be much more difficult to graduate, and take longer." Finally, students should begin research early in their graduate careers (5%) as this shortens time to degree completion and allows students to "accomplish much more in the long run."

Pairwise comparisons of the percentages of graduate students responding in each category between female & male respondents or American & international students revealed no statistically significant differences ($p > 0.1$, two-tailed t-test). This suggests that the themes emerging from the coding scheme address the structural realities of graduate education that similarly impact students across gender and nationality. The number of American students with coded responses who identify as belonging to underrepresented minority groups (African-American, Hispanic, Native American) was too small ($n=10$) to allow for valid comparisons to the responses for American students from other ethnic backgrounds.

DISCUSSION

To many engineering faculty members, these results are not particularly surprising, since they align with conventional

wisdom about graduate school. However, they highlight the lack of a systematic means for all engineering undergraduates to find out about and fully consider their options for graduate school. To address this, we have used our findings to compile a list of considerations that undergraduate students can use to guide them in the decision process. These recommendations could also be used by graduate programs as recruiting tools to provide information to prospective undergraduate students to start them thinking about graduate school.

1. What do I *really* want to do, and what type of degree is required to achieve it? Reflect on any research experiences you've had, particularly those you enjoyed. Talk to prospective employers at career fairs to gather information about the types of jobs engineers with undergraduate degrees can do versus applicants with a masters or PhD.
2. Engineering departments that offer graduate degrees have a graduate student advisor/director. If you have questions about graduate school at your department, start there. Questions might include how admissions works, GPA requirements, degree program requirements, etc. If you are at an undergraduate institution, undergraduate advisors (including faculty advisors) are also a good initial contact.
3. There are several funding packages available at the department level for research or teaching. Also, there are many national fellowships that provide even more financial support. Talk to other graduate students about typical funding amounts and look at your budget so you can make an informed decision about the financial costs of graduate school. In many cases, U.S. citizens attending U.S. institutions can have most or all of their PhD covered through assistantships and fellowships. (At the graduate level, these types of awards are much more likely to cover tuition and a living allowance vs. smaller undergraduate scholarships.)
4. Selection of the "right" graduate program includes the institution, department and advisor. In addition to considering reputation, make sure that you have similar aspirations and work styles. Have I talked to the advisor that I am planning to work with? Have I talked to their current/recent graduate students about their training experiences, support, post-degree career options, etc.?

CONCLUSION AND IMPLICATIONS FOR GRADUATE PROGRAMS

For current graduate students, the relationship with the advisor and research group were the most frequently mentioned factor affecting the graduate school experience. While preservation of academic freedom is important, graduate deans should consider mentoring or management training for faculty members to help guide them in working

with their respective research groups. Previous research has explored the influence of research group size in student learning [citation blinded], and offers suggestions for faculty relative to managing these groups.

Undergraduate students reported varying degrees of confusion about the application process, who to discuss graduate school with, and how their undergraduate education would prepare them for graduate school. Administrators and academic personnel should keep these things in mind when recruiting for their graduate programs. Information sessions with the graduate program director, or given by current graduate students, could help alleviate this confusion and increase the likelihood that students will feel comfortable applying to the graduate program. Conversely, undergraduate students who had discussions with faculty and current graduate students responded positively about their decision to apply. Faculty members working with undergraduate students, either in coursework or in undergraduate research, should be sure to discuss graduate school with their students or assign more experienced graduate students to answer students' questions and provide assistance.

FUTURE WORK

This study also offers several possible areas for future research. Knowing that a strong theoretical foundation is important, what mechanisms exist to help students refresh some of the basics? Might optional weeklong theory "bootcamps" prior to matriculation make the transition better for both students and faculty? Also, what sort of financial and programmatic supports exist to allow students to begin research early? In the biological sciences, students do research rotations, allowing them to get a sense of the lab environment before joining. Are there funding opportunities that are available only to first year students? How do decisions made in the first year of graduate study influence retention and ultimately degree completion in later years?

For recruiting undergraduate students into graduate programs, how might current graduate students be used to help recruit and assist students through the process, perhaps at a college scale rather than just the department? To what extent might this individual mentoring increase the representation of women and other underrepresented minorities in graduate engineering departments?

Work in Progress: Smart Teaching: Capture Lectures and Keep Students Engaged Online and in the Classroom

Dr. Loren B. Naffziger,

Abstract—

Classrooms of today are often present on the computer monitors, iPads, and Smart Phones of students. In order to keep the students engaged, professional educators need to utilize the technologies of the digital age to capture and maintain the interest of the students (Salazar [1], 2010). When students are in the traditional face-to-face classroom environments, the use of educational technology can be instrumental in student engagement and learning (Lisenbee [2], 2009). The use of Smart Boards, a technology interactive whiteboard, is one tool that educators can use to increase engagement in the classroom. The ability to present content on a SMART Board and capture the lecture for online learning is step further into the digital age for most institutions. By combining strong curriculum with educational technology, schools can utilize the assets of their faculty expertise to educate students in both on-ground and online venues. The use of the Internet is a powerful educational tool when it provides multimedia technologies for its students (Dey, Burn, & Gerdes [3], 2009). Capturing and delivering the lectures of faculty on the web allows students to engage the learning at their convenience and pace. Enhancing the lecture capture with the use of SMART Boards can provide a multi-sensory learning experience for the instructor as well as the student. When a lecture utilizes an instructor's presence and voice with written content (e.g., PowerPoint), the multimedia content engages the cognitive structures of the students in a positive manner (Dey et al. [3]). The study results presented by Dey et al. [3] suggest that students prefer to see their instructors during a lecture and their learning outcomes are enhanced by lecture capture technologies. National University (NU) is conducting a pilot project that utilizes SMART Board technologies with lecture

capture software. The project's goals include the integration of SMART Boards in on-ground classrooms, capturing lectures for immediate student use (e.g., reviewing content), and developing a video library of lectures for embedding in online courses. This presentation will provide an overview of the work in progress and a review of its current status.

Work in Progress: Smart Teaching: Capture Lectures and Keep Students Engaged Online and in the Classroom

I. INTRODUCTION

A key to effective teaching is keeping students engaged in the learning activities, which includes lectures in on-ground as well as online classrooms (Garrett [4], 2011; Palloff & Pratt [5], 2007). Garrett [4], in a discussion of the literature and research activities relating to student engagement to content, provides this definition of the goal of teaching: "I propose that engagement is the interactive space, or lack of space, between student and the subject, and we, as teachers, hope that, as an outcome, deep learning arises or is produced from that interaction." (p. 7). Palloff and Pratt [5], in discussing the importance of creating an engaging learning community in the online classroom environment advocate for faculty to promote "honesty, responsiveness, relevance, respect, openness, and empowerment." (p. 22). In any classroom, these goals and values can be enhanced through the effective use of educational technology (Salazar [1], 2010; Lisenbee [2], 2009; Akbas & Pektas [6], 2011).

The use of various technologies in the on-ground and online classroom can facilitate the engagement of students (Salazar [1], 2010; Lisenbee [2], 2009; Akbas & Pektas [6], 2011). Salazar [1], in a discussion of various educational technologies that may be a part of an online program, states "Video lecture capture technology (VCLT) supports student retention by engaging students, increasing student satisfaction, and promoting student achievement" (p. 54). The convenience for students in being able to download and view lectures at times as well as on devices of their choice is key attribute of VCLT according to Salazar [1]. Lisenbee [2] discusses how the use of interactive whiteboards can engage young students. The ability to provide an interactive technology rich environment is an advantage of this tool according to Lisenbee [2]. Akbas and

Pektas [6] discuss the effects of interactive whiteboards on the academic achievement of university students. In the discussion of the results of their research, Akbas and Pektas [6] summarize their findings in this statement:

“Even though interactive whiteboard use might not increase students’ academic achievement significantly, it was seen that it encouraged student participation in the lesson, created a more exciting and enthusiastic atmosphere, and led to more enjoyable lessons. In addition, many students in the experimental group stated that interactive simulations and virtual experiments involved situations that they did not normally encounter in real experiments and this enabled them to visualize the topic.” (p. 13)

The integration of VLCT and interactive whiteboards are two educational technologies that form the core of the work in progress at National University.

II. WORK IN PROGRESS PARAMETERS

National University (NU), which is the state of California’s (USA) second largest non-profit private university, is conducting a pilot project that integrates the use of VCLT with interactive whiteboard uses. The scope of the project includes using VCLT to record lessons and activities in traditional classroom settings for future uses. These uses include review by the traditional classroom student population as well as archiving the recordings for online courses. Based on the literature review presented in the introduction, the researchers expect the project will be beneficial to the students in the traditional classroom as well as those that may view the lectures or activities in online environments.

III. RESEARCH QUESTIONS

The primary research questions for this work in progress are as follows:

1. What are the benefits of using interactive whiteboards in combination with VCLT?
2. What are the challenges of using interactive whiteboards in combination with VCLT?
3. How can the use of interactive whiteboards in combination with VCLT be improved?

A. Participants

The participants for this project include the students and faculty that sign the informed consent form (Institutional Review Board approved). The participant pool will involve the students and faculty involved in coursework in the NU Teacher Education Department. A subset of research questions may come from the work with the students and

faculty members working in the department of Teacher Programs that lead to credentialing. These potential participants may present the researchers the opportunity to create a longitudinal study on the effect of exposure and use of educational technology has on future educators.

B. Method of inquiry

A survey to collect qualitative data in response to the three questions is in the beta development stage for this project. The survey will use an online delivery system to promote anonymity and encourage participation. The collecting of additional qualitative data may implemented by using one-on-one interviews or focus groups.

ACKNOWLEDGMENT

L. B. Naffziger, K. Fawson, and Erika McCulloch thank the faculty and students of National University for their willingness to explore new educational technologies and co-generate knowledge for improving its use.

Quality of Service, Quality of Experience and Online Learning

Alexander A. Kist and Lyn Brodie
Faculty of Engineering and Surveying
University of Southern Queensland
Toowoomba, Australia
kist@ieee.org, lyn.brodie@usq.edu.au

Abstract— Online learning tools are widely used in engineering education. This includes traditional face-to-face, but also distance education. Since these tools rely on Internet connections, the performance of those connections (speed, latency) can impact on how learning tools are experienced by students. Quality of Service (QoS) describes technical performance parameters that reflect the quality of an Internet connection. Quality of Experience (QoE) on the other hand has been widely used to describe how users experience a particular service. In the context of this work, users are students undertaking learning tasks. While technical literature addresses QoE and educational literature discusses online learning, a gap exists describing the relationship of QoS and the quality of the learning experience. This work uses a mixed methods approach to address the research question: What dimensions of QoE of online learning can be affected by QoS? To answer this question, two groups of students were exposed to changing QoS conditions while they were undertaking an online learning activity using remote access technology. Both technical performance parameters, as well as, the impressions were recorded. Subsequently, a focus group was held to get a better understanding of the students' perception of the relationship between QoS, QoE and online learning tools. It is concluded that QoS factors only have an intermediate impact on the quality of the learning experience of the students. Factors such as course design and pedagogy largely determine the quality of online learning.

Keywords—online learning tools; quality of service, quality of experience; quality of learning experience performance; distance education.

I. INTRODUCTION

Online learning activities are often seen as tools to assist student learning and to improve their engagement. This is of particular relevance for students that are remote from campus such as distance education students. Information and Communication Technology (ICT) is used to provide equitable learning opportunities for those students. Examples include audiovisual lecture recordings but also remote access to software and hardware experiments. As these tools depend on telecommunication infrastructure and the Internet; technical performance depends on Internet access speed, location and network traffic. These technical parameters are generally referred to as Quality of Service (QoS). "QoS is defined as the ability of the network to provide a service at an assured service level" [1, p. 3] and includes performance parameters such as

delay, jitter and throughput. These parameters can be measured, but are unable to capture the experience of a system user, e.g. whether the system is suitable to perform a particular learning task.

In recent years, the telecommunication industry has placed a higher focus on the consumer experience and Quality of Experience (QoE) has become a major research area. QoE is frequently used in a technical context and "refer(s) to the overall acceptability of an application or service, as perceived subjectively by the end user" [2, p. 216]; "how satisfied he or she is with a service in terms of, for example, usability, accessibility, retainability and integrity of the service." [1, p. 3]; or "as the basic character or nature of direct personal participation or observation" [3, p. 619]. However, no QoE definition is universally accepted or widely used. The term is also well established in psychology and other disciplines (e.g. [4]), where it has a more general meaning. Much of the educational literature in this area has focused on understanding QoS for online tools without reference to the significance of QoS for QoE of learners. QoE research in the technical domain does not directly apply, as learning is very different from the general consumer experience.

Online learning tools are becoming increasingly prevalent in education. This applies to both, face-to-face as well as distance education. Understanding the impact of technical limitations on learning that is occurring is therefore an important research area. This work takes a step forward from the current focus in educational literature on QoS to QoE. This is only a stepping stone as the ultimate goal is to understand the impact of QoS on learning, and not only on user experience. Understanding factors in online learning that are susceptible to changes in QoS is by its own right relevant and can lead to better online learning environments. Using the work of Mayer [4] and Gilbert, Moreton and Rowley [5], this study has developed a model which maps the factors contributing to the quality of the learning experience in online environments. Using a mixed methods approach, it addresses the research question: What dimensions of QoE of online learning can be affected by QoS?

The remainder of this paper is organised as follows: Section II discusses the general context and the background of this study. Section II introduces the interest in QoS for the quality of the learning experience and provides the framework

for this study. Section III outlines the methodology that was used and Section IV highlights initial findings. These are discussed in Section V and implications and further work are outlined in Section VI.

II. CONTEXT AND MOTIVATION

This section provides an introduction into the general context and the motivation for this study, the details do not directly relate to the research question. The University of Southern Queensland and the Faculty of Engineering and Surveying have a distinct student cohort with 76% of students studying in a distance mode, not located on campus. Courses are generally offered in an on-campus and external mode in parallel. Traditionally, print material has been used as means to provide learning materials; today teaching relies heavily on ICT tools and Internet technology. This includes the course management system, a branded Moodle instance as well as electronic lecture recordings. In an attempt to provide equitable learning opportunities, the Faculty of Engineering and Surveying has developed Remote Access Laboratory (RAL) technology [6] that provides external students with access to hardware and software experiments on campus.

The engineering courses that are offered by USQ are accredited by Engineers Australia, the Australian equivalent of ABET. To give students the opportunity to practice practical, hands-on skills, students have to attend practical on-campus sessions, so-called residential schools. During these residential schools, external students travel to Toowoomba to attend a week of laboratory sessions, usually one per semester.

Due to the cliental, the external student cohort is different from the traditional student body seen at many Universities. Most students are mature age and are working full time. The average age depends on discipline and cohorts, but is around 30. Generally they are highly motivated but time poor as they have competing family and work commitments. The quality of the learning experience becomes very important in this environment.

III. THEORETICAL FRAMEWORK

The field of research into online learning is very broad and detailed. Within this body of work, many studies with a technical focus pay particular attention to understanding the effect of QoS on QoE in the learning environment. This focus derives from related studies of QoS in telecommunications or other consumer-based Interactive Multimedia Environments (IMEs). As a result of this heritage, the QoS literature tends to treat users of technology for learning as consumers, with the associated needs and expectations [7]. Where multimedia environments are consumer driven, decades of market driven research into consumer uptake and acceptance of ICTs provides researchers with explicit understandings of what users expect, and how they behave and how they perceive the technology that they are ‘consuming.’ This ‘consumption approach’ is demonstrated by [8] who cite various formal and informal definitions of QoE from the available literature which reflect this: “the degree to which a system meets the target user’s tacit and explicit expectations for experience”; “subjective measure of a customer’s experiences with a

vendor”; “user perceived performance”; and, “the degree of satisfaction of users” (p. 483).

The consumption approach contains a shortfall in attempting to understand how users experience quality in online environments when the task at hand is learning. In attempting to adapt the broader body of knowledge about IME, consumption to environments where users are learners, it is necessary to address the fact that the relevant dimensions that make up QoE are unlikely to be the same. For example, the nature of technology use will be different in terms of users’ motivation, their purpose in completing tasks, as well as the nature of the tasks themselves. Each of these variables significantly influences user behavior and perception, and, thus, the nature of QoE. In evaluating the effect of QoS on QoE for learning, it is necessary to specifically consider how system performance issues have affected the learner in the process of carrying out their (learning) tasks. In other words, this requires observing if, rather than assuming that, QoS issues have affected the learning and what the effect has been.

Wu [8] make a significant step in this direction with a shift of focus from a system-centric view of IMEs to a human-centric one, encompassing theoretical frameworks from psychology, cognitive sciences and sociology as well as information technology. They attempt to “map the QoS-QoE relationship” by “capturing the human-centric quality modalities.” (p. 481). In doing so, they define QoE as “a multi-dimensional construct of perceptions and behaviours of a user, which represents his/her emotional, cognitive, and behavioural responses, both subjective and objective, while using [an IME] system” [8, p. 483]. Their model maps the relationships among various QoS and QoE factors drawn from these disciplines. This definition of QoE is useful in that it highlights that QoE must derive firstly from the “user.” Experience is necessarily based on perception, which derives partly from the characteristics of the user, but this definition also captures the complex, “multi-dimensional” nature of the environment in which the perception is based. Despite this step forward, Wu et al.’s model does not take a specific focus on experiences in learning environments.

The wide range of available literature on online learning highlights the many course design, learning tool design and pedagogical factors which have a significant influence on quality in online environments [9]. Sambrook’s [10] in-depth study demonstrated that many factors, such as user-friendliness, presentation, structure of tasks and navigation within tasks, all affect the perceived quality of online learning tools. Importantly, these are design and pedagogical issues that are central to how the learning takes place. Further, fundamental learning theory holds that factors such as a clear set of instructional goals, the perceived relevance of tasks in relation to these goals and the resultant motivation and cognitive processes of learners, are all central to how learners behave and perform [11]. In this respect, there are influencing factors in online learning environments that are not common to more general online environments. The effect of QoS on how these environments are experienced by users can be expected to be different than for general consumption. To understand the effect of QoS in online learning, it will be necessary to describe how it interacts with these other factors.

In attempting to deal with the issue of perception during learning, Moebis' [12] work focused on the effect of 'flow' (defined as complete immersion within a task, leading to intensive interaction within an activity) on QoE for learners. Flow is directly affected by QoS issues such as access speed and consistency. The detailed QoE model included many factors present in the learning environment which can mediate the relationship between QoE and QoS. These factors include "choice of learning path, learning styles, feedback, interaction" and "clear sets of goals". Despite this, her quantitative method of measuring the effect of flow on QoE did not account for these factors, and consequently, the model is not capable of explaining the relationships among all of the elements that are presented. The author uses a Delphi panel of technical (QoS) experts, rather than an instrument which captures data from the learners or the learning environment. Although flow is expected to be highly relevant to the effect of QoS on QoE, until it is understood how it is mediated by other factors and the learning tasks, the picture is incomplete

IV. METHODOLOGY

A mixed-methods approach has been chosen to capture data about learning from the learners themselves. The study was undertaken in two stages, a pilot study to explore the relevance and coverage of the original model [13] and a main case study to identify dimensions of QoE that are affected by QoS. Initially it was also intended to collect data at the actual student locations via traffic loggers [14]; however, due to unavailability of hardware this was not possible. The methodology, discussed below, was chosen instead.

A. Pilot Study

The purpose of the pilot study was to identify the data that needed to be collected in the main study to address the research question. The pilot consisted of a focus group and a student survey exploring their experience with online learning systems in a third year computing course; and any issues – technical as well as non technical they encountered. The survey questions were based on a comprehensive description of the learning environment by Sambrook [10] as tabled in [13, Table 1]. A focus group session was undertaken to validate the survey instrument and explore the answers in more detail. The pilot highlighted two key issues with implications for the main study [13]:

Students do not have a common understanding of "online learning tools" or "tools for learning". Student perceived many functions of tools of the Learning Management System (LMS) as administrative in nature rather than supporting or promoting learning. The implications of this were that what students perceive as significant for the learning experience may largely depend on how students understand the function of the tools. The pilot also highlighted another issue – the participants focused mainly on issues of course design and delivery when speaking about issues that were significant for their learning. This raises the question if QoS issues can be sufficiently isolated from education design and delivery issues to understand the effect of QoS on QoE.

To avoid these issues in the main study, a learning activity in the context of Remote Access Laboratory was used as the learning tool. These activities are perceived by students as sophisticated enough to be understood as a learning tool. Furthermore, variations in QoS such as issues with delay or bandwidth have a direct impact on the performance of the interactive system and help to create a better picture of the impact on QoE. To address the second point and to isolate design and delivery issues from the impact of QoS, students undertook RAL activities that were self-contained and not integrated into a scaffold learning program. Students also undertook the same activity several times, so they were aware of the expected outcomes

B. Main Study

The main case study was based on two groups of students of diversely situated distance students who were on campus for residential school. Due to their mix of near and far, urban and rural locations, these students routinely experienced different QoS in the same academic courses. During their time on campus they were each asked to perform a laboratory experiment, first under normal laboratory conditions and then remotely via computer using RAL technology. During the remote session they were given several attempts at the activity and in each attempt the QoS was varied. Subsequent to the experiment sessions, the students took part in focus groups to explore factors impacting their QoE both for their routine studies, and the test experiments.

To replicate different QoS conditions, a Wide Area Network (WAN) Emulator was used. It is based on NetEm [20] to emulate various network conditions including delay and bandwidth limitations. The emulator was placed in-between the user workstation and the corporate network. Testers configured network conditions with a simple web interface. To make the test environment more accessible to the test subject, network parameters were related to practical access options and locations. The following locations and associated RTT were selected as typical locations for potential system users: Local – Toowoomba (<1ms), Melbourne (50ms), Perth/New Zealand (100ms), Singapore/USA (200ms), Europe/Dubai (300ms) and other locations. These are only indicative values; in practice, RTT largely depends on routes packets take to their destination and routes depends on Internet Service Providers (ISP) and peering arrangements.

The first group of seven students was taking part in a second year hydraulics practice class on campus; a class providing "a broad introduction to the practical aspects of water engineering and focuses on the development of analytical, manual, diagnostic, communication and group interaction skills." The RAL activity was a hardware-based experiment setup of a *tapered passage (Bernoulli)* experiment, where students determine flow rate and pressure heads.
