CONFERENCE AT A GLANCE

Wednesday, October 3

| | |
|--------------------|--|
| 11:00 am – 6:00 pm | Registration Metropolitan Ballroom Prefunction Area |
| 1:30 pm – 6:00 pm | Exhibit Setup Metropolitan Ballroom |
| 1:30 pm – 4:30 pm | Pre-conference Workshops Session A |
| 5:30 pm – 8:30 pm | Pre-conference Workshops Session B |

Thursday, October 4

| | |
|--------------------|--|
| 7:00 am – 5:00 pm | Registration Metropolitan Ballroom Prefunction Area |
| 7:00 am – 8:00 am | Focus on New Attendees Breakfast Buffet Metropolitan Ballroom Prefunction Area |
| 8:00 am – 9:30 am | Plenary Session Grand Ballroom WIKISPEED - Revolutionizing Transportation through Agile, Lean and Scrum |
| 9:30 am – 5:00 pm | Exhibit Hall Open Metropolitan Ballroom |
| 9:30 am – 10:00 am | Exhibit Hall Break |
| 10:00 am – Noon | Technical Sessions (T1) |
| Noon – 1:30 pm | HP Terman and Rigas Awards Lunch Sponsored by the Hewlett-Packard Company Grand Ballroom AB |
| 1:30 pm – 3:00 pm | Technical Sessions (T2) |
| 3:00 pm – 3:30 pm | Exhibit Hall Break |
| 3:30 pm – 5:00 pm | Technical Session (T3) |
| 5:10 pm – 6:00 pm | Catalyzing Collaborative Conversations Sessions |
| 6:00 pm – 8:30 pm | Reception and Awards Banquet Ticketed Event Cirrus Ballroom |

Friday, October 5

| | |
|--------------------|---|
| 7:00 am – 5:00 pm | Registration Open Metropolitan Ballroom Prefunction Area |
| 7:00 am – 8:00 am | Breakfast Grand Ballroom AB |
| 8:00 am – 9:30 am | Plenary Session Grand Ballroom AB Is There a MOOC in Your Future? |
| 9:00 am – 4:30 pm | Exhibit Hall Open |
| 9:30 am – 10:00 am | Exhibit Hall Break |
| 10:00 am – Noon | Technical Sessions (F1) |
| Noon – 1:30 pm | Premier Award Lunch Sponsored by John Wiley & Sons, Microsoft Research, Autodesk, and TechSmith Grand Ballroom AB |
| 1:30 pm – 3:00 pm | Technical Sessions (F2) |
| 3:00 pm – 4:00 pm | Focus on Exhibits and New Faculty Fellows Metropolitan Ballroom |
| 4:00 pm – 5:50 pm | Technical Sessions (F3) |
| 6:15 pm – 9:30 pm | Transportation to and Reception at Museum of Flight Bus loading zone on Union Street: Walk to the left after exiting the main hotel doors |

Saturday, October 6

| | |
|---------------------|--|
| 7:00 am – 10:00 am | Registration Metropolitan Ballroom Prefunction Area |
| 7:00 am – 8:00 am | Breakfast Metropolitan Ballroom |
| 8:00 am – 10:00 am | Technical Sessions (S1) |
| 10:00 am – 10:30 am | Break Metropolitan Ballroom Prefunction Area |
| 10:30 am – 12:30 pm | Technical Sessions (S2) |

WELCOME FROM THE GENERAL CO-CHAIRS

On behalf of the three sponsoring societies and Seattle University, we are pleased to welcome you to FIE 2012. The lifetime of FIE, 42 years and counting, has been a time of many innovations in engineering and computing education. The Frontiers in Education Conference has become the premiere conference for presentation and discussion of excellent educational research and innovative curricula in engineering education. This accomplishment would not have been possible without the vision and strong leadership of the three sponsoring professional societies – ASEE Educational Research and Methods Division, IEEE Computer Society, and the IEEE Education Society. We, along with the sponsoring societies, are proud of the rich traditions of the FIE and the many

engineering educators and educational researchers from around the globe who have contributed so much to our present understanding of how students learn. We are excited to bring this year's conference to the West Coast, where it is more easily accessible to our colleagues around the Pacific Rim. The theme of this year's conference, "Soaring to New Heights in Engineering Education" focuses on expanding the diverse community of international scholars and enriching the foundation of educational research that FIE has built over its history. It seems only fitting then that we continue this celebration of "soaring to new heights" by hosting this year's reception at the Museum of Flight.

Also fitting with this year's theme and location, we have expanded our outreach efforts to include Asia and Australia and are quite eager to learn of your educational efforts. Welcome to all first timers at FIE, whether international or local. We hope you become ambassadors for FIE by supporting our goals of enriching engineering education and informing other colleagues of your experiences.

FIE 2012 has an exciting and innovative technical program which is made possible by the Planning Committee, a large group of dedicated professionals who volunteer their time to this cause. The program co-chairs from the sponsoring societies – Reid Bailey and Archie Holmes of ERM, Steve Frezza of the IEEE Computer Society, and Lance Perez of the IEEE Education Society – coordinate the paper review process and organize the technical sessions. The program co-chairs are joined by the International Program Chairs, Ming Zhang, Mark Lee, Edmundo Tovar Caro and Melany Ciampi and the Special Sessions Chair Kevin Gary. Ingrid Russell, as the New Faculty Fellows Chair, coordinates the new faculty fellows program, a valuable influx of new people and innovations. Robert Hofinger continues in his key role as Exhibits Chair and Ed Jones as Conference Historian. We are pleased to have had such a dedicated group of program chairs who provide countless hours to organize the technical sessions, workshops, and special sessions that make FIE the innovative and compelling conference that it is.

In addition to selecting the technical program, there is a great deal of logistics and support planning that must be accomplished to make FIE the special conference that it is. We are both fortunate and thankful for the logistics support from Kevin Curry, Assistant to the General Chairs, and the University of Kansas Continuing Education staff and to Chris Dyer, Publications Chair. In addition to providing all of the logistical support that is necessary for the conference, Kevin continues to provide the continuity and institutional memory that is necessary for the planning committee to do its job. In addition, we would like to thank Jennifer Karlin and Stuart Kellogg and the FIE 2011 Planning Committee who continue to offer the support and guidance for the FIE 2012 program. Finally, we would like to thank the FIE Steering Committee for their leadership in ensuring the uniqueness that is FIE.

FIE is more than just a place to present papers. It is a place to meet and welcome new people and reconnect with old colleagues. It is a place to interact and discuss new ideas and new innovations. In short, it is a place to build not only a community of scholars but a community of friends. While you are here, we hope that you will have an opportunity to enjoy some of the many attractions that Seattle has to offer.

Our conference hotel is located in the heart of downtown Seattle, within walking distance of many fine restaurants, the Seattle Art Museum, multiple live music venues, the Seattle waterfront with its stunning views across Puget Sound, and the unique Pike Place Market. If you are able to spend an extra day in Seattle, you can explore the natural beauty of the city and its surroundings, take a trip to Mt. Rainier National Park, or visit the Boeing factory to see the latest commercial airliners being constructed. Seattle offers something for every taste, including all of the great coffee you can drink!

Your Co-Chairs,
Richard Leblanc and Ann Sobel

MESSAGE FROM THE FIE STEERING COMMITTEE

Welcome to Seattle and the 42nd annual Frontiers in Education Conference. This year the conference continues its long tradition of offering an outstanding technical program. Each year I learn so many new things at FIE. I have always particularly liked the sessions on first-year classes, curriculum assessment, and cooperative learning because these are areas I spend significant time thinking about each day on the job. But, last year one of the sessions that had the greatest impact on me was a workshop on the Philosophy of Engineering Education because it asked tough questions to participants about the nature of engineering, engineering knowledge, and engineering education. The effect of this workshop on my thought processes has been profound. I am confident that this year you will find many conference events that can similarly transform the way you think about engineering and education. **Immerse** yourself in hands-on learning at a workshop on

Wednesday. **Start** Thursday and Friday at the Plenary sessions where you can interact with leaders from both industry and academia as they challenge you to think differently about modern product development and the education of engineering and computer science students. **Attend** and ask questions at scores of high quality paper presentations in the many parallel tracks. **Engage** with others at the unique Catalyzing Collaborative Conversations Sessions on Thursday evening where anyone can catalyze educational change by bring forth new topics for group discussion. Finally, **enjoy** the many opportunities to network with colleagues from around the world at the breakfasts, lunches, exhibit hall breaks, and the fantastic reception at the Museum of Flight on Friday evening.

Dr. Edwin C. Jones is the Frontiers in Education conference historian. He notes that FIE began in Atlanta in the year 1971 as an IEEE Education Society sponsored event. Thirty-four papers were presented in six sessions and enjoyed by approximately 100 registrants. In just a few years, the ASEE Educational Research and Methods (ERM) division joined as a sponsor, the conference community grew, and the conference matured into a premier event in engineering educational theory and practice. In 1995, the IEEE Computer Society became the third sponsor and helped to expand the community even more by reaching out to computer science and software engineering professionals. Over the past four decades, the conference has grown from these historic roots to a four day event with more than 400 papers and 600 registrants.

Each of the three sponsoring societies elects three members to serve on the FIE Steering Committee.

The Steering Committee is responsible for strategic mission and vision, long-term conference planning, conference management, and conference site selection. The committee meets in person twice each year and holds considerable discussion electronically throughout the year. Important questions that we have recently answered include:

- **Should FIE periodically move to a venue outside of North America (IEEE Regions 1 - 7)?** The Steering Committee recognized that FIE has a reputation as a premier North American conference. Thus, the committee wrote a long-term policy statement that encourages venues in other IEEE Regions but requires at least five years in North America after any such event. Be sure to reserve October on your calendar and join us in Madrid, Spain in 2014!
- **How can FIE continue to improve its technical program quality and impact factor?** The Steering Committee recognized that FIE has a highly respected proceedings record but also believed that a clear categorization of papers could help peer reviewers better judge the merit of each contributed work. Thus, the conference adopted three paper categories called innovative practice, research-to-practice, and research. The committee continues to work with Technical Program Chairs to improve the quality metrics used by peer reviewers in each category.
- **How can FIE assist its volunteers in learning about and contributing to the conference event?** The Steering Committee is working on a number of informational documents that describe the various volunteer conference roles, the city bid process, and the expectations of Technical Program Chairs. These documents will become visible on the main FIE conference website when they are finished (www.fieconference.org).
- **How can FIE provide the highest quality product while maintaining registration price?** The Steering Committee worked for a number of years to move to transparent bidding processes for publications and for conference logistics. Formal request-for-proposal documents were written describing the responsibilities of these two important aspects of conference management. Bids were received from a number of vendors and through this fiscal process we have been able to leave the FIE registration price fixed for a number of years.

These are just some examples of work going on behind the scenes to make your conference experience better. The Steering Committee works for the Societies and the member communities. We encourage you to contact any one of us to discuss the FIE conference. We can be identified by Steering Committee ribbons on our conference badges.

ASEE Educational Research and Methods Division Representatives

- Beth Eschenbach, Humboldt State University, Elizabeth.Eschenbach@humboldt.edu
- Archie Holmes, University of Virginia, ah7sj@virginia.edu
- James Morgan, Texas A&M University, jmorgan@civil.tamu.edu

IEEE Computer Society Representatives

- Stephen Frezza, Gannon University, FREZZA001@gannon.edu
- Fernando Naveda, Rochester Institute of Technology, jfnaveda@computer.org
- Arnold Pears, Uppsala University, Arnold.Pears@it.uu.se

IEEE Education Society Representatives

- Russ Meier (Chair), Milwaukee School of Engineering, meier@msoe.edu
- James Sluss, University of Oklahoma, sluss@ou.edu
- Edmundo Tovar, Universidad Politecnica de Madrid, etovar@fi.upm.es

I hope you enjoy your conference and I look forward to meeting and talking with you in Seattle!

Sincerely,

Russ Meier
Steering Committee Chair
Milwaukee School of Engineering
Milwaukee, WI, USA

CONFERENCE SPONSORS

FIE 2012 is sponsored by:

American Society for Engineering Education (ASEE)
Educational Research Methods (ERM) Division

Institute of Electrical and Electronics Engineers (IEEE)
IEEE Computer Society
IEEE Education Society

FIE 2012 is hosted by:

Seattle University

Seattle University, founded in 1891, is a Jesuit Catholic university located on 50 acres in Seattle's Capitol Hill neighborhood. More than 7,700 students are enrolled in undergraduate and graduate programs within eight schools and colleges.

Seattle University is the most racially and culturally diverse, the most genuinely urban, and the largest multidisciplinary independent university of the Northwest. Utilizing these three assets for the education of our students and the service of society presents opportunities unique to Seattle University. Three out of four Seattle University undergraduate students engage in community service, three times the national average. Students, faculty and staff contribute 200,000 hours of service annually.

CORPORATE AFFILIATES AND SPONSORSHIPS

Corporate affiliates play an important role in supporting FIE conferences. This support subsidizes the cost of the award presentations and of meal functions. We appreciate these supporters and the part they play in making the 2012 FIE conference an outstanding event.

Thursday Activities

Hewlett-Packard

Frederick Emmons Terman and Harriet B. Rigas Award Luncheon

Friday Activities

TechSmith, Wiley, Microsoft
Research, and Autodesk

Premier Award Luncheon
Special Session F2A will be devoted to the demonstration and dissemination of the award-winning software.

FIE 2012 PLANNING COMMITTEE

General Co-Chair

Richard LeBlanc
Seattle University

General Co-Chair

Ann E.K. Sobel
Miami University

Assistant to the General Chairs

Kevin Curry
University of Kansas

ASEE/ERM Program Co-Chairs

University of Virginia
Archie Holmes
University of Virginia

IEEE/Computer Society Program Co-Chair

Steve Frezza
Gannon University

IEEE/Education Society Program Co-Chair

Lance Perez
University of Nebraska - Lincoln

Workshop, Special Sessions & Panels Chair

Kevin Gary
Arizona State University

Exhibits Chair

Robert J. Hofinger
Purdue University

Publications Chair

Chris Dyer
Conference Catalysts, LLC

New Faculty Fellows Chair

Ingrid Russell
University of Hartford

International Co-Chair, Asia

Ming Zhang
Peking University

International Co-Chair, Australasia

Mark Lee
Charles Sturt University

International Co-Chair, Europe

Edmundo Tovar Caro
Universidad Politecnica de Madrid

International Co-Chair, South America

Melany M. Ciampi
VP COPEC- Science and Education Research Council

Conference Historian

Ed Jones
Iowa State University

Awards Chair

Manuel Castro
Spanish National Distance University

FIE STEERING COMMITTEE

ASEE Educational Research and Methods Division Representatives

Beth Eschenbach, Humboldt State University
(June 2010 - June 2013)
Jim Morgan, Texas A&M University
(June 2011-June 2014)
Archie Holmes, University of Virginia
(June 2012 - June 2015)

IEEE Computer Society Representatives

Fernando Naveda, Rochester Institute of Technology
(June 2007 - June 2013)
Stephen Frezza, Gannon University
(June 2011 - June 2014)
Arnold Pears, Uppsala University
(June 2009 - June 2015)

IEEE Education Society Representatives

Russ Meier, Milwaukee School of Engineering
(June 2007 - June 2013) Steering Committee Chair
Edmundo Tovar Caro, Universidad Politecnica de Madrid (June 2008 - June 2014)
James Sluss, University of Oklahoma
(June 2012 - June 2015)

FUTURE FIE CONFERENCES

FIE 2013 Oklahoma City, Oklahoma, October 23 – 26
FIE 2014 Madrid, Spain

Are you interested in hosting a future FIE conference?
Leave your business card at the registration desk, and
an FIE steering committee member will contact you.

FIE 2012 EXHIBITORS

The FIE vendor and association exhibits are a popular and rewarding tradition for both attendees and exhibitors. Exhibits will include materials, equipment, textbooks, software, and state-of-the-art tools applicable to engineering education. We thank the vendors for their financial support and contributions to making FIE 2012 a meaningful experience.

Exhibit Hall Hours

The exhibits will be open in the Metropolitan Ballroom 9:00 a.m.–5:00 p.m. Thursday and 9:00 a.m.–4:30 p.m. Friday. As of September 1, the following companies have committed to exhibiting at FIE 2012:

| EXHIBITOR | WEBSITE |

Focus on Exhibits and New Faculty Fellows Poster Presentation

Attendees and participants will be encouraged to visit the exhibit area throughout the conference. In order to provide full exposure for the exhibits, a special "Focus on Exhibits" session is planned for the afternoon of Friday, October 5th, during which time there will be no technical sessions scheduled. The New Faculty Fellows will also display their posters at this time. Door prizes contributed by some of the exhibitors will be awarded during the Focus on Exhibits. You must be present to win.

EXHIBITOR SHOWCASE PRESENTATIONS

Thursday, October 4

| | |
|---------------------|---------------|
| 10 am – Noon | Piazza |
|---------------------|---------------|

| |
|--------------------|
| Seneca Room |
|--------------------|

Topic: Peer-Based Learning with Piazza

Speaker: Nick LaVassar

Description:

Piazza is a **free** online question and answer platform built from the ground up to replace less effective discussion boards commonly adopted in classrooms. It was made popular by widespread use at Stanford, Harvard, Princeton, and MIT. Today, it's used by hundreds of thousands of students every term.

You are encouraged to bring your own laptop to the session to test drive Piazza, but are also welcome to just watch the demo and participate in the discussion. In this session, you'll learn how to:

- Solicit high levels of participation from students;
- Enable shy students to ask questions with varying degrees of privacy;
- Save time and eliminate redundant effort in larger classes

Again, Piazza is **free** and can be adopted by individual instructors. Sign up and get started in just minutes by visiting www.piazza.com.

| | |
|--------------------|----------------------|
| 1:30 – 3 pm | The MathWorks |
|--------------------|----------------------|

| |
|--------------------|
| Seneca Room |
|--------------------|

Topic: Enabling Project-Based Learning with MATLAB, Simulink, and affordable hardware

Speaker: Dr. Ye Cheng is a member of the Educational Technical Evangelist team at MathWorks who explore how best to work with universities to help prepare the next generation of engineers and scientists. Ye holds PhD and MS degrees in mechanical and aerospace engineering, specialized in advanced imaging techniques for the study of fluid mechanics. After four-years teaching of senior lab courses, Ye has been working with professors across disciplines from various universities to leverage MATLAB and Simulink for teaching.

Description:

Project-Based learning is extremely effective because students can see, hear, and touch what would otherwise be very abstract. In this presentation we will show you how MATLAB, Simulink, and the new Run on Target Hardware feature can easily interface with a broad range of very affordable hardware and experiments to teach courses focused on:

- Mechatronics
- Circuit design
- Programming
- Controls
- Robotics
- Renewable energy

New with Release 2012a of Simulink, the Run on Target Hardware feature can automatically generate standalone applications to run in real-time on the BeagleBoard, LEGO® MINDSTORMS® NXT, and Arduino Mega without the need for either MATLAB Coder or Simulink Coder™. Using this new capability, we explore integrating simulation and hardware to show the following concepts:

- Reading sensors and writing to actuators
- Interactive prototyping of algorithms for control and signal processing
- Testing algorithms with physical hardware components
- Deploying real-time algorithms to standalone hardware
- Integrating algorithms with robots and real-world systems

| | | |
|--------------------|-----------------|--------------------|
| 3:30 – 5 pm | Digilent | Seneca Room |
|--------------------|-----------------|--------------------|

Topic: Hands-on with Digilent chipKIT Arduino Compatible boards and Cerebot Pic32 Microcontroller Boards

Speaker: Mr. Gene Apperson, VP of Engineering, Digilent Inc.

Description:

Digilent will lead a hands-on review of the chipKIT™ and Cerebot™ line of microcontroller boards. Featuring compatibility with the popular Arduino™ open source platform, Digilent kits add the performance and functionality of the Microchip PIC32 microcontroller. Come learn how to enable students to easily and inexpensively integrate electronics into their projects, even if they do not have an engineering background. Participants will receive hands-on instruction on the use of chipKIT™ and Cerebot™ boards and how to integrate the boards into your curricula.

Friday, October 5

| | | |
|---------------------|--------------------------|--------------------|
| 10 am – Noon | Objet 3D Printing | Seneca Room |
|---------------------|--------------------------|--------------------|

| | | |
|--------------------|-----------------|--------------------|
| 1:30 – 3 pm | Digilent | Seneca Room |
|--------------------|-----------------|--------------------|

Topic: Hands-on Analog Design for Every Student - New Analog Discovery

Speaker: Mr. Clint Cole, Washington State University, and President of Digilent

Description:

The Digilent Analog Discovery is an inexpensive professional grade hardware and software system that provides a platform for students to explore principles of analog and digital circuits through hands-on design projects. Building on Digilent's successful EE board and with support of Analog Devices, the Discovery board is half the price of the EE board but contains the same key features. It allows students to build and verify real circuits and systems at their own pace and at any location. Participants will receive hands-on instructions on the use of the board and curriculum examples.

| | | |
|-----------------------|----------------------|--------------------|
| 3:30 – 5:50 pm | The MathWorks | Seneca Room |
|-----------------------|----------------------|--------------------|

Topic: Enabling Project-Based Learning with MATLAB, Simulink, and affordable hardware

Speaker: Ye Cheng is a member of the Educational Technical Evangelist team at MathWorks who explore how best to work with universities to help prepare the next generation of engineers and scientists. Ye holds PhD and MS degrees in mechanical and aerospace engineering, specialized in advanced imaging techniques for the study of fluid mechanics. After four-years teaching of senior lab courses, Ye has been working with professors across disciplines from various universities to leverage MATLAB and Simulink for teaching.

Description:

See the description for Thursday afternoon's showcase. This will be the same workshop that was given then.

PLENARY SESSIONS

Thursday, October 4, 8 – 9:30 am
Grand Ballroom A

WIKISPEED - Revolutionizing Transportation through Agile, Lean and Scrum

WIKISPEED is a globally distributed team of over 150 volunteers that are building 100 MPG cars that are safe, fun, light, fast, sleek and affordable. We've taken popular software development practices: - Agile, Lean and Scrum - and applied them to manufacturing. This has resulted in Extreme Manufacturing which leverages resources and team potential to quickly create viable prototypes and products in a short amount of time. WIKISPEED is now spreading these practices to organizations in other manufacturing sectors and helping them achieve even greater success.

Speaker

Tom Taber has been a very active volunteer with the WIKISPEED team for over a year. He has been able to leverage his experiences in software development, rock climbing, project management, competition barbecuing, 3D modeling, plumbing, social psychology, sweeping and public speaking to contribute to a number of team successes. He currently lives in Las Vegas, NV, but has been spending increasing long stints in Seattle working with the WIKISPEED team to help create a more awesome world to live in.

Friday, October 5, 8 – 9:30 am
Grand Ballroom AB

Is There a MOOC in Your Future?

This plenary session will examine current trends and future prospects in online education. Massive Open Online Courses (MOOCs) have gotten a great deal of publicity in the last year, although the most widely-known MOOC offerings do not capture all of the richness of the original MOOCs. Much of the attention paid to MOOCs in the press has been centered around the idea that they may challenge the organizational structures and cost models of higher education. The participants in this session will address many of these issues through a moderated discussion and a question and answer session with the audience.

Participants:

Fred Martin, Ph.D., Associate Professor, Department of Computer Science and Associate Dean, College of Sciences, University of Massachusetts Lowell

Fred Martin directs the Engaging Computing Group, which develops tangible computational materials for science education, robotics education, and computer science education. His publications include work on informal robotics education, teachers' attitudes toward inquiry-based science using data-loggers, artificial intelligence education, and robotic sensing. He recently published an essay in the Communications of the ACM detailing his experiences teaching in the "flipped classroom" style using a MOOC.

Dan Grossman, Ph.D., Associate Professor of Computer Science & Engineering, University of Washington

Dan Grossman has authored over 50 research publications in programming languages, including collaborations with researchers in computer architecture, software engineering, and databases. Dan has chaired the SIGPLAN Education Board and currently serves on the steering committee for the ACM / IEEE-CS 2013 Computer Science Curriculum. He is preparing to teach a programming-languages course on Coursera in January 2013 that is attracting roughly 300 registrations per day. More generally, he is leading the effort in his department to offer 4-5 courses over the next year while interacting with Coursera and other interests at the University of Washington to best align goals and plans.

Jennifer Dalby, M.Ed., Instructional Designer, Seattle University

Jennifer Dalby has supported faculty in the adoption of innovative learning technologies since 2001. In 2007, she began practicing Viral Professional Development, hosting open online learning sessions, which attracted international participation from faculty across disciplines. She practices open teaching and learning, connecting her students with external peers and experts. Through her consulting work, Jennifer advises administrators on emerging trends and opportunities in both profit and non-profit higher education. You may access her portfolio and shared resources at <http://portfolio.injenuity.com/>

GROUP MEETINGS

FIE 2012 WORKSHOPS

Wednesday, 1:30 – 8:30 p.m. (Pre-Registration is required.)

On Wednesday afternoon and evening, FIE features workshops—highly interactive sessions selected for their timeliness and value. Workshops offer a concentrated professional development experience. The wide range of workshop topics offers opportunities for everyone from new faculty members to the most experienced educators to expand their skills and knowledge.

Conference attendees must register separately for workshops. There is a \$50 registration fee for each workshop. Complete abstracts for the workshops can be found in the Wednesday schedule of the program book.

NEW FACULTY FELLOW PROGRAM

Each year, FIE invites new engineering and computer science faculty to submit applications for possible selection as New Faculty Fellows. A review panel of engineering and computer science faculty from assistant, associate, and full professorship levels completes a rigorous peer review of each applicant's conference paper, nomination letters and professional résumé. The fellowship provides a \$1,000 grant for conference travel expenses.

The purpose of the program is to promote the involvement of new faculty in the Frontiers in Education Conference so they will be exposed to the "latest and greatest" in engineering educational practices and will have the opportunity to exchange information with leaders in education innovations. This year, FIE 2012 will provide two registration and travel grants for awardees to attend the conference.

Focus on New Faculty Fellows

Each fellow will present a conference paper during FIE 2012. Join them in their session and share your thoughts and ideas about the future of engineering education. Also, during the Focus on Exhibits session Friday at 3 p.m., the Fellows will display posters describing their interests and activities and previewing the full papers that they will present as part of the FIE 2012 technical sessions.

2012 New Faculty Fellows:

Christine F. Reilly

Department of Computer Science
University of Texas – Pan American

Session T1H *The Impact of Real-World Topic Labs on Student Performance in CSI*, Christine Reilly (University of Texas - Pan American, USA); Noe De La Mora (University of Texas - Pan American, USA)

Adam Carberry

College of Technology & Innovation, Department of Engineering
Arizona State University

Session T1G *Peer Mentoring: Linking the Value of a Reflective Activity to Graduate Student Development*, Brook Sattler (University of Washington, USA); Adam R Carberry (Arizona State University, USA); Lauren Thomas (Virginia Tech, USA)

Session T2E *Work in Progress: Developing an Innovation Self-Efficacy Survey*, Elizabeth Gerber (Northwestern University, USA); Caitlin K Martin (Northwestern University & Stanford University, USA); Adam R Carberry (Arizona State University, USA); Elizabeth Kramer (Northwestern University, USA); Jennie Braunstein (Northwestern University, USA)

Session F1F *Work in Progress: Teaching Game Design and Robotics Together: A Natural Marriage of Computing and Engineering Design in a First-Year Engineering Course*, Adam R Carberry (Arizona State University, USA); Ashish Amresh (Arizona State University, USA)

Session F3F *Standards-Based Grading: Preliminary Studies to Quantify Changes in Affective and Cognitive Student Behaviors*, Adam R Carberry (Arizona State University, USA); Matthew Siniawski (Loyola Marymount University, USA); John Dionisio (Loyola Marymount University, USA)

CONFERENCE AMENITIES

Breakfast

7:00 a.m.–8:00 a.m. Thursday Metropolitan Ballroom Prefunction Area

7:00 a.m.–8:00 a.m. Friday Grand Ballroom AB

7:00 a.m.–8:00 a.m. Saturday Metropolitan Ballroom

Refreshment Breaks • Exhibit Hall - Metropolitan Ballroom

Morning and afternoon breaks Thursday and Friday

Lunches

Frederick Emmons Terman and Harriet B. Rigas Awards Luncheon - Grand Ballroom AB **Sponsored by the Hewlett-Packard Company**

Noon –1:30 p.m. Thursday

The Frederick Emmons Terman Award is presented annually to an outstanding young electrical engineering educator by the Electrical and Computer Engineering Division of the American Society for Engineering Education. The Harriet B. Rigas Award is presented annually to an outstanding woman engineering educator in recognition of her contributions to the profession.

Premier Award Luncheon - Grand Ballroom AB

Sponsored by John Wiley & Sons, Microsoft Research, Autodesk, and Techsmith

Noon –1:30 p.m. Friday

The Premier Award for Excellence in Engineering Education Courseware recognizes high-quality, noncommercial courseware that enhances engineering education. The award promotes successful courseware and provides models of excellence for educators.

Session F2A, directly following the luncheon, has been reserved for the presentation, demonstration and dissemination of the Premier Award Winner software.

Reception

6:15 p.m.–9:30 p.m. Friday

Join your colleagues as we board busses and take the short ride to the Museum of Flight for a reception. We will have drinks and heavy hors d'oeuvres catered by McCormick & Schmick's. We will also have exclusive access to the exhibits. Be sure to bring the drink tickets you received when you checked in at registration.

New Faculty Fellows • Exhibit Hall – Metropolitan Ballroom

3:00 p.m.–4:00 p.m. Friday

A special session focusing on the New Faculty Fellows will be held on Friday. This session will provide an opportunity to meet this year's New Faculty Fellows, a group of new CSET educators who were selected based on an application and a full paper being presented at this year's conference. There will also be an opportunity to view their poster presentations at this time.

Focus on Exhibits • Exhibit Hall – Metropolitan Ballroom

3:00 p.m.–4:00 p.m. Friday

Visit the FIE exhibits and check out the latest textbooks, computer software, lab equipment, and other innovations while enjoying refreshments provided by our sponsor.

Awards Banquet • Cirrus Ballroom

6:00 p.m.–8:30 p.m. Thursday

This year's awards banquet features fine food, drink, and camaraderie along with presentation of special awards from FIE, the IEEE Education Society, and the IEEE Computer Society. There is a separate charge for the banquet.

FIE Registration Conference Desk • Metropolitan Ballroom Prefunction

Registration will be open during these times:

| | |
|-----------|------------------------|
| Wednesday | 11:00 a.m. – 6:00 p.m. |
| Thursday | 7:00 a.m. – 5:00 p.m. |
| Friday | 7:00 a.m. – 5:00 p.m. |
| Saturday | 7:00 a.m. – 10 a.m. |

Hospitality Table • Near Conference Registration

If you are looking for a certain kind of a restaurant, shop, golf course, or health club, stop by the hospitality table close to the registration area. Maps and brochures of area attractions will be available.

FIE Message Center • Near Conference Registration

The conference will maintain a message board by the registration area. Messages received for conferees will be posted there. In an emergency, we will make every effort to locate you.

2012 FIE CONFERENCE AWARDS PRESENTATIONS

Thursday, October 4..... Terman/Rigas Awards Luncheon

Noon - 1:30 p.m.

ASEE ECE Division Hewlett-Packard Frederick Emmons Terman Award

IEEE Education Society Hewlett-Packard/Harriet B. Rigas Award

Thursday, October 4..... Awards Banquet

6:00 p.m - 8:30 p.m.

Frontiers in Education (FIE) Conference Awards

FIE 2011 Benjamin J. Dasher Best Paper Award

FIE 2011 Helen Plants Award

FIE Ronald J. Schmitz Award

IEEE Education Society

ASEE ECE Division Hewlett-Packard Frederick Emmons Terman Award

Presented by Martina Trucco

For an outstanding young electrical engineering educator in recognition of his contribution to the profession

Ali M. Niknejad received the B.S.E.E. degree from the University of California, Los Angeles, in 1994, and his Master's and Ph.D. degrees in electrical engineering from the University of California, Berkeley, in 1997 and 2000. During his graduate studies, he authored *ASITIC*, a CAD tool that aids in the simulation and design of passive circuit elements such as inductors into silicon integrated circuits. After graduation from Berkeley he worked in industry focusing on the design and research of analog RF integrated circuits and devices for wireless communication applications. He is currently an associate professor in the EECS department at UC Berkeley and co-director of the Berkeley Wireless Research Center and the BSIM Research Group. He served as an associate editor of the IEEE JSSC and on the TPC for ISSCC/CICC. Prof. Niknejad was co-recipient of the Outstanding Technology Directions Paper at ISSCC 2004 for co-developing a modeling approach for devices up to 65 GHz. He is also co-recipient of the 2010 Jack Kilby Award for Outstanding Student Paper for his work on a 90 GHz pulser with 30 GHz of bandwidth for medical imaging. His students have also been awarded numerous best paper awards at RFIC. Prof. Niknejad is a co-founder of HMicro and inventor of the REACH^(TM) technology, which has the potential to deliver robust wireless solutions to the healthcare industry. His research interests lie within the area of wireless and broadband communications and biomedical imaging (RF, mm-wave, and sub-THz), including the implementation of integrated communication systems in silicon using CMOS, SiGe, and BiCMOS processes. His focus areas of his research include analog, RF, mixed-signal, mm-wave circuits, device physics and compact modeling, and numerical techniques in electromagnetics. He is currently an IEEE Solid-State Circuits Society Distinguished Lecturer.

ASEE ECE Division Hewlett-Packard Frederick Emmons Terman Award (continued)

About the Terman Award

The Frederick Emmons Terman Award is presented annually to an outstanding young electrical engineering educator by the Electrical and Computer Engineering Division of the American Society for Engineering Education. The Terman Award, established in 1969 by the Hewlett-Packard Company, consists of \$5,000, an engraved gold-plated medal, a bronze replica of the medal mounted on a walnut plaque, and a parchment certificate.

The recipient must be an electrical engineering educator who is less than 45 years old on June 1 of the year in which the award is presented and must be the principal author of an electrical engineering textbook published before June 1 of the year of his/her 40th birthday. The book must have been judged by his/her peers to be an outstanding original contribution to the field of electrical engineering. The recipient must also have displayed outstanding achievements in teaching, research, guidance of students, and other related activities.

About Frederick Emmons Terman

Frederick Emmons Terman received his A.B. degree in chemistry in 1920, the degree of engineer in electrical engineering in 1922 from Stanford University, and his Sc.D. degree in electrical engineering in 1924 from Massachusetts Institute of Technology. From 1925-1965, he served as instructor, then professor of electrical engineering, executive head of the Electrical Engineering Department, dean of the School of Engineering, provost, vice president, and finally, as acting president of Stanford University.

Among the many honors bestowed upon him were: the IEEE Medal of Honor; the first IEEE Education Medal; the ASEE's Lamme Medal; the 1970 Herbert Hoover Medal for Distinguished Service to Stanford University; an honorary doctor's degree by Harvard; a decoration by the British government; the Presidential Medal for merit as a result of his war work; and the 1976 National Medal of Science from President Ford at a White House ceremony.

Dr. Terman was a professor at Stanford University when William Hewlett and Dave Packard were engineering students there. It was under Dr. Terman's guidance in graduate work on radio engineering that Mr. Hewlett built the first tunable and automatically stabilized Weinbridge oscillator. Partially through Dr. Terman's urging, Hewlett and Packard set up their partnership in an old garage with \$538 and the oscillator as their principal assets.

Dr. Terman died in December 1982. It is in appreciation of his accomplishments and guidance that Hewlett-Packard is proud to sponsor the Frederick Emmons Terman Award.

IEEE Education Society Hewlett-Packard Harriet B. Rigas Award

Presented by Martina Trucco

For her sustained work in creating a pipeline of robotics programs that effectively encourage young people to pursue careers in engineering

Dr. Tanja Karp received her Dipl.-Ing. (M.S.) and Dr.-Ing. (Ph.D.) degrees in Electrical Engineering from the Technical University of Hamburg-Harburg, Germany, in 1993 and 1997, respectively. She is currently an Associate Professor of Electrical and Computer Engineering at Texas Tech University in Lubbock, Texas. Prior to joining the faculty at Texas Tech in 2000, Dr. Karp was a Senior Research and Teaching Associate at the Institute of Computer Engineering at Mannheim University, Germany. Her research interests include digital signal processing, multicarrier communications, and STEM education. She has published over 75 journal and conference articles in these areas.

Since 2005, Dr. Karp has been involved in K-12 engineering outreach geared at attracting more and better qualified students into engineering careers and increasing the retention of engineering undergraduate students. She has taken a leadership role in among her colleagues at the university in organizing high school student summer camps at Texas Tech University and has implemented a pipeline of engineering activities for K-12 students during the academic year. She annually organizes the Get Excited About Robotics (GEAR) competition in Lubbock. During this 8-week long competition students from elementary and middle schools design LEGO NXT robots to autonomously perform tasks described in the annually changing challenge. Participants are mentored by engineering freshmen enrolled in a Service Learning introductory engineering course which she regularly teaches. Since 2006 the Lubbock GEAR competition has grown from a single participating school to over 600 students from 50 schools and attracts a large percentage of female participants (>40%).

Dr. Karp is a senior member of IEEE and a member of the Society of Women Engineers (SWE). Since 2011 she has served as the faculty advisor of the Texas Tech student SWE section, which organized the SWE Region C conference in Lubbock in January 2012. She also serves as the Fulbright Program Adviser for Texas Tech University.

Dr. Karp has received several awards for her excellence and innovation in teaching including the Lockheed Martin Aeronautics Company Excellence in Engineering Teaching Award (2003 and 2009), the Spencer A. Wells Creativity in Teaching Award from the Texas Tech Parent Association (2006), the College of Engineering George T. & Gladys Abell Hanger Faculty Teaching Award (2006) and the Butler Distinguished Educator Award (2012). She was a Service Learning Fellow during the academic year 2009/2010 and served as a Mentor for TTU's Service Learning Program in 2010/2011.

IEEE Education Society Hewlett-Packard Harriet B. Rigas Award (continued)

About the Rigas Award

The Harriet B. Rigas Award is presented annually to recognize outstanding faculty women who have made significant contributions to electrical/computer engineering education. The award consists of an honorarium, plaque, certificate, and Frontiers in Education Conference registration.

The recipient must be a tenured or tenure track woman faculty member in an ABET-accredited engineering program in the United States, with teaching and/or research specialization in electrical/computer engineering.

About Harriett B. Rigas

Dr. Harriett B. Rigas (1934-1989), an IEEE Fellow, was an electrical engineer with an international reputation for her hybrid computer and computer simulation research. At Washington State University between 1966 and 1984, she was eventually both full professor and chair of Electrical and Computing Engineering School. Later she chaired larger departments at the Navy's Postgraduate School in Monterey and, at the time of her death, Michigan State University.

Her achievements in engineering research, administration, and service were widely recognized. In 1975-76, Harriett was a Program Director at the National Science Foundation and, over the years, a member of numerous panels and advisory committees at both the NSF and the national Academy of Sciences.

Professor Rigas' success was achieved within a profession and within university administrative structures where there were very few women. Her character and courage were both evident in her strong advocacy of advancement for women. She was involved both locally and nationally in the Society of Women Engineers.

Frontiers in Education Conference Benjamin J. Dasher Best Paper Award

Presented by Arnold Pears

Developing Instruments to Assess First-year Calculus and Physics Mechanics Skills Needed for a Sophomore Statics and Dynamics Course
by K. Shryock, A. R. Srinivasa, and J. E. Froyd
FIE 2011, Session F1J

Kristi J. Shryock received her B.S. and M.S. degrees in Aerospace Engineering at Texas A&M University in 1998 and 2000, respectively. She received her Ph.D. degree in Interdisciplinary Engineering at Texas A&M University in 2011 with a research focus on engineering education. She currently serves as the Assistant Department Head for Undergraduate Programs and Outreach in the Department of Aerospace Engineering at Texas A&M University. She is also a Senior Lecturer in the Department.

Her teaching and research focuses on improving the undergraduate engineering experience through evaluating preparation in mathematics and physics. In addition, she works to incorporate new technologies, experiential education, and multi-disciplinary design into the classroom. The work in the Dasher paper specifically evaluates the alignment of the mathematics and physics students learn in their freshman year with the knowledge needed in their sophomore year and beyond in engineering.

Arun Srinivasa obtained his bachelor's degree from the mechanical engineering department in IIT Madras in 1986. He received his PhD from the University of California at Berkeley in 1991 in Mechanical Engineering with minors in Materials Science and Mathematics. His PhD thesis was on dislocation dynamics. He subsequently joined the University of Pittsburgh faculty from 1993 to 1997 and then moved to Texas A&M University, where he is a professor of mechanical engineering. He was the holder of the Halliburton Professorship between 2010 and 2011 and is now William Kheeler Faculty fellow. He spent a year at Texas A&M Qatar from 2011 to 2012. He is the author of the book *Inelasticity of Materials, An Engineering Approach and a Practical Guide* (World Scientific Press) along with Dr. Sivakumar Srinivasan from IIT Madras.

His research interests include simulation of materials processing and other dissipative phenomena, design of "smart components" using shape memory alloys and polymers, cosserat continua and algorithms for fast virtual reality simulations for educational purposes. He is very much involved in the use of technology in education and in the use of DIY toys and manipulatives for educational purposes.

Jeffrey E. Froyd (Fellow, IEEE) received the B.S. degree in mathematics from Rose-Hulman Institute of Technology, Terre Haute, IN, in 1975 and the M.S. and Ph.D. degrees in electrical engineering from the University of Minnesota, Minneapolis, in 1976 and 1979, respectively.

He is a TEES Research Professor in the Engineering Student Services and Academic Programs at Texas A&M University, College Station. Prior to this, he was an Assistant Professor, Associate Professor, and Professor of Electrical and Computer Engineering at Rose-Hulman Institute of Technology. He served as

Project Director for the Foundation Coalition, a National Science Foundation (NSF) Engineering Education Coalition in which six institutions systematically renewed, assessed, and institutionalized their undergraduate engineering curricula, and extensively shared their results with the engineering education community. At Rose-Hulman, he co-created (with Brian Winkel) the Integrated, First-Year Curriculum in Science, Engineering and Mathematics, which was recognized in 1997 with a Hesburgh Award Certificate of Excellence. He has authored over 70 papers on faculty development, curricular change processes, curriculum redesign, and assessment.

Prof. Froyd is a Fellow of the American Society for Engineering Education, an Accreditation Board for Engineering and Technology (ABET) Program Evaluator, and a Senior Associate Editor for the Journal of Engineering Education. He has served as a program co-chair for the 2003, 2004, and 2011 Frontiers in Education Conferences and the general chair for the 2009 Frontiers in Education Conference.

Frontiers in Education Conference Benjamin J. Dasher Best Paper Award (continued)

About the Dasher Award

The Benjamin Dasher Best Paper Award is given to the best paper presented at the annual Frontiers in Education Conference, as demonstrated by technical originality, technical importance and accuracy, quality of oral presentation, and quality of the written paper appearing in the Conference Proceedings. Papers are nominated for the award by reviewers.

A committee with representation from each of the organizing societies (ERM, IEEE Ed. Soc., IEEE Comp. Soc.) is formed to review nominated papers. During the FIE meeting, the committee attends presentations of the nominated papers. The committee then makes a final recommendation to the FIE Planning Committee for the Ben Dasher Award winner based on the overall quality of both the paper and the presentation.

About Benjamin J. Dasher

Benjamin J. Dasher was born December 27, 1912 in Macon, Ga. He earned his bachelor's and master's degrees in electrical engineering in 1935 and 1945, respectively, and graduated with a doctorate in electrical engineering in 1952 from the Massachusetts Institute of Technology. At MIT, Dr. Dasher worked on the electronics of instrumentation of electromechanical transducers and analog-to-digital converters. He was the author of "Dasher's method" for synthesis of resistance-capacitance two-port networks, which is found in standard textbook treatments.

While at Georgia Tech, Dr. Dasher served as a graduate assistant in 1936, then as an instructor in 1940, and became an assistant professor in 1945. While earning his PhD at MIT, he was an instructor from 1948-51. Before finishing with his PhD, he became an associate professor at Georgia Tech in 1951, was promoted to professor in 1952, and became director of the School of Electrical Engineering in 1954, where he served in that capacity until 1969. In 1968, Dr. Dasher was appointed associate dean in the College of Engineering. At Georgia Tech, Dr. Dasher served as director of network synthesis projects and transistor oscillator projects. His fields of interest included advanced network theory, electronic theory, electronic circuits, electrical engineering education, machine translation, speech analysis, and pattern recognition. He was credited for bringing undergraduate engineering education to the forefront at Georgia Tech and for increasing interactions between undergraduates and industry.

Dr. Dasher was a member of Phi Kappa Phi, ASEE, Sigma Xi, and the American Association of University Professors; he was a Fellow of both the IEEE and the Institute of Radio Engineers. He served as a regional director for IEEE and as the chair for the Atlanta section of IEEE; he was on numerous committees for IRE, AIEE, and IEEE. He served as President of the IEEE Education Group in 1970-71.

Ben Dasher organized the first Frontiers in Education Conference; it was held in Atlanta in 1971, and attracted 100 participants. There were 34 papers in six technical sessions.

Dr. Dasher died of congestive heart failure on December 13, 1971 in Houston, Texas.

Frontiers in Education Conference Helen Plants Award Best Nontraditional Session at FIE 2011

Presented by Susan Lord

Cognitive Processes Critical for Ill-Defined Problem Solving: Linking Theory, Research, and Classroom Implications

Şenay Purzer and Jonathan C. Hilpert, FIE 2011, Session T2A

Şenay Purzer is an Assistant Professor in the School of Engineering Education and is the Director of Assessment Research for the Institute for P-12 Engineering Research and Learning (INSPIRE) at Purdue University. She received a B.S.E with distinction in Engineering at Arizona State University in 2009 and a B.S. degree in Physics Education in 1999. Her M.A. and Ph.D. degrees are in Science Education from Arizona State University earned in 2002 and 2008, respectively.

Dr. Purzer is a NAE/CASEE New Faculty Fellow. She is also the recipient of a 2012 NSF CAREER award, which examines how engineering students approach innovation. Her research focuses on assessment, engineering innovation, and mixed-methods research. She is currently leading projects funded by NSF, NASA, and corporate foundations. She has published over 70 peer-reviewed conference and journal papers on engineering and science education. Her research laboratory, Engineering Learning Observatory, houses projects on video and discourse analysis methods to examine engineering students' approaches to innovation, design thinking, and collaborative decision-making processes. She is a 2009 National Effective Teaching Institute (NETI) fellow and currently teaches courses on educational research methods and engineering design.

Dr. Purzer has been active in engineering education since 2005 as an author and paper reviewer. She has chaired the ASEE Educational Research and Methods Division (ERM) best paper award selection committee in 2012 and is currently a Director of ASEE-ERM division. She serves in the review boards of several journals including the Journal of Engineering Education (JEE) and Science Education and is an editorial board member for the Journal of Pre-College Engineering Education (JPEER).

Jonathan C. Hilpert, a professor of Educational Psychology at Georgia Southern University in the College of Education, received his bachelor's degree in education from Pepperdine University in 2000 and his masters and PhD from Arizona State University in 2008. His area of expertise is the content application and statistical specification of domain general learning models to engineering classrooms. The models he develops are grounded in information processing theory and focus primarily on the intersection of motivation, cognition, and instructional strategies at the post-secondary level. Some notable accomplishments include being named an FIE new faculty fellow in 2008 and being awarded an NSF RAPID grant in 2009 to study the impact of engineering professors' efforts to improve instruction on student motivation and knowledge building.

About the Plants Award

The Helen Plants Award is given for the best special (non-traditional) session at the FIE conference, as demonstrated by originality, session content and presentation including the use of written materials and visual aids, and participation of session attendees.

About Helen Margaret Lester Plants

Helen Margaret Lester was born in Desloge, Missouri, in March 1925, the only child of Rollo Bertell and Margaret Stephens Lester.

She entered the University of Missouri as a journalism major, but soon switched to Civil Engineering. She received her BSCE in 1945. She joined West Virginia University in 1947 as a graduate student and Instructor in Mechanics, and received her MS in Civil Engineering in 1953. She was a Professor of Theoretical and Applied Mechanics and of Curriculum and Instruction in the Division of Education at WVU. She became Professor Emeritus, Mechanical and Aerospace Engineering in 1983. From 1985 to 1990 she served as Chair of Civil Engineering Technology at Indiana University-Purdue University - Fort Wayne.

Her husband Ken Plants had been a "bureaucrat" with the US Bureau of Mines in Morgantown - a chemical engineer with great expertise in cost estimation. Some of their "courting" evenings were spent manually checking the design calculations on the Star City, WV Bridge, designed by the Dean and State Bridge Engineer. While in Morgantown, Helen was active in Trinity Episcopal Church where she served as a Vestryman and Bishop's Man. For many years she was a Girl Scout leader. Helen died in Tulsa, Oklahoma in September 1999.

From the beginning of her academic career, she was a gifted teacher and a role model for the few women students at West Virginia University at that time. Later, she became an advocate of programmed and individualized instruction. She and Wally Venable wrote series of papers on these topics and several texts: *Introduction to Statics, a Programmed Text*, (1975), *A Programmed Introduction to Dynamics* (1967), and *Mechanics of Materials, A Programmed Textbook* (1974). She established the first doctoral program in Engineering Education at West Virginia University.

In 1975, the University of Missouri at Columbia recognized her with the Missouri Honor Award for Distinguished Service in Engineering. She became an ASEE Fellow in 1983 as a member of the first class of Fellows. She also received Distinguished Service Award, Western Electric Fund Award, and was an ASEE Vice-President (1974 – 1976).

Frontiers in Education Conference Ronald J. Schmitz Award

Presented by Susan Lord

For outstanding service to the Frontiers in Education Conference

Arnold Pears received his BSc(Hons) in 1986 and PhD in 1994, both from La Trobe University, Melbourne, Australia. He occupied positions as lecturer and senior lecturer at La Trobe University between 1991 and 1998. In 1999 he was appointed as senior lecturer at Uppsala University, Sweden. He was awarded the Uppsala University Pedagogy Prize in 2008, and appointed as Associate Professor of Computing Education Research in May 2011. Roles at Uppsala University include appointment to the University Academic Senate, Programme Director for the IT Engineering programme, member of the selection committee for the Uppsala University Pedagogy prize and as member of the educational advisory board of the Faculty of Technology and Natural Sciences.

He has a strong interest in teaching and learning research in computer science and engineering, and leads the UpCERG research group in computing and engineering education research at Uppsala University. He has published 25 articles in the area internationally, and is well known as a computing education researcher through his professional activities in the ACM, and IEEE. In the IEEE he serves as a member of the Board of Governors of the IEEE Computer Society, where he is active in the Education Activities Board, serving also on the steering committee of the Frontiers in Education Conference and as Chair of the newly established Special Technical Community (STC) for Education. In addition he is a Director of CeTUSS (The Swedish National Center for Pedagogical Development of Technology Education in a Societal and Student Oriented Context, www.cetuss.se) and the IEEE Education Society Nordic Chapter.

He as a reviewer for a number of major journals and conferences, including the Computer Science Education Journal (Taylor and Francis), the ACM SIGCSE and ITiCSE and Koli Calling International Computer Science Education conferences.

Recent publications include "Does Quality Assurance Enhance the Quality of Computing Education?", in the Proceedings of the 12th Australasian Computer Science Education Conference, 2010, and models for research driven education in Computing, "Conveying Conceptions of Quality through Instruction", in the 7th International Conference on the Quality of Information and Communications Technology, 2010.

Frontiers in Education Conference Ronald J. Schmitz Award (continued)

About the Schmitz Award

The Ronald Schmitz Award is given to recognize outstanding and continued service to engineering education through contributions to the Frontiers in Education Conference.

About Ronald J. Schmitz

Ronald J. Schmitz was born near Ionia, Iowa on April 25, 1934. He attended a one-room country school through the eighth grade and then, as was not uncommon at the time, decided to forgo high school and work on his father's farm. At age 18, he joined the United States Navy. He served as an Electricians Mate, spending much of his enlistment at sea and made a round-the-world cruise aboard the USS Saipan.

In the Navy, Ron found an interest in and an aptitude for technology and recognized the need for further education. He completed a GED program in the Navy and, when he was discharged, enrolled in electrical engineering at Iowa State University. He received all his degrees there, finishing his doctorate in 1967.

In the fall of 1967, he accepted appointment as Assistant Professor in the Department of Electrical Engineering at the South Dakota School of Mines and Technology in Rapid City. He was involved in various research activities and directed both masters and doctoral students, but his strongest interest was always in teaching. Ron was a consummate teacher, patient with students who were having difficulty but intolerant of sloth. He received the School of Mines Teaching Award in 1975 and the Western Electric Fund Award for Excellence in Teaching in 1981.

Dr. Schmitz was very active in the IEEE, especially the Education Society, and served as Secretary Treasurer of the Society. He was also active in ERM and attended, and contributed to, many Frontiers in Education Conferences. He served as general chair of FIE 1981 in Rapid City.

Ron was an avid hunter and fisherman, a devoted husband and father and a faithful friend. He served his church as Lector and Lay Minister and was active as a Boy Scout leader.

Ron contracted cancer in 1983 and died on July 19, 1984.

IEEE Education Society William E. Sayle II Award for Achievement in Education

Presented by Manuel Castro

For contributions to the theory and practice of education and educational technology through the creation of academic research centers, textbooks, software, and companies in the field of wireless communication engineering

Theodore (Ted) S. Rappaport is the David Lee/Ernst Weber Professor of Electrical Engineering at the Polytechnic Institute of New York University (NYU-Poly) and is a professor of computer science at New York University's Courant Institute of Mathematical Sciences, and professor of radiology at the New York University School of Medicine. Rappaport is founding director of NYU WIRELESS, a new kind of academic research center that combines wireless communications engineering and computer science with the practice of medicine and health care. He also serves as Director of the National Science Foundation (NSF) Industrial/University Collaborative Research Center for Wireless Internet Communications and Advanced Technology (WICAT), a national research center headquartered at NYU-Poly that involves five major universities, including the two wireless programs he founded at The University of Texas (WNCG in 2002) and Virginia Tech (MPRG in 1990).

Rappaport is a pioneer in the fields of radio wave propagation for cellular and personal communications, wireless communication system design, and broadband wireless communications circuits and systems at millimeter wave frequencies. His research has influenced many products and international standards for cellular and local/personal area wireless networks, and he and his students invented software radio and position location technologies in the early 1990's, and site-specific radio frequency (RF) channel modeling and design technologies for wireless network deployment in the late 1990's – technologies now used routinely throughout the field of wireless communications. As a faculty member, Rappaport has advised approximately 100 students who continue to accomplish great things in the communications, electromagnetics, and circuit design fields throughout industry, academia, and government.

In 2006, Rappaport was elected to the Board of Governors of the IEEE Communications Society (ComSoc), and to the Board of Governors of the IEEE Vehicular Technology Society (VTS) in 2008 and again in 2011. He is a fellow of the IEEE, is a member of the board of the Marconi Society, and serves on the editorial boards of several academic and technical journals. He received the Marconi Young Scientist Award in 1990, an NSF Presidential Faculty Fellowship in 1992, the Sarnoff Citation from the Radio Club of America in 2000, the Fredrick E. Terman Outstanding Electrical Engineering Faculty Award from the American Society for Engineering Education in 2002, and the Stuart F. Meyer Award from the IEEE Vehicular Technology Society in 2005. In 2008, he received the Industry Leadership Award from the Austin Wireless Alliance and the IEEE Communications Society WTC Recognition Award for outstanding achievements and contributions in the area of wireless communications systems and networks. The IET honored Rappaport with the Sir Monty Finniston medal in 2011 "for his outstanding academic and industrial contributions over almost three decades in the field of wireless communication." Rappaport has over 100 U.S. or international patents issued or pending and has authored, co-authored, and co-edited 18 books in the wireless field, including the best-selling textbook *Wireless Communications*

Principles & Practice (translated into 6 languages), Principles of Communication Systems Simulation with Wireless Applications, and Smart Antennas for Wireless Communications: IS-95 and Third Generation CDMA Applications. He has received three prize paper awards, including the 1999 Stephen O. Rice Prize Paper Award from the IEEE Communications Society for his work on site-specific propagation.

Rappaport has also been an entrepreneur, encouraging his students to create companies from their research. In 1989, he founded TSR Technologies, Inc., a cellular radio/PCS software radio manufacturer that he sold in 1993 to what is now Commscope, Inc. (taken private in 2011 by Carlyle Group). In 1995, he founded Wireless Valley Communications, Inc., a pioneering creator of site-specific radio propagation software for wireless network design and management that he sold in 2005 to Motorola. Rappaport has testified before the U.S. Congress, served as an international consultant for the International Telecommunication Union, consulted for more than 30 major telecommunications firms, and continues to work on many national committees pertaining to communications research and technology policy. He is a highly sought consultant and technical expert. He received BS, MS, and PhD degrees in electrical engineering from Purdue University in 1982, 1984, and 1987, respectively, and is an Outstanding Electrical Engineering Alumnus of his alma mater.

About the Sayle Award and William E. Sayle II

The William E. Sayle II Award is presented to recognize a member of the IEEE Education Society who has made significant contributions over a period of years in a field of interest of the IEEE Education Society. The award consists of a plaque, a certificate, and paid registration to the Frontiers in Education Conference.

Dr. William (Bill) E. Sayle received his BSEE and MSEE degrees from the University of Texas at Austin and his Ph.D. from the University of Washington. He joined the faculty in electrical engineering at Georgia Institute of Technology in 1970, just as Georgia Tech was beginning the transition from an undergraduate institution to a research university. He was the ECE associate chair for undergraduate affairs from 1988-2003 and, following retirement in 2003, served as director of undergraduate programs at Georgia Tech-Lorraine in France until 2007. Bill was a tireless advocate for students, putting in countless late night and weekend hours in addressing student issues, assigning teaching assistants, and meeting with prospective students and parents.

Throughout his career, Bill touched the lives of many people in the worldwide academic community. He was a leader and a pioneer in many areas. In the 1970s, he was a founding member of the IEEE Power Electronics Society, where he served in many leadership roles over the years. He was a champion of diversity and in recruiting underrepresented minorities and women to engineering and science, long before it became a national issue. He visited many high schools on behalf of the Southeastern Consortium for Minorities in Engineering, a role where he made many friends for Georgia Tech among high school administrators and students in the southern part of Georgia.

In his 30-year career at Georgia Tech, Bill received the ECE outstanding teacher award twice, as well as the Georgia Tech outstanding teacher award and outstanding service award. Bill lent his voice and efforts to Georgia Tech faculty governance throughout his career, serving as an elected member of Institute-level committees, the Academic Senate, and the Executive Board.

Bill was a long-time member and active volunteer in the IEEE Education Society and the Electrical and Computer Engineering Division of ASEE. He was a Fellow of both IEEE and ASEE. He was the recipient of the Education Society's 2001 Meritorious Service Award and 2004 Achievement Award and of the ECE Division's 2001 Meritorious Service Award and 2006 ECE Distinguished Educator Award. Bill was the General Chair of the 1995 Frontiers in Education (FIE) Conference, which is still remembered for its all-vegetarian menu, and received the 1996 Ronald J. Schmitz Award for outstanding service to FIE.

Much of Bill's professional career was devoted to engineering accreditation, serving at various times as member and chair of the IEEE Committee on Engineering Accreditation Activities and the IEEE Accreditation Policy Council. He participated in more than 20 visits as a program evaluator, in addition to serving as a team chair and member of the Engineering Accreditation Commission of ABET for more than five years. Bill received the IEEE Educational Activities Board Meritorious Achievement Award in Accreditation Activities in 2004.

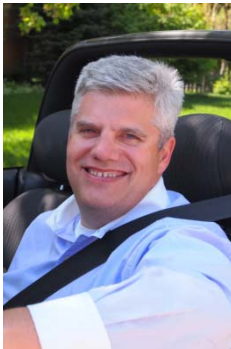

Dr. Sayle passed away on February 2, 2008.

IEEE *Transactions on Education* Best Paper Award

Presented by Manuel Castro

***Trajectories of Electrical Engineering and Computer Engineering
Students by Race and Gender, S.M. Lord, R.A. Layton and
M. W. Ohland, IEEE Transactions on Education
Vol. 54, No. 4, November 2011, pp. 610-618***

Susan M. Lord is Professor and Coordinator of Electrical Engineering at the University of San Diego. She received a B. S. with distinction in Electrical Engineering and Materials Science and Engineering from Cornell University and the M.S. and Ph.D. in Electrical Engineering from Stanford University. From 1993-1997, Dr. Lord taught at Bucknell University. Author of over eighty publications, her teaching and research interests include electronics, optoelectronic materials and devices, service-learning, feminist pedagogy, lifelong learning, and engineering student persistence. Dr. Lord's industrial experience includes AT&T Bell Laboratories, General Motors Laboratories, NASA Goddard Space Flight Center, and SPAWAR Systems Center.

Dr. Lord's research in engineering education has been supported by several National Science Foundation (NSF) grants from programs including CAREER, instrumentation and laboratory improvement (ILI), scholarships for STEM (SSTEM), gender in science and engineering (GSE), and research in engineering education. These projects span a range of topics from engineering student persistence, to helping military veterans transition to engineering programs to optoelectronics experiments for first-year students. Since entering college, Dr. Lord has been committed to increasing diversity in engineering particularly supporting women and underrepresented minorities. In 1995, she was awarded the Eta Kappa Nu Outstanding Young Electrical Engineer Honorable Mention for "outstanding technical contributions to the field of optoelectronics and dedication to education and promoting the engineering profession for minorities and women." She and her colleagues received the 2005 Helen Plants Award for "Feminist Frontiers." She was named the 2010 Outstanding Engineering Educator by the San Diego County Engineering Council.

Dr. Lord has been active in the engineering education community since 1993. She is a senior member of the IEEE and Society of Women Engineers (SWE) and a member of ASEE and Tau Beta Pi. In addition to regularly presenting papers at the Frontiers in Education (FIE) and ASEE Conferences, she has held several leadership positions including FIE Steering Committee Member, General Co-Chair of FIE 2006, FIE 2005 Program Co-Chair, and elected member of administrative boards of the IEEE Education Society (EdSoc) and ASEE Education and Research Methods (ERM) Division. She served as the Vice President of EdSoc for 2007 and 2008 and the President for 2009 and 2010. She was the 2011 National Effective Teaching Institute (NETI) fellow.

Dr. Lord and her collaborators have been recognized for their longitudinal studies of engineering students with the William Elgin Wickenden Award for the Best Paper published in the Journal of Engineering Education in 2011. She was Guest Co-Editor of the 2010 Special Issue of the *International Journal of Engineering Education* (IJEE) on Applications of Engineering Education Research. Dr. Lord is an Associate Editor of the *IEEE Transactions on Education* and a member of the Editorial Board for IJEE.

Richard A. Layton is an Associate Professor of Mechanical Engineering and past director of the Center for the Practice and Scholarship of Education at Rose-Hulman Institute of Technology. He received a B.S. from California State University, Northridge, and an M.S. and Ph.D. from the University of Washington. His professional work includes research in student teaming and student pathways (persistence, migration, and retention) and consulting in data visualization and graph design.

Dr. Layton's teaching practice includes formal and informal cooperative learning with a generous portion of learn-by-thinking-and-doing. For over a decade, he has worked to transform student labs from procedure-driven exercises (push this button, read that gauge, get the data and leave) to problem-based learning experiences. More recently, he and his colleagues have redesigned a first-year design course to incorporate substantive learning objectives in sustainability, communication, teaming, and professional ethics.

Dr. Layton is a founding member of the team that developed the CATME system, a web-based suite of tools for managing teams and winner of the 2009 Premier Award for Excellence in Engineering Education Courseware. He and his collaborators have been recognized for their longitudinal studies of engineering students with the William Elgin Wickenden Award for the Best Paper published in the Journal of Engineering Education in 2008 and 2011. Layton is a member of the Educational Research and Methods (ERM) Division of the American Society of Engineering Education (ASEE) and has served as Director, 2009 FIE Program Co-Chair, and 2012 ASEE-ERM Program Chair.

He is also a songwriter, singer, and guitar player who can occasionally be heard at an open-mic.

Dr. Matthew Ohland is a Professor of Engineering Education at Purdue University. He has a Ph.D. in Civil Engineering from the University of Florida in 1996. Previously, he earned an M.S. in Materials Engineering in 1992 and an M.S. in Mechanical Engineering in 1991 from Rensselaer Polytechnic Institute and a B.S. in Engineering and a B.A. in Religion from Swarthmore College. He has had previous appointments as Associate Professor of General Engineering at Clemson University, Assistant Director of the NSF-sponsored SUCCEED Engineering Education Coalition, and a National Science Foundation Postdoctoral Fellow for Science, Mathematics, Engineering, and Technology Education. His research on the longitudinal study of engineering student development, team formation, peer evaluation, and extending the use of active and cooperative learning methods has been supported by over \$11.8 million from the National Science Foundation and the Sloan Foundation.

Dr. Ohland serves the IEEE Education Society as a member of the Board of Governors (2007-2013) and as an Associate Editor of IEEE Transactions on Education. He was the Chair of the Steering Committee of IEEE Transactions on Learning Technologies (2007-2011). He has also served as an Expert in the IEEE Public Visibility program. He was elevated to Senior Member grade in 2009 and was previously recognized by IEEE with the Benjamin Dasher Award for the best paper/presentation in the 2004 Frontiers in Education conference and the Helen Plants Award for the best non-traditional session at the 2008 Frontiers in Education Conference.

Dr. Ohland is a Fellow of the American Society of Engineering Education and has served the Educational Research and Methods division as Chair (2009-2011), Director (2001-2003 and 2008-2009), and Vice-Chair for FIE Programs / Program Chair for FIE 2008. He also serves ASEE as an ABET Program Evaluator for

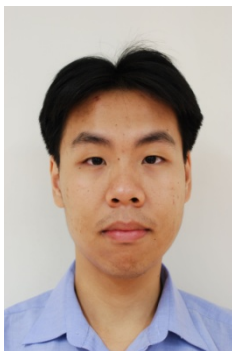

general engineering programs. Dr. Ohland was the 2002–2006 President of Tau Beta Pi, the national engineering honor society, and has delivered volunteer seminars reaching over 2000 students through the Association’s award-winning Engineering Futures program.

Dr. Ohland and his collaborators have been recognized for their longitudinal studies of engineering students with the William Elgin Wickenden Award for the Best Paper published in the Journal of Engineering Education in 2008 and 2011 and best paper awards at multiple conferences. The CATME and Team-Maker tools for managing teams developed under Dr. Ohland’s leadership received the 2009 Premier Award for Excellence in Engineering Education Courseware. Dr. Ohland was recognized by Clemson University in 2006 with the Byar’s Prize for Excellence in Teaching Engineering Fundamentals and by Purdue’s School of Engineering Education with the Best Teacher Award in 2007, 2008, and 2012.

IEEE Education Society Chapter Achievement Award

Presented by Edmundo Tovar

In recognition of the Chapter's proven results in spreading IEEE Education Society's interests in China and Southeast Asia, thanks to outstanding leadership by its officers

Dr. Yuen-Yan Chan (M'07–SM'08) received B.Eng., M.Phil. and Ph.D. degrees in information engineering and the M.Ed. degree in educational psychology from the Chinese University of Hong Kong, Hong Kong, in 1998, 2000, 2006, and 2009, respectively. She is the Founding Chair and the current Chair of the IEEE Education Society Hong Kong Chapter. She is with the Department of Information Engineering, Chinese University of Hong Kong, Shatin, Hong Kong.

Dr. Kai-Pan Mark is currently the vice-chair of the Chapters Committee, IEEE Education Society and also the vice-chair of IEEE Education Society Hong Kong Chapter. He received his Ph.D. in Information Systems from City University of Hong Kong, his Master of Science in Information Engineering from The Chinese University of Hong Kong and his Bachelor of Science and Associate of Science, both in Computer Studies from City University of Hong Kong. Dr. Mark's research interest is on the behavioral aspects of different stakeholders in e-Learning systems addressing issues on habitual behavior formation through personalization and IT artifact design. He is an active volunteer in an IEEE Teacher in Service Program project in Hong Kong to provide assistance and support to science and technology education in rural small schools. He was a recipient of IEEE Education Society Student Leadership award 2010, and was also a FIE New Faculty Fellow in 2010.

Ms. Doris Ng (M'2007-) supports the Hong Kong Chapter as the Honorary Secretary. She received her B.B.A. in China Business from The City University of Hong Kong and M.A. in Communication from Hong Kong Baptist University in 2001 and 2009, respectively. She is now the Regional Marketing Manager, Enterprise Business, South East Asia of Huawei Technology Investment Co., Ltd. Before joining Huawei, she served as the Marketing Manager at Hewlett-Packard Hong Kong S.A.R. Limited.

Honorary Treasurer –
James Ho

Mr. Yu-Ho Ho serves as Honorary Treasurer of the Hong Kong Chapter of IEEE Education Society. He received his Postgraduate Dip. in Education and Bachelor of Engineering in Information Engineering from The Chinese University of Hong Kong, Hong Kong in 2008, and 2007, respectively. Mr. Ho's current research interest is on the anthroposophy educational philosophy, Waldorf education, a humanistic approach to pedagogy based on the educational philosophy. He is active in Developmental Kinesiology, Educational Kinesiology sectors in Hong Kong. He is a professional security consultant on IT systems in business sectors.

IEEE Education Society Distinguished Chapter Leadership Award

Presented by Edmundo Tovar

The Colombia chapter and the activity in the Andes Region has increased directly due to his efforts. Being well-aware of the situation of the Latin America region, he has dedicated himself to changing its standing in the world.

Dr. German Cabuya Parra graduated as an electronic engineer from the Universidad Distrital "Francisco José de Caldas" in 1989 and completed a postgraduate specialist degree at Escuela Superior de Administración Pública (ESAP) in 2001. He is currently the Information and communications Technology Office Head of the Special Administrative Unit of Public Services of Bogota (UAESP). He also holds a position as professor and counselor at the University Francisco José de Caldas.

Dr. Cabuya is an IEEE senior member, a Nikkoryu-kai member, and a senior management specialist of the state. His interests include engineering, education, telecommunications, aerospace, robotics, recruitment, supervision, administration, ethics, and journalism.

IEEE Education Society Distinguished Member Award

Presented by Manuel Castro

For outstanding contributions in support of teamwork in higher education and student retention through research, courseware, archival publications, and presentations

Dr. Matthew Ohland is a Professor of Engineering Education at Purdue University. He has a Ph.D. in Civil Engineering from the University of Florida in 1996. Previously, he earned an M.S. in Materials Engineering in 1992 and an M.S. in Mechanical Engineering in 1991 from Rensselaer Polytechnic Institute and a B.S. in Engineering and a B.A. in Religion from Swarthmore College. He has had previous appointments as Associate Professor of General Engineering at Clemson University, Assistant Director of the NSF-sponsored SUCCEED Engineering Education Coalition, and a National Science Foundation Postdoctoral Fellow for Science, Mathematics, Engineering, and Technology Education. His research on the longitudinal study of engineering student development, team formation, peer evaluation, and extending the use of active and cooperative learning methods has been supported by over \$11.8 million from the National Science Foundation and the Sloan Foundation.

Dr. Ohland serves the IEEE Education Society as a member of the Board of Governors (2007-2013) and as an Associate Editor of IEEE Transactions on Education. He was the Chair of the Steering Committee of IEEE Transactions on Learning Technologies (2007-2011). He has also served as an Expert in the IEEE Public Visibility program. He was elevated to Senior Member grade in 2009 and was previously recognized by IEEE with the Benjamin Dasher Award for the best paper/presentation in the 2004 Frontiers in Education conference and the Helen Plants Award for the best non-traditional session at the 2008 Frontiers in Education Conference.

Dr. Ohland is a Fellow of the American Society of Engineering Education and has served the Educational Research and Methods division as Chair (2009-2011), Director (2001-2003 and 2008-2009), and Vice-Chair for FIE Programs / Program Chair for FIE 2008. He also serves ASEE as an ABET Program Evaluator for general engineering programs. Dr. Ohland was the 2002–2006 President of Tau Beta Pi, the national engineering honor society, and has delivered volunteer seminars reaching over 2000 students through the Association's award-winning Engineering Futures program.

Dr. Ohland and his collaborators have been recognized for their longitudinal studies of engineering students with the William Elgin Wickenden Award for the Best Paper published in the Journal of Engineering Education in 2008 and 2011 and best paper awards at multiple conferences. The CATME and Team-Maker tools for managing teams developed under Dr. Ohland's leadership received the 2009 Premier Award for Excellence in Engineering Education Courseware. Dr. Ohland was recognized by Clemson University in 2006 with the Byar's Prize for Excellence in Teaching Engineering Fundamentals and by Purdue's School of Engineering Education with the Best Teacher Award in 2007, 2008, and 2012.

IEEE Education Society Edwin C. Jones, Jr. Meritorious Service Award

Presented by Manuel Castro

For contributions to engineering education and the Education Society through service as President, Ad Com Member, General and Program Chairs for the Frontiers in Education Conference, Strategic Planning, Editorial Board Member, and the All Society Review Panel

Susan M. Lord is Professor and Coordinator of Electrical Engineering at the University of San Diego. She received a B. S. with distinction in Electrical Engineering and Materials Science and Engineering from Cornell University and the M.S. and Ph.D. in Electrical Engineering from Stanford University. From 1993-1997, Dr. Lord taught at Bucknell University. Author of over eighty publications, her teaching and research interests include electronics, optoelectronic materials and devices, service-learning, feminist pedagogy, lifelong learning, and engineering student persistence. Dr. Lord's industrial experience includes AT&T Bell Laboratories, General Motors Laboratories, NASA Goddard Space Flight Center, and SPAWAR Systems Center.

Dr. Lord's research in engineering education has been supported by several National Science Foundation (NSF) grants from programs including CAREER, instrumentation and laboratory improvement (ILI), scholarships for STEM (SSTEM), gender in science and engineering (GSE), and research in engineering education. These projects span a range of topics from engineering student persistence, to helping military veterans transition to engineering programs to optoelectronics experiments for first-year students. Since entering college, Dr. Lord has been committed to increasing diversity in engineering particularly supporting women and underrepresented minorities. In 1995, she was awarded the Eta Kappa Nu Outstanding Young Electrical Engineer Honorable Mention for "outstanding technical contributions to the field of optoelectronics and dedication to education and promoting the engineering profession for minorities and women." She and her colleagues received the 2005 Helen Plants Award for "Feminist Frontiers." She was named the 2010 Outstanding Engineering Educator by the San Diego County Engineering Council.

Dr. Lord has been active in the engineering education community since 1993. She is a senior member of the IEEE and Society of Women Engineers (SWE) and a member of ASEE and Tau Beta Pi. In addition to regularly presenting papers at the Frontiers in Education (FIE) and ASEE Conferences, she has held several leadership positions including FIE Steering Committee Member, General Co-Chair of FIE 2006, FIE 2005 Program Co-Chair, and elected member of administrative boards of the IEEE Education Society (EdSoc) and ASEE Education and Research Methods (ERM) Division. She served as the Vice President of EdSoc for 2007 and 2008 and the President for 2009 and 2010. She was the 2011 National Effective Teaching Institute (NETI) fellow.

Dr. Lord and her collaborators have been recognized for their longitudinal studies of engineering students with the William Elgin Wickenden Award for the Best Paper published in the Journal of Engineering Education in 2011. She was Guest Co-Editor of the 2010 Special Issue of the *International Journal of Engineering Education* (IJEE) on Applications of Engineering Education Research. Dr. Lord is an Associate Editor of the *IEEE Transactions on Education* and a member of the Editorial Board for IJEE.

About the Edwin C. Jones Award

The Edwin C. Jones Meritorious Service Award is presented to recognize a member of the IEEE Education Society who has made pioneering contributions to the administrative efforts of the IEEE Education Society over a period of years. The award consists of a plaque, a certificate, and registration to the Frontiers in Education Conference.

About Edwin C. Jones

Professor Jones served as a Society officer from 1970 through 1976; this service included two years as president. He served as Editor-in-Chief of the *IEEE Transactions on Education* from 1982-84. Since he first became involved in the Society in the late 1960s, he has held virtually every office in the Education Society. He is still actively involved with the Education Society. Professor Jones also serves the IEEE as a member of the IEEE Committee on Engineering Accreditation Activities. Dr. Jones is University Professor and Associate Chair, emeritus, Department of Electrical and Computer Engineering, Iowa State University. Prior to joining Iowa State in 1966, he was an Assistant Professor at the University of Illinois from 1962-66. He received his PhD in 1962 from the University of Illinois; the DIC in 1956 from Imperial College of Science and Technology, University of London; and the BSEE in 1955 from West Virginia University. Dr. Jones' honors and awards include: Fellow, Institute of Electrical and Electronics Engineers; Fellow, American Society for Engineering Education; Fellow, American Association for Advancement of Science; Fellow, Accreditation Board for Engineering and Technology; IEEE Centennial Medal, 1984; ASEE Centennial Medal, 1993.

Babak Ayazifar
University of California,
Berkeley

Past Recipients

IEEE Education Society Mac Van Valkenburg Early Career Teaching Award

Presented by Manuel Castro

For creative, lively, challenging, and caring teaching that has sparked broad excitement and engagement among his students, even in the largest core courses.

Babak Ayazifar joined the EECS faculty at UC Berkeley in 2005, where he is now a Lecturer with Security of Employment (Lecturer SOE)—equivalent to an Associate Professor in Teaching with tenure. He earned his B.S. in EE from Caltech, and his S.M. and Ph.D. in EECS from MIT. In his doctoral research, he applied spectral graph theory to the study of the mutual influence of a network's topology and dynamics. This led to his dissertation, *Graph Spectra and Modal Dynamics of Oscillatory Networks*.

At MIT, Babak received the *Harold L. Hazen Award* for outstanding teaching. He advanced to the rank of *Instructor-G*, which conferred teaching assignments ordinarily reserved for faculty. He won the *Goodwin Medal*, MIT's most prestigious award for a graduate student whose teaching is "conspicuously effective over and above ordinary excellence." And, in spring 2002, he took leave from his graduate studies to take an appointment as a *Senior Lecturer* at MIT's School of Engineering, teaching a graduate course in digital signal processing.

Immediately prior to his faculty appointment at UC Berkeley, Babak was a Technical Specialist in the *Intellectual Property and Technology Group* of *Ropes & Gray, LLP*. His intellectual property experience spans patent prosecution and related activities over a wide range of technologies, such as mechanical devices, intravascular MRI, DNA Microarray data analysis, and encrypted communication using chaotic systems. Babak is a patent agent, registered to practice before the *United States Patent and Trademark Office* (Reg. No. 56793).

At UC Berkeley, he has focused on teaching; student learning; curriculum development and reform; mentoring graduate and undergraduate teaching assistants; and sharing the results of his pedagogical innovations and insight at international conferences and other forums. In spring 2008, Babak received the UC Berkeley EE Division's *Outstanding Teaching Award for Excellence in Teaching*.

Elio San Cristobal Ruiz
Universidad Nacional de
Educación a Distancia

Past Recipients

- '09 Seiji Isotani
- '10 Emmanuel Gonzalez and
Kai-Pan Mark
- '11 Dario Schor

IEEE Education Society Student Leadership Award

Presented by Manuel Castro

***For his outstanding contributions to the consolidation of the IEEE
UNED (Spanish University for Distance Education) Student Branch***

Elio San Cristobal Ruiz has a Ph.D. degree in electrical and computer engineering from the Spanish University for Distance Education (UNED), Madrid, Spain, in 2010.

Currently he is working as an Assistant Professor with the Electrical and Computer Engineering Department, Industrial School of UNED. He is involved in several European projects and a NSF project in the field of education and the application of virtual and remote laboratories in distance learning.

He has been involved in IEEE activities since 2006, being chairman of the IEEE UNED student branch from 2009 to 2010. Currently he is a member of the Spanish Chapter of the IEEE Education Society.

Sergio Martin

- '11 Dario Schor

IEEE Education Society Student Leadership Award

Presented by Manuel Castro

***For his outstanding contributions to the consolidation of the IEEE
UNED (Spanish University for Distance Education) Student Branch***

Sergio Martin (M'06) was born in Madrid, Spain, in 1980. He received the Ph.D. degree in electrical and computer engineering from the Spanish University for Distance Education (UNED), Madrid, Spain, in 2010.

He has worked as an Assistant Professor with the Electrical and Computer Engineering Department, Industrial School of UNED, since 2007. Since 2002, he has participated in the department's national and international research projects. He has received two best thesis awards and four best paper awards.

Dr. Martin has been involved in IEEE activities since 2006, being chairman of the IEEE UNED student branch from 2007 to 2008. Currently he is an advisory board member of the Spanish Chapter of the IEEE Education Society and of the IEEE Technology Management Council of Spain.

REVIEWERS

This year, FIE 2012 had over 680 papers and presentations submitted for consideration. The FIE2012 Program Committee wishes to thank the following individuals for acting as abstract and paper reviewers. The program committee asked these individuals to help control the quality of the presentations at this year's conference by reviewing the submissions for FIE2012. Their outstanding effort has helped maintain the high standard that has become the reputation of each FIE conference.

If you are interested in becoming a reviewer for a future FIE conference, please visit FIEconference.org.

CATALYZING COLLABORATIVE CONVERSATIONS

Catalyzing Collaborating Conversations are open-invitation special sessions, where members of the FIE community present an educational challenge, idea, or research result where they would like to work with others to solve the challenge or develop the idea or result further. This special session concept is unique to FIE, and allows colleagues from around the world to propose a topic and organize an impromptu session where they and other researchers get together to discuss the idea and determine ways that the participants might come together to develop the idea further. These sessions are open to any FIE participant.

5:10 PM - 6:00 PM

T4A: Informed Decisions about Majors and Possible Careers in Engineering Catalyzing Collaborative Conversations

Chairs: Philip R Brown (Virginia Tech, USA), Holly Matusovich (Virginia Tech, USA)

Catalyzing Collaborative Conversations: This session consists of a facilitated panel discussion about the effects that informed (and uninformed) decisions about degree choices can have on students and engineering programs, current and possible research related to informed decisions, and practical implications for engineering programs with regards to how they can facilitate informed decisions.

Informed Decisions about Majors and Possible Careers in Engineering

Philip R Brown (Virginia Tech, USA)

Holly Matusovich (Virginia Tech, USA)

Deciding to pursue an engineering degree, for many students, comes at a tumultuous time between secondary and higher education. This is also a time students contemplate the possibilities of what they can do with the rest of their lives. Informed decision-making could help students make better choices by helping them relate how obtaining a certain degree can connect to their goals and desired career and life outcomes. However, there are a number of potential hurdles to approaching this informed decision. Students can be uncertain about their goals and desired outcomes. They can be misinformed or have misconceptions about how a degree relates to certain outcomes. In addition, students are often required to make decisions about their degree before they can fully consider what that decision means. This session consists of a facilitated panel discussion about the effects that informed (and uninformed) decisions about degree choices can have on students and engineering programs, current and possible research related to informed decisions, and practical implications for engineering programs with regards to how they can facilitate informed decisions.

T4B: Designing Engineering Endorsements for P-12 Teacher Licensure Catalyzing Collaborative Conversations

Chairs: Susan Donohue (United States & University of Virginia, USA), Larry Richards (University of Virginia, USA)

Efforts to bring engineering to P-12 classrooms may not be as effective as possible if opportunities for professional development are not provided. Endorsements are one logical place to start, and can serve as a foundation for the design of a truly integrated STEM undergraduate major. What subjects should a teacher demonstrate knowledge of to receive an endorsement in engineering?

Designing Engineering Endorsements for P-12 Teacher Licensure

Susan Donohue (United States & University of Virginia, USA)

Larry Richards (University of Virginia, USA)

As engineering knowledge and practice filter into the P-12 classroom setting and engineering becomes part of state and national P-12 educational standards in math, science, and technology, the call will arise to provide a means for certifying P-12 teachers in engineering. We thus have an excellent opportunity to have students involved in engineering throughout their elementary and secondary education careers, and to demonstrate the power of engineering design to integrate STEM knowledge and make math and science concepts tangible and understandable. However, P-12 STEM education has long faced the issue of teachers working "out of their field," and this situation has definitely had a negative impact on student learning and achievement. Thus, efforts to bring engineering to P-12 classrooms may not be as effective as possible if opportunities for professional development are not provided. Endorsements are one logical place to start, and can serve as a foundation for the design of a truly integrated STEM undergraduate major. What subjects should a teacher demonstrate knowledge of to receive an endorsement in engineering? This conversation is related to the one on the philosophical underpinnings of engineering education facilitated by John Heywood, Russ Korte, Karl Smith, Mani Mina, John Krupczak, Jr., and William Grimson: what does it mean to be an engineer? What are the essential knowledge, skills, and abilities?

T4C: Beyond the Classroom: Preparing Faculty to Enable Student Success Catalyzing Collaborative Conversations

Chair: Emily L Allen (San Jose State University, USA)

This session will be a moderated brainstorming and sharing discussion on the topics of better preparing faculty for roles in advising, mentoring, leadership development and other elements related to student success.

Beyond the Classroom: Preparing Faculty to Enable Student Success

Emily L Allen (San Jose State University, USA)

Classrooms and laboratories, both virtual and physical, have traditionally been the sole domain of faculty. As pedagogical methods have changed and researchers have focused more on how students learn, faculty development has grown to encompass various type of teaching techniques, and practitioners strive to change the classroom to accommodate our new knowledge. However, student success is an outcome which is impacted by many factors outside of the classroom. Faculty are called upon for many tasks beyond traditional teaching and research. The "service" area of our workload, including student advising and mentoring, increasingly requires a deeper understanding of student attributes, backgrounds, and challenges, and significantly better communication skills than in previous times. With the advance of online and flipped learning, the classroom may become a thing of the past and faculty may eventually become learning mentors. Do engineering faculty know how to effectively carry out such a role? This session will be a moderated brainstorming and sharing discussion on the topics of better preparing faculty for roles in advising, mentoring, leadership development and other elements related to student success.

T4D: A Research Plan for Mind Maps for Design and Word Problems Catalyzing Collaborative Conversations

Chair: Peter A Jamieson (Miami University, USA)

A Research plan for Maps and Design and Word Problems Peter A Jamieson (Miami University, USA)

In this session, our goal is to explore the challenges students have with word and design problems, and explore the possibility of using mind maps and concept maps to help them organize and solve (begin to solve) these types of problems. Concept maps and mind maps are useful class assessment techniques that can be used to explore a student's understanding of the relationship between concepts. These relationships are a form of organization, and this suggests that mind maps and concept maps could be used to organize the concepts in a design or word problem so that a student can see the connections for the relevant aspects of a problem. Our goal during this session is to explore this possibility and design an experiment(s) to test our ideas. To achieve the above, the session will be organized over four steps with group sharing and discussion. As a precursor, the facilitator will quickly describe the two types of mapping techniques and provide some examples. As a first step, we will discuss what experience we have observed with students and problems. Second, we will establish one or two (maybe more) research questions that the group thinks will be testable questions and have value to student learning. Third, based on the questions selected, we will propose a number of hypotheses and mapping methods based on our questions, which we can experimentally test. Finally, we will establish some metrics of measurement to assess the proposed methods. With these steps, we can then decide if there is interest in the participating group and prepare to test the research in the classroom.

T4E: Developing a Classification Scheme for "Introduction to Engineering" Courses Catalyzing Collaborative Conversations

Chair: Kenneth Reid (Ohio Northern University, USA)

This session invites those interested in developing a classification scheme for "Introduction to Engineering" courses. The goal of the session will be to catalog efforts underway toward the overall goal of developing a classification scheme and to create a community of practice to facilitate this development.

Developing a Classification Scheme for "Introduction to Engineering" Courses Kenneth Reid (Ohio Northern University, USA)

Many Universities and Community Colleges offer a course entitled "Introduction to Engineering" or similar. These are often designed from scratch and tend to be "personal courses" - designed by instructors to cover what they feel is important. Therefore, while they may be prerequisites to second-year courses, first-year engineering programs are not necessarily integrated into the curriculum. Further, since they are often designed with little consideration for existing models, overall outcomes and content vary widely. This leads to three issues: first, course developers often "reinvent the wheel" by failing to disseminate successful models. The problem is exacerbated by a lack of definition of first year models: a developer may know what they want in a course, but how do they find a course with similar outcomes with nothing more than "first-year engineering" as a description? Second, with little focus on specification of models for these courses, many become a grab bag of unrelated topics. Finally, there are issues preventing community colleges from offering "Introduction to Engineering" courses, leading to disadvantages for students who could transfer into 4-year programs. Without standard outcomes for a first-year course, students may receive credit for material that is much different than material they covered, and community colleges may not be able to design an introductory engineering course that is applicable to multiple institutions. This session will invite those interested in developing a classification scheme for "Introduction to Engineering" courses. The goal of the session will be to catalog efforts underway toward the overall goal of developing a classification scheme and to create a community of practice to facilitate this development.

T4F: Communicating an Engineering Curriculum via Concept Maps Catalyzing Collaborative Conversations

Chair: Jennifer French (Massachusetts Institute of Technology, USA)

The presentation will introduce session participants to the Map using VUE, a web-based concept-mapping tool created by researchers at Tufts. We hope to facilitate a group discussion to generate innovative ideas about how this work might be transformed to benefit a broader audience.

Communicating an Engineering Curriculum via Concept Map

Jennifer French (Massachusetts Institute of Technology, USA)

In order to develop a set of curricular materials for the Singapore University of Technology and Design, the Teaching and Learning Laboratory at MIT identified pivotal concepts and skills from the first three semesters of their engineering curriculum. This exercise led to the creation of an Engineering Curriculum Map (the Map). The Map is organized around four major intended learning outcomes (ILOs, as defined by Biggs and Tang), and connects them to concepts and skills that engineering students must master. The Map links to a series of smaller, more focused maps that show connections among concepts at a finer level of granularity. We believe the Map, and the process we used to develop it, could be useful to faculty designing engineering courses and curriculum, as well as to engineering students. We have gathered preliminary feedback from engineering educators on the content and presentation format of the Map, and we will use this FIE session to collect additional comments and suggestions. This session will involve a brief presentation followed by a group discussion. The presentation will introduce session participants to the Map using VUE, a web-based concept-mapping tool created by researchers at Tufts. We will also illustrate how we utilized the overarching themes identified in the Map to create a set of 15-minute instructional videos and accompanying instructor guides. We hope to facilitate a group discussion to generate innovative ideas about how this work might be transformed to benefit a broader audience.

T4G: Global Software Engineering Collaboration Catalyzing Collaborative Conversations

Chair: Wook-Sung Yoo (Fairfield University, USA)

This session will provide opportunity for educators to share the information of updated curriculum, process, tools, and to establish collaborative projects among multiple schools to prepare our software engineering students to be successful in global environment.

Global Software Engineering Collaboration

Wook-Sung Yoo (Fairfield University, USA)

Stephen T Frezza (Gannon University, USA)

In today's global economy, software engineers are expected to operate in a distributed professional environment with geographical, temporal, and cultural distance. Global Software Engineering has more complexities over the local software development and we need to educate our future software engineers to build skills necessary to create innovative software in this global environment and to manage global software projects. To participate, one simply needs to share an interest in preparing students to operate as global software engineers, and to help them to be more successful in a global environment. This session will provide opportunity for educators to share information on successes and failures, impacts to curriculum, identification of skill sets needed, experience with process, tools that facilitate global software engineering projects. Above all, the session aims to provide opportunities to establish collaborative projects among multiple schools.

SESSION GRID - WEDNESDAY, OCTOBER 3RD

| | | | | | | | |
|----------------|--|--|---|--|--|--|---|
| 1:30 PM | Workshop: A Workshop on How Learning Works | Workshop: Learning Agile Through Active Learning Activities | Workshop: Assessing Professional Skills for ABET | Workshop: What were we thinking? TECHNICAL SESSIONS TABLE OF CONTENTS

Wednesday, October 3rd

Track 1 - 1:30 - 4:30pm

Workshop: A Workshop on How Learning Works

Maura Borrego (National Science Foundation, USA)

Guy-Alain Ammoussou (National Science Foundation, USA)

Louis Everett (National Science Foundation, USA)

Susan Finger (National Science Foundation, USA)

Zhanjing (John) Yu (National Science Foundation, USA)

Track 1 - 5:30 - 8:30pm

Workshop: Evaluation of Educational Research and Development Projects 1

Zhanjing (John) Yu (National Science Foundation, USA)

Maura Borrego (Virginia Tech, USA)

Louis Everett (National Science Foundation, USA)

Susan Finger (National Science Foundation, USA)

Don Millard (National Science Foundation, USA)

Track 2 - 1:30 - 4:30pm

Workshop: Learning Agile Through Active Learning Activities 3

Jennifer Polack-Wahl (University of Mary Washington, USA)

Karen Anwalt (University of Mary Washington, USA)

Track 2 - 5:30 - 8:30pm

Workshop: Using Student Scrums for Course and Capstone Projects

Tom Reichlmayr (Rochester Institute of Technology, USA)

Track 3 - 1:30 - 4:30pm

Workshop: Assessing Professional Skills for ABET 4

Phillip Thompson (Seattle University, USA)

Denny Davis (Washington State University, USA)

Steven Beyerlein (University of Idaho, USA)

Michael Trevisan (Washington State University, USA)

Jay McCormack (University of Idaho, USA)

Howard Davis (Washington State University, USA)

Track 3 - 5:30 - 8:30pm

Workshop: Training students to become better raters: Raising the quality of self- and peer-evaluations using a new feature of the CATME system..... 6

Richard Layton (Rose-Hulman Institute of Technology, USA)

Matthew W Ohland (Purdue University, USA)

Misty Loughry (Georgia Southern University, USA)

Track 4 - 1:30 - 4:30pm

Workshop : What were we thinking? Critically examining our beliefs about the purposes and goals of engineering and engineering education

Russell Korte (University of Illinois at Urbana-Champaign, USA)

John Krupczak, Jr (Hope College, USA)

Mani Mina (Iowa, USA)

William Grimson (Dublin Institute of Technology, Dublin Ireland, Ireland)

Track 4 - 5:30 - 8:30pm

Workshop: Teaching Engineering Design to Middle and High School Students using STEAM Machines™

Shawn Jordan (Arizona State University, USA)

Odesma Dalrymple (Arizona State University, USA)

Nielsen Pereira (Western Kentucky University, USA)

Track 5 - 1:30 - 4:30pm

Workshop: Building Learning Tools using IMS Learning Tools Interoperability8

Charles Severance (University of Michigan, USA)

Track 5 - 5:30 - 8:30pm

Workshop: Case Study Teaching in Software Development Curricula

Thomas Hilburn (Embry-Riddle Aeronautical University, USA)

Massood Towhidnejad (Embry-Riddle Aeronautical University, USA)

Salamah Salamah (Embry-Riddle Aeronautical University, USA)

Track 6 - 1:30 - 4:30pm

Workshop: Interactive Education Tools for Earth Systems and Sustainability Applications.....10

Linda Hinnov (Johns Hopkins University, USA)

Andreas Spanias (ASU / SenSIP Center / School of ECEE, USA)

Karthikeyan Natesan Ramamurthy (Arizona State University, USA)

Girish Kalyanasundaram (Arizona State University, USA)

Track 6 - 5:30 - 8:30pm

Workshop: Project-Enhanced Learning in Engineering Science Education.....12

Razi Nalim (IUPUI, USA)

Manikanada Rajagopal (IUPUI, USA)

Robert Helfenbein (Indiana University--IUPUI, USA)

Track 7 - 1:30 - 4:30pm

Workshop: Teaching Computer Security Literacy to the Masses: A Practical Approach14

Doug Jacobson (Iowa State University, USA)

Julie Rursch (Iowa State University, USA)

Joseph Idziorek (Iowa State University, USA)

Track 7 - 5:30 - 8:30pm

Workshop: It's More Than Coding: Using Video Scenarios to Engage Students in Computing16

Madalene Spezialetti (Trinity College, USA)

Thursday, October 4th

10:00 AM - 11:50 AM

T1A: All About Design 1

Chair: Eric Pappas (James Madison University, USA)

Work in Progress: Student Outcomes of Design Projects Across the Curriculum.....18

Kathryn Trenshaw (University of Illinois at Urbana-Champaign, USA)

Jerrod Henderson (University of Illinois at Urbana-Champaign, USA)

Ayesha Boyce (University of Illinois at Urbana-Champaign, USA)

Lizanne DeStefano (University of Illinois at Urbana-Champaign, USA)

Differences between Same-sex and Cross-sex Mentoring Relationships in Capstone Design Courses20

James Pembridge (Embry-Riddle Aeronautical University, USA)

Marie Paretti (Virginia Tech, USA)

Work in Progress: Investigating the Engineering Design Process: Novices vs. Experts25

Ting Song (Utah State University, USA)

Kurt Becker (Utah State University, USA)

Design Considerations: Implications of Domain Expertise27

Kristina Krause (University of Washington, USA)

Cindy Atman (University of Washington, USA)

Jim Borgford-Parnell (University of Washington, USA)

Kate Deibel (University of Washington, USA)

A Comparison of Electrical, Computer, and Chemical Engineering Facultys' Progressions through the Innovation-Decision Process.....33

Stephanie Cutler (Virginia Tech, USA)

Maura Borrego (Virginia Tech, USA)

Charles Henderson (Western Michigan University, USA)

Michael Prince (Bucknell University, USA)

Jeffrey Froyd (Texas A&M University, USA)

Examining the Effect of Design Education on the Design Cognition: Measurements from Protocol Studies.....38

Christopher Williams (Virginia Tech, USA)

Workshop: Evaluation of Educational Research and Development Projects

Pre-Conference Workshop

Z. Yu, M. Borrego, L. J. Everett, S. Finger, and D. L. Millard
Division of Undergraduate Education
National Science Foundation
Arlington, VA 22230

Abstract— With emphasis on project outcomes and impact, project evaluation is increasingly becoming an integral part of a NSF project. Lack of an evaluation plan in a proposal for an education project may be viewed by many NSF reviewers as a weakness. The purpose of this workshop is to give the participants enough background information so that they can work with an external evaluator to develop and implement an evaluation plan for an education research and development project, particularly NSF project.

Keywords—evaluation; evaluation types; evaluation tools; evaluation plan; data interpretation; Pimmel Format

I. GOAL AND OUTCOMES OF THE WORKSHOP

The goal of this workshop session is to prepare engineering faculty members to work with an evaluator to plan and implement an effective evaluation of an education research or development project. By the end of the workshops, the participant should be able to: 1) understand the need for evaluation; 2) explain the types of evaluations; 3) translate project goals to measurable outcomes and then to evaluation questions; 4) list and compare the evaluation tools commonly used in project evaluation; 5) interpret evaluation data; 6) explore causation relation between project outcomes and interventions; and 7) develop an evaluation plan with an evaluator.

II. WORKSHOP DESCRIPTION

A. Workshop Contents

The workshop will use the NSF 2010 User-Friendly Handbook for Project Evaluation as a guideline to discuss evaluation issues related to STEM educational and development projects.

1. The Needs for Evaluation

There are a couple of reasons that NSF grantees conduct project evaluation. First, evaluation about an on-going project provides information about the progress of the project which can be used by the project personnel to determine areas of success and failure and whether the project activities deviate from

proposed work and make adjustment accordingly. The second reason is that evaluation provides information to the stakeholders and measures the impact of the project. The information can be used to determine whether the project has achieved its objectives and whether resources have been used efficiently and effectively. The information can also be used to meet reporting requirements such as those mandated by the Government Performance and Results Act (GPRA).

2. Evaluation Types.

In general, evaluations can be classified into two categories: formative evaluation and summative evaluation. The former provides information on implementation and progress of the project and the latter provides information on the outcomes and impact.

3. Translate Project Goals into Expected Outcomes.

Evaluation methodologies depend on the expected outcomes of a project. The first step in the evaluation process is to translate the project goals into expected outcomes. The characteristics of goals may be general, broad and abstract. The expected outcomes, however, are the narrow, specific, tangible, measurable results that one expects to see if the goals are achieved.

4. Translate Expected Outcomes into Evaluation Question

Once the expected outcomes are specified, the evaluation questions should not be difficult to formulate. However, they should be designed in such a way that a determination of a causation relationship is possible.

5. Evaluation Tools

Evaluation tools can be classified into three categories: quantitative, qualitative and mixed methods. The quantitative methods are considered more objective traditionally, in which data can be analyzed with sophisticated statistical techniques. However, these methods may not be able to probe an issue in depth and sometimes, data accuracy problem may arise. Qualitative methods on the other hand rely on descriptive data and can be used to examine a topic in

more depth, but these methods may lack the statistical rigor of the quantitative analyses. The mixed methods can catch the advantages of both. The tools discussed include surveys, concept inventories, standardized tests, rubrics, observations, interviews and focus groups.

6. Interpreting Evaluation Data

When an intervention is implemented, we hope that it will have a positive impact and in most cases, it does. However, in interpreting data, one has to list the confounding factors and consider alternative explanation before drawing the conclusion. Similarly, if the results get worse after the intervention, one cannot automatically conclude that the intervention has failed and again the confounding factors must be considered.

7. Development of Evaluation Plan for an NSF Project

In developing an evaluation plan, one should consider all the topics discussed above and work with an external evaluator. The external evaluator should get involved early on in the development of the project evaluation plan. The workshop will also discuss where to find a qualified evaluator and what to expect from her/him.

B. Workshop Format

The workshop will use the Pimmel Format, named after former NSF program director Russell Pimmel. The format is based on the theories on learning and it is an active and

collaborative learning format. The theories assume that we all have some kind of prior knowledge (no matter how little or incorrect) on a topic. To learn, one has to recall prior knowledge, connect it with new concepts, correct misconceptions and reflect on new knowledge. In this format, the presenter will give some background information on a particular topic and post the central question. The audience, divided into groups, will use a think-share-report format to share their answers with the audience. The presenter will then give her/his response to the question. This way, the participants learn from the presenter as well as each other.

C. Anticipated Audience

The workshop is intended for faculty members who are either seeking external support for educational research and development projects, particularly NSF projects or are engaged in efforts to improve the educational experience of their students.

DISCLAIMER

The information in this workshop represents the opinions of the individual program directors and presenters and is not an official NSF position.

Workshop: Learning Agile Through Active Learning Activities

Jennifer Polack-Wahl and Karen Anewalt

University of Mary Washington, japwahl@gmail.com, anewalt@umw.edu

I. GOAL(S) OF THE WORKSHOP

Games and simulation are a great way to learn theories and new behaviors that can be applied to software engineering activities. The presenters are going to teach three games that can be used in a software engineering course or any course that deals with agile methods. The presenters will talk about the benefits of agile development and how these games will solidify behaviors that are essential to successful agile processes.

II. DESCRIPTION OF TOPICS/SUBJECTS/CONTENT OF THE WORKSHOP

Agile software processes are becoming more pervasive in industry settings; however these same processes have not been widely adopted in academic settings. A common thread among agile software processes is the iterative approach to the software lifecycle. It can be challenging to integrate a pure agile process in a typical software projects course due to the time constraints of a semester, but integrating elements of the agile approach can be useful from both an instructor and student perspective.

This tutorial will introduce the participants to the key principles of the agile software process which proclaims to value:

- Individuals and interactions over processes and tools.
- Working software over comprehensive documentation.
- Customer collaboration over contract negotiation.
- Responding to change over following a plan.

There are many flavors of agile processes and this tutorial will focus the Scrum model. Examples of how Scrum can be used to organize a classroom software development project will be discussed. Several open source tools that can be useful in supporting agile software projects from the requirements gathering phase through development and testing will be demonstrated.

Participants will engage in a participatory game to illustrate some of the main components of the agile software process model. Attendees will leave this tutorial with ideas for integrating agile approaches into their own projects courses.

III. WORKSHOP AGENDA (PLEASE GIVE DETAILS AND APPROXIMATE TIME ALLOTTED FOR EACH ACTIVITY)

- Introduction to Agile Methods (30 Minutes)
- Marshmallow Tower Challenge (40 Minutes)
- The Marshmallow Challenge is a remarkably fun and instructive design exercise that encourages teams to experience simple but profound lessons in collaboration, innovation and creativity.
- Collaborative Origami (30 Minutes)
- Collaborative Origami shows the importance of face to face communication (vs. distributed)
- Ball Point Game (30 Minutes)
- The ballpoint game by Boris Gloger is a great game for introducing Scrum to new agile teams.
- Reflection & Lessons Learned (20 Minutes)

IV. DESCRIPTION OF THE ANTICIPATED AUDIENCE

Instructors who teach about software development and want to learn strategies that will help teach agile software development or other software engineering techniques. Instructors of courses with non-software projects will also be interested in agile methods and their applications to such project-based courses. Students will also enjoy the hands on nature of the activities and find the reflection to be instructional.

Workshop: Assessing Professional Skills for ABET

Phillip Thompson, Denny Davis, Steve Beyerlein, Mike Trevisan, Jay McCormack and Howard Davis
thompson@seattleu.edu davis@wsu.edu trevisan@wsu.edu sbeyer@uidaho.edu mccormack@uidaho.edu davish@wsu.edu

Abstract – The Integrated Design Engineering Assessment and Learning System (IDEALS) is a set of assessment instruments that focus on aspects of professional development such as leadership, ethics, project management and communication skills within the context of capstone engineering design projects. These instruments have been piloted across a broad spectrum of diverse engineering programs and are available in a web format that facilitates data collection from students and feedback from instructional staff. This knowledge has been synthesized into a set of engaging and transferable modules that include learning objectives, supporting resource materials, preparatory tasks, lesson plans for faculty, and recommendations for timely follow-up using the online assessments. In addition, the instruments enhance student development through both formative and summative feedback and can be used to provide evidence for demonstrating the achievement of ABET student outcomes and program specific criteria.

Index Terms – ABET, Student Outcomes assessment, professional development

INTEGRATED DESIGN ENGINEERING ASSESSMENT AND LEARNING SYSTEM (IDEALS)

The capstone engineering design course is used by many engineering programs to demonstrate the achievement of student outcomes for ABET accreditation. In particular, capstone courses often seek to assess technical outcomes such as problem solving or design and interpersonal outcomes such as teamwork and communication. Civil engineering programs may also use the capstone experience to assess program-specific ABET criteria related to management and leadership.

Since the design products of capstone courses are typically from a group of students, it can be difficult to assess individual student outcomes for ABET. To facilitate this assessment and to encourage students to be aware of professional skill development, the Transferable Integrated Design Engineering Education (TIDEE) consortium developed the Integrated Design Engineering Assessment and Learning System (IDEALS) [1].

The IDEALS assessment system targets the development of technical skills (problem solving and design) and interpersonal skills (teamwork and communication). It also

focuses on the student's growth as a self-reflective professional. The IDEALS professional development assessments consist of pre-class and in-class activities combined with a progression of two formative assessments (Professional Development Planning and Professional Development Progress) and one summative assessment (Professional Development Achieved) that are used to prepare for, monitor, and summarize student professional development during the capstone course [3]. A companion instructional module and scoring rubric is provided with each assessment instrument in an instructor-friendly format that helps the instructor guide student development.

To reduce the time associated with reviewing student work, the IDEALS assessments have been implemented in a secure, web-based environment that contains the IDEALS assessment instruments, instructor and student interfaces, data archives, data processing, reporting functions, and companion instructional modules [4]. The instructor specifies the assignment by indicating which students are to receive it, the due date for student completion, and the targeted date for receiving instructor feedback.

While the IDEALS assessments include lesson plans and recommended timelines for formative and summative assessments and other supporting materials, they are flexible and have been easily integrated into a variety of engineering programs at both large public and small private institutions. Instructors who have used IDEALS assessments often create assignments related to the ABET student outcomes of teamwork or communication. After completing a pre-class skills inventory, students identify areas of improvement and write a plan for developing those areas. The students may then be asked to evaluate their professional development progress throughout the capstone course (formative assessment) or their professional development achievement by the end of the course (summative assessment).

After students complete each assessment assignment they receive feedback from the instructor online. Instructors are prompted to use a web-implemented version of the scoring rubric for each assessment and are provided comment boxes for writing additional feedback. The web system automates data compilation for instructor and student viewing. The assessment cycle is completed when students log back into the system to read feedback from the instructor. These reports can be easily accessed, printed and included as student exemplars of achievement for ABET site visits.

WORKSHOP OBJECTIVES

This workshop will describe features of the IDEALS curricula and assessment instruments and will analyze feedback from early adopters. After a brief overview of the IDEALS learning model and curricular materials, participants will score samples of student work in small groups, discuss their results and share with the larger group. The workshop will also address how to use the assessment results for program accreditation.

WORKSHOP AGENDA

This Mini-Workshop will consist of the following interactive segments among participants:

1. Introductions
2. IDEALS Overview
3. Activity: Professional Development Assessment Review, Scoring, Group Discussion and Reporting
4. Team Member Citizenship Overview
5. Activity: Team Member Citizenship Assessment Review, Scoring, Group Discussion and Reporting
6. Using the assessments for ABET

Acknowledgment

The facilitators would like to acknowledge support from the National Science Foundation, Division of Undergraduate Education, Grant DUE 0919248.

Abstract—The goal of this workshop is to introduce participants to tools that can help them manage teams in their classes effectively and efficiently. We review some of the factors that instructors may wish to consider when administering self- and peer-evaluations and how they might improve the quality of those evaluations using rater training. Attendees with wireless-network-capable laptop computers will interact with the system in real-time.

Keywords— *peer evaluation; rater training; teamwork.*

I. INTRODUCTION

The workshop is for instructors who use or who want to begin using team-based learning strategies in their classes.

The goal of the workshop is to introduce participants to a suite of web-based tools that can help them manage student teams effectively and efficiently. We engage the participants in discussions about their own experiences and practices and briefly review literature that relates to participants' concerns. We review factors to consider when administering peer evaluations. We discuss rating accuracy and how to use and interpret self- and peer-ratings. We engage the participants in interactive, hands-on activities using the CATME system, however, this is not just a software demonstration—faculty will learn how the system supports cooperative learning.

Fig. 1 shows that as of March 2012, just over 2,000 faculty users at nearly 500 universities worldwide use CATME and nearly 93,000 unique students have used the system for one or more classes. The web interface was professionally developed; data are secure. The system was developed with funding from the National Science Foundation and is free for instructors in higher education. Instructors can request an account at www.catme.org.

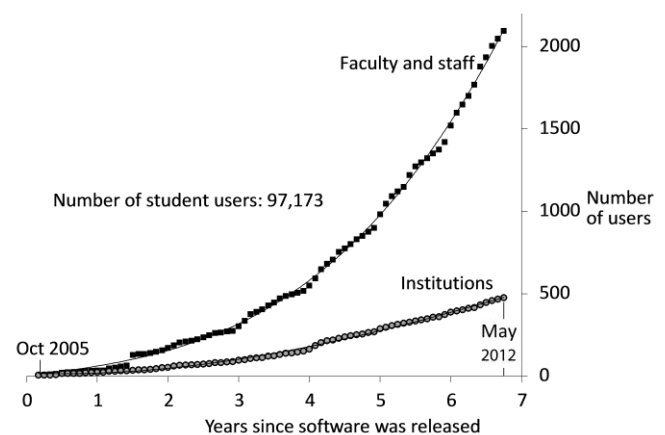

Figure 1. Growth of users of the the CATME Team Tools System

II. SELF- AND PEER-EVALUATION

The CATME self- and peer-evaluation tool uses a behaviorally anchored rating scale for assessing team-member effectiveness in five areas: contributing to the team's work, interacting with teammates, keeping the team on track, expecting quality, and having related knowledge, skills, and abilities [1, 2]. CATME provides the instructor a grade adjustment factor based on the relationship between each team member's ratings and the team average. The advantages of using the system are 1) peer evaluations increase students' accountability to their teammates and deter free riding, 2) using peer evaluations appropriately can help students learn to be more effective team members, 3) using peer evaluations is associated with more positive attitudes toward teamwork, and 4) completing self- and peer-evaluations also gives students experience with multi-rater systems, which are common in workplaces [3].

TABLE I. WORKSHOP AGENDA

| Topic | Activities |
|--------------------------------|---|
| INTRODUCTION [15 min] | Introductions of presenters and participants. Establish wireless connections. Introduce CATME SMARTER Teamwork System. Joining a community. Learning objectives. Faculty account request. |
| PEER EVALUATION [65 min] | Peer evaluation think-pair-share: Sharing problems encountered in peer evaluations. Discuss how the system addresses issues raised by participants. Importance of the instructor's role. Demonstrate creating a survey. Participants login as students and complete the survey. Demonstrate using CATME survey results for formative and summative assessment. Preview the student view of the results. Presentation of research on self-and peer evaluation. |
| [20 min] | break |
| RATER TRAINING [65 min] | Participants think/pair/share: What does it mean to be a good rater? How do you become one? Discuss how the system addresses issues raised by participants. Importance of the instructor's role. Demonstrate the instructor's CATME view for assigning training to students. Participants login as students and complete one iteration of the training. Preview the student view of results. Participants think/pair/share: How can we use this information to improve student teaming performance? Presentation on relevant literature & findings: issues in rating and types of training. |
| ASSESSMENT [15 min] | Summary of how these tools fit in an overall strategy of managing student teams. Participants create log-in passwords. Workshop assessment. |

In the workshop, we demonstrate how to create a survey for self- and peer-evaluation, how to focus on those rating patterns for individuals or teams that warrant close attention, how to use the ratings data for formative and summative assessment, and how to improve the quality of ratings using rater training.

III. TRAINING RATERS & USING RATINGS DATA

Effective use of a well-grounded peer-evaluation instrument benefits both students and faculty—students, from having an improved teaming experience, and faculty, by becoming better managers of the teaming experience. Effectiveness is enhanced when students rate accurately and faculty use rating data appropriately.

In support of these goals, we demonstrate how the system complies with research findings that peer ratings should be confidential though not anonymous [4]. The CATME system allows instructors to view each rating that each team member makes, and has a space for students to make confidential comments to the instructor. Instructors can require that students write comments to justify their ratings. Completing the peer evaluations on-line provides greater confidentiality than traditional paper-based evaluations, which are often completed during class with teammates watching.

We use the CATME system's rater calibration feature, which allows instructors to require that students practice rating fictitious team members using the peer evaluation system's behaviorally anchored rating scale. Requiring rater calibration ensures that students know how to use the scale correctly before they rate themselves and their peers. Using rater calibration before teamwork starts also ensures that

students are familiar with the components of effective and ineffective team-member behavior before they begin working with their teammates.

The CATME system flags a number of “special conditions” in the ratings data that warrant special attention. We show how to view and interpret these conditions and suggest ways to intervene with students or teams to provide targeted support to teams where needed.

Abstract— The use of case studies is an effective method for introducing real-world professional practices into the classroom. The term “case study” is used in a variety of ways. In its most naive form, it simply refers to a realistic example used to illustrate a concept or technique. Although the use of case studies in education has shown success in law, business and medicine, it is yet to be adopted in any wide ranging and significant way in software development education. One of the reasons for the minimal use of the case-study approach is the lack of sufficient material for this purpose. The main aim of the workshop is to introduce participants to case study teaching concepts and engage them with a comprehensive case study (the DigitalHome case study - <http://www.softwarecasestudy.org/>), which can be used throughout a computing curriculum, emphasizing full software development life cycle artifacts and exercises.

Index Terms— Case Study Teaching, Computing Curricula

I. INTRODUCTION (HEADING 1)

Many computing programs have a software engineering course that involves a software development project in which students are grouped into teams to work on a semester or year-long project. Unfortunately, this is too often isolated from the rest of the curriculum and does not form a real-world basis for the entire curriculum. As a result, these programs produce graduates who are familiar with the basic theoretical concepts in software development, but lack the skills to apply these concepts in real-world development environments. Therefore, it is imperative that computing curricula introduce professional and real-world education into the academic programs. The use of case studies is a widely-used method for introducing real-world professional practices into the classroom.

Although many computing textbooks include the use of case studies to explain computing topics, these cases typically serve a specific purpose (e.g., teaching programming, project management, requirements analysis, design, or testing). They often lack the following:

- Realistic artifacts (often space does not allow providing a complete requirements or design document)
- Completeness (covers only a portion of the life-cycle, and not an end-to-end), with a focus on design and implementation
- Ability to decouple from the text and apply in ways not intended by the author

- Techniques for integration into course activities or into the curriculum as a whole
- A scenario format that would motivate students to get engaged in problem identification and solution.
- Guidance to the instructor on how to use the case study to teach a course topic or concept

The DigitalHome case study [1, 2] is intended to address these shortcomings by providing a complete set of artifacts associated with software development as well as providing case modules that can be used by faculty in teaching different subjects in a computer science curriculum. Each case module represents a mini case study and is associated with a specific teaching subject and learning objectives (e.g. requirements analysis, object oriented design, testing, and team building). Case modules also include an exercise booklet and a set of guidelines to assist the instructor in teaching the session.

II. WORKSHOP GOALS

Upon completion of the workshop, participants will possess

- increased understanding and appreciation of the value of Case Study Teaching
- knowledge about and experiences with the use of the Digital Home Case Study material in teaching software engineering concepts and practices
- ideas about how the Digital Home Case Study material could be adapted to a software development curriculum

III. WORKSHOP OUTLINE

1. (15 minutes): Introductions and background
2. (15 minutes): Basics of Case Study Teaching, previous uses, and advantages.
3. (25 minutes): Description of the DigitalHome case study, its origins, artifacts, and case modules, and how it can be used across a curriculum.
4. (55 minutes): Group exercise on the use of the DigitalHome case modules. Participants will be broken into groups of 4-5. Each group will complete the case module exercise.
5. (45 minutes): Group discussion; groups report back on their DigitalHome exercise; individuals are encouraged to discuss their ideas on how to adapt DigitalHome case modules to their teaching.

6. (25 minutes): Workshop summary, final thoughts and discussions.

ACKNOWLEDGMENT

Initial work on the DigitalHome case study was funded as part of the NSF project: “The Network Community for Software Engineering Education” (SWENET) (NSF 0080502). In addition, the current work on the case study is funded through NSF’s (DUE- 0941768) “Curriculum-wide Software Development Case Study”.

Abstract- Earth system signals include indicators of climate change. In this workshop, the participants will use the Java-DSP/Earth Systems Edition in order to analyze and understand the components and drivers of climate change in the twentieth century. The session will be interactive and will be useful to researchers, practitioners and instructors with interests in Earth systems signal analysis. People with interests in general STEM related areas will also find this workshop useful as an important interdisciplinary application of signal processing.

Keywords- online labs; Java tools; climate change; Earth system; sustainability

I. DESCRIPTION

Analysis of Earth system signals is important to the assessment of global climate change and sustainability. The participants of this workshop will use the multidisciplinary education tools developed for such assessments using the Java-DSP/Earth Systems Edition (J-DSP/ESE) software. They will be introduced to instrumental records of Earth surface temperature, atmospheric carbon dioxide, and global sea level. Temperature is a rudimentary gauge of climate; pCO_2 controls temperature; sea level responds to temperature. The workshop will begin with an introduction to basic signal/data processing, followed by a tutorial on climate change assessment that examines modern records of global surface temperature, atmospheric carbon dioxide and sea level. The participants will investigate the variability of these three components, and the empirical evidence for their interactions. The objective is to understand the dynamics of critical Earth surface climate components, the evidence for and nature of their interactions, and how to forecast their behavior in the near future. Development of education materials for Earth sciences and geology will also be discussed. The session will be interactive with computers and participants will use and assess several exercises.

II. WORKSHOP OUTLINE AND OBJECTIVES

A. Learn basic signal processing with the online J-DSP/ESE laboratory

- Signal and noise
- Trend estimation

- Spectral analysis
- Filtering; differencing
- Correlation; coherency

B. Analyze time series data of critical climate components/drivers

- Global temperature records (GISS, NCDC, HadCrut)
- Atmospheric carbon dioxide/fossil fuel emissions records
- Global sea level records (tidal gauge v. satellite)

C. Address the following fundamental questions

- What are the variations (frequencies) in these records?
- Do fossil fuel emissions explain the rise in pCO_2 ?
- How is pCO_2 correlated with global temperature?
- Does global temperature correlate with sea level?
- Can we forecast for the next 10, 50, 100 years?

III. AUDIENCE AND EXPECTED OUTCOME

The intended participants for this workshop are researchers, instructors and practitioners with interests in time series analysis of earth systems data, and STEM related areas. They will benefit from a new intuitive environment for analysis of Earth signals, and obtain new materials and methods for studying and teaching global climate change and sustainability. Participants must bring their own laptop computers.

IV. THE J-DSP/ESE SOFTWARE

Java-DSP (J-DSP) (<http://jdsp.asu.edu>) is an educational program that enables on-line simulations and web-based computer laboratories. J-DSP is based on an object-oriented programming environment that enables students to establish and run DSP simulations on the internet. The J-DSP/ESE is a version of the software that is specialized to handle Earth system signals. Several papers on J-DSP and J-DSP/ESE have been published previously in archival conference proceedings and journals [1-9].

This workshop is supported in part by a Phase 3 CCLI-TUES project (award no. 0817596) funded by the National Science Foundation.

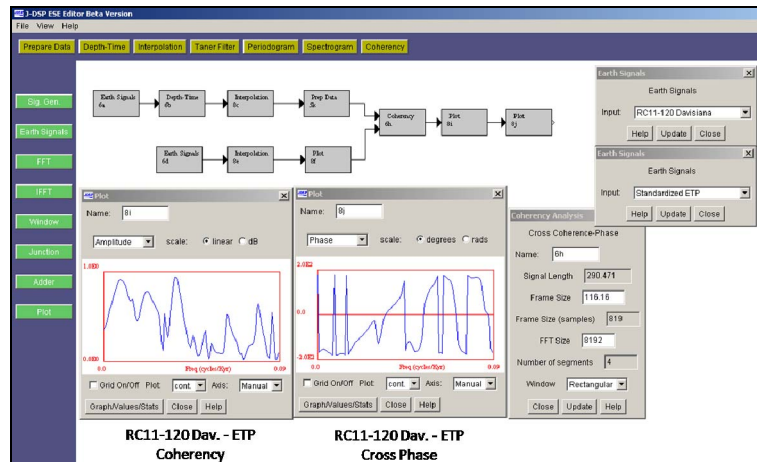

Figure 1: Analyzing the relation between pCO₂ and global temperature change using J-DSP/ESE.

I. BACKGROUND

Early drop out and poor retention rates are a major challenge to engineering education, which in many institutions have prompted a focus on improved first-year experiences. Retention and contributing learning challenges persists into the middle years, particularly when students confront the first engineering science courses in their major field. Students often perceive these courses as too abstract, intended to weed them out, and not meaningfully connected to their professional aspirations. A proven approach to improve student learning, self-efficacy, motivation, and retention is the use of active learning, including problems and projects [1-4]. Despite evidence of the benefits of active learning, engineering schools and faculty members have inadequate incentives to experiment with non-traditional approaches [5].

Over the past decade, the presenters and colleagues developed a particular model called project-enhanced learning (PEL) for core engineering science courses at the sophomore and junior levels. The project component enhances and does not replace traditional deductive exposition that most teachers find indispensable in these courses [6-7]. The requisite characteristics of project implementation in PEL evolved with experience. Critically, any intervention such as a project must be adoptable by the typical instructors of these courses, who may have career goals and incentive structures that limit teaching time commitment. Instructor willingness to add a project component in addition to traditional methods depends on project attributes that must be carefully constructed to minimize additional workload to the instructor as well as the student. Such a project component of engineering science courses at the sophomore and junior levels must be structured and mapped to the traditional topic sequence, and thus cannot be as open-ended as a senior level design project.

As reported previously [8,9], the PEL approach not only improved learning of the targeted engineering science content, but also enhanced peer-to-peer interactions, revealed student misconceptions, improved student motivation, and inculcated design skills and professionalism. The major benefits are improved learning in target courses, and potentially greater retention of students in engineering. Attendant learner benefits are improved self-efficacy in target courses, sense of belonging in the discipline, enhanced communication and team skills, and

project management skills. Benefits for the instructor include early feedback on student difficulties and misconceptions, and the relatively low workload required for the structured project.

In 2010, Indiana University – Purdue University Indianapolis (IUPUI) received a grant from the National Science Foundation (NSF) to implement and disseminate PEL in engineering science courses, as well as to identify barriers to adoption and to train faculty members. The grant activity aims to expand the PEL model to multiple courses at IUPUI and other institutions.

Project experiences were implemented in three different courses, based on initial experience in a course on *Thermodynamics*. PEL was introduced in two other courses: *Probabilistic Methods in Electrical and Computer Engineering*, and *Dynamics* in the mechanical engineering curriculum. One or two major projects based on systems, objects, or activities that are familiar to the students are designed and assigned to apply key course topics.

New instructors were initially reluctant to add the project to an already packed syllabus, but those who agreed to attempt it found that the tightly integrated project required very little extra grading effort. They also observed improved learning of the subject matter. Students were motivated to learn how to complete the project without errors, asking questions when something did not seem right, unlike with traditional piecemeal homework. Often, an online discussion forum for the project revealed student misconceptions and prompted early intervention to correct the errors.

II. GOALS OF THE WORKSHOP

The workshop is aimed at giving instructors an opportunity to evaluate and adapt the project-enhanced learning (PEL) model, which instructors at multiple institutions have found feasible and beneficial during the NSF-funded implementation program. The workshop format requires participants to actively work in groups on generating project ideas and materials for a course of interest. The expected outcomes are familiarity with the PEL methodology and rationale, increased interest in adapting PEL or other active-learning strategies in engineering education, and ideas for a project component in one or more courses.

III. CONTENT OF THE WORKSHOP

Project-Enhanced Learning (PEL) will be presented as an active learning strategy that integrates abstract concepts and deductive mathematical analysis with a concrete and meaningful project experience. The PEL experience is intended to motivate and anchor student learning and provide low-load feedback and assessment to the instructor. The workshop is intended to virally propagate an easily adaptable educational practice that is sustainable for the typical harried instructor. The experiences of project implementation (over the past ten years) and PEL dissemination make the proposed instructor-researcher team well equipped to lead this workshop.

The organization, planning, and implementation of PEL are modeled on past successes and resources available from educators who developed the method. The experiences of early adopters will be shared. Participants will review the strategies and implementation techniques of PEL, including the alignment of the most challenging course topics with project tasks, use of an on-line project discussion forum, substituting project tasks for traditional homework, and giving students ownership while managing workload and divergent thinking. Pairs or small groups of workshop participants will be formed to actively carry out a workshop 'project' to develop PEL for some common engineering science courses chosen by interest of the audience. Each group will brainstorm for project ideas for their course, and develop a feasible project outline, task structure, solution verification, and assessment approach for the project. Groups will reassemble to discuss their reactions, opinions, and ideas.

IV. WORKSHOP AGENDA

The following workshop agenda is based on a three-hour time allocation, and the goal of completing a 'project' task of developing PEL materials by each participant. It can be adapted to a different time allocation with a more or less ambitious agenda.

1. Retaining learning in students, and retaining students in engineering – what seems to work? [15 min]
2. Project-Enhanced Learning: Why and How? [15 min]
3. Minds-on learning by action – in pairs or small groups of participants:
 - a. Consider a traditional 'syllabus', with stated course topics and outcomes [15 min]
 - b. Brainstorm on possible and feasible project concepts [30 min]
 - c. Identify project tasks mapped to course outcomes [15 min]
 - d. Break and inter-group conversations [15 min]
 - e. Outline project guidelines for students; how to simplify and focus tasks [30 min]
 - f. Assess solution space for the project, and grading workload for the instructor [15 min]
4. Briefly report group experiences [15 min]
5. Review lessons learned and critique methods [15 min]

V. DESCRIPTION OF THE ANTICIPATED AUDIENCE

Workshop participants are likely to be engineering faculty members interested in new learning techniques in challenging and analytical engineering science courses, with the objective of improving learning and retention of students in engineering. Graduate students and post-docs with interest in engineering or similar STEM education can benefit as well.

Workshop: Teaching Computer Security Literacy to the Masses:

A Practical Approach

Doug Jacobson, Julie Rursch, Joseph Idziorek
Electrical and Computer Engineering
Iowa State University
Ames, Iowa, USA
dougj@iastate.edu

Abstract—We are losing the battle in cyber security. We heavily rely on technology as the main defense, instead of recognizing that the easiest attack vectors are the people who operate the computers. The general public does not understand the decisions they make each and every day have security implications for themselves, their projects and their companies. Since people are a primary target, education is one of the “secret weapons” in the cyber security battlefield. Further, if everyday users are the targets, then all audiences, not just technical staff, need training and education in cyber security basics.

We argue that computer security literacy is not only the next step in computer security defense; it may be one of the most important steps we can take. Through this workshop we want to encourage the profession to reach out to the populous and help make them security literate.

The goal of the workshop is to provide an alternative approach to teaching Computer Security Literacy. This approach, developed at Iowa State University, demonstrates how Computer Security Literacy courses for non-technical students benefit them in their daily lives, now as students and in the future as working professionals.

Keywords: security literacy, security education

I. WORKSHOP GOALS

We are losing the battle in cyber security. We heavily rely on technology as the main defense, instead of recognizing that the easiest attack vectors are the people who operate the computers. The general public does not understand the decisions they make each and every day have security implications for themselves, their projects and their companies. Since people are a primary target, education is one of the “secret weapons” in the cyber security battlefield. Further, if everyday users are the targets, then all audiences, not just technical staff, need training and education in cyber security basics.

The primary method for educating the general public about cyber security has been to construct top-ten security lists. This approach is neither effective nor sufficient as it is poor pedagogical practice to believe that students – or anyone for that matter - can remember, understand, and apply knowledge when the educator provides them with nothing more than

single-page, top-ten bullet point list of security tasks to perform.

We believe that formal computer security education is the key to combating the risks and vulnerabilities intrinsic to the Information Age. Each day, people are inundated with alerts and pop-ups informing them about patch updates, antivirus signature, and firewalls exceptions, but lack the proper education or vocabulary to make value-based decisions regarding the benefits and consequences of taking specific action on these items. What a formal pedagogical approach to practical computer security education provides is the context and knowledge for students to apply computer security best practices when faced with a novel situation and the ability to be proactive in the face of new threats, not reactive. We argue that computer security literacy is not only the next step in computer security defense; it may be one of the most important steps we can take. Through this workshop we want to encourage the profession to reach out to the populous and help make them security literate.

The goal of the workshop is to provide an alternative approach to teaching Computer Security Literacy. This approach, developed at Iowa State University, demonstrates how Computer Security Literacy courses for non-technical students benefit them in their daily lives, now as students and in the future as working professionals.

Currently course-based and security-focused learning initiatives have been primarily addressed at the university level through multiple levels of degrees. Efforts such as [1] have created a two-semester program that enables undergraduate students to learn about the technical facets of cyber security through focused learning models and laboratory environments. Similarly, Hazeyama et al. proposed a learning environment for software security education [2]. Others have sought to develop lab environments [3], and reconfigurable course modules [4, 5] to facilitate technical learning of specific and hands-on cyber security topics. More novel approaches include the use of hacking competitions [6] and capstone design courses [7].

Technical security education is also becoming a more common component of community college curriculums [8]. National Science Foundation sponsored efforts like CyberWatch [9] are committed to improve cyber security

education and have a primary focus on community colleges by providing support for curriculum development, faculty professional development, student development, career pathways, and public awareness. Opportunities are also provided to high school students by means of cyber defense competitions [10] and ad hoc courses or extracurricular activities.

Because the predominate bulk of the cyber security work force is technical in nature, the educational opportunities that support this career path have followed a similar technical emphasis. Although technical course-based initiatives are necessary, they are not sufficient to address current cyber security problems as they provide little opportunities for student of non-technical majors or for those who do not wish to pursue a career in cyber security with an opportunity to learn.

The proposed workshop centers on how two, one-hour, 8 week courses on Computer Security Literacy can be taught. The first course is on concepts found in Computer Security Literacy and the second course is a hands-on, lab-based course where students use the technology and experience how security affects them.

Participants will take home the course syllabi, labs, homeworks and lecture topics to develop Computer Security Literacy courses on their own campus.

II. WORKSHOP TOPICS

The proposed workshop will demonstrate a more effective manner in which to teach Computer Security Literacy. At Iowa State University, we have addressed the gap in security education by developing a course entitled "Introduction to Computer Security Literacy." The specific purpose of this 8-week, 16-lecture course is to provide both students from technical and non-technical majors with the opportunity to formally learn about the many facets of practical computer security knowledge. An emphasis is placed on technical and non-technical majors because previous research on this topic has discovered that despite the perceived advantage of students from technical majors (i.e., computer engineering, computer science, management information systems), students from non-technical majors are, on average, on an equal playing field with their non-technical cohorts when it comes to practical cyber security knowledge.

Because the goal of practical computer security is to provide security context to students concerning activities they already engage in on their computer and/or the Internet, the course topics and objectives of the corresponding lectures strive to keep the content focused and at a tangible level for all to learn.

What makes this course particularly effective at accomplishing its stated course outcomes is that students have the opportunity to apply the knowledge learned in lecture immediately when they leave the classroom when they begin to interaction with information technology. Furthermore, this constant interaction with technology increases the students' repetition leading to the goal of synthesis so that students can act in a safe manor when presented with a novel situation. Lectures are also incorporated with current event

topics so that students can see a direct connection to what they are learning in the classroom, often with an event that has occurred within days of the presentation of the lecture content.

Participants will take home the course syllabi, labs, homeworks and lecture topics so they can start Computer Security Literacy courses on their own campus.

III. WORKSHOP AGENDA

Introduction to the Topic (15 min)
 Current State of Computer Security Education (15 min)
 Concept of Computer Security Literacy (15 min)
 Target Audience (10 min)
 Experience in Courses at ISU (data) (15 min)
 Teaching a literacy course: (45 min)
 Syllabus/Course Outline/Topics
 How to reach a non-technical audience
 Example Lecture
 Teaching a hands-on introduction to security practice course (45 min)
 Syllabus/Course Outline/Topics
 Example Labs
 Wrap up and questions (20 min)

IV. ANTICIPATED AUDIENCE

Faculty in computer engineering, computer science, or anyone who is interested in teaching Computer Security Literacy. The audience does not need to have any security background. The materials and workshop is designed to show how security literacy can be taught.

Workshop: It's More Than Coding- Using Video Scenarios to Engage Students in Computing

Madalene Spezialetti
Department of Computer Science
Trinity College
Hartford, CT USA
madalene.spezialetti@trincoll.edu

Abstract- Studies indicate that students, particularly females, find computing most engaging when it is presented in relation to real-life problems, rather than when it is presented in ways that emphasize computing for the sake of computing. Video scenarios are a novel tool for encouraging students to explore computing in a problem-centric, rather than a code-centric, manner. Video scenarios are short films (2-5 minutes long) that depict individuals facing problems in life-like settings. The scenarios emphasize the diverse and often ill-defined nature of real world problems, and the potential for creative and entrepreneurial computing they present. The video scenarios and their associated discussion/exercise questions are freely available on the web at www.Virt-U.org.

Keywords- CS1, CS2, computing education, entrepreneurship, computational thinking, educational videos, video-based learning, problem solving, online tools ethics

I. INTRODUCTION

Using computing to find solutions to real world problems is a pursuit that presents many opportunities to be creative, entrepreneurial, inventive and imaginative. At the same time, understanding the problems to be solved can also be a complex task, requiring one to determine problem boundaries, identify parameters, clarify ambiguities and resolve unknowns, all while keeping in mind client/user expectations. Writing a computer program to solve a real world problem is not an isolated activity, but rather a step in a problem solving process. And it is far more than coding. Bringing this viewpoint into the classroom not only prepares students for the complexities they will face in real world programming, but even more importantly, brings a perspective to the programming process that is problem-centric rather than code-centric. Given that studies indicate that students, particularly females, find computing most engaging when it is presented in relation to real-life problems [1-4], it is all the more important to bring a problem-solving perspective into the computing classroom.

Video scenarios provide a novel tool for encouraging students to explore computing in just such a problem-centric manner. Video scenarios are short films (2-5 minutes long) that depict individuals facing problems in life-like settings. The scenarios emphasize the diverse and often ill-defined nature of

real world problems, and the potential for creative and entrepreneurial computing they present. They also provide everyday contexts in which to practice identifying computing algorithms, patterns and constructs.

While video scenarios provide a tool for emphasizing the problem-solving nature of computing de-coupled from coding, they are also designed to be integrated with traditional teaching approaches. The video scenario approach can enhance both the teaching and the learning experience in a variety of ways:

- The approach is highly flexible and can be used in a wide variety of contexts and for a variety of purposes. Video scenarios can be used to energize lectures with participatory activities via class or group discussions, can redefine the nature of lab activities by incorporating discussions and presentations into them and can serve as a basis for writing assignments.
- Since the scenarios reflect “real world” settings, they allow students to determine the problems to be solved and explore a variety of solutions based on their own interpretation of the scenes and the needs of the individuals depicted.
- The approach is designed to engage students in discussions to encourage critical analysis and creative problem solving. Since studies indicate that women, in particular, are drawn to problem solving rather than computing for the sake of computing, this approach has the potential to lead more women to become engaged in computing [1-4].
- By emphasizing problem solving first, and considering it as a prelude to programming, students can develop skills in computational thinking and creative problem solving at any level of experience, from general education through upper-level classes. Importantly, the scenarios can be used at the middle and secondary school levels, where studies indicate many women and minority students develop negative attitudes about computing [1].

II. TECHNIQUES FOR USING VIDEO SCENARIOS

Video scenarios are designed for a wide range of purposes, including developing computational thinking skills through critical listening and observation, encouraging creative, entrepreneurial and ethical thinking, and developing and reinforcing programming concepts and skills. Video scenarios come in a variety of styles which can be used to address the wide range of educational purposes and settings in which instructors may choose to use them.

A. Video Scenario Styles

Video scenarios come in a variety of styles which are suitable for a wide range of classroom goals and activities. These include *Enterprise* scenarios, which present fictitious companies experiencing a variety of problems that computing and on-line solutions can help, *Patterns and Constructs* scenarios, which focus on recognizing fundamental programming paradigms, constructs, patterns and algorithms in the problems presented, and *Ethics and Practices* scenarios, which present scenarios that explore the complexities of ethical dilemmas, client interactions and business practices.

B. Sample Uses and Exercises

Each video at www.Virt-U.org is accompanied by questions that can be used for a variety of exercises and activities. The following examples represent a range of activities and exercises that can be used in conjunction with video scenarios. The activities can be used in the classroom, laboratory or as the basis for written assignments, oral presentations or on-line (blogging) exercises.

- **Clients, Consultants, Critical Listening and Computational Thinking.** This role-playing exercise utilizes Enterprise Scenarios in which “clients” (members of fictitious companies) talk about their enterprises in a conversational manner as if addressing web design consultants (the audience). The “consultants” must listen critically to the conversation in order to identify the client expectations and requirements. In addition to identifying an overall concept and feature set for the web site, the consultants must also conceive of ways in which computing technologies can be utilized to enhance the client’s services, sales or web presence. This is an excellent exercise in any level of computer science class, as it is a very accessible way to encourage and develop student abilities in verbally expressing themselves to team members, presenting ideas to a critical audience and questioning and analyzing the ideas of others.
- **Problem Solving Scramble.** These exercises utilize Patterns and Constructs scenarios, which have a more computational or algorithmic flavor. In the scramble technique, small groups are given a short period of time to propose a computational solution to a video scenario problem. This time-limited technique is an ideal way of incorporating the use of videos into any setting where time is at a premium. This type of

exercise can also be used to motivate and reinforce the introduction of programming constructs at the CS1 or CS2 level.

- **Understanding the People, Understand the Problem: Recognizing and Resolving Ambiguities.** These exercises can utilize both Enterprise scenarios and Patterns and Constructs scenarios as a catalyst for exploring issues related to achieving effective interactions with clients in order to fully understand their needs and the parameters of their problems. For example, a video may feature a client explaining a task that must be replicated by a program, but the explanation contains ambiguities or contradictions. The associated exercises would involve identifying the ambiguities or inconsistencies and exploring approaches to interact with the client in order to resolve them.
- **What to Do and How to Do It: Ethics and Practices.** These exercises utilize Ethics and Practices scenarios, especially those in the *Notes from the Coach* series, to give students the opportunity to explore issues related to such areas as ethics, client relations and the value and importance of effective communication. The videos and associated discussion questions are designed to serve as a catalyst for the exploration of varying strategies and viewpoints.

III. CONCLUSION

Video scenarios provide a novel, engaging and highly interactive tool to explore computing in a problem-centric manner. Because of their flexibility and accessibility, video scenarios can be used in classes ranging from middle and high school through general education, introductory and upper-level college courses. At the pre-college, general education and CS1 levels, they can be especially useful in enhancing student perceptions of computing and in helping students envision computing as a relevant and creative problem-solving process that extends beyond writing code.

Work in Progress: Student Outcomes of Design Projects Across the Curriculum

Kathryn Trenshaw and Jerrod Henderson

Department of Chemical and Biomolecular Engineering
University of Illinois at Urbana-Champaign
Urbana, Illinois
Contact email: trensha1@illinois.edu

Ayesha Boyce and Lizanne DeStefano

I-STEM Education Initiative
University of Illinois at Urbana-Champaign
Urbana, Illinois

Abstract— This addresses the question, "To what degree can design projects integrated into the Chemical and Biomolecular Engineering (ChBE) curriculum affect student confidence in their design skills and perceptions of ChBE as a whole?" To answer this question, students were evaluated on their confidence with engineering design and their satisfaction with ChBE as a discipline before and after the design projects, as well as their perceived learning outcomes after completing the design projects.

Keywords— design, project, chemical engineering, capstone, curriculum, student outcomes

I. INTRODUCTION

Most previous research on engineering design education [1-4] focuses on capstone courses [3-4]. The research on design integration throughout a curriculum does not give concrete student outcomes as to whether changes improve the undergraduate experience for students or increase performance in the design capstone course [1]. Since design skills gained in capstone design courses are vitally important for students' careers in both industry and academia, design should not be introduced only at the end of undergraduate programs.

Design projects were integrated into two single semester courses in the Chemical and Biomolecular Engineering (ChBE) curriculum, Principles of Chemical Engineering (ChBE 221) and Momentum and Heat Transfer (ChBE 421). Student demographics (self reported, both domestic and international) for both courses can be seen in Tables I-III. One design project was incorporated per course. Students completed the projects in teams of four to five and stayed in the same team for the duration of the project. Students in ChBE 221 were grouped into diverse teams by their Myers-Briggs Type Indicator (MBTI) type [5] and in ChBE 421 by random selection from GPA quartiles. Each team was assigned a mentor (a student who had taken the course in a previous year) to assist with team management. For grading questions, a design project teaching assistant (TA) was available. Design projects accounted for 10 percent of the final grade in each course. In the ChBE 221 project, students calculated the mass balance for a chemical production process that maximized profit. In the ChBE 421 project, a multifaceted design of a pipeline system, students rendered scale pipeline schematics, sized the piping, and calculated the energy transfer through the pipeline. The top five teams from each course presented their work to a panel of

judges from British Petroleum, p.l.c. (BP) who awarded monetary prizes to the top three teams.

II. METHODS

Students in both ChBE 221 and ChBE 421 completed an online pre-survey immediately after assignment of the design projects and an online post-survey after completion of the design projects. The pre-survey gathered information about the students' initial expectations and attitudes related to the design projects and ChBE as a discipline. The post-survey revisited the themes of the pre-survey and gathered students' perceptions of the learning outcomes from the design projects. The surveys consisted of both closed- and open-ended questions. The pre-survey response rate was 37% for ChBE 221 and 35% for ChBE 421. The post-survey response rate was 33% for ChBE 221 and 27% for ChBE 421.

A one-hour semi-structured focus group was held for each course after the design projects were completed. Eight students participated in the ChBE 221 focus group and three students participated in the ChBE 421 focus group. Focus group

facilitators were not involved in grading to avoid conflicts of interest. Students received pizza and soda, but no monetary compensation.

III. PRELIMINARY FINDINGS

A basic thematic approach was used in data analysis. Each individual author analyzed the open-ended survey responses and focus group transcripts, followed by collaborative analysis and consensus building to draw out major themes. Closed-ended survey responses (not shown) supported results from the qualitative data. Five major themes were identified, including feedback/grading, project design, presentation opportunities, team design/experience, and overall experience/learning outcomes and are summarized below.

Students expressed frustration because they felt that there was a lack of feedback and they had a poor understanding of grading procedures for all portions of the design project. A majority of the focus group participants noted a lack of comments on reports. Further, students did not understand how the top five teams were selected or how winners were chosen. Similarly, students felt that there was not enough contact with, or feedback on projects from the TA. Students suggested that more TAs would be necessary to properly manage the course and provide support for student concerns.

Students responded positively to the projects' open-endedness and real-world applicability. In contrast, students disliked the lack of specificity in the project guidelines, the lack of coordination between different ChBE course assignment due dates, and the course percentage given for the project. Additionally, students in ChBE 221 desired more ability to evenly split the design project assignments between team members.

Students felt that the presentation to BP was an important part of the design project and that more teams, if not all, should have presented. Students recognized the importance of presenting their work to industry sponsors. Students also understood the logistical problems with every team presenting, specifically the amount of time it would take, but felt that the benefits to student experience outweighed these concerns.

The vast majority of students preferred the grouping methods used in both courses to choosing their own teams, but wished that grouping could have been completed earlier. Additionally, most students had positive team experiences. Focus group participants said that they favored the MBTI method to random selection, and random selection to choosing their own teams. In contrast to the focus groups, four survey respondents in ChBE 221 favored picking their own teams to the MBTI method. Additionally, students commented that they enjoyed making new connections within ChBE and developing team spirit throughout the design projects.

Overall, students had a positive experience with the project, but provided both positive and negative feedback. Focus group participants were satisfied with the experience provided by the addition of a design project to the course, and several mentioned that afterward, their attitudes toward ChBE as a discipline improved. When asked the open-ended post-survey

question, "List the three most important things you learned from this design experience," survey respondents highlighted several learning outcomes, which were classified into five categories. These survey responses are shown in Table IV.

TABLE IV. NUMBER OF SURVEY RESPONSES BY LEARNING OUTCOME

| | ChBE 221 | ChBE 421 |
|--|----------|----------|
| Teamwork Skills | 20 | 11 |
| Applying Coursework to the Real World | 5 | 3 |

IV. FUTURE DIRECTIONS

- **Refine the design project administration.** Instructors should specify the project guidelines more precisely and coordinate between course assignment due dates in different ChBE major courses.
- **Have more than one TA.** Having additional TAs would allow for distribution of course responsibilities and more total TA contact hours for students. Future evaluations should include TA interviews to better understand TA experiences.
- **Incorporate opportunities for more students to present.** Students who presented to BP consistently mentioned it as the highlight of their experience with the design project. Thus, providing an opportunity for more students to present would improve the overall experience.
- **Begin longitudinal studies.** Comparing final grades in the capstone design course and exit interviews between previous years and students who experienced integrated design projects will become feasible when current students begin graduating.

ACKNOWLEDGMENT

We thank Marina Miletic for rallying support in the ChBE department for integration of design throughout the curriculum and Paul Kenis as ChBE Department Head for his support of our evaluation. We also thank Daniel Pack and Brendan Harley for allowing us to study students in their courses.

Differences between Same-sex and Cross-sex Mentoring Relationships in Capstone Design Courses

Abstract— Within capstone design courses, the relationship between faculty and students can be classified as mentoring, where instructors fulfill functions that support career and psychosocial development of the students. Unlike traditional mentoring relationships, however, matching student teams to faculty mentors is not simply a process of one mentor and one mentee choosing each other. Project, team, and course structures are all dominant factors, resulting in both cross-sex and same-sex mentoring relationships. Literature on mentoring relationships in higher education has produced conflicting reports on which match yields better outcomes. Thus understanding the implications of same-sex and cross-sex relationships can be helpful in enabling faculty to effectively support the development of all students. This study applies an empirically derived model of capstone mentoring to data from a 2011 national survey of students enrolled in capstone design courses. The survey addresses students' perceptions of faculty teaching and their self-reported learning gains, and the data analysis presented in this paper focuses on similarities and differences based on the sex-pairing. The results provide preliminary insights regarding the impact of sex differences on the capstone mentoring relationship, and thus contribute to a more complete understanding of design teaching.

Keywords—Design teaching, mentoring, gender

I. BACKGROUND

The capstone course has been commonly recognized as one of the most prominent examples of project-based learning [1] in engineering. Throughout this course students are exposed to realistic design situations that simulate the engineering profession through the implementation of open-ended, hands-on projects [1-4]. This experience requires students to integrate domain knowledge from engineering sciences and design systems, and to utilize professional skills in the pursuit of the successful completion of the capstone project [5].

This work is commonly guided by faculty advisors. A recent study of faculty roles in the capstone course has shown that the faculty role is a form of mentoring where

faculty fulfill several functions commonly seen in formal mentoring environments [1].

Mentoring relationships, broadly defined, have been shown to positively influence retention and achievement among women and minorities [6]. Among women, mentoring is recommended as a means to offer the support, socialization, and direct assistance they may need to succeed; especially in alienating or hostile situations. While the capstone course is not intended to be hostile, the low representation of women on design teams can make women feel alienated and hostile environments can result [6,16]. Within mentoring literature there is conflicting reports on the effectiveness of same-sex and cross-sex mentoring [6]. Jacobi [6] indicated that there needed to be further studies towards the preferred and actual mentoring functions provided by mentors to protégés and the outcomes of these relationships.

A. Mentoring in Capstone Courses

To operationalize the mentoring that occurs in capstone courses, we applied the mentoring functions identified by Kram [7] in the workplace, to the capstone course and empirically developed operational definitions and practices [1]. Mentoring occurs in two domains, career development and psychosocial development, and each has an associated set of functions (Table 1).

TABLE I: IDENTIFIED MENTORING DOMAINS AND FUNCTIONS

| Career Development | Psychosocial Development |
|-------------------------------|-----------------------------|
| Employability-and-Sponsorship | Role Modeling |
| Exposure-and-Visibility | Acceptance-and-Confirmation |
| Coaching | Counseling |
| Protection | Rapport |
| Challenging Assignments | |

The career development domain consists of functions targeted at developing students' access and abilities so that they can find employment in the engineering industry and succeed in that employment. The related functions include providing sponsorship-and-employability, exposure-and-visibility, coaching, protection, and challenging assignments.

The mentoring associated with psychosocial development focuses on supporting the students' sense of community, identity, and effectiveness in their role with an emphasis on behaviors and values rather than skills as well as developing the students' self-identity and efficacy as a practicing engineer. The related functions include role modeling, acceptance-and-confirmation, counseling, and rapport.

Unlike traditional mentoring relationships, however, capstone mentoring represents a group-mentoring environment where students generally do not select their mentors individually and mentors generally interact with diverse student groups. Thus the implications of same-sex and cross-sex relationships are particularly crucial in capstone environments to insure that faculty can effectively support the development of all students.

B. Cross-sex/Same-sex Mentoring

Research on sex differences in mentoring relationships has focused on the selection of the mentor, the functions provided to the protégé, the perceived value of the relationship, and how effectively the protégé utilized the mentoring relationship. Unfortunately, several of the findings have been inconsistent. For example, Jacobi [6] and Erkut and Mokros [8], found that females were more likely to select female mentors [6, 8]. Erkut and Mokros also found that men tended to select mentors that could write influential letters of recommendation regardless of the sex of the mentor, whereas women were more interested in mentors that have an attractive lifestyle [8]. Moore and Amey [9] suggested that women may avoid male mentors due to a difficulty in relating to and learning from male mentors. In contrast, Olian [10] found no same-sex preference when selecting mentors.

While Erkut & Mokros saw selection preferences based on the sex of the mentor, they saw few sex differences in the type of support provided to students. In their study both groups experience similar mentoring functions, and both men and women indicated that they received no help in developing connections with people in graduate schools, professional schools or work environments despite the gender of the mentor [8]. Other studies, however, found that women saw more support of psychosocial functions, particularly role modeling with respect to the attitudes, values, and behaviors of the discipline, and opportunities to explore personal concerns more than men [11]. Otherwise there were no perceived differences and both men and women perceived similar value from the relationship [11].

When examining how effectively the mentoring relationship was utilized by each sex, Noe [12] found that in cross-sex mentoring relationships the protégés utilized the mentor more effectively than those in same-sex mentoring relationships. In addition, the male-male relationship was less effectively utilized than the female-female relationships. Moreover, an analysis of variance showed that the gender of the protégé accounted for more variance in psychosocial outcomes than the amount of time spent with mentor, utilization of the mentor, or the protégés job and career attitudes.

C. Research Questions

One of the difficulties in drawing general conclusions regarding the effect of sex on mentoring relationships is that the studies occur in a variety of contexts, including undergraduate education at small co-ed and all-female arts colleges, teacher education programs, and nursing education programs. This variation suggests that context may significantly influence the ways in which the sex of the mentor and the mentee affect the mentoring relationship. Given the importance of mentoring in capstone courses, and the group mentoring dynamic, where both male mentors and male group members dominate, this study explores the the following research questions have been investigated:

1) *How do students in same-sex and cross-sex mentoring relationships differ in their perception of mentoring received in engineering capstone design courses (ECDC)?*

2) *How do self-reported learning outcomes of students differ between students in cross-sex and same-sex mentoring relationships in ECDC?*

Addressing these questions enhances our understanding of design teaching in a way that can be used not only for professional development of current design faculty, but also in the training of new design educators.

II. METHODOLOGY

This study utilizes quantitative survey data from capstone students collected as part of a study examining the teaching practices of capstone design faculty (ExCDE) which led to an examination of mentoring functions in the capstone course.

A. Participants

Participants included 191 students enrolled in capstone design courses across the United States from 20 different institutions during the 2011 Spring term. The Spring term was chosen so that students would have a full capstone course experience, whether it was one or two terms.

The survey was distributed through faculty interview participants involved in the ExCDE project one month before the end of the school term. The faculty were asked to forward the recruitment email to their students during the last few weeks of the term and a reminder was sent to the faculty during the last week of their term to maximize response rate.

The student respondents were enrolled in capstone courses representing a variety of disciplines including mechanical (37%), chemical (34%), electrical and computer (12%), industrial systems (12%), and civil engineering (7%). The participating students were from both public (82%) and private (18%) institutions. Institution size also varied from under 5,000 students (14%) to 5,000-20,000(54%), and over 20,000 (31%). Out of the survey respondents there were 9 female students in groups mentored by females, 7 female students in groups mentored by males, 141 males students in

Identify applicable sponsor/s here. (*sponsors*)

groups mentored by males, 34 males students in groups mentored by females. (TABLE II).

TABLE II: DISTRIBUTION OF RESPONDENTS

| Mentoring → | | Students | | |
|-------------|--------|----------|--------|-------|
| | | Male | Female | |
| Faculty | Male | 141 | 7 | (148) |
| | Female | 34 | 9 | (43) |
| | | (175) | (16) | |

B. Data Collection

The student survey was developed in the Spring of 2010 using the Crocker and Aligna [13] process of survey development. It served as a means to triangulate responses from the faculty survey and interviews conducted during the first two phases of the ExCDE project. The student survey included questions that addressed course demographics, faculty roles and actions, self-report of learning outcomes, and the perception of frequency and value of interactions with capstone faculty. The questions concerning the students' perception of the capstone instructor's roles and actions included 15 questions directly related to the mentoring functions associated with career and psychosocial development identified in mentoring relationships (Table III). These items were developed specifically from the faculty survey, faculty interviews, and other quantitative studies that utilized Kram's mentoring functions [7] as a framework. These items were 5-point Likert-type, allowing for responses from strongly disagree to strongly agree. The learning outcomes, identified through the faculty survey and interviews, were evaluated on a 5-point scale from "None (I learned nothing in this area)" to "Very High (I learned a great deal in this area)".

TABLE III: MENTORING SURVEY ITEMS

| Functions | | Student Survey Items (The capstone instructor...) |
|--------------|-------------------------------|--|
| Career | Employability/ Sponsorship | <ul style="list-style-type: none"> Sponsored me for desirable positions such as assistantships, jobs, or internship |
| | Exposure/ Visibility | <ul style="list-style-type: none"> Encourage me to publish work Introduced me to experienced professionals in my field |
| | Coaching | <ul style="list-style-type: none"> Provide direct training or instruction for me |
| | Protection | <ul style="list-style-type: none"> Keeps up with status and progress of my project Keeps up with how well my team is functioning Guides the development of the project scope Acted as an intermediary between clients & team Checked work before submission |
| | Challenging Assignments | <ul style="list-style-type: none"> Allows me to synthesize and apply prior work Allows me to develop and design my project |
| Psychosocial | Role Modeling | <ul style="list-style-type: none"> Served as a role model for me |
| | Acceptance/ Confirmation | <ul style="list-style-type: none"> Offered me acceptance, support, & encouragement Allows me to interpret data and make decisions on my own |
| | Counseling | <ul style="list-style-type: none"> Provided personal guidance and counsel for me |
| | Rapport | <ul style="list-style-type: none"> Served as a friend |

Once the items were developed, they were reviewed by the research team and piloted using a convenience sample of capstone students. The pilot test allowed the students to take the full survey and provide comments on each question. The pilot test yielded a response of five students. Upon review of the pilot results, items were added that reflected student concerns and a section of items that included a drop down menu were altered for a quicker point-and click answering.

C. Data Analysis

The quantitative analysis for the surveys included descriptive statistics of the item responses for each group and comparison of differences between the item responses. The descriptive analyses for the survey included the mean, median, and modes of all items in Table III. These items were then examined to compare differences between the four groups using a Mann-Whitney U statistical test of sample medians. The Mann-Whitney U test determines if there is a significant difference between sample medians of two independent groups [14]. It is used to compensate for the non-normal distribution of the data and the use of Likert items as a data source [14]. It is also a stronger statistical measure given the low number of females represented as both faculty and students in comparison to the Male-Male relationships.

This analysis requires a pair-wise comparison of the four groups of same-sex and cross-sex relationships. These types of concurrent analyses have the tendency to increase the family-wise error rate, which can be alleviated by applying a Bonferroni correction to the alpha criterion (α) [14]. By dividing alpha by the number of comparisons being examined (α/m) a new acceptable alpha can be used to examine significance among the engineering disciplines [14, 15]. In examining the five engineering disciplines, ten pair wise comparisons were conducted. Using the nominal criterion of significance of $\alpha = 0.05$ and dividing it by the 6 statistical examinations, the new adjusted criterion became $\alpha = .0083$. Due to the small sample of female students and female faculty, effect sizes were calculated as a comparison despite the non-normality of the data.

III. FINDINGS

The analyses identified several differences based on the sex of mentor and student in terms of the mentoring functions, the self-reported learning outcomes, and other types of support and perceived value. In the following discussion, the the sex of the mentor is always listed first (Mentor/Student) – i.e. Female/Male is a female mentor and a male student.

A. Difference in Mentoring Functions

While Erkut and Mokros saw no difference in the functions of mentoring received by males and females in their work, this study identified a difference in the perception of receiving sponsorship. With respect to the functions identified in Table 1 and Table 3, the function of *sponsorship* was the only identifiable statistically significant difference between Male/Male and Female/Male mentoring relationships. Males mentored by other males perceived less

sponsorship than males mentored by females. In contrast, male students mentored by females experienced more sponsorship than females mentored by females; although this difference was not statistically significant ($p > .03$), the effect size was greater than 1. Finally, males mentored by females experienced more sponsorship than males mentored by males, though this difference was not statistically significant.

TABLE IV: DIFFERENCES PERCEIVED IN MENTORING

| Survey Items | Male ^a | | Female ^a | |
|------------------------|-------------------|---------------------|---------------------|---------------------|
| | Male ^b | Female ^b | Male ^b | Female ^b |
| Sponsorship | 2.28 | 2.89 | 3.56 | 2.14 |
| Undergraduate Research | 30% | 33% | 43% | %100 |

a. Faculty mentor sex
b. Student sex

B. Difference in Learning Outcomes

Previous studies suggest the sex of both mentor and mentee can affect the learning outcomes of the student. This study, however, found difference in the learning gains in only two areas: written communication and engineering ethics (Table V). In contrast, there were no differences in learning gains associated with project planning, concept generation, economics, design, and creativity.

TABLE V: PERCEIVED LEARNING GAINS

| Survey Items | Male ^a | | Female ^a | |
|-----------------------|-------------------|---------------------|---------------------|---------------------|
| | Male ^b | Female ^b | Male ^b | Female ^b |
| Written Communication | 3.11 | 3.66 | 3.78 | 3.71 |
| Engineering Ethics | 2.82 | 3.43 | 3.11 | 2.29 |

a. Faculty mentor sex
b. Student sex

The differences occurred between the male and female students when mentored by a male capstone instructor. In both cases, males indicated significantly lower learning gains. While not significantly different, female students saw lower learning gains in engineering ethics when mentored by females than when mentored by males (Cohen's $d > 1$), and female students saw lower learning gains in ethics that males when both were mentored by females.

C. Other Notable Differences

While not directly related to the mentoring functions described in Table 1 and Table 3 and gains in learning, one of the most notable differences between the same-sex and cross-sex mentoring relationship involved female students' perception of whether capstone instructors encouraged hands-on construction. Female students perceived significantly less ($p < .0083$) emphasis to participate in hands-on construction in comparison to male students, whether they were mentored by male or female faculty.

TABLE VI: DIFFERENCES IDENTIFIED IN HANDS-ON CONSTRUCTION

| Survey Items | Male ^a | | Female ^a | |
|-----------------------|-------------------|---------------------|---------------------|---------------------|
| | Male ^b | Female ^b | Male ^b | Female ^b |
| Hands-on Construction | 3.64 | 2.66 | 3.33 | 2.00 |

a. Faculty mentor sex
b. Student sex

IV. CONCLUSION

Capstone course represent a significant mentoring opportunity for most students. As a result, capstone faculty should work to ensure that the relationship is as effective as possible. The results of this preliminary study suggest that in many cases, male and female students experience this mentoring relationship differently, and thus the study highlights areas where, as educators and mentors, we have identifiable areas for both improvement and further study.

As Erkut and Mokros [8] noted, there are more similarities in the mentoring seen in same-sex and cross-sex relationships than differences, even within the engineering capstone course. The differences identified through this study, though, suggest that in some areas cultural stereotypes and socially defined roles may persist within the classroom. For example, the fact that females perceive less encouragement to participate in hands-on construction than their male counterparts could be a result of the capstone instructor, the group dynamic, or the environment of the capstone course or department. Thus while we see that females are experiencing mentoring at the same level as their male counterparts in many areas, more effort is needed to be made that encourage a full engineering experience that is not limited by those stereotypes and socially defined roles.

Work in Progress: Investigating the Engineering Design Process: Novices vs. Experts

Ting Song and Kurt H. Becker
Utah State University
Logan, Utah
ting.s@aggiemail.usu.edu, kurt.becker@usu.edu

Abstract - This study investigates the engineering design process. It compares expert and novice engineers during the processes of decomposition of a problem and the recomposition of sub-problems when working in teams. The paper describes the research questions, research design, and method of collecting data and analyzing data of the study.

Keywords - *teaming; engineering design; protocol analysis; FBS; problem decomposition; recomposition of sub-problems*

I. INTRODUCTION

Engineering design is a central subject for engineering education and a major activity for practicing engineers. There is a need for engineering graduates who are able to design effective solutions to meet customers' various requirements [1]. However, many researchers believe that engineering design is not taught properly. These problems in engineering education include focusing on analysis more than design [2] and spending insufficient resources on teaching design [3]. Engineering education has not prepared students with practical skills and knowledge, hence, engineering graduates have been considered to be unprepared to practice in the industry [4].

A series of studies shows that there is a gap between skills developed in universities and skills required in the industry [4, 5, 6]. Researchers believe that the teaching of design in engineering education is in need of improvement [3, 7]. Students need to learn more real world skills, because "the 'real world' provides the materials and devices with which engineers design, and the world is where the performance of systems is verified" [8]. To increase the quality of engineering education, researchers must study the engineering design in a real – world context, which means engineers work in teams to solve actual problems. This approach offers useful information to improve engineering education at the college level.

II. RESEARCH QUESTIONS

The vision of this research is to better understand the engineering design process as it relates to expert vs. novice. It investigates the design strategies employed by teams of engineering freshmen and teams of engineering experts. The following questions guide the study:

- How is the process of problem decomposition for teams of engineering freshmen different from teams of engineering experts?

- How is the process of problem recomposition for teams of engineering freshmen different from teams of engineering experts?

III. WORK PLAN

In this study, the engineering design process is investigated. Teams of college engineering freshmen and teams of engineering experts complete the same engineering design problem.

A. Participants

Participants including college engineering freshmen and engineer experts are selected by purposeful sampling. Student participants are from the College of Engineering at Utah State University. Participation in this study is open to all engineering freshmen regardless of their engineering major on a volunteer basis. Each student receives a \$10 honorarium to participate. Engineer expert participants are recommended by researchers at Utah State University. Emails are sent to potential engineer expert participants to introduce the purposes and procedures of the study. The engineer experts voluntarily participate in the study as well, and each engineer expert receives a \$50 honorarium for his or her participation. All participants sign informed consent forms before participating.

B. Research Setting

Participants are assigned to teams. Research [9] showed that instructors should form the student teams, because practicing engineers are not able to choose their teammates and students need to learn to work with a variety of teammates. A team of three to four students is considered optimal [9]. In this study, each team includes three members.

All the teams complete the same design problem in similar settings within two hours. They are asked to design a double-hung window opener that assists the elderly with raising and lowering windows. This design problem has been used by Gero [10] to study engineering design thinking. There are various engineering and social constraints in this problem which make it a typical engineering design problem. In addition, because a double-hung window is commonly used in households, students are able to complete the design problem without any specific engineering knowledge or background.

Due to the limitation of time, participants are not expected to completely finish the design problem. Instead of presenting practical products by the end of design process, participants

only submit design proposals as final outcomes. They do not build, test, and analyze their design.

C. Data Collection and Analysis

Data is collected mainly through Verbal Protocol Analysis (VPA). The process of performing the task is recorded by audio. At the same time, video data are collected to record participants' nonverbal communication. In addition, participants' sketches are collected as supplemental materials to the study. The data will be collected in September, 2012.

After all the participants finish their design problem, audio data are transcribed, segmented, and coded. The data are coded according to the coding system after segmenting. The coding system has two dimensions: reasoning mode and level of the problem. This two-dimension coding system has been used to investigate design strategies used by individual engineers [11]. The first dimension is the reasoning mode. It utilizes a framework known as Function-Behavior-Structure (FBS). FBS represents the process of design and was developed by Gero and Kannengiesser in 2004 [12]. They illustrated the definition and conceptualization of the framework as shown in Figure 1. Function represents designers' expectations of the products, behavior represents the ways designers accomplish their goals, and structure represents the solutions to the problem. The second dimension of the coding system is the level of the problem. Engineers decompose the design problem into multiple sub-problems and work on each sub-problem in order to find the solution. The level of the problem runs from 0 to 3. The meanings of each number are showed in Table 1.

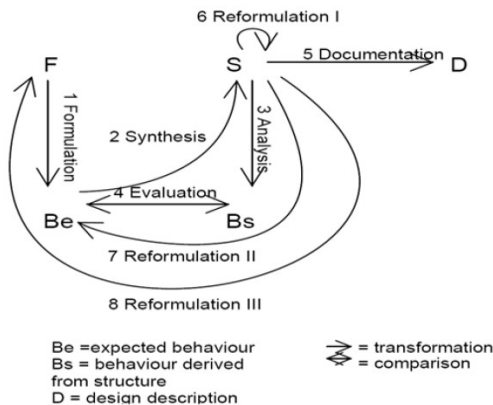

Figure 1. FBS framework

TABLE I. LEVEL OF THE PROBLEM

| Level of the Problem | Definition |
|--------------------------|---|
| 0: System | Designers consider the problem as an integral whole. |
| 1: System and subsystems | Designers consider interactions between subsystems. |
| 2: Subsystems | Designers consider details of the subsystems. |
| 3: Design details | Designers consider the detailed working of the subsystem. |

There are two raters participating in the coding section. The training content of raters includes learning references about FBS framework and problem decomposition-recomposition, and practicing the coding of previous engineering design challenges. After coding data, researchers apply nonparametric tests in analyzing quantitative data. The analysis of qualitative data is connected with the context of engineering design and allows any themes or new phenomena to emerge. These data are triangulated against each other. The data analysis is expected to be finished by the end of October, 2012.

IV. EXPECTED OUTCOMES

By analyzing the data, differences in decomposition-recomposition of the problem between engineering experts and college engineering freshmen are found. By examining those differences, we better understand engineering design thinking which can be applied to improving engineering education, especially the teaching of engineering design. The results of this research will be available at the 2012 FIE conference.

Abstract — This paper describes how four playground experts and five engineering experts completed a task of designing a playground. The findings, derived from a qualitative coding analysis, showcase the playground experts in this sample considering social contextual factors, paying attention to human actors' playground use, and relying mainly on professional knowledge. The engineering experts in this sample also paid attention to use of the playground by people and used a combination of professional and personal knowledge as they completed a playground design task. In support of ABET's goals for the engineering discipline, the research highlights how expertise in a particular domain may be helpful for one's capacity to also focus on social and human-related elements through the design process. These outcomes aim to support the educational discussion on how to enable engineering students to develop expertise that involves broader design considerations.

Keywords - domain expertise; design process; design thinking; engineering education; context; broad thinking

I. INTRODUCTION AND BACKGROUND

The contexts in which engineering projects are situated are becoming more complex. While expert engineers hold a myriad of experiential knowledge in their domains of expertise to aid them in highlighting important contextual factors; novice engineers rely predominately upon their educational backgrounds. ABET, the engineering accreditation body, specifically states in Criterion 3H that engineering programs should help engineering students achieve "the broad education necessary to understand the impact of engineering solutions in a global, economic, environmental, and societal context" [1]. Teaching these skills to engineering students is a difficult task.

The research presented in this paper addresses this challenge by seeking to understand the relationships between the possession of expertise in a particular domain and the potential accompanying ability to situate problems and consider context more broadly in design processes. A domain is defined as a shared system of knowledge and activities that focus on a particular subject and expertise and "...refers to the characteristics, skills and, knowledge that distinguish experts from novices and less experienced people" [2]. Focusing on domain expertise is important for what it may encompass, as science and technology studies have long taught us that becoming expert is not simply about one's intended role, but the amalgamation of experiences that have led a person to achieve a particular level of skill and knowledge [3].

If expertise is enactment, it is also fundamentally a process of becoming rather than a crystallized state of being or knowing. So although certain forms of expertise may be culturally cast as natural or spiritual endowment, it is clear that one can learn to be an expert. [4]

In learning to become a domain expert, the literature is clear in stating that many hours of practice and experience are essential [5, 6, 7]. While a person may gain the experience to become a domain expert through several paths, for engineers, primary introductions to a discipline are encountered through their education. As Leckie [8] stated:

Undergraduates, particularly in the lower years, are exposed to certain disciplines for the first time. This exposure frequently consists of a textbook, reserve materials, and lectures. The students have no sense of who might be important in a particular field, and find it difficult to build and follow a citation trail. They do not have the benefit of knowing anyone who actually does research in the discipline (except for their professor) and so do not have a notion of something as intangible as the informal scholarly network. They have never attended a scholarly conference. Because of their level of cognitive development, ambiguity and non-linearity may be quite threatening. [8]

Reference [8] brings up an important point: having a general sense of how a discipline works is essential to developing expertise and being situated within a community helps to enable this. Lave and Wenger's [9] idea of *communities of practice*, where individuals are socialized in an environment co-constructed by its participants, are able to learn, participate, and further their particular community; modifying the implicit and explicit rules that guide them on their way. Carr [4] and Sosniak [7] also stated that disciplinary experience is the common reasoning for placing individuals in situations of apprenticeship and training, or areas of socialization, so as to allow individuals to become familiar with various cultural artifacts and processes, along with the vernacular of the domain. This "insider" knowledge becomes a first step in distinguishing oneself as an expert.

In meshing the hours of practice, knowledge derived from education, and involvement within the community itself, the development of methods for efficient participation surface through new mental capacities that foster the ability to organize information learned from an expert's domain into larger chunks

[10, 11]. If some cognitive tasks do not become automated, then other growth cannot occur [12].

[...] for instance, problem-solving activities in which a number of steps that are repeated over and over coalesce into a chunk that can be retrieved as an entity containing all of the steps, thereby eliminating the need for repeated searches of long-term memory [13]

This leaves room for higher levels of cognitive activities [10] and capacity to pay attention elsewhere or focus on the creation of new solutions [14]. While there is not space to fully discuss the literature detailing the cognitive development of expertise, the purpose of this background is to showcase the importance of experience, something domain experts possess, which may allow greater processing, connecting, and implementing of ideas that are broad in scope and linked to the world in multiple ways.

II. METHODOLOGY

A. Methods

This exploratory analysis is designed to complement the greater body of engineering education literature and the research conducted at the Center for Engineering Learning & Teaching (CELT). CELT's prior studies focused on the same playground design task wherein engineers, with varying levels of design experience, were asked to think-aloud while designing a playground in a fictitious neighborhood in a three hour time-frame. Participants gave a verbal protocol while they solved the problem. A transcript of the protocol was segmented and coded for design activity, and the playground that the participant designed was evaluated and given a quality score ranging from 0 to 1.

The initial work included first year students, graduating students and expert engineering designers as participants. These studies found differences across these three levels of engineering expertise in terms of time spent, problem scoping, information gathered, and design activity transitions throughout the design process [15, 16, 17]. Data from expert playground designers were collected in the same time period that data from the expert engineering designers were collected. Experts for both groups were identified by their peers as expert designers in their field. The analysis in this current paper is intended to provide qualitative insights for the playground expert data and for a subset of the engineering expert data.

This research is situated as a predominately qualitative analysis, with coding completed by a singular graduate research assistant at CELT. The coder was purposefully provided no details regarding the goals of this study, and had not read any papers related to previous playground analyses. Here, the intention was to diminish researcher bias, allowing themes to emerge from the data [18]. The design task transcriptions were processed using an inductive or "open" coding analysis [19]. Initial stages of coding involved a read-through of content to generate preliminary codes, followed by three iterations of application that involved code addition, and altering code applications, nomenclature, and definition. Revisions were further supported as codes were discussed in CELT research meetings to clarify definitions and application.

Finally, code application was checked by a senior researcher as an expert peer review of two randomly chosen participant transcripts for each expert type. This review resulted in a high level of agreement and confirmation of code application.

The qualitative data from the coded transcriptions were then counted and entered into Excel spreadsheets to create visualizations that showcased each instance of a code on the full three-hour timeline of the design task. These visualizations were used as tools to uncover themes and patterns in the data. The code categories discussed in this paper are: context (social, environmental, economic, political); people (actors, use); and knowledge (professional, personal) More specific code definitions will be discussed in the findings section below.

B. Sample

The participant sample included for this analysis consisted of five of the original 19 engineering experts (E) and data for all four playground design experts (P). The five engineers were selected from the 19 to both show breadth of solution quality and to match the high quality design scores displayed by the playground experts. In past publications focusing on design processes we presented timelines of three of the expert engineers: one with each of high, average and low quality scores (see reference [16] for more details). We selected these subjects as representative of the range of quality scores for the engineering experts. All four of the playground experts achieved a high quality score. The final two engineering experts, we included, matched the playground experts for high quality score and similarity in terms of design process codes in previous studies. The resulting sample of engineers had three high, one average and one low quality score.

The engineering experts were screened to ensure that they did not have in-depth knowledge of playground design so that all engineering participants would not have domain experience. The playground designers were not screened for absence of engineering knowledge. This resulted in one subject, Paul (P4), having some engineering knowledge as he was about to finish a degree in mechanical engineering. Table 1 presents a summary of the participants, note that the pseudonyms for the engineering experts start with "E" and the playground experts start with "P".

III. FINDINGS

A. Considering Context

In addition to descriptive information about the participants, Table 1 presents the total amount of time that the participants spent designing the playground, and the time spent in each of the code categories (context, people, knowledge). Fig. 1 then presents how the participants distributed their time within each category as a percentage for each of the codes in that category. In this section we describe how the participants chose to use their time as described by these codes. One of the notable findings was the amount and type of contextual information considered by both the playground experts and the engineering experts. Context can be defined as background information that situates and provides a framework for moving through a design task. This analysis identified four context categories in the data: economic, environmental, political, and social.

TABLE 1: ENGINEERING EXPERTS (E) AND PLAYGROUND EXPERTS (P): PARTICIPANT BACKGROUND AND DATA

| Pseudonym | Evan (E1) | Earl (E2) | Eldon (E3) | Eric (E4) | Elizabeth (E5) | Phil (P1) | Perry (P2) | Patrick(P3) | Paul (P4) |
|-------------------------|---|---|---|---|---|---------------------------------|------------------------------------|--------------------------|---|
| Quality Score | Low | Avg | High | High | High | High | High | High | High |
| Current Title | Product Design Engineer | Product Development Engineer | Core Tire Pressure Monitoring | Leader Engineering – Passenger Systems | Consulting Engineer - System Protection | Playground Equipment Designer | Playscape Designer | Product Designer | Engineering and Safety |
| Years in Profession | 30 | 13 | 18 | 17 | 19.5 | 42 | 14 | 20 | 5 |
| Gender | Male | Male | Male | Male | Female | Male | Male | Male | Male |
| Age Range | 51-60 | 41-50 | 31- 40 | 31-40 | 41-50 | 61-70 | 31- 40 | 41-50 | 31-40 |
| Background and Training | Electrical engineering, electronic systems integration, control systems | Mechanical Engineering , Materials science, Physics | Systems Engineer Electrical Engineering | Mechanical engineering and design, many CAD classes | Electrical Engineering | Art, design & child development | Undergraduate in industrial design | BFA in Industrial Design | Currently pursuing degree in mechanical engineering |
| Overall Times | | | | | | | | | |
| Total Time | 02:25:29 | 03:01:16 | 02:28:36 | 03:01:08 | 02:50:15 | 02:43:49 | 02:58:37 | 02:56:26 | 02:56:48 |

| People | 7:42 | 7:30 | 6:24 | 5:24 | 11:54 | 29:36 | 8:48 | 36:48 | 12:06 |
| Knowledge | 1:36 | 2:24 | 1:12 | 3:54 | 4:54 | 6:24 | 4:12 | 3:06 | 10:00 |

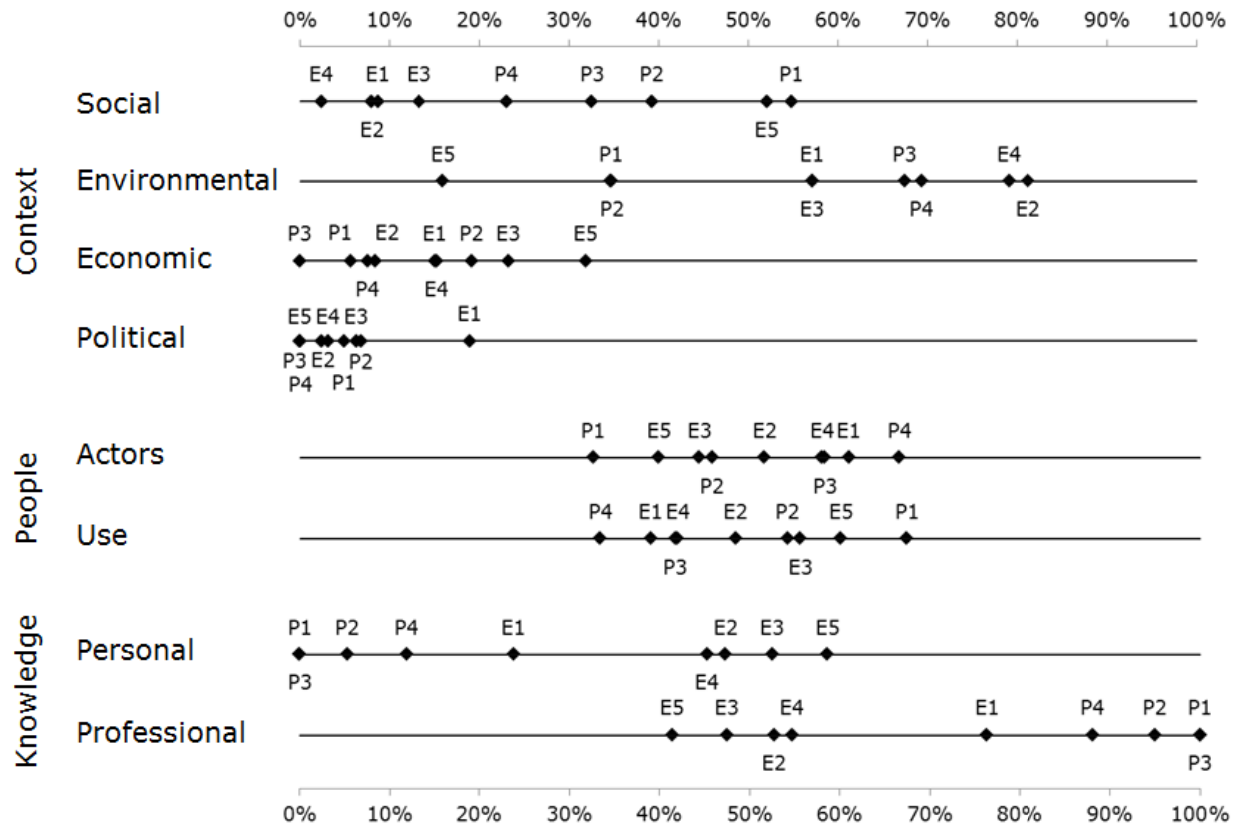

Figure 1: Allocation of time spent for each code within code category (shown as percent of total time in that category).

E1= Evan, E2=Earl, E3=Eldon, E4=Eric, E5=Elizabeth, P1=Phil, P2=Perry, P3=Patrick, P4=Paul)

All participants spent time considering context in varying amounts (see Table 1). It is interesting to note that the two who spent the most time on context issues were playground experts, and the two who spent the least amount of time on context were engineering experts. Paul (P4), the playground participant who spent the least amount of time considering context, had the fewest number of years in the field of playground design. It is also interesting to note that in the code *social* in the context category as seen in Fig. 1, the four participants who spent the least amount of time considering social issues were all engineering experts.

More interesting, may be the difference in type of context each participant considered. As demonstrated in Fig. 1, four of the five engineering experts considered environmental context more prominently than they considered social, political and economic context. As Eldon (E3) stated, "Is this a northern city that has snow, or is this a southern city that's never going to see snow?" The one exception, Elizabeth (E5), the sole female participant in this study, considered social context more than environmental. In this statement, she addressed social context in how parents would be able to situate themselves in the playground; "Seems like it might be nice to include some shade, perhaps for the neighborhood gathering area or the moms -- wow -- the parents' area, where they can sit and watch the kids."

Within the overall time participants spent on context, all the playground experts focused on social and environmental context for a large percentage of their time. Few of the playground experts spent a notable amount of time on issues of economic and political context. Perry (P) stated,

I'm trying to imagine that space, I'm imaging the families, and I'm trying to kind of feel the energy of the people and what their lives are like and how they know each other or don't know each other and trying to imagine standing in the middle of that space and thinking about the different seasons there and, um, how the sun moves through the space in the daytime and think about summer when it's hot, and maybe you need shade in places, and then thinking about wintertime and when they're plowing and wondering if they'll plow.

This greater consideration of social context by the playground experts may be the result of domain experts' capacities to pay attention elsewhere, as discussed by [14].

B. Considering People

Part of what makes noteworthy the consideration of social context by the playground experts is the fact that the engineering experts, while not as frequently as the playground experts, did consider the people-oriented codes, *actors* and *use* (Fig. 1). *Actors* relate to any human involved with the playground being designed and *use* is how the playground equipment could or should be used. It appears that the engineering experts considered people and playground use as concrete elements of specific problems in the playground task. The playground experts made broad connections to what they know about actors and playground use. As an example, Eldon (E3) stated, "Picnic tables will be handicap-accessible meaning that the table-tops will extend farther than the benches to allow

a wheelchair to be pushed up underneath". This passage was coded with *actors*, in reference to handicap users, and *use* for how the wheelchair would fit. The following excerpt illustrates how the playground expert Phil (P1) considered actors, use, and social context in a broader frame.

ADMINISTRATOR: Let me see if I have anything that addresses that. What do you mean when you say "access"?

Phil (P1): In other words, if this was a Jewish community center it would be very different from a local neighborhood. [Phil is given an information slip by the experiment administrator.] It says a lot, but it doesn't really give me a sense of whether or not we can restrict access.

Phil (P1) addressed *actors* and *use* by using the example of the Jewish community center, wherein that particular social setting provided opportunities to regulate and restrict how actors use the playground for purposes of safety. In attempting to make this playground safe, Phil noted potential issues of social context that would change the way in which the playground could or could not be enclosed.

Paul (P4), the playground expert with the engineering background, also spent a minimal amount of time considering *actors*, *use*, and *social context* together. As described previously and as seen in Fig. 1, four of the five engineering experts considered people related codes less than the playground experts. Again, Elizabeth (E5), as the sole female participant, spoke about people more often than the other engineering experts.

C. Types of Knowledge Used

Personal knowledge stems from experiences within one's personal life and interests, whereas *professional knowledge* is gained from experiences in training, education, and professional practice. While this is exploratory work with a small sample, the findings of the types of knowledge used by the engineering experts and the playground experts displayed in Fig. 1 are notable. Specifically, the engineering experts appear to be looking to their own lives and personal background to make decisions about the playground design in lieu of professional knowledge within the domain of playground design. Elizabeth (E5) stated:

So one year olds need rather small equipment. They need some large motor activity, like climbing, sliding. So, let's say one to four year olds. They also seem to enjoy the sort of places where they can climb through things and play hide and seek. Bigger kids might enjoy, ah, like a jungle gym or some sort of climbing equipment, maybe digging equipment, um. I'm thinking about the places where my kids have had the most fun playing.

Elizabeth (E5) cemented her decision on equipment choice through personal knowledge she believed to be true. The playground experts, on the other hand, tended to make decisions based on their professional knowledge. Phil (P) stated:

Okay. Well, first I would question that the neighborhood does not have time or money to buy ready-made pieces of equipment, because my experience is that it actually takes considerably more time and money to construct a quality

piece of playground equipment than a manufactured one. It's the same thing as if you were to -- if I was to say the only chairs you can have in your house are from the local lumber yard. You could not possibly duplicate a chair reasonably.

Both participant groups accessed past experiences, while the playground experts were largely focused on professional domain knowledge, and the engineers utilized both personal knowledge and professional engineering knowledge. While our participant sample was chosen to contain domain experts, this finding portrays the use of the playground experts' domain knowledge. This leads us, again, to contemplate the relationship between these domain experiences and the prominence of social and people-oriented thinking that the playground experts displayed.

IV. DISCUSSION

It is an open question as to what the engineering experts would do if designing within their own domain. Presumably, an engineering expert put in their area of domain expertise would approach a given task differently. This research suggests, however, that domain experience allowed the playground experts stronger broad contextual thinking. Again, our findings state that the playground experts were inclined to consider context (especially socially oriented factors) more often, and to think about actors' and playground use in greater amounts and in a broader fashion. The playground experts also utilized more professional knowledge, whereas the engineering experts relied on professional engineering and personal knowledge to supplement the details given to them during the task. As was shown, the knowledge the engineering experts utilized did not seem to further their consideration of broader contextual issues. Not only did the use of professional knowledge showcase that the playground experts, were domain experts, but it points toward a discussion on how greater experience in one's profession may provide a stronger base for thinking about social contextual factors and the potential for making broader connections.

Bucciarelli described the engineering discipline as one that is object oriented and focused on concrete problem solving activities, making engineers unconcerned with issues outside their area of education [21]. He stated, "What engineers do, and are expected to do, includes much more than rational problem solving and constructing efficient means to reach desired, externally specified ends". Our research describes a similar story, where the engineering experts made use of the personal and professional knowledge they believed to be applicable to complete the task of designing a playground. The playground experts we studied also showcased the importance of experience and provided an example of designers who satisfied the requirements of the task, while also considering social context and connecting people oriented factors in their design processes.

We are drawn to participants Paul (P4), a playground expert, and Elizabeth (E5), an engineering expert. Paul was pursuing a degree in mechanical engineering and he was the participant who considered social context the least, along with lesser amounts of the codes *actors* and *use*. This potentially points towards an example of engineering processes overriding

domain experience. In contrast, Elizabeth considered *social context* in the greatest amount, with the highest numbers in *actors* and *use* of the engineering experts (Fig. 1). In other work, we have documented instances where female engineers were more likely than their male counterparts to consider context while solving a design problem, showcasing evidence that inclinations to think more broadly may be partially due to differences in life experiences [20].

Overall, the findings direct us to think about domain experience as a component of expertise that is helpful in approaching any given problem. Even more, it highlights how domain experience may allow individuals to be more comprehensive in utilizing contextual factors, supplying them with the mental tools to be flexible and broad thinking in their work [22, 23].

V. IMPLICATIONS

Reference [21] again pointed to the engineering discipline as one that focuses on working to complete the task at hand, but is less concerned with external forces that may alter their designs. "The way we structure our curriculum and teach our subjects all conspire to instill in the student the idea that engineering work is value-free" [21]. Such straightforward, linear thinking in design processes may be detrimental to broader thinking. Ball and Beaty [22] prescribed activities and experiences that allow individuals different modes of exploration resulting in expanded and more creative outcomes. Others also argue for more experiences within engineering education for students to more quickly learn the industry standards as the base that will allow them to think more broadly and creatively [24].

This study seems to indicate that it is incumbent upon engineering educators to ensure that the professional knowledge that is the content of our educational programs incorporates contextual issues, so that it becomes embedded as a professional - not just a personal - concern in engineering praxis.

ACKNOWLEDGMENTS

This work was supported by National Science Foundation grants ROLE-0125547 and RED-9358516 and the Center for Engineering Learning and Teaching at the University of Washington. We would like to express our gratitude to all the participants in the study. We would also like to acknowledge the work of the research team at the University of Pittsburgh who conducted the research comparing student design processes that provided the foundation for this current study and also Robin Adams, Monica Cardella and Jennifer Turns who collaborated with us in the design and execution of the study of engineering expert designers. In addition, we would like to thank Sally Fincher and Janet McDonnell for their insights in analyzing this data, and Jennifer Turns and Ken Yasuhara for their insights in how to present our findings. Finally we would like to thank our anonymous reviewers for their thoughtful comments.

Abstract— Research in Engineering Education has led to the development and dissemination of a number of different instructional strategies (such as active learning, problem based learning, and concept tests) contributing to greater student learning in the classroom. However, there is little research to demonstrate how Research Based Instructional Strategies (RBIS) are being propagated from the developers to engineering faculty for use in the classroom. To examine the process of dissemination, this study uses Rogers' Diffusion of Innovation framework, which has traditionally been used to examine the dissemination of technological innovations through a population or organization. Rogers discusses five stages (knowledge, persuasion, decision, implementation, and confirmation) of the innovation-decision process to explain how adopters make a decision about an innovation. To investigate faculty members' participation in the innovation-decision process, we conducted a survey of electrical, computer, and chemical engineering faculty ($n = 221$) teaching engineering sciences courses. The results show that ECE and ChE faculty members are located at a variety of stages throughout the innovation-decision process. However, most respondents have progressed past the knowledge phase; they are aware of the different RBIS. It is important to account for this when presenting an innovation or trying to encourage adoption of new practices, such as RBIS. It was found that workshops and presentations can influence the trial and use of RBIS when faculty are at the persuasion and decision stages. Also, women are more likely to try and use an RBIS than men. Many of the results found here are consistent with those found in a similar study done in physics education.

Keywords - *Diffusion of Innovation; Engineering Sciences; innovation-decision process*

I. INTRODUCTION

Over the past 20 years tremendous effort and funding have been invested in improving engineering education, producing a number of Research-Based Instructional Strategies (RBIS) such as active learning [1], cooperative learning [1], and problem-based learning [2]. These RBIS can be seen as innovations that have been developed for implementation in the classroom. There has also been increased focus in recent years on ensuring that engineering education research is incorporated into teaching practice. However, little work has been done to examine how this is occurring or ways to help facilitate the process.

This paper investigates the intersection of these two efforts by asking how RBIS are transitioning from engineering education research to the engineering classroom. To do this, Rogers' Diffusion of Innovation framework [3] was used, specifically his discussion on the innovation-decision process which demonstrates how adopters (in this case, faculty members) make decisions about using an innovation (in this case, a RBIS). Specifically, this study seeks to answer the following research questions

- 1) At what points/stages do electrical, computer, and chemical engineering faculty members leave the innovation-decision process?
- 2) What faculty member characteristics, if any, correlate with being at the different stages of the innovation-decision process?

Engineering education is not the first field to investigate these questions. A similar study was completed by Henderson et al. in physics education [4]; adding the additional research question:

- 3) How do the results of this study compare to a similar study in physics education?

II. LITERATURE REVIEW

A. Diffusion of Innovation

To answer these research questions, we used Diffusion of Innovation (DOI). DOI describes the innovation-decision process in five stages:

- 1) Knowledge - the potential adopter gathers knowledge of the innovation's existence
- 2) Persuasion – the potential adopter develops an opinion about the innovation.
- 3) Decision - the potential adopter makes a decision about whether or not to implement the innovation.
- 4) Implementation – the potential adopter actually implements the innovation
- 5) Confirmation - when the adopter decides whether or not to continue using the innovation [3].

Within this research, the potential adopters are the engineering faculty members teaching the courses, and the RBIS will be viewed as innovations to the traditional lecture-based classroom.

Depending on where potential adopters are in the innovation-decision process, there are different ways to aid them in making adoption decisions. For example, if a faculty member is unfamiliar with an RBIS, providing him or her with more general information about the RBIS is important. On the other hand, a faculty member who is beginning to implement the RBIS in the classroom may need more detailed information about logistics. This is important to keep in mind when introducing an innovation to different audiences.

There have been multiple studies within educational contexts that have used elements of the DOI framework. Pundak and Rozner used the DOI stages in an attempt to encourage college staff to adopt active learning [5]. Tabata and Johnsrud focused on the characteristics of the innovation and the impact on adoption [6]. Borrego, Froyd and Hall investigated the adoption status of RBIS in engineering departments across the country by surveying department heads and mapping with the DOI framework [7]. Henderson and Dancy used the DOI stages to see where faculty left the innovation-decision process when adapting research-based instructional strategies (RBIS) in the introductory physics classroom [4].

III. METHODS

In spring 2011, we surveyed electrical, computer, and chemical engineering faculty teaching engineering sciences courses (thermodynamics, fluid mechanics, heat transfer, circuits, electronics, or introduction to digital logic and/or digital design) at their university. ECE and ChE ABET accredited departments were contacted to identify the faculty members teaching the desired courses.

An individual invitation was then e-mailed to each participant. Each person received up to three weekly reminders (if the survey had not been completed). To increase the response rate, the e-mail was endorsed and signed by a member of the survey committee of AIChE or the President of IEEE Education Society. Gift cards were offered as raffle incentives to those who completed the survey. The survey was sent to 1425 faculty members. A total of 241 responses were obtained; of those, 30 had not taught the courses of interest in the last 5 years, resulting in 211 usable responses. Four additional responses were removed because they did not respond to a majority of the questions, resulting in an n of 207. The overall response rate was calculated at 17%.

To understand potential response bias, a second round of data collection was conducted in fall 2011. This resulted in an additional 13 usable responses. Statistical comparison using Fisher's exact test revealed no significant differences between the two data sets for the variables reported here, so they were combined, increasing the response rate to 19%.

Of the 221 who completed the survey, 18% were female and 81% male (3 did not respond); 17 (7.7%) were lecturers (i.e., not tenure track), 63 (29%) assistant professors, 62 (28%) associate professors, 72 (33%) full professors, and 6 (2.7%) who listed their position as other (3 did not respond).

To analyze the data, each respondent was associated with one of four categories representing Rogers' stages in the innovation-decision process. Each faculty member was asked his/her level of awareness of 12 RBIS (Table I; for descriptions of the RBIS and references see [8]) ranging from "I currently use" to "I have not heard of it". Based on his/her response to these questions, each faculty member was assigned to a stage in the process; see Table II. This is similar to the analysis conducted by Henderson et al. [4]. For a respondent to have "no knowledge," he/she would have responded "I have heard the name, but know little else about it" or "I have never heard of it" for more than 10 (out of 12) RBIS. For a faculty member to be classified as "had not tried," he/she would have responded "I am familiar with it, but have never used it" or the responses listed above for more than 10 RBIS. The faculty member was classified as a "user" if he/she responded "I currently use" or "I have used it in the past" for more than 5 RBIS. To investigate the difference between those who use multiple RBIS, the faculty members were divided into a "high user" group (responded "I currently use" for more than 5 RBIS) or a "low user" group (responds "I currently use for less than 5).

The final stage, confirmation, represents the decision to continue use, which was not included in this analysis. Once a faculty member had been placed in one category, he/she was not considered for the subsequent categories, so if a faculty member is classified as “had no knowledge,” he/she was not considered for the remaining categories.

To address research question 2, non-parametric analysis was completed to investigate the relationship between the different stages and demographic considerations (See Table III for list of demographics.).

Chi Square analysis or Fisher’s exact test were used, depending on the cell size. All comparisons were based on 2x2 matrices comparing faculty members who were categorized into a specific stage and compared to all others (2nd column) who were not categorized into that stage. The rows contained demographic data for comparison. In some cases, demographic data were combined to fit into the 2x2 matrix format. For example, job rank was collapsed from Lecturer, Assistant, Associate, and Full Professor to Tenured (Associate and Full) and Not Tenured (Lecturer

and Assistant). Significance was determined using an alpha of 0.05. All calculations were completed using SPSS statistical software.

TABLE III. DEMOGRAPHIC VARIABLES

| <i>Demographic Variables</i> |

| Teaching Responsibility |
| Frequency of teaching discussions with colleagues |
| Number of talks/workshops on teaching attended |
| National Effective Teaching Institute attendance |
| Other one day or longer teaching workshop attendance |
| Rank |
| Gender |
| Discipline |

IV. RESULTS

From the analysis, we found that a large majority of faculty members had moved past the knowledge stage in the innovation-decision process and were more likely to have tried or to be using some of the RBIS (Figure 1). There were a number of faculty members who tried a RBIS, but then discontinued use (n = 78; 35%), but also a significant number who are currently using more than 5 RBIS in their classroom (n=58; 26%). Figure 1 shows the number of faculty members that were identified at each stage of the innovation-decision process.

| | | | | |

| Has Knowledge | Has Tried | Currently Using | High User | 58 (26%) |
| | | | Low User | 54 (24%) |
| | | Not Currently Using | 78 (35%) | |
| | | Not Tried | 24 (11%) | |
| No Knowledge | 7 (3.2%) | | | |

Figure 1. Number of EE and ChE Faculty at each stage of the Innovation-Decision Process

There were very few significant differences with respect to demographics of faculty at different stages in the process. The differences can be seen in Table IV. It was found that faculty who were at the secondary persuasion phase (deciding whether or not to “try” the innovation in the classroom) and had not tried the RBIS, also had not attended very many talks about teaching. It was also found that women were more likely to try the different RBIS than men. At the next stage, where implementation has occurred and the faculty are currently using the RBIS, it was found that attending none or a few talks about teaching resulted in even use or non-use whereas attending many talks about teaching

resulted in higher use compared to non-use. Also, attending

the National Effective Teaching Institute increases the

TABLE IV. SIGNIFICANT DEMOGRAPHIC INFLUENCES ON STAGES OF INNOVATION-DECISION PROCESS

| Stage | Demographic | | p-value | Consistent with Physics Study? |
|------------------------|---|---|---------|--------------------------------|
| Tried vs. Not Tried | Number of presentations about teaching attended | 100% who attended more than 4 presentations have tried 3 or more RBIS; 86% who attended 3 or less have tried 3 or more RBIS | 0.003 | Yes |
| Tried vs. Not Tried | Gender | 100% of women have tried 3 or more RBIS; 86% of men have tried 3 or more RBIS | 0.010 | No |
| Current vs Former User | Number of presentations about teaching attended | 72% who attend more than 4 presentations also use an RBIS; 55% who attend 3 or less also use an RBIS | 0.031 | Yes |
| Current vs Former User | Attended National Effective Teaching Institute | 87% of NETI attendees use an RBIS; 57% of non-attendees use an RBIS | 0.028 | Yes |
| Current vs Former User | Attended another one day or longer workshop | 73% of workshop attendees use an RBIS; 45% of non-attendees use an RBIS | <0.001 | (Not measured) |
| Current vs Former User | Gender | 73% of women use an RBIS; 55% of men use an RBIS | 0.047 | Yes |

likelihood of using an RBIS as does attending a different 1-day or longer workshop. Also, a higher percentage of females indicated using an RBIS than males.

When comparing with the physics study, a number of results were consistent. Both studies found that attending teaching presentations at the trial and use stages (persuasion, decision, and implementation) showed an increased likelihood of trying or using an RBIS. Attending a new faculty workshop and being female correlated with using an RBIS in both studies. However, in the physics study, gender was also found to be correlated at the level of use (high or low user) and not related to trying an RBIS, as it is here.

V. DISCUSSION

These results help communicate to the Engineering Education research community how Research-Based Instructional Strategies are being disseminated into the engineering classroom and considerations for how to expedite the process. In addressing research question 1, it was found that engineering faculty members are located at every step in the innovation-decision process. Most engineering education dissemination work focuses on raising awareness of RBIS, but few faculty lacked this knowledge. Researchers and developers need to ensure that they are communicating to faculty at all levels of the innovation-decision process, for example, by emphasizing more details about implementation.

Rogers discusses the impact of different communication channels on the different stages of adoption. The conclusions drawn by Rogers are supported by the results found in Stirman [9]. Mass media channels, such as conference papers and journal articles, are more appropriate for generating initial levels of knowledge. [3]. At later stages of the process, more interpersonal communication (face-to-face exchanges) is needed [3]. This can be seen through our results in which workshops and presentations were more influential in the later stages. More efforts should be directed at the later stages, in addition to raising

awareness. The implications for this are that as a change agent or an innovation developer, it is important to account for an audience that is at different stages in the innovation-decision process.

By investigating research question 2, it was found that a number of different variables correlated to the different stages of the process. For example, ensuring that faculty members have access to workshops, such as NETI, or on-campus presentations may help faculty try an innovation, but attention also needs to be placed on helping them to continue their use of RBIS. There were a number of faculty members who had tried a RBIS, but had since discontinued their use; this is also consistent with the results found in physics education [4]. Developers should ensure that faculty have resources to help them while trying an RBIS, such as an outlet to talk to others experienced with the RBIS or access to documentation of how other faculty address frequently experienced problems.

It was also found when investigating research question 3 that there is considerable consistency between the engineering results presented here and the physics results presented by Henderson and Dancy [4]. The commonalities between the engineering and physics results aids in triangulating these results and helps show the generalizability of the RBIS to different contexts across STEM education.

VI. LIMITATIONS AND FUTURE WORK

It is suspected that due to the low response rate, even after late respondents were contacted, there is a degree of response bias. To better understand the differences, qualitative methods will be used to interview a selection of ECE and ChE faculty members teaching the courses of interest.

It is also suspected that due to the self-reported nature of the survey, faculty may have over-reported their use of RBIS or reported using an RBIS which is not supported by the activities completed in their classroom, as was found by

Henderson and Dancy [10]. Thus, these results are more useful for comparisons between and among the various stages than as absolute percentages representative of the larger engineering education community.

Future work will investigate the consistency between the reported use of RBIS and what is occurring in the classroom by investigating the percentage of class time spent on the activities associated with the different RBIS. The study will also be expanded to incorporate the engineering sciences course of statics.

VII. CONCLUSION

In conclusion, electrical, computer and chemical engineering faculty members teaching engineering sciences courses are at different stages in the innovation-decision process. However, most have progressed past the knowledge phase and are aware of various RBIS. It is important to account for this when presenting an innovation or trying to encourage adoption of new classroom practices. More information needs to be readily available regarding implementation and overcoming challenges.

It was found that workshops and presentations may influence the trial and use of RBIS when faculty are at the persuasion and decision stages and that resources should be proved to help faculty to attend such presentations or workshops. Also, women are more likely to try and use RBIS than men. Many of the results found here are consistent with those found in physics education research, which is another means of triangulating our results.

Additional work is needed to investigate the impact of the potential response bias and the accuracy of self-reported use of RBIS.

VIII. ACKNOWLEDGEMENTS

This work was funded by the U.S. National Science Foundation through grants 1037671 and 1037724, and while M. Borrego was working for the foundation. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation. The authors wish to thank Margot Vigeant of AIChE, Susan Lord of IEEE Education Society, and the Virginia Tech Center for Survey Research for their partnership and assistance on this project.

Examining the Effect of Design Education on the Design Cognition: Measurements from Protocol Studies

Christopher B. Williams, Yoon Suk Lee, John S. Gero, and Marie C. Parette
cbwilliams@vt.edu, yoonlee@vt.edu, mparette@vt.edu, john@johngero.com

Abstract – This paper reports the progress of a three-year longitudinal study on the impact of design education on students' design thinking and practice. Students from two curricula at a large research-intensive state university are being studied. The control group is a major focused on engineering mechanics, which has little formal design education prior to the capstone experience. The experimental group is a mechanical engineering major that uses design as a context for its curriculum. A task-independent protocol analysis method grounded in the Function-Behavior-Structure (FBS) design ontology is utilized to provide a common basis for comparing students across projects and years. This paper presents results of two years of the study, which included students at the beginning and the end of their sophomore year, and at the end of their junior year. The results of analyzing and comparing the percent occurrences of design issues and problem-solution index from the protocol analysis of both cohorts are presented. These results provide an opportunity to investigate and understand how students' design cognition is affected by a design course.

Index Terms – Design cognition, verbal protocol studies, design education

BACKGROUND

How does design education affect design cognition? To answer this fundamental question, the authors are embarking on a longitudinal study of two groups of students as they progress through their undergraduate curricula. The students of the experimental group are enrolled in a mechanical engineering curriculum that contains several design courses throughout the 4-year curriculum. The students in the control group are enrolled in an engineering mechanics curriculum, which has a core focus on engineering science and theory.

To analyze effects of design education on students' design cognition, the authors compare the results of think-aloud protocol analysis of students' participation in controlled design experiments across several years. The use of verbal protocol analysis to study design behaviors is

primarily found in prior work from the Center for Engineering Learning and Teaching (CELT) at the University of Washington [1]. Atman and her colleagues at CELT used a coding scheme derived from representations of the design process in engineering texts [2]. With this methodology, CELT researchers have examined differences across experience levels (freshmen, seniors, experts) [3-5], the influence of reflection [6], team self-evaluations versus observed performance [7], and the ability to effectively contextualize design problems [8-10]. However, further research is needed to explore potential differences across engineering curricula and students' experiences throughout.

To fill this research gap, the authors in this study use the Function-Behavior-Structure (FBS) ontology as a principled coding scheme to determine design cognition [11], [12]. This coding scheme is applicable across all process-based views of designing and therefore produces results from different sessions by different designers using different design methods in such a way that the results are comparable and commensurable. In their previous work, the authors have explored the effect of a sophomore design class on the experimental group [13, 14] and a comparison of the two groups in their sophomore year [15]. In this work, the authors present a comparison of the two groups in their sophomore and junior years.

ANALYZING DESIGN COGNITION: THE FBS ONTOLOGY

I. FBS Ontology

The FBS ontology models the design process based on three classes of ontological variables: function, behavior, and structure, plus a design description [11]. It posits that the purpose of design "is to transform a set of functions into a set of design descriptions (D). The *function* (F) of a designed object is defined as its teleology; the *behavior* (B) of that object is either derived from the structure (Bs) or expected (Be) from the structure, where *structure* (S) represents the components of an object and their relationships." In addition, R is used to designate external requirements given to the designers (Figure 1).

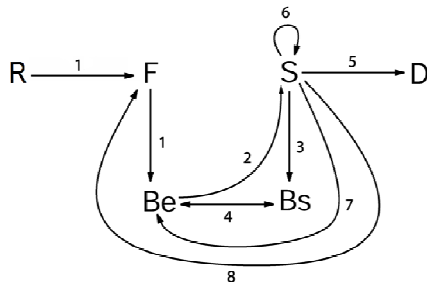

FIGURE 1
THE FBS ONTOLOGY

These ontological variables, in turn, help define a set of processes that reflect the transformations from one variable to another. In this case, the FBS ontology identifies eight separate processes. These design processes, denoted numerically in Figure 1, include 1) *formulation* which transforms requirements and functions into a set of expected behaviors; 2) *synthesis*, where a structure is proposed to fulfill the expected behaviors; 3) an *analysis* of the structure produces derived behavior; 4) an *evaluation* process acts between the expected behavior and the behavior derived from structure; and 5) *documentation*, which produces the design description. The remaining processes are types of reformulation: 6) *reformulation I* – reformulation of structure, 7) *reformulation II* – reformulation of expected behavior, and 8) *reformulation III* – reformulation of function.

II. FBS Coding Scheme

In this project we use a principled, design-based coding scheme based on the FBS ontology that translates the ontology into six design issues that map onto the ontological variables. Each design issue is coded using the FBS ontology. The six codes for the six cognitive design issues, which are used to label segments in protocol analysis, can be combined to produce eight design processes, as seen in Table 1, where “>” indicates unidirectional transformation and “<” indicates comparison. The numbers listed next to each design issue corresponds with the labels presented in Figure 1.

TABLE 1
FBS PROCESSES

| | |
|-----------------------|-----------------|
| Formulation (1) | $R > F, F > Be$ |
| Synthesis (2) | $Be > S$ |
| Analysis (3) | $S > Bs$ |
| Evaluation (4) | $Be < Bs$ |
| Documentation (5) | $S > D$ |
| Reformulation I (6) | $S > S$ |
| Reformulation II (7) | $S > Be$ |
| Reformulation III (8) | $S > F$ |

METHODS

I. Participants

Participants were recruited from mechanical engineering (ME) and engineering mechanics (EM) departments at a

large mid-Atlantic land grant university. The EM majors are considered the control group in this research, as the EM curriculum has a theoretical orientation that focuses on mathematical modeling based on first principles but has little formal design education. The ME curriculum, and its focus in design, is the experimental group. Student participation is provided by major in Table 2.

TABLE 2
PARTICIPATION IN EACH SEMESTER BY MAJORS

| | Semester 1 ($n=20$) | Semester 2 ($n=16$) | Semester 3 ($n=14$) |
|----|--------------------------|--------------------------|--------------------------|
| ME | 17 | 13 | 11 |
| EM | 3 | 3 | 3 |

The participants are a representative sample of their peer group, as determined by a series of spatial reasoning ability [16]. Students with significant design experience, as identified through a preliminary interview, were not selected as participants for this study. Those who agreed to participate in the study were compensated with a gift card to an online retailer.

Both groups had a brief first-year design experience that emphasized the engineering design process. At the time of the first data collection, the first semester of the sophomore year, the primary difference between the EM and ME students’ coursework was a focus in design. During the sophomore year, the EM students had no specific course related to design, but the ME students had a course that exposes students to engineering design methodologies. This 3-credit design course provides students with several hands-on team-based activities, which include a semester design project, product dissections, and designing products for various speculative scenarios. Further, the ME students were enrolled in a hands-on laboratory course focused on manufacturing processes (welding, machining, casting, etc.).

At the time of second and third data collection, in the second semester of participants’ sophomore and junior years, neither group was enrolled in design-related courses. Both sets of students were involved in engineering science courses (e.g., dynamics, mechanics of materials). In this regard, the two curricula are very similar aside from a handful of courses from their respective major’s core technical areas.

II. Experimental Design

Participants attended three out-of-class experiments: at midway through the fall semester (Semester 1), just after spring break (roughly mid-semester) in the spring semester (Semester 2) of their sophomore year, and late March or early April in their junior year (Semester 3). In these experiments, pairs of students worked together at a whiteboard to solve a speculative design task. In the first session, students were asked to design a device to help disabled users open a stuck double-hung window without relying on electric power. In the second session, students were asked to design a device to help stroke patients who are unable to perform bilateral tasks with opening doors

(adapted from [17]). In the third session, students were asked to design an add-on device to a hand/arm-powered wheelchair, so that paraplegic users can easily traverse over a standard roadside curb.

Student pairs worked together on the assigned design tasks for 45 minutes. Working in pairs provided for natural verbalization that was audio and video recorded, transcribed, and analyzed.

III. Protocol Analysis

A protocol analysis was conducted using the video and audio recordings of the design sessions. The research team manually transcribed all the students' verbalizations as they proceed through the design sessions. The verbalizations were then segmented and coded based on the FBS coding scheme. Two researcher assistants independently identified and coded the segments and arbitrated differences to determine the final design protocol for each session. Typical inter-coder reliability obtained by this method is in the range 85–95%. Agreement between coders is obtained using the Delphi method [18].

RESULTS

I. Design Issues Sliding Window Results

A sliding window technique was used in order to calculate moving average results, which provide a description of the dynamic behaviors across design sessions. The number of data points that will be produced from each sliding window needs to be the same for each protocol to allow for direct comparisons. In this study, 150 data points were computed from each protocol. Throughout the window movement, an independent calculation of the averages of the design issues in that window is carried out at each window position. By putting the calculated results together, a dynamic model is produced, which shows the changing values of the design issues in the course of a design session.

Figures 2 and 3 show the design issue distribution sliding window results by majors. The x-axis represents 150 segments from the design protocol and the y-axis represents the amount of cognitive effort expended in percentage. For each sliding window result, a linear regression was computed using a statistical software JMP 9.0 to calculate the goodness of fit (R^2) and the slopes (β).

For the design issue of requirement, ME students spent more cognitive efforts in semester 1, followed by semesters 2 and 3. Slight negative trends of slopes ($\beta < 0$) were identified for all semesters. For the design issue of function,

students spent significantly more cognitive effort in semester 2 than in semesters 1 and 3. Similar to the design issue of requirement, the slopes showed a slight negative trend for all semesters. These results indicate that students generally discuss design functions and requirements more in the beginning and less towards the end of the design session.

For the design issue of expected behavior, a significant difference of cognitive efforts was identified across semesters. Specifically, students expended more cognitive efforts in semester 3 followed by semesters 1 and 2. A slight negative trend was identified for semesters 2 and 3, while a slight positive trend was observed in the 1st semester.

For the design issue of structure, a noticeable difference was identified among semesters. Students spent more cognitive effort associated with structure in semester 1, followed by semesters 2 and 3. The slopes for each semester showed a slight negative trend except in semester 3.

Students expended more cognitive effort of behavior from structure as they progressed through the design session in semester 3. The change of cognitive effort was less noticeable in semesters 1 and 2. The slopes for semesters 1 and 3 showed a positive trend, while a slight negative pattern was identified in semester 2.

For the design issue of description, students spent more cognitive effort in semester 2, followed by semesters 3 and 1. While the amount of cognitive effort slightly increased towards the end of the design session in semesters 1 and 2, the amount of change in students' cognitive efforts in semester 3 was negligible.

Figure 3 illustrates the sliding window results for EM and mixed majors. In general, the amount of cognitive efforts varied more across semesters when compared to those of their ME counterparts. The changes in slopes (β) were also greater when compared to those of ME majors. This result can mostly be accounted by the change of slopes in semester 2.

For the design issue of requirement, a similar negative trend was observed for all semesters. Specifically, students expended significantly more cognitive efforts in the beginning of semester 2, followed by semesters 1 and 3. For the design issue of function, the difference of the amount of cognitive efforts among semesters were almost negligible among semesters and the slopes for each semester were all very close to zero. However, a slight increase of students' cognitive effort was identified in the middle of design sessions in semester 2.

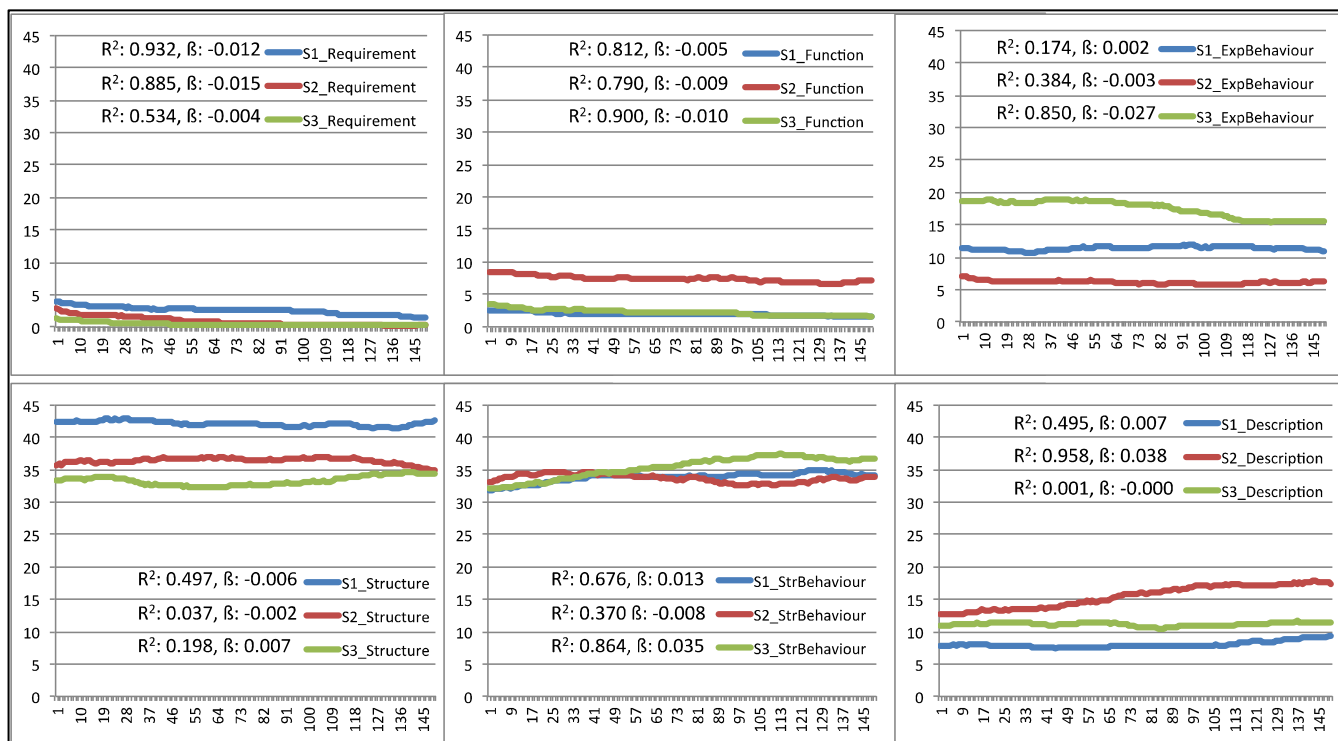

FIGURE 2.
ISSUE DISTRIBUTION SLIDING WINDOW RESULTS—ME MAJORS

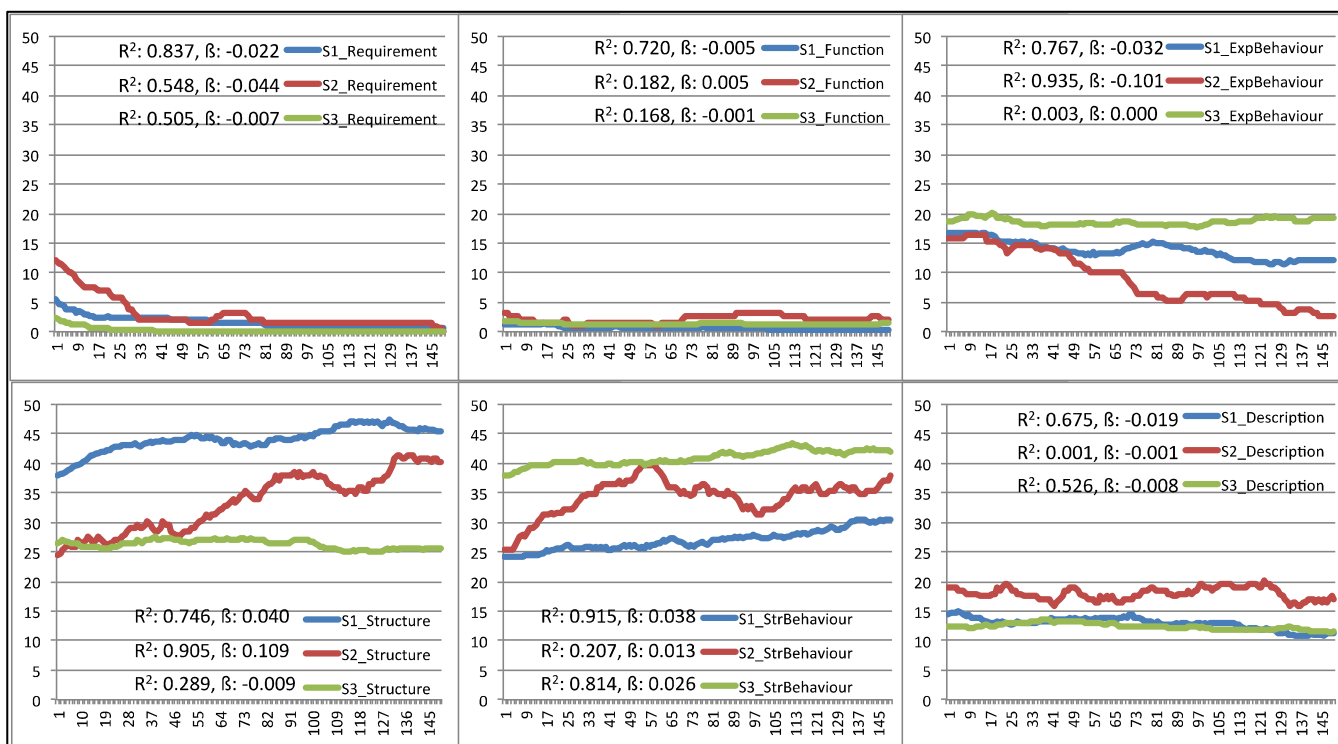

FIGURE 3
ISSUE DISTRIBUTION SLIDING WINDOW RESULTS—EM & MIXED MAJORS

For the design issue of expected behavior, students spent more cognitive efforts in semester 3, followed by

semesters 1 and 2. The amount of cognitive effort remained almost equivalent throughout the design session

in semester 3, while a significant decline was observed in semesters 1 and 2.

For the design issue of structure, students spent more cognitive efforts in semester 1, followed by semesters 2 and 3. Interestingly, the amount of cognitive efforts in semesters 1 and 2 increased as students progressed through the design session, while a slight negative trend of cognitive effort was observed in semester 3.

For the design issue of behavior from structure, students expended more cognitive efforts in semester 3, followed by semesters 2 and 1. Although the slopes for all semesters showed a positive trend, semester 2 showed the most variation throughout the design session, and more similar pattern was identified for semesters 1 and 3.

For the design issue of description, students expended significantly more cognitive effort in semester 2, when compared to semesters 1 and 3. The slopes for all semesters showed a slight negative pattern.

II. Problem-Solution Index

One method to measure meta-level design behavior is to divide all cognitive effort into that focused on the problem or focused on the solution. The ratio of cognitive effort on the problem to cognitive effort on the solution is called the problem-solution index. When the cognitive effort relates to design issues it is called the problem-solution issues index. The method to calculate this index is given in Figure 4.

$$P-S \text{ Issue Index} = \frac{SUM (Requirement, Function, Expected Behavior)}{SUM (Structure, Behavior from Structure)}$$

FIGURE 4
P-S ISSUE INDEX EQUATION

The moving averages of the problem-solution issue index describes the dynamic meta-level behavior and is

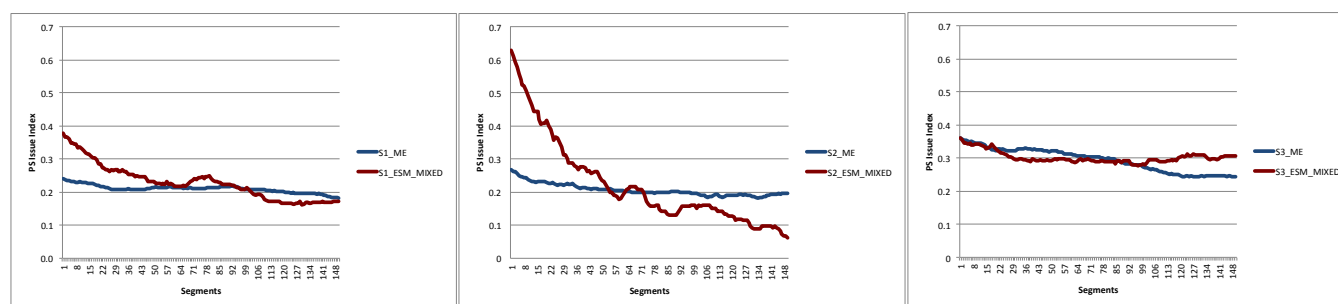

FIGURE 5
PROBLEM-SOLUTION ISSUE INDEX: SEMESTER COMPARISON BY MAJOR

Also of interest is that the control group spends very little time on discussing function. This does not change across the three semesters of experiments, which could relate directly to their curricula's lack of a design focus.

Looking at the two groups' P-S indices in semesters 1 and 2, the students of the control group spend more time

calculated in the same way as for design issues themselves. When graphed these provide the basis for observing the qualitative differences between semester and between majors.

Figure 5 shows the problem-solution issue index moving averages for each of the three semesters by major. Two qualitative differences can be observed. First the behavior of ME and EM students differ markedly in their first two semesters and converge in their third semester of this study. ME students commence with a P-S issue index value that declined only slightly in their first two semesters and dropped noticeably in their third semester. The behavior of CM students was the reverse of this. Second the P-S issue index of ME increases in their third semester.

DISCUSSION

Due to the lower number of participants in the control group, it is not feasible to quantify differences between the teams using descriptive statistics. However, qualitative observations can be made by comparing the two student groups' design issues and P-S indices. From these observations, we can note that there are differences between the two groups' behaviors.

Regarding design issues, it is interesting to note how the design cognition of the experimental group changes according to their involvement in design-related courses. For example, there is a large positive increase in the amount of time spent on function related issues from Semester 2 from Semester 1; however, the time reduces in Semester 3. The increase corresponds to the students' time in a design course focused in problem scoping and definition.

focused in problem definition than those in the experimental group (as seen by the higher P-S value). This is slightly surprising, given that the experimental group has received distinct instruction on the importance of, and strategies for, problem scoping.

While the control groups' P-S value changes sporadically across the three experiments, the experimental groups' P-S value regularly increases. As higher P-S values correlate to more expert-like design behavior, this is a positive progression for the experimental group. This progression is also evident in comparing the slopes of the experimental groups' sessions in semesters 1 and 3. A P-S slope indicates the rate of change of focus, and should be negative as the problem solving process progresses. The experimental groups' P-S slope is more negative during each semester.

In future work, the authors will close their longitudinal study by capturing the data following the students' senior years. This dataset will offer valuable insight as both groups will have concluded their capstone design courses and projects. We look forward to exploring how these formative experiences (and the two majors' varying interpretations) affect student behavior.

GLOBAL ENGINEERING: CYBER SECURITY, BRICS, AND CULTURE

Syed Nasr and Maurice Aburdene

Electrical Engineering Department

Bucknell University

Lewisburg, PA, USA

satn001@bucknell.edu aburdene@bucknell.edu

Abstract—This paper discusses our approach to a global engineering course at Bucknell University in the Spring semester of 2010-2011. The format or course-plan for the course is presented, along with suggested improvements for an expanded version covering two semesters. The course takes a multidisciplinary approach, drawing on the resources of several academic departments at Bucknell University, and presents its content in a series of stand-alone sessions or modules. These sessions were not necessarily connected to each other regarding content; instead, they were meant to provide knowledge outside of engineering which the global engineer of the 21st century needs to be aware of, but would not normally encounter in the usual course of the engineering curriculum.

Keywords—Global Engineering; Cyber Security; BRICS.

I. INTRODUCTION

A. The Need to take a Broader View

The engineer of the future will need to have the ability to navigate a multinational environment and collaborate with people with different cultures and background. Information and transportation networks, trade and economic alliances, international business and labor mobility, and humanitarian and environmental concerns have linked the world together. Engineers will need more than just core engineering skills and knowledge in order to succeed. The global nature of collaboration and work means that engineers have to interact with colleagues hailing from unfamiliar cultures and backgrounds who have different styles of working, different expectations of the work-place, and different views on how things should be done. In other words, the engineering graduate of the 21st century is likely to be faced with a number of unfamiliar situations, or with some amount of uncertainty unrelated to the technical aspects of his or her job, but stemming from the global dimension of engineering work.

To be properly prepared to work and compete globally, engineers will need to draw on knowledge from a variety of academic areas in addition to their core specialty. Taking a cue from the “Triple Bottom Line” concept in business, which measures organizational performance in terms of “People, Planet, and Profit” [1], and modifying that idea for the

purposes of this course, engineers will need a better understanding of the following.

- **People:** In order to coexist and collaborate with people from different countries and backgrounds, both inside and outside of the work-place, engineers will need to recognize similarities and differences in people, realize there may be multiple valid perspectives and approaches to problems, be able to both teach and learn cultural norms, and understand that positive contributions can come from differing points of view.
- **Planet:** Engineers will need an awareness of the social and environmental impacts attendant to work and business, in addition to the importance of both community satisfaction and approval of the solutions involving finite natural resources. Responsible action demands acknowledging these concerns in decision making.
- **Profit:** In addition to engineering expertise and experience, a basic understanding of business, management, and economics is crucial to success. Since work happens in the context of a business, this is meant to help engineers navigate their work-place better, and to develop a more thorough understanding of their business environment and the macro-level factors which impact it.

Together with their core engineering specialty, the expanded knowledge base will increase engineers’ awareness of global and cultural differences, making them more readily adaptable to their environment, and will give them greater confidence in tackling new challenges. In short, it will properly equip them to ride the waves of globalization.

B. Global Engineering Education at Other Institutions

The importance of a global dimension to engineering education has been emphasized repeatedly in the related literature; what that global dimension should actually consist of and how to implement it in the engineering curriculum have also been debated. Generally, global engineering programs

will consist of foreign-language study along with the engineering major, and will involve a study-abroad with an internship-abroad component [2]. For instance, the well-known global engineering program at the University of Rhode Island [the International Engineering Program or IEP] follows a 5-year dual-degree format, where students earn Bachelor's degrees in both engineering and in a foreign language[2]. Students study abroad and complete an internship abroad for their fourth year. Another example is Purdue University's Global Engineering Alliance for Research and Education (GEARE) program which follows a student exchange format and involves foreign language study, internships in both domestic and overseas locations for the same company, and a study-abroad component during which students begin an engineering design project at the overseas university [3].

While larger universities may possess the necessary resources to successfully run dedicated global engineering education programs, for smaller institutions, a separate program may not be feasible. Given size and resource constraints, the presentation of the global dimensions of engineering is a bigger challenge.

II. BUCKNELL UNIVERSITY AND GLOBAL EDUCATION

Bucknell University is primarily an undergraduate institution. Although a liberal arts university, Bucknell has a College of Engineering and is noted for the strength of its engineering programs. Approximately 3,500 undergraduate students attend Bucknell [4], and roughly 600 of those students choose to major in Engineering [5]. Our students have a number of opportunities for international exposure such as:

- **Bucknell-in Programs:** These offer Bucknell students the opportunity to spend a semester or an entire year abroad in Spain, France, or England, taking courses in the overseas location [6].
- **Bucknell Approved Programs:** A semester or full academic year study-abroad programs offered by non-Bucknell institutions in various locations around the world [7].
- **Engineering 290 (ENGR 290) – Engineering in a Global/Societal Context:** ENGR 290 is a summer program, three weeks in length, during which selected engineering students travel abroad and visit industrial sites, office locations, educational institutions, and other points of interest in the foreign country, while gaining exposure to the local culture. Previous trips have included locations in England, Brazil, Sweden, and Norway, and a trip to China is scheduled for the summer of 2012 [8].

In the classroom, Bucknell offers an elective course titled “The Global Engineer”, designated ENGR 291; the course is for a quarter-credit, meets once a week for two hours, and is taught in both the fall and spring semesters. Students will typically take the course multiple times (four times) to accumulate one course credit, which can then be used to fulfill Bucknell University's global and societal perspectives requirement for graduation. ENGR 291 has usually been taught with an engineering-related topic or theme in mind; previous themes for the course have included: Infrastructure and the

Global Economy (Fall 2009-2010), The Global Engineer and the Green Economy (Spring 2009-2010), and The Economics and Ethics of Global Energy Production (Fall 2010-2011).

III. OUR APPROACH TO ENGR 291: THE GLOBAL ENGINEER

We started with the assumption that students receive sufficient instruction in engineering from their engineering courses, and therefore, ENGR 291: The Global Engineer would focus on the “global” aspect of the curriculum. We focused on providing students with exposure to topics that would facilitate an understanding of peoples, cultures and the business environment and less on engineering content. A similar approach to global engineering education is taken by Lehigh University as part of their Global Citizenship Program (GCP) [9].

Since Bucknell does not have a separate global engineering program, it was a real challenge to fit all the desired material into one course. Therefore, courses which are commonly included in a global engineering program were compressed into eleven two-hour sessions, which comprised a single global engineering course. The remaining three sessions were devoted to an introduction to the course, an international dinner featuring food from the Brazil, Russia, India, and China (BRIC countries), and student presentations. Each session was designed to be a stand-alone module and was not necessarily connected to the others with regard to content; instead, each was intended to provide knowledge that the engineer needs to know. The aim was to introduce students to the topics, make them aware of the established tools and frameworks for specific interactions, and provide them with a starting point from which they can continue learning in the future.

The ENGR 291 course was divided into the following components:

- **A technical component relating to communications and security (3 sessions):** The first session focused on the use of wireless communication and information networks in China; the second session dealt with internet crime and cyber-attacks, and the third session covered computer and network security measures. Each of the three sessions was presented by a different guest speaker, from both on and off campus.
- **A country-specific component (4 sessions):** Each of the four sessions focused on one of the BRIC countries: Brazil, Russia, India and China. The term “BRIC” was coined by Jim O'Neill, an economist at Goldman Sachs, in a paper titled “Building Better Global Economic BRICs” in 2001 [10]. The paper postulated that the economies of the four BRIC countries would become a more significant part of the global economy, symbolizing the rising economic strength of the developing world, as opposed to the developed G7 countries (U.S.A., U.K., France, Germany, Italy, Japan, and Canada). Each of the country-sessions was led by a guest speaker from that respective country, who gave an overview of the country from a historical, political, economic, and cultural point of view, and also facilitated classroom discussion based on assigned readings for that particular class. All the readings were sourced from Harvard Business Publishing (<http://hbsp.harvard.edu/>). There were two readings for each country: “Brazil Under Lula:

Off the Yellow BRIC Road” and “Vale: Global Expansion in the Challenging World of Mining”; “Russia: Revolution and Reform” and “Gazprom (A): Energy and Strategy in Russian History”; “Leadership Lessons from India” and “Infosys: A Profile of One of India's Pioneering Multinationals”; “China: Building Capitalism with Socialist Characteristics” and “HNA Group: Moving China's Air Transport Industry in a New Direction”.

- A business and management component (2 sessions): The first session covered negotiation techniques, including Geert Hofstede's cultural dimensions - psychological dimensions, used to describe cultures. Professor Hofstede is a well-known social psychologist whose research delves into national cultures and their effects on organizations. Hofstede's cultural dimensions consist of: power-distance, individualism, masculinity, uncertainty avoidance, and long-term orientation [11]. The second session covered industry analysis using the research of Michael Porter, professor and leading authority on management strategy and competition. Specifically, we used his five forces framework (competition or rivalry within the industry, barriers to new entry, availability of substitutes, bargaining power of supplies and bargaining power of customers [12]), to examine industry attractiveness. In addition, we highlighted scenario planning, which is a strategic planning and forecasting method used by organizations to facilitate long-term decision making [13].

- A cross-cultural communications component (1 session): This session focused on how perceptions, decision-making, and approaches to problem-solving may differ from culture to culture, with China and Germany serving as examples. One of the guest speakers for this session was the International Student Services director at Bucknell University, who introduced the Intercultural Competence Model developed by Dr. Darla Deardorff, which provides a framework for interacting with other cultures successfully [14]. The other speaker for the session was from Exxon Mobil and had traveled abroad extensively on job assignments. He shared his experience in dealing with other cultures in the context of international business and how culture affects business communications. The reading assigned for this session was “Cultural Shock: Adjustment to New Cultural Environments” by Kalervo Oberg [15].

- An expatriate experiences component (1 session): This session discussed what qualities make for a successful expatriate. The guest speakers were two Bucknell professors who had lived and worked in Japan for a number of years. They recounted how they had gradually acclimated to a new country and shared their advice on living abroad. The assigned reading for this session was “Up or Out: Next Moves for the Modern Expatriate”, a report from the Economist Intelligence Unit about the state of expatriate assignments in the 21st century [16]. Given the fact that students may go abroad while at college or in the course of their professional careers, addressing the challenges of overseas assignments and the requirements for success are particularly important.

IV. IMPROVING ENGR 291

Building on the experience of our first ENGR 291 attempt, improvements are suggested for the content of the sessions, for the assigned readings, and for the course as a whole. Since ENGR 291 is a quarter-credit course and almost all students who take it will do so multiple times to earn one full credit hour, we believe enough material can be added to develop two courses to be offered in the fall and spring semesters. The technical component could be reduced or eliminated, since that material is covered in other courses. Following is a suggested plan for the two-part ENGR 291 course, with the contents of the sessions updated in order to improve upon our implementation.

A. For the fall semester (part 1 of the course)

- Drivers of Globalization (1 session): Globalization is a fact of the modern world and the better understanding students have of its origins and its impact, the better they will be able to compete in their professional careers and to successfully negotiate their own futures. A number of formative world events occurred in the closing decades of the 20th century, which helped bring about globalization [17], and because everything cannot be covered, we have chosen to highlight events of the 1980's and 1990's, including:

- Technological events: Advances in microprocessor capabilities leading to the rise of personal computers and mobile computing devices; the rise of fiber-optic communication systems to enable large volumes of information flow across the globe, and the rise of the World Wide Web [17].

- Financial events: The deregulation and liberalization of international financial markets, and the emergence of private international banking and credit services, which made global capital transfer easier and quicker, and powered the growth of international business [18].

- Political and Economic events: The dissolution of the Soviet Union in 1991; the disintegration of Yugoslavia in 1991 – 1992; the reunification of Germany in 1990; the end of apartheid in South Africa in 1994; the emergence of China as a superpower due to economic reforms in the 1980's and 1990's; the economic liberalization of India in 1991; the establishment of the European Union in 1993; and the establishment of the World Trade Organization in 1995 to promote more liberal international trade policies.

- Environmental events: International environmental treaties such as the Montreal Protocol of 1987 aimed at addressing the depletion of the ozone layer and the Kyoto Protocol of 1997 aimed at mitigating global warming.

It is important to emphasize to students that while “globalization” has received a lot of press of late, the phenomena is not new: different peoples and different cultures have been interacting with each other for purposes such as trade, exploration, or conquest for hundreds of years.

- **Macroeconomic Principles (1 session):** Engineering students may have gleaned a cursory exposure to certain topics in macroeconomics through news media, but do not have a working knowledge of the concepts. To provide them with the necessary background in this area, we give them a primer on measures of national income and output, unemployment, inflation, and instruments of monetary and fiscal policy.

- **Environmental Studies (1 session):** The addition of this topic is to address the lack of an environmental component (the “Planet” aspect in the previously mentioned desired areas of knowledge) in the first version of the ENGR 291 course. It will cover issues regarding water, energy, food production, population growth, land use, pollution control, and sustainability.

- **Country-specific sessions (4 sessions):** Brazil, Russia, India, and China will remain as the focus of the country-specific sessions. However, only one reading can be assigned for each session instead of two, specifically: “Brazil under Lula: Off the Yellow BRIC Road”, “Russia: Revolution and Reform”, “India on the Move”, and “China: Building Capitalism with Socialist Characteristics”. The readings are all purchased by the students from Harvard Business Publishing.

- **Business and Management sessions (2 sessions):** There is no need to make any significant changes to either the readings or the emphasis for this portion of the course; it could have the same content as before: negotiations and Hofstede’s cultural dimensions for the first session, and industry analysis and scenario planning for the second session.

- **Cross-cultural communications (1 session):** Greater emphasis could be placed on the dimensions of cultural orientation, such as the different perceptions of environment, time, action, and communication; the presenter(s) can also illustrate cross-cultural communication issues in the business world and during trips abroad so that students can better understand the relevance of the topic. The suggested reading for this session is an article titled “Cultural Differences in Business Communication” by Professor John Hooker of Carnegie Mellon University’s Tepper School of Business [19].

- **Expatriate Experiences (1 session):** As before, this session will discuss what qualities make for a successful expatriate, and will also cover the phenomenon of culture shock as one arrives in a new country for the first time, and tries to adjust to living there. The suggested readings for this session are “Making It Overseas” from Harvard Business Publishing, and “Cultural Shock: Adjustment to New Cultural Environments” by Kalervo Oberg.

B. For the Spring Semester (Part 2 of the Course)

- **Philosophy and Ethics (1 session):** The basics of Western philosophical thought will be explored, starting with rationalism (the idea that knowledge is derived from pure thinking and reason) and empiricism (which holds that knowledge is derived from sensory input and experience) [20], moving on to deontological or rule-based ethics, contrasted

with utilitarianism or consequence-based ethics, and ending with a look at contemporary ethical theory.

- **Psychology (1 session):** As an introduction to this topic, the basic concepts of psychology will be presented, followed by the aspects of both social and cultural psychology, with an emphasis on theories of social interaction and the effect of cultural traditions on human behavior.

- **Political Science (1 session):** This review of the important international events and changes since WWII will include the topics of national decision making, conflict resolution, diplomacy and war.

- **World Religions (2 sessions):** Religion and culture are inextricably intertwined and exert an influence on the behavior of individuals and societies. The three major monotheistic faiths of Christianity, Islam, and Judaism will be covered, followed by other major world religions, including, Buddhism, Confucianism, Hinduism Shinto, and Taoism.

- **Country-specific sessions (2 sessions):** Two countries will be examined in detail, Mexico and South Korea. Mexico’s proximity to the United States, along with its unique relationship and history with the U.S. makes it an interesting candidate for study. South Korea warrants a look because of its economic history as one of the Four Asian Tigers, its technological and industrial strength, and its continued exceptional growth despite being a developed country. The suggested readings are “Mexico: Crisis and Competitiveness” and “Transforming Korea Inc.: Financial Crisis and Institutional Reform”; both readings are from Harvard Business Publishing.

- **Accounting and Finance Basics (1 session):** Given that all organizations need to keep accounts of how they fund themselves and what they spend their money on, it follows that having an elementary understanding of accounting is important. This session will introduce the basic accounting statements – the income statement, the statement of cash flows, and the balance sheet – and will also cover financial ratios used to mathematically assess the financial health of a business.

- **Marketing and Selling (1 session):** A knowledge of marketing and selling techniques would be beneficial, firstly because engineers are generally not trained in such techniques, and secondly because, regardless of where careers paths may take our engineers, it is highly probable that somewhere along the line, they will have to engage in some form of promotion or selling, be it for a product that they helped to develop or for a service. This session can cover marketing concepts such as the marketing mix or the Four P’s (Product, Price, Place, and Promotion), aspects of brand management, and personal selling techniques.

- **Operations Management (1 session):** A business’s operations can all be broken down into processes which can be analyzed and optimized in order to improve the business’s performance and to give it a competitive advantage over its rivals [21]. This session will introduce the basic concepts of Process Analysis, and will involve a case-study to give the engineering students a better grasp of the topic. The suggested case for this session is “Benihana of Tokyo” from Harvard Business Publishing.

- Business, Government, and Society (1 session): A case-study involving stakeholders from business, government, and society will be the basis for discussion and debate. The objective of this session is to introduce engineering students to the thorough nature of case discussions, and to the complexities created when conflicting interests, perspectives, and beliefs collide, which is often the case in the real world. The suggested case-study for this session is “Royal Dutch/Shell in Nigeria (A)” from Harvard Business Publishing. This session is modeled on and named after a management course offered at Bucknell University titled “MGMT 312: Business, Government, and Society.

V. CONCLUSION

We presented our approach at Bucknell University to the course “ENGR 291: The Global Engineer” followed by suggested improvements for future offerings. It is our belief that having a more diverse academic background will make engineers more open to new experiences, more comfortable handling uncertainty, and more well-rounded as individuals.

As the world becomes increasingly interconnected and different countries rise up to participate in the global economy, it is not possible to train our engineers to handle each and every culture and unfamiliar situation they may encounter. Perhaps the single most important result a global engineering course can achieve is for its students to possess an awareness of the complexities of the future and the confidence to face them. It is our hope that this objective has, at least to some extent, been realized through the global engineering course discussed in this paper.

ACKNOWLEDGMENT

We would like to extend our appreciation to the following for their participation as guest speakers in the Spring 2011 offering of “ENGR 291: Global Engineer” : Xiannong Meng, Professor of Computer Science, Bucknell University; Luiz Felipe Perrone, Associate Professor of Computer Science, Bucknell University; Colonel Barry L. Shoop, Professor and Deputy Head of Electrical Engineering, United States Military Academy – West Point; Param S. Bedi, Chief Information Officer, Bucknell University; Slava I. Yastremski, Associate Professor of Russian, Bucknell University; Zhiqun Zhu, Associate Professor of Political Science and International Relations, Bucknell University; Michael E. Johnson-Cramer, Associate Professor of Management, Bucknell University; James J. Orr, Associate Professor of East Asian Studies, Bucknell University; Margaret G. Wismer, Assistant Professor of Physics and Engineering Technology, Bloomsburg University; Paula C. Myers, Director of International Student Services, Bucknell University; and Dean Runkle, Senior Crude Oil Trader for North America Crude Trading, ExxonMobil Refining and Supply.

Work in Progress: An International Engineering Certificate: Incentivizing Engineering Students to Pursue Global Experiences

John Paxton, Heidi Sherick, Robert Marley

College of Engineering
Montana State University
Bozeman, MT 59717 USA
paxton@cs.montana.edu, {hsherick, rmarley}@coe.montana.edu

Abstract—An innovative, easy to implement International Engineering Certificate is introduced in this work-in-progress, innovative practice paper. The certificate enhances a four year engineering or computer science major without delaying the time to graduate. Other benefits include low cost, flexible structure, appeal to diverse audiences and potential for external support opportunities. The certificate is compared to four international opportunities provided by other engineering programs.

Keywords—international engineering certificate, international engineering education, global experiences

I. INTRODUCTION

As the world's economy becomes increasingly integrated, the marketplace demands engineering and computing graduates who have more sophisticated international knowledge and skills. It is important for the engineering education community to help its students prepare for work in a global context and the challenges of the globalized world [1].

To help meet this demand, the Montana State University (MSU) College of Engineering (COE) created an International Engineering Certificate [2] that was approved by the Montana Board of Regents in September 2011. To earn the certificate, a computer science or engineering student must (1) select a country or region of focus, (2) earn 15 credits of relevant coursework and (3) spend two weeks or longer in that country or region as part of a study abroad, work abroad or service abroad experience. If MSU offers a relevant language, the first three language courses must be completed.

II. RELATED WORK

University of Rhode Island – International Engineering Program. URI's program [3] allows a student to earn two majors simultaneously; one in engineering and one in a language. The program takes five years to complete and requires the fourth year to be a study abroad year.

In contrast, the MSU certificate can be completed in four years with less stringent language and international experience requirements. The MSU certificate is thus less demanding as would be expected when comparing the requirements of a

second major to the requirements of a certificate. Consequently, the MSU certificate is more accessible to a larger population of students.

Purdue University – College of Engineering Global Minor. Purdue's program [4] requires a student to demonstrate proficiency in a second language, study engineering abroad for one semester, undertake an internship for a global corporation (three months domestically plus three months abroad), and participate in a two semester project that involves a co-located global team for a portion of the project.

Purdue's Global Minor is similar to the MSU certificate in that it requires a student to focus on a non-native country or geographic region. However, Purdue's Global Minor requires living abroad for at least six months whereas the MSU certificate requires living abroad for a minimum of two weeks. Not surprisingly, there are more requirements to earn a minor than to earn a certificate. Once again, the MSU certificate is more accessible to a larger population of students.

University of Colorado – International Engineering Certificate. UC's program [5] requires a student to earn at least 15 relevant credits pertaining to one of the following six languages: German, French, Spanish, Italian, Chinese or Japanese. An international study or co-op experience is encouraged, but not mandatory.

The Colorado and MSU certificates are comparable with respect to the number of credits required and the number of language courses required (when relevant). The Colorado certificate is easier to earn if a student chooses not to engage in an international experience. However, there is much value in requiring a student to be immersed in another culture. In addition, the MSU certificate provides more flexibility by enabling a student to choose any non-native country as a focus.

MIT International Science and Technology Initiatives (MISTI). The MISTI Program [6] provides both undergraduate and graduate students with paid internships and research opportunities around the world. The requirements to participate in an internship vary slightly from country to country. In general, students need to complete two years of

language study (if the language is offered at MIT) and a relevant culture course. MISTI also provides global seed funds to help faculty jump-start international projects.

Although the MISTI program does not confer additional degrees upon a student, it is exemplary in providing guaranteed internship opportunities as well as seed funds for faculty. MSU strives to develop such opportunities.

III. CONTRIBUTIONS

Diversity. Women comprise 15% of the students in the COE. Yet, 34% of the 68 students who have expressed an interest in pursuing the IEC are women. The certificate could prove instrumental in attracting more women to study engineering.

Ease of Attainment. With careful planning, the certificate can be earned alongside a COE degree in four years. Once a country or region of focus is identified, many of the 15 credits can be earned in the context of university core requirements.

Low Cost of Implementation. The certificate does not require any new courses to be developed. It takes advantage of existing courses that are offered by departments that range from Modern Languages to History to Economics. The costs incurred thus far include the time to develop the certificate, the time to keep the certificate updated with respect to current opportunities, the time to advise students and the time to certify that students have earned the certificate.

Flexibility. The certificate caters to both domestic and international students by allowing any non-native country to be chosen as a focus. Thus, international students could focus on the United States and automatically satisfying the study abroad requirement. Furthermore, because a student can choose any non-native country or region as a focus, the world is literally each student's oyster!

Advancement Opportunities. The certificate provides advancement (development) opportunities for both individuals and corporations. As one example, scholarships would help make the study abroad or service abroad requirement more affordable to a greater number of students. As a second example, corporations might be engaged by asking them to provide guaranteed work abroad opportunities to qualified students.

Enhanced Student Skill Sets. A student who earns the certificate should be more marketable upon graduation, as well as a better global citizen.

IV. FUTURE WORK

Assessment. We must determine how we will assess the success of the certificate once significant numbers of students begin to earn it. Certain information is easy to obtain such as

the gender of the student, the major of the student, the country or region chosen, and whether the student chose to study abroad, work abroad or perform service abroad. We need to identify learning outcomes and develop an assessment method for these outcomes.

Work Abroad Opportunities. If a student wants to work abroad, she is responsible for finding the opportunity. Because this is difficult for a student to do, the COE strives to identify guaranteed opportunities in diverse locations. For example, it would be beneficial to offer an automotive internship in Stuttgart, Germany. MIT's MISTI Program [6] is an exemplary model of providing such opportunities.

Service Abroad Opportunities. The COE has a vibrant chapter of Engineers Without Borders (EWB) that enables students to perform service in Kenya each year. COE students may also affiliate with the Montana Tech chapter of EWB to perform service in El Salvador. We need to identify more service opportunities in diverse locations.

Study Abroad Opportunities. In addition to the standard study abroad opportunities, the COE strives to offer more short-term, faculty led study abroad opportunities for its students. These opportunities appeal to a segment of our student population who are not yet ready to venture forth on their own. An example of this occurred last summer when an MSU computer science professor led nine computer science students on a six week study abroad trip to Kyoto University.

Advancement Initiatives. The certificate provides ample opportunities to engage individuals, corporate partners and our advisory board. We must formulate and execute a plan to provide travel scholarships, work abroad opportunities, etc.

Student and Faculty Awareness. Because the certificate is at the college level as opposed to the departmental level, it presents special challenges in terms of making students and faculty aware of its existence. Students should ideally learn of the certificate early in their academic careers so that they can earn it without delaying graduation. Faculty need to be aware of it for advising purposes. Strategies are under development to accomplish these goals.

yousof.alhammadi@kustar.ac.ae

Abstract— New studies in the United Arab Emirates (UAE) have delved into investigating the factors why students do or do not appreciate Science, Technology, Engineering, and Mathematics (STEM) courses. Many indicators point mainly to the effectiveness, or ineffectiveness, of teachers. The main purpose of this paper is to identify significant factors that affect a teacher's effectiveness. This is done through an analysis of the results of a twenty-four-question survey, developed by the authors, given to 200 Science, Technology, and Mathematics teachers, from Kindergarten to Grade 12, in public and private schools across the country. A literature review consisting of comparable studies in other countries served as a backdrop to the many trends discovered in the analysis of teachers' responses. Furthermore, the authors provide additional critical interpretations to address the unique nature of the findings in the UAE educational system. Overall, the findings point to the dire need to address teachers' dissatisfaction with the teaching profession in the UAE. Specifically, addressing monetary compensation, improving the curricula, lack of resources and providing professional guidance via development courses and seminars is necessary if teachers are to be more effective in the classroom.

Keywords- Grade K-12; STEM; Teacher Effectiveness; UAE.

I. INTRODUCTION

Extensive research has been conducted globally by many academic entities into what proves to be an effective educator in knowledge-based economy. In the previous UAE studies presented in [1,2], analysis of secondary and post-secondary students in the UAE provided useful information about why students choose or do not choose to enroll in Science, Technology, Engineering, and Mathematics (STEM) programs. These studies revealed that the most important factor that determines a student's desire to like or enroll in STEM is based on the capability of the STEM teacher. In other words, the studies [1,2] urge a strong need to increase the capability of STEM teachers in order to get students to like STEM classes and therefore significantly increase the likelihood that they will enroll and graduate from STEM academic programs. Thus, this paper seeks to identify the factors that enable and prevent teachers from being capable educators.

Investment in human capital, teachers and administrators, is one of the cornerstones of the UAE's educational overhaul [3]. So far, the UAE's school systems have opted to hire licensed educators from surrounding

Arab countries, and in the past 3 years, from Western, English-speaking countries. Governmental agencies, such as the Abu Dhabi Education Council (ADEC) and the Ministry of Education, have taken measure to help ensure that they are hiring and retaining teachers who are qualified to carry out the task of preparing the Emirati young generation to create and sustain a knowledge-based economy [3,4]. Given that STEM is the centerpiece for jumpstarting and maintaining a knowledge-based economy, an importance has been placed on ensuring that STEM teachers and programs are given much attention [3,4]. However, it is almost commonsensical to understand that even though a teacher may be qualified to teach, the environment surrounding these qualified professionals is also crucial.

In all, students in the UAE have already provided a glimpse of what motivates and demotivates them to join STEM programs [1,2]. Seemingly, at the center of their choice is the capability of the teachers. This paper serves as an investigation into the minds of STEM teachers in the UAE dissecting what they are doing or attempting in their classrooms and what they believe are factors that are aiding and hindering their abilities to be capable educators. In the subsequent sections, this paper will discuss results and conversations from other similar research, present the methods used to collect the data for the research and provide a deep analysis of the research results. Finally, this study will provide a conclusion that compares this research with previous ones discussed in the literature review and provide suggestions for potential research projects to advance the understanding and effective implementation of this topic.

II. RELATED WORK

Similar studies on determining factors that affect teachers from optimally performing have been conducted in other countries. However, considering the different contexts and variables due to culture, religion, etc., research specific to the UAE is necessary. Nevertheless, using the findings from these earlier scholars is still useful as a backdrop to this research. The following is a review of prominent academic research and commentary of what makes teachers feel that their work is effective.

Many international studies show that job preparation and skills development are vital factors in the recruitment and retention of professionals. For teachers, this usually means

the foundational learning of modern pedagogy and frequent updates to the changes in the field. According to previous research conducted in the USA [5,6] and Canada [7], the lack of preparation and professional development has led to high levels of teachers' incompetence. In addition, another study [8] declared that a considerable amount of first-year educators in New York commented that teacher preparation institutions did not effectively prepare them for their first-year of teaching; thus, professional development and mentoring are key.

Furthermore, the lack of input teachers have in the school's decision-making and professional development adds to the feeling of lack of autonomy. Experienced teachers in the USA are concerned with how autonomous they feel and the value of their input [9]. Moreover, a significant number of teachers in the USA would sacrifice the higher wages of other professions to work in a school where there is a positive environment [10-14].

Thus, this assertion may neutralize the age-old debate and assumption from the USA and the UK studies that state relatively low wages offered to teachers are why "talented" professionals do not choose to become teachers or do not stay in education. For example, in a 2002 survey, California educators, who were prepared to leave the teaching profession, listed "salary considerations" as the number one reason that led to their decision [15]. Salary compensation was also ranked in [16] as a highly influential factor that Washington male and female teachers will consider for remaining in the profession or leaving. The comparative study [17] found out that poor salary was the major reason behind the teacher demotivation or attrition in the UK.

Moreover, the inadequate amount and/or access to resources such as textbooks and computers, adds to teachers' job dissatisfaction according to some research carried out in the USA [8]. Moreover, the physical quality of the school facility is another important predictor of teachers' motivation, satisfaction and success. The research conducted in Sweden [18], and different USA studies [19-22] link facility quality to learning outcomes and teacher morale.

Additionally, stability and coherence of government education policies like curriculum professional standards and certification procedures play a major role in a teacher's job satisfaction. In a New York study [8], many teachers vented their anger toward the fickle nature of education policies and the lack of clear and accurate information. The study, conducted in rural middle schools of North Carolina [23], affirmed the assertion that curriculum changes, such as adoption of new standards or procedures, added to factors that affect teachers' performance and competency.

In addition, the number of students in classrooms is a major factor that dictates what type of teaching method an educator employs. Essentially, class size weighs heavy on teachers' pedagogical styles. The research conducted in the Netherlands [24], the UK [25] and the USA [26] suggested that the smaller the student to teacher ratio is, the more flexible the teacher could be. Basically, smaller class sizes

allow the educator to take heed to the individual needs of his/her pupils more than larger ones.

Finally, according to research conducted in the USA [15] and Australia [27], the dual perception that people have of the teaching profession also affects the effectiveness of teachers. These two studies demonstrate that public perception of the profession as relatively easy (because of its vacations, preferable hours, etc.) means that teachers are treated as a lower caste in the professional rung and this tends to alienate educators. In all, teachers may become mentally fatigued with having to battle negative stereotypes about the "ease" of their job and low social status of the profession in the eyes of the community. This may also lead to teachers' frustration and low esteem.

Overall, worldwide academic studies about what has led to teachers feeling effective in their profession vary to certain degrees. Literature from the past three decades from different countries point to factors that affect an educator's effectiveness such as low wages, undesirable work conditions and incoherent governmental policies which lead to frustration and attrition. Additionally, the social stigma that some societies have towards their educators sometimes has an effect of creating a professional inferiority complex. In all, these prominent studies will serve as a background to facilitate a comparison with the information that will be presented in this research's findings.

III. RESEARCH METHODS

This research project started with a survey, developed by the authors, given to Science, Technology, Engineering and Mathematics (STEM) track teachers in the K-12 public and private school sectors across the UAE. In all, 200 teachers took the questionnaire. The survey was distributed in Arabic or English, according to the preference of the teacher, and was completely anonymous in order to ease teachers' anxieties over possible reprisals for their responses. Of these 200 teachers, 102 currently teach in public schools while 98 are in private schools. The gender breakdown of the participants consisted of 93 males and 107 females. In terms of nationality, 100 identified themselves as UAE nationals and 100 as non-UAE nationals. This survey collected the ethnic, gender, and professional identities of the participants in order to compare the results and understand if these factors altered the responses given.

The questionnaire itself contained 23 multiple-choice questions and one open-ended question. The first thirteen questions were split into five categories:

1. Teachers autonomy in their classroom.
2. Curriculum changes made by policymakers.
3. Role of the administration in the classroom.
4. Teacher's influence in the school's curricular decisions.
5. Job satisfaction.

Response options for these 13 questions ranged from strongly disagree, disagree, neutral, agree, to strongly agree. These questions were formed with the intention of

pinpointing the factors that may be enhancing or hindering the teacher's effective performance in class.

The remaining 10 multiple-choice questions gauged the frequency of an action that the teacher has done in the span of a school year. These questions tried to identify how often basic effective methods were used by the participant. Four categories also comprised this section of the questionnaire. They included

1. Sharing of pedagogical knowledge with colleagues.
2. Direct instructional strategies used with regard to students and their parents.
3. Assessment and data evaluation.
4. Attendance of professional development workshops.

Response options for these 10 questions ranged between 1-3 times a year, 4-6 times a year, 7-9 times a year, 10 or more a year, and never.

Finally, the open-ended question was: "*In your opinion, what are the effective strategies you would recommend for your school to improve students' achievements in STEM subjects?*" This final question was used to gauge teachers' most impending need to become more effective in the classroom.

IV. RESULTS AND DISCUSSION

The UAE's policy of drastically improving its education system include actions such as building new schools, incorporating technology into classrooms and revamping its educational workforce. The latter tactic needs special attention because the educator labor force and its effectiveness can significantly determine whether a school is successful or not. Considering that the UAE is in pursuit of establishing a respectable and competitive innovative economy, strengthening STEM is foundational. However, in order to achieve this goal, understanding whether UAE teachers, in public and private sectors, feel effective as educators is essential. In the following sections, we analyze how UAE teachers responded to the survey that aimed mainly to understand what factors affect K-12 STEM teachers' performance. We will discuss the aggregated data, i.e. the nine categories, as main points of discussion and point to specific questions in the categories when necessary.

Autonomy, or the feeling of self-governing or control over something or someone, can be a reality that some teachers want and others do not. Essentially, the concept of autonomy in the school context is the idea of being independent in one's work and classroom rules, procedures, etc. and not being hassled by higher ranking authority figures. For the 200 teachers in the study, 92% agreed to the fact that, as a teacher, they receive autonomy over their classes (as shown in Fig. 1). However, the concept of autonomy can be mapped to a spectrum of total trust in one's professional wherewithal from the school administration (and thus allowing the educator to do what he/she sees fitting) or sheer neglect. The questions asked in the survey probed the limits of teachers to use creativity and

their own teaching strategies. This appears to show that the schools are not insisting on any specific methods or strategies of teaching and instead put the burden on the teacher. Some teachers may welcome this approach because it may give the educator a sense of being trusted and a complete ownership of his/her class. Furthermore, if teachers, more than likely veterans, interpret autonomy given to them from their superior colleagues as "I trust your skills" then this may give the teachers a positive perception of the profession.

On the other hand, new teachers, specifically young ones, may see this "autonomous" approach as another word for "indifference" toward the educator. If perceived in this negative light, the educator may feel neglected and unguided; consequently, this could lead to teachers performing below effective levels and eventually resigning. But overall, 92% of the respondents stated that the schools leave them to use their own creativity and strategies to reach the students.

The following category in Fig. 1 deals with curriculum changes. This pertains to the issues of whether the teacher keeps up with new mandates from school policymakers and whether the curriculum is appropriate for the age and interest-levels of students. In general, this second category is seen in a negative light. Only 30% of teachers state that curriculum changes are monitored for their effectiveness and fit students' performance levels and interests. However, 60% of the respondents believe that entities in charge of creating a certain curriculum do not follow-up on whether it is effective and whether the material is in-touch with students' abilities or not.

Major disconnections between the curriculum and the students' levels of ability and interest have the potential of resistance from students who may see the curricular material as difficult or oppressive. In response to student unrest over "esoteric" curricula, teachers may feel frustrated given that they must deal with the fallout of students who are weary of an unpopular curriculum. Furthermore, it is difficult for teachers to feel effective in their students learning process if the curriculum is seen as irrelevant or disconnected.

The role of administrators, their philosophies, attitudes and decisions pertaining to the classroom can alter one's outlook on the classroom environment. Administrators are the leaders of the school and can have positive or negative influence on the teacher. In this portion of the questionnaire, the role of the administration in regards to setting high standards for STEM and providing enough resources for STEM teachers were questioned. While 30% of teachers agreed, 58% of the respondents disagreed and strongly disagreed with the idea that their administration provides enough materials and curricular standards for STEM. Some teachers can interpret this as a lack of support and/or a lack of a central vision from their leaders. If a leader does not give the materials needed to the ones he/she leads, then the followers may not trust or even want to work for the leader. Possessing a feeling of not being supported alienates workers and can easily lead to negative feelings toward the job.

The most nuanced responses came from the fourth category presented in Fig. 1 which is teacher's influence. The two questions that comprise this category received opposing responses. While teachers overwhelmingly stated that they had no influence in selecting the type of professional skills they need or want, almost the same number of respondents claimed that they have an influence in choosing the books that will be used in STEM courses. It seems that while there is agency given in one area (choosing books), it is void in another (skill development courses). The latter poses a potential problem because teachers may feel that their pedagogical needs are not being addressed. These pedagogical deficiencies will remain unless the teacher takes the extra time to address them on his or her own. As a result of not being able to improve deficiencies that are known to the teacher, their effectiveness may stagnate or even regress. In all, 42% of teachers agreed while 50% disagreed that they had some influence in choosing STEM supplementary books and the content of skills' development programs. The majority of those who agreed believed that teachers have an advantage in choosing supplementary resources for the STEM classes, however, most teachers feel that they do not have a say in what type of professional development needs to be issued by the school.

The response scale pertaining to job satisfaction was the most negative and resolute of all the categories. Overall, while 32% of participant answers to this category expressed dissatisfaction with their current profession, 58% were strongly dissatisfied. The respondents overwhelmingly expressed their discontent with the class sizes and salaries. Furthermore, they expressed their willingness to change profession if offered a better salary. The sheer number of negative responses to questions in this category is alarming. According to the respondents, teachers' pay is too low, while class sizes are too large. Furthermore, the large number of participants who said they would leave the profession to go to another industry points perhaps to a lack of identity and/or professional bond to the teaching profession itself as if it is just a temporary occupation to hold over until something better comes along.

Responses to the next four categories presented in Fig. 2 are not based on opinions or feelings of the respondent but on the frequency of strategies used by the participating teachers. The sixth category breaks down how often collaboration with other teachers occur. These collaborative efforts range from sharing teaching methods to assessing the scope of STEM topics taught in school. Approximately 39% of teachers responded that sharing knowledge with other teachers happens more than 10 times a year (this is the most frequent of all the responses). Thus, teachers frequently collaborate in pedagogical matters.

Since many of these same respondents claimed that they do not get much support from their administration, these teachers may have become closer knit and open to helping each other professionally as a result of this lack of support. Overall, sharing teaching methodologies seems to be very common among the teachers who responded.

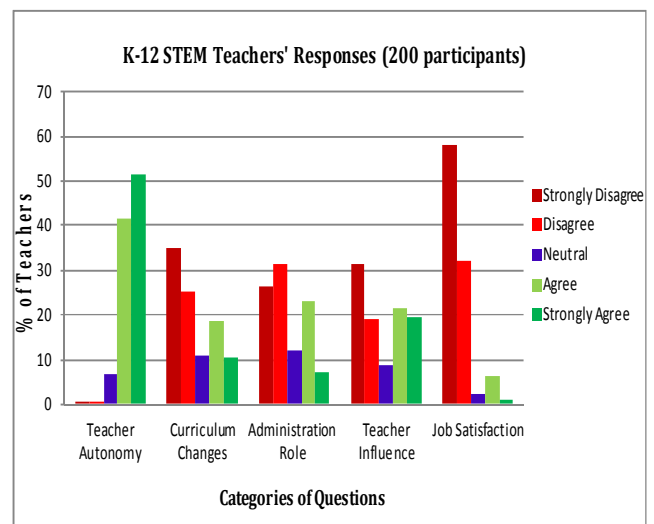

Figure 1. STEM Teachers' Responses - Questions Categories 1 to 5.

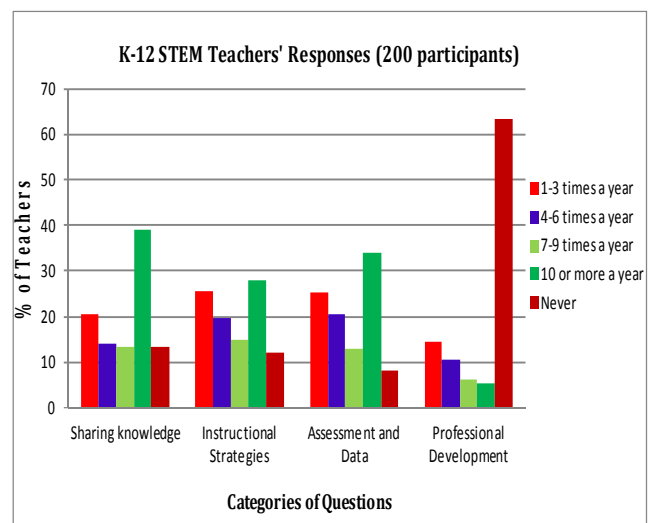

Figure 2. STEM Teachers' Responses - Questions Categories 6 to 9.

The seventh category examined in Fig. 2 displays the frequency of teachers contacting parents about the STEM curriculum and how they could help their children academically, use heterogeneous groupings and help struggling students. This category produced mixed results because while many teachers shared information with parents quite infrequently, the surveyed teachers conceded that they overwhelmingly help struggling students and use mixed achievement groups in order to boost peer-to-peer teaching.

Nevertheless, the low frequency (12%) is largely due to the fact that outside tuition is not offered by most teachers. The responses to these questions could be skewed due to the fact that many education employers do not allow teachers to give after-school tuition and the large number of "never" answers may be defensive answers in order to save their jobs. Moreover, the relatively high number of "1-3 times a

year” responses which is around 25%, could be due to the large number of responses for teachers contacting parents. Considering that many schools have “parent night” at least once per trimester, this could serve as a large bulk for parent contact. In essence, the surveyed teachers may not be taking the initiative to seek out parents and share instructional strategies but could simply be passively waiting for them to attend parent nights and discuss instructional information with them.

Assessment and data category consisted of two questions, evaluating students’ progress with administration and participating in STEM grade-level meetings for curricular improvements. This category had the lowest frequency of “never” responses with only 8%. 34% of teachers stated that they assess data with administration and other STEM colleagues at least 10 times per year. However, 25% responded that evaluating students’ progress and participating in STEM meetings occurred “1-3 times” a school year. The “1-3 times” option may be high because of mandated administration-teacher conferences for job review; however, teachers should be meeting at least once per week. Therefore, the 25% of teachers in the “1-3 times” option, along with the 8% in the “never” option, are an anomaly that needs to be addressed. Essentially, these respondents are not, or are barely, meeting with colleagues or administrators to improve the STEM curriculum data. This could be because they have already reached an “indifference” stage of teacher burnout.

Finally, the professional development category in Fig. 2 holds a very eye-opening statistic. This category only had one question: “did the respondent attend professional development activities on or off campus to improve STEM pedagogies?”. A disturbing 64% answered that they never attend professional development. This is very alarming because not developing the professional expertise of teachers makes their skills regress. In fact, the lack of attendance of professional development sessions may be the foundation of why teachers feel neglected by administrators, frustrated with new curriculum changes, and overall, dissatisfied with their job. Professional development may not be given in many UAE schools because there is an absence of professional development centers, as school districts in other countries have, provided by the schools or by subcontracted entities. Furthermore, although there are many online opportunities to attend professional development activities, teachers’ ignorance of these opportunities, lack of desire to do them outside of school hours or even pay out of their pocket, may be reasons why they do not utilize them. In all, school administrators and teachers largely ignore professional development. Ignoring the development of pedagogical skills, especially for academically important subjects such as STEM, can be very detrimental. When STEM teachers are professionally left behind, their students will suffer.

V. CONCLUSION

In conclusion, the categories of Figs 1 and 2 show many determining factors on gauging the effectiveness of teachers. The most significant categories seem to be: teacher

autonomy, job satisfaction and professional development. Although teachers are autonomous entities in the school, this may not be by deliberate design. Furthermore, an overwhelming number of teachers did not like their jobs due to poor pay and class size. Moreover, the lack of professional development may be at the core of this discontent among the participating teachers.

Overall, the 200 STEM teachers who participated in this study provided some very insightful information about what is hindering or promoting their effectiveness in class. The collection of responses exposed many critical barriers that need to be addressed. For example, many teachers complained of low salary. This perception has led to their job dissatisfaction similar to the findings in studies done in the USA and the UK [15-17] as discussed earlier. However, higher wages is not the sole answer to the problem even though “throwing money” at the problem may be the solution as many may believe. Even with higher salaries, if professional realities in the other troublesome realms of the profession, do not occur, issues such burn out, indifference, and “doing just enough for regulators in order to get by” will continue. The high discontent among participants also correlates with the findings in the Netherlands, the UK and the USA [24-26]. It is positive to note that the teachers have stated that they try to help struggling students frequently and use the heterogeneous grouping method, smaller classes, as according to the study; this may help facilitate the critical thinking needed in STEM classes and alleviate job stress for the teacher.

Curriculum changes committed by school policymakers are also a barrier for teacher effectiveness. Very few of the respondents answered that the new curricula meet students’ interests and/or are feasible challenges for the students’ comprehension levels. The feelings resulting from these curricula changes appear in studies done in the USA [8,23] that claim teachers grow angry at these changes and feel discontent with their profession. Furthermore, a large percent of teacher participants stated that they are not properly equipped with necessary school resources. This deficiency hinders teachers from performing at their highest levels of effectiveness. Research in Sweden and the USA [8,18-22] also concludes that this problem leads to teacher attrition due to the frustrating inadequacies of their school.

Lastly, professional development, according to the respondents, is clearly neglected on the part of the schools and the respondents themselves. Without the ability to keep up with the ever-changing pedagogical methods of STEM teaching, educators may become frustrated and essentially obsolete because they may not be able to meet students’ needs as they change with time. Professional development keeps teachers relevant in the minds of learners and it provides teachers a platform to collaborate with other professionals (whether at the same school or not). Research in Canada and the USA [5-8] already proves that proper professional development and mentoring can help improve teachers’ capability and retention rates. Hopefully in the UAE context this can also occur and thus raise job satisfaction among teachers in order to help increase their effectiveness at work.

ACKNOWLEDGMENT

The authors wish to offer their sincere gratitude to the Ministry of Education, the National Bureau of Statistics in the UAE and the Abu Dhabi Education Council for their support, as well as to all the teachers who contributed to this research by responding to the survey.

Abstract - Previous studies indicated that misconceptions related to heat transfer, fluid mechanics, and thermodynamics, persist among engineering juniors and seniors even after they completed college-level courses in these subjects. Researchers have proposed an innovative instructional approach, the ontological schema training method, which helps students develop appropriate schemas or conceptual frameworks for learning difficult science concepts. Three online training modules were designed to help engineering students develop appropriate schemas in heat transfer, diffusion and microfluidics. The effectiveness of these modules was examined with two different student populations from two different universities (US and Hispanic). At each institution, participants were assigned randomly to a control or experimental group. The treatment for each group at both institutions was exactly the same. Preliminary results indicated a mixed effectiveness of the training modules among these populations.

Index Terms – Cultural Differences, Ontological Schema Training, Quantitative Analysis

INTRODUCTION

Previous studies conducted by Streveler and Miller [1] indicated that misconceptions related to heat transfer, fluid mechanics, and thermodynamics, persist among engineering juniors and seniors even after they completed college-level courses in the subjects. Researchers argued that in order to repair and correct student's misconceptions, it is critical to facilitate conceptual change through training students in the appropriate mental framework or schema for some difficult concepts. [2] Chi and her colleagues proposed an innovative instructional approach, the ontological schema training method to help students develop appropriate schemas or conceptual frameworks for learning difficult science concepts. [3] Chi's studies are grounded in the assumption that students learn new concepts by assimilating or encoding new information into an existing schema or framework. This assimilation allows students to make inferences about and assign attributes to a new concept or phenomenon. Furthermore, an incorrect inference, based on an incomplete or incorrect schema, affects negatively students' understanding of a new and difficult concept by making

common errors associated to the targeted concept[2]. In addition, social cultural characteristics factors of learners, such as race and ethnicity, language, social environments are believed to affect students' conceptual change and their approaches to construct meanings[4].

Based on Chi and her colleagues' work, three online training modules were designed to help engineering students develop appropriate schemas, which are needed to understand some key engineering concepts, such as heat transfer, diffusion, and microfluidics. To tests the efficacy of these learning modules, researchers tested and compared performances of two populations at different institutions: a public engineering institution in the Midwest (MPI) and a Hispanic engineering serving institution (HSI). Thus this paper presents results from a study whose objective was to compare the performance of two different populations on the effectiveness of the Schema Training Modules (STM) developed to assess conceptual understanding. The research question that guided this study was: **Are there differences in student conceptual understanding of concepts in thermal and transport sciences based on their cultural backgrounds?**

BACKGROUND

I. Theoretical Framework – Ontological Schema Training Method

Previous studies reported students' difficulty understanding concepts related to heat transfer, fluid mechanics, and thermodynamics. Furthermore, the presence of misconceptions has been identified, even after students have completed college-level courses in the domain subjects [1], [5],[6]. These misconceptions have been proven to be robust and resistant to traditional instruction because the correct understanding requires students to not only acknowledge the presence of the misconception, but also to "conceive" them differently [3]. Chi and her colleagues have proposed an innovative instructional approach to repair misconceptions among students. This approach is referred to as the ontological schema training methods (STM). STM focuses on helping students develop appropriate schemas or conceptual frameworks for learning difficult engineering concepts [3], [7]-[9].

Chi has identified Emergent Processes as those "properties of a system that result from its constituent

elements interacting over time, often in conjunction with equilibration” [1]. Research has shown that Emergent Process misconceptions are particularly resistant to traditional instruction because they are made at the ontological level – where students ascribe a fundamental characteristic to the concept that is at odds with the scientifically normative view [1],[3]. In order to help students learn concepts of the Emerging Process ontology, instruction should first identify the ontology and provide them with some rich examples and properties of that ontology [3],[7], [9]. This would help students develop a “schema” or mental model for that ontology which would make subsequent examples easier to understand. Referred to as “schema training,” this instructional methodology has been successful with both middle school students and undergraduate psychology students [3], [7], [9]. Previous work has identified difficult concepts in heat transfer, diffusion and electricity as emergent processes [5], [10].

II. Description of Ontological Schema Training Modules (STM) in Thermal Sciences

A group of researchers developed the STM following the work done by Chi and her colleagues. As shown in Figure 1, the experiment design uses both experimental and control groups of students matched for equivalent levels of engineering education.

| Day | For Control Group | For Experimental Group | Expected Completion Time |
|-------|--|--|--------------------------|
| Day 1 | Nature of Science | Sequential and Emergent Processes: Part I | 3 – 4 hours |
| | Demographic Survey | | |
| | Heat Transfer Concepts Assessment (Pre Test) | | |
| | Scientific World View Instruction | Processes Instruction | |
| | Diffusion Instruction <i>Not described as an emergent process</i> | Diffusion Instruction <i>Described as an emergent process</i> | |
| | Diffusion Concepts Assessment (Post Test only) | | |
| Day 2 | Sequential & Emergent Processes: Part II | | 2 hours |
| | Heat Transfer Instruction | | |
| | Heat Transfer Concepts Assessment (Post Test) | | |
| | Microfluidics Instruction | | |
| | Microfluidics Concepts Assessment (Post Test only) | | |

FIGURE 1
SCHEMA TRAINING MODULES

Specifically the modules consist of a pre-test in heat transfer concepts, used as a further measure of the “equivalence” of the two groups’ prior knowledge. The experimental group completed a training module describing the characteristics of two kinds of processes (sequential and emergent processes), which was intended to facilitate students’ conceptual change. The training modules for the experimental group also describe why diffusion concepts are an emergent process. The control group completed an approximately equivalent module that describes the nature of science. Diffusion is described but no mention is made of emergent processes. Then, both groups completed the same instruction module on heat transfer principles. Later, post-test concept questions were answered by both groups. The

post-test was followed by a far transfer experiment in microfluidics instruction and concept assessment. The far transfer experiment was designed in such way because the concept of microfluidics represents an ideal application of emergent process principles, which the participants were unfamiliar prior to the study. This paper discusses quantitative analyses performed on the shaded activities presented in Figure 1.

METHODS

Specifically, we conducted an experimental study with junior or senior engineering students at two universities, a Public Institution located in the Midwest (MPI) and a US Hispanic Serving Institution HIS. A description of the institutions and participants is presented in the following section.

I. Descriptions of participating populations

1. Midwestern Public Institution (MPI)

The selected MPI is a Land Grant institution founded in 1869 and enrolls over 40,000 students across campus. It has been identified as an institution with the largest international student population of any U.S. public university. The undergraduate enrollment for 2011 had a total of 30,776 with 57% male and 43% female. From these students 60% are state residents, 26% other U.S. states, 14% other countries and 13% minority domestic student population. From the total enrollment of undergraduate students approximately 20% are pursuing engineering degrees. Engineering programs at the MPI consist of a four-year curriculum with 12 engineering programs including Aeronautics and Astronautics, Agricultural and Biological, Biomedical, Chemical, Civil, Construction Engineering and Management, Electrical and Computer, Industrial, Materials, Mechanical and Nuclear. The undergraduate engineering program is positioned in ninth place among the national rankings.

In total 60 participants were selected for this study. They were typical college junior and senior students who majored either in mechanical, chemical, or material science engineering. Also, the majority of participants were male and their primary language was English, which is representative of the engineering population at the MPI.

2. Hispanic Serving Institution (HSI)

The College of Engineering (CoE) of the selected HSI is among the largest engineering institutions in the U.S., ranking fifteen in the nation in undergraduate enrollment, about 5000 students (approximately 98% are Hispanic), 67% males and 33% females [11]. Because of this, researchers have an excellent opportunity to impact both Hispanics and women, who are traditionally underrepresented populations in engineering. The HSI’s engineering programs were initiated in 1913, two years after the campus was founded as a Land Grant Institution in 1911. As of today, there are six broad ABET-accredited undergraduate programs as well as strong graduate programs in Civil, Chemical, Computer, Electrical, Industrial, and Mechanical Engineering.

Moreover, this institution has played a critical role in the training of future Hispanic scientists and engineers in the U.S. Some key national rankings as described by the ASEE Profiles of Engineering and Engineering Technology Colleges [12] published in June 2010 include:

- # 1 in Engineering Bachelor's degrees awarded to Hispanics (614)
- # 3 in Percentage of Bachelor's degrees awarded to women (39.6%)
- # 3 in Engineering Bachelor's degrees awarded to women (243)
- # 15 in Engineering Undergraduate Enrollment (4,981)
- # 26 in Engineering Bachelor's degrees awarded (614).

The sample size of this study consisted of forty-five students, from which 65% of them were male. These participants were primarily junior (26%) or senior (70%) students who majored either in chemical (35%) or mechanical engineering (63%). Refer to Figure 2.

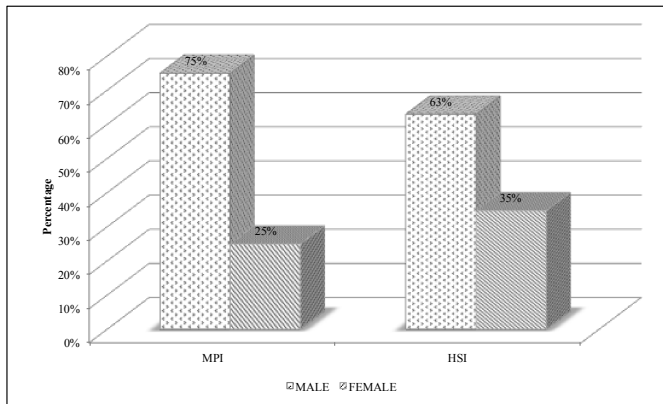

FIGURE 2
GENDER DISTRIBUTION

II. Participant Selection Process

Engineering students were invited to participate in the study via email. Participants had to have completed at least one of the following courses: thermodynamics, fluid dynamics, or heat transfer. At each institution, selected participants were assigned to either a control or experimental group according to their gender, major, grade point average (GPA), and total courses approved. The objective was to have a uniform distribution amongst both groups, control and experimental, within each institution.

Participants were recruited primarily from the chemical and mechanical engineering programs. Students were required to have approved at least one course in thermodynamics, heat transfer and/or fluid dynamics; being 18 years of age or older; being fluent in written English; and haven't previously participated in the study. They were invited by e-mail, which were provided by HSI's Office of Institutional Research and Planning. A description of selected participants is presented in Tables 1 and 2.

TABLE I
DESCRIPTION OF PARTICIPANTS FROM MPI

| | | MPI | | | |
|---------|----------------|---------|-----|--------------|------|
| | | Control | | Experimental | |
| Gender | Male | 27 | 82% | 21 | 68% |
| | Female | 6 | 18% | 10 | 32% |
| Year | Sophomore | 1 | 3% | 1 | 3% |
| | Junior | 13 | 39% | 18 | 58% |
| | Senior | 19 | 58% | 12 | 39% |
| GPA | 4.00 - 3.50 | 13 | 39% | 7 | 23% |
| | 3.49 - 3.00 | 7 | 21% | 14 | 45% |
| | 2.99 - 2.50 | 11 | 33% | 9 | 29% |
| | Other | 2 | 6% | 1 | 3% |
| Major | Chemical | 4 | 12% | 5 | 16% |
| | Mechanical | 17 | 52% | 13 | 42% |
| | Other | 12 | 36% | 13 | 42% |
| Courses | Thermodynamics | 31 | 94% | 31 | 100% |
| | Fluid Dynamics | 15 | 45% | 11 | 35% |
| | Heat Transfer | 6 | 18% | 4 | 13% |

TABLE II
DESCRIPTION OF PARTICIPANTS FROM HSI

| | | HSI | | | |
|---------|----------------|---------|------|--------------|-----|
| | | Control | | Experimental | |
| Gender | Male | 14 | 45% | 15 | 65% |
| | Female | 9 | 29% | 7 | 30% |
| Year | Sophomore | 0 | 0% | 1 | 4% |
| | Junior | 8 | 26% | 4 | 17% |
| | Senior | 15 | 48% | 17 | 74% |
| GPA | 4.00 - 3.50 | 7 | 23% | 5 | 22% |
| | 3.49 - 3.00 | 11 | 35% | 9 | 39% |
| | 2.99 - 2.50 | 5 | 16% | 8 | 35% |
| | Other | 0 | 0% | 0 | 0% |
| Major | Chemical | 9 | 29% | 7 | 30% |
| | Mechanical | 14 | 45% | 15 | 65% |
| | Other | 0 | 0% | 0 | 0% |
| Courses | Thermodynamics | 31 | 100% | 23 | 74% |
| | Fluid Dynamics | 11 | 35% | 22 | 71% |
| | Heat Transfer | 4 | 13% | 17 | 55% |

Specifically, the percentage of women participating in the study was higher for the HSI than for the MPI. This tendency was expected since the number of women enrolled

in engineering is higher for the HSI. Also, the HSI had more participation from senior students as compared with the MPI that had more junior students. An exception occurred for the experimental group at the MPI that had more senior than juniors. In terms of GPA, the majority of the students had a GPA of 3.0 to 3.49, except for the control group at the MPI that had more students at the highest range (3.5 to 4.0 GPA). At both institutions, the majority of the students belonged to the Mechanical Engineering department. Finally, students from the HSI had more courses approved from the thermal and transport sciences (either thermo, fluids mechanics, or heat transfer). A summary of the course distribution is depicted on Figure 3, which shows a bigger variability for the samples at the MPI within each of the groups (control or experimental).

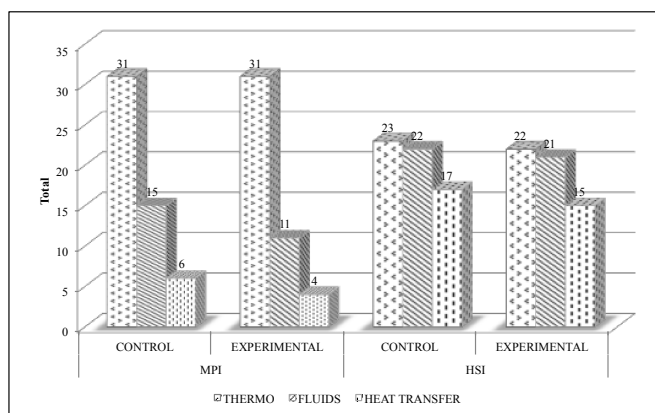

FIGURE 3
COURSES APPROVED

In summary, there are similarities and differences among these populations (HSI vs. MPI). Some of the similarities are as follows. First, participants were primarily from mechanical or chemical engineering. Second, both group were traditional engineering students in terms of age. Finally, participants have taken one, two or three courses in thermal sciences. The main differences include: (1) different ethnicity (Hispanic vs. non-Hispanic participants), (2) primary language differences (Spanish vs. English), (3) type of institution (undergraduate education vs. research intensive institutions), (4) program duration (5-yr vs. 4-yr academic programs).

III. Data Collection Process

Once participants were selected, at each institution, and randomly assigned to either the control or experimental group. They were given a user name and password to access and complete the learning modules available on-line through Blackboard. During the first day, participants completed the activities corresponding to Part 1, which required 3 to 4 hours to complete. The following day, they completed activities corresponding to Part 2. These activities required approximately 2 hours of time to complete. Participants were asked to take their time while completing the modules and researchers were asked to identify those who took less time and expected. Participants' confidentiality was

protected according to IRB requirements. Participation was voluntary and they received a compensation of \$60 after they completed the modules.

DATA ANALYSIS AND RESULTS

Quantitative comparisons for HSI and MPI participants were conducted on the pre- and post-test of heat transfer and post tests on diffusion and microfluidics. The shaded sections of Figure 1 represent the activities that were analyzed quantitatively, Table 3 depicts the mean gain for the experimental and control groups and Table 4 depicts the summary of the p-values that resulted from comparing significant differences between pre-test and post-test. Firstly, in terms of the mean gain for the experimental and control groups for both student populations (MPI and HSI), results show a significant average gain for the experimental group at the HSI as shown on Table 3.

TABLE III
MEAN GAIN

| | Group | Count | Average Gain | Std. Dev. |
|-----|--------------|-------|--------------|-----------|
| MPI | Control | 33 | 0.030 | 0.133 |
| | Experimental | 31 | 0.029 | 0.132 |
| HSI | Control | 20 | 0.050 | 0.139 |
| | Experimental | 20 | 0.105 | 0.101 |

Secondly, the p-value obtained for MPI's control group was equal to 0.500 (greater than 0.05), meaning that the difference between the average results of the pre-test and the average results of the post-test is not significant. Similar results were obtained for the MPI's experimental group (p-value = 0.510) and the HSI's control group (The p-value = 0.172). On the contrary, the p-value obtained for the HSI's experimental group was equal to 0.006, which means that the difference between the average results of the pre-test and the average results of the post-test is significant.

Thirdly, a two-way ANOVA was conducted to examine if either the group differences (control or experimental) or the test differences (pre- and post- Heat Transfer tests) had any significant influence over participants' results. The two-way ANOVA Test for the MPI population produced p-values of 0.128 and 0.467 for the group and test, respectively. This shows that neither the group (control or experimental) nor the test (pre- and post-) had significant influence on students' performance. For the HSI population results indicated that the group difference did not have an influence on students' results (p-value = 0.068), but on the contrary, the pre- and post-tests indicated an impact on participants' results (p-value = 0.021). Some students were eliminated from the ANOVA analysis because their post-test was incomplete.

Finally, a two-sample t-test was performed to determine if there is significant difference on students' performance on Diffusion, Microfluidics, and Heat Transfer items. Table 4 shows all the p-values obtained for both group of

participants (MPI and HSI) for the two-sample t-test. Results indicated a significant difference between average group results (control and experimental) for MPI and HSI for Diffusion items. In Microfluidics items, results from MPI participants showed significant difference between average group results. No significant difference was obtained for Heat Transfer items.

TABLE IV
SUMMARY OF P-VALUE RESULTS FOR T-TESTS

| | Two Sample T-test | | |
|------------|----------------------|--------------------------|--------------------------|
| | p-value Diffusion | p-value Microfluidics | p-value Heat Transfer |
| MPI | 0.044 (Y) | 0.018 (Y) | 0.976 (N) |
| HSI | 0.044 (Y) | 0.305 (N) | 0.0160 (N) |

DISCUSSION AND CONCLUSION

This paper discusses the effectiveness of the STM among populations from two different institutions (MPI and HSI). The outcomes of this study provided some evidence about the variability of performance of the different populations on the STM. Results indicated a greater effectiveness of the STM among the Hispanic population as evidenced from the average gains depicted in Table 3. But as shown in Table 4, in general, participants from the MPI performed better having significant differences in their post-test performance in the Diffusion and Microfluidics concepts. We have previously suggested that one potential explanation of the low effectiveness of the STM on student learning could be that robust misconceptions are resistant to be repaired through traditional teaching methods. For the case of HSI students an additional factor to consider could be the fact that the learning resources were not in their mother tongue—i.e., Spanish.

The main contribution of this study was the comparison of performance on STM with different populations. STM has been designed to help repair robust misconceptions, which are resistant to repair by traditional teaching methods. Further qualitative analyses of students' verbalization of their reasoning are being conducted to determine the role of language in students' conceptual change.

ACKNOWLEDGMENT

The authors would like to thank the National Science Foundation for supporting this project: Developing Ontological Schema Training Methods to Help Students Develop Scientifically Accurate Mental Models of Engineering Concepts (EEC-0550169). We would also like to acknowledge the collaboration with the recruitment and data collection process of undergraduate students Rosaurelis Marín, Laura Nieves, and Paola Pacheco.

Work in Progress: What do engineering students do with non-academic information as they address authentic socio-technical problems?

Annette Berndt

Faculty of Applied Science
The University of British Columbia
Vancouver, Canada

ayberndt@apsc.ubc.ca

Abstract—This paper focuses on the knowledge construction process in a technology and society course in which engineering students propose solutions to authentic socio-technical problems in India. Student definition and use of non-academic information is examined with the recommendation that documentation practices be further developed to accurately reflect community contribution. Implications for the global engineering workplace are also addressed.

Index Terms—community service-learning, global engineering, information literacy, problem-oriented learning, social context, technical communication.

I. INTRODUCTION

With the call for “high impact, high engagement” activities [1] becoming louder, faculty members across the disciplines are looking for ways to integrate individualized experiential learning opportunities, such as those fostered by Community Service-Learning (CSL) projects, into their classes and assignments. The integration of CSL activities into the curriculum raises many questions that were previously considered irrelevant. Within the context of engineering, several questions arise: How do students value and document non-academic information as they are drawn into the co-creation of a new knowledge base? What implications does this broad approach to knowledge-making and problem-solving have for life-long learning, after engineering students have graduated and may no longer have access to traditional academic databases as they work in a global workplace, where they may work on interdisciplinary teams without direct contact to their clients?

II. CONTEXT

This study explores these questions through the context of a technology and society course subtitled “The Global Engineer” at the University of British Columbia, in Vancouver, Canada. As an elective three-credit course, Applied Science 263 introduces students to the emerging discourse on global engineering [2], [3], [4] and satisfies the

“Impact of Technology on Society” requirement for the Bachelor of Applied Science degree. The course is mainly taken by students in all engineering disciplines but is also open to students in the Faculty of Arts, and interdisciplinary perspectives are strongly encouraged through a variety of assignment genres to open discussion on questions of legitimate knowledge, to encourage critical thinking, and to instill notions of life-long learning: requirements set out by ABET Criteria 3 [5].

As a variant of CSL, this course enables students to address authentic socio-technical problems identified by rural artisans in India without travelling to India. Information about the problems is sparse, mainly photographic in nature, and transmitted through a social entrepreneur (Maiwa Handprints Ltd.) based in Vancouver and active in the organic textile and crafts sector in India. Many of the 3000 Maiwa-affiliated artisans are part of the “Dalit” or “untouchable” caste and have little access to public resources.

Although students have no direct contact with the artisans themselves, they have informally reported that they are motivated by the impact their assignments may have. With a focus on social context, the course requires students to expand their research skills and explore a broad range of resources, spanning academic and non-academic information, in order to develop culturally appropriate, technically feasible and sustainable solutions to the given problems. As Barsky et al point out, students in this kind of course have learned the value of broadening their traditionally defined disciplinary knowledge by acknowledging that “other” people may hold useful knowledge and insight that may not be documented in double-blind, peer-reviewed journals [6]. Several students have also commented on the intersection of written and oral cultures in the course. Students are encouraged to engage in “contextual listening,” as posited by Lucena et al [7], but what does this mean if students cannot, for various reasons, communicate with the artisans? How then can students gain access to contextual information needed to develop socially appropriate, feasible, and sustainable technical solutions?

III. METHODOLOGY

This study consists of quantitative and qualitative data, the implications of which are part of a larger ongoing research project on multimodal literacy practices among engineering students across five cohorts of Applied Science 263 at the University of British Columbia. Of the 2012 class (the fourth cohort), 31 students volunteered to participate in an anonymous survey of six questions on their use of non-academic sources to gain insight into the social context of the given technical problems. After final grades had been released, the identity of the participants was revealed, so that the survey results could be reviewed in relation to the sources referenced in the respective Recommendation Reports and Formal Reports. Survey results were tabulated in quantitative terms and compared with the quantitative use of academic and non-academic sources listed in the reference sections of their Recommendation Reports and Formal Reports.

The Recommendation Reports constituted integrative literature reviews of the Formal Reports submitted by previous cohorts (used with permission) to generate new perspectives and frameworks for further investigation of the problems. Students in the 2012 cohort then used their Recommendation Reports as a basis for their own investigation documented in the Formal Reports, “concluding” with recommendations for further investigation for the incoming cohort in 2013.

IV. FINDINGS

A. Quantitative Results

This paper will focus on the first, fifth, and sixth questions in the survey. Firstly, to define what “non-academic” might mean, students were provided with an open-ended checklist of possible sources that included the following: “blogs, industry newsletters, magazine articles, photographs, podcasts, radio and television shows, websites from government organizations, websites from private-sector companies and corporations, YouTube videos, other_____.” Twenty-nine percent of the students checked off all sources, with one student stating “anything not published in a journal” and another student checking off none, commenting that “it depends on who produces the material and how it is referenced.” Of the remaining 71% who did not check off everything or nothing, YouTube videos received the largest vote, with 48% considering information derived from this source to be “non-academic.” Blogs, photographs, and websites from private-sector companies and corporations also received a clear “non-academic” vote at 45% each. While these results may seem conservative in their implications, they reveal a significant shift in thinking that is expressed more clearly in the final question.

In the final question, students were asked to what extent they think the use of non-academic sources is important “to understand the socio-cultural context of any technical problem anywhere” and were given four possibilities: not important, somewhat important, very important, and essential. Unexpectedly, the “essential” and the “very important” categories received approximately 2/3 of the responses. No one responded “not important.”

B. Qualitative Results

Reviewing work by previous cohorts demonstrated to students that “solving” (i.e. addressing) authentic socio-technical problems is a work in progress that extends beyond student timetables, academic calendars, and university classrooms. The Recommendation Reports were difficult to gauge in light of the above findings. Slightly over half the Recommendation Reports contained citations to additional sources, which were primarily non-academic in nature, in the critique of the sources used by previous cohorts.

With regard to the Formal Reports generated from the Recommendation Reports (integrative literature reviews), 23% of students reported in the fifth survey question that slightly 3/4 of their research for the Formal Reports was based on information from non-academic sources, with 45% stating roughly 1/2 and 26% indicating approximately 1/4 of their research for the Formal Reports was. While the information referred to in the Formal Reports suggests that the majority of students underestimated their actual use of non-academic sources, this becomes difficult to ascertain given the above shift in definition of “non-academic” and, in some cases, the incomplete documentation of sources.

V. PRELIMINARY CONCLUSIONS

The cumulative layering of knowledge across cohorts for a problem-oriented CSL course illustrates the complex nature of addressing, if not solving, authentic socio-technical problems in a global environment; it also demonstrates that instructors and students need to clarify together how to value and document the use of non-academic sources in such an endeavor.

Further work in this study involves strengthening the link between quantitative results and qualitative assessment. Student self-reports on their estimation of how much of their research was based on academic and non-academic sources need to be more closely tied to the type and quality of research coverage in their Formal Reports rather than simply using the Reference section of the Formal Reports as an indicator of the use of academic and non-academic sources. To increase awareness and ownership of students in the knowledge creation process, next steps involve working with students to further develop content analysis expectations. Further work is also required in the re-mapping of documentation conventions, as they pertain to the broader ramifications for information access and ownership by the community, with a view to indigenous scholarship [7].

As universities become more engaged in community work, non-academic voices will gain in participatory parity and the use of non-academic sources will become increasingly legitimate. Students will need to learn how to negotiate boundaries and definitions of academic and non-academic information for the benefit of engineering in service to the non-academic community. The need to uphold both student and professional codes of ethics also presents the challenge of knowing how to document non-academic sources in a manner that accurately reflects the contributions, information access and ownership of the non-academic community. These

challenges hold far-reaching implications for student development of critical thinking skills and life-long learning values, as required by the 21st-century engineer in a complex and dynamic global workplace [2], [8].

ACKNOWLEDGMENTS

The author thanks her colleague, Dr. Carla Paterson, for feedback on the survey questions and her collegiality in co-developing and co-teaching Applied Science 263. Many thanks to all the students in the 2012 cohort of Applied Science 263 who volunteered to participate in this study.

Abstract—Data were collected using the *Draw an Engineer* test followed by unstructured informal interviews to determine individual conceptions of engineering and what engineers do, as well as to make a comparison between teachers' conceptions from two states of the Yucatan peninsula. Drawings and open-ended responses were analyzed following an inductive data analysis approach. Four main categories emerged: 1) engineers in action, 2) characteristics of an engineer, 3) gender, and 4) work context. The majority of participants in this study perceive engineers as male individuals that perform activities related to construction (in the case of Quintana Roo) or oil (in the case of Campeche) industries. Interviews supported main findings while helping researchers gain insight into individual reasoning behind the interviewed teachers' drawings and answers. Our results suggest differences on how Yucatan peninsula teachers perceive engineering and engineers based on the state where they are from, their gender, and grade in which they teach.

Keywords—*Draw an Engineer; images of engineering and engineers; Yucatan*

INTRODUCTION

Mexico is one of the countries with the largest percentages of students performing below the baseline Proficiency Level 2 in mathematics and sciences among the *Organisation for Economic Co-operation and Development* (OECD) nations [1].

Given the crisis that Mexico faces in mathematics and science education in the P-12 levels, *Universidad de las Américas Puebla* started a research program to develop solutions to help overcome this situation. This investigation is part of a broader project funded by the Campeche State Council for Science and Technology (*Consejo Estatal de Investigación Científica y Desarrollo Tecnológico de Campeche*). Its goal is to promote an early approach to engineering and science among the student population at the upper elementary, middle and high school levels of the State of Campeche by creating high quality learning environments that promote interactive classrooms and contribute to a better understanding of science and mathematics while promoting careers in science, engineering and technology [2].

In general, Mexican teachers have an incomplete understanding of engineers and engineering as a profession [3]. Images shape the way individuals view the world [4], thus, eliciting and understanding the image teachers have of engineers and engineering is extremely important in order to

develop programs and curricula that encourage engineering teaching and learning at the P-12 school levels [3-13].

Subject-produced drawings offer a simple and unique way for researchers to assess individual conceptions. These individual-produced drawings offer a window into human sense making that is often beyond description using mere words [5]. Psychologists, scientists, sociologists, anthropologists, and education researchers, among others have used and continue to use subject-produced drawings in their research. In the 1950s, the famous anthropologist, Margaret Mead, asked US students to draw pictures of scientists [6]. The "Draw a Scientist (DAS) test" has been widely used to assess students' attitudes about scientists [7], even with Mexican students [8]. To help assess students' ideas about engineering a "Draw an Engineer test" was developed [4, 9, 10] derived from the DAS test. In order to explore and document teachers' perceptions about engineering and engineers, the following sections describe a study conducted in the Yucatan peninsula using drawings and open-ended questions as the primary data collection tools. The primary goal of this study is to provide an original account of the sort of images teachers from two states from the Yucatan peninsula have of engineers. From this overarching goal, this study attempts to answer the following research question: how do gender, grade level, and state where they are from influence Campeche and Quintana Roo teachers' images of engineers?

METHODS

Data were collected using the *Draw an Engineer* (DAE) test followed by unstructured informal interviews [2-3, 6-8]. 179 teachers participating in the study were given the DAE test at the beginning of two unrelated workshops in the Yucatan Peninsula, one in the state of Campeche (45 participants) and the other in the state of Quintana Roo (134 participants). The purpose of the DAE test was to determine individual conceptions of engineering and what engineers do as well as to make a comparison between teachers' conceptions from two states of Yucatan Peninsula.

Teachers were given 10 min to draw an engineer (previously they were asked to close their eyes and imagine an engineer at work) and then 10-15 min to answer three question prompts related to what they had drawn: 1) Describe what the engineer is doing in your drawing. Write at least two sentences. 2) List at least three words/phrases that come to mind when you think of an engineer. 3) What kinds of things do you think

an engineer does? A copy of the test worksheet is provided at the Appendix. It is worth noting that Spanish language places nouns into gender classes; therefore, the instructions mentioned both a male (*ingeniero*) and a female (*ingeniera*) engineer to ensure gender neutrality in the test directions [2].

Workshop facilitators were careful not to talk about engineers or engineering during the administration of the DAE test. Facilitators offered help to clarify directions and question prompts, but they did not offer any ideas or assistance that would influence teachers' original conceptions of engineers or engineering [2, 3]. Thirty informal interviews (which were videotaped) were performed during the DAE test and consisted of one-on-one discussions between a facilitator and teachers (10 from Campeche and 20 from Quintana Roo) to further investigate reasoning's behind his/her drawing and responses.

Drawings and open-ended responses were analyzed by three researchers (i.e., the last author and two doctoral students, which are the first two authors). Following the procedure described by Oware *et al.* [13], an inductive data analysis approach was utilized to code the drawings and written responses. After reading and re-reading the questionnaire responses and discussing their impressions of the entire data set, the researchers created a coding scheme that included four main categories to describe the data. Using this coding scheme, researchers coded each participant's response at the same time. This procedure allowed the researchers to resolve any discrepancies during the coding process [2].

RESULTS AND DISCUSSION

Gender detailed information regarding the demographic status of the teachers' population is presented in Table 1. Approximately 42% of the teachers were from elementary school (grades 1-6 in Mexico), 25% from middle school (grades 7-9 in Mexico), 15% from preschool and kindergarten, 12% from high school (grades 10-12 in Mexico), while the rest were university teachers.

TABLE I. PARTICIPANTS BY GENDER

| GENDER | QUINTANA ROO | | CAMPECHE | |
|--------|--------------|--------|----------|-------|
| MALE | 27 | 20.1 % | 28 | 62.2% |
| FEMALE | 107 | 79.9 % | 17 | 37.8% |
| TOTAL | 134 | | 45 | |

In this section we will use the term *drawing* to represent a teacher's drawing and question responses. Interviews supported main findings while helping researchers gain insight into individual reasoning behind the 30 interviewed teachers' drawings and answers.

In the case of Quintana Roo, as previously reported [3], analysis of the teachers' drawings and answers to question prompts indicated the emergence of three main categories: 1) Engineers in action, 2) Occurrence of gender, and 3)

Engineering tools. Key elements that depicted engineers in action included drawings of engineers building, repairing, designing, supervising, or experimenting. Drawings recorded as Repairing-Building represented 22% and portrayed mainly engineers working on a construction site. Further, 83% of the drawings were recorded as Designing-Supervising-Experimenting, depicting individuals who are mainly supervising others work. Engineering tools corresponded to the activity depicted in the pictures and included specific tools, equipment, and clothing, such as helmets, blueprints, drafts, cranes, and shovels. The most common activities related to engineering were supervising, designing, and directing a construction, process or people; some Quintana Roo teachers draw other activities and tools including some engineers experimenting, laboratory materials, lab coats, glasses & goggles, in these particular drawings were depicted female engineers doing research [3].

Many figures from Quintana Roo teachers displayed images of an engineer focusing on the mental aspects of engineering. The fact that so many teachers portrayed engineers with high level of mental functions (explaining and/or experimenting) is very interesting. It reveals that many Quintana Roo teachers' perceived an engineer more as a "thinker" rather than a "doer" which represents a lack of perception instead of an inaccurate perception [3].

In the case of Campeche (Figure 1), four main categories emerged from teachers' drawings and open-ended responses: 1) engineers in action, 2) characteristics of an engineer, 3) gender, and 4) work context. 62% of Campeche teachers describe engineers in action (engineers working in oil related activities, construction related work, or office related work as depicted in Figure 2).

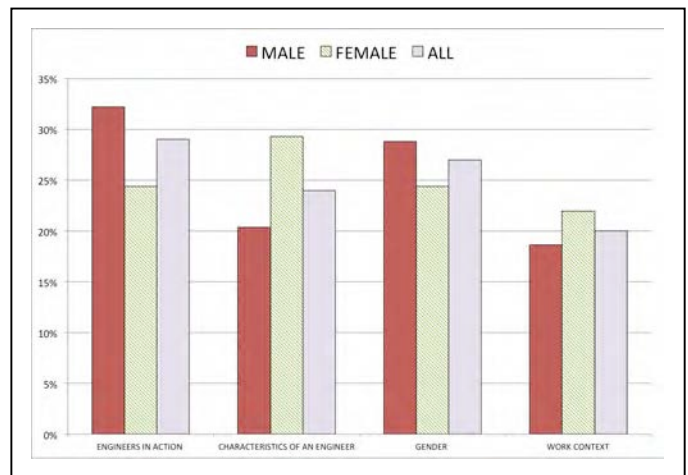

Figure 1. Distribution of images in Campeche teachers' drawings of engineers.

It is important to point out that close to 39% of Campeche teachers mention a category that does not come up in the case of teachers from Quintana Roo, i.e., an engineer working in the corresponding area of expertise of the teacher (drawing of his/her profession, i.e., university professor drawing of himself in Figure 3). 53% of teachers mention that among the characteristics of an engineer are the wit, intelligence,

enthusiasm for mathematics, as well as abilities for design, administration, planning, and supervision. Furthermore, 60% of Campeche teachers refer to an engineer working in a specific context, like at the Mexican oil company (PEMEX: *Petróleos Mexicanos*).

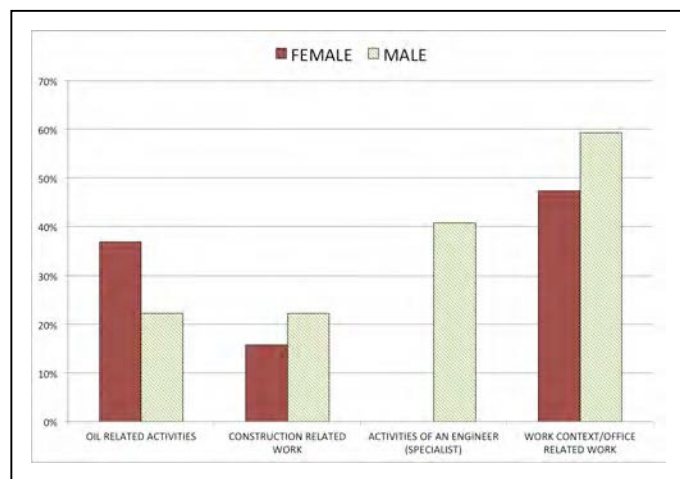

Figure 2. Distribution of images for the category "Engineers in Action" in Campeche teachers' drawings of engineers.

Figure 3. Examples of an engineer drawn by a university professor (top) and a middle school teacher (bottom).

With regards to gender, Yucatan peninsula teachers' responses were classified into one of three categories (i.e., female engineer, male engineer, or unknown-gender engineer) according to the characteristics depicted in their drawings as

previously reported [2]. Pictorial representations were categorized observing stereotypical features associated to a specific gender; for instance, long hair was associated to a female engineer (see top of Figure 5) and short hair to a male engineer. Drawing descriptions also helped to figure out the characters' gender. Furthermore, some participants made explicit the gender of their character using the nouns *ingeniera* or *ingeniero* for a female or male engineer, respectively. In those cases with no clear indication of a specific gender, characters were coded as unknown-gender (both/neutral figure) engineers.

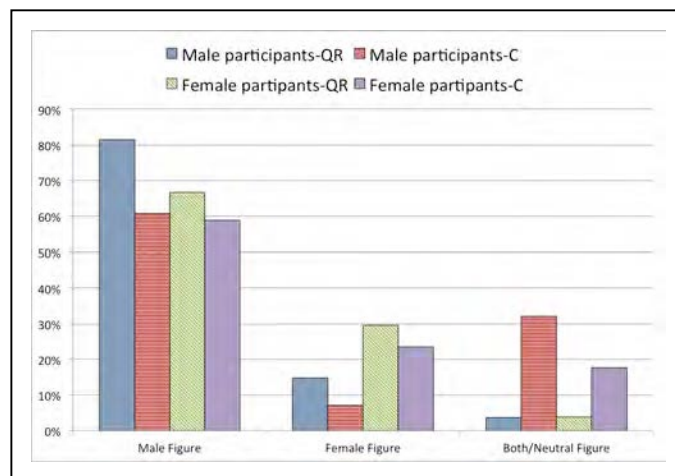

Figure 4. Occurrences of gender among male or female participants' drawings from Quintana Roo (QR) or Campeche (C) teachers.

Even though the female participants (124) were almost three times the number of male participants, the majority of Yucatan peninsula teachers perceived engineers as male individuals (Figure 4) that perform activities related to the construction (in the case of Quintana Roo) or oil (in the case of Campeche) industries as depicted in Figure 5. Female participants displayed a stronger tendency to draw female engineers than their male counterparts (Figure 4).

Perceiving science related fields as male-dominated arenas is the stereotypical image among the general population across borders [14], including Latin American countries [8, 15]. In the particular case of engineering, recent studies based on the DAE test have shown that the male-dominated stereotype is the predominant view held by P-12 United States [4-5, 9-12] as well as Mexican [2, 3] students and teachers.

Living in a state where the oil industry is the economic driver of the region, most Campeche participants' drawings depicted what they see in their everyday life near Ciudad del Carmen (where the Campeche workshop took place): oil rigs and jumpsuits from PEMEX; while living in the Mexican state where most building is taking place, the majority of Quintana Roo participants' drawings depicted construction sites as representative of what is usual nearby Playa del Carmen (where the Quintana Roo workshop took place). Results from this study confirm that cultural models to which Yucatan peninsula teachers are exposed can contribute significantly to their mental schema, as suggested by Gardner [16].

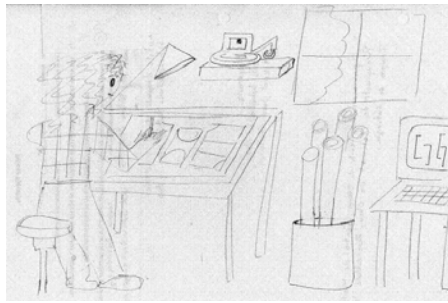

Figure 5. Drawing examples of an engineer from Quintana Roo (top) and Campeche (bottom).

It is important to mention that the two subcategories that more frequently appeared in this study exhibited some variation by gender. 30% of the men from the study in Quintana Roo mentioned features related to the oil industry, while 21% of the women mentioned aspects regarding this subcategory. In contrast, 21% of the men from Campeche mentioned characteristics related to oil industries, while 41% of the women did it. With regards to the subcategory related to construction work, 28% of the teachers in Quintana Roo mention it, but 36% women stated aspects related to it. The percentages by gender of Campeche teachers in this category were similar (21% of men vs. 17% of women).

Very few Quintana Roo or Campeche teachers had accurate perceptions of engineering. Selected answers to the question “Describe what the engineer is doing in the picture” probe an accurate knowledge about what an engineer does as can be seen in Figure 6. However, most of them are far from actually depicting an engineer in action [3]. This means that if Yucatan peninsula teachers’ perceptions of and attitudes toward engineering are not accurate, they could play a significant role in perpetuating incorrect perceptions about engineering [3, 17]. This could be reflected into their curricula and in the way they deliver messages about the nature of engineering to their students. As already stated, images shape the way individuals view the world [4], thus, eliciting and understanding the image Quintana Roo and Campeche teachers have of engineers and engineering was deemed extremely important in order to help the development of programs and curricula that could encourage engineering learning in the Yucatan peninsula.

FINAL REMARKS

Outcomes from this study confirm that cultural models to which humans are exposed can contribute significantly to their mental schema. Our results suggest differences on how Yucatan peninsula teachers perceive engineering and engineers based on the state where they are from, their gender, as well as the grade in which they teach.

Given that teachers’ ideas, knowledge and attitudes towards engineering and science might influence their students’ perceptions toward these fields, it was considered necessary to explore the conceptions held by Yucatan peninsula teachers to prevent (or correct) potential misconceptions. Addressing potential misconceptions is of critical importance since it has been established that student’s negative images and stereotypes about engineers and engineering can influence their career choice, making them less likely to pursue a career in this field [2, 18]. Therefore, we are implementing a program to encourage engineering learning at the P-12 school levels in the Yucatan peninsula, which consists of engineering teaching kits (ETKs), corresponding lesson plans, and professional development workshops in order to help teachers learn about engineering as well as implement the ETKs in their classrooms where their students are learning science and mathematics through guided inquiry, conceptual change, and engineering design [19, 20].

- She is carrying some blueprints to show her colleagues the projects that she has planned, since these blueprints are a lot, a friend comes down to help her.
 - *Está llevando los planos para mostrarle a sus compañeros los proyectos que tiene planeados, como son bastantes un amigo baja para ayudarlo.*
- He is supervising the construction work of a school, he is comparing his notes to the work that has been done by the workers and he is indicating how to perform the work.
 - *Supervisando los trabajos de la construcción de una escuela, comparando sus apuntes con lo que hacen los trabajadores e indicando cómo hacer las cosas.*
- Directing a construction, verifying that all the workers are carrying out their function and supervising.
 - *Dirigiendo una construcción, verificando que todos los trabajadores estén realizando su función y supervisando.*
- The engineer is collecting rubble from the construction.
 - *El ingeniero está recogiendo escombros de una obra.*
- The engineer thinks and works making models of buildings, physical and natural phenomena.
 - *El ingeniero piensa y trabaja en la elaboración de modelos de obras, fenómenos físicos y naturales.*
- He/she is thinking about how to relate his/her knowledge with new technological applications.
 - *Está pensando como relacionar sus conocimientos con las aplicaciones tecnológicas.*
- The engineer is working offshore in an oil rig.
 - *El ingeniero se encuentra trabajando en altamar en una plataforma.*
- The engineer is making blue prints, solving technological problems for oil extraction.
 - *El ingeniero está haciendo planos, resolviendo problemas tecnológicos para la extracción de petróleo.*

Figure 6. Selected quotes as examples of accurate perceptions from Quintana Roo and Campeche teachers.

The *Draw an Engineer* test used in this study proved to be a useful tool to identify Yucatan peninsula teachers' perceptions about engineering and engineers as previous studies suggested for students and teachers [2-5, 9-12]. However, the particular characteristics of the study context, the sample size, and some limitations related to the instrument utilized to collect the data [14], prevent us from making generalizations from our findings. In future studies, we will explore the suitability of the DAE checklist developed by Fralick *et al.* [21] and its flexibility to identify perceptions heavily based on a particular context [2].

ACKNOWLEDGMENTS

The Government of the State of Campeche and the National Council for Science and Technology (CONACyT) of Mexico are funding the project 2009-01-126164: *Aprendiendo ciencia y matemáticas a través de la indagación dirigida, la reestructuración conceptual y el diseño en ingeniería en los salones de clase de los niveles básico y medio superior en Campeche*.

We thankfully acknowledge financial support for the Quintana Roo workshop from *Calizas Industriales del Carmen*.

Authors Cruz and Guillermo gratefully acknowledge financial support for their PhD studies from *Programa de Mejoramiento del Profesorado (PROMEP)* of the Mexican Ministry of Public Education (SEP), *Universidad Autónoma del Carmen*, and *Universidad Juárez Autónoma de Tabasco*.

We appreciate Yucatan peninsula teachers' work and thoughtful critiques.

Abstract—A new metric, “stickiness,” is proposed, tracking longitudinally all students who have contact with a discipline to determine the likelihood those students will “stick” to that discipline and graduate in it. This metric has the versatility to be relevant for students making contact with engineering through a variety of pathways. Stickiness exhibits significant disciplinary differentiation. Whereas earlier work has shown that Industrial Engineering is the most successful at attracting and retaining students, the disciplinary distribution of stickiness shows that Industrial Engineering is exceptional. Disaggregating by race/ethnicity and gender, much larger variations in stickiness are observed (as much as 48 percent), and positive and negative outcomes are identified where students in particular subpopulations are more or less likely to stick than expected. Aggregated by race/ethnicity and gender, the stickiness of transfer students ranks the disciplines in the same order as the stickiness of first-time-in-college students, but transfer stickiness exhibits less disciplinary variation and transfer students in all disciplines exhibit higher stickiness than first-time-in-college students.

Keywords—retention; persistence; metric; transfer students; longitudinal

I. MEASURING PERSISTENCE IN ENGINEERING EDUCATION

A review of approaches to measuring persistence in engineering education has been presented by Ohland, Brawner, Camacho, Layton, Long, Lord, and Wasburn [1]. That work catalogued measures of persistence, characterized philosophical differences in the assumptions underlying those metrics, and described how the choice of metric results in underestimating or overestimating persistence in certain populations. That earlier work does not discuss in detail how the choice of a metric affects the population that can be studied. A discussion of various study designs and metrics follows. The population restrictions imposed by each are discussed along with the effect of those restrictions on the interpretation and impact of the results. These approaches are used by many researchers, but

our goal is to focus on methodological issues, so the examples here are drawn from earlier work using the same data source.

A. Graduation rate of a matriculating cohort

One of the most common research designs is a cohort study in which persistence of a cohort matriculating at the same time (or at least approximately the same time) is computed at various points, typically culminating with a six-year graduation rate. This is consistent with results that are submitted for accountability to external bodies [2, 3]. Cohort studies are primarily limited by who is included in the cohort. Since 1997, “Graduation Rates (GR)” from the Integrated Postsecondary Data System (IPEDS) [3] have been used to satisfy the terms of Student Right-to-Know legislation. These report the fraction of full-time, first-time, degree / certificate-seeking undergraduate students in a particular year (cohort), by race/ethnicity and gender completing a program in 150 percent of normal time. Because these rates are used to satisfy that legislative mandate, they are among the most commonly known and cited measures of an institution, yet this definition fails to consider part-time students and transfer students. Each of these populations poses challenges to the determination of “normal time”. The expected graduation time of part-time students can only be guessed. Inferring the cohort of each transfer student based on the number of credits transferred not only risks overestimating the contribution of those credits toward each student’s degree program, but also results in a cohort size (denominator) that changes with time, which can result in confusion or suspicion. These populations are left out of most studies [1, 4, 5, 6], which results in a lack of understanding of an educational pathway that is used by a large and growing number of students, particularly students from low socioeconomic backgrounds. Community colleges enrollments are 45 percent minority students, 42 percent first-generation students, and 46 percent students receiving aid (though there is certainly overlap among these groups) [7].

B. Cohorts of students in a single discipline

Studying persistence of disciplinary cohorts results in similar challenges to studying matriculation cohorts, but poses some additional challenges as well. If the study population (the denominator) is the number of students enrolled in a particular discipline at matriculation, then students who graduate in that discipline but who matriculated in other disciplines are removed from consideration. This overestimates the negative impact of the department in which the student matriculates, because it counts all students who switch majors as a loss, and also underestimates the contribution of the discipline that attracts and graduates the student. Particularly in engineering education, the diversity of matriculation models [8] poses problems for disciplinary cohort studies. A disciplinary cohort that is formed after students have completed a first-year engineering program will naturally have a higher graduation rate than a cohort formed at matriculation. Variation in time to complete the first-year engineering program adds further confusion to the establishment of disciplinary cohorts. In some cases, cohorts are formed from students enrolled in a particular discipline in the third semester (with the limitation that this represents varied levels of curricular progression) [1], and in other cases, institutions with first-year programs are excluded from study [6].

C. Composition of a graduation cohort

Focusing on the composition of the students graduating in a year or other time period is also valuable. This converging design provides a profile of the completers, which is therefore a description of the alumni of an institution. Comparing graduation cohort profiles to matriculating cohort profiles identifies populations that are not being successful to graduation. Further, comparing graduation cohort profiles to the institution's target population (the state population in the case of a public university) reveals the degree to which that target population is being served. The biggest risk in studying graduation cohorts is that the researcher is required to notice who is missing from the population.

D. Criteria for developing a new metric

Thus, there is value in developing a metric that can be used to study part-time students, transfer students, students who switch disciplines, and students who choose a discipline after entering in a non-disciplinary pathway (first-year engineering, or various "undeclared" or "undesigned" pathways). Transfer students are of particular interest because community colleges are more diverse than four-year institutions, both in terms of race/ethnicity and in a socioeconomic sense [7]. A new metric should minimize the effect of pooling students from multiple cohorts, who may be different in important ways as population changes occur over time. Satisfying these criteria will increase the size of the populations available for study, increase the applicability of the findings to populations of interest, and include a more diverse group of students and institutions.

II. INTRODUCING "STICKINESS" AS A NEW METRIC

We propose a new metric, "stickiness," that permits considering all these subpopulations with a single, unifying assumption: selecting a major indicates intent to graduate in that major. The stickiness of a major describes how likely students are to "stick" to a particular major once they choose it—regardless of what other majors they have had previously, what other institutions they have attended, or how long they have been in college when they first enroll in that major. The term "stickiness" is derived from Gladwell's use of the term in *The Tipping Point*, in which stickiness is defined as the specific content of a message that renders its impact memorable [9]. In the case of a disciplinary degree program, it is the specific content (or culture) of a program that makes students stay through to graduation.

A. Mathematical definition of stickiness

Specifically, the stickiness of a major is calculated as the number of students who graduate in that major divided by the number of unique students who have ever been enrolled in that same major, so it is a number between 0 and 100 percent. If this number is the "specific stickiness" of a major, two corollary numbers can be calculated: the "group stickiness" of a major is the percentage of students ever enrolled in that major who graduate in a group of related disciplines (engineering is the disciplinary group of interest in our work, although Science, Technology, Engineering, and Mathematics (STEM) more generally is of broader interest to the National Science Foundation and other national groups). Similarly, the "university stickiness" of a major is the percentage of students ever enrolled in that major who graduate from the university in any major. In our work, all these graduations occur in six years or fewer from when the student first matriculated to the institution from which they graduated.

B. What stickiness really measures

The assumption that students who select a major intend to graduate in that major leads to a corollary assumption: *when a student is allowed to major in a degree program (through any pathway), a commitment has been made by the institution and/or program that the student will be supported to succeed and graduate in that major*. Thus, stickiness is not just a measure of attractiveness to students, but it is fundamentally a measure of the degree to which a degree program (or group of degree programs, or university) makes and lives up to that commitment. Because stickiness is focused on measuring this degree of commitment, the effect of pooling students matriculating in different cohorts that may change in various ways over time is not perceived as an issue. In other words, even if there is variation among the populations that are pooled, we do not believe this introduces a bias in the measurement of interest. Stickiness allows direct comparison of majors, groups of majors, or universities. While the stickiness per se may not be that important, the relative stickiness of one group compared to another gives an indication of how that group is faring. This can be done at the level of major, race, gender, groups of majors, institution, or entry point (FTIC vs. transfer). This minimizes biases because the same metric is applied to all so if all have the same treatment, all should have the same result.

III. A DATASET FOR TESTING THE STICKINESS METRIC

The stickiness metric is tested using the Multiple-Institution Database for Investigating Engineering Longitudinal Development (MIDFIELD). MIDFIELD comprises a census of undergraduate students that attended eleven public institutions in the U.S. between 1988 and 2009. Accounting for 11 percent of U.S. engineering graduates, MIDFIELD institutions represent public universities that educate large numbers of engineering students. A detailed description of the MIDFIELD database is available elsewhere [4]. From the records of 977,950 students in MIDFIELD, we restricted our sample to those who (a) were domestic students identifying as Asian, Black, Hispanic, or White (927,350), (b) entered the data set early enough to have the possibility of graduation within six years (662,736), and (c) ever declared a major in engineering or otherwise expressed an intention to study engineering (145,579). Race/ethnicity is based on student self-reporting from among institutional choices. Three of the institutions have first-year engineering programs while the rest permit direct matriculation into an engineering discipline. Note that all institutions can be included in analyses with the stickiness metric. At FYE schools, students must wait to declare a specific engineering discipline as their major. However, each discipline at these schools is in the same situation so useful comparisons can be made.

We wanted to explore a range of disciplines that are likely to have different cultures and variation in student outcomes. Majors with large populations and higher-than-average percentages of women were included. Electrical (EE) and Mechanical (ME) each contribute to more than 20 percent of the engineering students in our dataset. These are the only majors offered at all 11 MIDFIELD institutions. Chemical (ChE), Biomedical (BE), and Industrial (IE) engineering all have more than 30 percent women at graduation. Computer Engineering (CpE) was also included for several reasons. It is often combined into a single department with Electrical, has a very similar curriculum to Electrical but our prior work has already seen different outcomes for students, and it has the smallest percentage of women of any engineering major [6]. All disciplines included were offered at a minimum of 8 schools in our dataset for at least four years.

To enable us to illustrate the usefulness of the stickiness metric with various populations, we have chosen to use dot plots and multiway plots. These are tools for visualizing, exploring, and presenting categorical data [10]. Here, we consider the stickiness metric for different engineering disciplines, disaggregated by race/ethnicity and gender, as well as different matriculation pathways. Thus the six engineering disciplines are the rows and the horizontal axis is the stickiness in percentage. Each dot represents the stickiness of a particular population in a specific engineering discipline.

IV. DISCIPLINARY DIFFERENCES IN STICKINESS

In introducing this new metric, we show that stickiness varies more than 20 percent among engineering disciplines, that the stickiness of a particular major varies by race/ethnicity and gender, and that transfer students are “stickier” than FTIC students. Here we focus on the specific stickiness of engineering disciplines rather than groups or institutions.

A. The Specific Stickiness of Six Engineering Disciplines

Figure 1 illustrates the variation of specific stickiness among six engineering disciplines. As described earlier, the stickiness of each discipline is the number of students who graduated in that major divided by the number of students who ever declared a major in that discipline (N^e). Here, stickiness is expressed as a percentage. For example, in IE, the stickiness is about 55 percent, meaning 55 percent of the 9532 students who ever declared a major in IE graduated in IE in six years. In contrast, the stickiness of CpE is much lower with only about 33 percent of those students who ever declared a major in CpE obtaining a degree in CpE. EE, with its similar curriculum to CpE, also has relatively low stickiness. However, ME, which has the larger number of students, has the second highest stickiness. Thus stickiness is not a function of program size. It appears that there is a continuous distribution of increasing stickiness for CpE, BE, EE, ChE, and ME. IE has particularly high stickiness.

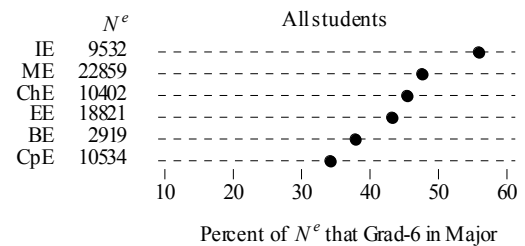

Figure 1. IE has the highest stickiness: variation in stickiness of six engineering disciplines. N^e is the number of students who ever declared a major in that discipline.

B. Variations in Disciplinary Stickiness by Race/Ethnicity and Gender

Does this success of IE apply to men and women? Does this vary by race/ethnicity? When studying underrepresented students in engineering, it is important to adopt an intersectional lens and consider race/ethnicity and gender [11, 12] as shown in the multiway plot in Figure 2. Here each panel displays the variation in stickiness for six engineering disciplines for a particular race/ethnicity and gender. For example, the top left panel shows the results for Asian women while the bottom left panel shows the results for Asian men.

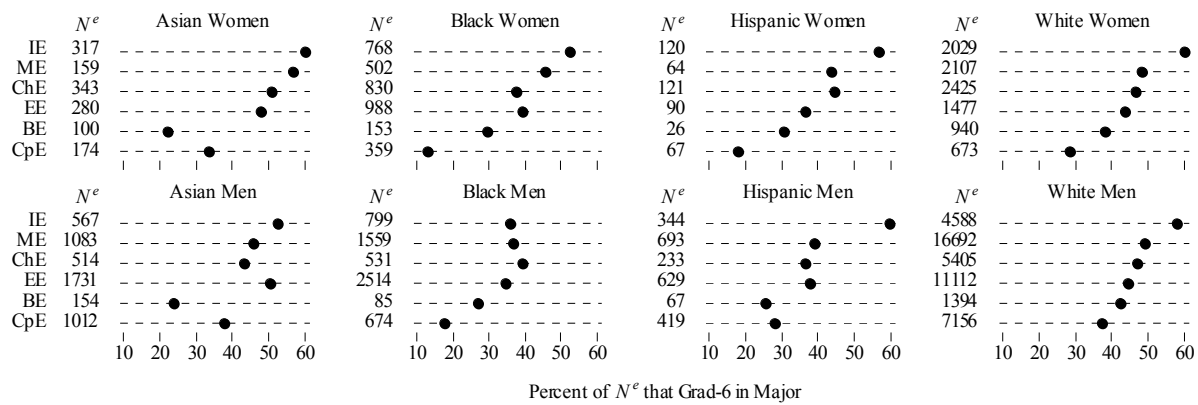

Figure 2. Stickiness of six engineering disciplines disaggregated by race and gender. N^e is the number of students who ever declared a major in that discipline.

Several interesting stories emerge from Figure 2. As expected, the overall shape of Figure 1 is best represented by the panel for White men, the largest population in engineering. The order of majors changes for several subpopulations. For Asian men and women and Hispanic men, BE, not CpE, has the lowest stickiness of any discipline. For Black men, ChE, not IE, has the highest stickiness. Asian students have overall high stickiness, with unexpectedly high stickiness in EE and CpE for Asian men. Women of all races appear to have particularly low stickiness in CpE and high stickiness in IE. Other poor outcomes include Hispanic men and women in ME, Hispanic men in ChE, and Black men in all disciplines with the possible exception of ChE. On the positive side, Black women have higher stickiness in EE than expected and Hispanic women and men appear to do quite well in IE. What are these programs doing well that helps these students “stick”?

C. Variations in Disciplinary Stickiness by Matriculation Pathway

If we disaggregate Figure 1 by matriculation pathway rather than by race/ethnicity and gender, Figure 3 results. Figure 3 shows the variation in stickiness for the six engineering disciplines for students who matriculated as first-time-in-college (FTIC) students and those who transferred (XFR) from another institution.

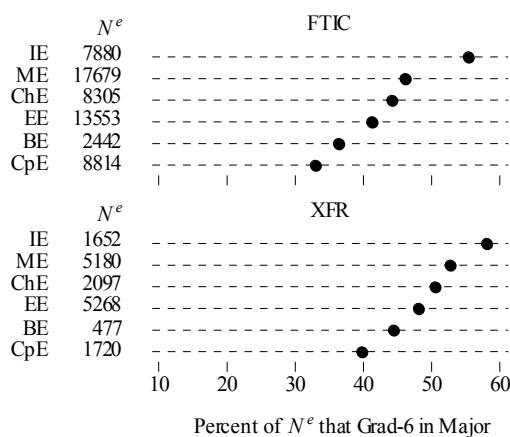

Figure 3. Stickiness of six engineering disciplines for FTIC and transfer (XFR) students. N^e is the number of students who ever declared a major in that discipline.

Figure 3 shows that the matriculation pathway makes a difference. The stickiness of transfer students ranks the disciplines in the same order as the stickiness of first-time-in-college students shown in Figure 1. However, transfer stickiness exhibits less disciplinary variation than FTIC stickiness (18 percent vs. 22 percent range). This might be expected since transfer students declare their major after some preparation at their prior institution suggesting a stronger commitment to their declared major at their four year institution. For all disciplines, transfer students have higher stickiness than FTIC students ranging from about 6 percent higher for ChE to 8 percent for BE. Again, IE appears to exhibit different behavior. Note that the stickiness for transfer students in IE is about 2.5 percent higher than that for FTIC students. This is much closer than for any other discipline.

V. CONCLUSIONS

The proposed stickiness metric has been shown to be effective in comparing outcomes for FTIC, transfer, FYE, and other populations that were difficult to include in the same study previously. It distinguishes among disciplines and provides new information that could not be inferred as easily from other metrics. We will continue to explore the use of stickiness, and encourage other researchers to use it.

As earlier work has shown, industrial engineering has remarkable characteristics [13, 14]. Qualitative work has helped explain its unique role among the engineering disciplines [15]. The authors continue to encourage other engineering disciplines to learn from industrial engineering. Other disciplinary findings from this work—both positive and negative—suggest that further investigation is warranted through both quantitative and qualitative study.

Because the stickiness metric can explore the outcomes of students in such diverse pathways, it holds promise as a metric that can be used to study the entire enrolled population in a single study. This elusive study design would be valuable in understanding the collective experience of all the students enrolled in a particular degree program at the same time. Thus, stickiness has the potential to relate persistence to climate (as expressed by conditions experienced by students taking classes at the same time) and program demographics (to explore whether a critical mass of a population affects outcomes).

ACKNOWLEDGMENT

The authors appreciate the help of colleagues, particularly George Ricco and Catherine Mobley, who helped consider the design and implementation of stickiness as a metric.

On Deployment of Effective Instructional Strategies: Students' Engagement through Cooperative Learning

Waddah Akili

Principal, Geotechnical Engineering, Ames, Iowa, USA, w.akili@isunet.net

Abstract - Engineering education in the Arab Gulf States (the Region) faces significant challenges as it seeks to meet the demands on the engineering profession in the twenty first century. This paper focuses on classroom-based pedagogies of engagement, and *cooperative learning strategies* in particular. The paper is a follow up to previous work by the author, on viable strategies to improve the classroom environment of engineering colleges in the Region. At the start, the paper provides an overview of relevant benchmarks of engineering education in the Region. Then, relates author's preliminary findings on *teaching/learning* practices in Region's colleges, sheds light on the *pros and cons* of the *lecture format*, and examines the literature on substance of different *active learning* protocols, focusing on *cooperative engagement strategies*. Next, it identifies barriers to *reformation* in general, and to the use of modern pedagogical skills in particular. The paper also argues that any meaningful change in Region's classroom practices (dominated by traditional lecture-based methods) should be supported by the university administration. What is necessary to create a change, is for the department or college, to have a comprehensive and feasible set of plans: articulated expectations, opportunities for faculty to learn about new pedagogies, and an equitable reward system.

Index Terms –Arab Gulf States, Lecture format, Active learning protocols, Cooperative learning.

Introduction

“To teach is to engage students in learning.” This quote, from *Education for Judgment* by Christenson et al,⁽¹⁾ captures the meaning of the art and practice of pedagogies of engagement. The theme advocated here is that student involvement is an essential aspect of meaningful learning. Also, engaging students in learning is principally the responsibility of the instructor, who should become less an imparter of knowledge and more a designer and a facilitator of learning experiences and opportunities. In other words, the real challenge in college teaching is not trying to cover the material for the students, as many of us believe and

practice today; but, rather uncovering the material with the students. This is a call for all faculty involved with teaching engineering courses, and as members of faculty teams who develop, maintain and implement engineering programs, to consider not only the content and topics that make up an engineering degree but also how students engage with these materials. It is primarily a call to consider how students engage in their college experience, and what tools can be deployed to stimulate learning.

There are numerous tools available to select from, including the models predicated on cooperation; i.e., working together to accomplish shared goals. Within *cooperative* activities, individuals seek outcomes that are beneficial to them and to all other group members.^(2, 3, 4)

Cooperative learning researchers and practitioners have shown that positive peer relations are essential to success in college. The positive interpersonal relationships promoted through *cooperative learning* are regarded by most as crucial to today's learning communities. They reduce uncertainties about college attendance and increase integration into college life. Isolation and alienation do, often, lead to failure. Two reasons for dropping out are: failure to establish a social network of classmates, and failure to become academically involved in classes.^(4, 5, 6)

In the Arab Gulf States (Saudi Arabia, Bahrain, Kuwait, United Arab Emirates, Qatar, and the Sultanate of Oman) traditional methods of teaching/learning dominate the classroom environment. Calls by some academics to introduce *engagement pedagogies* have not been effective in changing the “mind set” of most involved. Therefore, the traditional mode of lecture where the information passes from instructor's notes to students' notes (without passing through the mind of either) continues as “the norm”.

The paper renews the call for deployment of effective instructional strategies in the classrooms of the Region, stressing on *cooperative learning* practices as a viable alternative to the traditional (low-interaction lecture-based) environment that has gripped the engineering education of Region's institution for decades. The paper sheds light on: research support, current practices, and ways of redesigning classes to stimulate interaction to help break the lecture dominant pattern, using *cooperative learning* protocols.

A number of relevant questions do come to mind, including: What needs to be done to move the process forward? What are the key components of successful deployment of *active learning* in general and *cooperative learning* in particular? How to foster and expand the community of faculty who decide to use *cooperative learning*? Achieving the change needed across the Region requires collective effort by all involved, namely: the institution, the faculty, and the students.

An overview of engineering education in the Region

Engineering education in the Arab Gulf States (the Region) started, in earnest, during the early to mid sixties. Initially, colleges of engineering were founded in Riyadh, Jeddah, and later, in Dhahran, Saudi Arabia. In the other states of the Region, engineering colleges were founded soon after these states have gained their independence.^(7, 8)

The strong political and economic ties between the States of the Region and western countries - the USA in particular - has helped enormously in setting up, manning, and providing needed guidance to these fledgling institutions during their early years. The dramatic increase in oil revenues during the 70s, and 80s, coupled with lack of skilled professionals in areas deemed necessary for growth and development of oil-related industries, has been pivotal in the start-up of higher education in general and engineering in particular. There are today eight main public colleges of engineering in the Region (Table 1) in addition to several, recently established, private and semi private colleges and/or universities that offer engineering degrees.

These eight public colleges (shown in Table1), have since their inception, been guided by advisory committees drawn from US colleges. Previously, the Grinter's Report⁽⁹⁾ and the Goals Report⁽¹⁰⁾ have guided the educational process forward. Recently, ABET Engineering Criteria 2000⁽¹¹⁾ has been the subject of seminars and workshops, intended to assist colleges of the Region in making use of the EC2000, whenever possible. Indeed, the EC2000 has generated a lot of interest and challenges in the Region.

Admission policies, for all eight colleges, are based on grades obtained in an examination sanctioned by the Ministry of Education, upon completion of the 12th grade. Additionally, an entrance exam and evidence of proficiency in English, a requirement imposed by many of these colleges, may exempt the applicant from a pre-engineering "prep year", administered as a separate unit from the college. Statistics have shown that over 80% of first year engineering students do attend the "prep year", during which students embark primarily on improving their English skills. The author has proposed to reform the "prep year" by making it two years, and widening the scope of the subject matter to include (in addition to building up English language skills to a pre-set level):(i) math and science courses-to prepare for engineering "gateway" courses;(ii) hands-on "pre-college" training period; and,(iii)

fostering a "proper learning environment", to help students acquire desirable attributes such as: analytical skills, creative thinking, and social skills⁽⁷⁾

TABLE 1
THE EIGHT MAIN ENGINEERING COLLEGES OF THE ARAB GULF REGION.

| Country | COLLEGE OF ENGINEERING | Year Established |
|----------------------|---|------------------|
| Saudi Arabia | King Saud Univ, Riyadh | Early sixties |
| Saudi Arabia | King Abdul-Aziz Univ, Jeddah | Early sixties |
| Saudi Arabia | King Fahd Univ of Petroleum and Minerals, Dhahran | Late sixties |
| Bahrain | University of Bahrain, Manama | Mid seventies |
| Kuwait | Kuwait Univ, Kuwait City | Mid seventies |
| Qatar | Univ of Qatar, Doha | Early eighties |
| United Arab Emirates | UAE Univ, Al-Ain | Early eighties |
| Oman | Sultan Qaboos Univ, Muscat | Mid eighties |

In a recent **survey** directed at graduates of engineering colleges of the Region on: the *pros and cons* of the engineering education they have received, and any advice they may be willing to offer? **Fifty seven** out of a total of **sixty five** respondents were critical of the classroom environment and teaching styles practiced during their college years. Majority of the respondents were between 25 to 30 years of age, citizens of the Arab Gulf States, and either employed or practicing engineering on their own.

The **Survey**, aimed at getting first hand information from the graduates on a number of topics, including: (i) curricula, classroom environment, and *teaching-learning issues*; (ii) alumni-college relations; and, (iii) industry-academe relationships, as perceived by the graduates. Of particular interest here are the remarks made by the respondents, on the need to replace *traditional teaching* that has persisted with better and more effective methods of course delivery⁽⁸⁾. Some of respondents have come to the realization, after having finished college, that learning is not an automatic consequence of pouring information into student's head. The process should have an enduring value beyond the classroom! It was also a call for the colleges of the Region to begin transforming learning and teaching, by sponsoring new initiatives that will promote and encourage faculty to adopt "classroom-based *pedagogies of engagement*". This raises a general question: How can the Region, as one entity, promote systematic change to the education process, taking advantage of the wealth of

available information on *teaching and learning*? There is no easy answer. But, developing a new cadre of faculty who are comfortable using novel *engagement strategies* would be a step in the right direction.

Teaching and learning practices in the Region: preliminary findings

To get first-hand information on teaching practices and classroom activities in the colleges of the Region, the author traveled - during the spring of 2008- to the Region and was able to meet with faculty members and administrators from three engineering colleges, in an effort to learn about current teaching and learning practices, and instructors' views on ways to improve the classroom environment in the Region. A total of 24 faculty members responded voluntarily – on a rather short notice - and expressed their views, supplemented with written statements. The main headings/questions raised by the author, during the interviews, were:

- Have you been exposed to *active teaching/ learning strategies*? Have you kept up with recent developments in the arena of *pedagogies of engagement*?
- Are you willing to deploy any of those strategies (*pedagogies of engagement*) when the need arises?
- Preliminary information reveals that *engagement strategies* are not currently utilized in the Region, at any level, why not?
- Do you believe that *active learning* should be deployed in your department, and if so, what are the barriers?
- Based on your experience, what would you suggest to improve the classroom environment?

While answers to the above noted questions varied considerably from one member to the next; there were, nonetheless, some agreements amongst many, on certain issues that would be worthy of consideration. The general consensus of views/opinions expressed by the majority of the interviewed faculty asserts and/or amplifies the following points: **First**, nearly all have been exposed to one form or another of *active learning* through work shops and seminars offered at their universities' Learning Centers. Some have acquired the knowledge on their own, i.e., through their own personal endeavors. **Second**, all have expressed their wish to learn more about *active learning strategies*; and most do not believe that they are sufficiently competent to deploy an *active learning strategy* as yet. **Third**, many have expressed their wish to improve their classroom strategies within the framework of traditional methods, arguing that there is a great deal of room for improvement within the traditional lecture approach. **Fourth**, some members have stressed that the success of any *active learning strategy* requires students' participation, raising the question whether students are ready and willing to become active participants in the process? **Fifth**, most members were mindful of the time and effort needed to

become a more effective instructor; and concerned that teaching is undervalued in comparison to research.

The interviewed faculty members have been teaching undergraduate classes at their present institutions for a minimum of five years. Most of the classes taught by the aforementioned faculty are small size, seldom exceeding 35 students per class. The lecture format dominates the seen. Students listen, take notes, and are allowed to ask questions at the end of the lecture or during office hours. There seem to be less interest (by most of the interviewed faculty) in the process by which the course content is delivered, and more of a concern whether the rate of delivery would allow the instructor to finish the course on time. The views expressed by the faculty and the impression(s) arrived at by the author, leads one to believe that it is highly unlikely that new more effective *teaching-learning strategies* would be deployed any time soon, unless drastic measures are undertaken⁽⁸⁾. The author is more convinced now than ever, that classroom reformation, including deployment of *active learning strategies*, would happen only if the institution mandates it!

The pros & cons of the lecture format

Lectures have a number of characteristics that does make them, for the right subject matter, desirable in the classroom^(2, 12, 13). It depends on the abilities and experience of the lecturer. An able and committed lecturer can accomplish the following:

1. Relate the material proficiently and effectively, in a manner that reflects lecturer's personal conviction and grasp of the subject matter;
2. Provide students with a thoughtful, scholarly role model to emulate;
3. Supplement the subject matter with current developments not yet published, or interject lecturer's own views derived from his/her own experience;
4. Organize material in ways to meet the particular needs of a given audience;
5. Efficiently deliver large amounts of information when the need arises, without confusing his/her audience; and,
6. Underscore key points, simplify complexities, illustrate with facts and figures, and arrive at well "thought-out" conclusions.

In addition, lectures are presumably cost-effective, in that they can reach many listeners at one time; also, provide an advantage for those students who find learning by listening enjoyable⁽¹²⁾. As most students will attest, not all lectures or lecturers achieve these goals. Also, the effectiveness of the lecture varies inversely with the difficulty of the material presented, and listeners retain factual material better when presented in short sentences. Speaking extemporaneously is more effective than reading from lecture notes, and it is desirable to change the pitch, intensity, and the timbre of one's voice⁽¹²⁾. These characteristics presume that the lecturer is an enthusiastic and knowledgeable scholar. But we realize that most campuses have a few that fit this description, and can be

labeled as gifted practitioners who could keep most students interested during the formal 50-minute lecture. Even if it is assumed that most engineering lecturers possess these necessary characteristics, research has shown that *the exclusive use of the lecture in the classroom constrains students' learning*.^(12, 13, 14)

One of the most important problems associated with *total* reliance on the lecture method is the inability of most students to listen effectively to any lecturer, no matter how skillful, over a sustained period. Ten to 20 minutes into the lecture, confusion and boredom sets in and assimilation falls rapidly, remaining at a low state until a brief period toward the end of the session when students are revived by the knowledge that the lecture will soon be over.⁽¹⁵⁾

If a faculty member is hesitant about selecting one or more of *active learning strategies*, because some questions exist about its comparative effectiveness with the lecture method, he or she should consider the following: research has shown, beyond the shadow of doubt, that these strategies do deliver content as well as lectures while providing diverse presentations that enhances students' motivation and achievement, and helps in building up desirable personal traits.^(14, 16, 17)

Examining the literature on meanings and substance of active learning

Active Learning is generally defined as any instructional method that *engages* students in the learning process. It is widely accepted that *active learning* requires students to take part in "pre-planned" learning-related activities, believed to spark and stimulate their learning, while in the classroom. It is understood that during *active learning*, less emphasis is placed on transmission of information and more on developing students' skills. Additionally, during an *active learning* cycle, emphasis is placed on students' exploration of their own abilities, including: their thinking process, their value system, their intellect, and their courage to express themselves orally and in writing.⁽¹⁸⁾

Collaborative Learning refers to any and all of the instructional methods where students work together in small groups towards a common goal.⁽³⁾ It can be viewed as encompassing all group-based instructional methods, including *cooperative learning*.^(5,13) Some researchers view *collaborative* and *cooperative learning* as having two distinct historical developments and differing philosophical roots. Despite differences and similarity of the two approaches (*collaborative* vs. *cooperative*), the fact remains that the core element of both is the emphasis on student interactions, as the primary source of learning, rather than learning as individuals. *Cooperative Learning* is a formalized active learning structure where students work together in small groups to accomplish shared learning goals and to maximize their own and each others learning. The most common model of *cooperative learning* in engineering is that of Johnson, Johnson and Smith⁽¹⁶⁾. This model has five elements: mutual *interdependence*,

individual *accountability*, face to face *interaction*, *interpersonal* and small group *skills*, and individual *assessment* of group *functioning*. Although different cooperative models exist, the core element in all is the emphasis on cooperative incentives rather than competition in the promotion of learning. Before adopting a specific method of *active learning*, faculty members need to become familiar with the literature and, in particular, the various strategies that promote *active learning* in the classroom. Despite familiarity with the literature, ambiguity and confusion may result, at times, from reading the literature; particularly when the effectiveness of any instructional method is examined and/or compared with another method. Assessing "what works" requires looking at a broad range of learning outcomes, interpreting results carefully, and quantifying the magnitude of any reported improvement. To assess critically "what works" for a given set of conditions, the reader has to attain sufficient knowledge and familiarity with the subject matter. This should not, by any means, discourage faculty from moving toward *active learning*; but rather intended as a "precautionary" observation, to new instructors: Not "to make too much" out of what they have read unless it is credible, and substantiated with facts and figures. Despite some pitfalls, faculty should be encouraged to examine the literature on *active learning*, including the common barriers that may arise as a consequence of its application.

Promoting student engagement using cooperative learning structure

The positive interpersonal relationships promoted through *cooperative learning* are regarded by most as crucial to today's learning communities. They increase the quality of social adjustment to college life, reduce uncertainties about attending college, and increase integration into college life. Isolation and alienation, on the other hand, often lead to failure. Two major reasons for dropping out of college are: failure to establish a social network of classmates and failure to become academically involved in classes.^(14, 17)

Cooperation is more than being physically near other students. It is actually a state of mind. A willingness to open up to others, exchange information and views with others, and accept the fact that working together is more beneficial to all involved in the exercise. For a *cooperative learning* experience to be successful, it is imperative that the following be integrated into the class activity:^(13, 14)

- Positive Interdependence- Students should perceive the need for one another to complete planned activity.
- Face to Face Interaction- Students should work together in planning, executing, and arriving at conclusions. They should share the work load, and share the credit, thus promoting each others learning.
- Accountability- Each student's role and performance is to be assessed, and the results are those of the group (and for the group). Keeping track of the contribution and knowledge gained by each could be monitored, as

well, by either testing each and every student in the group, or by randomly selecting a group member (or members) to be tested and thus proxy for the group.

- Sharing known skills- Students who possess certain knowledge or skills (examples: computer skills, laboratory skills, data reduction skills, presentation skills) should be willing to pass it on, and/or share it with their group members.

As noted earlier, relying solely on the traditional lecture approach, no matter how competent the lecturer is, fails to *engage students in learning*, thus indirectly depriving students of learning experiences and opportunities that could only materialize utilizing *engagement strategies*. Under the umbrella of *engagement strategies*, there are numerous models available to select from. The work by Johnson, Johnson, and Smith ⁽¹⁶⁾ indicates that students exhibit a higher level of individual achievement, develop more positive interpersonal relationships, and achieve greater levels of academic self-esteem when participating in a successful *cooperative learning* environment.

Barriers to change in the classroom

To address adequately why most faculty in the Arab Gulf region have not embraced recent calls for educational reform, it is necessary first to identify and understand some common barriers to instructional change that seems to apply in America and elsewhere, and have been reported on in the literature ⁽²⁾. Many of these barriers seem applicable to the institutions of the Region, including:

- The powerful influence of educational tradition,
- The discomfort and anxiety that change creates,
- The potential problem/difficulty that may result from not covering adequately the assigned course content in the limited class time available,
- The increase in the amount of preparation time, and
- Lack of needed resources to proceed with the new method, when applicable.

Perhaps the single greatest barrier of all, is the fact that faculty members' efforts in employing a new approach would involve risk - the risk that students would not participate, or learn, the fact that faculty members may feel a loss of control, lack necessary skills, or be criticized for teaching in unorthodox ways. Faculty universally "know" that their institution expects excellence in teaching, but few campuses have critically examined and discussed explicitly how "excellence" is best achieved and assessed. Research has shown that faculty perceptions about the underpinnings associated with "superior teaching", almost always, place "knowledge of the subject matter" well above all others.

Faculty members see few incentives to change for several common reasons. **First and foremost**, is the pervasive belief that "we are all reasonably good teachers?" **Second**, there is very limited financial incentive, if any, to devote the effort acquiring alternatives to traditional approaches of teaching. **Third**, the perception shared by most faculty that time and effort spent pursuing research and research

money, is more rewarding, from an institution point of view, than time spent improving one's teaching skills.

Looking forward?

A root question: What is an engineering education for? – should be on the table for an evolutionary debate, referring, in particular, to the future of engineering education. What engineering students need to learn, and **how** can they best learn it, as well as **how** can engineering schools best teach it? are among the "questions" to be considered. The "**How**" is at the crux of the matter. Changing the *status quo* is never easy, but time has come for Region's colleges to turn a "new leaf" and begin moving in the direction of *active learning strategies*, in general, and *cooperative learning* environment in particular.

The author believes that in addition to mandating the "change", an effort should be made to create a climate for improvement in classroom instruction by changing the social and cultural norms that have prevailed for decades. Such an effort should permeate throughout the academic arena, re-defining the role of teaching faculty, underscoring the fact that learning is a consequence of students' engagement with the subject, and emphasizing that the simultaneous presence of interdependence and accountability are essential to learning. The specifics of such an effort ought to include the following:

- Rid classroom teaching environment from prevailing passive approaches to learning, and plant the seeds for active learning protocols throughout the public education system.* Propagate the idea that: student-teacher interactions are a "priori" to stimulate learning at all levels.
- Provide the manpower and support necessary to "in-house" education units and/or centers that define, promote, and encourage the art of appropriate teaching, including active learning protocols.* Scholarly research about teaching, should be encouraged, and openly discussed.
- Provide instructors with clear and consistent communications about expectations regarding teaching.* Faculty become frustrated and confused when told that teaching plays a vital institutional role, but to find out that rewards are for research. Effective teaching should also be rewarded, and poor teaching needs to be remediated.
- Encourage instructors, when using alternative instructional strategies, to try to meet the specific needs of students' different learning styles.* Students are inherently different, and so are their learning styles.
- Target new instructors, in particular, and help them to make the transition from traditional methods to active learning strategies.*

Invariably, different scenarios may be arrived at, and faculty members who have had some prior experience in deploying *engagement practices* should be given the opportunity to lead in this effort. However, leaving change up to individual faculty members without a supportive culture that values effective teaching/learning pedagogies for classroom reformation and educational development, doesn't work. Piecemeal efforts - an initiative here or a

success story there - could result in pockets of improvements but will not change the *status quo* within the Region as a whole. What is necessary to plant the seeds and sustain the “change” is for the university (i.e., the department and the college) to arrive at a comprehensive and integrated set of plans: clearly articulated expectations and a reward system aligned with these expectations.

Concluding remarks

To keep pace with fast changing global marketplace, engineering education in the Arab Gulf States has to undergo major “reformation” including revitalization of the classroom environment. There is concern among students, faculty, and graduates of Region’s institutions- arrived at through a survey targeting new engineering graduates & the feedback from Region’s faculty interviewed recently - that current teaching practices (traditional teaching) appear to have adversely affected outcome. There is an urgent need to adopt new and innovative approaches in teaching.

The paper reviews the *pros and cons* of the traditional lecture approach, defines common forms of *active learning* relevant for engineering faculty in the Region, and argues that the introduction of classroom-based pedagogies of engagement can help break the traditional lecture-dominant pattern. One way to get the students actively involved is to adopt a *cooperative learning strategy*: getting them to teach one another, dig below superficial levels, learn “to learn”, get to know their classmates, and build a sense of community with them.

This is a call for Region’s faculty to learn the new ways of teaching, and strive to reach a high level of pedagogical knowledge and competence. In the dialogue between administrators and faculty, needed to bring about the change, faculty will rightfully identify barriers including the time and resources needed to embark on the change. Also, should request authorization to experiment with new ways of teaching without risking low teaching evaluations.

With regard to implementations, author’s findings assert that classroom practices today have remained, by and large, very traditional. And none of the novel approaches to teaching, including *pedagogies of engagement*, are deployed anywhere in the Gulf region. Therefore, unless the “change” is mandated by the institution, it is highly unlikely that the classroom environment would witness any noticeable shift toward *classroom engagement practices* any time soon. If and when the “change” is mandated, the challenge then will be: how to infuse the new pedagogies without causing disruptions or trigger some undesirable consequences? Said another way, is there an optimum balance between maintaining traditional lecture-based practices and the deployment, of an *active learning pedagogy*? If so, what does the balance depend on? (Type of course? Students’ background? Instructor’s skills?).

Implementation of said “change” may have to be carried out in phases and /or steps over time. It may take years before it reaches optimum condition. Change will only be brought about through the determination of the leadership

(deans, department heads, etc.), appropriate support and resources, and faculty members’ willingness to learn and change their current classroom practices. The myth expressed by some faculty that “*I am willing but they won’t let me*”, is a common response from faculty members to calls for reform in education. To the contrary, and as eloquently expressed by Combs⁽¹⁹⁾: “*Teachers may not be able to change the educational system, but the variations possible within the classroom are almost limitless.*”

Abstract— High failure rates are common in many programming courses worldwide. Many causes for the learning problems have already been identified and different solutions have been proposed. However, the situation remains mostly unchanged. So, new pedagogical approaches are necessary, looking to create learning contexts that motivate students, increase their involvement with course activities, and maximize their learning possibilities. In this paper we present the changes made in the structure of a non-majors introductory programming course, and discuss the results obtained. We also present the results obtained in the first implementation of the new course structure.

Keywords: *learning to program; non-majors; motivation; pedagogy;*

I. INTRODUCTION

Introductory programming courses at the Department of Informatics Engineering from the University of Coimbra suffer from high failure and dropout rates as reported in many other high educational institutions [1, 2, 3]. This is a situation that affects mostly novices as those courses are usually placed at the beginning of the curricula [4, 5, 6]. Many authors suggested possible causes for students' difficulties, such as the nature of programming, the students' background and study attitudes as well as the pedagogical strategies commonly used in introductory programming courses [1, 2, 7, 8].

In many higher education institutions, introductory programming courses are offered not only to computer science freshmen, but also to students in other degrees. Consequently, courses normally have many students with different backgrounds, needs and interests. The high number of students that fail or drop out worsens the situation. All these factors prevent teachers from giving individualized attention to each student (or even group of students). The same has happened with the first programming course (called IPRP, a Portuguese acronym for Introduction to Programming and Problem Solving), at our Department. This course is common in Informatics Engineering, Industrial Engineering and Design and Multimedia. As the results were not satisfactory, with high rates of failure and drop outs, the Department decided to make several changes in the teaching structure and strategies, aiming to improve the students' results. This decision was reached after some successful experiments that were made in the three previous years in a small introductory programming course

directed to Design and Multimedia Master students, who had very limited or no previous programming experience [9, 10]. The new structure was introduced for the first time in the first semester of the academic year 2011/12.

In this paper we present a detailed view of the changes made and their pedagogical consequences in the context of a non-majors introductory programming course directed to Design and Multimedia students. To assess the results we use official information, like the drop out and failure rates of the last few years including this year and the students' answers to the official pedagogical surveys regularly made by the University. We also use the results of another survey, directed only to students that were repeating the course (they had dropped out or failed in the previous year), which was explicitly focused on the changes made. These students followed the course in the two formats, so their views are important to assess the changes made.

In the next section we present the changes made and the rationale behind them. In the following section we present the results obtained, both in terms of failure rates and the students' opinion. We finalize with some conclusions.

II. WHAT CHANGED

The changes decided at management level were essentially organizational: to create separate courses for students following different degrees and to modify the course class structure. These decisions created the opportunity to make crucial changes at the pedagogical level, especially in the case of the course to Design and Multimedia students (we will call it IPRP-LDM from now on).

The Design and Multimedia degree was offered for the first time in the academic year 2008/2009. Since then, the introductory programming course adopted a weekly 2 hour lecture with all the students together, 3 hours of lab classes in groups of 24 students and 2 hours of free tutorial classes in groups of about 60 students. The new class structure includes only one type of class, with students divided in groups of about 24 students. Each group has 5 hours of classes per week, divided in two different days, one with 2 hours and the other with 3 hours. The same teacher is responsible for all classes of a particular group during the semester. Each class consists of

both the introduction of theoretical concepts and practical assignments.

The rationale behind the changes made included a better use of class time, as traditional lectures were not as useful as they should be (class rhythm, examples, and activities were not suited for many students due to the dimension and the very heterogeneous nature of the group). Also, this new class structure would allow the presentation and immediate practice of the different concepts, eliminating problems due to the split between lectures and the different lab groups (even more clear in the case of students who missed lectures and arrived to the lab without a clue about the relevant concepts for that day).

The separation of students following different degrees in separate courses reduced the number of students in IPRP-LDM to 103, 45 freshmen and 58 repeating the course after previous failure or drop out. More importantly, the separation allowed us to shape the course considering the interest most Design and Multimedia students had in design and digital art issues. This was the main reason for choosing the Processing language for the course, instead of Python that was previously used in the joint course. The reason was not language simplicity (on the contrary), but its ability to easily support the development of applications that display drawings, animations and art works. Most course activities had a visual nature, while involving programming concepts common in introductory courses (e.g. selection, repetition, arrays, and an introduction to object oriented programming).

A recurrent question of IPRP-LDM students in previous years was: Why should we learn to program? Many of them did not have any motivation to face the difficulties inherent to learn to program. They felt it was not useful for their professional future. As motivation is very important for student involvement in learning activities the teachers addressed this question in the first class. However, instead of telling them how important programming can be, they asked each student to make a web search about Processing made projects. Each of them had to select a project to present in the next class. The teachers noticed a positive impact in the second class because students wanted to know how those projects were made and also to be able to create their own projects.

The possibility of working with small groups of students and the increase of time availability (5 hours of class per week), allowed the teachers to better know each student, her difficulties, preferences and reactions to teacher interactions. To reinforce the teacher – student relationship we used a less conventional activity in programming courses: students were asked to write about their learning experience every two weeks. Reflections were written in the course Learning Management System (Moodle) and were accessible only to the teacher. This activity allowed teachers to know better each student, as many of them seemed to find easier to write about their problems than to speak about them. It was possible to identify and address some learning issues that were causing difficulties to some students, and also prevent some drop outs through direct interventions with the specific students.

To keep students as committed as possible was one of the teacher's main objectives. To achieve this, some other strategies were used:

- In several assignments students were allowed to include a more creative component. For example, the teacher defined the minimum visual requirements for the assignment (e.g. it has to include a windmill with rotating sails), but the rest of the specification was left open, allowing each student to design and program other components that she/he felt interesting;
- Teachers often tried to encourage students to recognize their efforts and achievements. Errors were always presented as learning opportunities, showing that all programmers make mistakes (including the teacher). It was important to make students conscious of their own progresses, so that they understand that learning is possible if they commit enough;
- Assignments given to a particular student took into consideration her current level as much as possible. This means that in the same class different students could be working on different assignments;
- Students were made aware of their role in learning and the necessary attitude and commitment to be successful. The teachers frequently reminded students about the importance of an active and pro-active attitude towards learning;
- Teachers closely followed students' progress, trying to early detect any difficulties. This allowed teachers to provide early corrective actions, both to small groups sharing similar problems and at an individual level.

Although the changes made in the course structure were essentially organizational, their consequences were mostly pedagogical. There was a better learning context, more suitable to the students' characteristics, and a higher degree of consideration of individual difficulties. All this resulted in more motivation and a deeper student involvement that had a positive impact in their final results, as presented in the next section.

III. THE RESULTS

The results accomplished with the new course structure in the introductory programming course for Design and Multimedia students were measured using three different sources of information: the students' final grades, the results of the university official pedagogical survey, and the results of a questionnaire directed to the students that were repeating the course.

A. Final grades

To evaluate the impact of the innovations introduced in the course, we compared the course final information with the two previous years. The data is presented in Table I. This table shows, for each year, the number of enrolled students, the number of students who followed the entire course (including the final exam), the number of approved students, the rate of assessed students (assessed/registered), the success rate (approved/assessed), the approved rate (approved/registered) and the average of the final marks (expressed in the scale 0 – 20 as used in Portugal).

TABLE I. COMPARATIVE DATA IN THE THREE ANALYSED YEARS

| ALL STUDENTS | | | | | | | |
|--------------|-------------------|-------------------|-------------------|------------------------|--------------|---------------|---------------------|
| | Enrolled students | Assessed students | Approved students | Assessed students rate | Success rate | Approved rate | Final marks Average |
| 2011/12 | 103 | 82 | 59 | 79.6% | 72.0% | 57.3% | 12.9 |
| 2010/11 | 91 | 78 | 18 | 86.8% | 23.1% | 19.8% | 12.1 |
| 2009/10 | 64 | 57 | 17 | 89.1% | 29.9% | 26.6% | 12.0 |

It is possible to observe that there was a very positive evolution in most figures, especially in success rate and approved rate. The evolution of the last indicator can be seen in Fig. 1.

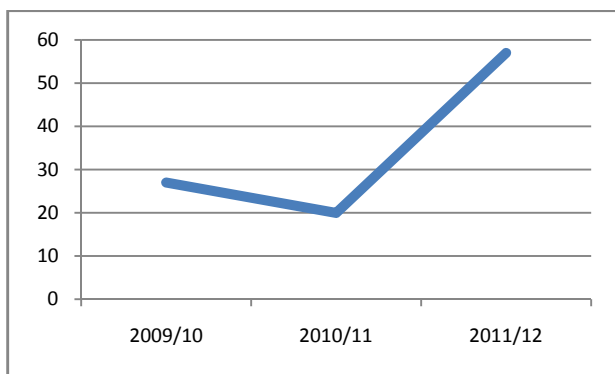

Figure 1. Percentage of approved students

The percentage of approved students increased from 26.6% and 19.8% in the previous years to 57.3% in 2011/12. Considering only the students that were in the final exam, the approved percentage increased from 29.9% and 23.1% to 72%. We performed the same analysis considering freshmen and non-freshmen separately. The results can be consulted in Tables II and III.

TABLE II. COMPARATIVE DATA FOR FRESHMEN IN EACH YEAR

| FRESHMEN | | | | | | | |
|----------|-------------------|-------------------|-------------------|------------------------|--------------|---------------|---------------------|
| | Enrolled students | Assessed students | Approved students | Assessed students rate | Success rate | Approved rate | Final marks Average |
| 2011/12 | 45 | 36 | 22 | 80.0% | 61.1% | 48.9% | 13.3 |
| 2010/11 | 48 | 41 | 9 | 85.4% | 22.0% | 18.8% | 12.6 |
| 2009/10 | 38 | 37 | 9 | 97.4% | 24.3% | 23.7% | 12.7 |

TABLE III. COMPARATIVE DATA FOR NON-FRESHMEN IN EACH YEAR

| NON-FRESHMEN | | | | | | | |
|--------------|-------------------|-------------------|-----------------|---------------------|--------------|-------------------|-------------|
| | Nr of enrollments | Nr of assessments | Nr of approvals | Rate of assessments | Success rate | Rate of approvals | Global Mean |
| 2011/12 | 58 | 46 | 37 | 79.0% | 80.0% | 64.0% | 12.8 |
| 2010/11 | 43 | 37 | 9 | 86.0% | 24.0% | 21.0% | 11.7 |
| 2009/10 | 26 | 20 | 8 | 77.0% | 40.0% | 31.0% | 11.3 |

The resulting curves are similar to Fig. 1, although the results were slightly better with non-freshmen than with freshmen (64% approved students versus 48.9%). This is consistent with the idea that learning to program needs time and maturation.

Although average grades also increased, the difference was not so impressive, as it was 12.9 (in a 0-20 scale) this year versus 12.0 and 12.1 in the two previous years (approximately 0.9% increase from previous years). The same analysis separating freshmen and non-freshmen shows that freshmen average grade was higher in the three years.

The percentage of students in the final exam decreased from 89.1% and 86.8% in the two previous years to 79.6% in the last year. This situation causes some concern, as it means that a number of students consistently register for the course, but do not follow it or drop out before concluding it. Further investigation is necessary to understand the reasons for this decrease.

Comparing the percentage of students that got approved in the three years, it is possible to say that the evolution is very positive. The overall approved rate had a sharp increase, supporting the teachers' view that the changes made were benefic for most students.

B. Official pedagogical survey

At the end of the semester the University pedagogical services conducted an anonymous survey about every course offered at the University. The survey included questions about the general conditions of learning (spaces, library, and so on) and particular questions about the student's enrolled courses.

The survey used a Likert type scale with five points (1 to 5), where higher marks mean a better opinion.

The first point to mention is the fact that 90% of IPRP-LDM students answered the survey (a high number when compared with other courses).

The survey consisted of 11 questions about each course followed by the student, such as:

- Appreciate the average quality of learning in the course
- Classify her own learning
- Rate her own participation in learning activities
- Globally classify her own performance in the course

The average marks to each question were between 4.0 and 4.3, reflecting a positive view about the course. Considering that the highest possible mark was 5, this means that most students had a positive view about the course and what they were able to learn.

It is noteworthy to compare IPRP-LDM results in this survey with the global results for the Design and Multimedia degree (considering all courses). In this case the average results in the survey questions went from 3.7 to 3.9. This means that IPRP-LDM was rated above average in all questions included in the survey. This is a very relevant result considering that many other courses could be more appealing to the students, as they are more design and multimedia oriented.

It is also significant to note that in 2010/11 the same survey had already been used, and the average of the student answers about IPRP-LDM were between 2.9 and 3.8, clearly below 2011/12 results.

The University survey also included some questions that allowed the students to give their opinion about the teachers. The results were coherent with the course results, as all averages were between 4.0 and 4.7 for the three course teachers. This means that most students appreciated the efforts the teachers made to promote learning.

C. The Non-Freshmen Questionnaire

To have a deeper insight on the way students reacted to the changes made in the course, we asked the non-freshmen to answer a specific questionnaire, as they had experienced both models. The questionnaire included 10 questions. It was put online and the teachers sent an email to the 58 non-freshmen asking them to give their answers anonymously. Only 30 students answered the questionnaire (17 male and 13 female). Answers were given before students knew their final grades.

The first question asked the students whether they consider the activities in class more adequate or not than those in the previous year. It was a free text answer, but the answer was unanimous. In a way or another, students expressed their agreement with the changes made. They appreciated the use of Processing and considered visual oriented programming activities more interesting and adequate to them. Some also wrote that it was easier to understand the effect of the programming instructions due to the visual impact of the programming language. Finally, some students appreciated the fact that teachers often allowed them to progress at their own pace, giving different exercises to students in different learning stages.

The survey asked students to indicate how often they attended the different types of classes (lectures, labs and free tutorials) in the previous year and classes in the current year. The results are shown in Table IV (in percentage of the total number of classes).

TABLE IV. ATTENDANCE BY CLASS TYPE AND YEAR

| | <i>Lectures 2010 - 2011</i> | <i>Labs 2010 - 2011</i> | <i>Free Tutorials 2010 - 2011</i> | <i>Classes 2011 - 2012</i> |
|--------------|---|-------------------------------------|---|--|
| [0-25%] | 26.67% | 0.00% | 53.33% | 16.67% |
| [25%-50%] | 30.00% | 13.33% | 30.00% | 6.67% |
| [50%-75%] | 30.00% | 40.00% | 10.00% | 16.67% |
| [75%-100%] | 13.33% | 46.67% | 6.67% | 60.00% |
| Total | 100.00% | 100.00% | 100.00% | 100.00% |

From the table it is possible to reach some conclusions about these students' class attendance:

- Most of these students did not attend the free tutorials, as more than 80% of them attended less than 50% of those classes.
- More than half of the respondents (56.67%) attended less than 50% of the lectures.
- Most students (86.67%) attended 50% or more labs.

Therefore, it is possible to conclude that the labs were more appealing for the students. As they had difficulties in learning to program, one could expect that they would take advantage of all classes to improve their situation. However, that was not the case, maybe because they did not feel that lectures and free tutorials were useful for them.

On the contrary, in 2011/12 60% of the students attended more than 75% of classes, showing that they felt them useful for their learning.

The questionnaire also included a question to identify drop out situations. The number of students that did not drop out increased from 33.3% in 2010/11 to 96.7% in 2011/12.

For those students who did drop out, the questionnaire included a question about the reasons for that decision. The students mentioned several reasons. The most frequent one was related to failure to achieve the minimum allowed grade in the course project or in some mini-tests that existed in the course evaluation schema. Some students mentioned that they found the course uninteresting, especially lectures. They found them difficult to follow, and useless to clarify doubts, as there was an excessive number of students. The separation between lectures and labs was also mentioned. The teachers at the labs were expecting that the students had understood the concepts and examples presented in the lectures. When that did not happen labs were not very useful, as students could not solve the exercises or even understand the solutions presented by colleagues or the teacher. The time between lectures and labs was also pointed out as a reason for drop out, as some students mentioned it as an added difficulty (when they came to the labs they could hardly remember lectures). Some students simply said that they dropped out because they could not keep up with the course pace.

Analyzing the students' justifications for dropping out in the previous year, we may think that the course structure and activities failed to motivate students to get involved and make

the necessary effort to learn. This lack of commitment is obvious when students mention the time between lectures and labs. Of course, teachers expected some autonomous study in that time, but that simply did not seem to have happened in the case of the respondents.

The questionnaire included a question that asked students to express their opinions about the advantages and disadvantages of the new course structure. Some statements were given and the students had to classify each of them in a five points scale: -2 = "strongly disagree", -1 = "disagree," 0 = "neither agree nor disagree," 1 = "agree" and 2 = "strongly agree". The statements were:

- a) *There was a better connection between theory and practice.*
- b) *There was a higher proximity between student and teacher.*
- c) *The teacher monitored students more closely.*
- d) *There was more time to clarify doubts.*
- e) *The teaching was more personalized.*
- f) *There was more time to practice programming.*
- g) *It was more tiring due to more practical and intensive work.*
- h) *Time was better organized.*
- i) *The reduction of contact hours (7 hours per week in 2010/11 to 5 hours in 2011/12) was disadvantageous.*
- j) *There was more motivation to program.*

The results obtained are presented in Table V. We can conclude that the students had a very positive opinion about the changes. In statements a) to f), h) and j) almost no student expressed disagreement, and even neutral positions were a small minority. This means that for the respondents there were clear advantages in the changes made.

The statement g) got more disperse answers, as 40% of the students were neutral, 46.6% expressed disagreement (saying it wasn't more tiring) and 13.4% expressed agreement. We see this as natural, as the new approach requires a much more active attitude from the students, both in classes and outside classes. Possibly some students see this as tiring, while others like it, since they are learning better than before and think the extra work was worthwhile.

The new model implied a reduction of the number of contact hours. Previously, there were 7h per week (2h lectures, 3h lab and 2h free tutorials), while in the new model the number was reduced to 5h (mostly due to staff constraints, as in the new model all classes were in small groups, creating the need to use more staff hours). Anyway, considering the answers to statement i) 56.7% of the students did not consider this to be a problem, while 33.3% were neutral. So, it seems that, for these students, the changes in the pedagogical strategy compensate the reduction of contact hours.

TABLE V. NEW MODEL ADVANTAGES AND DISADVANTAGES

| | -2 | -1 | 0 | 1 | 2 | Σ |
|----|-------|-------|-------|-------|-------|----------|
| a) | 3.3% | 0.0% | 16.7% | 43.3% | 36.7% | 100% |
| b) | 0.0% | 0.0% | 10.0% | 26.7% | 63.3% | 100% |
| c) | 0.0% | 0.0% | 16.7% | 23.3% | 60.0% | 100% |
| d) | 0.0% | 0.0% | 20.0% | 36.7% | 43.3% | 100% |
| e) | 0.0% | 0.0% | 13.3% | 40.0% | 46.7% | 100% |
| f) | 0.0% | 0.0% | 16.6% | 36.7% | 46.7% | 100% |
| g) | 23.3% | 23.3% | 40.0% | 6.7% | 6.7% | 100% |
| h) | 0.0% | 0.0% | 23.3% | 50.0% | 26.7% | 100% |
| i) | 30.0% | 26.7% | 33.3% | 10.0% | 0.0% | 100% |
| j) | 3.3% | 0.0% | 13.3% | 36.7% | 46.7% | 100% |

The students were also allowed to mention other advantages and/or disadvantages of the new model. Apart from the issues already covered in the statements a) to j) the students also mentioned as advantages:

- The change to the Processing programming language, as it allowed more interesting activities and is a language used in the creative industries;
- The separation of the Design and Multimedia students from the Informatics Engineering students, as they felt that previously the course was essentially designed for the latter students;
- The students felt more motivated with the learning context, as some of them explicitly mentioned the quality of the teachers and the supportive environment in classes.

As disadvantages, some students mentioned:

- As each group only has one teacher, it is possible that different teachers have different assessment criteria;
- It is possible that different programming issues are presented and practiced differently in the various groups, creating an unbalanced situation when those issues appear in the final exam.

Finally, the questionnaire gave each student the possibility to include any other remark not covered before. Some students used that possibility to reinforce some ideas previously mentioned. Others wrote that this experiment and its pedagogical approach should be extended to other courses in the degree. One student expressed the hope that the better programming knowledge acquired in the course would be helpful in other courses. Some students stressed the pedagogical difference between the current and the previous year.

IV. CONCLUSIONS

This paper describes a pedagogical experiment designed to create better learning conditions for a non-majors introductory programming course.

As the students' results in previous years were far from satisfactory, the Department decided to support a change

proposal made after some experiments in a small size course. There were two main modifications: The separation of students following different degrees in separate courses, and a modification in the class structure. The main idea behind these changes was the creation of a context that improves student motivation and learning support.

We presented the results obtained in the first implementation of the new course structure. To verify the differences we compared the students' results with the two previous years. We also used information obtained from the official pedagogical survey, and from a questionnaire we asked all non-freshmen to answer.

All information available points to the success of this approach in the course. There was a clear increase in the success rate, both considering all students together and freshmen and non-freshmen separately. The official survey brought also positive results, as the students' evaluations on the course were well above the previous year, and also above the average of all courses in the degree. The views of the non-freshmen, that had followed the course in the previous year, were also very positive, stressing the motivational and supportive context created in the course.

The positive evaluation leads us to continue this experiment in the next academic year. The course will have fewer students, due to this year success rate. From the Department point of view this is good news, as less teaching resources will be necessary. The teaching staff is considering some small improvements, but the approach will be similar.

ACKNOWLEDGMENT

The authors would like to thank all students that participated in the experiment.

Abstract—Low enrollment and high drop-out rates in computer science (CS) have led to an alarming decrease in number of graduates in western countries. What are students' learning experiences, how do these affect their attitudes towards learning CS? This question was explored by investigating diverse students, of a broad study program with courses in humanities and technology, at the end of an introductory course in CS (CS1), which has been designed to enhance students' engagement. The results of a first questionnaire were remarkably positive: All students reflected their experiences as overall positive. Almost half of the students stated, that they had been skeptical towards learning CS before the course. All of these students described positive transformations of attitudes. These results provided an interesting starting point for further research using interviews: What exactly have these students experienced and how do they reason about future engagement? We point out students' experiences that were crucial for a positive transformation of attitudes as well as critical aspects in students' reasoning on future engagement in CS.

I. INTRODUCTION

Computer science (CS) has become a driving factor for the development of today's society. Why is it that the number of students that engage in learning CS is so low? Could it be due to unfortunate learning experiences or perceptions of CS?

A survey of research reveals gaps in the understanding of students' engagement. The Review Task Force, a working group of the IEEE and ACM, reviews low engagement in the latest CS curriculum in 2008, referring to the "computing crisis" [1]. The authors state that the curriculum seems to be unattractive for students and that it is vital to engage with the students to improve recruitment and retention [1, p. 29]. Several recruitment projects exist to attract students at upper secondary school [2]–[4]. However, non-completion and drop-out rates at universities are comparatively high [1], [5], [6], and research on drop-out concludes that the problem is very complex [7]. In this study, we focused on students' experiences and resulting attitudes towards learning CS as those have not received much attention in research [8], [9] and appear to be important in the endeavor to enhance engagement in CS.

The following research questions were important and central in this study. What is the role of students' learning experiences, how do they affect students' attitudes towards learning CS? What are students' experiences that lead to positive or negative

attitudes towards learning CS? Are there students who do not decide to (further) engage in CS due to unfortunate learning experiences, perceptions, attitudes etc. – students that would engage if they had only experienced CS differently? Aiming at a better understanding of students' learning experiences that affect students' attitudes towards learning CS, our goal is to be able to plan further research and to inform the endeavor of enhancing students' engagement.

Based on our research questions, we decided to investigate diverse students, who have an interest in IT and technology but who have not decided to major in CS, as they take an introductory course (CS1), which was developed with the explicit goal to enhance students' engagement [10]. The study was carried out in two steps: A first questionnaire aimed to get insights in learners' course experiences and attitudes through collecting data of a greater number of students. Subsequent interviews were carried out with a smaller selected group of students to get a deeper understanding of learning experiences, students have made in the course and beyond.

The report begins with a summary of related research. After that, the first part of the study follows, its research questions, the questionnaire, and the results, which were the basis for the follow-up study. We then state research questions for the second part of the study, describe the selection of students, the interview questions, and results. Finally, we summarize results and conclude with issues for future research.

II. RELATED STUDIES

Students' computer-related experiences before university and resulting attitudes and expectations were studied by Magenheimer, Schulte and Knobelsdorf [8], [11], [12]. Knobelsdorf distinguishes between "users" and "designers" to describe students' experiences and resulting expectations, that are very different for these two groups of students [8]. However, in her summary of related research in 2011, she concludes that the learners' backgrounds, their understanding of the subject, and their individual interests have not received much attention in research so far [8, p. 31].

Why are some students interested and others not? A lot of research has been done with a focus on gender [13] or minorities [14], [15]. A general finding is that conceptions of

CS and attitudes towards learning CS have a major impact on girls' engagement [16]. Overall, CS is often perceived to be a male field [17], [18] and women often perceive themselves as less capable than males while objectively having the same skills [13]. Further findings lead to the following suggestions to enhance womens' engagement: It is important to arrange a positive climate, to foster positive experiences, to convey a broad, relevant image of CS, and to make use of teaching concepts that provide pathways into CS [19].

Providing pathways into CS points towards the theory "community of practice" and the terms "outsiders" and "insiders" [20], [21], that are rooted in social theories of learning. Wenger considers "identity" as one component of learning, which Ulriksen et al. find to be a key aspect to explain students' drop-out [9] and students' decision to choose or not choose engineering as a study program [22]. Holmegaard and Ulriksen state that students do not choose engineering because they do not see opportunities for constructing attractive identities. In contrast, students that do choose the study program see themselves as someone engaging in a cross-disciplinary and innovative subject. However, this is often not conveyed during the first year of education and can lead to drop-out [22].

Kinnunen gives a review of literature on students' drop out in CS and investigates CS minors' reasons for drop out of a CS1 course using qualitative interview research [7]. Her overall conclusion is that reasons for drop-out are complex, thus the most frequent reasons reported by Kinnunen's informants were "lack of time" and "low motivation". Simon et al. furthermore state that non-majors, contrary to majors, more likely experience the course as miserable or pointless [23]. Another important aspect related to students' motivation is "perception of self-efficacy", which is considered in gender studies and also recently by Kinnunen [24]. She gives recommendations on how to enhance self-efficacy and argues that this would likely improve academic performance and persistence. Furthermore, she recommends that more research should be done on how students experience different parts of the course, e.g. assignments and lectures, to understand students' orientation and persistence within their studies.

III. PART 1: AIMING FOR AN OVERVIEW

The aim of this part of the study was to get an overview of students' course experiences and how those affect their attitudes. We purposefully focused on course experiences here, to target interesting related experiences beyond the course in the second part of the study.

A. Research question

A general conclusion from the literature review is that students' experiences are not well understood and that they affect students' perceptions of CS and future engagement. In view of this conclusion and the aim of this part of the study, we state the following research questions (RQ):

RQ 1.1: What do students experience in the introductory CS course that supports or changes their prior attitudes towards learning CS?

RQ 1.2: How do the students' attitudes towards learning CS relate to their broader interests?

The intent of the second research question is to find out about students' interests and how learning CS could be meaningful to them. Are there students that have positive course experiences and attitudes towards studying CS that do not relate to their broader interests? Are there students that have unfortunate negative course experiences or attitudes, meaning that those could be positive, if they had just experienced CS in another way, e.g. more conform to their interests?

B. Data collection

A questionnaire [25] is an efficient method to collect data of a greater number of students. To collect data with which to explore the research questions, we designed a survey consisting of four sections: First, the students were asked for their interests that made them choose their study program. Hereby, we hoped to get broader interests that, through the focus on the study program, are informative to explore RQ 1.2. In the second part of the questionnaire, the students briefly stated their prior programming experiences. This question, contrary to the others, explicitly focuses on programming experiences rather than experiences in CS in general. With this focus, we hoped to get precise information on students prior experiences, that we assumed have a big influence on students' experiences when being introduced to CS, which is commonly done through teaching programming. In the next section, the students were asked to check one of two checkboxes for each contradictory pair of attitudes: Had the students thought that learning CS is rather interesting or uninteresting, boring or exciting, difficult or easy, useful or irrelevant? The idea of this part was to make students decide whether their feelings or attitudes were rather negative or positive. This is helpful for the last section, in which the students were asked to describe two to three of the most important experiences during the course that either supported or changed these feelings or attitudes which aims at exploring RQ 1.1.

C. Sampling

As the goal of this study was to explore different experiences and their affect on attitudes, we decided to investigate diverse students, that have an interest in technology, but that have not decided to major in CS, at the end of an introductory course in CS (CS1). The students of the "Sociotechnical Systems Engineering" program at Uppsala University are an adequate group: Their study program offers courses in both, the humanities and technology. The ratio of male and female students is balanced in that program. The students take CS1 in their second year. About half a year later, they choose whether they want to specialize in CS or energy systems. The CS1 course was designed in recent years, explicitly with the goal to enhance students' engagement, taking into account various results from Computing Education Research [10]: The students work in pairs in the lab. The pairs and assignments change every week. Lab assistants are present to help when it is needed. At the end of every week, the students explain

their results to the teaching assistants who grade the students immediately. There is no final exam. Towards the end of the semester, the students work on a project.

D. Results

Altogether 36 students have filled in the questionnaire using English language¹. Two datasets were excluded because one student did not fill out the last, most informative question and the other student copied the answers from the neighbor. Contact information were provided by 25 students. According to these students' names, 15 of these respondents are male, 10 female. More than two thirds, 26 students, state that they had no prior programming experiences.

In view of the findings reported in related research, the overall impression of the students' experiences is surprising: All of the students have experienced this course as overall positive. Even the students that have experienced the course as relatively difficult, mostly state that it was "fun" and "useful". The most notable result was that all of the 16 students that thought of themselves as rather skeptical before the course (learning CS is rather uninteresting or boring or irrelevant) describe a change towards a more positive attitude. Some statements contain prior stereotypical thinking or prejudices, such as²:

Before, I thought of computer science as very boring and like it was all about sitting in a dark room in front of a computer drinking coca cola. (Anna)³

In other descriptions, this can be found rather implicitly:

Before the course, I thought learning about computer science was difficult and nothing I had done before, thought it was for people who had been programming since they were little, having it as a hobby. (Sofia)

In the last statement, Sofia describes her perception that learning CS is for certain people. It seems as if she doesn't see herself as such a person. Frank expresses this even stronger:

Before the course, I thought learning computer science/IT would be boring, difficult and irrelevant. That it wouldn't fit me. (Frank)

These statements point to "identification", which Ulriksen finds to be an important aspect to explain drop out [9].

Overall, emotions were very often reflected on. Furthermore, the students describe that they now understand how learning CS can be useful or relevant and what CS is all about. The descriptions of students' experiences are relatively short (up to about 100 words). They do not contain details on what exactly the students have done or seen, that made them feel the way they describe it. However, it is possible to categorize the students' descriptions of course experiences using content analysis. Through that, we can distinguish different foci of experiences. Four categories emerged, which can be summarized and further explained through students' statements, mostly

from students that describe a positive attitude transformation. *Emotion*: Experiences are described through emotions, such as CS being "fun", "challenging" etc., as it was also described by Simon et al. [23]. Examples are:

Before, I thought of computer science as very boring [...] But since I started this course, I think it's a lot of fun, though difficult. I think, it's a good feeling to be able to do a program. (Anna)

First I thought, it would be boring, something that only a real geek could enjoy. But I think it's intriguing, it's like a challenge and I get honestly happy when the code is not red. So, I'm positively surprised. (Ulrika)

Usefulness of learning about CS: Experiences of how learning has been useful are described. Such experiences are often pointed out to be important for females [13], [19]. However, in this data seven male students and only three females as well as four students that we don't have information on their gender, write about how they have experienced CS as useful. Examples are:

Even though it's hard and I sometimes feel like crying during the lessons when nothing works out, it's very necessary for my learning experience. (Anneli)

It's still very difficult according to my opinion, but I could really be working with this in the future. I also believe that it can be useful when I'm starting to work to know a little about programming and computers. (Karl)

Before the course, I didn't see courses in computer science as important as I see them now. It's really important to create good programs, that are easy to understand for others to make work easier for the masses. (Andreas)

Understanding of the discipline: The students' descriptions focus on having gained an understanding of the discipline CS as a whole. The fact that we find this focus underpins the recommendation to convey a broad and meaningful image to recruit and retain students [1], [13], [14], [19]

Now, I think computer science is interesting because learning about it has made me understand what it is all about and I know the structure. (Rebecca)

I have noticed that there is a whole world around computer science. It's much wider than I thought and it's interesting to be a part of it. (Emil)

Social aspects doing CS: The students focus on the social setting, in which activities in CS are carried out. Kalle is the only student that states this explicitly. However, according to his choice of checkboxes, he seemed to have had a positive attitude towards CS already before the course.

Before the course, I had the picture of computer science that it was a thing you did on your own, and not in groups. That it only was a non-social job. (Kalle)

E. Summary and Key Aspects for Follow-Up Study

The results of this study are surprisingly positive. Almost half of the students seemed to have undergone a positive transformation of attitudes and no student seemed to have made "unfortunate learning experiences" (see section III-A). Through the different categories, we point out different foci in students' experiences. Overall, the course experiences seemed to have had a relatively strong and positive influence on students' attitudes towards CS. Furthermore, we got the

¹The students' mother tongue is Swedish, but the students are usually relatively fluent in English.

²A few minor spelling corrections were made in the students' statements.

³All student names were changed and chosen in accordance to the respondents' gender. The same names were used for the same student, also for the second part of the study.

impression that the students infer from their specific course experiences, mainly in the area of programming, to more general perceptions of and attitudes towards CS as a whole. Noticeable are the statements in the category *understanding of the discipline*. Both students express that they now know “what CS is all about”. Fortunately, their new image of CS seems to be attractive to them. However, the course is not designed to convey what CS is all about and could thus lead to inappropriate perceptions or attitudes. However, this could have been fostered by the question in the questionnaire, which asked for students’ attitudes towards learning CS/IT.

Unfortunately, the descriptions of experiences were not very detailed (up to about 100 words). Hence, we used the second part of the study to aim for a better understanding of those experiences. Also, the students were not asked whether or not they plan to engage in CS in the future. However, this is an important information. Maybe these students do not plan to engage in CS in the future. One observation that supports the relevance of this question is that the students seldom relate their course experiences to their broader interests that they were asked to describe in the first part of the questionnaire.

IV. PART 2: AIMING FOR DEEPER INSIGHTS

In view of the results of the first part of the study, a follow-up study was conducted to get a better understanding of the students’ course experiences that led to a positive transformation of attitudes. This is interesting, because existing research mainly aims at understanding negative experiences, attitudes, or drop-out. Furthermore, we get the opportunity to explore how these students, that have had very positive learning experiences, reason about future engagement in CS.

A. Research questions

Based on the results of the first study, the aim stated above, and the overall goal of the study described in section I, we pose the following research questions:

RQ 2.1: What have the students experienced that has led to a change of perception: From learning CS is boring or uninteresting or irrelevant to learning CS is useful or interesting or relevant?

RQ 2.2 a: Do the students plan to engage in CS in the future, and during their study by choosing more CS courses?

RQ 2.2 b: How do the students reason about future engagement?

B. Data collection and analysis

The students’ descriptions of experiences in the questionnaire brought up questions such as: How exactly is CS useful to the student? What exactly was interesting, fun etc. about it? Those questions can be best elaborated on in a dialogue with the student. Hence, we decided to use semi-structured interviews that allow follow-up questions [25]. Four lead-questions were prepared. We started the interview by asking the students to explain their experiences and attitudes prior to the course, referring to their choice of either option in the

questionnaire, i.e. CS is rather boring vs. exciting or useful vs. irrelevant. Then, we asked the students to describe their course experiences that affected these prior attitudes (RQ 2.1). The second part of the interview dealt with future engagement (RQ 2.2 a, b): First, we asked the students for their career plans. From there, we moved on to the question whether or not the students are planning to take more IT courses and why.

The categories that were developed in the first part of the study were used to select five students, that described a positive transformation of attitude, but with different foci in their descriptions of experiences. The interviews were transcribed. Then, we did a thematic analysis to explore the research questions. In-depth analysis of the data, as well as further investigations are currently being worked on.

C. Results

First, experiences that led to a positive transformation of attitudes (RQ 2.1) are summarized. Then, reasoning about future engagement in CS will be reported (RQ 2.2 a, b).

Building up students’ self-efficacy is one important aspect that was considered in the course design [10]. Indeed, in the interviews, the students often describe their attitudes before the course similar to Sofia:

I thought, it was gonna be hard and I thought, I shouldn’t be able to understand anything.

The feeling of being capable has strengthened positive emotions, e.g. programming is fun or challenging. Working in pairs that change every week, hence having a partner to find and discuss solutions with, was reported to be very supportive. Furthermore, reflections of last weeks’ lab assignments in the lecture and the increasing difficulty of the lab assignments every week, “starting from zero”, were reported to be helpful.

The experience to be able to create a program that others can use has also led to positive attitudes towards learning CS. Lina for instance states that she thought she would have to study a lot about the computer before being able to write a program, that she would study something that she is not able to use. She says:

I’ve changed now. [...] we actually produced a couple of games, clocks and stuff.

Furthermore, Andreas describes that he has become aware that programming is a creative activity:

First you have to think about how do I solve this problem, then you have to put input parameters, then you have to create the interface. I think that it’s creative work actually – do something and get something real out of it. [...] You can see results that actually I have created and that works. I like that.”

Providing opportunities for creativity was another aspect, that was explicitly considered in the course design [10].

A central and important experience that was reflected on by all interviewees in different ways is that problem solving is an important aspect in programming. Sofia, a student who had not “really anything to do with programming before” and who was thinking that programming is “kind of a nerd thing”, reflects that she has learnt a new way of thinking. After having

made many mistakes by just typing code without planning in the first two labs, she realized:

You had to work in another way, you had to sit down and talk to each other and you had to maybe write down on a paper before, like I wanna do, I have five steps that I have to do: I first have to make this matrix [...]

The importance to communicate was fostered by programming assignments in pairs and groups. Working out problem solutions on a piece of paper before typing was also an important experience for Anneli, a student with a prior attitude of CS being rather uninteresting and boring. Before the course she had the impression that “programming is something that you can only do if you are spending a lot of time in front of the computer”. The importance of a systematical approach was emphasized by the teacher. According to Sofia, he said:

Programming is not just about coding, it's about thinking how to structure the code before you write it on the computer and that's maybe 90% percent of the programming. That's one of maybe the greatest lesson I have learnt from this course.

Usefulness was elaborated on several times, both usefulness of learning CS and usefulness of CS in different contexts.

In the beginning, I just thought we can learn code [...], but after being through the course [...] we actually learned how to create interfaces that people can use – you can feed in your numbers, then get answers.

Here, Andreas refers to programs that are used in research. Further applications mentioned were programs for a bank or ticket system in a bus. When reasoning about socially relevant applications of CS, the students often referred to the internet, which allows people to speak freely. However, only Sofia seems to be able to relate her course experiences to a broader, relevant meaning of CS: “All solutions in the future will have something to do with computers and connecting things”. Sofia finds the fact that she can learn a special way of thinking to solve problems, such as structuring programs, appealing, and argues that all future computer systems will be constructed through such a process of problem solving.

Four of five students express doubts about engagement in the future (all except Sofia). Anneli relates to capabilities: “It's kind of hard for me, or I don't think, that I'm really good at it, yet”. Lina, a student that has worked at a company before, has doubts about the people that she will work with in CS:

I don't think that open mindedness and computer science go very much hand in hand.

To Lina, it seems as if computer scientists often accept only one solution and are sometimes very rude to each other.

Andreas and Kalle are relatively certain that they will not take more courses in CS. Andreas described that, before the course, he expected to just learn how to code. In the course, he experienced that he could learn “how to actually create stuff that others would use”. However, he argues:

I would pick energy because it's interesting and I see the relevance and I would pick the other [CS] mainly because I think it's fun.

How would he reason if he had experienced the relevance of CS for our society on the same level as he can think of the relevance of energy systems?

Kalle argues that he does not want a job where he “sits with a computer and programs”. Asking what computer scientists do, he states:

Solving problems all day long [laughs]. And [...] it's like - [...] if you are an engineer, you work with problem solving. When you are a programmer, I think, you work with problem solving but in, I don't know, like easier way. It's not that complex. You write this code and it's not like you have to think of eh I don't know society [laughs] and eh economy and eh things like that.

How would he reason, if he had experienced the complexity and potential of CS to address current societal problems?

Furthermore, Kalle argues:

Personally, I would like to learn more about it [CS]. Programming is fun, [...] but for the relevance of our course, the STS course, I don't see why we have to learn every little detail in programming. There are a lot of programmers out there. There are guys that are really good at programming so for me, for our course, I don't see the relevance of learning any more.

Kalle seems to understand CS as programming and doesn't see himself as a programmer. Hence, he does not see the relevance in taking more courses in CS. Sofia, the only student that is certain about taking further CS courses, who has experienced CS as meaningful to solve future societal problems, also takes a distant position to the “real guys”. However, she is able to see herself working with CS in a certain way:

Since computer science is the future, I want to work with it [...], maybe I don't wanna be like this hacker, coding, [...] but I wanna be maybe the person deciding what to code or making it work in society and if someone, maybe a computer student, is doing code, you have to figure out where to use it and how and that's what I wanna work with. Maybe be a consultant?

D. Summary and Conclusion

According to the interviewees, the experience of CS being a fun, social, creative activity, that they are capable of, through which problems are solved, turned out to be an important experience. This was supported through assignments to develop different programs, that were worked on in pairs, that changed every week, as well as group work during a project, and through emphasizing the importance of systematically approaching programming problems.

However, one critical aspect is a limited understanding of CS, reduced to programming. Other areas, such as networks and databases, as well as aspects of complexity and relevance of CS to solve societal problems have not been experienced in most cases. This however seems to be of importance for the interviewees. Accordingly, they argue that, since they do not want to become programmers, they do not need to learn more CS than the basics in programming that they learned in the course, and hence they will not take more courses in CS.

This points out the importance of two aspects in students' reasoning about engagement: identification and understanding of CS and its meaning. These aspects seem to relate and appear to be specific for this student group. However, these findings emerge from five interviews with students that belong all to the same study program and that have stated skepticism before

the course. Further research is needed, as existing research has not dealt with identification in relation to understanding of CS.

V. CONCLUSION AND FUTURE WORK

The aim of this study was a better understanding of students' learning experiences that affect students' attitudes towards CS. Therefore, we investigated diverse students of a broad study program at the end of an introductory course in CS (CS1).

The study was carried out in two steps. Data, collected through a questionnaire, convey a favorable image: All students describe overall positive learning experiences. Almost half of the students state that they were skeptical before the course (CS being rather boring, irrelevant, or uninteresting) and point to experiences that supported them to revise their attitudes. Aiming for a better understanding of those experiences, the descriptions of experiences were categorized by the students' foci. This served as a basis to select five students with possibly different experiences for subsequent interviews. The interviews revealed a better understanding of course experiences, that have fostered positive transformations of students' attitudes, and critical aspects in students' reasoning about future engagement.

Two aspects appeared to be significant in these students' reasoning about future engagement: Students understanding of the discipline CS and its meaning and their ability to identify with engaging in the area of CS. Overall, we found a relatively narrow and meaningless understanding of CS being programming. Since the students do not see themselves as future programmers, learning more CS appears useless in many cases.

In conclusion, we believe that more research is needed on how students identify with CS and IT. The ability to relate to the discipline appears to be an important factor for student retention and continued engagement. In particular, we recommend investigation of what students believe a "real computer student" is. Research on these issues will help us to develop meaningful education in CS and IT, and enhance student engagement in these, and related, educational programs.

ACKNOWLEDGMENT

We would like to thank Anders Berglund, Anna Eckerdal and Michael Thuné for their inspiring contributions in various discussions throughout this study.

Identifying the Impact of the SPIRIT Program in Student Knowledge, Attitudes, and Perceptions toward Computing Careers

Alka Harriger, Alejandra J. Magana, and Ryan Lovan

Purdue University, harrigea@purdue.edu, admagana@purdue.edu, rlovan@purdue.edu

Abstract – Declining interest in computing programs nationwide presents a threat to America’s security and limits potential for innovation across all domains. One way to address this problem is to remove misconceptions held by the nation’s youth about computing, including information about how it positively impacts many subjects and showing them that applying computing can be fun and rewarding. One program at a Midwestern university accomplished this goal through a week-long, residential, summer camp for high school students to educate them about career opportunities and possibilities for people with Information Technology skills. Participants completed a variety of hands-on activities daily, along with listening to work experiences of computing professionals. Feedback collected from the student participants showed that in addition to raising awareness about computing opportunities, the program increased youth interest in IT, prompted many to enroll in computing/engineering courses, and improved their performance in school. This paper shares details about the program and participant feedback to make a case for offering similar programs to correct the knowledge people have about computing.

Index Terms - computing attitudes, outreach programs, STEM, youth interest.

INTRODUCTION

The occupational outlook for computer-related careers through 2018 is considerable when evaluating careers with either the fastest growth and/or the largest numerical growth increase [1]. Unfortunately, student interest in computer science and information technology at the college level has been declining for the past decade to match the levels of 1999-2000 [2]. Given the increasing support that computing provides to all domains, these continuing, insufficient levels of information technology expertise threaten America’s security and opportunity for critical innovation across all disciplines.

A program called Surprising Possibilities Imagined and Realized through Information Technology (SPIRIT) was created in 2008 to address this problem. The premise of the SPIRIT project takes advantage of the coupling of IT with

disciplines that can make a positive difference to society through its support of STEM disciplines. By conveying this same knowledge to high school students, especially women, more will be open to studying IT in college.

SPIRIT includes a two-week professional development summer program for up to 30 high school teachers and guidance counselors, and a one-week summer camp for up to 75 high school students. During the first week, teachers and counselors learn how to use Alice, a 3D storyboarding tool, to present visual information about their subject areas or career planning to their students. Each one creates a minimum of three Alice-based classroom lessons that they will use during the subsequent school year. This indirect exposure to IT through a variety of mostly non-computing subjects is intended to get more students to begin thinking about computing in more positive ways.

During the second week of SPIRIT for the teachers and counselors, students also arrive. Everyone listens to a variety of IT professionals and completes numerous hands-on activities designed to broaden the participants’ awareness of the utility and positive impact of computing across many facets of society. Students are also taught about Alice and complete a project using Alice by the end of the week. Unlike the teachers and counselors who receive one week of focused instruction on Alice, students only need a brief introduction and short hands-on sessions throughout the week mixed in with the other hands-on sessions that introduce different tools and technologies. This part of the SPIRIT program is designed to help participants recognize that computing is an essential tool that can be employed in many fun, interesting, and beneficial ways. Additional details about the SPIRIT approach are available in [3]. The remainder of this paper will focus on the student participants who participate in the summer camp.

High school students apply to SPIRIT through an online application system that includes responses to several short answer questions. A team of 3 reviewers evaluate all applicants separately using an online evaluation tool that allows them to view the students’ responses to these short answer questions. Numerous criteria, including year in school, GPA, ACT/SAT scores, and the scores given by the reviewers are used in scoring the applicants. The goal of the program is to convince students who may not be considering a major in computing to change their minds. Therefore, it

should be noted that applicants who showed definite interest in IT were rated lower than applicants with no definite interest. After all reviews are done, a rank-order list of all applicants is produced and the top 75 applicants are invited to attend the summer program. If any of these students are unable to accept the invitation, the next applicant on the list is invited.

There is no cost for students to attend the program, other than travel to and from the university. Additionally, they receive a daily stipend as long as they complete required assessments. Approximately ten months after the summer program, a follow-up survey is sent to all students. Three cohorts (in 2008, 2009, and 2010) have completed the summer programs to date.

The response rate for the follow-up survey from the first two cohorts was too low to draw any conclusions. Too much time had passed since they completed the program and there were no incentives to encourage their response because the first two cohorts received all monies by completion of the summer program. For the third cohort, a small portion of a deposit was withheld until all SPIRIT obligations were fulfilled, and the completion was the last of these. Not surprisingly, the third group's response rate was very high and enabled conclusive analysis of the data, which are reported in this paper.

This study investigates the impact of the SPIRIT program by investigating the following research question:

What is the impact of the SPIRIT program in student knowledge, attitudes, and perceptions toward computing careers?

METHODS

For the third SPIRIT cohort group from 2010, the previously paper-based follow-up survey was converted into a web-based version using Qualtrics survey software [4]. The primary reasons for this change were (1) to eliminate data transcription errors when manually entering responses on paper forms, and (2) make it easier for students to respond online, eliminating the need and cost for return via postal mail.

Links to the online, voluntary survey were sent to program participants via the email address they provided during initial registration. Once the allotted survey time had passed, the results were collected. The survey results were exported to .pdf and .csv files using the features available in Qualtrics. Many of the responses were open ended. These were coded and placed in appropriate categories for identifying quantitative values for these responses.

The survey collection method was voluntary, but the response rate was 87% for the 2010 cohort, likely due to withholding payment of their small deposit. Of the 75 SPIRIT attendees a total of 65 responses were received although not all questions were required to be answered.

The program participants were all high school students: 12% grade 9, 24% grade 10, 35% grade 11, and the remaining 29% grade 12. The gender distribution was

largely female with 67% being female and 33% male. There was a fairly even representation of ethnicities largely representative of the US populace and the local community demographics with 64% white/Caucasian, 17% black/African American, 9% Hispanic/Latino, 6% Asian, and 3% other ethnicities.

The questions focused on the participants' opinions of the program, changes that occurred academically as a result of the program, and changes in career goals as a result of the program. Several yes or no questions had related free response prompts if the response was "yes." These are indicated below.

The following are the survey questions, including yes/no and free response: (identification and similar questions have been omitted)

1. Did attending SPIRIT change the courses you selected to complete during the 2010-2011 school year? (if yes, prompt next question)
 - o Please explain how SPIRIT influenced your course selection process.
2. Did attending SPIRIT change your performance in any of the courses you took during the 2010-2011 school year? (if yes, prompt next question)
 - o Please explain how attending SPIRIT influenced your course performance in 2010-2011.
3. BEFORE attending SPIRIT, did you have a career goal? (if yes, prompt next question)
 - o Please explain what your career goal was BEFORE attending SPIRIT.
4. AFTER attending SPIRIT, did your career goal change? (if yes, prompt next question)
 - o Please explain how your career goal changed AFTER attending SPIRIT.

Please respond to the following questions on a scale of very unlikely to likely. (0 to 4, 0=very unlikely to 4=very likely)

5. You had plans to attend college BEFORE attending the 2010 summer camp
6. You had plans to attend college AFTER attending the 2010 summer camp.
7. You had plans to pursue a career in information technology BEFORE attending the 2010 summer camp.
8. You had plans to pursue a career in information technology AFTER attending the 2010 summer camp.
9. What was the most important thing you learned during the SPIRIT 2010 summer camp?
10. Do you have any additional comments or advice in regards to the SPIRIT program?

Once results were collected from the survey site, a qualitative analysis of the open-ended responses was done in order to get insight into the students' perceptions of the program as well as effects it may have had in their lives, especially regarding future career plans.

Constant comparison [5] was utilized to analyze the qualitative data. The first step was grouping similar statements and responses together from the survey results. Once initial categories were formed, individual responses

were compared within the category. For example, if a student responded “I decided to take a programming class so that I would be better able to consider a major in Informatics” or “I decided to take an elective in computers”, these responses were coded into the category “enrolled in computing related course.” Statements that were occasionally longer and contained more content were oftentimes placed in two categories. This approach explains why the percentages of the results may exceed 100%. Two of the authors conducted the qualitative analysis independently and the initial categories were compared. The percentage of agreement for the categories was of 90%. Occurrences of categories were then turned into percentages. The results report all of the survey results, in that no responses have been omitted in the totals.

RESULTS

The survey results explained the participants’ views about the program and, more importantly, what they learned during the time spent at SPIRIT and its impact. This section will elaborate on the strength of the responses to each of the key questions, clarifying the impact based on the students’ explanations for their affirmative responses. For each of the categories we also provide sample of quotes to better describe student responses.

I. Influence of SPIRIT Program in Course Selection

The first survey question addressed the impact SPIRIT had on the participant’s course selection during the 2010-2011 academic school year. 85% of the survey participants responded to the question, and 40% of these respondents selected “yes” and were prompted for the next question.

In general, the responses were positive to the survey prompt statement “Please explain how SPIRIT influenced your course selection process.” 63% of respondents to this question stated they enrolled in a computing related course as a result of the SPIRIT program. For example, one student stated, “SPIRIT got me more interested in computers and programming. I actually chose to take a 3D Art Modeling class because of SPIRIT.” All such responses were categorized into students who made an effort to enroll in computing-related courses.

18% of the respondents stated that the SPIRIT program influenced their career objectives. Similar responses were categorized into students who expressed that the program had an influence on their future plans regarding college education and the fields in which they would like to work or study. To illustrate, one student explained, “I decided to take a programming class so that I would be better able to consider a major in Informatics.”

17% stated the program increased awareness of careers and opportunities. These types of explanations were grouped into the category of those who expressed that they were made more aware of opportunities that exist in computing related fields of study and work. For example, one student stated, “SPIRIT showed me opportunities and

career choices associated with Information Technology that I did not know of before.”

One category included those respondents who stated their interest in the field of computing and information technology was increased. 17% stated that the program increased general interest in technology and computing. For example, one student explained, “I realized I enjoyed computer classes more than I do sitting and listening to a teacher talk.”

The general feel of the responses were positive. The significant majority of responses showed that respondents acted as a result of the program and altered their current courses. At a minimum, the respondents displayed an increased interest in technical and computing related fields of study. The effects of the program are evident even in this first survey prompt.

II. Influence of SPIRIT Program in Course Performance

Students were asked to identify if attending SPIRIT changed their performance in any of the courses they took during the 2010-2011 school year. This question received a 59% response rate meaning that respondents had said selected “yes” in saying their school performance had been affected. These “yes” respondents were then prompted for the next question asking for an explanation. These students then were prompted to explain how attending SPIRIT influenced their course performance in the 2010-2011 academic year. The responses were classified according to different categories.

The first category included responses from those who stated that their performance at school had been influenced or that the program had given them an edge or some level of boost in their coursework. 40% of respondents stated it helped them improve their work performance at school, e.g., “I received a better grade in a project due to the Alice world I created and impressed my teacher with.”

The next category included the students who had become more comfortable in working with the technology or software used during SPIRIT. 25% of responses were placed in this category. One such response is, “I felt more comfortable using a similar program.” Then, 21% of students remarked that they became more interested in technology and computing. These responses often demonstrated change in career objectives. For example, one student stated, “I found that I am very interested in the BCM program in the College of Technology. I have spoken to my school counselor about taking courses in that area.”

Other 13% of responses were categorized as saying the student felt they were more thoughtful and/or put more effort into their work with technology. This category was more specific than the first one, which tended to be more general schoolwork improvement. To illustrate, one student stated, “I was a lot better with being quick to use computer software in place of paper and pencil things for planning projects and such.”

The final category grouped those respondents who gained knowledge of available career paths regarding

technology. 6% of responses fit this category. For example, one student stated, “It showed me that IT isn’t just one specific career path but it can be integrated with many things.” Again, the general feel was positive throughout the responses. A large portion of students mentioned the program had influenced their schoolwork either in general or using the technology worked with during SPIRIT.

III. Career Goals of Participants before SPIRIT

The following question, “BEFORE attending SPIRIT, did you have a career goal?” received an 83% response rate with 61% of these selecting “yes.” The participants were then prompted for the next question: “Please explain what your career goal was BEFORE attending SPIRIT.” The purpose of this survey prompt was simply to establish the possible preexisting career objectives of participating students in order to determine possible changes as a result of the program.

The largest portion of respondents stated they were interested in medicine and biological sciences. 36% of responses were placed into the medicine/biological sciences category. Responses were direct for the most part and typically had little overlap. For example one student responded “to become a Pharmacist.”

The results of the responses are depicted on Table I. The results are followed with the percentage of the category found, the field of interest categories for the responses, and examples from the responses. These results show the largest portion of students were interested in medical and biological sciences fields of study before the program.

TABLE I
CAREER GOALS OF PARTICIPANTS BEFORE SPIRIT

| Percent | Field of Interest | Example |
|---------|------------------------------|------------------------|
| 36% | Medicine/Biological Sciences | “Pharmacist,” “Doctor” |
| 18% | Engineering | “Mechanical Engineer” |
| 18% | Technology/Computing | “CIS - Networking” |
| 15% | Related | “Interior Design” |
| 9% | Liberal Arts | “Stock Broker,” |
| 6% | Business/Economics | “Accountant” |
| 3% | Law | “International Law” |
| | Education | “Elementary Education” |

IV. Career Goals of Participants after SPIRIT

The question “AFTER attending SPIRIT, did your career goal change?” received an 83% response rate, of which 44% selected “yes.” These respondents were then prompted for the next free response “Please explain how your career goal changed AFTER attending SPIRIT.”

A stunning 50% of students said their career goals had changed to a technology related field and their response was placed in the appropriate category. Responses in this category expressed interest in technology related careers or integrating technology in their career goals. Two representative quotes are: “it made me want to pursue a career within the information technology field,” “I now aspire to be a meteorologist because of the intertwined use of computers and mathematics - two things I am very

passionate about,” and “Before, I was interested in sociolinguistics. Though I maintain that interest, I am now looking to research technology’s impact on language.”

Responses as the latter two are certainly welcome as the students’ initial interests are maintained and have simply likened to integrating technology into their interests.

The remaining categories fell below 15% and are shown in the following table containing all the totals of both, before and after for comparison.

TABLE II
PARTICIPANTS PREFERRED DISCIPLINES TO PURSUE AS CAREERS BEFORE AND AFTER SPIRIT

| Percent Before | Percent After | Field of Interest |
|----------------|---------------|-----------------------------|
| 18% | 50% | Technology |
| 15% | 12% | Arts/Design |
| 9% | 8% | Business/Management |
| 18% | 8% | Engineering Related |
| 36% | 8% | Medical/Biological Sciences |
| 6% | 4% | Law |

There is a significant increase in interest in technology related fields after the SPIRIT program. The following table shows percentages from before (taken from the previous survey prompt) and after the program alongside the similar categories from both free response sets. The shift in career goals to technology related fields is more evident here. The SPIRIT program has significantly affected the participating students’ career goals as displayed here by the 32% increase.

V. Plans to Attend College Before and After SPIRIT

The next questions in the survey were “Please respond to the following questions on a scale of very unlikely to likely.-You had plans to attend college BEFORE attending the 2010 summer camp” and “Please respond to the following questions on a scale of very unlikely to likely.-You had plans to attend college AFTER attending the 2010 summer camp.”

Both of these questions had an 81% response rate and similar percentages. The first of the two, “You had plans to attend college BEFORE attending the 2010 summer camp” results were 94% “very likely” and 6% “likely.”

The question “You had plans to attend college AFTER attending the 2010 summer camp.” Results were 96% “very likely” and 4% “likely.” Although small, the camp did have an effect on participants’ plans on enrolling in college. After the program, they were more likely.

VI. Plans to Pursue a Career in Information Technology Before and After SPIRIT

The results of this portion of the survey yielded the most interesting results. Participants were asked for a scaled response from “very unlikely” to “very likely” whether or not they intended on pursuing a career in information technology. They were asked for this response in reference to before and after the SPIRIT program.

The first of the two questions, "Please respond to the following questions on a scale of very unlikely to likely.- You had plans to pursue a career in information technology BEFORE attending the 2010 summer camp." received a 75% response rate of survey participants and of those, the responses were as follows. Simply put, there were not very many respondents who stated they would likely pursue a career in information technology before the SPIRIT program.

The following survey question asked the natural follow up of the participants in having them state the likelihood of pursuing an information technology related career after the SPIRIT program. This question received a 77% response rate of survey takers and the results are depicted on Table 3.

Clearly the program had an effect on the participants' career goals. For better comparison, the results are placed side by side on Table 3.

TABLE III
CAREER GOALS OF PARTICIPANTS BEFORE AND AFTER SPIRIT

| Percent Before | Percent After | Likelihood |
|----------------|---------------|---------------|
| 22% | 6% | Very Unlikely |
| 51% | 16% | Unlikely |
| 33% | 34% | Unsure |
| 6% | 34% | Likely |
| 4% | 10% | Very Likely |

Here the shift is obvious. There was only a 6% increase in "very likely," but a surprisingly large 28% shift in the "likely" category. The "very unlikely" and "unlikely" both suffered large reductions from the "before" column.

These results demonstrate the SPIRIT summer camp's effect on participants' interest in the information technology field.

VII. Important topics learned during the SPIRIT program.

The final survey question was "What was the most important thing you learned during the SPIRIT 2010 summer camp?" This question was more open ended than the others and allowed for the students to share what they thought to be the most valuable part of the time spent in the program. This question had an 83% response rate. Responses were categorized in the same manner as in previous free response questions.

The largest of these categories from the results was "learned more about career options." This category was designated for those responses which expressed that an increased awareness of available careers in technology from the program. 39% of responses fell into this category. For example, one student stated: "The breadth of the positions available in information technologies."

The next largest category was more general in that responses stated they learned more about computing and technology in general. 33% of responses were placed into this category. One student mentioned: "I learned that IT can be applied to many other things other than programming."

Then, 13% of respondents mentioned they learned more about the importance of technology and I.T. in the world as

well as other fields and careers. For example, a student stated "How technology played an important role in the medical field."

The remaining categorized responses fell below 7% and are shown in the table of all categories found from the responses.

TABLE IV
MOST IMPORTANT THING FROM THE SPIRIT PROGRAM

| Percent | Important Topic |
|---------|--|
| 39% | Career options |
| 33% | Learned more about computing/technology as a whole |
| 13% | Importance of technology |
| 7% | Learned a new skill |
| 6% | Making friends and/or socializing |
| 6% | Learned about women's role in IT |
| 4% | Learned more about self |
| 4% | Meeting professionals |
| 2% | Learned about college life |

The largest two categories that respondents fell into were "career options" and "Learned more about computing/technology as a whole." The remaining, were much less, but certainly not less important.

A notable topic would be the category "learned about women's role in IT." This is an important and noteworthy category as the majority of SPIRIT attendants were female.

4% of respondents mentioned meeting professionals was an important aspect of the program. For instance, one student stated: "Meeting people who work in the industry and hearing how their careers use information technology."

Bringing in industry and experienced IT professionals is important to demonstrating to the students the role that IT has to play in the work force. Although few mentioned this as the most important, it is important to note that this is a worthwhile pursuit for the program.

DISCUSSION

The goal of the program is to raise awareness of the societal impact of computing and the variety of career opportunities it offers people with IT skills. Before discussing the relevance of the results, it is important to understand the target group. The program is marketed to high school students who most likely have not yet decided on pursuing a computing major. In fact, those who have decided to pursue IT receive much lower scores during the selection process. Thus, even if one student decides to pursue computing based on what s/he learned from SPIRIT, it represents one more person filling the demand for skilled IT workers. Results from many of the survey questions suggest that several students are now considering a college major in computing and/or engineering.

Positive experiences in high school courses tend to influence selection of majors in college [6,7]. Based on their SPIRIT experience, 14 students (21%) planned or had already enrolled in a computer-related course while in high school. One of these students sent an unsolicited email message relating a poor experience in the high school engineering course she took, but went on to explain that she

still plans to pursue engineering in college based on her positive experience in SPIRIT. Furthermore, she planned to form a robotics club at her school to encourage others who may have been equally dissuaded by the high school course, so they could know how interesting and important computing and engineering study really can be.

In addition to more students taking computer-related courses they would not have taken, 38 students (58%) stated that the SPIRIT experience improved their academic performance in the high school courses they took after the SPIRIT program. Some said they were more confident, while others thought their newly acquired technology skills improved their performance.

When asked if their SPIRIT attendance changed their career goals, 24 students (37%) responded that it had changed to a technology-related career. Although some of the detailed explanations from cited disciplines that are peripherally-related to computing, given that SPIRIT sought to show how far-reaching computing is, it is clear that the students that responded affirmatively to this question recognize that computing skills are essential regardless of the specific career path chosen.

The most important set of responses relative to the intended impact of the program were in response to questions about their intentions to pursue a career in IT. The change in response from before SPIRIT to after SPIRIT showed that the level of interest in pursuing an IT career increased significantly.

CONCLUSION

Misconceptions about computing careers are still prevalent in today's society. Educational programs that are able to erase these misconceptions can begin to positively influence young people to consider computer-related careers. Student feedback from SPIRIT demonstrates that providing students with this information not only increases the potential for them to pursue IT, but also enhances their academic performance in their high school courses. Many more programs are needed, however, to make an adequate impact to sufficiently address the predicted computing workforce needs in the foreseeable future. Many of the teachers' and counselors' Alice-based lessons are freely available from the SPIRIT website (www.ITPossibilities.org). Details about developing a similar program, including a schedule of sample activities

will be made available on the website in summer 2012, including detailed steps for a select group of these activities.

ACKNOWLEDGMENT

SPIRIT was supported by a grant from the National Science Foundation, #DRL-0737679.

Cluster Analysis of Motivation and Early Implications for Educational Research and Practice

Alex Dillon and Jonathan Stolk
Franklin W. Olin College of Engineering
Needham, MA 02492

Abstract— The type of motivation that a student evinces can shape such outcomes as academic engagement, performance, and satisfaction. In this paper we explore student motivation using cluster analysis, a quantitative method that has been proven useful in examining group-based motivational profiles within academic settings. We apply a range of clustering techniques to a data set comprising motivational survey responses of undergraduate engineering students at three different colleges. We confirm the outcomes of previous clustering analyses, revealing the existence of different student motivational profiles in academic settings, and we offer several new perspectives on engineering student motivation. First, different cluster analysis methods describe similar trends in motivational profiles, but divergent judgements in the distribution of students into these profiles. Second, examination of longitudinal data illustrates that students' endorsements of the various motivations fluctuate significantly, and sometimes dramatically, within the duration of a single course. This challenges the "they either have it or they don't" concept of motivation, and highlights the importance of understanding of students' situational motivational responses to classroom activities.

Keywords—motivation, self-determination, cluster analysis

I. INTRODUCTION

Motivation has been used as a window into understanding people's behavior and outcomes since psychology moved from a philosophical to an applied discipline in the mid 1800s. Contemporary needs-based motivation theories found in educational research have their roots in early humanistic psychological work by Maslow [1], whose distinction between physical and psychological stimulation in a hierarchy of needs evolved into the concepts of intrinsic and extrinsic motivation. After Maslow developed these macroscopic, life-long interrelations, others sought a framework for investigating the interplay of intrinsic and extrinsic motivation within more discreet contexts. One model that has proved both flexible and insightful is called self-determination theory (SDT) [2-4], which was developed in the 1970s and has since been applied to educational environments, as well as contexts from behavior intervention to sports [5-7].

In this study, we used surveys based on the constructs of SDT to gain insight into students' perceived motivations in a variety of materials science course environments, and will presently investigate the results in light of applied psychology's overarching goal of improving outcomes through understanding their determinants.

II. SELF-DETERMINATION THEORY (SDT)

A. Essential Constructs

SDT investigates the congruence between a person's intrinsic motivations and their environment. The degree of congruence relies on the extent to which an interaction satisfies three basic needs: autonomy, competence, and relatedness [4]. These needs are the cornerstone of SDT, and are understood to influence a person's observable characteristics such as affect, behavior and cognition. This relationship is particularly important in social contexts, where these outward effects partially define the environment as perceived by others. SDT posits that an interaction is integrated into the sense of self, which in turn widens the scope of relatedness and allows for further development within the environment; if unsupportive, it reduces perceived relatedness and decreases the environment's appeal. This process, called internalization, is how intrinsic motivation is facilitated [4]. Furthermore, SDT research posits that individuals perceive motivation at three hierarchical levels of generality (Figure 1), categorized by the persistence of their influence: from most to least recurring they are the global, contextual, and situational levels [8-11]. Influences have been observed to flow both top-down and bottom-up within these levels.

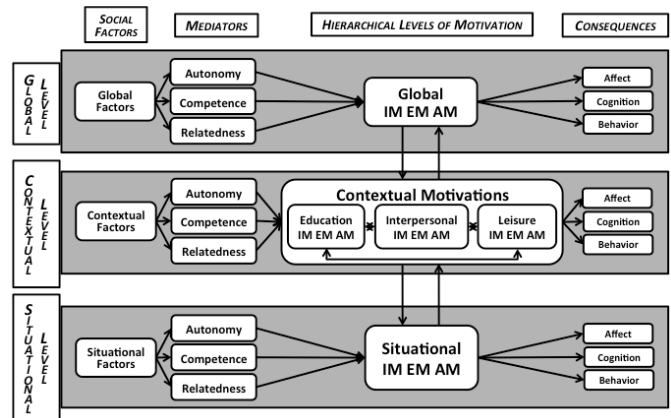

Figure 1. The hierarchical model of motivation, from Vallerand et al. [8].

B. Measuring Motivation

In addition to the theoretical constructs, SDT researchers have also developed survey instruments that can be applied to measure the apparent magnitudes of the hypothesized constructs. The present study made use of the Situational Motivation Scale (SIMS), a 16-item, Likert-scaled (1=corresponds not at all, 7=corresponds exactly) instrument

that uses four subscales that lie along the self-determination continuum: intrinsic motivation (in which one senses an activity's personal relevance), identified regulation (one senses the activity is related to something else personally relevant), external regulation (one does not see the activity's relevance, and so is driven by extrinsic factors), and amotivation (feelings of incompetence and uncontrollability, when one understands neither the activity nor its relevance). SIMS subscale scores for intrinsic motivation, identified regulation, external regulation, and amotivation are calculated as the means of four survey items for each scale. The SIMS has been shown to have internal reliability and construct validity [12].

The four SIMS subscales can be collapsed to a single value called the self-determination index (SDI), defined as: $SDI = 2 \times (\text{intrinsic motivation}) + 1 \times (\text{identified regulation}) - 1 \times (\text{external regulation}) - 2 \times (\text{amotivation})$. SDI values are described as a continuum of controlled to autonomous motivation, with a corresponding range of possible scores from -18 to +18. While some studies have demonstrated SDI's validity in examining learner motivation [10,11,13-15] others have noted its potential to obscure trends in data due to oversimplification [16]. We use it primarily as an easily referable metric to orient an otherwise complex analysis.

Typically, motivation studies have sought to link motivational levels with specific contextual outcomes via correlational factor analysis. Of particular interest to the authors, however, was an analysis method called a *person-oriented approach* [16]. This approach assumes the surveyed factors are related to each other through some combination of origin and/or effect, and thus allows for a more nuanced analysis. Consider two students who both register high intrinsic motivation, but only one of who reports significant external pressure. One can imagine their behaviors and experiences might be different; a person-oriented analysis enables a statistical investigation of this situation. This type of analysis is carried out by employing a data clustering methodology, for which there are various techniques. Specifics are discussed below and in the analysis section.

C. Prior Studies of SDT

Variable-based analyses of motivation have shown that the satisfaction of the three basic needs postulated within SDT does indeed foster increased intrinsic motivation, more persistence, improved academic performance, and healthier learner development [5-7,15-18] – research that lends much credibility to the SDT framework. More recently, a person-oriented study by Ratelle et al. [16] sought to identify distinct “motivational profiles,” that is, trends within the relative values of reported motivations. Using a sophisticated cluster method initially developed for longitudinal social analyses, they studied three datasets: two gathered in a high school setting and one from a college setting. Their analysis revealed four different motivational profiles, however each setting showed only three of the four. Two profiles were shared among all settings: one had moderate levels of both autonomous and controlled (extrinsic) motivations (which they named moderate AU-C), the other had high levels of both (named high AU-C). Unique to the high school setting was a profile dominated by extrinsic and amotivation characteristics; unique within the college

setting was a profile dominated by autonomous characteristics (named truly AU). Ratelle et al. found that performance in high school was best in the high AU-C group; in college they found performance to be similar between the high AU-C and the truly AU groups, but found academic persistence to be greater among the truly AU group. In light of this more nuanced analysis of motivation, we sought to examine the motivations that engineering students adopt in undergraduate classroom settings. We pose several research questions: What motivational profiles do engineering students adopt in undergraduate courses? How are students distributed across these profiles? How do these motivational profiles change over time? What cluster analytical techniques are most useful for examining engineering student motivations?

III. PRESENT STUDY

A. Participants and Methods

Data for this analysis were gathered as part of a larger, mixed-methods investigation of student outcomes in introductory materials science courses. Participants were engineering students enrolled in four different materials courses at three predominantly undergraduate institutions. A total of 404 students participated in the study. The participant group included 93 students in project-based materials science courses at a small engineering college, 137 students in lecture-lab materials science courses at a small liberal arts university, and 174 students in lecture and lecture-lab courses at a large public university. Data were collected via a web-based implementation of the SIMS instrument described above. All students were surveyed at the beginning and end of their term; however one difference was that students in both courses at the small engineering school were surveyed nine additional times throughout the semester, providing longitudinal data for a subset of study participants. In total, our dataset comprised 1278 complete survey responses, 707 of which were collected during the beginning or end of the respective course.

B. Basic Analysis – Dataset Characteristics

Our complete dataset gave mean values for intrinsic motivation, identified regulation, external regulation, and amotivation of 4.5, 4.7, 3.8, and 2.0, with standard deviations of 1.3, 1.1, 1.6, and .96, respectively (Figure 2). This resulted in a mean SDI rating of 5.9, with a standard deviation of 5.4 (Figure 2). The low amotivation mean and relatively high identified regulation and intrinsic motivation values indicate that, on average, the study participants adopt internalized forms of motivation in their materials science course. The mean values do not, however, indicate the extent to which students simultaneously develop more than one type of motivation, e.g., external regulation combined with intrinsic motivation.

A comparison of the data from the beginning against those from the end provided an interesting result for the present context: a Welch two factor t-test revealed statistically significant ($p < .01$) increases in both intrinsic motivation and amotivation within the dataset. At first this seems counter to self-determination theory, which posits these two factors are the least related and should correlate negatively. This result may be explained, however, by considering the classroom context: there could be a statistically significant group of

students who find the courses very interesting, as well as a mutually exclusive but still statistically significant group who find them amotivating. To address individual student needs, it is important for instructors to better understand the origins of these motivational changes. This is an intriguing platform from which to start our person-oriented analysis.

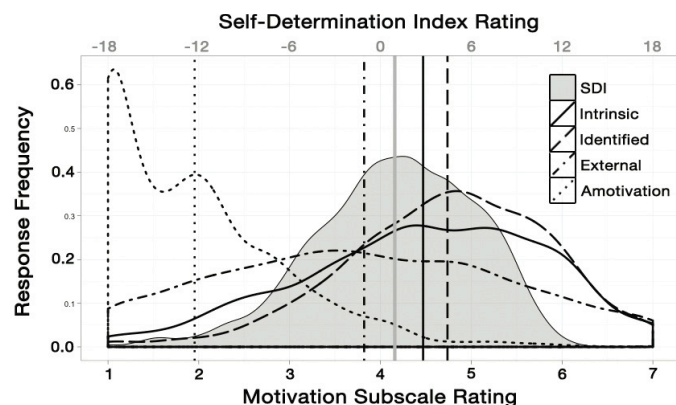

Figure 2. Means and distributions of SIMS subscale (black, line weight relative to scale autonomy) and Self-Determination Index (grey) values.

C. Person-Oriented Analysis – Cluster Methods and Results

Clustering analysis, an approach applied to multivariate social science data to identify similar instances of responses by looking for homogeneities in defining variables, has proven useful in examining student motivations [19-22]. Cluster analysis depends on a family of data grouping techniques which differ in their underlying function but have one common aspect: they will always provide some type of answer. When seeking to apply cluster analysis to a dataset, one must contextualize the results in order to identify whether and why a result is of significance to the researcher. The two main questions to answer when seeking a person-oriented analysis, therefore, are: what method should be used, and how many clusters should be sought? As of yet there is no agreed-upon best approach for the present application, so we take this opportunity to explore these fundamentals before we ascribe too much significance to their practical implications.

One of the most basic cluster methods is called k-means clustering, so named because it asks the user how many clusters to form (k) and does analysis to return the k sets of mean values. This approach treats each instance of supplied data (in this case, the values from one completed survey) as a vector of spatial information, and then inserts k points within the dataspace. All given data are grouped to the nearest inserted point, and a center for each group is calculated. The algorithm then reassigns cluster membership based on the new centers, and continues this process until the change in centers no longer results in a change in the clusters' members.

Basic k-means analysis always has certain characteristics that may in some contexts be drawbacks: first, the cluster results depend on the seed k values and thus can be susceptible to getting "caught" in local minimums or maximums, and second, because cluster discrimination occurs halfway between means, the algorithm is insensitive to cluster-specific density characteristics and tends to make clusters similarly sized. This last drawback is particularly important to us, since we would

ideally like to identify any persistent motivational profile even if it describes a smaller proportion of students than the others.

These drawbacks have led to the development of algorithms that are more sophisticated in their clustering process and that include built-in appropriateness assessment tools. The previously mentioned Ratelle et al. study used such a tool in their analysis, a SAS extension called TRAJ [16]. Ratelle et al. touted its ability to guide the model fitting process, and we were interested in applying this technique. Although the TRAJ module is freely available, it requires the costly SAS base to run. Fortunately, a methodology of similar sophistication, MCLUST, is freely available, and runs on an R base, which is also freely available. MCLUST includes steps to address k-means' shortcomings by attempting to intelligently choose initial centers and allowing for varied, cluster-specific distribution densities. It also employs the same appropriateness assessment tool used by TRAJ, called the Bayesian Information Criterion (BIC). BIC is a widely used metric for selecting which among a finite set of modeling options provides the best relative fit. A single model provides a single BIC value that is always negative, so model selection occurs by iterating model assumptions for a dataset and choosing the assumptions that result in the highest actual (lowest absolute) BIC.

By default, MCLUST will take a dataset and extract BIC values for ten different mixture model assumptions applied to k-values of 1-9. This default analysis investigates a broader range of possible clusters than in Ratelle et al. [16], which compared only k values of 2-4. Their k value limitation, however, is logical given only four psychometric variables rated on a 7-point scale. In our preliminary k-means clustering analysis with k from 2-6, we identified four clusters as a qualitatively useful number for discussing motivational response profiles. The Ratelle et al. study suggested that three clusters provided the optimal solution. We were somewhat surprised to find, then, that the default MCLUST method suggested that a 7-cluster model as best fit for our dataset of motivation subscale ratings. We then ran MCLUST on a dataset of the raw SIMS survey responses, rather than the subscale averages, and found that despite the dataset having 16 factors instead of 4, the algorithm arrived at a simpler, 4 cluster solution (Figure 3). In analyzing BIC values for a range of 2 to 20 clusters, we concluded that it was not particularly helpful in identifying optimal analysis parameters, and that ultimately the best "fit" would still have to be determined by qualitative contextualization of the quantitative analyses. Since both our practical consideration of student motivations and the most data-rich MCLUST analysis suggested 4 clusters, we used that as our k value and compared the outputs of three different cluster procedures forced to a 4 cluster solution: Method 1 was MCLUST on the unmodified motivation averages, Method 2 was MCLUST on the raw question responses, and Method 3 was a basic k-means algorithm.

Tables 1 and 2 provide statistical profiles of our entire dataset and each of the derived clusters, in terms of their means, standard deviations, SDI values, and inter-factor correlations and reliabilities. Within each methodology, clusters are ranked by their calculated mean SDI. Figure 4 shows the Method 1 cluster results with overlaid SIMS subscale mean values. Comparing the various methods' output

clusters reveals several similarities. Each method identified one group with a relatively high SDI, two with mid-range values within two points of each other, and one with low SDI. In terms similar to those used by Ratelle et al. [16], these might be named high AU, high AU-ID, high ID, and high EX. Of the eight inter-factor correlations that were statistically significant among cluster ranks between methodologies, only one correlation was significant in every cluster: IN-ID. This is interesting to consider in light of the fact that, when the entire dataset was analyzed, each inter-factor correlation reported statistical significance.

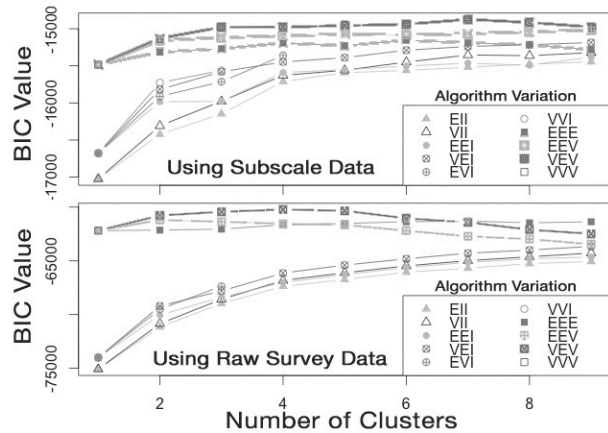

Figure 3. BIC-based model parameter analysis conducted by MCLUST, using survey subscale data (top) and raw survey data (below). Legend indicates model type, and curve maxima indicate optimal cluster number.

Differences among the cluster methods are also readily apparent: principally, the size of clusters varied dramatically. For example, the lowest ranked cluster from Method 1 (MCLUST on averages) was by far the largest within the method with 477 responses. In Method 2 (MCLUST on raw data), however, the largest group (504 resposes) has the second highest SDI, and the lowest ranked cluster is only 55% of the size of that described using Method 1. The clustering methodologies managed to describe similar trends in motivational profiles yet came to different conclusions about

what percentage of the student responses belongs in each. This is especially interesting considering that the subscale averages used in Method 1 are intended to accurately represent the raw responses used in Method 2.

Finally we can see the basic k-means tendency toward equal distribution in action, as its cluster sizes range from 223-393, in contrast to Method 1's range of 217-477 and Method 2's range of 203-504. The cause of this tendency, simple nearness assignment, is born out in that Method 3 has the smallest factor-wise standard deviations. It is again interesting to consider that these tighter looking statistics may in fact portray a characteristic of a less accurate methodology.

D. Implications for Classroom Practice

Although our analyses of student motivation are ongoing, preliminary findings highlight the potential practical value of this approach. Specifically, the cluster-based analyses help identify groups of students who may respond well to motivation-focused interventions, and the longitudinal analyses reveal both group- and individual-based changes in motivational orientation throughout the academic term.

When considering these results within the broad context of SDT, the clusters align on the self-determination continuum. Given this, we found one cluster to be particularly interesting in the context of classroom practice: Method 2 cluster 3. Examining the mean values for this cluster, we find a predominant motivation of identified regulation (4.5) with near-neutral intrinsic motivation (3.7) but low external regulation (2.7) and amotivation (2.0). The correlations for this cluster indicate uncertainty around amotivation's relationship with intrinsic and extrinsic motivation in this student group. We hypothesized this could be the group whose interest could be most readily made or broken by classroom experiences: they may be there of their own volition and sense the material could be relevant, but are not exactly sure why, and are apt to experience bouts of amotivation due to this ambiguity. Examining responses in light of specific classroom activities may help us further explore this hypothesis.

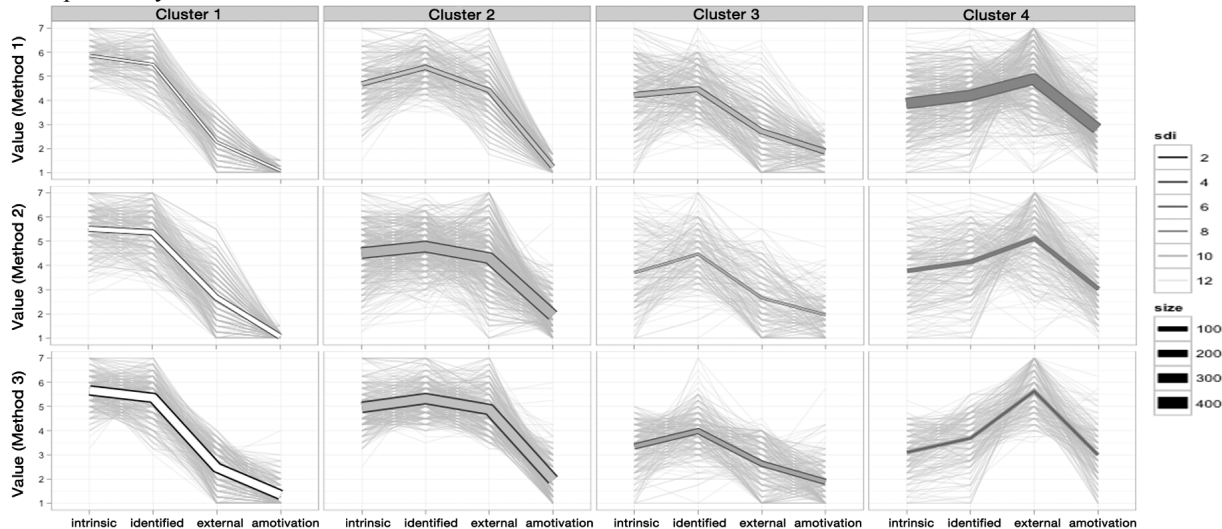

Figure 4. Visualization of Method 1, Method 2 and Method 3 cluster analysis means overlaid on constituent motivation data. Mean curves are sorted and shaded by their implied SDI, and their width varies according to membership size. Note the similarity in each methods's means, but the disparity in member allocation.

TABLE I. STUDENT MOTIVATIONAL RESPONSE CLUSTERS BASED ON THREE ANALYTICAL METHODS

| Method | Cluster Characteristics | | | | | |
|--|-------------------------|---------|------|------|------|-------------|
| | Rank (by SDI) | Members | SDI | Mean | SD | Motivation |
| Entire Dataset | - | 1278 | 5.9 | 4.5 | 1.3 | Intrinsic |
| | | | | 4.7 | 1.1 | Identified |
| | | | | 3.8 | 1.6 | External |
| | | | | 2 | 0.96 | Amotivation |
| Method 1 MCLUST on motivation averages | 1 | 217 | 12.8 | 5.9 | 0.57 | Intrinsic |
| | | | | 5.5 | 0.78 | Identified |
| | | | | 2.3 | 0.75 | External |
| | | | | 1.1 | 0.14 | Amotivation |
| | 2 | 278 | 8 | 4.7 | 1.04 | Intrinsic |
| | | | | 5.4 | 0.77 | Identified |
| | | | | 4.4 | 1.12 | External |
| | | | | 1.2 | 0.27 | Amotivation |
| | 3 | 306 | 6.4 | 4.2 | 1.3 | Intrinsic |
| | | | | 4.5 | 0.96 | Identified |
| | | | | 2.7 | 1.2 | External |
| | | | | 1.9 | 0.46 | Amotivation |
| | 4 | 477 | 1.5 | 3.9 | 1.25 | Intrinsic |
| | | | | 4.2 | 1.15 | Identified |
| | | | | 4.9 | 1.3 | External |
| | | | | 2.8 | 0.93 | Amotivation |
| Method 2 MCLUST on raw responses | 1 | 307 | 11.5 | 5.5 | 0.87 | Intrinsic |
| | | | | 5.4 | 0.92 | Identified |
| | | | | 2.7 | 1.11 | External |
| | | | | 1.1 | 0.13 | Amotivation |
| | 2 | 504 | 5.7 | 4.5 | 1.1 | Intrinsic |
| | | | | 4.8 | 0.93 | Identified |
| | | | | 4.3 | 1.35 | External |
| | | | | 1.9 | 0.68 | Amotivation |
| | 3 | 203 | 5.2 | 3.7 | 1.4 | Intrinsic |
| | | | | 4.5 | 1.1 | Identified |
| | | | | 2.7 | 1.1 | External |
| | | | | 2 | 0.77 | Amotivation |
| | 4 | 264 | 0.6 | 3.8 | 1.3 | Intrinsic |
| | | | | 4.1 | 1.3 | Identified |
| | | | | 5.1 | 1.3 | External |
| | | | | 3 | 1 | Amotivation |
| Method 3 Basic k-means on motivation averages | 1 | 370 | 11.7 | 5.7 | 0.67 | Intrinsic |
| | | | | 5.4 | 0.82 | Identified |
| | | | | 2.5 | 0.81 | External |
| | | | | 1.3 | 0.5 | Amotivation |
| | 2 | 393 | 6.4 | 5 | 0.82 | Intrinsic |
| | | | | 5.3 | 0.73 | Identified |
| | | | | 4.9 | 0.85 | External |
| | | | | 2 | 0.84 | Amotivation |
| | 3 | 282 | 4.2 | 3.3 | 0.93 | Intrinsic |
| | | | | 4 | 0.9 | Identified |
| | | | | 2.6 | 0.95 | External |
| | | | | 1.9 | 0.77 | Amotivation |
| | 4 | 223 | -1.7 | 3.1 | 0.91 | Intrinsic |
| | | | | 3.7 | 0.98 | Identified |
| | | | | 5.6 | 0.92 | External |
| | | | | 3 | 1.03 | Amotivation |

Analysis of our subset of week-to-week data demonstrates that changes in situational motivational orientation and cluster association occur throughout the semester, i.e., *student motivational responses are unstable*. By shading the SIMS motivation output by cluster membership, for instance, we see a shared sensation of externally-dominated orientation during week four of one of the introductory materials courses (Figure 5a).

TABLE II. CORRELATIONS FOR MOTIVATIONAL SUBSCALES WITHIN CLUSTERS

| Method | Pearson Correlations (lower) and P-values (upper) | | | | | |
|----------------|---|-------|--------|--------|-------|-------------|
| | Rank (by SDI) | IN | ID | EX | AM | Motivation |
| Entire Dataset | - | | 0 | 0 | 0 | Intrinsic |
| | | 0.66 | | .0041 | 0 | Identified |

| | | 0.03 | -0.22 | -0.1 | | Amotivation |

This external motivation peak corresponds to the time when the first large, individual, written assignment is due in the course. We also witness different types of evolution through the course duration: some students are consistently positive, others steadily develop a positive orientation, some falter and regain their bearings, and others engage in activities seemingly because they have to and only vary in their level of frustration (Figure 5b, top to bottom).

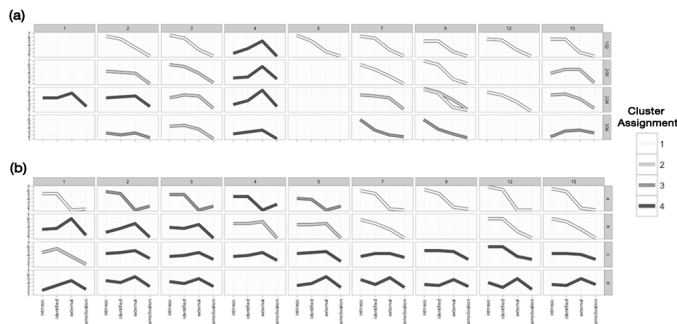

Figure 5. Week-to-week motivational responses of several students in a project-based course. Figure (a) shows a dramatic shift in motivational orientation in week 4. Figure (b) shows different temporal evolutions of individual self-determination. See Figure 4 for reference cluster shapes.

IV. SUMMARY AND FUTURE WORK

Our application of quantitative cluster analyses to student motivation data provided several findings. First, the group-based analysis reveals information that is hidden in variable-based statistical analyses but potentially important to instructors: namely, that engineering students adopt a range of situational motivations that do not fall neatly into the conventional “intrinsic” and “extrinsic” categories. Although the clustering analyses produce groupings that may be arranged by increasing SDI values, a large percentage of students simultaneously adopt both external and internal drive to engage in course activities. Second, although some students adopt fairly stable motivations within a single course, other individual responses change dramatically over time, shifting the distribution of students across clusters. Examining when and how these shifts occur may provide useful information to instructors who wish to revise course activities to maximize internalized motivations. Third, the specific clustering methodology matters. Different analyses provided different cluster means and different distributions of students across clusters, highlighting the need for further investigation of these techniques prior to widespread application. Future analyses will include a more thorough exploration of the temporal changes that occur in student motivations and the effects of these changes on the clusters; and linkage of the cluster analysis results with student interview data for development of qualitative descriptions of motivational responses reflected in the clusters.

Abstract— This paper presents the experience of designing and implementing an educational content creator adapted to mobile devices in a K-12 environment. Two main issues have been detected when designing this tool. The first one is the screen size, which will limit the contents' size and the quantity of contents presented at the same time in the screen. The second issue is related to the touch screens these devices have, which changes the whole user experience. Four types of resources can be generated with this tool considering these issues. Firstly, a virtual microscope where the user can select a sample and study it in detail through the microscope. Secondly, a quiz where the user has to join words to their corresponding definitions or images. Thirdly, a virtual chemistry experiment where the user has to drag and drop pipettes to complete chemical formulas. And finally, a generic flashcard that presents a background image and several "hot zones" where the user can touch and see additional contents that the teacher has previously tagged. Details about the technologies and details related to its implementation are described in the paper.

Keywords; *interactive learning objects; science in education; multi-device resources; virtual experiments*

I. INTRODUCTION

As technology evolves, new powerful devices with more capabilities are available for the end user, smartphones, tablets, laptops or desktop computers. Even televisions and cars should be considered as they are starting to incorporate a browser, applications and Internet connection. All these devices entail new challenges for teachers to adapt their contents, teaching methods and tools.

With these devices, new opportunities appear to increase student's motivation and engagement while they learn [1] [2]. Nevertheless, learning object repositories usually do not contain suitable resources for this kind of device. Sometimes because they depend on the operating system installed. In other cases because of the differences in the device hardware like screen sizes, touch screens, RAM or CPU capabilities. As a consequence, teachers have to use traditional less interactive resources.

On the other hand, although sometimes they can find suitable resources for these devices, the content does not fit, it can be for example oriented for other ages or in another language, being impossible to customize it. Therefore, in those

cases teachers need to generate their own resources from scratch.

This was the main issue that was pointed out by the teachers participating in the project called GLOBAL excursion (Extended Curriculum for Science Infrastructure Online) [3]. GLOBAL excursion is a supporting action funded by the European Commission under the Research and Innovation Infrastructures programme of FP7.

The project will develop a common understanding, teaching use cases, as well as pedagogical and technical artifacts. The main purpose of the GLOBAL excursion project is to enable students and teachers access to the experimental laboratories and resources of selected e-Infrastructures in order to improve science curricula by enriching school's existing teaching and learning materials.

The scientific partners participating in the project are initially three, the Institute for Biocomputation and Physics of Complex Systems (BIFI) from Spain, the Nanoscience Centre from the Cambridge University (UCAM) from the United Kingdom and the Computer and Automation Research Institute (SZTAKI) from Hungary. Other scientific centers are expected to participate in the near future. The materials currently provided by all partners are based on the following topics:

- Biotechnology and biology from BIFI.
- Grid computing and volunteer computing from STZAKI.
- Nanoscience from UCAM.

These scientific materials are very diverse. However, as they are very technical and specialized they can be difficult to understand for young students. To make these materials attractive and enjoyable for students and to allow the creation of interactive learning multi-device objects, we have designed the Virtual Experiments creator. It is a web tool to integrate the contents that scientific centers provide, like images, videos or texts, or other contents and learning materials that the teachers upload into multi-device applications.

This paper explains with detail the Virtual Experiments creator tool and some examples of how these resulting Virtual Experiments are viewed in mobile and desktop devices. To do

so, we first review related work of ubiquitous learning and other authoring tools. Section 3, 4 and 5 explain the Virtual Experiments, the viewer and the creator. Section 6 follows with the technology we chose and the issues that arose when designing and implementing for multiple devices. We finally end with some conclusions and a short summary of possible research lines related to this tool in the near future.

II. RELATED WORK

Ubiquitous learning or u-learning enables students to learn at any time, anywhere and on any devices. From a real perspective, building a ubiquitous learning environment requires a “ubiquitous” learning device accessible by every learner all times [4]. Ubiquitous learning systems should consider various factors like support for heterogeneous devices with different screen sizes and resolution, storage, processing power, format handling capabilities and network connectivity [5].

Most learning objects have been designed for viewing within learning management systems (LMS) and web browsers. In order to include these learning objects into ubiquitous learning systems, content adaptation is needed. Content adaptation concerns the act of transforming learning content to adapt it to any mobile device capabilities [6]. This adaptation will ensure learning objects can be properly visualized in different access methods and devices, such as mobile phones, laptops, tablets, etc. Numerous initiatives have proposed different content adaptation approaches [7], [8], [9]. [10] even propose a content adaptation tool that provides different templates to reproduce high-quality learning content for specific handhelds.

Although content adaptation is very useful for web pages, it cannot be automatically done with non-web based applications, as they have to be installed, nor with some contents that were specifically created for desktop computers and they are not resizable.

However, a good approach to avoid content adaptation issues is to create the learning objects with ubiquitous or multi device tools. In this case, the contents will have to be properly designed and developed for devices with higher restrictions [11] and then tested with the rest of the devices.

In [12] we can find a comparison among different authoring tools. Only half of them generate adaptable learning resources, and in most cases these resources consist of web pages with text and multimedia resources (videos, audios) integrated.

Other open source, free or commercial tools to create e-learning resources can be found, like Xical [13], eXe [14], and Wink [15] among many others. Most of them allow the user to create web educational resources or flash based objects that won't work on modern handheld devices.

III. THE VIRTUAL EXPERIMENTS

The Virtual Experiments can be considered learning activities or learning design according to the characterization that Allison Littlejohn does of e-learning resources in [16]. They use the digital assets and information objects to compose the structured sequences of information and tasks.

This tool has been designed following the principles explained by Clark and Mayer in [17] related to multimedia learning resources. Together with the principles of interfaces design and mobile interfaces design of [18] and [19]. This way we have created an attractive and useful interface for the generated Virtual Experiments to be used by K-12 students in a pedagogical way. There are no toolbars full of options that can distract the student's attention. The educational content is very visual. It is based on images and videos. The student can interact directly with the learning objects themselves and not only consume the information in a passive way.

Another big concern was about students' motivation. Jere Blophy in his book “Motivating Students to learn” [20] states that students are motivated when they believe they are able to succeed at a given task and when they understand and value the outcome of the task. Here, the simple and usable interfaces will help with fostering students' motivation. Students with a quick look will know how to interact with the Virtual Experiment and will value the outcome of the task. These Virtual Experiments will suppose also a challenge for them. Instant feedback after any action is also provided to engage them.

IV. THE VIRTUAL EXPERIMENTS VIEWER

Four types of learning objects can be created with the Virtual Experiments tool. The only difference among them is the interface design. Images, videos and texts can be integrated in all of them. In the following subsections, we will explain the four interfaces related to the different Virtual Experiments that can be created.

A. Virtual Microscope

This first possibility allows the teacher to create a visualization of a microscope and some petri dishes (Fig. 1). The learner will be able to interact with this microscope either with a mouse (if he/she is on a desktop computer) or with his/her fingers (if using a touch screen on any other device such as smartphone, tablet, etc.).

When the learner clicks/touches a petri dish, the microscope view appears full screen (with or without explanation depending on the teacher's decision) as we can see in Fig. 2. In this view, the student can move around the zoomed in sample in order to see it with more detail.

Figure 1. Virtual microscope main screen

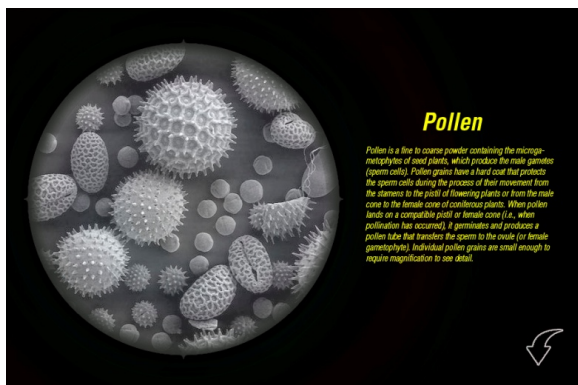

Figure 2. Virtual microscope sample

B. Chemistry Experiment

Fig. 3 illustrates this Virtual Experiment in which the teacher defines some chemistry formulas with some unknown compounds in them. The learner will get the drawings representing these formulas and a test tube holder with the compounds that lack in the formulas (represented in them by a question mark).

The learner has to drag and drop the test tubes to the questions marks in order to get instant feedback if the answer is correct or not (Fig. 4).

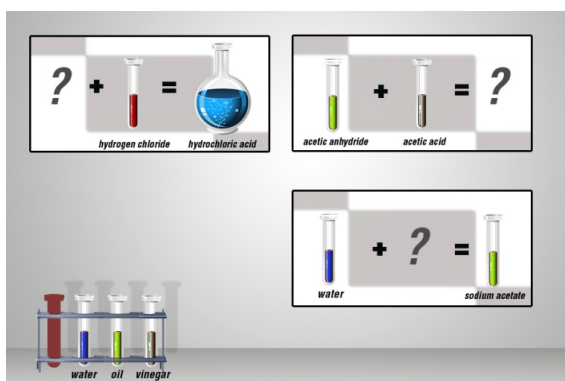

Figure 3. Chemistry experiment main screen

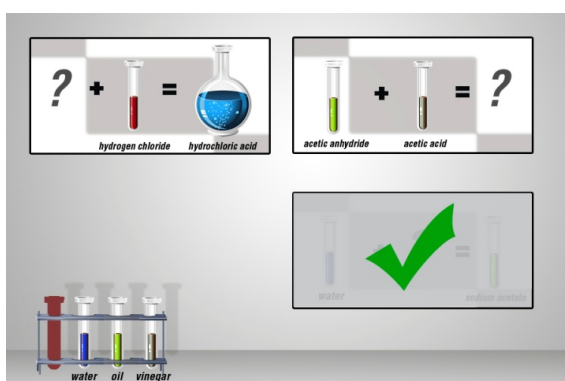

Figure 4. Chemistry experiment result

C. Quiz

In this case a visual graphical quiz can be created. The student will have to click or touch the different options

represented by text (Fig. 5) and images or videos (Fig. 6) to join them. Again, he/she will receive instant feedback about the matching.

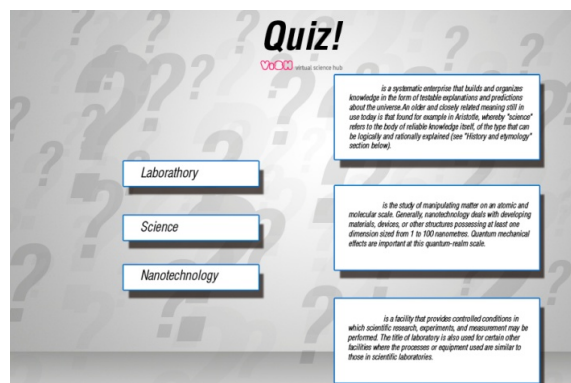

Figure 5. Quiz with texts

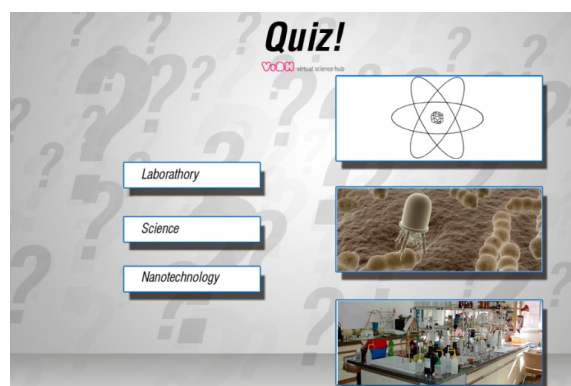

Figure 6. Quiz with images

D. Flashcard

This final Virtual Experiment is the most generic of all, as it does not force a specific interface or scenario. The teacher is the one in charge of uploading or selecting a background image and indicating hot zones on it, linking them with another educational content (text, images, or videos).

The learner will see something similar to Fig. 7 in which there is a background image with several hot zones with moving arrows. If those zones are clicked/touched, the system shows the explanations that the teacher has assigned to each zone.

By using the flashcard learning object, teachers can generate any kind of educational content related to their subject. This way they can re-use their materials.

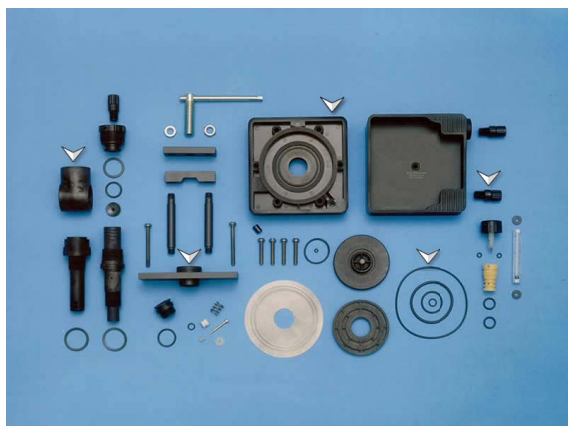

Figure 7. Generic flashcard

V. THE VIRTUAL EXPERIMENTS CREATOR

The Virtual Experiments creator tool (Fig. 8) allows the creation of the multi device learning objects described above. It is also developed in HTML5 and so it is multi device. However, as in this case the teacher has to enter text and explanations, it is more comfortable using it on a desktop computer with a real keyboard instead of a virtual keyboard in a handheld device.

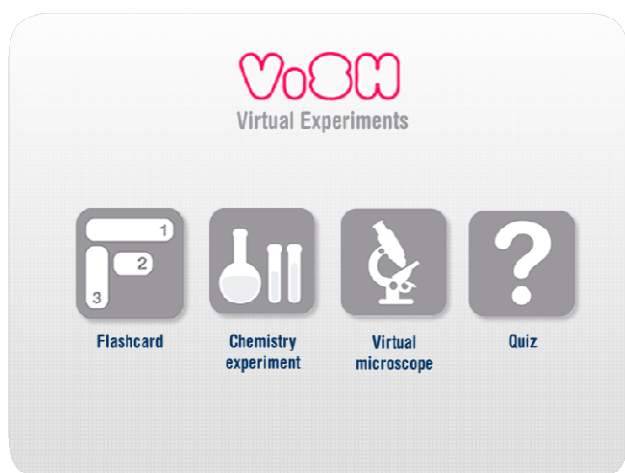

Figure 8. Virtual Experiments creator

The creation process is quite similar in the four types of experiments previously described. We can divide that process into three steps:

1. Select the type of experiment to create: all the possible experiments are shown, and after selecting one of them, the interface for that experiment appears.
2. Click or touch the zone to add content: for example, touch a petri dish to add a new sample in the virtual microscope or to add a new hot zone in the flashcard experiment. The content added can be selected from the pool offered by the platform (previously uploaded by the scientific e-Infrastructures or other teachers), but it can also be uploaded if the teacher does not find anything that fits his purpose and even can be

referenced as an external resource by introducing its URL.

3. Fill in the title and description to show together with the content when the pupil clicks or touch that zone (optionally).

VI. TECHNOLOGY AND IMPLEMENTATION

The Virtual Experiments run on any modern web browser as they have been developed with HTML5 [21], the new standard for the web. For this same reason, once created, they can be integrated with any learning platform or learning management system (LMS). HTML5 offers a lot of possibilities such as geolocation, videoconference and multimedia communications, games, animations, etc.

The Virtual Experiments architecture is quite simple (Fig. 9). Consist of a web server and a database to store the generated Virtual Experiments. The communication between client and server is done via HTTP and AJAX (Asynchronous JavaScript And XML) calls and the Virtual Experiments are defined in JSON (JavaScript Object Notation). The JSON contains all the text and the absolute URLs to the information objects.

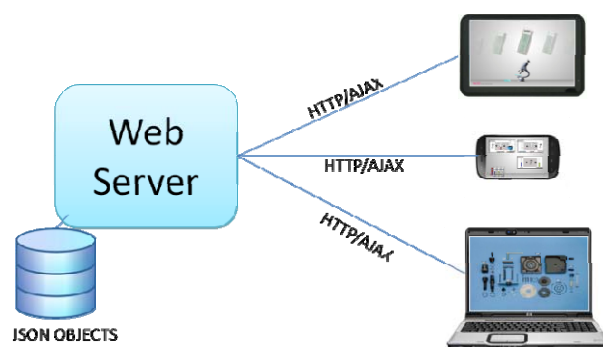

Figure 9. Virtual Experiments architecture

One of the most interesting and difficult issues that we had to address was the multi-device issues. The next section is dedicated to cover it and how we addressed those difficulties.

A. Multi-device issues

Unlike native applications, we can be sure that with HTML5 our application will run in any modern device as this is one of its main features. It only needs to have a browser with HTML5 support.

However, there are multiple device constraints that will make our application to be less usable. As Miller stated in [22], user experience plays a critical, and even primary, role in determining which products stand out. Bearing this in mind, we have to take care of usability to avoid students closing the application and never come back (aborting in this way the learning process).

The main constraints to consider are:

1) *Screen size:*

Screen size is the biggest problem to deal with when designing for mobile devices. It is different from screen resolution since modern mobile devices have big screen resolution (reaching even HD screens). Smartphones for example usually have 3 to 4.5 inches of screen size, and we want to introduce the same information both, in mobile screens and in desktop screens.

Following the principles of [18] and [19] we kept the design of the viewer simple enough to be used in either a big or a small screen. We promote the use of images and videos over texts to avoid as much as possible zoom in/out actions (although they are allowed by touch gestures to see details). As a compromise, we do not let the user to enter lengthy texts as they will not be easy to read in small screens.

2) *Touch screens:*

User interaction is different between devices with keyboard and mouse compared to touch-based screens. In devices with touch screens the keyboard will be virtually drawn and so the resulting screen size to write is even smaller.

Furthermore, HTML5 touch events have to be used together with click events. Otherwise, some special behaviors like zoom in/out gesture (commonly known as pinch action) also had to be implemented as it is very useful and it is becoming a “de facto standard” in touch screens user interaction.

3) *Different browsers:*

There is a high variety of browsers (e.g. Explorer, Chrome, Firefox, Safari, Android, etc.). All of them follow the standards and support HTML5, but there are always small differences that have to be considered. Those differences can be appreciated when entering with a browser in <http://html5test.com/>. Taking this into account, it is necessary to set a minimal set of features generally supported by the majority of the mobile browsers in order to use them in the Virtual Experiments viewer and creator.

4) *Format handling capabilities:*

Although in HTML5 any image or text is recognized by any browser, the same does not happen with video codecs. Three video codecs are supported in HTML5, Ogg Theora, H264 and VP8 (WebM). But not all browsers support all codecs, and this can be a problem nowadays. Fortunately the HTML5 video tag is prepared for this. We can indicate it inside two sources with different codecs and the browser will use the one that can play [23].

The main drawback of this solution is that any video that is uploaded to the platform will have to be encoded in two different formats.

5) *RAM and processing power:*

RAM and processing power does not suppose a problem in modern smartphones that can even have 1GB RAM and 1.2GHz Dual Core. But when the smartphone market started they had 128 MB RAM and 400 to 600Mhz. Right now, the current specifications of the majority of mobile devices is enough to manage images, texts and videos.

6) *Network connectivity:*

Mobile devices usually have 3G/4G and Wi-Fi network connections. In both cases it can be a slow network connection and not enough bandwidth to see a video in streaming or to load several images at a time. This can cause problems in the user experience. We have solved this issue pre-loading all the content before the Virtual Experiment starts, making it transparent to the user.

VII. CONCLUSION AND FUTURE WORK

The work exposed in this paper allows teachers to create customized learning objects that work in any device. Four types of experiments can be created with this tool: a virtual microscope, a chemistry experiment, a quiz and a generic flashcard. Their interfaces are easy to use and reusable as foundations to create more Virtual Experiments that can be implemented with the same technology only changing those interfaces.

Although the technology chosen is multi-device, many issues have appeared. We have described them and have given details about how we dealt with them, so these solutions can be reused by the community.

There is some functionality that we have considered to add to the Virtual Experiments in the future. The first one is based on providing an evaluation and assessment method in the quiz and chemistry experiment, so the teacher can get the pupil's results to be aware about the learning process. This could be done following a standard like IMS QTI.

In the current version, the Virtual Experiments are saved in JSON format. Another important functionality that we want to add is to export the generated resources to standard e-learning formats such as IMS-CP, SCORM or LOM.

On the other hand, to reduce download time and data consumption (in case of 3G/4G connections) we are considering encoding the videos with lower resolution for small screen devices, allowing the system to select the suitable format depending on the context.

Moreover, as we have pointed out before, new types of Virtual Experiments could be developed with little effort by changing the interface design (e.g. a virtual telescope instead of virtual microscope).

Finally, due to the current all-mobile lifestyle and taking into account that everyday mobile devices are getting popular and starting to be used by the general public, we will have to consider them to test the Virtual Experiments on as many devices we can, making small changes in the interface and interactions if needed.

ACKNOWLEDGEMENTS

We wish to acknowledge our gratitude and appreciation to all the GLOBAL excursion project partners, and each one of the project team members, for their contribution during the development of various ideas and concepts presented in this paper. This work is financially supported by the European Union under FP7, Infrastructures.

An INSPIRED Game Programming Academy for High School Students

Peggy Doerschuk, Jiangjiang Liu, Judith Mann

Lamar University

Beaumont, Texas

peggy.doerschuk@lamar.edu, jane.liu@lamar.edu, judith.mann@lamar.edu

Abstract—The demand for computing professionals is growing, but the number of college freshmen selecting computing majors has declined in recent years. Many organizations host academies that attempt to engage students in computing at an early age by exposing them to fun applications. Lamar University's Increasing Student Participation in Computing Program has developed a high school computing academy that uses game programming as an engaging hands-on approach to teach kids computing concepts. The game programming platform is freely downloaded and so is easily accessible to teachers and students. A formal assessment of the 2011 academy found that the high school participants experienced a significant increase in knowledge and interest in computing. This paper describes how the academy is organized, taught and assessed. The paper also has pointers to a website from which the instructional and assessment materials for the academy can be freely downloaded. The intent of the paper is to provide all of the information that is needed for others to host such academies and further promote the effort to increase participation in computing.

Keywords: *game programming, high school, introductory computing, Greenfoot, increasing participation in computing*

I. INTRODUCTION

Lamar University's National Science Foundation supported Increasing Student Participation in Research Development Program ('INSPIRED') was designed to increase the participation of females and underrepresented minorities in computing [1]. The project provided support for small teams of undergraduates from these populations to participate in research and outreach under the direction of faculty mentors. As part of its outreach, the project hosted five-afternoon non-residential high school computing academies from 2008 through 2011. The academies taught computing concepts to high school students through fun hands-on applications with the goal of increasing their interest and knowledge of computing. The first three academies used robotics as the primary teaching platform. The INSPIRED robotics academies are described in a previous paper [2]. Although the robotics academies were effective in engaging the students, buying and maintaining robot software and hardware can be an obstacle to

INSPIRED was supported by Lamar University, a Broadening Participation Grant from the National Science Foundation under Grant No. 0634288, and by grants from ExxonMobil. The development of the instructional materials for the academy was supported by the Collaborative Research Experience for Undergraduates (CREU) program made possible by the Computing Research Association's Committee on the Status of Women in Computing Research (CRA-W) and the Coalition to Diversify Computing (CDC).

establishing and maintaining a robotics-based academy.

In its last year the project moved to a game programming based approach so as to make the academies easier to adopt by others. The 2011 INSPIRED high school academy used a free game development platform as a teaching tool in place of robotics. A team of undergraduate students created the instructional materials, organized, taught and helped assess the effectiveness of the academy. The assessment found that the game programming based academy significantly increased the high school participants' interest and knowledge of computing. This paper will serve as a guide for others who may want to host such academies and further promote the effort to increase participation in computing.

Section II describes the motivation for the academy, related work, and how the INSPIRED academy differs from other academies. Section III describes how the INSPIRED Game Programming Academy is organized, taught, and assessed. It discusses how undergraduates are prepared for their roles in conducting the academy. It includes a brief description of the instructional materials, the concepts taught in each hands-on session, the materials that are used to assess the academy, and the methodology used. Section III discusses the assessment results, including the demographics and comments of the high school and undergraduate participants. Section IV draws conclusions and has pointers to a website from which the instructional and assessment materials for the academy can be freely downloaded.

II. MOTIVATION, RELATED WORK, CONTRIBUTIONS

Although demand for computing professionals is growing [3], the number of computer science bachelor's and master's degrees awarded has sharply decreased sharply from the 2004 levels, and the proportion of bachelor's degrees awarded to women has declined over the last ten years [4].

Many organizations have hosted academies that attempt to engage students in computing at an early age by exposing them to fun applications. Robotics is one such application that has been used extensively. A sample of current robotics camps includes Arizona State University's two-week 9Up RobotCamp [5], University of Houston's Girls Reaching And Demonstrating Excellence ('G.R.A.D.E') week-long day camp [6], and the University of Utah's five-day Graphics and Robotic Exploration with Amazing Technology ('G.R.E.A.T') High School Robotics with Arduino camp [7].

Recently, educators have developed game programming platforms to teach introductory computing concepts. Games are just as attractive to kids as robots, and they offer several advantages. Game programming platforms are easier to install and maintain compared to robotics. In addition, many game programming platforms are free. Therefore, game-oriented academies can be more readily adopted by other schools. Also, the learning curve on game programming platforms is much shorter than that of robotic platforms, which require application-specific knowledge of sensors, actuators, and robot-specific libraries. This shortens the preparation time for instructors and allows the lessons to concentrate more on general programming concepts. Popular game development platforms used for education include Greenfoot, Alice, Scratch, GameMaker, XNA, and Pygame. A summary of the characteristics of these platforms is found in [8].

Greenfoot is a free Java game development environment that was designed for high school and undergraduate education [9]. A textbook has been written for teaching introductory computer science with Greenfoot [10]. Because it is a free download, Greenfoot is easily accessible to both schools and students. Greenfoot also includes a facility to share one's games with others, which helps to broaden the exposure to a wider audience. Greenfoot supports both graphical development and textual coding in Java. Because it uses Java, Greenfoot gives students a taste of a language that is currently used in many introductory computer science courses. Greenfoot won the Premier Award for Excellence in Engineering Education Courseware in 2010. For all of these reasons, Greenfoot was the platform of choice for the INSPIRED academy.

Several institutions are now using game programming in high school academies. The University of Utah hosts a two-week GREAT High School Advanced Programming camp in which 9th – 12th grade students learn to program games in Python [7]. University of North Texas hosts a one-week Xbox Game Programming Camp that uses Microsoft's XNA and Xbox to teach rising 8th through 12th grade students programming concepts [11]. The two-week residential summer camp at the University at Denver [12] teaches rising 9th and 10th grade students introductory programming using a game-oriented curriculum, Pixels, Programming, Play & Pedagogy (P4Games) with Greenfoot.

Several things set INSPIRED academies apart from others. First, they are organized, taught and assessed by undergraduates. This is beneficial in several ways. It helps to reduce costs and removes much of the burden from faculty and staff who often lead these efforts. The undergraduates can serve as role models to the high school students, demonstrating by example that computing can be for kids like them. The undergraduates themselves benefit from the experience as well, in several ways that will be described later. Second, INSPIRED academies are easy to replicate. Because they are non-residential, short duration, and student-conducted, these academies require relatively small investments in time and money, which makes them relatively easy for others to implement.

III. ORGANIZING, TEACHING AND ASSESSING THE ACADEMY

A. Organizing the Academy

The academy is organized by a team of undergraduates under the direction of faculty mentors. Two undergraduates serve as Coordinators for the academy. Typically one has experience coordinating a previous academy, and the second is in training.

To advertise the event, undergraduates prepare a promotional brochure with application form and distribute it to students and teachers at various outreach events. They also prepare an online application form, online packet of consent forms, and online information on the academy. In addition, they help post notices of the event on community bulletin boards, local online event calendars, and other sites.

The Coordinators are responsible for monitoring applications, selecting high school participants, and communicating with the participants' parents. They are also responsible for lining up undergraduate team members to handle the other tasks involved in preparing for, organizing, teaching and assessing the academy.

Other pre-academy preparations include:

1. scheduling a computer lab where the hands-on activities will take place;
2. making sure the software and data files are properly installed and working on the computers;
3. preparing a folder for each participant that holds the assessment forms to be completed by the kids, the academy schedule, information on the department's computing program, and promotional materials; and
4. putting together a bag for each student that holds the folder, souvenir pens and pencils, etc.

The academy is held on five afternoons during the summer. This schedule fits the needs of kids who often want to sleep late in the summer or work in part time summer jobs. It also fits the schedule of the undergraduates who conduct the academy, many of whom take classes in the morning.

The INSPIRED academies are small so as to allow for a low student to teacher ratio. The size is also limited by the size of the computer lab, which houses 24 computers. In the game programming academy, students work individually on their games, with one undergraduate lending hands-on assistance as needed to a few students.

The schedule for the 2011 academy is show in Table I. Each day's activities include hands-on labs in game programming, a short hands-on lab on creating web pages, and a half-hour break with refreshments and guest speakers. Day three of the academy includes a lab session on Scratch, a drag and drop animation program developed by MIT to teach middle and high school kids programming concepts [13].

In the Cookies 'n' Chat sessions, students talk with guest speakers about careers in computing, preparing for college, and other topics. Our guest speakers typically include alumni who

are working locally in the computing industry, a representative from Admissions, and computing professionals who are members of our Computer Science Advisory Board.

B. Teaching the Academy

Undergraduates create the instructional materials and teach the academies under the direction of faculty mentors. The materials for the Web labs were developed by INSPIRED undergraduates as part of their INSPIRED duties. They were used in previous INSPIRED high school academies and described in [2]. The materials for the Scratch lab were developed by an undergraduate in an independent study course under the direction of the first author. They were used in prior INSPIRED middle school academies and are described in [14].

The game instructional materials for the 2011 academy were developed by a team of three undergraduates as a year-long project supported by a Collaborative Research Experience for Undergraduates (‘CREU’) grant under the direction of the first two authors. The three undergraduates had served as instructors in INSPIRED High School Robotics academies in previous years and used those materials as a guide [15]. The game instructional materials include (1) PowerPoint slides that introduce the computing concepts, (2) instructor folders that contain the source code for the completed games, (3) student folders that contain game source code that must be modified or completed by the students in hands-on exercises, (4) a User’s Guide; and (5) assessment materials. These materials can be downloaded from the following website: <http://javagonegreen.blogspot.com/p/teaching-materials.html>.

One of the CREU students served as instructor for each of the game programming labs. In the labs, the instructor uses a projecting monitor to first introduce and explain the computing concepts and then demonstrate how to apply the concepts in hands-on activities. The students follow along, with other undergraduates lending assistance to the students as needed. A good student to teacher ratio is no more than four to one. The setup is shown in Fig. 1.

Figure 1. Set-up in the Hands-on Labs. Undergraduate leader (left) helps a student (foreground) while undergraduate instructor demonstrates at the front of the class.

In the academy’s first four days, the students work with games created by the CREU students and make modifications/additions to them in directed hands-on activities. On the fifth day, students use the Asteroids game in unstructured exploration with hands-on help.

The games developed by the CREU team are loosely tied into a story line. The story line is that an alien is forced to land on Earth when its ship runs out of fuel. The game for each day is a step towards helping the alien to return home. In the Gathering Biofuel game, the alien stops on Earth to gather biofuel in the form of bananas. When the alien returns with the bananas, it finds that the Spaceship Acquisition CREU (excuse the pun) has stolen the ship. The player must solve the Sudoku game to unlock the door to the SAC fortress. Once inside the fortress, the player must help the alien navigate a Maze to get to the spaceship. Then the player must help the alien sneak past the sleeping SAC agents in the Agent Sweeper game. Once the alien has its ship again the player helps it to travel home safely by dodging and shooting Asteroids.

The topics covered in the game programming labs include an introduction to Java and Greenfoot, arithmetic and Boolean operations, control structures, data structures represented as arrays and matrices, and object oriented programming. The concepts, corresponding hands-on activities, sample quiz questions and scoring rubrics for each day are summarized in Table II.

TABLE I. SCHEDULE FOR 2011 INSPIRED ACADEMY

| | 1:00 – 2:45 | 2:45 – 3:15 | 3:15 – 4:30 | 4:30 – 5:00 |
|----|--|--|---|-----------------|
| M | Opening Session, Introducing Greenfoot | Cookies ‘n’ Chat Computers in Medicine | Programming lab, Your first game: Gathering Biofuel | Web lab |
| Tu | Programming lab, The game of Sudoku | Cookies ‘n’ Chat Computers in Business | Programming lab, Sudoku | Web lab |

| Th | Programming lab, AgentSweeper | Cookies ‘n’ Chat Computers in Science | Programming lab, AgentSweeper | Web lab |
| F | Programming lab, Asteroids | Cookies ‘n’ Chat Preparing for College | Programming lab, Asteroids | Closing Session |

C. Assessing the Academy

Undergraduates participate actively in the assessment of the academy. The undergraduates develop content-based quizzes for each of the labs, as well as rubrics that are used to score the quizzes. Two undergraduates independently score each of the high school students’ quizzes using the rubrics. The undergraduates’ scores are analyzed to determine inter-rater reliability of the instruments. The instruments are refined as needed to improve reliability.

The high school participants complete the content-based questionnaires before and after participation in each lab module. A t-test is performed on the pre- and post-participation scores to assess whether they have learned the concepts.

The three CREU students developed the content-based quizzes and scoring rubrics for the game programming labs.

These materials were reviewed and refined by other undergraduates on the INSPIRED team prior to their use in the

academy. Table II shows a few samples of concepts, quiz questions and scoring rubrics used to assess learning.

TABLE II. CONCEPTS, HANDS-ON ACTIVITIES, AND SAMPLE QUIZ QUESTIONS AND SCORING RUBRICS FOR EACH DAY

| Day 1 | | |
|---|---|---|
| Concepts: <ul style="list-style-type: none"> Intro to Java and Greenfoot Classes, API, objects | Hands-on activities: <ul style="list-style-type: none"> Create a banana object and set its location Rotate an image by incrementing a variable and calling a method | Sample quiz question and scoring rubric: What are the three main types of classes in a Greenfoot scenario? Score: (cumulative) 1 point each: World, Actor, and Other classes |
| Day 2 | | |
| Concepts: <ul style="list-style-type: none"> Data types Arithmetic, Boolean, relational operators If statement | Hands-on activities: <ul style="list-style-type: none"> Work with integer arithmetic Work with Boolean operators Work with if statements, Boolean and relational operators Write get and set methods Import images | Sample quiz question and scoring rubric: boolean aBoolean; boolean anotherBoolean = false; aBoolean = false; //What is the value of "aBoolean" ? false aBoolean = true; //What is the value of "aBoolean" ? true aBoolean = anotherBoolean; //What is the value of "aBoolean" ? false Score: 1 point awarded for each correct answer, for a total of 3 points |
| Day 3 | | |
| Concepts: <ul style="list-style-type: none"> Sequence Selection Repetition | Hands-on activities: <ul style="list-style-type: none"> Write complex conditional statements, nested ifs Use a switch statement Work with the while loop | Sample quiz question and scoring rubric: Name 3 repetition structures used in Java Score: (cumulative) 1 point each: while, do-while, for |
| Day 4 | | |
| Concepts: <ul style="list-style-type: none"> Arrays, matrices Nested for loops | Hands-on activities: <ul style="list-style-type: none"> Use images in Greenfoot Create an array Create, initialize, manipulate a matrix | Sample quiz question and scoring rubric: What repetition structure can be used to fill an array/matrix? Score: 2 pts - for/nested for 1 pt - while, do-while, or something along the lines of having to set the values in the array/matrix manually 0 pts - anything else |
| Day 5 | | |
| Concepts: <ul style="list-style-type: none"> Objects, classes Inheritance | Hands-on activities: <ul style="list-style-type: none"> Create private variables Create a constructor Practice with nested if statements Manipulate images in Greenfoot Detect collision in Greenfoot | Sample quiz question and scoring rubric: An object is defined by a class A class is the model or blueprint from which an object is created. Score: 1 point awarded for each correct answer., for a total of 2 points |

In addition to the content-based quizzes, the high school students also complete pre- and post- academy questionnaires that measure students' self-reported interest, confidence and knowledge of computing. The post-academy questionnaire also asks students what was their most and least favorite part of the academy, what can be done to improve the academy, and what they plan to do with what they learned. A sample questionnaire is shown in Fig. 2.

D. Preparing Students for their Role in the Academy

Faculty mentors direct students in the design and creation of instructional materials for the academy. The materials for the Scratch lab were developed by an undergraduate in an independent study class in the summer under the direction of the first author. The Web lab materials were developed by INSPIRED students under the direction of the second author. The game programming materials were developed by a team of three CREU undergraduates during one academic year under the direction of the first and second authors. The third author held an initial training session on the design of content-based quizzes and scoring rubrics used for assessment and instructed

the students on the procedure to use in scoring the quizzes independently.

After these initial faculty-led efforts peer instruction is used extensively to prepare students for their roles. The undergraduates who will teach the labs hold training sessions for other undergraduates who will provide hands-on help to the high school participants. These sessions also give the instructors practice and feedback that they use to improve their teaching skills. The typical progression is for an undergraduate to start participating as a student helper and progress to being an instructor. Similarly, undergraduates who have experience creating, grading and refining assessment quizzes train others who have no experience, and the same progression from trainee to trainer holds. Coordinators are typically students who have participated in previous academies in several different roles. Because Coordinators have many responsibilities, two undergraduates serve as Coordinators for each academy: one experienced and one in training to become the lead Coordinator in the next academy. The peer learning approach is not only effective but also helps develop friendships and can engage and help retain the undergraduates [16]. It also relieves the faculty

mentors of much of the burden of preparing students for the academies.

IV. ASSESSMENT RESULTS

Eighteen students from nine area schools participated in the 2011 INSPIRED Game Programming Academy, including eight girls and ten boys. Eleven of the eighteen were underrepresented minorities.

The third author, a Psychology faculty member with extensive experience in program evaluation, analyzed the assessment data. The results are reported here.

Significant gains in knowledge were documented through the content quizzes in all of the sessions for game programming, Scratch, and web page development (Table III). Strong internal consistency was noted among all of the content quizzes as well with correlations ranging from 0.709 to 0.988.

Participants reported a significant increase in knowledge as measured on the pre/post academy questionnaire ($t=6.84$, $p<0.000^*$), and 81% of students reported an increase of interest in computer science as a result of participation in the academy. Another meaningful outcome from the high school academy was that 81% of the participants reported that they would take a computer science course either in high school or college, if offered, as a result of their experience.

Here are some comments from the high school participants:

- *"Today was fascinating!"*
- *"I liked how we learned to edit certain programs in simple games."*
- *"It is very interesting and inspiring."*
- *"I enjoyed working on game programming."*
- *"I liked learning about the for-loops for the matrix squares."*
- *"The camp is interesting and I have been taught more stuff than I've learned in the school year"*

The academy not only benefits the high school students but also has an impact on the undergraduates who led the academy. The experience benefits the undergraduates in several ways:

1. They get valuable experience in teamwork, organization, leadership and taking responsibility. For some it is the first event of any significance for which they have been responsible.

TABLE III. 2011 HSA CONTENT QUIZ RESULTS

| Day | Content Area | t score | p value |
|-------|----------------------------|---------|-------------|
| Day 1 | Game Programming Session 1 | 8.60 | $p<0.000^*$ |
| | Web Session | 6.866 | $p<0.000^*$ |
| Day 2 | Game Programming | 6.43 | $p<0.000^*$ |
| | Web Session | 5.10 | $p<0.000^*$ |
| Day 3 | Scratch | 3.74 | $p<0.002^*$ |
| | Game Programming | 5.08 | $p<0.000^*$ |
| Day 4 | Game Programming Part 1 | 5.70 | $p<0.000^*$ |
| | Game Programming Part 2 | 5.51 | $p<0.000^*$ |
| Day 5 | Game Programming Session | 5.05 | $p<0.000^*$ |

* Indicates significant results

Figure 2. Sample post-academy questionnaire used for assessment

2. The instructors get experience teaching and making technical presentations and demonstrations. The process of explaining concepts to the high school kids helps the instructors and undergraduate helpers solidify their knowledge and hone their communication skills.
3. The undergraduates gain the satisfaction of helping others.

These are educational experiences that are not often encountered in the classroom.

Here are some comments from the undergraduate participants:

- “I had the opportunity to help introduce people to some topics that are a bit difficult to grasp at first.”
- “It was additional practice at teaching computer science...”
- “I learned how to talk to students so they can have a better understanding about programming”.
- “I learned that I still need more practice teaching computing concepts.”

V. CONCLUSIONS AND FUTURE WORK

A five-afternoon academy with hands-on activities in game programming can not only be effective in teaching introductory programming concepts to high school students but can also help increase their interest in computing and interest them in taking computing courses in high school or college. With initial guidance from faculty mentors and extensive use of peer instruction, undergraduates can conduct these academies, from developing instructional materials to advertising, organizing, teaching and helping assess the impact of the academy on participants. This experience in turn can help develop the undergraduates by giving them valuable experience that can increase their teaching, communication, organizing, teamwork, and leadership skills.

Because the game software is free and students conduct the academy, the cost is kept low. This short duration five-afternoon academy also takes a relatively small commitment of time and resources. All of the game instructional and assessment materials can be freely downloaded from: <http://javagonegreen.blogspot.com/p/teaching-materials.html>. It is hoped that this will encourage others to host an academy and continue the effort to increase participation in computing.

Future work will focus on using the game programming materials in other settings and further refining them. The first of these is a two-week residential high school mathematics academy to be hosted by Lamar University in summer of 2012. This academy will target females, underrepresented, or economically disadvantaged students rising to grade 10 or 11 who have a strong interest in exploring mathematics and science. In the 2012 computing academy, the material will be taught by two computer science undergraduates in a series of seven two-hour sessions with a 15-minute break in the middle.

The undergraduate teachers will use feedback from a formal assessment of the 2012 game computing academy to make improvements to the instructional materials as needed.

ACKNOWLEDGMENT

The game instructional materials for the academy were developed by Lamar undergraduates Kathlyn Doss, Valerie Juarez, and Daniel Vincent in a project supported by a CREU grant under the direction of the first two authors.

Abstract - *Computational thinking (CT) does not require profound knowledge of computer science (CS). Vice versa, it helps students organize and build up new knowledge around the core CS concepts they encounter on the daily basis. Furthermore, CT provides a set of problem-solving skills and enhances analytical abilities that are crucial for the young generation to succeed in modern world pervaded with technology. Teaching the principles of computing to students with non-computing tracks of study provides them with a competitive advantage and breaks down stereotypes around CS. Our approach is to introduce a topic related to world issues and students' interests while concealing its relation to CS until students' interest and attention are captured. The approach takes advantage of pattern-matching abilities that are naturally wired in our brain to improve understanding and make the obtained knowledge persist in memory. The paper discusses some of the modules developed as part of the Inspire-CT project that can be delivered in one or part of a class period at high school or middle school.*

Keywords - computational thinking; Fault Tree Analysis.

I. INTRODUCTION

CT gives students the freedom and flexibility in finding new effective solutions supported by analysis and validation of the results. It helps students decompose the problem into manageable steps, employ abstraction to deal with complexity, recognize patterns and create scalable algorithms to solve real world problems. Another important skill associated with CT is the ability to collect and analyze data using proper tools and techniques to derive meaningful conclusions. CT is interwoven with numerous scientific fields such as mathematics, physics, biology, chemistry, economics, sociology, and, of course, engineering disciplines. One of the goals of the project is to reveal the benefits of CT to non-computing students. Middle and high school students often neglect computer science, as it seems overly intricate and tedious, and not relevant to their field of study or interest. However, the ubiquity of technology makes computational thinking a necessity and source of novel solutions.

The developed modules present CS concepts under the cover of the world issues and/or students' interests. However, the relation to CS is concealed until the very end of discussion. Some of the modules start with a recent exciting, intriguing, or even disturbing events supported with abundant visual materials, such as a nuclear disaster, or a skydiver that will free fall from 120,000 feet and break the sound barrier. Modules focus on the core CS concepts that even non-computing students have a prior knowledge of without being consciously

aware of it. Students encounter these concepts on a regular basis, e.g. when playing video games, using Facebook, searching for a movie on Netflix, etc. Such relevant emotionally charged information better captures and holds students' interest and attention and makes it more memorable. Creating associations between real life events, students' experience, and underlying CS concepts helps students' learn foundations of technology with minimum knowledge of science and math.

II. FAULT TREE ANALYSIS AND CHEMISTRY

Working with our collaborating high school teacher, we decided to deliver the first CT module as part of 10th grade chemistry class. Given this requirement, and the recent nuclear accident in Japan we decided to use Fault Tree Analysis (FTA) [1] for our first module. FTA is a technique widely used in safety-critical systems engineering for root cause analysis, risk assessment and design safety assessment. Fault tree is a graphical representation of events and conditions within a system that can lead to a top-level undesired event. We chose FTA for two reasons: 1) FTA is based on fundamental computing and mathematical concepts including Boolean algebra and logic, logical gates, set theory, probability, reliability, redundancy, etc. 2) FTA can model a wide range of systems, it is intuitive and easy to apply, and it finds practical application in the real world.

The module starts with a brief review of nuclear chemistry. It uses real life examples to demonstrate that nuclear energy can be extremely dangerous if not handled properly. To underline the significance of proper management of safety-critical issues the module presents two examples of the nuclear plant accidents. The first example is a recent accident that occurred in Fukushima in Japan. The second example presents Chernobyl disaster that occurred in the Ukraine in 1986. The module discusses weaknesses of the structure, operational failures, and concatenation of circumstances that led to the tragic events.

The module proceeds to basic scenarios of the potential system failure [2]. The examples focus on a water pumping system as one of the critical systems that supplies coolant to the reactor. At a high level of abstraction the system consists of an inexhaustible water source, two pumps, and a valve to supply water to the reactor. The first scenario discusses a condition when a pair of pumps fails. Because of the pump redundancy, a possible way the system could fail is if both pumps fail to run. Using simple blocks, Fig.1 illustrates the AND relation between these two events.

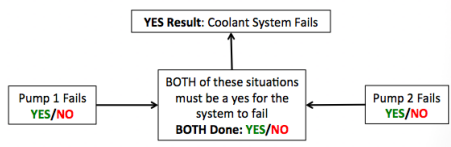

Figure 1. Failure scenario 1.

The next scenario represents OR relation between events. The water pumping system could fail if the valve fails to open or if the coolant supply is lost (Fig. 2).

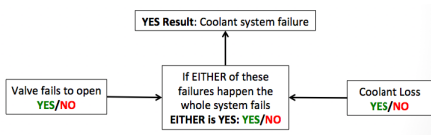

Figure 2. Failure scenario 2.

Next, students are introduced to Boolean numbers by substituting initial “yes” and “no” evaluations for computer science terminology such as “high”, or “1”, or “true” and “low”, or “0”, or “false” respectively. Additionally, natural language descriptions of potential failures are replaced with logical AND and OR gates. Two scenarios illustrate the difference between two types of gates from reliability standpoint. Based on previously discussed definitions of logical gates, the students were asked to fill out the truth tables and discuss their results with class.

Next step is to compile the failure scenarios into a single fault tree, and ask the students to come up with sets of events that can lead to system failure. Without knowledge of probability and reliability theory, the students intuitively came to the conclusion that probability of occurrence of multiple events simultaneously is less than that of an individual event. Therefore, AND gate- are intuitively more reliable than OR gate connections.

To consolidate FTA knowledge in practice, we asked the students to create a fault tree for a game console. We divided the class into groups of 3-5 students. Each group focused on causes of some common error conditions and relations among them, e.g. a console does not produce the sound, controllers fail, game does not load and so on. Upon completion of work in groups, representatives from each group compiled their resulting fault tree analysis on the board, and share their logic with the classmates. A tree representation helped the students diagnose faults that can cause the entire system to fail, estimate their likelihood and severity, and analyze overall reliability of the system based on the types of gates.

The preliminary results of the exercises are as follows: 1) over 50% of students volunteered to share their work with class; 2) the level of creativity and details of some of the solutions greatly exceeded our expectations; 3) almost all students actively participated in the class and team discussions, 4) over 3/4 of the students achieved 100% grade on their Boolean logic/FTA quiz, and 5) upon the completion of the module students expressed their willingness to participate in such

activities more often. According to the teacher, the degree of participation and level of participation greatly surprised him.

III. CURRENT AND FUTURE WORK

We are currently working on adaptation and introduction of other modules, and collection and analysis of results in order to obtain more accurate evaluation of both short- and long-term educational value of the developed modules. One of the modules explains the concepts of a set, Boolean, stack, queue, graph, database, etc. in relation to Facebook functions and structure. In another module, the concepts of an algorithm, searching, sorting and flowcharts are revealed during the discussion of how YouTube, Netflix, and Google search for artifacts. Another module covers physics concepts of speed, velocity, acceleration and rate and presents the story of a skydiver that attempts to break the world record and jump from 120,000 feet. Students collect and analyze data about the jump in Microsoft Excel. Next, the module shows the relation between speed in physics and rate in music, which leads to an exercise where students are asked to compute the size of a music album knowing the duration and rate of each song, thereby highlighting the concepts of algorithm, data storage, and compression techniques.

IV. CONCLUSION

CT does not necessarily involve the use of a computer, and it is not merely about “computer literacy”. School students come across CT concepts on a daily basis and, hence, have some prior knowledge of them. Despite this fact, they will most likely spurn CT principles if they are presented in a straightforward manner. Our approach uses the elements of constructivist learning theory combined with emotionally competent stimuli to introduce concealed CT concepts. The modules are presented in the form of a guided exploration supported with numerous hand-on problem-solving activities. Such approach ensures better students’ engagement, makes the material more memorable, eliminates the fear of complexity of CS, and even stimulates curiosity and interest in this field in non-computing students.

Abstract—This work highlights a program that pairs Drexel University graduate PhD students with School District of Philadelphia high school teachers through academic fellowship to enhance the math and science education of high school students through the context of the National Academy of Engineering (NAE) Grand Challenges while concurrently illustrating the global nature of these societal issues. An analysis of survey results generated from the first and second years of the program is made public with the goal of demonstrating the program's efficacy in increasing: (1) High school teacher perceptions of their engineering knowledge; (2) Graduate student perceptions of their teaching and communication skills as well as their interest in teaching as a profession; (3) High school students' perceptions of what an engineer is and does; and (4) High school student perception of him/her becoming an engineer.

I. INTRODUCTION

The United States is seeing a decline in the number of science and engineering undergraduate and doctoral students, which puts the US at a disadvantage in globalization. Graduate students are at the front-end of cutting-edge research and provide the best opportunity to innovate transformative technologies and to encourage young people to pursue an education in the STEM fields and become productive engineers and scientists. This premise is being explored in a National Science Foundation (NSF) STEM K-12 program in a 5-year fellowship project at Drexel University. The Drexel NSF STEM K-12 program pairs 10 College of Engineering graduate students (Fellows) with 10 School District of Philadelphia high school Teachers to help introduce engineering concepts to high school students through the context of the National Academy of Engineering (NAE) Grand Challenges. The 10 Teachers reside from 5 unique schools that explore multiple student learner types, including: (1) an all girls school (Philadelphia School for Girls); (2) a public Science and Leadership Academy (Science Leadership Academy); (3) a performing arts public school (Girard Academic and Music Program); (4) Central High magnet school; (5) and an urban neighborhood high school (University

City High School). This paper explores the efficacy of the Drexel STEM K-12 program by examining the methods and results of the first and second year assessments of the program.

II. METHODOLOGY

In partnership with Drexel University staff, Combined Resource Solutions, Inc. (CRS, Inc.) designed K-12 program assessments. Assessments include summer session (pre-school year), mid-year and end-of-year surveys for Teachers and Fellows and beginning-of-year, mid-year and end-of-year surveys for high school students. Qualitative and quantitative assessment tools are utilized. CRS, Inc. analyzes all results.

This manuscript will report on the following questions surveyed in year one and year two:

- 1) Teacher perceptions of their engineering knowledge;
- 2) Fellow perceptions of their teaching and communication skills as well as their interest in teaching as a profession;
- 3) High school students' perceptions of what an engineer is and does;
- 4) High school student perception of him/her becoming an engineer.

III. PRELIMINARY FINDINGS

A. Teacher Perceptions of their Engineering Knowledge

Preliminary findings represented in Figure 1 show an increase in teacher confidence in their knowledge of engineering from the pre-summer session survey in Year 1 to the pre-survey in Year 2. Of the 8 Teachers who completed the pre-survey in Year 2, 87.5 have participated in the Drexel K-12 program previously, compared to 0% in Year 1. On average, the teachers in Year 2 have 8.29 years of teaching experience compare to 6.44 years in Year 1. Teachers mostly teach Physical Science, Biology and Chemistry. At the beginning of Year 2, Teachers rated their current engineering knowledge 2.71 on the 4-point Likert scale, which is an increase from 2.33

in Year 1. Figure 1 shows no one selected Poor in Year 2 as compared to 22.2% selecting Poor in Year 1.

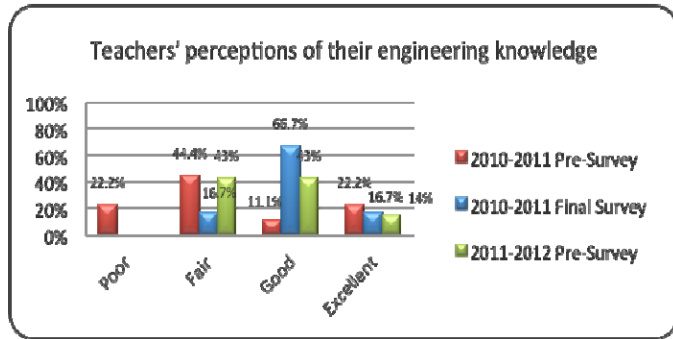

Figure 1: Year 1 and Year 2 analysis of Pre-Program Survey results of teacher evaluations of their current engineering knowledge and Year 1 Pre-survey and Final Survey comparisons.

B. Fellow Perceptions of their Teaching skills as well as their Interest in Teaching as a Profession

All 10 Fellows completed the pre-summer session survey both years. As of Year 2, 70% of the Fellows have participated in the program previously, compared to only 10% in Year 1. All of the Fellows in both Year 1 and Year 2 indicated previous teaching experience, and 90% selected either Interested or Very Interested in teaching as a profession. This results in a 3.10 on the 4-point Likert scale. In Year 2 90% categorized their teaching skills as Good, with the remaining 10% selecting Fair, resulting in a 2.90 on the 4-point scale, which is higher than the 2.30 rating from Year 1.

C. High School Students' perceptions of What an Engineer Does

A total of 248 high school students took both Survey 1 and Survey 2 in Year 1, and 255 took both in Year 2. All students were asked to select all types of problems engineers try to solve. The list was populated with each of the NAE Grand Challenges as well as the additional non-engineering problems. In year 2, the top selection was *Engineer the tools of scientific discovery*, selected by 81.7% of the students. This was also the top pick in Year 1 with 71.7% selection. Both of the top picks in both Year 1 and Year 2 are NAE Grand Challenges. In Year 2, the least selected problem was *Correct grammar in*

newspaper articles selected by 10% of the students, which was down from 10.6% in Year 1.

D. High School Student Perception of him/her becoming an Engineer

From Survey 1 to Survey 2 in Year 1 and 2 there was an increase in the percentage of high school students who selected Yes when asked if they could envision themselves becoming engineers one day. Similarly, there was a decrease in the percentage of students that selected No. Figure 2 represents these results.

IV. CONCLUSION

Overall, data analysis of complete Year 1 surveys and the initial surveys of Year 2 point to the K-12 program having a positive impact on a Teacher's perceived ability to design engineering based materials and to integrate them into the classroom. Similarly, Fellows gain significantly in their perceived ability to engage the classroom and develop a greater interest in professorial or teaching professions. High school students are presented with a context for their STEM education via the NAE Grand Challenges and develop an understanding of and increased desire to pursue careers in engineering.

V. FUTURE WORK

Prior to the end of Year 2, high school demographic data will be collected from the Teachers so that results can be analyzed by gender, race/ethnicity, standardized test scores, attendance records and GPA. This will enable the program to report on the efficacy of the NAE Grand Challenges as a high school learning tool for multiple student learner types.

ACKNOWLEDGMENT

This material is based upon work supported by the National Science Foundation under Grant No. DGE-0947936. We would also like to thank the Drexel University Department of Electrical and Computer Engineering and College of Engineering as well as the School District of Philadelphia. Many thanks to all Drexel GK-12 partnership schools, Teachers, Fellows and project co-investigators for your efforts.

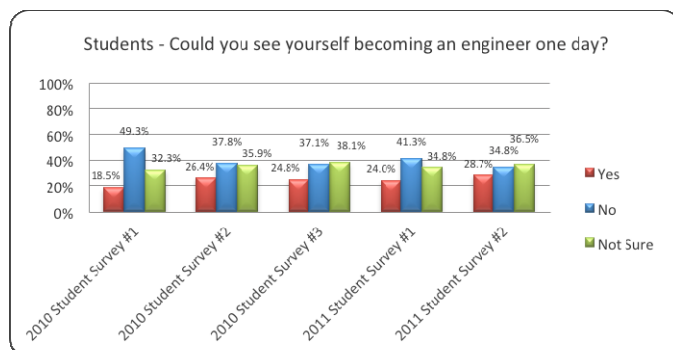

Figure 2: Year 1 and Year 2 comparisons for Survey 1 and Survey 2 data of high school students' responses to if they can see becoming an engineer one day and Year 1 comparisons for Surveys 1, 2 and 3.

“Inform, Experience, Implement” – Teaching an Intensive High School Summer Course

Ryan Layer, Mark Sherriff, and Luther Tychonievich

Department of Computer Science

University of Virginia

Charlottesville, Virginia 22904

Email: {rl6sf, sherriff, lat7h}@virginia.edu

Abstract—During the summer of 2011, twenty-four high school students participated in an intense, three-week computer science course at the University of Virginia. The course met for twenty-one three-hour sessions, thus encompassing more contact time than a standard college-level course. The course was structured in an “Inform, Experience, Implement” active-learning format: students were exposed to the history of a particular problem in context and participated in an active learning lesson regarding the topic before learning how to address the examined problem through programming. This structure helped integrate into the course best practices from experiential learning, kinesthetic outreach activities, and active learning pedagogy. Utilizing this three-part rotation curriculum achieved some important goals, including holding the interest of students during the summer for six hours a day and successfully motivating students who had no programming background.

I. INTRODUCTION

Diversity continues to be a challenge in many Computer Science departments [1]–[5]. While work is ongoing in fostering diversity inside existing CS programs, many have noted that early exposure to computing, such as in middle school and high school, is essential in eliminating many of the stereotypes and misconceptions about computer science and thus helping to improve the numbers of incoming students into the discipline [6], [7]. However, many middle schools and high schools lack the resources and personnel needed to run such programs during the school year. To help fill this gap, numerous computing summer camps have cropped up at universities around the United States sponsored by various companies and organizations.

One of the main difficulties faced by computing summer camps is in creating a curriculum that can hold students attention for several hours a day, particularly during a time that they are accustomed to spending in more leisurely pursuits. Some summer camps minimize this difficulty by recruiting students that already have some familiarity and fascination with computing. While teaching such students in a concentrated learning environment is both exciting and rewarding, not every summer program has students that come in with that level of familiarity or drive. Indeed, these pre-motivated students are the ones who least need the early outreach of a summer camp in order to choose a computing field.

We embarked on creating a curriculum for students without prior interest in computing during the summer of 2011 at the

University of Virginia. Our camp consisted of 24 fifteen-year old students from traditionally underrepresented demographic groups in computer science. All but two of these students had no programming experience whatsoever and mainly came to the program out of curiosity. Further, we were to have these students for six hours a day, separated into two three-hour blocks, over the course of three weeks. This equated to more contact hours than a standard three-credit college course.

We faced two main challenges with our summer experience: 1) how to hold a young student’s attention during a traditional break time; and 2) how to cover enough material to make an impact without overwhelming the students.

In this paper, we describe the curriculum that we developed for an intensive summer computer science experience for high school students with no programming background. Our goals in this camp were twofold. First, we wanted to treat the camp as an outreach program, with the goal of building interest and excitement in the students. Second, we wanted to provide the students with practical programming skills and experience they could use in the years that would likely elapse before their next exposure to computing instruction. Thus, we decided to include the kinesthetic activities that have been shown effective in outreach, the student-focused educational techniques that have been shown effective in internalizing knowledge, and some degree of direct instruction as the students would not have the time to investigate course topics on their own before experiential instruction. We combined these elements in a curriculum that was based around the mnemonic of “Inform, Experience, Implement”, where our instructional style progressed from contextual history lessons, through active learning experiences, and ending with programming implementation of various solutions. This methodology allowed us to integrate our various objectives in a direct and accessible way, both building interest and developing skills in the students. We found that keeping this mnemonic in mind through our teaching was an effective method for this age group and experience level combination.

II. RELATED WORK

In this section, we describe related work in computer science summer camps and teaching computer science material in the context of the real world.

A. CS Summer Camps

There have been many studies that indicate computing summer camp programs can increase the interest of females and under-represented minorities in computer science (see, e.g., [8]–[21]) and that have discussed other aspects of summer camp design (see, e.g., [22]–[29]).

We note that there is a breadth of discussion on summer camps in educational venues in part because of the many different potential combinations of student age, experience level, demographics, and affluence, along with the wide varieties in contact hours with the students. For example, Miller et al. describe their one-week camp in Colorado as being targeted specifically for middle school students from low-income families [9]. Meanwhile, Carmichael created a day camp specifically for girls in the realm of video game development [15]. Camps range from one to several weeks, with students living on campus and off, and with contact hours ranging from one to seven per day. Ages range from ten to eighteen, with some camps specifically for girls, other for boys, and others still for students that are from underrepresented demographics in computer science.

Our goal is to add to the growing body of knowledge on how computer science educators can successfully run a summer experience for younger students. We feel that our experience is unique from the others in two distinct ways. First, our number of contact hours was greater than the other camps that we examined, totaling more total contact hours than a standard three-credit college course. We believe that our experiences with a camp of this scale can help other instructors tailor their own efforts effectively. Second, our students came from many different cultures and locations. We had students from across the country, not just local to Virginia, and all were from traditionally underrepresented demographics in computer science. Only two of our students had any programming experience prior to coming to the camp.

B. Teaching CS in Context

Teaching computer science in the context of computing problems is something that has been debated in CS education. The argument for contextualized CS education focuses on the idea of grabbing the interest of the student and using that hook to then introduce various computing topics. If the context is “good enough,” then students are more likely to stick through a CS course and go on to a second one [30], [31]. The counter-argument states that students learn computing topics regarding that one context and that introductory students have a difficulty abstracting the concepts that they have learned to be able to apply them to other problems. Further, teaching the context takes up valuable lesson time, which might be spent on covering possibly more advanced programming topics that could have the same luring effect as the problem context [31].

Guzdial argues that if students don’t learn the material in the first place, then they won’t have the opportunity to transfer what they learned from one context to another [31]. Thus, if teaching in context helps students decide to stick with CS where without such context that would leave the course, then

there is a net gain. The main idea behind this and other contextualized instruction arguments is that students want to know why what they are learning is relevant and useful [31], [32].

The desire to teach computing in context is almost axiomatic in summer camp and enrichment programs, with camps focussing on such topics as robotics [11], games [15], [23], [24], [26], publishing [16], web development [20], [21], fashion [14], and creativity through computing [10], [29], [33] to name just a few. We likewise found this desire to understand relevance manifest with our group of high school students. With this age group and experience level, we quickly determined that if we did not provide them with context early on, attention and interest waned.

We had six hours a day with the students which allowed time to cover both the context and the programming in reasonable depth. Our “Inform, Experience, Implement” concept came specifically from the mentality that we had to sell the students on the problem first, have them experience the problem personally, and then learn how to solve the problem through programming.

Multiple studies have argued that mixing various media and motivated examples improve student involvement and learning [33]–[37]. These fit into broader trends in science education to engage students in the learning process through various problem-oriented and student-directed learning structures [38]–[42]. Recent studies have also observed that some activities that have been shown to engage students are not well suited to teaching computing at a deeper level [43], [44], suggesting there may be additional value in mixing instructional approaches.

The main challenge we faced was in devising a structure that would allow us to easily integrate teaching the context of problems, instructing students in core elements of programming, and utilizing kinesthetic, inquiry-based, and student-directed learning. We developed the mnemonic “Inform, Experience, Implement” as a tool to help guide our lesson development, providing a framework that aided our lesson planning to give students opportunities to engage through classroom instruction, learning activities, and programming experience.

III. THE COURSE

In this section, we describe our curriculum and provide an example lesson that we used during the course.

A. Overview

The goals of the 2011 summer program at the University of Virginia were to instill excitement in students about computer science and to provide students with a solid foundation in a production-level programming language, Python. We selected the Python programming language because we believed it balanced accessibility and power. The interactive command shell allowed students to dive directly into programming without the added complexities of editors, interpreters, and environment setup. The students easily moved from typing

short commands in the shell to writing programs in text files as the commands became too long for comfortable shell use.

Our 2011 class had 24 rising high school sophomores and juniors from seven states. A large majority of the students identified themselves as having no or very little programming experience, a small portion had experience with HTML, and two students had a working knowledge of at least one programming language. For three weeks, our students lived in on-campus dorms, attended classes, went on field trips, and completed nightly homework assignments. Their typical day consisted of two three-hour classes and a two-hour study hall session. In total, students attended 21 three-hour-long classes, totaling more contact hours to a standard college course. In addition to class-based instruction and assignments, students worked in small groups on a final project that they presented to a representative from our corporate sponsor on the last day of the program.

B. Staff Composition

The course was taught primarily by one CS faculty member and two graduate students with significant teaching experience. Other CS faculty members and grad students were brought in for either a full three-hour session or a half session to cover a lesson in their particular research area. By splitting up the teaching and having several guests speak on their expertise area, we were able to avoid over-utilizing any particular instructor and kept the instruction fresh for the students. Guest instructors framed their lectures however they liked, with the main instructors of the program arranging the schedule such that the “Inform, Experience, Implement” rhythm was continued.

C. Course Content

One of the messages we wanted to convey to the students is that computing is a broad and enabling field that impacts every aspect of the modern world. To this end, we touched on many topics, including cryptography, GPS and mapping, the Internet, artificial intelligence, game programming, and scientific computing. Additionally, we had pairs of students team up to create projects to show off at the end of the course, and provided time for problem-based learning to accomplish that goal. A full outline of course topics can be found at <http://stardock.cs.virginia.edu/lead>.

We included the “Inform, Experience, Implement” approach within each topic, but not always in a straightforward sequence. For example, in game programming we used extreme programming to repeatedly iterate from experiencing a functional but incomplete game to discussing how it could be improved and implementing those improvements. Another example of adjusting the design is path planning, where we did some of the implementation in advance and used it to increase the learning during the subsequent experience activity.

IV. EXAMPLE LESSONS

To better illustrate how our mnemonic of “Inform, Experience, Implement” informed our course creation, we provide

several example lessons from our camp. A full course schedule and outlines of other lessons may be also be found at <http://stardock.cs.virginia.edu/lead>.

A. Cryptography

After a couple basic introductory lessons, we began the “Inform, Experience, Implement” methodology by teaching cryptography.

The “Inform” lesson was organized around the history of cryptography. The first hour introduced the concepts of encryption and decryption, starting with classic ciphers such as Caesar, pigpen, and Vigenère. Students worked in teams to encode and decode simple messages provided by the instructor. In the second hour, the instructor described how modern computing has cracked classic ciphers through brute force, frequency analysis, and other similar techniques. Students then learned how cryptography has evolved, looking at modern schemes such as RSA. The third hour the students developed their own encryption schemes. Each pair of students was given a standard deck of playing cards. The pairs had to come up with their own encryption methodology, write down a detailed algorithm of how their scheme worked, and then encode their deck of cards to send a message to another pair. Thus, the “Inform” activity in this case actually ended with teaching a lesson about how to write basic algorithms for others to follow.

The “Experience” lesson began during the next morning’s three-hour block. As the students had not yet seen most of the campus, a scavenger hunt was arranged for them to find various clues around the grounds. However, each clue was encrypted with a different scheme, some from the day before and some that they had not yet seen. This lesson both gave the students a well-needed active exercise to get their mind focused for the afternoon and emphasized examining and applying new algorithms in a repeated fashion.

During the afternoon’s “Implement” block, students were asked about the encryption schemes they used. Several students noted that doing Caesar cipher shifts by hand was tedious and that they wished there was a way to automate the process. Similar sentiments were expressed with the other ciphers as well. This desire motivated our introduction of the concepts of strings and loops as we showed the students how to write programs that could encrypt and decrypt these cyphers more rapidly and more reliably than the students could do by hand.

B. GPS and Maps

Another good example of our curriculum pattern is a lesson set on GPS. The “Inform” lesson began with a history of celestial navigation using a sextant and worked up through modern GPS technology. Particular attention was paid to the impact software has had on navigation, including algorithms to deal with errors such as skew and jitter. Students also learned about the great circle distance formula used to find the shortest distance between two points on the surface of a sphere, and calculated several distances by hand.

For the “Experience” lesson, students used Android-powered smart phones to map buildings on grounds. Each

smart phone ran a simple custom application that continuously displayed the current GPS coordinates, had a button to add the current coordinates to a list, and another button to email the coordinate list to the user once the activity was completed. Students were divided into teams, and each team was given a list of buildings to map. While the list of buildings each group of students mapped were unique, each building was mapped by at least two groups. This organization allowed the full set of points to be combined into a larger map, and the duplicate points demonstrated issues with GPS coordinate gathering.

In the “Implement” lesson students learned to read data from a file, graph points, and implement custom functions. Prior to this point in the class, each values had been either hard-coded or read from the keyboard. The long list of coordinates, where each coordinate consisted of many characters, motivated the need for file input. Once the coordinates were read from the files, students learned to graph points on the screen and connect points to form shapes. The class combined coordinates from all groups to form a rough map of grounds. Finally the class wrote a function that implemented the great circle distance formula. Later on in the camp, students also used these coordinates when learning about optimal paths as we had them act out the traveling salesman problem by delivering “packages” to buildings on campus.

V. DISCUSSION

As an instructional staff, we took several lessons from this experience.

A. Classroom Management

We found managing class time was challenging. A typical day in our course consisted of two three-hour sessions with an hour lunch break between sessions. In our experience, few students enjoy sitting through courses lasting more than an hour, and college instructors typically lack experience managing three-hour class periods. A partial solution was to split each three-hour session into two sessions separated by a short break. However, we found it difficult to make breaks long enough for the students to relax and take care of personal business while still short enough that the students didn’t lose focus and initiate lengthy social activities. The most effective counter to this problem was having lessons that were more active and open (“Experience” lessons), which helped the students to feel that they were not trapped in the lab.

PowerPoint slides were not an effective teaching tool for this type of course. We first tried having slides that contained both definitions of various Python concepts and annotated examples of Python code for the students to type in and experience. While the students fully participated in typing in the code, there was a clear disconnect between the slides and the programs. Many students focused on entering the list of commands, not on understanding the commands and the relationship between commands and results.

Because of this disconnect, we switched to executing the commands along with the students. This switch gave us more flexibility to demonstrate the dynamics of each command and

made it easier to field questions from the students. After the switch from slides to the command environment, we polled the class about the two styles, and the students overwhelmingly preferred the command environment.

One drawback of using the command environment instead of slides is the inability to annotate commands. Without annotations, all our explanations were verbal and students who were learning at a slightly different pace sometimes missed our explanations. While it may be possible to use both environments, we found that switching between slides and the command environment was cumbersome and disruptive.

B. Student Participation

The rotation between “Inform” lessons, “Experience” lessons, and “Implement” lessons had several positive effects. First, the students stayed engaged during the three-hours lessons. Putting problems in context and making the assignments meaningful did have a significant effect on the group. Knowing that an active learning session was coming up seemed to keep them more attentive during the lecture and lab sessions. By the time we got to an “Implement” session, students were eager to try out their own ideas on how to solve certain problems.

The students reported that game programming was their favorite topic. For their final projects, all but two of the teams created some form of game. Students indicated that the interactive nature of their projects played a large role in why it was interesting to them. Other interesting projects included a networked, chat-enabled version of Tic-Tac-Toe, a quiz application, and an interactive music creation system. The final project teams each gave a formal presentation of their projects to the camp’s corporate sponsor on the last day of the program.

C. Results

The results of our camp experience can be evaluated from at least two perspectives. As instructors, we found that “Inform, Experience, Implement” greatly streamlined the process of creating lesson plans that incorporated kinesthetic activities, problem-based inquiry learning, topical instruction, and practical hands-on experience in many topics within computer science. Recalling the mnemonic allowed us to easily check if a particular lesson plan was likely to include each of these research-backed pedagogical and outreach elements.

The students also seemed to benefit from the course. Three months after the program completed, we sent informal surveys to the students asking about their experience. Results indicate we achieved our goals of motivating students to explore computer science and providing a foundation for further study. Selected results from the survey are below.

- 1) We asked students how comfortable there were with computer programming. On a scale from one (not comfortable at all) to seven (very comfortable), half of the respondents rated themselves as a three or less before the program; 75% of students rated themselves as a six or higher after the camp.

- 2) We asked students to rate how enthusiastic they felt about computing. On a scale from one (not enthusiastic at all) to seven (extremely enthusiastic), half of the respondents rated themselves as a four or less before the program, all picked at least a five and 63% of students chose seven after the camp.
- 3) We asked students if they are more likely to pursue computing in college or a career after the camp. On a scale from one (No!) to seven (Yes!), 88% of the students rate five or higher.

In addition to these statistics, each individual student rated themselves as more comfortable with and more enthusiastic about programming after the camp than they were before.

VI. USE IN COLLEGE COURSES

After the success of the first instance of our course, we looked to find ways to incorporate our methodology into standard college classes. As one of the authors is the primary instructor for Introduction to Programming at the University of Virginia, we felt it best to pilot some of our lessons in this course. Introduction to Programming is a required course for all engineering students at the University of Virginia and is also taken by a large number of students from the College of Arts and Sciences. In a given year, over 1000 students take some version of our introductory course, with around 750 taking this particular version. We felt that this class would be a good fit for the technique due to its diverse population of student backgrounds and interests and the natural fit the methodology would have with a close lab format.

“Inform, Experience, Implement” lessons were conducted on encryption, GPS, and Python programming. For the most part, the lessons were well received. Many students anecdotally reported that they enjoyed doing things outside of the traditional classroom lecture format, particularly when the classroom has nearly 300 students in it. However, there was a vocal minority that disliked being asked to do something that required them to leave the classroom. Student performance on test questions on this material was, on average, similar to other question score distributions. However, as these topics had not been introduced into this class in any other fashion, we cannot draw any conclusions as to whether the technique itself improved learning. We plan to revamp existing course material to reflect the “Inform, Experience, Implement” methodology to make a better comparison in our future work.

VII. FUTURE WORK

As discussed in the previous section, we are branching out to utilize the “Inform, Experience, Implement” methodology in other courses and formats. Besides using the methodology in introductory college courses, we will use the methodology again in the summer of 2012 with the next iteration of our LEAD summer camp. This summer, however, we will be running two one-week courses, thus substantially changing the amount of time we have with the students. Further, our age group is dropping by a grade level, to rising ninth grade students. Our goal this summer is to evaluate the efficacy of

the methodology when compressed into a tighter schedule. We plan to continue to do lessons on encryption, GPS, and Python, while introducing a new topic on robotics using Lego Mindstorm NXT kits.

Early results from the 2012 summer course are generally positive, with student-reported comfort with computing increasing from 2.7 to 5.0 on a scale of 1 to 7, with 7 being most comfortable. We plan to present more complete results from the 2012 camps in the future.

VIII. CONCLUSION

During the summer of 2011, twenty-four high school students participated in an intense, three-week computer science course at the University of Virginia. The course itself encompassed more contact hours than the standard college-level course. Due to the amount of time that students spent in class (six hours a day split into two three-hour sessions), we looked for novel ways to keep students’ interest and enthusiasm high. We found that teaching CS in context for this specific demographic and experience level was highly effective. The course was structured in an “Inform, Experience, Implement” active-learning format: students were *informed* about the history and importance of a particular problem in context, *experienced* the problem in an active learning lesson, and then *implemented* a program that could help to solve the problem. We feel that this three-part rotation curriculum achieved many of our goals, including instilling in students an excitement about computing and also teaching them the basics of a general-purpose programming language.

IX. ACKNOWLEDGEMENTS

We would like to thank the LEAD Computer Science Institute for giving us the opportunity to participate in their summer programs, and Google for their generous support of the program. We would also like to thank Carolyn Vallas, Assistant Dean for Diversity, in the School of Engineering and Applied Science at the University of Virginia for facilitating the summer experience.

Computer Science Learning Made Interactive – A One-Week Alice Summer Computing Workshop for K-12 Teachers

Jiangjiang Liu, Cheng-Hsien Lin, Ethan Philip Hasson, and Zebulun David Barnett
Lamar University
Beaumont, USA

jane.liu@lamar.edu, cheng-hsien.lin@lamar.edu, ephasson@lamar.edu, zdbarnett@lamar.edu

Abstract— In this paper, we present our experience, findings, and lessons learned from conducting a one-week Alice summer computing workshop for K-12 teachers. Our workshop focuses on using Alice, a 3D programming environment, to introduce computing concepts to K-12 teachers in all subjects so that these teachers can pass on their knowledge and inspiration to their students. During the workshop, the teachers developed curriculum materials for the subjects they will teach in the following semesters with the help of our workshop tutors. Workshop assessment results show a 52% increase in confidence level in teaching computer science and a 44% computing knowledge level increase.

Computer and Information Science Education – computer science education, information systems education, curriculum

I. INTRODUCTION

The Bureau of Labor Statistics predicts that the demand for computer and mathematical occupations will grow more than twice as fast as the average for all occupations in the U. S. over the next decade [1]. However, in recent years the number of degrees earned in computer science (CS) has been decreasing. According to the Higher Education Research Institute (HERI) at the University of California, Los Angeles (UCLA), between 2000 and 2005 there was a 50% decline in the number of newly declared CS majors and a 70% decline in the number of incoming freshmen who expressed an interest in CS major [2]. A similar steep decline had been reported in the Computing Research Association (CRA) Taulbee Survey during the 2000's. As a result, we might face a shortfall in the computing workforce in the next decade. Even though the 2008-2009 CRA Taulbee Survey reported a two-year increase of 14% in the total number of undergraduate majors with a broader number of degree programs included in the statistics, the College Board discontinued the Advanced Placement (AP) Computer Science “AB” course following the May 2009 exam administration due to the low participation in that course [3][4]. Therefore, the education crisis in computer science still draws critical attention and compels us to produce more computer scientists.

Computer science educators have tried different ways to attract more students to computing fields: computing camps for K-12 students, outreach programs for K-12 teachers, new teaching tools, changes of policy, professional networks, etc.

In this paper, we present our experience, findings, and lessons learned from conducting a one-week Alice summer computing workshop for K-12 teachers. The organization of the rest of this paper is as follows. We review related work and outline our contributions in Sec. II. Next, in Sec. III, we describe workshop organization including learning objectives, schedules, and lesson plans. Then, in Sec. IV, we discuss our experience and lessons learned throughout the workshop. In Sec. V, we present assessment results. Finally, we conclude in Sec. VI.

II. RELATED WORK AND OUR CONTRIBUTIONS

K-12 teacher outreach programs have been shown to be an effective means of making computer science accessible to those teachers. In this section, we first present successful work that has been done on K-12 teacher outreach to improve computer science education. Then, we discuss our contributions.

A. Related Work

Carnegie Mellon University offered the CS4HS and CSbots programs which targeted high school computer science teachers [5][6]. Many workshop materials are shared on the CS4HS website, and the CS4HS model has now spread to many other universities. In 2010, Marquette University led the “Computational Thinking for the Sciences” workshop, a three-day summer workshop for high school science and mathematics teachers. Lamar University (LU) offered a summer workshop for K-12 teachers in 2010 [7]. The goal of the workshop was to introduce fundamental computer science concepts to teachers. LU also conducted a survey on computer science K-12 teacher training programs in 2011 [8].

Duke University has conducted several Alice training workshops for middle school teachers since 2008 [9][10]. Saint Joseph's University became the site at which the Teacher Enrichment in Computer Science course was based [11]. The course spanned two weeks; the first focused on teaching Alice itself while the second allowed teachers in attendance to develop Alice-based curricula that would engage their students.

The Georgia Institute of Technology put in an effort to improve the aging computer science education pipeline currently employed in the state of Georgia by offering a series of teacher workshops, starting in 2006, to influence CS teaching styles in a positive manner [12]. Half of the

participants reported they had been able to effectively use the knowledge and materials gained from the workshop. Through the medium of bioinformatics, Winona State University conducted a computer science based workshop geared for K-12 science teachers between 2006 and 2008 [13]. UCLA offered a yearly program called the Summer Institute for Advanced Placement Computer Science (APCS) teachers in 2004 [14]. The course consisted of a series of lectures and curriculum development opportunities. As a result of this program, the number of students in APCS courses in Los Angeles Unified School District (LAUSD) tripled.

B. Our Contributions

Our work builds upon some of the successful strategies for teacher workshops mentioned in the related work section, and our main contributions are the following:

1. This workshop, unlike most of the workshops mentioned in the related work, is designed for K-12 teachers of all subjects at all levels. Our goal is to equip teachers in not only computer technology, math, and science, but also English, art, and music so that students of all types would have the chance to experience at least a brief interaction with computing in a form they would be able to understand and use. Most students with an interest in computer technology or other computing-related subjects may have already been aware of computer science as a college major and career choice, but the same cannot be said for students in seemingly unrelated fields of interest. We think that expanding our target group can only increase the number of students who eventually decide to become part of the computer science field and fill those positions the future will desperately need.

2. Our workshop focuses on introducing fundamental computing concepts to ensure the learning objectives of the workshop are applicable to the teaching environment of K-12 teacher participants. Our immediate learning objectives target program structure, flow of program execution, objects, methods/functions, conditional branches, variables, loops, user input, and Boolean logic. With the fundamental computing concepts, workshop participants were able to design and implement their own curriculum materials in Alice within only five days.

3. The afternoon sessions offered curriculum development opportunities to the workshop participants. At the end of the workshop, the participants presented their curriculum project to the other participants and submitted their project materials to the workshop staff; those materials include: Guideline to K-12 Teachers, Project Presentation, Project Introduction, Readme, and Alice project file. The curriculum project presentations were the highlight of the workshop. This allowed the participants to share their curriculum they planned to use in their classrooms, exchange ideas in order to better their own curriculum, and help each other locate issues or bugs that could impair students' learning.

Since the goal of this workshop is to better prepare K-12 students for college, the time devoted to curriculum development is crucial, as it ensures the teachers will be able to use their knowledge of Alice to enrich their students' learning experience. The participants could directly take back the

curriculum projects and use them in their classrooms. The materials are also available on our program website for other K-12 teachers.

4. We designed and developed all five-day Alice instructional materials based on the workshop learning objectives. The instructional materials include PowerPoint presentations, hands-on exercise templates, and projects. In addition, all lecture sections were recorded in video. All instructional materials and videos of workshop sections are available to other outreach programs for download on our website. The instructors of other outreach programs can watch videos to learn the details of each section. The materials could be used all together for a week-long workshop or separately for day-by-day workshops.

5. We worked with a program evaluator and designed assessment materials for the workshop. The assessment materials include a pre-workshop survey, post-workshop survey, and pre- and post-tests for each day of the workshop. All assessment materials are available to other outreach programs if any other programs would like to adopt them for their own use.

III. WORKSHOP ORGANIZATION

A. Learning Objectives and Schedule

In order to help the teachers understand fundamental computing concepts, we compiled the following workshop learning objectives.

- Program Structure and Flow of Execution: be able to identify the start of the program and trace its path.
- Objects: know what makes up an object and how it can be used to simplify program design.
- Methods/Functions: know how and when to create a separate method to accomplish a small, recurring task.
- Conditional Branches: how they affect the normal flow of execution based on the value of a Boolean expression.
- Variables: know how to create, change, and use three basic types of variables—numbers, strings, and Booleans.
- Loops: how they can be used to repeat a sequence of steps until a certain condition is met.
- User Input: how to accept and use data and keystrokes supplied by the user to trigger events, call methods, and store information about the user for later use in the program.
- Boolean Logic: understand core Boolean operands such as NOT, OR, and AND and how they can be used in while loops or conditional branches.

Computing concepts for each session and workshop schedule are given in Table I. Participants worked on the curriculum materials that they would use in the subjects they will teach in the following semesters. On the fourth day, each

TABLE I. WORKSHOP SCHEDULE

| Schedule | Day | | | | |
|-----------------|-----------------------------------|----------------------------|----------------------------|--------------|------------------------|
| | Monday | Tuesday | Wednesday | Thursday | Friday |
| 9:00am-9:30am | Opening Session | AS-2 Conditional Branching | AS-4 Variables | AS-6 Arrays | Curriculum Development |

a. Alice Session.

participant presented and shared his/her work with the other participants in order to get feedback and finish the project on the fifth day.

B. Alice Lesson Plans

The first session, or session zero, was a perfect way to start the Alice workshop. Alice is a 3D programming environment and a teaching tool for introducing computing concepts [15]. All of the participants were attentive and able to follow the simple overview of Alice's interface. There are three main components of an object in Alice and in this session, they were only briefly explained. The instructions were given one-by-one with small explanations in places that were necessary. The program consisted of creating a vehicle object, programming it to move, and programming a wheel to spin at the same time the car was moving. All participants knew exactly what to do and were able to complete this task with little help.

In session one, participants were shown how to gather input from the user and how that input can be used to affect a running program. They were also introduced to the problems that could arise when invalid input is accepted by a program. This type of error is seldom encountered due to Alice's strict types but still can be duplicated in some manner. These concepts, while basic to experienced programmers, were eye-opening to the participants in the workshop, who garnered new-found respect for the programs they use on a daily basis and the programmers who created them. At the same time, the almost magical aura felt by non-programmers when dealing with the inner-workings of computers began to vanish, and they realized that they too would be able to tell the computer what to do in a way they had not dreamed of before.

Session two focused on conditional branching as a way of altering the normal flow of execution in a program based on a Boolean expression. The instructor explained this concept with small snippets of Alice programs. The programs were basic and could easily be understood by simply reading. This was done so the participants could understand how these structures can be used in the simplest of tasks. After the participants were fairly familiar with this concept, the instructor moved on to concept of nested if/else structures. With this knowledge, the participants were able to start work on their question and answer games, using if/else blocks to handle right and wrong answers.

In session three, we introduced the concept of loops in Alice. This had been the missing piece in some of the participant's projects and was quickly adopted to minimize the number of blocks needed and provided functionality not possible without loops. The instructor explained each type of

basic loop found in Alice by constructing a very small example using them. The end of the session project required participants to use nested loops. All participants were able to complete it successfully; however, it did require more time for the participants to fully understand nesting of loops. At this point, the participants began to express interest in seeing how other participants, as well as the instructors, had implemented their designs and they started to appreciate elegant, well-formed programs.

Variables were the primary topic of session four. Participants were introduced to various types of variables. They were also shown how to create, use, increment/decrement, and set variables through the use of multiple examples. By storing input in variables, the participants realized that data could be used more than once in whatever order desired. This session should have been taught before session 1 and contained 2 projects. Most participants did not have time to finish the second project, so they finished it during the curriculum development time. The first project showcased behavior not possible without the use of variables, taking the average of a set of values entered by the user. The second project was slightly more difficult and required the participants to switch the values of two variables.

Session five was considered one of the more difficult sessions. In session zero, the instructor briefly explained methods and functions. In session five, instructors not only explained these concepts in much more detail, but they also taught participants how to design and create their own methods and functions. This new concept was perfect for some participants, but sadly, only a small portion understood methods and functions to their full extent. The participants that did not understand how to create their own method or function became more familiar with doing this during the curriculum development time.

Session six contained the most complex ideas covered in the workshop. Participants were introduced to advanced Boolean expressions and arrays. The AND Boolean expression and the OR Boolean expression were received very well and teachers could instantly see how these expressions could help simplify things in their own projects. However, the NOT Boolean expression seemed quite difficult to explain. Even after several very simple examples, many participants simply said "no" to using it in their own programs, even if they had to create more code to accomplish this. The arrays section of this session was extremely difficult for both the instructors and participants. The data structure as a whole was very simple to understand for them, but the methods of stepping through the array using a loop and an index to access each element

individually were overwhelming. The instructor used a small array to store correct answers to a spelling test and this seemed to work really well. They understood that the loop needed to step through the array and check each value to see if the user answered the question correctly, but they had trouble constructing such a loop on their own.

Lists were discussed in session seven. Everyone was very happy to learn about lists and found them much easier to work with. This was because of the way lists are implemented in Alice. Alice has a loop that steps through a list, exactly the way participants stepped through an array in the previous session. This solved the issue the participants had of not being able to create a loop that would access each element one at a time. Since lists are so similar to arrays, an example wasn't necessary. The instructors only explained the methods and functions that belong to a list, and this was sufficient for participants to understand.

IV. WHAT WORKS AND WHAT DOES NOT

A. What Works

1) *Positive Elements Adopted from Previous Workshop:*

The organization of the sessions was much appreciated by the participants. Based on a concept-by-concept progression, the sessions were fairly easy for everyone to understand and keep up with. The content in each session built on the content taught in the previous sessions, forming a strong framework on which to link related concepts together in order to memorize and utilize them to create the desired program behavior. The projects at the end of the sessions proved to be extremely useful for the participants. This hands-on experience was necessary to solidify the concepts in their minds while at the same time, causing them to feel good about themselves when a project was completed successfully. Curriculum development time was sometimes used as an extension of the session project development time to complete difficult projects or modify existing projects in creative ways that often could then be incorporated into curriculum ideas.

Participants were strongly encouraged to apply concepts they had learned during the morning sessions to projects they felt would be useful in their respective classrooms. Since the goal of this workshop is to better prepare K-12 students for college, the time devoted to curriculum development is crucial, as it ensures the teachers will be able to use their knowledge of Alice to enrich their students' learning experience. This opportunity turned out to be the high point of the day for most participants and gave them a chance to really put their new knowledge to work. Project ideas were very creative and often incorporated characters, stories, animations, and sounds. Some of the final projects are summarized in Table II.

2) *Successful Changes from Previous Workshop:*

We adopted the successful strategies in our previous workshop and did our best to correct or avoid the elements it claimed did not work so well. In this section we detail three elements that were not successful in the previous workshop but were more successful in the current workshop.

Of the three, the biggest improvement has to be focusing on teaching just one program. In the previous workshop, we

introduced both Alice and Scratch in the same week which proved to be overwhelming for most participants. This year, we alleviated the problem by focusing on just Alice for the entire workshop. With this much simpler schedule, the participants were able to make more progress on their curriculum projects and forgo the added stress of learning two separate programs in one week.

In order to evaluate the effectiveness of our previous workshop, we developed a series of pre- and post-tests for each of the 13 sessions which consisted of 5-7 questions and determined how much the participant had learned during that session. Towards the end of the week, many participants were experiencing a bit of test fatigue after completing 26 tests, not counting the pre- and post-workshop evaluation and other evaluation materials we had prepared. This year, instead of tests for every session, we decided to group them by day, so participants only had a total of 8 tests (pre- and post-tests for the first 4 days) with each test consisting of 6-8 questions. The participants did not seem to mind this new arrangement nearly as much as they did the previous one and had no trouble completing it in a timely manner. This reduction in test time also had the added benefit of allowing more time for the session projects. This enabled the participants to experience a more complete understanding of Alice and the computing concepts in general.

TABLE II. CURRICULUM DEVELOPED DURING WORKSHOP

| Curriculum Material | Subject | Grade |
|---|--|-----------------------------------|
| Alice in the Classroom | Computer Science | 10 – 12 th |
| A Visit with Mortimer | Science, Geography, Citizenship | 5 – 8 th |
| Super Simple Alice | Technology Apps | 6 th & 7 th |
| A Very Gentle Introduction to Programming Using Alice | Computer Science I, Computer Programming | 7 – 12 th |
| Science Writing Prompts | Science | 8 th |
| Desert Biome | Science, Geography | 3 – 6 th |
| Alice & Mathematics | Mathematics | 6 – 8 th |
| Sig Fig | Science – Significant figures | 6 – 12 th |
| Introduction to Alice | Information Technology, Multimedia, Web | 9 – 12 th |

B. What Does Not Work

While the workshop as a whole was a success, there are always things that could be done to improve the experience and learning potential of the five day period allowed. In this section we will explore elements of the workshop that were not considered positive by either the participants or workshop staff.

The single most common complaint from both workshop staff and the participants was Alice itself. Alice, although a great introduction to programming concepts, has quirks and bugs. There were times a participant would create a program that appeared to be correct upon examination of the blocks themselves, but when ran would not produce the expected result, throw a vague error, or crash the program completely. These problems could sometimes be corrected by discarding

the blocks and curriculum developed during the workshop and recreating the program, but in some cases a solution was unable to be found. It is accepted that no programming environment, however simple or complex, is without fault, but the amount and severity of bugs in Alice appears to be much higher than other applications of similar type (e.g. Scratch). Feature organization in Alice, while trivial for experienced Aliceans, can be counter-intuitive for newcomers.

For example, many commonly used blocks like Boolean comparisons and user input are found in the functions tab of the world object when, as object-oriented programming principals suggest, we would expect them to be considered general utilities not associated with an object. Working with arrays in Alice is also needlessly complex even for the instructors and tutors who have experience with Java and C++. Due to the nature of Alice, (a purely graphical, drag-and-drop programming environment) a degree of uncertain feature organization is to be expected, but when compared to the highly organized and intuitive layout of Scratch, it is clear that Alice leaves a lot to be desired.

Another recurring complaint concerned the availability of the presentation slides during the workshop. In the previous workshop, participants were given all presentation materials at the beginning of the workshop and were able to peruse them at their leisure; however, in order to keep everyone on the same page, we did not include any presentation slides on the flash drives this year. Instead, we decided to post the presentations for all the sessions for that day on our website immediately following the morning sessions of that day. This was also done to prevent the participants from using the answers found in the slides on their pre- and post-session tests. Unfortunately, this caused more problems than it corrected. Participants were no longer able to follow along with the presentation on their own computers, and consequently were not able to grasp the concepts as quickly as they could have. A few participants had trouble keeping up with the pace of the more advanced sessions and expressed a desire to have their own copy of the slides during the session so they could go back and re-read the sections they did not understand. This is a valid problem, and we are in the process of developing a method that will allow the participants to have access to the slides whenever they need them, yet, at the same time, prevent that access from skewing workshop assessment results.

The wording of the pre- and post-tests was again the subject of criticism from the participants. After receiving similar feedback from our previous workshop, we examined the questions contained in those tests for any ambiguity or poor wording. Even though corrections were made, the participants again voiced their dissatisfaction with the quality of the test questions. These questions are extremely important to us as they tell us how well the workshop is meeting its goals. While we feel the current questions were precise enough for a valid workshop evaluation, it is clear we must continue to refine their wording and structure.

V. ASSESSMENT RESULTS

An outside program evaluator worked with us and developed all workshop assessment materials. Our assessment approach includes two types of assessment: workshop

participant self-assessment and assessment by the workshop instructors to avoid self-interest issues in the workshop effectiveness outcomes.

- Workshop participant self-assessment includes a pre-workshop survey with 57 questions and a post-workshop survey with 62 questions.
- Assessment by the workshop instructors includes pre- and post-tests with a total of 28 questions with 7 pre- and post-questions each day.

Both pre- and post-assessment results show significant improvement in participants' knowledge of computing subjects taught at the workshop.

Twelve participants arrived the first day, but only ten participants were able to complete the workshop. Results from the pre-workshop survey showed that three participants have a bachelor's degree and seven participants hold a master's degree. The workshop had a good mix of middle school teachers and high school teachers. Six participants teach middle school and four teach high school. Their areas of teaching range from Science, Chemistry, Math, Web Mastering, English, Tech/teacher training, and other computer related subjects.

Pre- and post-surveys were given at the beginning and end of the workshop allowing participants to rank themselves in their conceptual knowledge of the items taught. All self-assessment questions are ranked on a scale from 1 to 5; 1 indicating they felt very uncertain and 5 indicating they felt very comfortable with the concept. The post-workshop self-assessment per-person average was 4.1, which was an appreciable improvement from the pre-workshop average score of 2.7.

From our in-depth face-to-face interviews, participants mentioned several suggestions. Some found the pace of the presentations not conducive to their learning style and would like to have had some step-by-step directions to be better able to follow along. Another suggestion was to offer workshops for different programs that target teachers of certain age ranges. Some suggest that Alice may be too difficult for most middle school students and that it may be impossible for elementary teachers to take advantage of Alice in their classrooms. These suggestions indicate that Alice is most effective in high school and tertiary education.

We also developed a number of questions to measure the amount of material the participants would take away from the workshop. We did this by creating pre- and post-questions to test their knowledge of the subject discussed during each session. Table III shows average percentage increases ranging from 31.2% to 63.1%. The rubric used for grading these tests is given in Table III.

VI. CONCLUSIONS

Our workshop focuses on using Alice, a 3D programming environment, to introduce computing concepts to K-12 teachers at all K-12 levels to expose students to computing at an early age and to reach more students. During the workshop, the teachers develop curriculum materials for the subjects they will

teach in the following semesters. Based on the pre- and post-workshop assessment results, the participants were able to indicate their confidence in the concepts presented in the workshop. In the pre-workshop assessment, the results indicate a confidence level average of 2.7 out of 5. However, the average post-workshop assessment score was 4.1 out of 5, indicating a 52% increase in confidence level. A similar change was observed upon analysis of the pre- and post-tests (graded by workshop instructors) for each session. Participants scored an average 2.5 out of 5 on the pre-session tests, but that score rose to 3.6 on the post-session tests, which resulted in a 44% knowledge level increase.

TABLE III. PRE-TEST AND POST-TEST ASSESSMENT RESULTS

| Session | Pre-Test Average score/ per participant in each session | Post-Test Average Score/per participant in each section | Score changed (percentage increased) |
|--|--|---|--|
| Day-1 | 2.44 | 3.98 | +1.54(63.1%) |
| Day-2 | 2.81 | 3.74 | +0.93(33.1%) |
| Day-3 | 1.99 | 3.01 | +1.02(51.3%) |
| Day-4 | 2.79 | 3.66 | +0.87(31.2%) |
| Rubrics: 1. Posses no understanding of the concept 2. Posses very little understanding of the concept 3. Posses little understanding of the concept 4. Posses moderate understanding of the concept 5. Posses complete understanding of the concept | | | |

Teaching Software Inspection Effectiveness: An Active Learning Exercise

Walter W. Schilling, Jr.

Department of Electrical Engineering and Computer Science

Milwaukee School of Engineering

Milwaukee, WI 53202

Email: schilling@msoe.edu

Abstract—This paper discusses a novel active learning exercise which teaches students how to perform and assess the effectiveness of formal software inspections. In this exercise, students are responsible for selecting an artifact from their senior capstone design projects. The students then use fault injection to strategically place faults within the artifact that should be caught by the inspection exercise. Based on the needs of the team, students prepare an inspection packet consisting of a set of inspection instructions, applicable checklists, and the inspection artifact. Students then “hire” a set of inspectors based on classmates’ backgrounds and experiences. The team leader then holds two inspection meetings and reports the results. The results are then used to assess the effectiveness of the inspection. Overall, in analyzing 5 years worth of data from this exercise, it is found that students are capable of selecting appropriate materials for inspection and performing appropriate software inspections. The yield of students is lower than an experienced professional might have and the inspection rates tend to be slightly higher than desired for their experience. However, the yield is related to individual preparation time. Students overall find this to be a highly educational experience and highly recommend it be continued for future classes.

I. INTRODUCTION

Software inspection has long been viewed as one of the most effective mechanisms for ensuring the quality of developed software. Ever since Fagan [5] published his proverbial paper on the subject in 1970, inspections have been used by industrial practitioners to aid in improving the quality of software products. While there have been improvements in the inspection processes used in software development, the basic inspection process has remained virtually unchanged.

Typically software engineering courses may lecture on the benefits of software inspections as a quality assurance component, but active learning exercises are not included. Research has shown that students’ acceptance of inspections increases with watching a video showing an inspection in progress [2]. However, the acceptance of the practice increases even further after students actively participate in an inspection session [2]. Active participation in software inspections has also been shown to increase a student’s critical thinking and analysis skills [11].

The classical approach for teaching inspections using active learning is a case study based approach. With a case study based approach, students are provided with a predefined artifact and are then broken into teams to inspect the artifact

[3], [10], [13]. While this method can be effective, it also suffers from problems. Students may lack domain knowledge of the material being inspected, and because they see the exercise as purely an educational exercise and lacking a long term stake, they may not be as interested in the outcome. A second approach to teaching inspections involves a project based approach. In this approach, students work on a project, and as part of that project, the team members hold one or more inspections with the team members working on that project [1], [6].

II. THE LAB EXERCISE

The objectives for this active learning exercise are multifaceted. First and foremost, at the completion of this exercise, students are to have an appreciation for the process of conducting a formal inspection. Students should be able to describe the roles for each participant and explain the interactions between inspection participants. Students should be able to define inspection objectives and determine the appropriate scope for an artifact inspection given a fixed time constraint. Students should recognize the importance of inspection preparation, and should be capable of quantifying the effectiveness of the inspection. Students should also obtain an understanding their own personal capabilities and limitations when inspecting others’ work.

A. Exercise Specifics

The exercise is based upon the Team Software Process (TSP) [7] inspection procedure, though it does not follow the steps verbatim. The exercise is designed for a course which does not have an associated project, but has the majority of students enrolled in a co-requisite capstone design course.

The exercise sequence begins with teams selecting their artifact for inspection. The artifact is selected from those which are substantially complete as well as significantly important to the senior design project. Students are provided with guidance as to the desired size of the artifact based on the time allocated for the in lab review, as well as instructions indicating that, if necessary, it is acceptable to only review a subset of an artifact. Students are informed that the inspection meeting is planned for 50 minutes, and they should plan on approximately 60 minutes preparation time from their inspectors. Previously in

lecture students were provided with generally accepted rates for effective inspections [7], [8], [12].

At this point, teams are tasked with determining a team leader. The team leader is responsible for handling the coordination of the inspections with other classmates. Tasks given to the team leader include distributing the artifact to inspectors as well as moderating the inspection meeting. The team also selects one member to be an inspection scribe. The scribe is responsible for recording the defects encountered during the inspection meeting. Those who are not tasked with being either the team leader or the scribe are tasked with being inspectors for other teams.

After selecting the moderator and scribe, the team is responsible for “hiring” a set of inspectors. Depending on the class size and composition, each artifact will be inspected twice by two independent sets of inspectors. While at first selecting inspectors may appear to be a simple exercise, effective inspector selection involves significant analysis. Team members must think about which classmates have relevant technical experience or knowledge of the given product or technology. Team members also must deal with the fact that their desired inspectors may have already been “hired” by two other teams and thus are unavailable for the given inspection. To help in this step, students prepare a resume (properly sanitized to avoid FERPA issues) which is posted on the “hiring board” in the lab. Teams can use these resumes to screen potential inspectors during the “hiring process”.

B. Fault Injection

Once the inspectors have been hired, the teams are responsible for using fault injection to place faults in the inspection artifact. Since the assumption is that the initial artifact is a quality artifact, the goal is to ensure that there is something for the inspectors to find during their inspection. However, these injected defects also can be used to estimate the effectiveness of the overall inspection process. In some cases, teams will revert to a previous version of an artifact which had been corrected, while in other cases the team injects faults which are of a similar classification to those found during their own informal review process. The exact details of the type of faults to be injected as well as the number is left up to the teams aside from the suggestion that the faults be of varying difficulty to detect as well as somewhat evenly distributed throughout the artifact. Once the team has completed injecting faults into the inspection artifact, it is appropriately labeled as an inspection artifact and placed into their configuration management system.

The team leader then distributes the artifact to the inspectors. In nearly all cases, this has been accomplished electronically, though students are given the option of distributing a hard copy of their artifact. The team leader also distributes a set of instructions to the inspectors. The instructions indicate the scope of the inspection, any known defects which the inspectors should ignore, and a checklist that they should use for their individual preparation.

C. Individual Preparation

Once the inspectors receive the artifact from the team leader, they are tasked with preparing for the inspection meeting. In specific, inspectors are tasked with individually going through the artifact and recording the location, the type, the severity, and a short description of each discovered defect on a log form. The inspectors are also tasked with recording their preparation time. While inspectors are not specifically told how much time they should spend preparing for the inspection meeting, they have previously been lectured on the impact of inspection rate on inspection effectiveness.

As the inspectors complete their individual logs, they are responsible for submitting them to the instructor to verify their own preparedness for the meetings. Students are not graded based on the number of defects found or the correctness of the defects, as the instructor does not have appropriate knowledge to assess the correctness of the inspection results. Rather, the submission of the log is used simply to ensure that the student performed some preparation.

D. Inspection Meetings

During the following lab session, the inspectors will meet back with the team leader for the inspection meeting. During this meeting, the team leader will go through the artifact with the inspectors. Using their inspection logs as a guide, the inspectors will highlight the defects they uncovered. Discussion may occur as to the validity of the defect, the severity, or the categorization of the defect. Once the inspectors are in agreement, the scribe will log the defect on the inspection log. Additionally, the scribe will record which of the inspectors actually found the defect.

Once the inspection meeting is completed, the scribe will record metrics associated with the the inspection meeting. If time permits, the team leader and scribe will review the injected defects which were not found by the inspectors. This provides the inspectors with valuable feedback on the types of defects missed during individual preparation.

The instructor for the class attempts to visit each inspection meeting to act as an external auditor. This act is not intended to directly assess the students on their work, but rather, to ensure that they are following the guidelines for an effective inspection. The instructor specifically avoids answering technical questions related to the artifact. The instructor does, however, attempt to ensure that there are no hostilities toward the team leader or the inspectors.¹

The inspection meeting occurs twice with two independent sets of inspectors. By holding the inspection meeting twice, it provides the inspection leader with two chances to lead an inspection meeting, as well as the opportunity for each inspector to inspect two different artifacts. It also provides two data points which can be used for statistical measurement of the effectiveness of the inspection process.

¹It should be noted that the instructor for this course is actually not a stakeholder for the artifacts which are being inspected. The instructor for this course does not teach the capstone project course, and is entirely independent of any project assessment.

E. Post Inspection Analysis

Once the inspection meetings have been completed, the original team meets again in order to assess their artifact and the effectiveness of the inspection.

The teams are asked to assess how many of the injected defects were found during the inspection process. A high yield in this aspect can be considered to indicate that an effective inspection has occurred. A low yield in this aspect may indicate that there are problems with the inspection process. Using the injected defects and a capture-recapture approach [4], [7], students are asked to calculate approximately how many additional defects remain within the artifact.

Teams are then asked to compare the effectiveness of the two inspection meetings. In this analysis, students again use capture-recapture to estimate the number of remaining defects in the artifact by comparing the defects found in inspection meeting A and inspection meeting B. This calculation is completed twice, once with all defects being included and once with the injected defects being excluded from the calculations.

Teams are then asked to analyze the overall effectiveness of the inspection if only a single inspection meeting had occurred but certain inspectors had not participated. In doing this, the results of both inspection meetings are combined together into a single data set. Calculations are then performed on the data set with the defects found by the most effective inspector and / or the least effective inspector removed from the assessment.

As a last assessment, teams are asked to compare the inspectors' yield versus the individual preparation time reported by the inspectors. The goal is to attempt to detect trends in the preparation time and the resultant inspection yield amongst inspectors.

F. Lecture Review

Following the completion of the lab and after all students have completed their individual analysis and assessments, the instructor prepares summary lecture slides showing the pertinent trends from within the student data. While this summary information has varied from offering to offering, in general, it includes a cursory assessment of the overall effectiveness inspections as well as a demonstration of the relationship between preparation time and inspector yield. Both inspectors and leaders are encouraged during this lecture review to discuss with the class any observations that they had about the process and their findings.

III. STUDENT PERFORMANCE

A lab exercise such as this involves many aspects to be successful. Students have not previously used formal inspections, and they are inspecting an artifact with which they may not have extensive technical knowledge. This potentially makes in-depth student analysis difficult. However, with 5 years of data, certain trends can be analyzed.

A. Artifact Selection

The first question to ask is did the teams select an appropriate artifact to review in terms of size, complexity, and

TABLE I
ARTIFACT SELECTION BY TYPE

| Artifact Type | SRS | Software Design | Source Code |
|-------------------|-------|-----------------|-------------|
| Percent Selecting | 52.9% | 17.6% | 29.4% |

TABLE II
ARTIFACT SIZE AND INJECTION DETAILS

| | Artifact Size (Pages) | Injected Fault Count | Injected Density | Overall Density |
|---------|-----------------------|----------------------|------------------|-----------------|
| Average | 10.78 | 11.95 | 1.39 | 4.22 |
| Median | 10 | 10 | 1.3 | 3.58 |
| St. Dev | 5.73 | 6.29 | 0.76 | 2.21 |
| Max | 22 | 35 | 3 | 10 |
| Min | 3 | 7 | 0.32 | 1.74 |

scope. Table 1 provide a summary of the artifacts selected for review. In essence, the majority of students desired to inspect their Software Requirements Specification (SRS) artifact. This is most likely a product of where students are within their project. The timing of this course within the Capstone design sequence is such that the SRS artifact is usually complete and some design work has started. However, a significant percent of students choose source code as well, as they may be using a shorter cycle time on their project and may have portions of their code nearly completed. Software designs which have been selected typically involve UML class, state chart, and sequence diagrams with supporting narratives. It is usually found that the teams have not used any systematic review mechanisms in their own process.

Table 2 provides a summary of information relevant to the artifact selected. In essence, most teams select an artifact that is around 10 pages in length. To convert source code into page counts, the lines of code was divided by 40. Most teams also selected around 10 defects to inject into their artifact. 10 defects is large enough to provide a fair number of defects for analysis but is small enough to avoid skewing the results. The injected density shows how many defects were injected per page, and the overall density shows how many defects were detected during the inspection meeting. It should be noted that, in general, for each injected defect, there were three other unknown defects uncovered during the inspection, indicating that the artifacts may not have been as high of quality as the teams thought during artifact selection.

B. Individual preparation

The next risk to an exercise such as this one is the preparation of the students. In order for this exercise to be effective,

TABLE III
INSPECTOR INDIVIDUAL PREPARATION RATE

| | Preparation Time (Minutes) | Preparation Rate (Pages per hour) |
|---------|----------------------------|-----------------------------------|
| Average | 64.8 | 13.02 |
| Median | 60 | 10.43 |
| St. Dev | 40.95 | 11.60 |
| Max | 300 | 79.8 |
| Min | 5 | 1.86 |

the students must perform their own individual preparation in advance of the lab session. Being unprepared will result in an ineffective inspection.

Unfortunately, the analysis of student preparation time and review rates yields significantly more variability than would be desired. While the average and median results for preparation time and review rate are very close to that which would be desired based on accepted inspection rates, the variance in time spent is quite large. Some of this may be brought on by the fact that each inspector is assigned to inspect two different artifacts from two different teams, resulting in the first artifact being inspected “properly” and the second artifact being “rushed”. Some of this also may have come from the inexperience of the inspectors. Since they are not necessarily familiar with the domain or knowledgeable about the product, they may have felt that further time being spent may not have been productive. On the other extreme, some of the reviewers spent significantly more time than would be expected for an inspection of the given size. This also may be attributable to inexperience with the product and the domain.

Another explanation for the variability in this data is that it is student self reported data. It is very possible that the students did not keep accurate track of how much time they spent or how many interruptions in their work occurred. This may have resulted in the actual preparation time being significantly different than that which was reported.

C. Review Effectiveness

The most important metric for any formal inspection is the inspection yield. In essence, this metric indicates how many of the existing defects were found by a given inspector, and, as an overall metric, how many of the defects were found. Overall, the yield from a formal inspection varies from a low of approximately 20% yield to a high of approximately 75% yield based on training and experience level [9].

Table 4 provides an overall summary of the inspections yield for the conducted inspections. For each inspector and artifact, three calculations of yield have been made. The first calculation shows their yield versus the injected defects. In essence, a high yield for this value indicates that they were effective at finding the injected defects. The second calculation shows the individual inspectors yield versus all of the defects found in the artifact during the two inspection meetings. A high value here would indicate that an inspector was effective at finding most of the defects within the artifact. The last column calculates the inspector’s yield versus the estimated total number of defects within the artifact.

In general, the yields found within the exercise were lower than would be desired. However, because this represented the students first formal inspection, it is not unexpected that their individual performance would be lower than that of an experienced professional.

An interesting analysis that can be conducted from this data is to determine if the inspection yields were consistent between the injected defects and the overall review. A high correlation here would indicate that the inspectors were

TABLE IV
INSPECTION YIELD ASSESSMENT

| | Individual Injected Defect Yield | Overall Individual Yield | Overall Yield versus Total Estimate |
|---------|--|--------------------------------|---|
| Average | 0.404 | 0.348 | 0.297 |
| Median | 0.364 | 0.323 | 0.279 |
| St. Dev | 0.194 | 0.160 | 0.158 |
| Max | 0.857 | 0.758 | 0.710 |
| Min | 0.000 | 0.000 | 0.000 |

equally effective at finding injected defects as they were at finding general defects within the artifact. To determine if such a correlation existed, the total yield and injected yield for each inspector were plotted, yielding the plot shown in Figure 1. This plot indicated a general correlation between the two measures. This correlation was confirmed by calculating the Spearman Rank order correlation coefficient for the data set, $\rho_s = 0.6335$, $P = 0.000001$. From this analysis, it can be concluded that an inspector who did well at finding the injected defects also did well at finding the other defects within the artifact.

D. Individual Preparation Versus Yield

The next relationship that would be desirable to show is the relationship between preparation time and yield. Establishing this relationship would indicate that those who spent an adequate amount of time in their individual preparation were more effective at finding defects. It is also desirable to see if there is a correlation between the total yield and individual preparation given that the relationship between the injected yield and the overall yield. Based on industrial data [7] it is expected that those with a lower preparation rate would have a higher yield.

To prove this hypothesis, a Spearman Rank Correlation was calculated between the overall inspection yield and the preparation rate. This resulted in $\rho_s = -0.1956$, $P = 0.08591$, which indicates a weak negative relationship between the two items. These relationships match what would be expected in an industrial setting. While this relationship is somewhat weaker than would be ideally desired, this weakness can be accounted for by the students lack of experience with inspections and generally low yields due to inexperience. It is expected that this relationship would become stronger as overall yields increased with more experience.

IV. STUDENT ASSESSMENT

With any active learning exercise, an important question to ask is have the students gained an understanding of the activity, and do they feel that they have learned from the activity. As part of the course assessment, an exit survey is conducted which asks the students to assess the effectiveness of each lab activity conducted in the class. The majority of the survey uses a 5 point Likert Scale. The responses from three of the questions specifically relevant to this activity are given in Table 5. Note that while the exercise has been performed for five

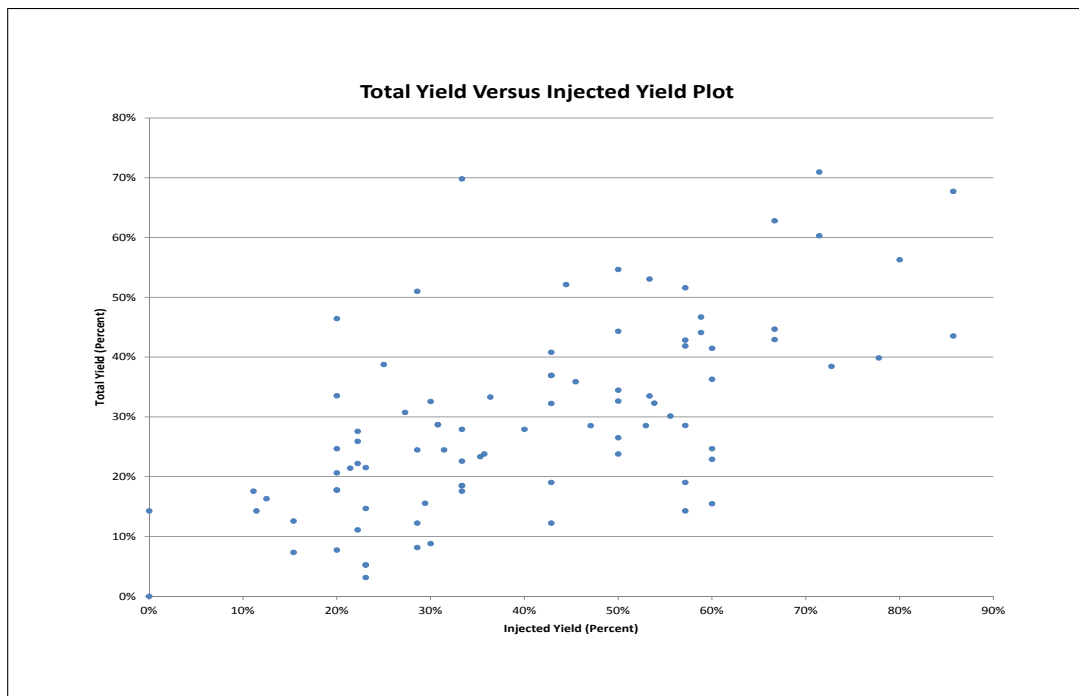

Fig. 1. Rank plot of total versus injected yield.

TABLE V
SUMMARY RESPONSES FROM LIKERT SURVEY

| Question | Offering 1 | | | Offering 2 | | |
|---|------------|-----------|------|------------|-----------|------|
| | \bar{x} | \hat{x} | s | \bar{x} | \hat{x} | s |
| I learned a lot from this lab. | 4.29 | 4 | 0.78 | 4.00 | 4 | 0.78 |
| This lab helped me in my senior design project. | 3.95 | 4 | 1.02 | 3.75 | 4 | 1.03 |
| This lab should be continued for future students. | 4.52 | 5 | 0.60 | 4.25 | 4 | 0.60 |

years, these particular questions have only been specifically asked in the past two years.

In essence, 84.8% of students either “Agreed” or “Strongly Agreed” with the notion that they learned a lot from this lab. Of all survey responses, only two people “Disagreed” with this statement, and no one “Strongly Disagreed”. Similar results were also found for the statement “This Lab should be continued for future students”, where in fact, 93.4% of students either “Agreed” or “Strongly Agreed” with the statement. In essence, this set of responses indicates that the students felt this active learning exercise was beneficial to them and would continue to offer a benefit to future students.

Student response was less supportive to the statement “This lab helped me in my senior design project.” While a secondary intent of the assignment was to provide a mutualistic relationship with the co-requisite senior design sequence, this relationship was not as strong as it could have been for all teams. Part of this may stem from a problem selecting inspectors. Due to the diverse nature of the capstone design

projects, finding inspectors with adequate knowledge proved difficult for some teams. On rare cases, inspectors were not very effective, and this may have influenced teams to feel that the activity was not beneficial to their project. That being said, 64.7% of participants felt that this activity did help with their senior design project.

While the quantitative assessment provides an indication that this activity was successful, further understating of the students thoughts about the assignment can be derived from the student comments written within the lab reports and course assessment forms. For course assessment forms, 75% of students provided meaningful written commentary related to this project. Table 6 provides selected comments related to this lab from the end of the course evaluation forms. It should be noted that the comments have not been edited to remove negative comments; there simply have not been any significantly negative comments within the course assessment surveys.

Another area of assessment for the effectiveness of the lab was in the student lab reports. As part of the activity, all teams submitted written lab reports including a “things gone right” and “things gone wrong” write-up where students were tasked with critiquing the lab and suggesting future improvements. In reviewing these write-ups, the majority of the students identified that their current review processes had failed to catch problems within their artifacts. They also supported the idea of independent inspectors looking at their artifact. Another common thread was a realization of the fallibility of their own inspection skills. While many students seemed to feel that the defects they injected were obvious, the significant number of inspectors that missed the defects demonstrated that this may

TABLE VI
SAMPLE COURSE EVALUATION COMMENTS

| |
|---|
| Most of the issues found in our review were irrelevant. There was not enough shared knowledge between students to have useful results. |
| We made process improvements in our project as a result of this lab. |
| The formal inspection (& the statistics calculations) helped formalize our peer review process. |
| Useful statistics |
| Using actual projects for the lab was the best part of the class. |
| The Formal Inspection was the best part of the class. |
| Helped to identify issues, but didn't use process afterwards to review future artifacts. Distributions of documents was not streamlined well. |
| It found a lot of useful bugs and suggestions for my senior design project. |
| My reviewers weren't very good. |
| Very useful lab and study. |
| I learned a lot from this lab. |
| (The best part of this class was) incorporating real documents from senior design and SDL into lab activities. |
| We got real experience with real projects, and the errors found improved the documentation of our project. |

TABLE VII
SAMPLE LAB REPORT COMMENTS

| |
|---|
| We have discovered that our current review process is inadequate to discover all of the defects within our artifacts. |
| This lab really showed the importance of reviews and what they can accomplish. While we only injected 7 defects (and 4 of our 5 reviewers found all 7) there were plenty more defects that we didn't find and they did find. |
| We learned quite a bit from this lab activity. We found that our own reviews didn't go as expected, since there were a lot of spelling errors in the document. |
| This experience, of doing a code review the correct way and parsing statistics out of it, was very good. |
| Overall, we found the process of doing reviewing and discussing to be an effective use of time. |
| The injected defects showed us a lot. Only three of the nine injected defects were found. This made us not very confident in the reviews that were performed on our documents. |
| Quality was improved, and we gained experience with the software review process. |
| We have concluded that the capture-recapture method of inspection along with injected defects is an effective way to analyze quality. Our results suggest that we should not use a single reviewer, no matter how effective he/she may be, but use teams of reviewers instead. ... We have determined that this method of reviewing is much more effective and helpful than a regular code/document review. |
| The formal inspection (and the statistical calculations) helped to formalize our peer review process. |
| This lab has provided us with not only general knowledge about increasing software quality through effective reviews, but we have also come out with a helpful product for our senior design project. The input gathered from our peers has already been put to good use in our project. |
| We also learned a bit about each of our effectiveness's during the lab activity. |
| In addition to lessons learned about review activities, we also benefited from a review of a document that we may not have realized contained as many defects as it did. |
| In regards to the inspection of our team's artifact, we were able to find a major bug that was overlooked. |
| The performance of our peers was somewhat surprising; it was lower than expected. This was their first time participating in a formal inspection, however; it can be postulated that with practice their effectiveness will improve. |
| In conclusion we learned that Fagan inspections can be very effective in estimating the total number of defects in a document. We also learned that having outside inspectors review our artifacts helps to find defects that our senior design team was unable to find in our own inspections. |

not be true. Other reports commented on how important it was to review the injected defects that they missed in order to improve their own inspection skills.

V. CONCLUSION

This article has discussed an active learning exercise developed to teach students the advantages and disadvantages of formal inspection of software artifacts. From this exercise, students gain the skills necessary to critique the effectiveness of formal inspections, as well as insight into their own capabilities and limitations. Students view the exercise favorably and demonstrate comprehension of the exercise objectives.

While the lab activity offers many benefits to students, there are potential improvements. One idea involves making this the second part of a two exercise sequence. The first exercise would involve all students inspecting the same artifact. This would give students practice with a standard artifact that can be tailored to their skill level before inspecting a random artifact, improving the yield. A second idea involves the addition of auditing roles. An auditing role would provide students with the opportunity to critique teams adherence to the inspection process.

Bothell, WA, USA

hazeline@u.washington.edu, rangotti@uwb.edu, ksung@u.washington.edu

Abstract—Teaching Software Engineering (SE) based on “real-world” projects engages students with practical application of software engineering concepts—students develop a deeper interest in the project deliverables while they acquire the skills of critically analyzing the problem and determining the best course of action. It can be challenging to find and maintain a reliable stream of suitable software projects that match learning outcomes, technical scope, and academic calendar of an SE class. On the other hand, a typical university campus has many non-Computer Science (CS) technology classes that require their students to study, understand, and evaluate existing software applications in specific areas. With purposeful coordination, these non-CS technology classes can serve as effective source of real projects for SE classes. This paper describes our experience of collaborating with the Education Program in their Technology in Education course. While we encountered some challenges, our experience has demonstrated that it is indeed mutually beneficial and rewarding for students in both courses. We offer recommendations on choosing non-CS technology classes and logistical guidelines to ensure the success of such collaborations.

Keywords—software engineering education; education

I. INTRODUCTION

Integrating “realistic” projects in Computer Science (CS) classes increases student engagement while strengthening student learning outcomes [1, 2, 3]. However, as pointed out by many (e.g., [3, 4, 5]), coordination and logistic arrangements for external “real-world” projects can be demanding. Establishing and maintaining relationships to ensure a healthy supply of such projects can be difficult and in the absence of systematic institutional support (e.g., office of Service Learning), faculty often must be “courageous” [1]. On the other hand, the key characteristics of “realistic project” that motivate students are not the demanding “relationships”; rather, the key characteristics are the actual clients and “real-world” problems [6, 7, 8]. With these observations, instead of looking externally outside the university, many educators search internally for opportunities for collaboration, and design classes with less

logistically demanding projects. In the case of Software Engineering (SE) classes, video games [9], or even other CS classes [10], have been used as “real-world contexts” for teaching the involved concepts. A natural continuation of this “internal approach for real-world project” is to explore the possibilities of integrating projects from non-CS classes into an SE class. Such integration will be advantageous for CS students: working with real clients who may not have CS expertise or knowledge, yet having real demands for CS skills.

At the University of Washington, Bothell, interdisciplinary collaboration is encouraged, as evidenced by the establishment of the Collaboratory, an on-campus facility where faculty and students from various disciplines can collaborate on research or course projects. In one of the Collaboratory planning meetings, we discussed the possibility of having the Master’s Prep SE students work with the Master’s Education students. The SE students were tasked with developing software that can help the Education students with the technical aspects of their pedagogical assignments (i.e., collecting data on the web and visualizing the data). The Education students in turn would act as a customer for the SE students. As the students interact with each other, we intended that the SE students could also answer any technical questions that the Education students may have, thus making the interaction mutually beneficial to students in both courses (see Figure 1).

The Technology in Education course featured in this work is a course for pre-service and in-service teachers currently working on a Master of Education degree. The course is designed for teachers of any subject at the K-16 level to explore ways to use emerging technologies to enhance classroom instruction. Students in this class may have a traditional teacher education background or may be career-changers from multiple disciplines who are seeking a teaching certificate. The students taking the Technology in Education class have a wide range of abilities both in personal use of technology as well as application of technology in Education.

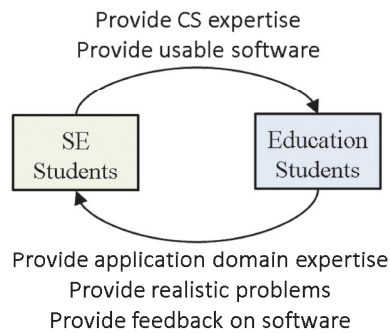

Figure 1. Mutually beneficial interaction between SE and Education students

Our SE class is a typical Junior/Senior-level class that covers traditional topics such as software development life cycle (SDLC) models, requirements analysis, design, implementation, quality assurance, and process improvement [11]. The class is organized based on projects to maximize student engagement [12]. In the previous offerings students worked individually on projects they proposed while they worked in groups on other class activities.

One of the main goals of the SE course in collaborating with the Education course was to give the students the opportunity to apply the concepts they learned to a project with real customers. Thus, the students were tasked to perform software lifecycle activities in the context of their projects. The collaboration was designed to help students acquire skills in interacting with their customers and teammates, managing and prioritizing requirements, and incorporating existing software into the system they are tasked to develop.

This paper describes our experience of collaborating with the Education Program in their Technology in Education course. The paper begins with a survey of existing efforts in bringing real-world projects into SE classes. Section 3 covers the backgrounds of the involved classes, discussing the logistic arrangements, project and team coordination. Section 4 presents student project deliverables. Section 5 provides an evaluation of the course collaboration and Section 6 elaborates on guidelines and recommendations.

II. BACKGROUND

Using real-world software projects as contexts is effective in engaging students with learning abstract CS concepts [1, 2, 3]. This is especially the case for SE, where the discipline itself is the study of software development process. A real-world software development project can naturally serve as practical context for topics covered in an SE class.

Many educators in SE seek real-world projects for teaching their classes either via direct collaboration with industry partners (e.g., [13, 14, 8]), or working with community partners through Academic Service Learning format (e.g., [3, 15]). These kinds of collaboration generate excellent projects for SE classes because the customers are knowledgeable in the problem domain, are genuinely concerned with the outcome of the project, and the projects themselves are usually based on

real problems that require custom solution design and hands-on implementations. An additional benefit of these real-world projects is that the scope usually dictates team work which helps students develop interpersonal and communication skills [7].

Before projects from external to the institution can proceed, it is important to communicate and align class learning outcome requirements with customers' priorities. The students should be coached about industry culture and professionalism while the customers must appreciate students' course workload, understand the needs for assessments and support academic-oriented evaluations, and most importantly the customer must develop a realistic expectation [3, 14]. On the faculty side, it is essential to work with external partners to develop projects with proper scope of work that align well with academic calendar. For all the above reasons, it is a significant challenge to identify potential partners, and the partnership requires careful nurturing and maintenance [3, 4, 5].

The key engaging factors of "real-world" projects are the real customers and the real problems [8]. It has been noted that there are many potential benefits for such projects coming from within the institution [10, 7]. There has been approaches that integrate SE with other CS classes. For example, Fenwick and Kurtz interfaced a lower level data structure class, a human-computer interface class, and a database class with their SE class [10]. The students from the different classes worked together to simulate a real-world project, with the SE students acting as project managers and dictating the specifics of lifecycle activities such as requirements, design, testing, and management. Tvedt et. al. further integrated SE into CS curriculum where students are required to take eight semester sequence of Software Factory courses to assume the different roles (e.g. tester, designer) in software development process [12].

The main advantages of projects from within the institution are the similar cultural background, simpler logistics requirements (e.g., academic calendar, expectations, assessment requirements), and long-term sustainability. The main shortcomings of using CS classes for projects and CS students as customers are that the problem domain is closely related to SE and that the customers are often highly knowledgeable and fluent in CS concepts. These issues can be avoided if the projects and customers are from classes that are completely unrelated to CS. We have observed no reported attempts of collaboration between SE and classes from outside of CS discipline.

III. OUR COURSES

A. The Education Class

In the Technology in Education course, students, who are all teachers, learn how to use emerging dynamic visualization software to create interactive visualizations related to their subject area that can then be used in their classrooms. This particular class focused on Google motion charts and Tableau software as their two primary software sources.

In order to implement their projects, the Education students also had to find appropriate data sets to import into the software in order to create the visualization. This task proved to be their biggest hurdle and the one which required the most assistance from the SE students. Once the students found an appropriate data set, the SE students helped them extract and/or organize the data in the correct format for the software program they were using. To facilitate this task, SE students wrote or configured software to convert the data to the appropriate form.

The characteristics of the Education class were suitable for the SE class. First, the students are well-advanced in their fields (e.g, students are teachers). Second, there is a well-defined task that the Education students needed to perform. Finally, there is a recognized need by the Education students that SE students can fill. These characteristics will be discussed in detail in Section 5.

B. The Experiment Setup

We planned to have our classes meet at the same time in the Collaboratory. This setup allows meetings with the customer, the Education students, to be built-in to the class meeting times. Due to logistical reasons, our classes were not scheduled at the same time. As a result, the students had to meet outside of class times, or the SE students would meet the Education students during their class times. For the SE students, more meetings with the customer were necessary at the beginning of the quarter in order for them to gather customer requirements.

A group of SE students (2-5 students each group) was teamed up with a group of Education students. Having more than one customer for each team was a good setup because some of the customers later became unable to continue meeting with SE students. For the teams that did continue to have more than one customer, it was an added challenge for the SE students to learn how to find a common set of functionalities that caters to all their customers. Since the Education students were free to choose the type of data and the type of visualization they wish to create, they have different requirements for the SE students.

For the SE course, assessment included an exam and deliverables for each milestone such as requirements document, design document, test document, and working software. Deadlines of milestone deliverables were flexible, but final delivery of software was fixed.

For the Education course, assessment included four visualization tools packaged with curriculum questions to use in a K-16 classroom, a final project paper, and a reflection on the collaboration process.

Before the end of the quarter, the SE students delivered the software to the Education students. The Education students then performed trial usage of the software. Overall, the Education students were happy with the software they received, with some of the students even taking the software to use in their classrooms.

The expected gains for the Education students as well as the CSS students included an opportunity to work with a group of people from outside their subject area and experience a true trans-disciplinary collaboration similar to what happens in the

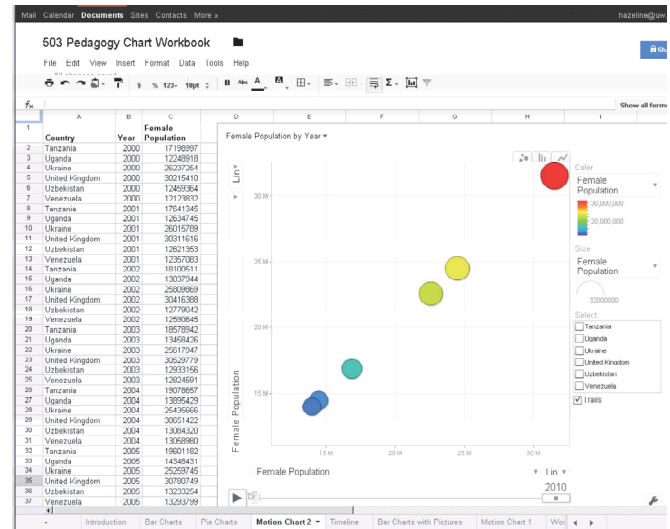

Figure 2. Pedagogy Chart Workbook Template allows users to simply enter data and the charts are automatically updated.

real world. The Education students would gain experience in articulating their projects to people from other disciplines who were unfamiliar with the software they were using and the pedagogical applications of that software. The CSS students would gain experience in responding to clients, having to listen to their needs, and finding appropriate solutions.

IV. RESULTS

The SE students gained the following skills while working on this project: communicating with customers, managing requirements, interacting with their teammates, and creating a software program either from scratch or with existing third-party tools. The SE students also learned a new language or development platform on their own.

The SE students also learned how to cater to the requirements of a customer or multiple customers, for some SE groups. Consequently, students learned to analyze, prioritize, and manage requirements. Having the students work with real customers also helped them realize the challenges of eliciting requirements from non-technical users. Requirements elicitation can be considered one of the most crucial activities in software development. Without a proper understanding of customer requirements, the likelihood of project failure increases [6]. In addition, customers and users often do not know exactly what they want. Thus, it is the task of the developers to help customers determine what they need [16].

The SE students were also given the option of developing the software from scratch, developing the software with third-party tools, or configuring an existing software to be used by the users. An industry project often involves reusing existing software; being able to incorporate existing software into software under development is a necessary skill [17].

The software projects produced by the students include DataGrabber, Pedagogy Chart Workbook Template, and VizTool File Prep. DataGrabber is an Excel add-in that allows users to extract data from a webpage, a text file, or a

spreadsheet and to import the data into an Excel spreadsheet. The Pedagogy Chart Workbook Template provides pre-configured spreadsheets where educators can simply enter data and the charts/graphs are automatically updated. The Template also allows users to enter data that is automatically fed into Google Motion Chart, as shown in Figure 2. The VizTool File Prep allows users to extract data from multiple PDF files, formats them into the Open Doors Data format (specified by customer), and saves the data into a text file (see Figure 3).

Students in the Education course enjoyed working with the CS students. Initially there was frustration due to their inability to communicate. Education students could not articulate their requirements because of the language barrier and because they did not know what was possible from the CS students. They felt that the CS students were not responsive to what they needed at first, but that through an iterative process were able to overcome the communication barrier to appreciate the “value-added” that the CS students gave to the project.

Although our results are based on more mature students with real-life working experience, we expect the results to be transferable to a *typical* undergraduate SE class. Our graduate students, not from CS background, are typically more experienced, but less fluent with existing technology, e.g., slower to learn new technologies or application programming interfaces (API). Though typical undergraduate students may lack life experience and maturity, they are savvier with current software technology, and have the advantage of being better prepared and having more familiarity with recent programming techniques.

V. EVALUATION

A key measure of success is whether the SE students were able to deliver software that was useful to the Education students. At the end of the quarter, all the Education students were happy with the software provided by the SE students because it conformed to their requirements—automating the extraction of data or visualization of data.

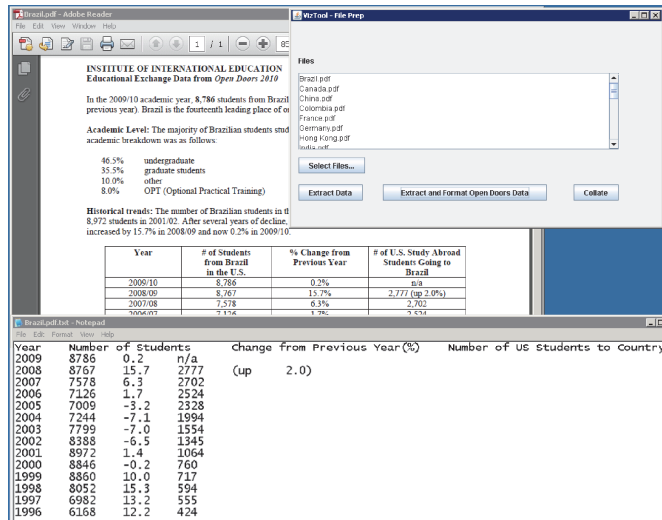

Figure 3. VizTool File Prep extracts data from pdf files (shown in the background) and saves the data into a text file (bottom).

In the course of our collaboration, we encountered three main challenges: scheduling, language barrier, and time constraints. We now discuss these challenges in detail.

The first challenge is scheduling in terms of student meetings and synchronizing the assignments. Since we were not able to have the two courses meet at the same time, the SE students met with their customers outside of class times, which was a problem for some of the students since they were working full time. To work around this issue, only one representative of the group was required to meet with the customer. Outside the class meetings were also identified as a problem in [7], but the difficulties occurred within the teams, not with the customer. The SE students did not have issues with team meetings because the class met twice a week in the evenings and students often stayed after class to conduct team meetings.

It was also important to ensure that the class assignments between the two courses are synchronized. Since it took the SE students a bit of time to understand the requirements for the software, the SE students were not able to support the Education students for their first deliverable. They were, however, able to support them in their final project deliverable, which was due at the end of the quarter.

Language barrier was another key challenge we faced. The SE and Education students had difficulties communicating with each other since both groups lacked the understanding of technical terms used by the other group. It was also difficult for the Education students to express the functionality they needed and it was difficult for the SE students to elicit requirements. This difficulty, however, is not unique in this setting. There are industry software projects where developers lack the understanding of the domain of application—which can sometimes be costly [18]. One of the key skills a software engineer must have is the ability to interact with experts from other domains [19].

For the SE class, there was the additional challenge of time constraint. The course was only ten weeks long and the students were required to perform an entire software lifecycle which includes requirements, design, implementation, and testing. In this context, the requirements phase took longer than expected. Thus, the other phases had to be shortened.

VI. GUIDELINES AND RECOMMENDATIONS

We now offer logistical guidelines for course collaborations and recommendations for selecting a technical course that satisfies SE project requirements.

Guideline 1: Schedule the two courses at the same time. It would be optimal to have the classes co-located in one room. If not, the classrooms should be closely located to each other so that students can easily meet each other.

Guideline 2: Minimize the language barrier by briefing students with background information regarding the other course. We suggest having all students meet in one room with both professors on the first day of class. This will allow instructors to address issues and questions before the students collaborate with each other. It will also enable students to

build community and rapport with each other. This allows collaborators to build a level of understanding of group members in an informal way either before they formally start as a project team or concurrently.

Guideline 3: Explore ways to address the time constraint. Both the SE and Education courses were limited to one quarter (ten weeks). Because of this time constraint, it is important that students understand the requirements quickly so that they have time to analyze the problem and develop the software. This could potentially be achieved by minimizing the language barrier between the two classes. Another possible approach is to allow the SE students to select which software development lifecycle (SDLC) method to use, as long as the delivered software is acceptable to the customers.

For the Education students, even though they understood their course assignments, the major time barrier was in trying to determine what the SE students could actually do for them that they could not do themselves. Teachers tend to work in isolation, in individual classrooms, so when they need something done they are conditioned to reasoning it out and doing it themselves. It was a major hurdle for them to even determine what the CS students could do for them and then articulate that in a way that the CS student could understand. This created a roadblock for the CS students and they were not able to help the Education students with their first deliverable.

The following are our recommendations for choosing non-CS technology classes:

1. The non-CS students are in the advanced courses in their major (i.e., students are at least junior standing in their major). This will ensure that they have a good understanding of their field (i.e. they know the tasks they need to perform, the processes or procedures in their area) so that they can identify their requirements for a software tool.

2. The projects or assignments of non-CS students require custom technology. For example, technologies that are currently available do not exactly meet the requirements of the non-CS students (i.e. students still need to perform time-consuming manual steps). These opportunities will allow SE students to be creative on how they can develop a software tool to meet the customer requirements.

3. Software developed by the SE students will be used by the non-CS students in their project deliverables and the course schedule should allow for this integration. With this structure, both the SE and non-CS students will have an interest ensuring that the software project succeeds. As a backup, the non-CS students may also use an existing technology in the event that SE students are not able to deliver the software.

4. The deliverables of the non-CS students is multi-part (or graduated) to allow SE students the time to understand the requirements at the beginning of the course. For example, the project of non-CS students may be in three parts:

Part 1: Project deliverable uses an existing technology. Prior to this deliverable, SE students will gather requirements by observing how the customer interacts with existing software and by asking the customer's opinion of the software.

Part 2: Project deliverable uses another existing technology and/or uses the first version of software developed by SE students. Prior to this deliverable, SE students will solicit feedback on their software with regards to problems encountered or new features.

Part 3: Project deliverable uses 2nd or final version of software developed by SE students. Prior to this deliverable, SE students have performed various software tests (integration tests, usability tests, acceptance tests).

Non-CS students can then compare how the software developed by SE students, with their guidance in the design, is an improvement over existing software for their task.

VII. CONCLUSION

We took the approach of collaborating with the Education course because it would provide SE students the opportunity to apply software engineering concepts to a realistic project while minimizing the overhead in project coordination. We initially encountered several challenges such as scheduling, language barrier, and time constraints. Students from each class were also unsure of how to collaborate with each other. The Education students felt unsure of the capabilities of the SE students. The SE students also felt unsure of the requirements for the software they will deliver. Over time, the students in both classes overcame the language barrier. At the end of the course, students from both classes were happy with the results. Education students felt more confident in their abilities both in terms of technology and interdisciplinary collaboration. SE students also liked the idea of working with real-life customers. Based on this collaboration, we offered logistical guidelines and recommendations to faculty who may wish to take a similar approach in teaching SE courses.

ACKNOWLEDGMENT

We wish to thank the students in the BEDUC 566 and CSS 503 in Spring 2011 for providing us feedback.

Work in Progress: Transitioning From Novice to Expert Software Engineers Through Design Patterns: Is It Really Working?

Arbi Ghazarian

Department of Engineering, Arizona State University
Arbi.Ghazarian@asu.edu

Abstract— Since their wide adoption by the software engineering community in the mid-90's, design patterns have become an important educational component in the training of novice software engineers due to the common belief that, as distilled experience of seasoned software designers, they can transform novice software engineers into skilled professionals in a relatively short time frame. This paper questions the validity of this commonly-held belief about the educational value of conventional patterns, arguing that although there is tremendous value in capturing and disseminating software engineering experience in the form of patterns, conventional design patterns cannot deliver on this expectation to significantly shorten the experience growth curve. We report initial results from an ongoing research project that aims to not only identify the difficulties in using conventional patterns as educational means for novices, but also to use such insights to develop new forms of patterns to help educators and experts to more effectively communicate and transfer their software engineering knowledge, experience, and understanding of best practices to novices.

Keywords- *Software Engineering Education; Design Patterns;*

I. INTRODUCTION

Since their wide adoption in the mid-90's, design patterns [1] have become an important component in the education of novice software engineers; they have entered software engineering text books and are discussed and taught as part of various courses such as software architecture and design, software engineering, as well as courses on programming and software development. Design patterns are recurring software design problems along with their solutions, which are captured and documented in a reusable format. Since design patterns capture the design experience of seasoned software engineers, they are believed to help novice software engineers to become professionals in a shorter time frame. In other words, the underlying claim about the educational value of design patterns is that instead of taking the natural and lengthy route to becoming an experienced software designer through trial and error over many years, one can study design patterns that capture the essence of expert design knowledge and as a consequence become experienced in a significantly shorter amount of time. The common belief is that, after all, design patterns are supposed to help inexperienced software engineers to come up with the same design models as experts, without much need to gain experience over a long period of time. This paper questions the validity of this commonly-held belief about the educational value of conventional patterns, arguing that although there is tremendous value in capturing

and disseminating software engineering experience in the form of patterns, conventional design patterns cannot make novice software engineers perform at the level of experienced software professionals in a short period of time. In this paper, we will argue that design patterns do not replace design experience; in fact, paradoxically as it may seem, one must be experienced to correctly identify opportunities for the application of patterns and implement them appropriately. Based on our observations, we provide an explanation as to why this is the case and accordingly propose criteria for alternatives forms of software patterns to make expert software design knowledge more accessible to beginning software engineers. This paper reports on an ongoing project that aims to improve software engineering education by understanding how expert software engineering knowledge can be made more accessible to novice software engineers.

II. OBSERVATIONS AND ANECDOTAL EVIDENCE

Our observations of software engineering students, who learn about design patterns as part of their program courses, are that a great majority of these students, when asked to apply the patterns they have learned to their course projects, misuse design patterns. This misuse of patterns takes various forms, perhaps the most notorious being the application of a pattern to a design problem that does not warrant the use of that particular design pattern. That is, a design pattern is forced, as a solution, to a design problem, for which the pattern was not originally intended as a potential solution. The ill-definedness of design problems in typical software engineering contexts, on the one hand, and the imprecision in the specification of the problem and the context components of a pattern, on the other hand, make the objective and correct recognition of opportunities for the application of a pattern a great cognitive challenge, especially for inexperienced software engineers. This inexactitude in distinguishing when, a chunk of software engineering knowledge, codified experience, or best practice, represented as a pattern, is the right solution to a software engineering problem is not peculiar to novices as we have seen numerous examples of applications of patterns in industrial software projects to problems to which they do not offer a solution, resulting in an unnecessary increase in the complexity of the system and consequently software comprehension and maintenance problems. Unfortunately, in software engineering, in the absence of hard physical laws, it is always possible to produce numerous functionally-correct solutions to a problem, most of which are deficient in several

ways in terms of non-functional aspects of the solution including its understandability and the maintainability.

III. PROJECT STATUS, RESULTS, AND EXPECTED OUTCOMES

An underlying premise of this current research project is that, in order to address the above-mentioned problem with software engineering education, we must shift our research focus in the direction of investigating effective ways to more accurately specify both software engineering problems and the patterns that are intended to provide reusable solutions to these problems. In technical terms, the goal is to find a *match* function or operation that, given a problem and a list of predefined solutions (e.g., a catalog of patterns), accurately determines whether the conditions that warrant the application of a pattern (i.e., the problem description component of a pattern) match those of a given problem. It is precisely the complexity of the cognitive match operation that confronts the beginning software engineer. To make the cognitive match operation for a pattern accurately possible, we need to rethink how we specify software engineering problems and patterns.

Our research project draws on both theoretical and empirical software engineering research to address this problem. On the theoretical side, our goal is to develop a formal foundation for the specification of software problems and their corresponding patterns. Formal specification can be a fruitful avenue of research to address the problem as the observation is that the informal and inaccurate definition of problems and patterns make them subject to individual interpretations, which, in turn, makes it difficult to achieve an objective mental match operation on the part of the software engineer. Our work in formalizing the specifications of software engineering problems and patterns has resulted in two formalisms, namely the Problem Decomposition Scheme (PDS) [2] and Systematic Translation Scheme (STS) [3]. The former formalism provides a way to accurately and objectively classify software problems into requirements categories or problem dimensions, while the latter links each problem category to a set of design regularities [4] that form a predefined solution, resulting in a form of pattern known as traceability patterns [5][6]. Design patterns are, for the most part, meant to address non-functional problems such as extendibility and maintainability. An accurate characterization and definition of such non-functional concerns, due to their abstract and somewhat vague nature, is difficult to achieve. Design patterns, in effect, attempt to link from such non-functional problems to a predefined solution and are consequently subject to difficulties arising from the lack of accurate problem definitions. In contrast, traceability patterns link a category of functional problems, such as business rules category of requirements in enterprise information systems, to a predefined solution. Initial results from a previous study shows that functional problems, when stated as atomic requirements statements, can be objectively recognized [2]. This suggests the hypothesis that, software engineering knowledge, represented as traceability patterns, should be easier for novice software engineers to consume. We plan to test this hypothesis as part of our ongoing research effort.

Traceability patterns aim to solve some of the issues associated with conventional patterns through tracing problem dimensions that can be objectively recognized to their corresponding predefined solutions. This predefined solution contains the wisdom we try to transfer to the software engineer. This capability to objectively and consistently recognize problems that have predefined solutions, without much reliance on experience on the part of the software engineer, makes traceability patterns a more appropriate educational tool for software engineers, at least for novices. To enrich the theoretical foundation underlying traceability patterns, we are currently investigating the use of ontologies [7][8][9][10][11] and domain models as a formal means to capture and communicate software engineering knowledge.

On the empirical side, we have conducted a user study to empirically verify whether indeed software problem defined in PDS-based functional specifications are objectively recognizable by software engineers (i.e., is an accurate mental match operation possible?). Initial results have been reported in [2] and are promising. The technical feasibility of traceability patterns in software projects has been demonstrated in a proof of concept system [5][6]. We plan to further evaluate traceability patterns by putting them into practical use in industrial software projects. We expect that these efforts will positively impact educational outcomes for software engineers. We also expect that results from our project will be of importance to the software engineering education community as they will afford us the knowledge and insight necessary to devise better approaches to bridge the gap between novice and skilled software engineers.

A Snapshot of Current Languages Used in Industry

Jennifer Polack-Wahl, Stephen Davies and Karen Anewalt

University of Mary Washington, japwahl@gmail.com, stephen@umw.edu, anewalt@umw.edu

Abstract— We provide results from a nationwide survey of advertisements for jobs in the technology sector. This snapshot of 521 job postings provides an interesting glimpse into the state of the computing industry in the U.S., quantifying the programming languages most frequently requested by employers today. This study reveals industry preference for Java and C++ skills. C++ is requested most frequently in the South Atlantic Region and was also favored on the west coast. Additionally, SQL skills were more requested for positions related to testing, JSP skills were more requested in architect positions, and both C and C++ were more requested in analyst positions. While academic practices should not be based solely on industry practice, industry demand for languages serves as one useful data point when institutions make pedagogical choices.

Keywords—computer science education; languages; curriculum; industry

I. INTRODUCTION

In 2010, the first U.S. national survey of programming languages and practices used in introductory Computer Science courses in colleges and universities was conducted [1]. The survey showed that Java was the most frequently taught language in both CS1 and CS2 courses. One reason often cited by educators for languages choice in a particular course is industry demand [3,4] but few resources exist to quantify the industry demand. Our study provides a current data point about language popularity and also provides more specifics about the correlation of language popularity to other variables such as geographic region and job classification.

Trends in language use nationally as well as regionally are examined. Additionally we report on trends seen for various job categories. While academic practices should not be based solely on industry practice, industry use of languages does provide an important consideration for institutions to consider when making pedagogical choices. Comparing the data based on geographic regions and job categories can potentially allow faculty to consider the data in a more meaningful way for their institution and the students that they serve.

II. BACKGROUND

Several past studies have reported on language prevalence in industry. In 2002, a national survey of languages used by industry in Australia was conducted. Educators sampled employment advertisements in the IT section of The Australian newspaper and recorded the languages mentioned

for programmer positions. It was found that the average advertisement required 1.84 languages, that 48% of jobs required more than one language, and the most popular languages were C++ and Java (30% each)[2]. TIOBE Software conducts ongoing surveys of programming language popularity by tracking the number of hits when querying popular web sites such as Google, Blogger, Wikipedia, YouTube, Yahoo!, Bing, and Baidu. The results as of August 2011 show Java as the most widely used language (19%), followed by C (17%) and C++ (8%)[5]. As reported by TIOBE, these three languages have maintained the same popularity for the last 12 months.

These previous works provide interesting data about language choice, but fail to correlate the languages required to common programming jobs and also do not report on regional differences in language prevalence within the U.S. This study provides a current data point about language popularity and also provides more specifics about the correlation of language popularity to other variables such as geographic region and job title.

III. PROCEDURE AND METHODS

We gathered computer science related job advertisements from online newspapers for major U.S. cities from the various geographic regions of the country, specifically: Silicon Valley, California; Seattle, Washington; District of Columbia; Denver, Colorado; New York City, New York and Detroit, Michigan. We also included other major newspapers and geographically dependent publications to get a balance of geographic regions. The online job search engines associated with the newspapers used are shown in Table 2.

The data was gathered every fourth day from January 29, 2011 until August 8, 2011. We gathered fifteen different job advertisements each day until April 2011, half using the keyword “programmer” and the other half using the keywords “computer science”. Additional data was collected during the summer months. Jobs that had no reference to requested language or experience in language were discarded, otherwise, every third entry was manually parsed into the following; date, keyword used, language, job title, location and URL. If the job was already entered with the alternative keyword (programmer or computer science), the job was discarded and the next job in the list was entered.

After collecting and parsing the data set we categorized the jobs by the regions and divisions listed in each job description. We used the US Census Regions and Divisions as shown in Table 1 [6].

TABLE I. U.S. CENSUS DEFINED GEOGRAPHIC REGIONS

| US Census Regions | | | |

IV. RESULTS

We collected data on a total of 521 job postings over an eight-month period. These postings appeared in a variety of sources, from geographically dependent publications (e.g., Maine Today) to national job boards (e.g., dice.com.) The number of ads represented from each source is depicted in Table 2.

TABLE II. SOURCES FOR JOB ADS

| Source | Number of Postings Used |
|---------------------|-------------------------|
| Washington Post | 67 |
| Dice.com | 58 |
| Nytimes.monster.com | 56 |
| Denver Post | 55 |
| SJ Mercury News | 54 |
| Detroit Free Press | 47 |
| Seattle Times | 45 |

| Source | Number of Postings Used |
|-------------------------|-------------------------|
| Minnesota Star | 24 |
| Boston.com | 23 |
| Job hunt | 23 |
| Tennessean | 17 |
| News OK | 16 |
| Careerbuilder.com | 14 |
| Maine Today | 12 |
| Lexington Herald-Leader | 10 |

For simplicity, we use the most conservative "universal" margin of error in computing the confidence interval for all languages, using 0.5 as the sample proportion \hat{p} . We assume an infinite population, and use 521 for the sample size, which gives us a (conservative) margin of error of

$$1.98 \times \sqrt{\frac{\hat{p} \times (1-\hat{p})}{n}} \pm 4.29\%.$$

(1)

A. Overall Language Prevalence

Table 2 and Figure 1 depict the overall prevalence of the most popular languages and technologies, in terms of the total percentage of all sample job ads containing that language. Java was mentioned most often, but this is (just) within the margin of error, and so we consider Java, C++, SQL, and C# in a virtual tie. C, presumably used mostly in operating systems and embedded applications, still has a very strong showing despite its age. Note that many of the Web-only languages and technologies (PHP, ASP, Ajax, etc.) are much less frequently requested overall than the mainstream application development languages, although the number of different choices here makes the overall Web contribution still quite significant. Python, despite its popularity in academic circles, is still far from mainstream in industry.

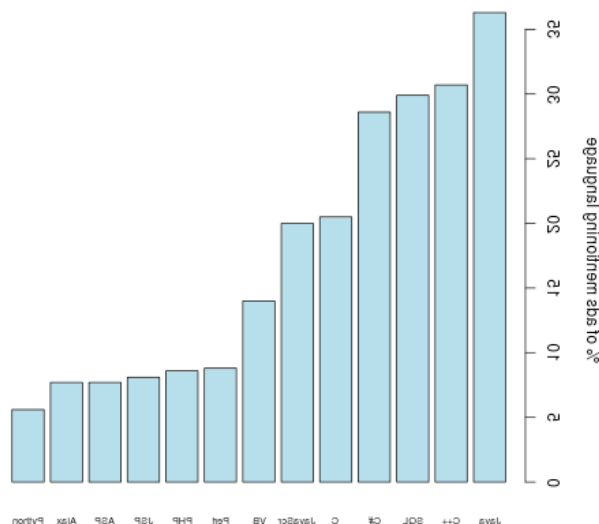

Figure 1. Percentage of all sample job ads that mentioned certain languages. (Only languages that appeared in at least 20 of 521 job ads are shown.) Note that most job ads mention more than one language, so the total is much greater than 100%.

B. Results by Job Title

We attempted to gain insight into how language use varies among workers with particular job functions. A typical software development effort involves not only programmers but also architects, analysts, testing and QA, and support staff. How do the languages advertised correlate with these sets of responsibilities?

It is difficult to get a precise measure because postings are highly variable in the language they use to describe job positions. One company advertises for a "software developer" and another for a "programmer." Are these essentially the same? Does "software engineer" imply programming, or is it a broader term encompassing other aspects of the development process? "Programmer/analyst" is a common catchphrase; so are "programmer" and "analyst" still different descriptions?

Although the data is thus a bit dirty, we still believe there is value in ferreting out some of these subtleties. We defined five broad categories of job positions -- architect, analyst, programmer, tester, and miscellaneous -- and used the following decision procedure to classify each ad:

1. If the word "test" or "tester" appeared in the job title, it was classified as a **tester** position (even if other indicative words appeared; see below.)
2. If "development," "developer," or "programmer" were in the title, it was classified as **programmer**.

Note that this is true even for the numerous "programmer/analyst" descriptors, since we reasoned that such positions would involve writing substantial project code.

3. If "analyst," "engineer," or "researcher" were in the title, it was classified as **analyst** (except as indicated above.)
4. If "architect" or "designer" were in the title, it was classified as **architect**.
5. Finally, if none of the above rules applied, the ad was classified as **miscellaneous**.

The totals for each job classification are presented in Table 3.

TABLE III. NUMBER OF ADS CLASSIFIED IN VARIOUS BROAD JOB CATEGORIES.

| Job Classification | Number | Percentage |
|--------------------|--------|------------|
| Architect | 41 | 7.9% |
| Analyst | 120 | 23.0% |
| Programmer | 288 | 55.3% |
| Tester | 46 | 8.8% |
| Miscellaneous | 26 | 5.0% |

To detect correlations between job classifications and language prevalence, we used a χ^2 test for each popular language with α set conservatively to .01 (instead of .05) to compensate for the total number of tests being so large. Even with α so low, there were still a large number of languages whose null hypothesis was rejected. To cross-check and further refine the results, we examined the job classification's standardized (adjusted) Pearson residuals for each language whose χ^2 test was positive. Only if at least one residual had an absolute value greater than 2.5 (meaning that its observed value was more than 2.5 standard deviations away from its expected value) do we include it in the list of significant results as shown in Table 4.

TABLE IV. SIGNIFICANT CORRELATIONS BETWEEN LANGUAGE PREVALENCE AND JOB CLASSIFICATION. RESULTS ARE SHOWN IN THE TABLE ONLY FOR LANGUAGE/CLASSIFICATION PAIRS WHOSE χ^2 TEST HAD $P < .01$ AND A STANDARDIZED (ADJUSTED) PEARSON RESIDUAL WHOSE ABSOLUTE VALUE WAS GREATER THAN 2.5.

| Language | More prevalent among | Less prevalent among | Overall Percentage |
|----------|--------------------------------------|----------------------|--------------------|
| C | Analysts (29.2%) Misc (42.3%) | Programmers (16.3%) | 20.5% |

| Language | More prevalent among | Less prevalent among | Overall Percentage |
|----------|----------------------|----------------------|--------------------|
| C++ | Analyst (47.5%) | Testers (10.9%) | 30.7% |
| VB | Programmers (19.8%) | | 14.0% |
| JSP | Architects (31.7%) | | 8.1% |
| SQL | Testers (45.7%) | Analysts (19.2%) | 30.0% |
| PL/SQL | Misc (11.5%) | | 2.1% |
| Ruby | Misc (15.4%) | Programmers (0.7%) | 2.5% |

Several tentative observations can be surmised from these results. SQL is prominently demanded for tester positions, perhaps indicating that managing a suite of test cases, and implementing scenarios to test an application's edge cases, frequently involve database skills in today's software processes. JSP appears far more often in ads for architects/designers than anything else, which may be a signal that the majority of "programming" work in a typical J2EE Web application is actually done in Java libraries rather than JSPs or servlets themselves, which are the realm of architects and designers. Ruby and PL/SQL, two languages that appear very rarely in the overall data set, are actually fairly frequent among miscellaneous ads. This may indicate that these languages are rarely used in product implementation, but can be important tools employed by "utility players" on the support staff.

Interestingly, the term "programmer" appears to be used more often to describe (perhaps) developers of high-level end user applications, as evidenced by the prevalence of Visual Basic requested for those job titles. "Analyst," on the other hand, correlates more often with C and C++ development, and less with database interfaces, perhaps indicating lower-level infrastructure.

C. Results by Geographic Region

Our sample job postings obviously contained information about the physical location of the job opportunities, so it is interesting to explore whether there are overall geographic trends. Following the above reasoning, we again used a χ^2 test with $\alpha=0.01$ for each language, and identified standardized Pearson residuals greater than 2.5 for specific region or division.

The results reveal some dramatic differences between different parts of the country. For one, the South Atlantic region (stretching from Delaware down to Florida) is a hotbed of C/C++ development, far more than most other areas of the country. This area features the Research Triangle Park in North Carolina, the Florida High Tech Corridor, and Virginia's strong Department of Defense presence. It is possible that sites like these have influenced projects to adopt proven, reliable, natively compiled, and fast implementation languages. C++ is also very strong on the west coast, which may be surprising to those who associate that region with Web applications and rapid prototyping. By contrast, the C language -- while still retaining an important niche throughout most of the country -- has nearly disappeared from the northeast region, especially New England where it is largely absent.

The most atypical region overall is the midwest, and particularly the East North Central division of Illinois, Indiana, Michigan, Ohio, and Wisconsin. This area has been hit as hard as any other by the recent economic downturn, and hence its economy is distinctive in many ways. Perhaps this has had some influence in driving high-tech project decisions away from the national norm. In any event, this region is currently strongly focused on Microsoft environments like VB and ASP, and only rarely searches for C++ developers. The prevalence of Visual Basic is also very noticeable in the neighboring East South Central region of Alabama, Kentucky, Tennessee, and Mississippi.

Note that Java, the programming language most heavily sought after overall, did not appear in any of the correlations in this section or the previous one. It is strong and well-represented in all sectors, and can almost be considered the lingua franca of the high-tech world.

TABLE V. SIGNIFICANT CORRELATIONS BETWEEN LANGUAGE PREVALENCE AND GEOGRAPHIC REGION. RESULTS ARE SHOWN IN THE TABLE ONLY FOR LANGUAGE/REGION OR LANGUAGE/DIVISION PAIRS WHOSE χ^2 TEST HAD $P<.01$ AND A STANDARDIZED (ADJUSTED) PEARSON RESIDUAL WHOSE ABSOLUTE VALUE WAS GREATER THAN 2.5.

| Language | More prevalent among | Less prevalent among | Overall Percentage |
|----------|--|--|--------------------|
| C | South Atlantic (31.3%) | NE (7.7%), especially New England (4.5%) | 20.5% |
| C++ | West (41.9%) Especially Pacific (46.9%) also South Atlantic (45.8%) | Midwest (16.0%) especially East North Central (12.3%) | 30.7% |

| Language | More prevalent among | Less prevalent among | Overall Percent age |
|----------|---|----------------------|---------------------|
| VB | East North Central (31.6%) and East South Central (38.9%) | | 14.0% |
| ASP | East North Central (17.5%) | | 7.7% |

D. Co-occurrence of languages

Finally, it is of interest to consider which languages often appear together in the same job ad. To do this, we use the Phi coefficient ϕ to measure statistical significance of co-occurrence. $\phi \times \sqrt{N}$ gives a distribution that is approximately standard normal, in which positive values indicate positive correlations. It is a more accurate measure of correlation than a simple count of co-occurrences would be since it adjusts for the overall frequency of appearance of each language by itself. Following our previous benchmark, we consider values whose $\phi \times \sqrt{N} \geq 2.5$ (that is, more than 2.5 standard deviations from its expected value) to be significant. The results are shown in Table 6.

As can be seen, C and C++ are by far the most tightly correlated languages, appearing together in 87 ads, which works out to a phi statistic over 12 standard deviations higher than the expected mean. Many of these co-occurring languages are not surprising (for instance, JavaScript is a necessary component of Ajax, and Java of JSP, while VB and C# are two of the most common CLI languages used in ASP.)

One bit of insight can be gleaned by observing that Perl frequently occurs with a number of different languages, probably indicating that it serves a utility role in many development teams, complementing a main implementation language. It is also perhaps surprising that C++ and Java co-occur so frequently, since they are often seen as implementation alternatives. On the other hand, the pairing may simply represent an industry preference for object-oriented language experience, rather than a specific language. The same could be said for C++ and Python. This could be an indicator of multi-language projects that include both a low-level, performance-driven component in addition to a user interface that benefits from a virtual machine's features. Clearly, there are numerous job opportunities that require developers to have experience with both.

TABLE VI. SIGNIFICANT CO-OCCURRENCES OF LANGUAGES. THE "FREQUENCY" COLUMN GIVES THE TOTAL NUMBER OF TIMES THE TWO LANGUAGES WERE MENTIONED IN THE SAME JOB AD (OUT OF 521 ADS), AND

THE " $\phi \times \sqrt{N} \geq 2.5$ " COLUMN GIVES AN APPROXIMATE STANDARD NORMALLY DISTRIBUTED STATISTIC INDICATING THE STRENGTH OF THE CO-OCCURRENCE. LANGUAGE PAIRS WHOSE PHI STATISTIC IS GREATER THAN 2.5 ARE SHOWN.

| Language 1 | Language 2 | Frequency | $\phi \times \sqrt{N}$ |
|------------|------------|-----------|------------------------|
| C | C++ | 87 | 12.78 |
| JavaScript | Ajax | 29 | 8.67 |
| Python | Perl | 15 | 8.45 |
| Java | JSP | 36 | 6.85 |
| VB | ASP | 20 | 6.85 |
| VB | C# | 44 | 6.39 |
| PHP | JavaScript | 25 | 6.16 |
| ASP | C# | 27 | 5.71 |
| SQL | PHP | 28 | 5.02 |
| PHP | Ajax | 11 | 4.34 |
| Java | Perl | 28 | 3.65 |
| C++ | Java | 74 | 3.20 |
| C++ | Python | 16 | 2.97 |
| C++ | Perl | 23 | 2.97 |
| C | Perl | 16 | 2.51 |

V. CONCLUSION

As many institutions report that popularity of a language in industry is one item taken into consideration when a language is selected for classroom instruction, it is interesting and useful to compare the industry results to those of the previously conducted national survey of languages used in introductory programming courses [1]. Table 7 compares the top 4 languages mentioned in job ads to the same languages' reported use in CS1 ad CS2. In both studies, languages could be selected multiple times, *i.e.* an institution may have indicated that some sections of CS1 used Java and some sections used C++ and similarly a job ad may have mentioned multiple languages. As a result the percentages do not sum to 100% in either study.

TABLE VII. COMPARISON OF LANGUAGE PREVALENCE IN INDUSTRY AND EDUCATION.

| Language | Industry job ads mentioning | CS1 | CS2 |
|----------|-----------------------------|-------|-------|
| Java | 36.3% | 48.2% | 55.8% |
| C++ | 30.7% | 28.8% | 36.1% |

| Language | Industry job ads mentioning | CS1 | CS2 |
|----------|-----------------------------|------|------|
| SQL | 29.9% | N/A | N/A |
| C# | 28.6% | 1.9% | 1.6% |

As can be seen, C# is often requested in industry job ads but seldom taught in CS1 and CS2 courses. Java and C++ are frequently requested by industry and frequently taught in CS1 and CS2. SQL is rarely if ever taught in introductory programming courses. The previous study referenced did not collect data about languages used in upper level or elective courses, so it unclear whether students typically receive experience in SQL as part of their undergraduate education. Given the relative frequency in which job ads mention multiple languages, it is interesting to observe that in the previous study approximately 50% of institutions reported teaching the same language in CS1 and CS2. Additionally we observe that 63% of CS1 and CS2 courses used only object-oriented languages, while in industry, languages supporting a range of paradigms are used. Again, it is possible that institutions are teaching these alternate paradigms in upper level courses, which were not included in the previous survey [1].

As a final note, we remark that it may be beneficial to the computer science education community to develop a practice

of collecting data about language use in industry and education, as this can provide a practical consideration as we develop curriculum for the future.

ACKNOWLEDGMENT

We are grateful to Dr. Debra Hydorn for invaluable advice on statistical analysis and methods.

Work in Progress: Modeling Employer Assessments

Using Professionalism in Computer Science Courses

Alice Armstrong & Carol Wellington

Computer Science Department, Shippensburg University

Shippensburg, Pennsylvania

ajarmstrong@ship.edu, cawell@ship.edu

Abstract—This paper outlines a grading system designed to replicate a manager’s perception of an employee’s reputation which starts out high and sinks with the employee’s unprofessional behavior. By modeling this perception, our program has begun to increase the number of seniors who can successfully complete their capstone projects on time. This program stands out from other similar attempts increase consistent effort and conscientiousness because it increases the impact of unprofessional behaviors on a student’s overall grade. Results from the senior capstone course inspired the use of professionalism grades in our freshman lab courses as a way to help students understand how the demands of college are different from the demands of high school and to help them take responsibility for their academic success. **Keywords**—*professionalism; senior capstone; CSI*

I. BACKGROUND

There is consensus that teaching professionalism should be part of all computer science curricula as evidenced by its inclusion as a core topic in the ACM’s 2008 Curriculum Update [1]. That standard defines professionalism to include “care, attention and discipline, fiduciary responsibility, and mentoring.” The 2008 Update is an interim revision of the 2001 standard [2] that specifies that aspects of professionalism should be addressed in introductory and intermediate courses and as part of a senior capstone experience. Fuller et al. [3] acknowledge that assessment of professionalism requires different techniques than assessing computer science content in the curriculum. In fact, their work reveals a “lack of alignment between learning outcomes and assessment practice in the area of professionalism.” They advocate for addressing “students’ lack of commitment to good engineering principles” by specifically evaluating that commitment through the use of self, peer, and instructor assessment of affective characteristics including professional attitudes and values.

There are a number of existing strategies for assessing professionalism in students. Clark [4] runs a team project course in which professionalism is assessed three ways: the instructor evaluates the team’s professionalism, the team’s customer assesses their professionalism three times throughout the project, and, finally, self and peer evaluations are completed four times in the semester. All of these assessments are combined and become 10% of the student’s grade. Sabin [4] runs a similar course with similar levels of assessment (self and peer, instructor, customer, and external evaluator). These assessments were weighted and combined as 12% of the course grade. In general, when characteristics related to professionalism are directly assessed and given as feedback to

students, the grading strategy is to use that assessment as a small portion (5-15%) of the final grade.

II. MOTIVATION

A. Professionalism in the Senior Capstone Course

In recent years, we detected a trend developing in the capstone course: a significant minority of students was unable to successfully complete the course and graduate on time. As an isolated incident, this might have been dismissed; however, this pattern repeated itself for several years running and seemed resistant to incremental changes made to the course.

The core of this problem does not appear to be in the technical skills of our students. Instead, most projects failed because students did not pursue them consistently throughout the term. As one student said, “April seemed so far away in January.” During this trend, only the standard grading strategies for assessing the professionalism of the student were used. Specifically, up to 10% of a student’s grade resulted from status reports and meeting commitments.

B. Professionalism in CSI Labs

In AY 2011, we added a freshmen seminar that was designed to help our students develop the general survival skills needed to transition from high school to college. This course was an ideal place to include a professionalism component to the grade. By grading the professionalism of the freshmen, we helped reinforce the expectations of college classes and prepare them for what was to come in their senior capstone.

III. MODELLING EMPLOYER ASSESSMENT WITH A PROFESSIONALISM GRADE

Based on discussions with members of the department’s Industrial Advisory Council, an employer’s overall perception of an employee’s professionalism has two main characteristics. First, it starts high and generally goes down, requiring a dramatic event or a long period of time to raise it. Second, unprofessional behavior taints the perception of the quality of the employee’s work. We wanted to model how professionalism affects perceptions of quality, so final grades are calculated based on two major grades, the professionalism grade and the quality grade. The quality grade is the traditional portion of the grade; it starts at 0% and builds up over the course of the semester based on the student’s deliverables. The professionalism grade starts at 100% and can only go down; when a student fails to perform in a professional way, her professionalism grade is reduced. The final grade the student

receives is the *product* of the quality and professionalism grades. If the quality grade is on a border, a small reduction in professionalism can lower the letter grade, and, even if the quality is perfect, the maximum grade that the student can achieve is the professionalism grade.

This was a radical shift in grading scheme, and so every effort was made to make this change clear to students. The syllabus spelled out the grading scheme and explained what behaviors were considered unprofessional and what the consequences of such behavior were (*i.e.* -5% professionalism for an unexcused absence). On the first day of class, the slide presentation that covered the syllabus used music and arresting imagery to grab student attention. After the syllabus was discussed, students were asked to sign an agreement stating that they understood the grading policy and the effects of not passing the course. Finally, the grade sheet was posted on the course website that tracked the professionalism grade and the quality grade and showed the estimated final grade. Daily updates to the grade sheet gave students real time feedback on how their professionalism influenced their final grade.

IV. PROFESSIONALISM FOR SENIORS

The Shippensburg University Computer Science program requires an individual senior capstone project that is completed in two semesters. The first semester includes content on research methods and requires the student to complete a literature summary and to plan and propose a project. In the second semester, students implement and complete their projects.

Students who graduate from our program should be ready for the workplace or graduate school. Failing to complete the senior research project delays graduation by a year. We set two goals for the most recent revision of the course. First, we wanted to reduce the number of course failures and incompletes. Second, if failure seemed likely, we wanted to make that clear to the student as early as possible.

V. PROFESSIONALISM FOR FRESHMEN

We used the professionalism grading scheme to help students quickly understand differences between the expectations of high school and college. In AY 2011, the 4-credit CS1 course was restructured to accommodate a first year seminar for computer science majors, packaging conceptual material into a traditional 3-credit lecture and adding a small-sized 1-credit lab focusing on active learning material. The labs met for three continuous hours a week with two hours dedicated to lab exercises and a third hour nicknamed “boot camp”.

The boot camp material addresses the “soft skills” that our freshmen lack and helps students develop a graduation plan. In AY 2011, topics included: professionalism, new skill acquisition, time management, study skills, and awareness of campus resources [6].

In order to accommodate for the fact that this was the first semester for most students, a small change was made to the professionalism grade: there were a few opportunities for students to earn back professionalism points. These opportunities involved pursuing the seminar topics above and

beyond the required assignments, and they were always focused on improving a student’s college skills.

The overarching goal of the boot camp for computer science majors was to help them understand and adjust quickly to the expectations of the program. Professionalism was used to help students develop good self-management habits.

VI. RESULTS

A. Senior Capstone Results

Table 1 shows the grade distribution for the second semester of Sr. Research since AY 2007. Failing and incomplete grades are presented as a single group to control for changes in course policies. The professionalism component of the grade was instituted in AY 2010. Of necessity, this study has a small sample, making it difficult to draw statistically significant conclusions from the results; however, the initial results are promising. The same instructor has taught the course from AY 2009 through AY 2011. The academic content has been the same throughout that period.

Table 1: Grade Distributions for the 2nd Capstone Semester

| | A | B | C | D | F / I | Total Students |
|----------------|-----|-----|-----|----|-------|----------------|
| AY 2007 | 18% | 36% | 5% | 9% | 32% | 22 |
| AY 2008 | 50% | 14% | 7% | 0% | 29% | 14 |
| AY 2009 | 12% | 35% | 12% | 0% | 42% | 26 |
| AY 2010 | 60% | 12% | 0% | 0% | 28% | 25 |
| AY 2011 | 55% | 22% | 4% | 4% | 17% | 23 |

AY 2010 and 2011 show improvement over the previous years. The AY 2008 class was significantly smaller than the other years, and so it is difficult to know how well the AY 2010 numbers really compare with that year. Table 1 also shows that there was a significant increase in the number of As and Bs starting in AY 2010, but it is difficult to identify the source of this change as opportunities to earn extra credit were also included in the grading policy. The extra credit may account for higher passing grades in AY 2010 and AY 2011, but extra credit could not be used to save a student from failing; therefore, the evidence suggests that the lower number of Fs and Incompletes was due to the professionalism grading scheme.

B. CS1 Results

The long-term goals of the changes we made to CS1 include increased retention and early voluntary attrition. While it is not the intention of the department to “weed out” students, it is important that students settle on a major as soon as possible to maximize their chances for long-term success. Both long-term goals will be measured over the next several years to assess the impact of the first year seminar.

The effect of the professionalism grading system on CS1 lab grades was noticeable, but not catastrophic; no student lost more than one letter grade as a result of professionalism. We will continue to monitor the attrition and success rates of students who have passed CS1 as they move towards graduation. Currently, there is no clear impact on CS2 grades.

// TODO: Help Students Improve Commenting Practices

Peter J. DePasquale*, Michael E. Locasto[†], Lisa Kaczmarczyk[‡] and Mike Martinovic*

*The College of New Jersey

[†]The University of Calgary

[‡]Independent Evaluator

Abstract—One implicit purpose of writing software code is to communicate ideas. Commenting source code helps explain these ideas and provides background on the semantics of a program. Yet, enabling students to acquire good commenting practices remains difficult. Instructors can find it hard to meaningfully discuss such practices in both introductory and advanced undergraduate courses. Furthermore, comment *grading* is an imprecise, labor-intensive procedure at best. But just what practices should we be encouraging students to emulate?

To help address these issues (learning about professional code commenting patterns and best practices, objectively grading student comments), we developed the *COMTOR* tool as an open source project and web service. *COMTOR* provides a platform for helping assess source code documentation in an objective, structured fashion. We conducted two experiments using *COMTOR*: one that examines a set of popular open-source Java code projects and one that measures a baseline of student-generated code comments. The latter are based on three semesters worth of data from two different undergraduate courses.

Our aim is to extract knowledge about the state of professional practice in source code comments and how these properties vary over the lifetime of a project. We can then begin to make recommendations and communicate best practices (or a lack thereof) to our students.

I. INTRODUCTION

For students, the process of documenting software is unlike almost any other activity in the traditional Computer Science undergraduate experience. The act of writing high quality source code comments requires developing skills in clear, concise technical writing and applying these skills in concert with a deep understanding of both the practical and theoretical underpinnings of a code modules and subroutines. Although the design of algorithms and the use of a programming language to encode them does require clear, disciplined, and creative thinking, mathematical rigor almost always constrains the expression of a solution. At the very least, this expression is restricted to a language with unambiguous semantics and highly structured syntax.

In contrast, source code comments offer a freedom of expression that students can struggle to make full use of. Source code comments can help describe a wide array of software properties at a variety of abstraction levels. For example, comments might indicate what the code can or should do, what the history of a function or module is, what the properties of certain data structures are, what error or failure modes the code might have, what the implications of a particular implementation trick are, any external interactions,

and assumptions the programmer may have made. Unfortunately, teaching undergraduates to write good documentation — particularly source code comments — presents an imposing challenge for two tightly coupled reasons.

Learning Challenges From a learning perspective, students can find it difficult to create good documentation because they believe that the code is ultimately more important than the prose explaining it, and they can struggle to gain an understanding of how such a construct might be evaluated by their instructors, peers, or employer. Early programming courses reinforce this attitude because assignments tend to focus on basic ideas and first principles, and students (naturally) focus more on learning the syntax of a language.

Evaluation Challenges Since comments possess a more free-form nature than most constructs in traditional programming languages, the process of grading or evaluating this type of documentation requires a significant amount of *manual* effort (despite the existence of schemes like Javadoc [1]–[3]). Due to the freedom that students have in expressing themselves and the reluctance of many students to spend time on writing documentation (a goal that they can easily — and understandably — view as secondary to constructing a working solution), actually assessing comments can present a monumental task for faculty, teaching assistants, tutors, and graders, especially when dealing with large class sizes or extensive assignments.

As a result, many grading efforts rely on only a cursory examination of the presence or absence of certain key commenting practices (even if in-depth assessment is conducted, the inherently manual nature of such activity almost ensures that any such in-depth assessment is unsustainable beyond a few exercises). Furthermore, almost no general tools exist for helping students vet the quality of their own comments as a form of active learning [4] — bringing us full circle back to the learning challenge listed above.

A. Motivation

Comments supply an ongoing conversation between multiple developers (or even a single developer over a period of time) by explaining the logic expressed in the code itself. Comments are often the most immediately intelligible part of a module's source to a non-developer or other non-technical audience. As such, they serve an important role in the design, maintenance, and use of software programs [5]. **But how can**

we teach students to adopt and nurture practices and skills that lead to the production of high quality software documentation? From our experiences as Computer Science educators and the anecdotal evidence of our colleagues, we observe that this major need of students and their future employers is not being met.

B. Contributions

Although many faculty members and software engineers might argue that commenting is important, such skills are rarely mature in undergraduates. One way to support their skill development in this area is to provide them with tools for assessing the quality of the comments they write. We believe that comments and other documentation serve a vital role in helping students engage with the practice of design and continuous evaluation of their software.

We built an automated analysis tool called COMTOR (Com^{ment} Men^{TOR}). COMTOR helps to observe the evolution of commenting practices across versions of a single project and across projects. Applying COMTOR to both student baseline code (i.e., code that students write for assignments and labs in the absence of any specific training for code commenting best practices) and to professional open-source code can help show how wide the “gap” between industry and academia is on this topic. Analysis of code using COMTOR is one way to help students nurture good habits by getting them to buy into evaluating their own code and making them a partner in the process by giving them control over a feedback process.

II. THE COMTOR SYSTEM

The primary mode of operation of COMTOR is aimed at gathering and summarizing properties of source code comments. COMTOR was designed to process source code through a pipeline of analysis and reporting modules. We chose to focus on analyzing comments in Java source code because it serves as a relatively common language for use in undergraduate programming courses, and it provides the Javadoc [1], [3] convention for structuring comments and automatically producing API documentation. We benefit from the flexibility of the Javadoc interface by building some of our analysis modules on Javadoc’s facilities for adding new tags and other comment constructs. We used COMTOR as a command line tool for the experiments this paper describes.

COMTOR currently includes these analysis modules:

- 1) *Check for Tags* (relies on the presence of Javadoc-style comment tags [1]) – Searches the submitted source code to evaluate whether all user-defined methods contain the correct use of three core Javadoc tags (*@return*, *@param*, and *@throws*).
- 2) *Percentage Methods* – Measures the percentage of methods in a class that are documented with a Javadoc header; in essence, this module measures the “density” of commented code.

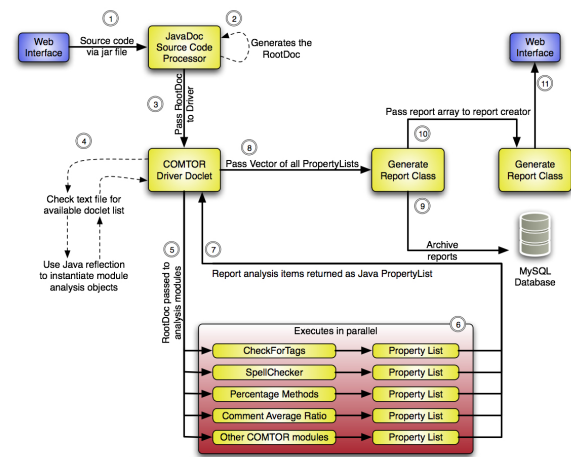

Fig. 1. *The COMTOR Architecture*. COMTOR can be driven by the command line or as part of a web service. Its main mode of operation is to take a collection of packages and source files, run them through a series of specialized doclets, and gather the output of each module.

- 3) *Comment Average Ratio* – Calculates the length of documentation (in number of words) for all the methods in a given class, and computes the average.
- 4) *Spell Checking* – The spelling of the words present in source code comments is checked against a modified version of the Linux words file as well as other dictionaries and word collections. This module automatically incorporates symbols like method, variables, and class-names.
- 5) *Offensive Words* – Checks comment bodies for the presence of potentially offensive words and phrases.
- 6) *Check Author* – Profile the use and presence of the *@author* Javadoc tag.
- 7) *Pre- and Post- Conditions* – COMTOR defines custom *@pre* and *@post* tags.

Although many of these modules report on relatively simple measures of comment properties, we believe that they provide an objective basis for evaluating the quality of comments as a whole. Indeed, we seek to provide a range of reporting on many different features of comments: some dealing with the quality of the actual prose and others dealing with how well the comment describes the source code features associated with it. While some modules are simplistic in nature, they help to automate the process of a basic sanity check for grading purposes – a widely appealing prospect to a number of faculty doing this work currently “*by hand*.”

III. APPROACH

The main line of argument in this paper is that we as educators need to do a better job of teaching students professional code commenting and documentation tactics and strategy — but we need a real-world basis for our recommendations. So what do “real world” code commenting practices look like?

Our best approximation is by looking at large, popular, widely-used open source projects.

This section describes our research methodology and provides an overview of our experiments. The current focus is twofold: (1) evaluating student code to get a sense of the “gap” and (2) observing properties of established open-source code. Although we are currently using COMTOR in the classroom to assess its impact on student commenting practices, those latter experiments are ongoing and not ready to be reported.

A. Student Baseline Code Experiment

We first use COMTOR on three semester’s worth of student code from two different introductory computer science courses. This student data was collected under conditions that were not influenced by the presence of COMTOR; in other words, students and instructors had no knowledge of COMTOR and received no special guidance or encouragement to alter their standard commenting or teaching practices. This data is purely historical data from the past few years.

We gathered this data to serve as a baseline for comparison with similar courses that *did* use COMTOR and to give us an idea of the kinds of commenting practices communicated to students early in the computer science undergraduate course sequence. This paper focuses on this latter purpose. We measured an Introduction to Programming course and a Data Structures course; raw results are shown in Table I.

| # of: | CSC 220 | CSC 230 |
|-------------------|---------|---------|
| Students | 43 | 29 |
| Projects | 561 | 299 |
| Classes | 1395 | 951 |
| Constructors | 1460 | 1074 |
| Methods | 11599 | 4688 |
| Fields | 7168 | 3043 |
| Commented methods | 2170 | 2794 |
| Correct spellings | 15808 | 17233 |
| Mispelled words | 899 | 717 |
| Offensive words | 0 | 0 |

TABLE I

Using COMTOR on Student Baseline Code. AN OVERVIEW OF RUNNING COMTOR ON BASELINE DATA: CODE FROM STUDENT PROJECTS AND ASSIGNMENTS IN WHICH STUDENTS DID NOT USE COMTOR AND WERE NOT EXPOSED TO ANY FORMAL COMMENTING BEST PRACTICES.

CSC 220 (Introduction to Programming) has nearly double the students and projects, slightly more classes, double the number of fields, and three times the number of methods as CSC 230 (Data Structures). Nevertheless, the number of methods commented is relatively the same. CSC 230 students commented methods at a rate of about 50% while CSC 220 students commented less than 20% of the methods they wrote. Most methods were lacking Javadoc-style tags. Overall, these numbers and results are a stark illustration of the gap between what we think students should learn and what they pay attention to: for a skill that is not routinely tested or evaluated, students simply do not put effort into it, and this trend persists across multiple courses and semesters.

B. Jakarta Experiment Overview

We next seek to derive some characteristics of professional source code documentation to inform best practices and recommendations to students. Focusing on such code helps us calibrate our expectations about the types of properties and comment quality we can expect COMTOR to pick up on, in turn helping us to summarize and convey commenting practices in the real world to our students.

We used COMTOR to assess a large amount of existing open source Java code from the Apache Jakarta project (specifically: POI, Oro, Maven, Tomcat, and Ant). These projects represent a variety of software: a format parsing framework (POI), a regular expression library (Oro), a network server and execution container (Tomcat), a build management tool (Maven), and a tool and scripting platform that performs software builds (Ant). This experiment observed how comment properties vary both within (i.e., from early to current versions of a single software application) and across (i.e., between different projects) this software collection.

The goal of this experiment is to provide an independent calibration of COMTOR on non-student code and to help us derive an assessment of existing best practices and pressures on commenting practice in real-world code. *Even though we use relatively simple metrics, automated assessment of even simple features provides value because it helps scale an otherwise a manual task.*

| Version | # classes | # constructors | # methods | # fields |
|---------|-----------|----------------|-----------|----------|
| 4.1.40 | 853 | 966 | 9640 | 5105 |
| 5.5.0 | 797 | 947 | 8979 | 4514 |
| 5.5.33 | 929 | 1092 | 10404 | 5717 |
| 6.0.0 | 1204 | 1392 | 12696 | 6721 |
| 6.0.18 | 1272 | 1470 | 13217 | 6891 |
| 6.0.33 | 1310 | 1512 | 13670 | 7178 |
| 7.0.0 | 1387 | 1595 | 13254 | 6983 |
| 7.0.2 | 1398 | 1607 | 13309 | 7001 |
| 7.0.4 | 1411 | 1618 | 13310 | 7013 |
| 7.0.5 | 1415 | 1620 | 13180 | 7071 |
| 7.0.6 | 1428 | 1627 | 13176 | 7072 |
| 7.0.8 | 1426 | 1626 | 13178 | 7088 |
| 7.0.10 | 1431 | 1630 | 13197 | 7085 |
| 7.0.11 | 1429 | 1628 | 13204 | 7076 |
| 7.0.12 | 1433 | 1621 | 13238 | 7112 |
| 7.0.14 | 1437 | 1626 | 13267 | 7133 |
| 7.0.16 | 1449 | 1637 | 13310 | 7139 |
| 7.0.19 | 1452 | 1642 | 13334 | 7166 |
| 7.0.20 | 1454 | 1644 | 13352 | 7175 |

TABLE III

Size of Tomcat Codebase. WE ALSO TESTED A NUMBER OF EARLIER RELEASES IN THE 3, 4, AND 5 SERIES, BUT COMTOR COULD NOT PROCESS SOME OF THEM WITHOUT REVERTING TO EARLIER VERSIONS OF THE JAVA LANGUAGE; WE EXCLUDE THESE PARTIAL RESULTS.

C. Caveats and Limitations

One criticism of our approach and experiments is that we do not process the semantics of the comments we find; we restrict ourselves to coarse-grained measures of overall commenting practice quality (e.g., density of comments, length/size of comments, and a measure of misspelled words in those comments).

| Version | # classes | # constructors | # methods | # fields | % commented | # misspelled | # offensive words |
|---------|-----------|----------------|-----------|----------|-------------|--------------|-------------------|
| 1.6.0 | 895 | 963 | 7100 | 4102 | 79 | 1741 | 10 |
| 1.6.1 | 900 | 968 | 7191 | 4167 | 79 | 1757 | 10 |
| 1.6.2 | 926 | 1002 | 7380 | 4283 | 80 | 1403 | 10 |
| 1.6.3 | 962 | 1041 | 7652 | 4396 | 81 | 1420 | 10 |
| 1.6.4 | 962 | 1041 | 7653 | 4396 | 81 | 1420 | 10 |
| 1.6.5 | 962 | 1041 | 7656 | 4396 | 81 | 1421 | 10 |
| 1.7.0 | 1068 | 1200 | 8503 | 4893 | 88 | 1486 | 10 |
| 1.7.1 | 1079 | 1215 | 8691 | 5131 | 88 | 1451 | 10 |
| 1.8.0 | 1144 | 1313 | 9207 | 5410 | 86 | 1489 | 12 |
| 1.8.1 | 1145 | 1317 | 9226 | 5423 | 86 | 1488 | 12 |
| 1.8.2 | 1159 | 1337 | 9339 | 5485 | 85 | 1500 | 12 |
| 1.8.3 | 1161 | 1339 | 9376 | 5511 | 85 | 1499 | 12 |

TABLE II

Size of Ant Codebase. AN OVERVIEW OF THE “SIZE” OF THE ANT CODEBASE FROM RELEASE 1.6.0 TO 1.8.3 IN TERMS OF MAJOR CHARACTERISTICS LIKE NUMBER OF CLASSES, CONSTRUCTORS, METHODS, AND FIELDS.

| Version | # classes | # constructors | # methods | # fields | % commented | # misspelled | # offensive words |
|---------|-----------|----------------|-----------|----------|-------------|--------------|-------------------|
| 1.5.0 | 285 | 547 | 2788 | 1399 | 63 | 544 | 3 |
| 1.5.1 | 290 | 552 | 3959 | 1415 | 62 | 555 | 3 |
| 2.0.0 | 370 | 724 | 4683 | 1848 | 61 | 809 | 3 |
| 2.5.1 | 445 | 840 | 4851 | 2669 | 59 | 868 | 3 |
| 3.0.0 | 510 | 826 | 7416 | 2869 | 59 | 937 | 3 |
| 3.5.0 | 920 | 1227 | 8643 | 4555 | 50 | 1494 | 5 |
| 3.7.0 | 994 | 1320 | 7956 | 4907 | 49 | 1605 | 5 |
| 3.8.0 | 1105 | 1457 | 8675 | 5232 | 49 | 1737 | 0 |

TABLE IV
POI Characteristics.

| 2.0.7 | 62 | 92 | 329 | 306 | 60 | 152 | 0 |
| 2.0.8 | 65 | 96 | 332 | 312 | 55 | 147 | 0 |

TABLE V
ORO Characteristics.

We do not perform analysis that correlates the natural language in the comments with the semantics of the code it describes.

In the graphs in Section IV, we mainly compared commenting density against the size of the codebase in terms of methods; we did not perform an in-depth analysis of the comments relating to fields and data members of classes. In addition, COMTOR only captures Javadoc-style comments (i.e., not those starting with a double slash or a slash-asterisk). Also, code from Jakarta-based projects may not be representative of all large-scale, widely-used Java code (and commenting practices). The commenting practices found within this software may also differ from commenting practices in other languages and projects (e.g., the Apache web server, the Linux kernel).

We note that the code we examine is professional code in the sense that Jakarta is a large, well-known incubator of mature and widely-used Java projects; many developers of the software hosted by this organization are professional soft-

ware engineers contributing back to an open-source project. However, this code is not proprietary software produced by large software engineering firms, and may not represent code organization and commenting disciplines adopted by such organizations and companies (nevertheless, this code is publicly available and allows others to reproduce our approach). Finally, these projects are not representative of student code in certain aspects — they are typically larger, reflect the input of multiple people, and have a significant history.

IV. EVALUATION

This section discusses our measurement of the aforementioned Jakarta projects.

A. Results From Apache/Jakarta Code

We examined Ant versions from 1.6.x to 1.8.x. In this range of releases, there appear to exist two significant changes in the nature of the codebase: one from 1.6.5 to 1.7.x and again from

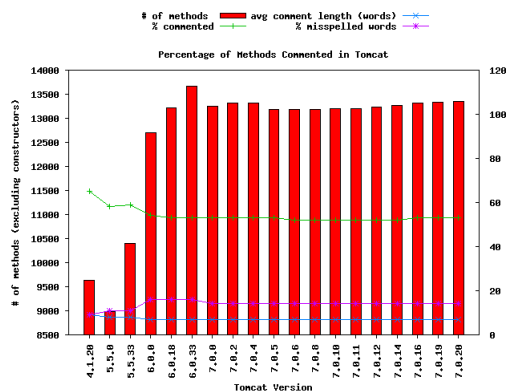

Fig. 2. *Tomcat Comment Characteristics*. The percentage of methods commented declines from 65% to 53%. Average comment size (in words) gradually decreases from 9 to 7. The existence of misspelled words increases from 9% to 14%.

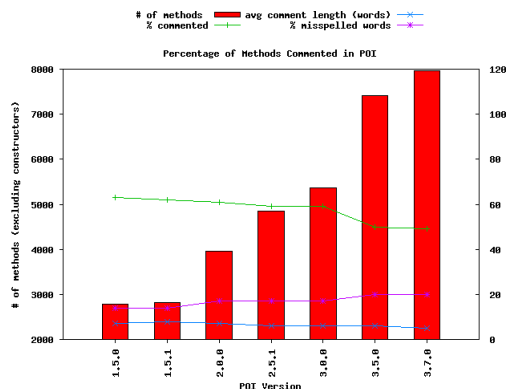

Fig. 3. *POI Comment Characteristics*. The percentage of methods commented starts above 60% but declines below 50%, particularly as more code is added in 3.5.0 and 3.7.0. The average size of each method comment (in words) gradually decreases from a high of 8 to 5. The existence of misspelled words increases to 20%.

1.7.x to 1.8.x. The density of commented methods increases until the second change; at this point, it looks like the addition of new methods either (1) didn't warrant the addition of new comments or (2) the developers did not keep up with documentation efforts. Nevertheless, of the three projects we examined, Ant has the best overall rate of commenting.

We performed a longitudinal study of Tomcat, covering a sampling of versions 3, 4, 5, and 6 as well as all point revisions of Tomcat 7. Tomcat had the largest codebase and maintained a fairly steady rate of around 50% of all methods commented.

We processed seven POI versions from 1.5.x to 3.7.x. We can see that the codebase generally increased in size, and that the density of comment coverage of methods decreased. Like other projects, the average comment size (in number of words) hovers in the high single digits. As in other projects, the percentage of misspelled words across all comments ranges in the high teens.

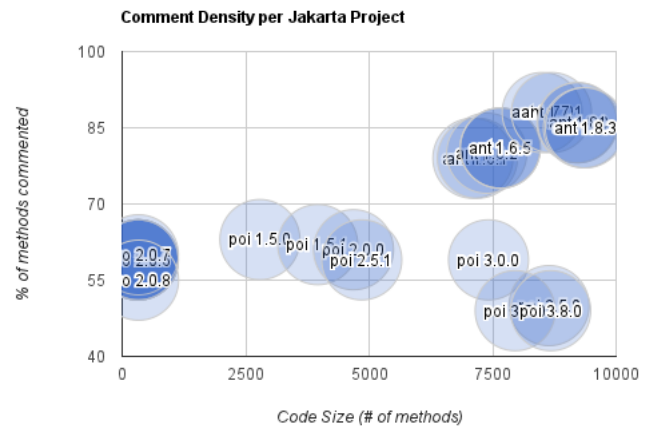

Fig. 4. *Project Code Density Clusters*.

B. Cross-Project

Most of the projects have the percentage of methods commented hover around 50% while Ant maintains a rate above 80%. We plotted the rate of change of a codebase size (in terms of methods added) versus the rate of change in percentage of methods commented as a way to depict how efficient the developers for each project were in keeping up with the addition of code. Figure 5 depicts this relationship and offers one way to perform a comment analysis across comments.

In Figure 5, the horizontal axis depicts time by enumerating releases; this axis does not depict real time, in that the first versions of Ant, POI, and Tomcat that we measured (1.6.0, 1.5.0, and 4.1.20, respectively) did not occur simultaneously. The vertical axis depicts the gain or loss in comment density (in terms of number of methods). A value of zero on the vertical axis means that the project "kept up" with the addition of code; a positive value means that the developers actually documented *more* than the number of methods that were added, and a negative value means that developers documented less than the number of methods added to the code.

V. PEDAGOGICAL USE

What did we learn about commenting best practices? What can we tell our students?

In early releases of Ant, even as code size increases, the percentage of methods commented increases, indicating that developers actively generated more comment coverage. After the shift to version 1.8.x, however, the percentage of methods commented decreased slightly. This is a good lesson for students: even in real-world code, large code changes can dominate efforts to generate or keep documentation relevant. Nevertheless, Ant seems to have a very high rate of documentation compared to other projects (around 80% compared to 50% for other projects).

We also learn that most method header comments are pithy, with an average of below ten words. This may be enough

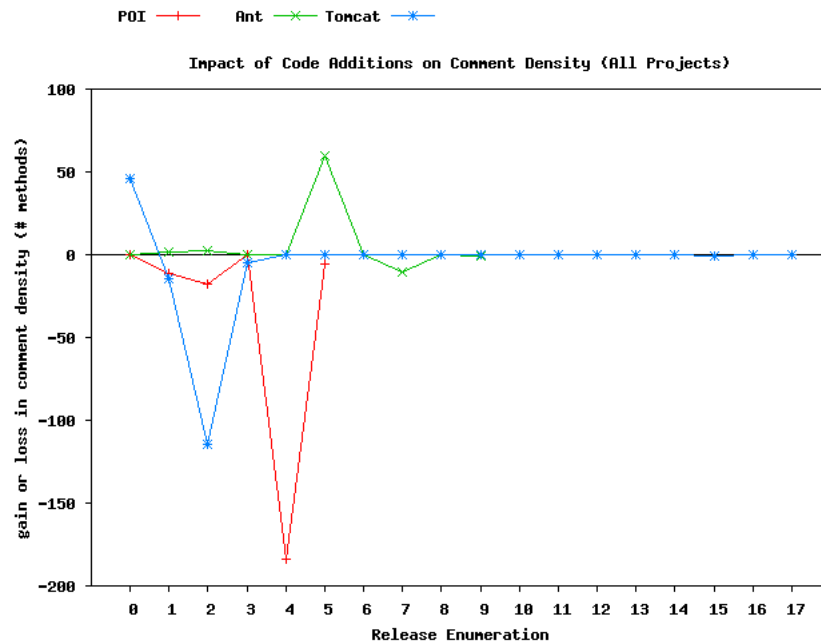

Fig. 5. *Impact of Code Size Changes on Comment Density.* This graph displays a cross-project comparison of how changes to code base size affect the density of comments. Both POI and Tomcat struggle with the addition of code but recover to maintain a balance. In contrast, Ant increased comment density, even after adding code, with only a slight dip for another code increase. A value of zero on the vertical axis means that developers kept up with the addition of code, negative values mean that added code remains uncommented, and positive values indicate that code beyond the new code was commented.

for a short, descriptive sentence, but hardly leaves room for discussion of underlying semantics or failure modes (which may partially be addressed by @throws clauses, @param descriptions, and one-line comments sprinkled throughout the method body).

Some project coding guidelines (e.g., the Linux kernel) recommend *not* writing extensive comments; they adopt this rational for several reasons, including (1) not “polluting” the source code with a large amount of extra text to sort through and (2) the perceived cost of keeping such comments up to date and in sync with the code it describes.

While the type of data that COMTOR generates from Jakarta code or student code is interesting from a software engineering perspective, and can help drive home what happens in the construction and maintenance of real-world software, the potential for analysis of this type of data in the classroom itself is quite large. For example, as Figure 5 shows, this type of analysis can be usefully applied back into the classroom to help analyze large, collaborative student projects and progress. Open source projects provide large amounts of data for analysis and visualization courses.

VI. CONCLUSION

This paper examines the design, development, and application of our tool for evaluating source code comments. Comments provide vital information about the semantics and behavior of code, yet little progress has been made on ways to help our students gain proficiency at writing high-quality documentation. In this paper, we examined a preliminary step: gathering information from open source projects about source

code comment properties. Such information can help form the basis of advice, recommendations, and best practices for our students. Through observations like this, students can learn to balance the tradeoffs involved in spending time and effort to document code.

Abstract — This paper describes the effort of creating a joint international graduate program in the area of semiconductor product engineering and power electronics. As a first step, a joint summer course for undergraduate students is implemented with the intention to create a larger interest in the program among the current undergraduate population at Texas Tech University and the University of Applied Sciences, two of the institutions jointly offering this degree.

Keywords- *international experience, joint degree programs, graduate education.*

I. INTRODUCTION

The Program for Semiconductor Product Engineering (PSPE) has been in place at Texas Tech University for the past 14 years [1]. Its primary focus has been training MSEE product engineers and test engineers for the semiconductor industry. Although several companies (Intel, Advanced Micro Devices, Applied Materials, Freescale, Texas Instruments) have invested in the program from time to time, the majority of the financial and technical support has come from Texas Instruments (TI), and the preponderance of professional placements has been with TI. Indeed, the history of the program shows that approximately 80% of the students who participate in the program have been offered and have accepted full time positions with TI, and the total number of engineers thus placed exceeds 200. By most metrics, this would be regarded as a highly successful program with an enviable record.

Students are accepted into PSPE from a variety of backgrounds but most have baccalaureate degrees in Electrical Engineering, Computer Engineering, Physics, Mathematics, Mechanical Engineering, and Industrial Engineering. For those students in fields other than Electrical Engineering and Computer Engineering a few (<4) leveling courses generally suffice to ensure adequate preparation. A typical program of study includes three semesters of coursework and a 3 - 6 month cooperative education or internship experience. With less than 1% exception all students pursue the thesis option, usually based on work accomplished during the coop and directly relevant to the business unit sponsoring the student. Courses include Engineering Analysis (mathematical tools), Statistics, Microprocessor Architecture, Modeling and Simulation of Electronic Systems, Parametric and Functional Device Testing,

Analog Circuit Design, Advanced Digital Circuit Design, Testing of Digital Systems, Communication IC Design, Low Power VLSI Design, Solid State Devices, VLSI Processing, Power Semiconductor Devices, Power Converter Design and Test.

Texas Tech faculty meet with TI technical and management personnel on a regular basis to understand changing business environments and how they impact desired course content and demand for students. Flexibility in student schedules is important in matching students to opportunities. Most recently TI has indicated a desire to include undergraduates in a similar program that would lead to BSEE hires. A partnership with TI has resulted in funding in form of a National Science Foundation grant [2] to encourage undergraduates to consider careers in the semiconductor industry.

Partly due to the success of the program and partly in spite of this success, TTU is pursuing a different sort of expansion to include more companies and international partners. Students would benefit from exposure to diverse corporate cultures. A less narrow technical focus would also allow students to look at other positions and in other related industries. Finally, all involved agree that the increasingly global nature of industry demands exposure to other cultures, business models, and general perspectives. The achievements of PSPE at TTU have led our sponsors to attempt to adapt the model to other institutions, notably the University of Applied Sciences (UAS) Landshut in Germany. What started as an attempt to build a PSPE-like program between UAS Landshut and TI in Freising, Germany, has evolved into a partnership between UAS Landshut and TTU that includes TI Freising as one of many corporate contacts in the Greater Munich area. Faculty from TTU feel that their students will benefit from broader technical coverage in an electronic product engineering curriculum. UAS Landshut faculty feel their students will benefit from expertise at TTU in the areas of power electronics and testing and from the experiences made through PSPE. The commitment of TI Freising is important but all agree that including other industries is crucial for the successful implementation of the program.

II. JOINT SUMMER COURSE

This summer (August 2012) we will offer a short course in international product engineering at UAS Landshut that will be attended by students from TTU and UAS and will be taught by a faculty member from TTU. The content of the course includes the core of TTU's Parametric and Functional Device Testing and exposure to IC automated test equipment and will have a lab component accompanying the lecture. Courses will be held on the UAS campus and TTU students will live in UAS Landshut dormitories. Through the joint enrollment of students from both institutions and an instructor from TTU a personal look at the different education systems will be given to all participants. The preparation for this course included collaboration with TI Freising which will donate testing equipment to UAS Landshut. Participants from TTU will bring expertise in the usage of this instrument with them from prior usage at TTU and will share this knowledge with faculty and students from UAS Landshut. Excursions for all participants to semiconductor companies in the area are planned for at least 2 afternoons per week. The geographical area (Bavaria) is rich in German heritage and history, and participants will take advantage of this as well.

III. EVALUATION OF SUMMER PROGRAM

We will analyze the results of this program and report our preliminary findings at the conference in October. We are developing pre- and post- surveys to help determine changes in attitudes toward awareness of cultural differences, studying abroad, and interest in graduate school among the participants. Of course, we will examine students on technical content as well. For the TTU students, we will have an extended opportunity to work further in the fall semester to improve the offering. Funding opportunities with the National Science Foundation and German and European organizations will also be explored.

IV. JOINT GRADUATE PROGRAM IN ELECTRONIC PRODUCT ENGINEERING

The joint graduate program in electronic product engineering, which is currently under preparation will be open to students from Germany, the US, and Asia. It is motivated by the need of multinational companies (MNCs) operating manufacturing facilities in countries like Malaysia, Thailand, and Vietnam to also aim at innovative and applied research and development. The focus of the new program will be application oriented and driven by industry needs. Electronic Product Engineering (EPE) will be an executive postgraduate Master's program taught in English at UAS Landshut and TTU with an international student body mainly from South East Asian countries as well as US and German nationals. Students or their employers are required to pay tuition fees making the program self supporting.

To be admitted into the program, students must hold a bachelors degree in electrical engineering or a related field, have a minimum of one year practical experience, and be on sabbatical leave from their employer during term period.

Participants are anticipated to return to their employer after completing the program of studies.

The curriculum will consists of courses in electronic and system engineering, technology and production methods, quality and testing, customer relations, intercultural competence, and project management.

Educational objectives of the program are to train engineering graduates to the highest international level, train the next generation of university lecturers to the highest international level, and promote their personal development in order to contribute to the focal country's development.

V. CONCLUSIONS

Interest in the summer program among students has been high at TTU. Subscription filled the target number very early after the initial offering, and there have been lively conversations on social media sites regarding many aspects of the program. Much of this conversation has focused on the cultural aspects of the visit – where to go, what to do, etc., but there has also been a highly cooperative thread of discussion on the logistics of the flight to Germany.

Planning for the coursework is continuing. We will no doubt encounter issues with unfamiliar equipment, a different power system, laboratory layout, and other challenges to our assumptions but that is part of the program, and there is real value in exposing the students to these issues and to their participation in the development of solutions.

VI. AUTHOR INFORMATION

Richard Gale, Ph.D., is a Professor of Electrical and Computer Engineering at Texas Tech University. He is the director of the Program for Semiconductor Product Engineering (PSPE) at Texas Tech University. He also serves as the graduate advisor for the Electrical and Computer Engineering Program.

Tanja Karp, Ph.D., is an Associate Professor at the Department of Electrical and Computer Engineering, Texas Tech University, Lubbock, TX 79409-3102. She has gained her degrees from the Technical University of Hamburg-Harburg and thus has experienced higher education systems in Germany and the USA. She serves as the Fulbright Program Adviser at Texas Tech University and chairs the U.S. Student Fulbright committee at this institution.

Helmuth Gesch, Ph.D., is the Vice President for Competence and Technology Transfer and a Professor of Electrical Engineering at the University of Applied Sciences in Landshut, Germany. He also serves as the Director for the Landshut Automotive Competence Center.

Work in Progress: Student lab on graphics cards' multi buffer architecture implemented in an FPGA

Dag A. H. Samuelsen and Olaf H. Graven

Faculty for Technology
Buskerud University College
Kongsberg, Norway
dag.samuelsen@hibu.no, olaf.hallan.graven@hibu.no

Abstract—This paper presents a laboratory assignment for a module in VHDL programming. The purpose of the laboratory is to demonstrate sophisticated, state of the art solutions to current challenges in digital hardware design. The goal is to avoid setting up tasks that have a complexity beyond what the students are able to handle, but at the same time keeping the essential parts of the solution. The laboratory assignment presents to the students the principal solution to a problem or challenge, and the students' task is to develop a practical implementation of this solution in an FPGA, with I/O units connected, that demonstrates the effectiveness of the solution.

Keywords—VHDL programming; digital hardware design; laboratory assignment.

I. INTRODUCTION

A continued challenge in giving engineering students up-to-date skills and knowledge on new developments and strategies is the continued development and sophistication of computer peripheral devices as computing power is moved from the main processor into the I/O devices. In the student assignment presented in this paper, the graphics card found in modern computers is used as an example of highly sophisticated functions implemented in complex digital hardware for handling challenges involved with data transfer between asynchronous processes. The assignment is given to bachelor students in their third and final year of their computer science course. The FPGA is chosen as the development platform in this paper, and the students are given an introductory module on this topic the year before. Problem based learning (PBL) is an attractive strategy when the tasks the students are set to solve have not one but infinitely many solutions. In [1] and [2] FPGAs are demonstrated to be very useful for this purpose as they provide a large, flexible solution space. Giving students hands-on experiences with the design and implementation of digital structures of this kind is considered important, but is a not a trivial task. In [3] the complexity of implementing a five-stage pipeline 32-bit MIPS design requires the use of active measures such as milestones to allow the students finish the assignment within the full nine weeks set aside for this in the sixteen week module. At the authors' university it is not possible to run a module for more than around 13 weeks, and the length of the assignment has to be reduced accordingly. In order for the students to be able to finish the laboratory work in time, an assignment will typically be a downscaled version of a full system. The challenge lies in how to reduce the size and

workload of the project without losing important elements that are part of the solutions to the original challenge. The project should also be inspiring for the students, adjustable for the actual skill level of different students, and low cost.

II. PROBLEM DESCRIPTION OF THE ASSIGNMENT

The student assignment will be an implementation of a downscaled version of the dual- and triple-buffer architecture [4] found in modern graphics cards, which is used to eliminate the problem of synchronizing the transfer of data between two asynchronous processes: The program running in the CPU used for generating the image, and the graphics card used to transfer the image to the computer screen (LCD). The challenge here is that the CPU uses a variable amount of time to generate a complete image, when the connected LCD requires a constant transfer rate. Three challenging situations are presented to the students: (i) the CPU generating images more slowly than the LCD can receive data, (ii) the CPU generating images faster than the LCD can receive data, and (iii) the CPU generating images at the same rate, but time shifted from the LCD writing process. The solution is basically to use two or three image buffers in the graphics card. One or two are used as back buffers for receiving the image data from the CPU, while the front buffer is used for transferring the image to the LCD, as described in the next sections.

A. The problem of flickering

When the process of transferring the image to the screen buffer is not properly synchronized with the image generation process, two effects are visible on the screen: tearing and flickering. Displaying a new or altered object requires changing a least some of the pixels. Instead of tracking the pixels that must be changed, the more efficient strategy of resetting all pixels and drawing the object only by setting the pixels covering the object, is chosen in practice. Modern graphics cards support hardware blanking, which is utilized here as it is more efficient than software blanking. A negative side effect of this is that the temporary image that appears just after the blanking, before the object is drawn, might appear on the screen. Although this happens in a very short timeframe, this is often visible to the user as flickering. This is resolved using a dual buffered graphics memory, where the image can be withheld in the back buffer, until the whole image is complete, i.e. all pixels are set correctly. The function of the two buffers

is switched when the CPU has finished updating the back buffer and the screen update from the front buffer is about to start a new update cycle. An important point here is that data are never copied from the back buffer to the front buffer. Rather the role or function of the two buffers is switched, so that when the image in the back buffer is completed, this buffer is used as the front buffer when a new update cycle is started. The front buffer is then made available for the CPU as a back buffer where a new image is drawn, after clearing the buffer.

B. The problem of tearing

Another problem associated with the single buffer architecture is the tearing effect. Images are transferred from the video ram to the screen from top to bottom, and left to right while the CPU can produce the different parts of an image in a random order. If a scene is produced where the viewer is performing a panning movement, all parts of the image should move simultaneously. If, for instance an object in the middle of the image is moved before the background is processed, it will appear as if the object is moving relative to the background instead of the viewers heading which is actually moving. The dual buffer solution contributes to reduce or remove this problem. A drawback of the dual buffer architecture can be found in situations where the current image has finished generating and the graphics card has just started a new transfer of the previous image to the screen. Now the CPU must wait for the graphics card to complete the screen update and then switch the two buffers before the CPU can start generating the new image. This means that valuable CPU processing power is lost due to waiting. In order to keep the CPU busy as much as possible, a triple buffer arrangement is introduced. In this arrangement there are two back buffers and one front buffer, so there is always a back buffer available for the CPU to store images that are being generated. The previous image is kept in the front buffer during data transfer until the complete image has been transferred to the screen, while the current image is stored in the first back buffer, and the new image under development is stored in the second back buffer.

III. ASSIGNMENT GIVEN TO THE STUDENTS

The creation of the memory modules used in this scheme is simple in FPGA/VHDL programming, and is not the challenging part of the assignment. By use of a small graphics display, the required size of the memory modules is small enough to fit within the FPGA, and the block-RAM modules will be used for this purpose. The challenge for the students is the design of the digital hardware needed for timing, synchronization and handshaking, allowing for successful data transfer.

The first task for the students is the implementation of the dual buffer according to the description of the architecture given in the previous sections in this paper. This involves the creation of two memory modules, and the synchronization of the modules external to this: the image processing unit and the LCD module. It is considered important that the students fully understand the problem and the solution as described in section II of this paper. At startup, the back buffer must accept data from the image processor and the front buffer must transfer its contents to the LCD module.

The latter process must be repeated until the image processor has finished producing a complete image in the back buffer. Now, the front buffer should complete the current transfer process while the image processor is stalled, whereupon the two buffers must be switched and the "new" back buffer is cleared, so that the image processor can start creating a new image into the "new" back buffer and the front buffer can start new cycles of transferring the current image to the LCD module. The second task is the addition of a second back buffer for temporary storage of the finished image, before it is transferred to the LCD. In this architecture, the function of the three buffers is circulated between front, first back and second back buffer. The control logic involved in managing a successful transfer of data is even more complex than in the dual buffer case, but is considered manageable for students.

In both of these tasks, the students start by drawing the chart for the algorithmic state machine (ASM) for the finite state machine with data path (FSMD). The overall purpose of the FSMD is to control the data transfer between the image processor and the LCD module. More specifically the FSMD will control the data transfer to and from the buffers, as well as perform the circulation of the functions of the individual buffers.

The system for which the system will be implemented, is an FPGA demo board from Avnet-Memec [5], with a custom designed add-on board where a simple monochrome graphics LCD (132x32 pixels) [6] and two incremental encoder knobs are mounted. The latter is used for input data to the image processor. The FPGA allows for easy demonstration of all different scenarios revealing any problems or faults of the implemented architecture.

IV. PRELIMINARY AND FURTHER WORK

A student laboratory platform for demonstration of sophisticated functions realized in complex digital hardware is suggested. The idea behind the hardware solution is that these functions should be realizable in an FPGA, within the timeframe of a student laboratory project, without losing the elements that identify the state-of-the-art of the technology. The hardware is designed, built and tested, and the laboratory will have a first run on a group of students in autumn 2012.

Educational Software Tool for Signals and Systems Theory

Juan Heredia Juesas, Emilio Gago-Ribas, Sara Menéndez García
Signal Theory and Communications Area, Department of Electrical Engineering
University of Oviedo
Gijón, Asturias, Spain
jheredia@tsc.uniovi.es, egr@tsc.uniovi.es, UO173765@uniovi.es

Abstract— One of the most important subjects in the educational background of electrical engineering as well as in other important scientific areas of knowledge is the Signals and Systems Theory (SST). Taking into account the connection of the SST with the algebraic representation and the mathematical understanding of physical problems –electromagnetic radiation, scattering and inverse problems in our particular case–, a generalized scheme of the SST (GSST) is currently under development. While the usual point of view of classical SST is valid for practical purposes, it usually avoids many important concepts which become fundamental in the generalization of the analysis of physical problems. Some examples of this generalization are concerned with representations of physical problems different from those in the usual time-frequency domains –using a general variable–, the description of the problem in terms of infinite dimensional vector spaces and the algebra associated, the description of the Dirac delta function in terms of the distribution theory, etc. The most important purpose of obtaining a GSST is to connect the usual SST with important mathematical representations that lead to obtain more general representations that may be rigorously applied to model general physical problems. This generalized theory is focused on the algebraic concepts of signals and operators spaces, identifying each problem into their corresponding vector spaces and representing it in terms of the GSST scheme. One important point within this generalization is the concept of the *Generalized Transform*. Choosing a set of functions which play the role of a base, each signal of the space may be expressed in terms of a *Generalized Linear Combination* operator of this base weighted by a set of coefficients which identify the transform –their expression is directly related to the metric defined initially in the associated algebra–. Spectral analysis of systems is also contemplated, representing the signals in terms of their coefficients once a set of basis functions is chosen. The generalized theory let to obtain integral characterizations of linear systems –invariant and non invariant–, leading to the *Generalized Spectral Analysis* concept, closely connected to the operator theory. While the mathematical analysis of the GSST and its application, for instance to generalize the Green's function theory, has already been presented in several symposium –like 2009 IEEE AP and URSI Meeting–, a software tool based on the GSST is being worked out in parallel to the theoretical works. The aim of this tool is to facilitate both students and practical scientific and engineers the understanding of the main algebraic concepts of this generalized scheme, providing some examples of many signals and many systems in

five different signal spaces. The user can select the signal and the system with their appropriate parameters and analyze the properties of the systems as well as the output signal both in real and different spectral domains. The last version of this tool, *SSTv4.5*, lets to analyze linear non invariant systems and to visualize the set of impulse responses as well as the spectral analysis under some transformations such as Fourier, Hilbert or Bessel Transforms –depending on the signal space–, thus exemplifying some particular cases of the *Generalized Spectral Analysis*. The description of the current version of this software tool is presented in this paper.

Keywords— *Signal Theory, Operators, Linear –invariant and non invariant– Systems, Software Tool, Infinite dimensions –countable or continuous–*

I. INTRODUCTION

Signals and Systems Theory (SST) plays a fundamental role in the educational and professional background of electrical engineering as well as in other scientific areas. Many references can be found about this topic, for instance [1]-[2]. But it is not difficult to realize that the way used to approach this theory avoids some important concepts that may lead to conceptual problems: the treatment of the Dirac delta function and the set of impulse responses without considering the theory of distributions, for instance, 0. The aim of our generalization of the SST (GSST), which is being carried out, is to avoid these problems as well as to be connected with the mathematical representation of physical problems in real and complex variable, [4]. The scheme is based on the algebra of infinite dimensional functions and operator spaces, together with the theory of distributions. This scheme is currently used to present the SST to both undergraduate (in a simplified form) and postgraduate students as well as to connect this theory with other important concepts in wave theory, for example the complexifications of time-space coordinates. Additionally, many research activities are directly related with this scheme, especially those involving Rigged Hilbert Spaces (RHS) theory, [5], the extension of the GSST to non linear operators, [6], the generalization of the Green's function theory, [7], or a generalized mathematical approach to inverse problems, [8].

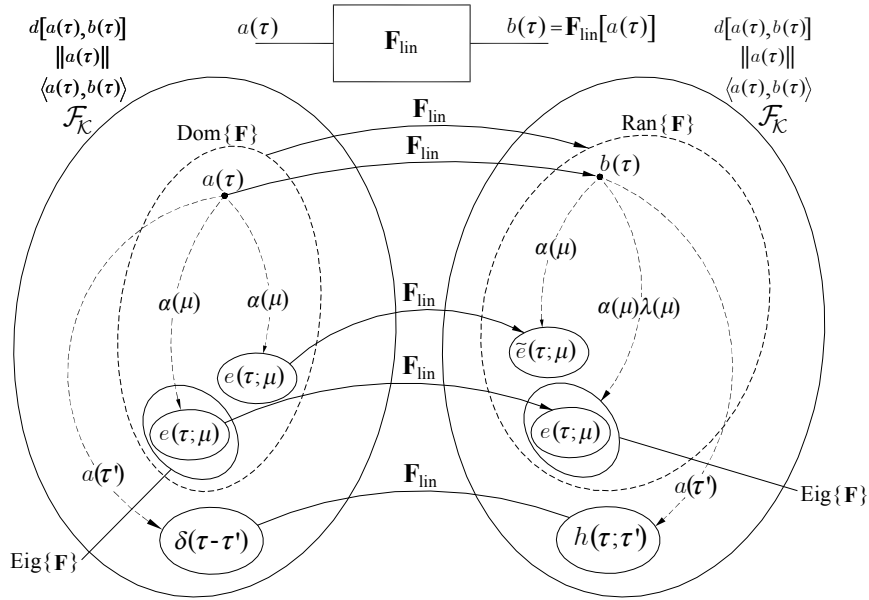

Figure 1. Graphical representation of the GSST scheme underlying the usual 'black box' representation in the usual schemes. Dashed lines identify generalized linear combination operators with coefficients those crossed by the lines. The input and output spaces are supposed to be the same only for simplicity.

With all this considerations in mind, a software tool where the user can learn and understand all these underlying concepts the GSST scheme is being developed. The current version is called *Signals & Systems Theory v4.5 (SSTv4.5)*, which is updated with the last and novel results of our research activities. This tool tries to emphasize the most important aspects of the generalization, emphasizing those that we consider more relevant from the educational point of view. In this sense, the tool becomes very significant because the students can appreciate more clearly the SST from a general point of view than the usual one appearing in the regular literature; even, the tool becomes important in order for the students to compare our GSST with the usual contents that they find in the usual bibliography, in particular those concerning: (i) the infinite dimensional vector space algebra under the GSST, (ii) the *Generalized Transform*, comparing different transformations (Fourier, Hilbert, ν -order Bessel, etc.), and (iii) the capability of the software to visualize not only regular functions but also generalized functions (distributions). Before presenting the potential of this tool, a brief summary of the GSST is presented in the next section. More details about this theory may be found in [9]-[10].

II. SUMMARY OF THE GSST

A. Initial Algebra

The most important concepts associated to the GSST are graphically summarized in Fig. 1. In the present paper, the mathematical developments will be avoided and only the most important expressions will be recalled in order to better understand the final aim under the software tool presented in this paper.

The theory is constructed considering an initial vector space \mathcal{F}_K of complex signals denoted by $a(\tau)$. The independent variable may represent either discrete or continuous variable ($\tau \equiv n \in \mathbb{Z}, \tau \equiv x \in \mathbb{R}$), representing any physical magnitude: time, space, frequency, etc. The dimension of the space can be discrete, countable-infinite or continuous-infinite. The algebraic structure of the space is built by the definition of the distance $d[\circ, \circ]$, the norm $\|\circ\|$ and the scalar product $\langle \circ, \circ \rangle$, which, together with the composition laws, determinate the vector space and the different associated ways of operating within the space. These definitions establish not only the way of measuring within the space \mathcal{F}_K but also it has an important influence in the definition of many distributions as the Dirac delta.

In this general scheme, a new parameter μ is introduced in order to identify a function into a subset. It can represent finite, countable-infinite or continuous-infinite subsets of functions; nevertheless it must be clear that this parameter μ is not initially a variable in the original problem, but it is an identification parameter which corresponds later in the usual cases with the so called "spectral variable". These subsets of functions will be denoted as $u(\tau; \mu)$, emphasizing that the semicolon indicates that the original variable is τ , while μ is just the parameter used to identify functions into the subset, instead of a usual comma which indicates a two variable function. Later analyses will lead to the possibility of understanding $u(\tau; \mu)$ as a surface-type function.

B. Linear Combinations and Generalized Transforms

The concept of a generalized linear combination may be introduced from the composition laws required in a vector space. Once a set of functions $e(\tau; \mu) \in \mathcal{F}_K$ –which play the role of a base–, is chosen, any element $a(\tau) \in \mathcal{F}_K$ can be described as a generalized linear combination operator in μ , \mathbf{LC}_μ , of this set of basis functions weighted by a set of coefficients $\alpha(\mu)$, as schematized in Fig. 1. The way to calculate $\alpha(\mu)$ directly depends on the definition of the distance, which lead to the next generalized representation:

$$a(\tau) = \mathbf{LC}_\mu [\alpha(\mu)e(\tau; \mu)], \quad (1)$$

$$d\{a(\tau), \mathbf{LC}_\mu [\alpha(\mu)e(\tau; \mu)]\} \rightarrow 0 \Rightarrow \alpha(\mu). \quad (2)$$

The pair of equations (1)-(2) represents the concept of the *Generalized Transform*. $\alpha(\mu)$ are not only the coefficients of $a(\tau)$ but also the so called direct transform of $a(\tau)$ in the $e(\tau; \mu)$ base. On the other hand, $a(\tau)$ in (1) is the inverse transform of $\alpha(\mu)$. In many cases –usually when $e(\tau; \mu)$ is an orthogonal subset with respect to the defined scalar product–, $\alpha(\mu)$ can be obtained by the orthogonal projection of the function $a(\tau)$ by each base function $e(\tau; \mu)$; in this case, (1)-(2) reduces to the pair of equations

$$a(\tau) = \mathbf{LC}_\mu [\alpha(\mu)e(\tau; \mu)], \quad (3)$$

$$\alpha(\mu) = \langle a(\tau), e(\tau; \mu) \rangle. \quad (4)$$

This representation can be particularized to any concrete transformation, either if τ represents a discrete or continuous variable; for instance, the well-known Fourier transform can be analyzed by this scheme taking into account the theory of distributions (both the usual and also the generalized Fourier transform).

Also, the general representation in (1)-(2), or the more specific in (3)-(4), takes into account that the generalized linear combination \mathbf{LC}_μ may be finite or infinite series, or continuous sums (Riemann or Lebesgue integration); also this representation connects with the theory of distributions.

C. Real Domain Characterization of Systems

One of the most typical set of basis functions is the ideal set of generalized delta functions, $e(\tau; \mu) = e(\tau; \tau') = \tilde{\delta}(\tau - \tau')$, where $\tilde{\delta}(\tau)$ denotes the Kronecker delta function in discrete variable or the Dirac delta distribution in continuous variable. Using this set, it is possible to represent the output of any linear system described by the operator \mathbf{F}_{lin} as

$$a(\tau) = \mathbf{LC}_{\tau'} [a(\tau')\tilde{\delta}(\tau - \tau')], \quad (5)$$

$$b(\tau) = \mathbf{F}_{\text{lin}}[a(\tau)] = \mathbf{LC}_{\tau'} [a(\tau')\mathbf{F}_{\text{lin}}[\tilde{\delta}(\tau - \tau')]]. \quad (6)$$

We will define the “set of impulse responses functions” of a linear system as

$$h(\tau; \tau') = \mathbf{F}_{\text{lin}}[\tilde{\delta}(\tau - \tau')]. \quad (7)$$

These functions define mathematically the physical properties of the system \mathbf{F}_{lin} . The equations (5)-(6) become a particular case of (1)-(2) being $\mu \equiv \tau'$ the spectral variable. In the case of dealing with continuous variable ($\tau \equiv x \in \mathbb{R}$), which is very common, the interpretation of the \mathbf{LC}_μ operator has to be understood under the theory of distributions. The rigorous relationship between functions and distributions are being studied through the RHS theory, [5], trying to incorporate them into the GSST scheme. The representation and interpretation of the real domain characterization of linear non invariant systems constitute the main incorporation in the last version of the software, *SSTv4.5*.

D. Spectral Characterization of Systems

Going back to equation (1), when a signal passes through a linear system \mathbf{F}_{lin} , the output can be expressed as

$$\mathbf{F}_{\text{lin}}[a(\tau)] = \mathbf{F}_{\text{lin}}\{\mathbf{LC}_\mu [\alpha(\mu)e(\tau; \mu)]\}, \quad (8)$$

$$b(\tau) = \mathbf{LC}_\mu \{\alpha(\mu)\mathbf{F}_{\text{lin}}[e(\tau; \mu)]\}. \quad (9)$$

Additionally, if the set of basis functions belongs to the subspace of eigenfunctions of \mathbf{F}_{lin} , $e(\tau; \mu) \in \text{Eig}\{\mathbf{F}_{\text{lin}}\}$, (9) reduces to

$$b(\tau) = \mathbf{LC}_\mu \{\alpha(\mu)\lambda(\mu)e(\tau; \mu)\}. \quad (10)$$

Thus, the product $\alpha(\mu)\lambda(\mu)$ is the spectral representation of the signal $a(\tau)$ under the base $e(\tau; \mu)$, where the coefficients $\lambda(\mu)$ are the eigenvalues of \mathbf{F}_{lin} associated to $e(\tau; \mu)$. Equation (10) describes the usual “spectral representation” of linear systems, which is frequently used to represent of linear invariant systems under the Fourier transform, due to the well-known properties of the complex exponential functions $e(x; \xi) = e^{j\xi x}$ which are eigenfunctions of any linear invariant system. If $e(\tau; \mu) \notin \text{Eig}\{\mathbf{F}_{\text{lin}}\}$, a *Generalized Spectral Analysis* may be defined expanding the usual interpretation under *Spectral Analysis* and redefining this concept, [11]-[12].

III. SOFTWARE TOOL

SSTv4.5 has been projected keeping in mind all this algebraic concepts, but focusing on including the representation of linear non invariant systems, especially those which representation requires three dimensions. The spaces, transforms and spectral analysis are the same of previous versions, which are summarized in table I.

A. Initial View

The software tool holds five different signal spaces implemented with different algebra, transformations and spectral analysis in each one. Although the norm and distance currently implemented are those induced by the usual definition of the scalar product for each space, the software is ready to implement any other algebraic definitions.

TABLE I. SPACES, TRANSFORMS AND SPECTRAL ANALYSIS IMPLEMENTED IN SSTv4.5

| Continuous variable signals - Functions and distributions | | |
|--|--|------------------------------------|
| $S(-\infty;\infty)$ | Fourier transform ($\mu \equiv \xi$): | $e(x;\xi) = e^{j\xi x}$ |
| $a(\tau) \equiv f(x)$ | Hilbert transform ($\mu \equiv x'$): | $e(x;x') = \frac{1}{\pi(x-x')}$ |
| Continuous variable signals - Functions and distributions | | |
| $S(0;\infty)$ | Bessel transform ($\mu \equiv \xi$ and order ν): | |
| $a(\tau) \equiv f(x)$ | $e_\nu(x;\xi) = \sqrt{\xi x} J_\nu(\xi x)$ | |
| Continuous variable periodic signals - Functions and distributions | | |
| $P(X_0)$ | Fourier series ($\mu \equiv m$): | $e(x;m) = e^{jm\frac{2\pi}{X_0}x}$ |
| $a(\tau) \equiv f_0(x)$ | | |
| Period X_0 | | |
| Discrete variable signals | | |
| $D(-\infty;\infty)$ | Fourier transform ($\mu \equiv \Omega$): | $e(n;\Omega) = e^{j\Omega n}$ |
| $a(\tau) \equiv x(n)$ | | |
| Discrete variable periodic signals | | |
| $D(N_0)$ | Fourier series ($\mu \equiv k$): | $e(n;k) = e^{jk\frac{2\pi}{N_0}n}$ |
| $a(\tau) \equiv x_0(n)$ | | |
| Period N_0 | | |

After the visualization of the presentation screen, the main window is displayed (Fig. 2). It is designed for having a similar appearance than the algebraic structure of the signals theory scheme. In this one it is possible to choose the working signal space. It is important to recall that the software tool has two different ways to return the results depending on the characteristics of the signal: (i) searching them into a theoretical database (infinite support functions and distributions), or (ii) implementing numerical methods (finite support functions).

B. Some illustrative cases

In order to give an idea about the most important capabilities of the last version of the software, some practical examples and visualizations of many signals and set of impulse responses are shown in this section. The most illustrative space is $S(-\infty, \infty)$, –continuous variable functions and

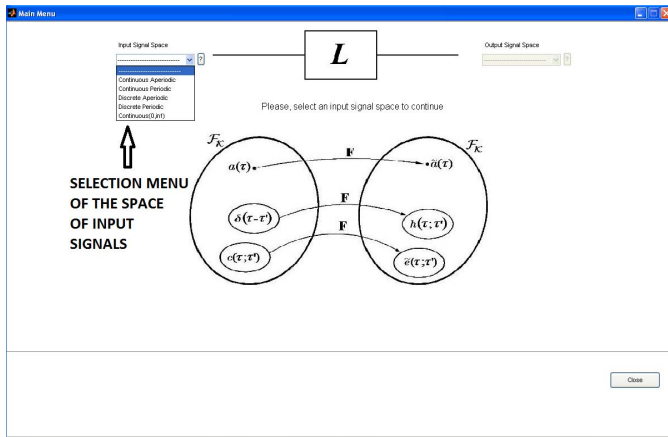

Figure 2. Main window of SSTv4.5.

distributions– but examples from other spaces are presented. Fig. 3 shows the interface window once the space $S(-\infty, \infty)$ is selected. It is divided into four main sections:

- SECTION 1 - *Input vector space*: the user selects the input signal with their parameters and the algebra of the space (some help buttons explain the definition of the algebra selected). The values of the norm and energy are shown in appropriate boxes.
- SECTION 2 - *System*: it is possible to choose between basic operations –such as addition, multiplication, etc.– and a specific operator, in which case, the main properties are shown (linearity, invariance, causality, stability, memory and invertibility). Different kinds of operators are available in the software, from basic operators –such as shifting, scaling, addition, etc– to more advanced operators –convolution, modulation, etc.– Moreover, some important transformations – Fourier, Hilbert, Bessel, etc.– seen as operators are implemented. If any other signal definition is required, the user can do it in this section like in section 1. An exemplification of the system in terms of a typical black box is shown on the top of this part.
- SECTION 3 - *Output vector space*: the space in this section is determined by the input vector spaces and the system. Input and output vector space may be different. The user can only select the algebra of the space (but currently there is only one algebra defined). The values of the norm and energy are shown in the appropriate boxes as well as the distance and scalar product if more than one signal is required to define the system.
- SECTION 4 - *Spectral Analysis*: the user can select the transform under he wants to visualize the spectral analysis of the system. A specific button gives access to the visualization window which is represented in Figs. 4 and 6. Here it is possible to clear general values or close the program too.

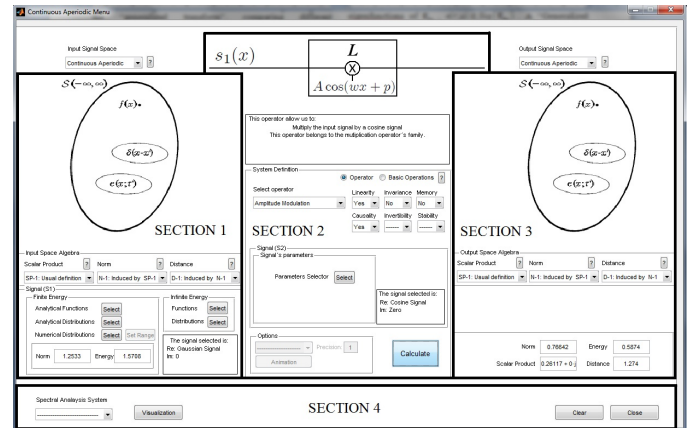

Figure 3. Interface window when the space $S(-\infty, \infty)$ is selected.

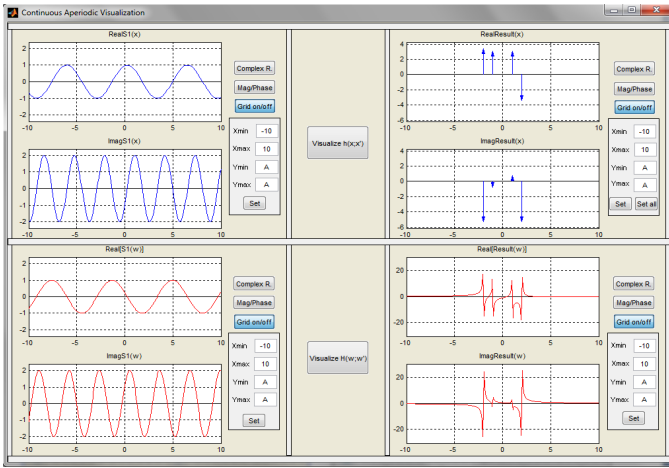

Figure 4. Visualization window when the space is $S(-\infty, \infty)$, the system is the Fourier transform operator, and the spectral analysis is performed under the Hilbert transform.

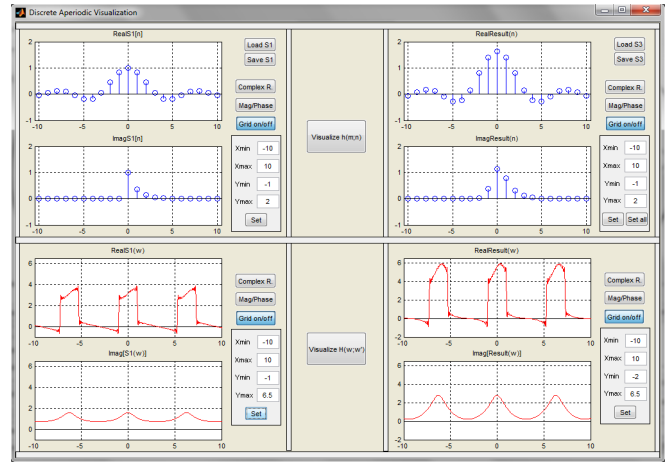

Figure 6. Visualization window when the space is $D(-\infty, \infty)$, the system is the convolution operator and the spectral analysis is performed under the Fourier transform.

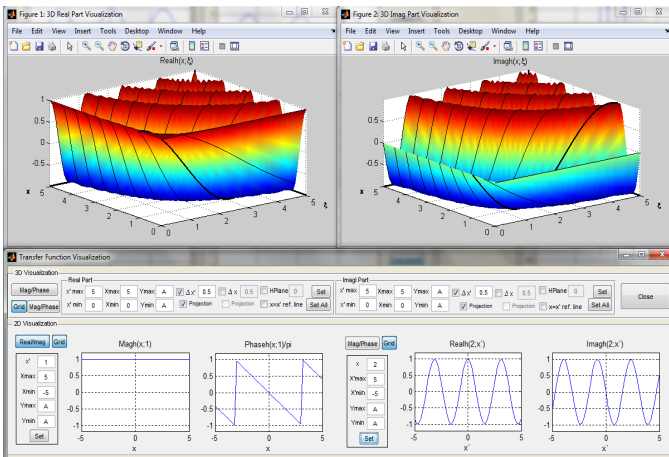

Figure 5. Set of impulse response functions when the the system chosen is the linear non invariant Fourier transform.

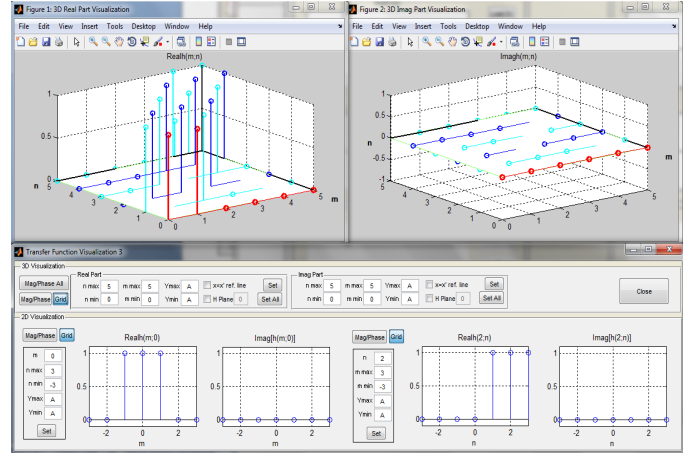

Figure 7. Set of impulse response functions when the systems chosen is convolution in the space is $D(-\infty, \infty)$.

Fig. 4 shows the representation when the Fourier transform is seen as a linear non invariant operator selected in the space $S(-\infty, \infty)$, and when the spectral analysis is performed under the Hilbert transform. The upper part of the window shows the real domain analysis –real and imaginary parts in this case– and the lower part shows the spectral domain analysis. In this example it is possible to visualize both functions and distributions. The set of impulse response functions in this example is shown in Fig. 5 –particularizing (6) as $h(\tau; \tau') = h(x; x') = e^{-jxx'}$ – where real and imaginary parts are displayed and some particularizations of any value of x or x' may be represented. This set only depends on the system.

Selecting the space $D(-\infty, \infty)$, an example of the convolution operator is provided in Fig. 6. The spectral analysis under the Fourier transform let see the spectral signal belonging to the space $P(2\pi)$. The set of impulse response functions –once (6) is particularized as $h(\tau; \tau') = h(n; m) = P_2(n - m)$ – are shown in Fig. 7 and

allow us to understand the invariance of the system due to the symmetry over the axis $m = n$.

There are other interesting capabilities, as the simulation in real time of the convolution, correlation and modulation (Fig. 8), complex representation (Fig. 9), switching the view of signals between real-imaginary parts and magnitude-phase, showing the grid, changing the definitions of the axis and saving or loading signals to external files.

C. Further implementations

Generalized Spectral Analysis has been developed recently and the theoretical results may be found in [11]-[13]. This analysis let to interpret any output signal in the spectral domain for linear invariant and non invariant systems and under any kind of transformation. The current version of the software is being extended nowadays in order to include this generalization of the spectral analysis for the systems and transforms defined up to date. In addition, more systems, even non linear ones, will be included in future versions of the software tool.

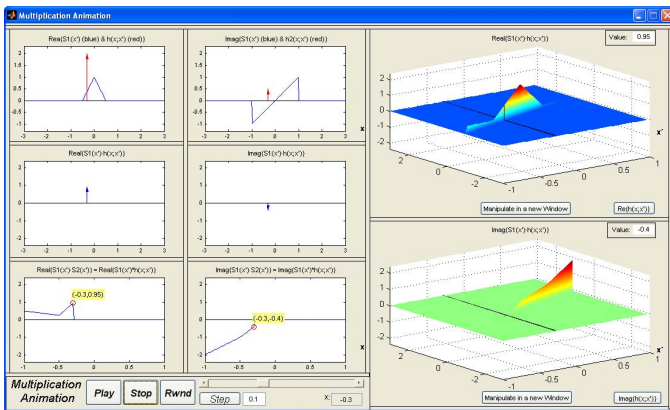

Figure 8. Real-time simulation of the modulation operator.

IV. CONCLUSIONS

A brief summary of the current development of the Generalized Signals and Systems Theory as well as the last version of the software *SSTv4.5* has been presented in this paper. The aim of it has been to present the most important characteristics of this theory through the implementation of that software tool, showing many practical examples where the GSST may be applied, most of them according to the actual level of undergraduate students (in particular Fourier and Hilbert analyses). The students can learn through this tool the way the GSST is constructed, observing some important and conceptual differences between the usual SST and our GSST, for instance, the differences between ordinary functions and generalized functions or distributions, which they can interpret it through their graphical representation, realizing that the visualization of the distributions are an intuitive representation of functions that really are not true functions. The theoretical analyses under the software tool are becoming increasingly important in research activities, especially those concerning wave problems and its connection with the Green's functions theory, as well as the extension of real variable problems to their complexified versions. It is also being important to understand the relation between functions and distributions through the RHS theory. Finally, nowadays it is being studied the possibility to include the analysis of non linear systems, very important in the interpretation of inverse problems. More details about the tool *Signals & Systems Theory* may be found in [14]-[15].

Work in Progress: Mesoscopic Analysis of Engineering Education Scholarship in Electrical and Computer Engineering, 2002-2011

Farrah Fayyaz and Brent K. Jesiek
School of Engineering Education
Purdue University
West Lafayette, IN, USA

Abstract— Engineering education remains a relatively new and rapidly developing research field. As a result, there are significant variations in the quantity and kinds of engineering education research being conducted and published in different engineering disciplines and local/national contexts. Responding to a lack of systematic attempts to study such dynamics, this paper describes our ongoing efforts to investigate the quantity and nature of engineering education scholarship in Electrical and Computer Engineering (ECE) and allied fields over the last ten years. More specifically, we report preliminary results of an in-depth quantitative and qualitative analysis of journal articles (n=664) published in *IEEE Transactions on Education* from 2002 to 2011, including co-authorship patterns, geographic distribution of authors, and research funding reported. To help contextualize the study, the authors also discuss other studies of publication trends in engineering education research.

Keywords- ECE; electrical and computer engineering; engineering education; engineering education research; mesoscopic analysis

INTRODUCTION

As leading reformers contend, engineering education needs frequent evaluation and revision to keep pace with rapid changes in the profession [1]. Yet even well-established engineering education innovations are promoted and accepted with varying degrees of success [2]. Further, engineering education is a relatively new but rapidly developing research field, and there remain considerable gaps in this growing body of scholarship. According to Wankat, one of the reasons for these gaps is a lack of communication between engineering educators in different engineering disciplines [3]. To further explore these issues, we are investigating recent trends related to publication of education-related research and scholarship in electrical and computer engineering (ECE), one of the largest and fastest evolving engineering disciplines. Our efforts to highlight trends in ECE scholarship across the world will help: 1) bridge the communication gap between educators and researchers both within and beyond ECE, 2) reveal biases that may be unique to the disciplinary culture of ECE, and 3) explore strategies to perform “mesoscopic” analyses of other domains of engineering education. This paper describes our initial efforts to investigate and highlight the subjects and

contexts of scholarship in ECE education, as well as a variety of authorship trends. We begin with a review of related literature and then turn to methods and preliminary findings.

LITERATURE REVIEW

There have been a number of previous efforts to investigate general trends in engineering education research [4]. Wankat, for instance, performed content and citation analysis of every paper published in *Journal of Engineering Education (JEE)* from 1993 to 2002 [5]. This study also included investigation of funding trends for research in engineering education. Whitin and Sheppard similarly analyzed papers (n=398) published in *JEE* from 1996 to 2001 to identify topical and research trends [6]. Osorio and Osorio, on the other hand, performed quantitative and qualitative analysis of papers in *JEE* (n=212) and *European Journal of Engineering Education (EJEE)* (n=119) from 1998 to 2000 to highlight subject coverage, authorship characteristics, most common topics and types of scholarship [7]. Osorio later compared results of prior studies by Wankat [5], Whitin and Sheppard [6], and Osorio and Osorio [7] to discuss prevailing subjects, author demographic data, article types, and citation data [8]. Jesiek et al. [4] performed a similar analysis of more than 800 engineering education research papers published 2005-2008. Still other studies have looked at more specific domains. In 2001, Martin, Adams and Turns conducted citation analysis on five years of engineering design education papers [9], while Beddoes, Borrego and Jesiek performed bibliometric analysis of 60 papers concerned with gender [10]. Beddoes, Jesiek and Borrego also analyzed a large set of papers published 2005 to 2008 to report research trends in problem/project-based learning (PBL) in engineering [11].

Yet despite this growing body of research, Wankat was one of the first to deeply examine trends at the intersection of educational research and specific engineering fields through his study of papers published in major engineering education journals and proceedings during 2009 [3, 12]. He observed that dissemination and “cross-fertilization” of engineering education research and development is limited, which in turn hinders the research-practice cycle [3, 12]. As the author explained: “This is exactly the behavior we would expect if

there are silos in engineering education” [3, p. 521]. Our research extends this line of inquiry through in-depth investigation of education-related scholarship in one field.

METHODS

Our research involves the use of a “mesoscopic” approach to investigate the quantity and characteristic features of engineering education scholarship in ECE and allied fields [13]. The preliminary work reported here is based on in-depth quantitative and qualitative analysis of 664 journal articles published in *IEEE Transactions on Education* from 2002 to 2011. The initial themes addressed by our research are: 1) number of co-authors per paper; 2) geographical distribution of co-authors, and 3) research funding reported. Other themes will be addressed in future work. The lead author compiled all bibliographic data in Endnote, then moved to Microsoft Excel to perform analysis of relevant characteristics for all papers, e.g. recording country affiliations for each paper’s author(s).

RESULTS

The average number of authors per paper in our data set is 2.96. In addition, 144 of 664 papers (21.6%) were single authored, 151 papers had two authors, 166 papers had three authors, and 203 papers had four or more authors, up to a maximum of 25 authors. Further, 65 countries of author origin/affiliation are represented in the data set, with 255 papers (38.4%) listing one or more authors affiliated with institutions in the US. Authors affiliated with institutions in European Union (EU) member countries appear on 240 papers (36.1%). Top author locations in the EU are Spain (105 papers), the UK (36), and Greece (21). Other high-ranked countries are Taiwan (31 papers), Canada (22), Australia (18), Brazil (18), and India (18). Additionally, 64 papers (or 9.6%) have co-authors affiliated with institutions in two or more countries. Among these, the US has highest representation (30 papers), followed by the UK (14) and China (10). Of these 64 papers, 53 have co-authors from two different countries, with US-China and UK-Spain the most common pairs (4 papers each). Eight papers include authors from three countries, and two include authors from five countries. Finally, 17 papers (2.5%) had co-authors with private sector affiliations, and 262 papers (39.4%) acknowledged some source of funding.

DISCUSSION AND FUTURE WORK

Our analysis identifies the US and EU as particularly active in ECE education research, matching more general trends reported elsewhere [4]. In the EU, Spain is a very significant contributor, and Taiwan, Canada, Australia, Brazil, and India are also relatively active. The average number of authors per paper (2.96) shows that ECE education research is quite collaborative, as compared to an average of 2.6 found in a more general study of engineering education research literature [4]. There is evidence of significant funding acknowledged in many papers, which may help explain larger research teams and more co-authors. Multi-national

collaboration trends (9.6% of papers) are also notable, and consistent with an 8% general figure reported previously [4].

In future work we plan to investigate: 1) types of scholarship published in ECE education (e.g., descriptive vs. empirical work), 2) topical coverage of papers across ECE subfields, and 3) coverage of papers across major areas of educational research and practice (e.g., content, assessment, pedagogy, etc.). To analyze these themes, we are developing a taxonomy based on prior literature [e.g., 4, 5, 7, 14].

Abstract— The major aim of this research was to develop new instructional materials and strategies to support engineering students, who are not electrical engineering majors, to learn electric circuit concepts. The study focused on activity Phase #3 of the Work in Progress paper presented at the 41st Frontiers in Education conference. The implementation of this phase included: (1) implementing enhanced guided-notes (EGN) with a collaborative note-taking effort; and (2) evaluating students' notes shared in collaborative notebooks. Selected students were provided an iPad 2™ and an application which allowed editing of the EGN, while other students were provided hard copies of the different sets throughout the semester. Furthermore, students were asked to complete online social networking surveys at the beginning and end of the semester. The instructor developed EGN to facilitate note-taking and note-sharing during the semester. An online repository system was created to allow iPad-groups of students to complete and edit EGNs that were created to facilitate note-sharing submission. Students worked in groups of three or four to complete the EGN and self-evaluation sections beginning in EGN 6 and continuing to EGN 11.

Keywords—collaborative note-taking; enhanced guided notes; metacognition; electric circuit; social networks

I. INTRODUCTION

Research suggests that traditional classroom activity does not stimulate students to actively engage in learning. Instructors often experience difficulty in creating engaging learning environments, especially when dealing with large classes. Metacognitively passive students, characterized by merely listening, watching, and seldom thinking critically about the material being presented, are easily found during traditional lectures [1]. Chickering and Gamson suggested that instructors need to encourage students to engage in learning through discussion, practicing, and applying concepts and ideas that will improve academic experiences [2]. However, these activities require substantial effort in terms of lecture preparation and management. In view of the challenges, the use of guided notes has been perceived by engineering instructors and students to be useful in increasing concentration on the lecture content [3][4].

It is worth considering alternative note-taking techniques in that previous studies have proven a positive relationship

between note-taking and student performance on exams [5][6]. These new techniques may eliminate some of the shortcomings exhibited in student note-taking. Because encoding and external storage are central issues of the note-taking efforts, this study focused on 'semi-structured' or guided notes provided by the instructors. These notes reduce students' cognitive load, thereby helping them to engage in cognitive processing of lecture content, while developing relatively complete notes for later review.

II. THEORETICAL FOUNDATIONS: ENHANCED GUIDED NOTES AND COLLABORATIVE NOTE-TAKING

Standard guided notes have been used in classrooms for quite some time, and multiple studies have been conducted to evaluate their effectiveness. The guided notes consist of incomplete information with blank spaces available for student notes. They may consist of concepts, diagrams, problems, and conclusions. Previous studies revealed that students who used a guided note-taking method performed better on conceptual tests than students who did not and increased their attention level during lectures [3][4][7]. Kiewra argued that this effectiveness is associated with the increased encoding required by the students as they strive to complete the missing details [8]. Compared to standard guided notes, the enhanced guided notes (EGN) do not only contain blank spaces in which students need to provide detail information. The EGN of the current study, based upon lessons learned from previous research [3], included two new components that are not present in standard guided notes: (1) questions that prompt students to assess their metacognitive knowledge throughout the guided notes [9], and (2) the notes will be further enhanced through the inclusion of outside class activities.

This study added additional note-taking activities with a metacognitive knowledge component to the standard guided notes. Metacognition is a fundamental tool that enables learners to control their own cognition [10]. This leads learners to learn better [11]. By imposing note-sharing with others in the class and prompting metacognition of this collaborative process, we will further enhance the students' metacognition. Lehl and Fischer connected the information processing theory to the social constructivist theory introduced by Vygotsky, which suggested that learning occurs when students actively construct

This material is based upon work supported by the National Science Foundation (NSF) under Grant No. 0942942. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the NSF.

their knowledge based upon social interaction [12]. In educational practice, these interactions should assist students to become actively aware of their knowledge.

III. PURPOSE, GOALS, AND SIGNIFICANCE OF THIS STUDY

The purpose of this research was to develop new instructional materials and strategies to support engineering students, who are not electrical engineering majors, learning electric circuit concepts. The goals of the study were: (1) to develop, implement, evaluate, and understand the metacognitively and collaboratively EGN for classroom instruction in electric circuit concepts, and (2) to understand how students' note-taking is impacted by collaborative online note-taking activities and to develop guidelines for EGN.

The collaborative note-taking was added to our EGN for three reasons: (1) to help students explore other essential information that may not be included in the guided notes; (2) to become familiar with different views of interpreting information from other students; and (3) to expose students to alternative note-taking strategies. The first reason for including collaborative note-taking is that for each topic, there are aspects of the course materials that are not covered during the lecture. The materials may be part of the course materials, but insufficient time is available for detailed coverage during lectures. The second reason is to help students to become familiar with different views and clarify information with their classmates. When the faculty is unavailable, access to information occurs through the social networks. Moreover, the collaborative note-taking implemented electronically will give new learning experiences to students.

IV. THE STUDY

During the spring semester 2012, two activities were conducted: (1) implementing the EGN with a collaborative note-taking effort; and (2) evaluating students' notes shared in the collaborative notebooks. Furthermore, an online social networking survey was asked twice, at the beginning and end of the semester. The subjects for this research were 66 engineering students enrolled in the Fundamental Electronics for Engineers course at Utah State University. Twenty-six randomly selected students were provided an iPad 2TM and an application which allows editing of the EGN, while the remaining students were provided hardcopy version. In addition to the randomly-selected students, five students who had their own iPad and were interested in participating were assigned into the iPad-group students. Students worked in groups of three or four to complete the EGN.

Thirteen sets of EGN were developed for the class and six of them were selected (e.g., Network Theorems, Capacitance) to facilitate note-taking and note-sharing during the semester. A network attached storage (NAS)-based online system was created to allow the iPad-group students to complete and edit EGNs on PDF-formatted files and to facilitate note-sharing submission (see Figure 1). When homework was due, paper-group students submitted a single completed copy of the corresponding EGN represents their group to the instructor and each iPad-group member submitted their own copy through a

repository server. Centrality Social network analysis technique will be employed to examine the impact of collaborative, online note-taking activities on the students' informal social networks. Upon completion of this phase, we will answer 3 research questions: (1) Does the collaborative component of collaborative note-taking impact the social networks (and implicitly social capital) of the student learners?; (2) If the collaborative component impacts the social networks, does this change impact student performance?; and (3) Does the use of EGN with collaborative note-taking impact the contents and form of students' notes compared to EGN alone?

gerson@ece.uprm.edu, mjimenez@ece.uprm.edu, reinaldo.mulero@upr.edu, alexander.ortiz2@upr.edu

Abstract - This paper discusses the tradeoffs of using two different approaches for designing and implementing digital control systems for electrical engineering course projects. The usage of an off-the-shelf microcontroller unit (MCU) is explored and contrasted to the more traditional approach based on personal computers (PCs), data acquisition cards (DaqCs), and programs like RTW, LabView, and Matlab/Simulink. We discuss how an MCU-based approach was developed and tested in the design and implementation of a two-loop digital feedback control system for a Ball-and-Beam mechanical system. Results show that by using an MCU it is possible to achieve a performance comparable to that of using PC's and data acquisition cards with the added advantage of exposing students to an experience closer to the actual way most digital control systems are implemented in practice.

Keywords – *Control systems education, ball-and-beam system, microcontroller applications, laboratory experiences.*

I. INTRODUCTION

Control systems education is one of the core education components in most accredited Electrical Engineering (EE) programs in the nation. An early study found that within a representative sample of EE programs in the US, roughly, 50% require at least one course in control systems, and from these, more than three quarters require laboratory work [1]. An informal search in the public information of schools in that study revealed that this pattern is still prevalent or has improved, highlighting the relevance of an experimental experience in control systems education.

The traditional way of carrying control systems laboratory experiences and implementation projects has revolved around the usage of personal computers (PCs) and software-based environments. Multiple evolving modalities have been reported through the years, ranging from command-line based interfaces to graphical user interfaces, including virtual and remote environments with diverse features and educational objectives [2-8].

A few implementations in the academic environment have reported the use of circuit components and digital controllers, mainly for demonstrational purposes [9-11].

PC's, data acquisition cards, programs like LabVIEW, Matlab/Simulink, and other similar tools are used because they make the implementation details transparent to students, requiring them to concentrate mainly on the control algorithms and mathematics behind a particular problem. While this proves convenient at introductory levels, for advanced courses like the senior capstone design project, where students shall be prepared for real-life experiences, using exclusively this approach for implementations might result limiting. Hiding details like dealing with data converters (ADC/DAC), sensor conditioning, and actuator drivers and their integration, might hinder student's practical abilities for dealing with real life problems, like those found in industry environments. Senior students need to recognize all the details behind a digital control system implementation.

In his paper we discuss tradeoffs of using several approaches for designing and implementing digital control systems for electrical engineering course projects. In particular, we have developed different implementations of the digital feedback control systems for a Ball-and-Beam mechanical system. We have been using the Ball-and-Beam system (BBS) as an educational tool in our Process Instrumentation and Control Laboratory since 1994. Originally, the digital controller implementation used LabVIEW, but since 1998 we moved to use WinConTM modules with data acquisition cards and personal computers running MATLAB/Simulink. WinCon runs Simulink generated code using a real-time environment (RTW). The alternative approach presented in this paper implements the controller directly on a commercially available microcontroller unit (MCU). Having the same application implemented both ways allowed us to analyze the pros and cons of having students familiarize with digital control systems by going through all the implementation details.

The rest of this document has been organized as follows. The next section provides information of the educational setting where this experience took place. Section III discusses the implementation experience using both, a Matlab/Simulink approach and an MCU. Section IV provides a comparative analysis of the technical merits of each implementation, to then discuss in the last two sections the lessons we learned with this experience and our concluding remarks.

II. BACKGROUND

A. Educational Background

The experience reported in this paper was developed in the Process Instrumentation and Control Laboratory (PICL) of the Electrical and Computer Engineering Department of the University of Puerto Rico at Mayagüez. The story of this laboratory was reported in [12] and later results on digital control design projects were reported in [13]. The laboratory is a workshop type environment for designing, simulating and implementing digital control systems for term projects of several control area courses. The educational goals of the laboratory are to provide a real implementation experience for students taking the courses.

B. Traditional Control System Education

The PICL serves both introductory and advanced level students. At the novice level, PICL supports the Introduction to Control Systems course (INEL 4505), a required core course for all EE students in our program. Students choosing Control Systems as emphasis area must also take the Digital Control Systems course (INEL 5508) as well as other advanced control systems courses. In this paper we focus primarily on these two courses.

In INEL 4505, students complete several homework problems and implement them in the laboratory; there is no term project requirement. The BBS is used as the system for these homework problems. In the first homework set, students develop the system's mathematical model, linearize its nonlinear equations, and determine the system's transfer functions in the s-domain. In the second homework set, students design, simulate, and implement a controller for the SRV02, a servomechanism developed by Quanser, Inc. which is used as the actuator of the BBS. In the fourth and last homework set, students design, simulate, and implement the controller for the BBS. These designs are done assuming that the controller will be implemented in continuous-time. The implementation is done using a digital computer with a fast sampling rate so that the effects of sampling are insignificant. This eases the implementation in a convenient way for students in an introductory course. Since digital control is not taught in this course, it is not necessary to enter into the issues of sampling effects.

In INEL 5508, a term project is assigned with the BBS. In this project, students have to take into account the effects of sampling. They select a sampling period to comply with the Shannon's sampling rate, discretize the continuous-time system, design a controller in the z-domain, simulate the controller performance, implement the controller in a digital computer, and validate the controller performance. Traditionally we have implemented these controllers using Simulink and WinCon. This approach works fine, but lacks the experience of dealing with a digital controller's hardware and directly implementing a difference equation in the hardware. Implementing the controller with a MCU adds this experience.

C. Alternative Approach

The alternative approach uses an MCU to implement the digital controllers. Using an MCU brings additional

experiences into the project. Students will not only need to concern about the traditional control concepts, but also will need to deal with signal conditioning issues, algorithm development, and MCU programming to implement the digital controllers. This experience is closer to the way digital controllers are implemented in industry.

To develop the BBS controller, the MCU selected was a Texas Instrument's MSP430. All control algorithms were written in C language using Code Composer Studio. In particular, the system was implemented on an MSP430FG4618/F2013 experimenter's board. This platform resulted particularly convenient due to its on-chip analog front-end. The availability of an embedded 12-bit DAC along with 12- and 16-bit ADCs in the MCU, plus plenty of timers and a friendly programming interface made the FG4618 an appropriate choice for this application.

III. IMPLEMENTATION EXPERIENCE

A. System Description

The Ball-and-Beam System is a classical application that provides a naturally unstable, nonlinear, open-loop system frequently used to teach modern control systems theory. Figure 1 shows a simplified diagram of a BBS mechanical assembly. We use a BBS unit developed by Quanser, Inc. [14].

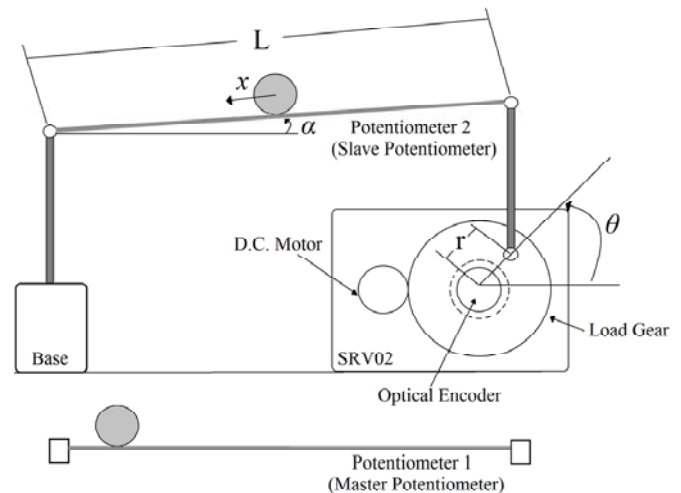

Figure 1: Diagram of the Ball & Beam System.

The BBS is equipped with two beams that form potentiometers when a metallic ball rolls over them. One of them, namely the master beam, is fixed while the other, designated the slave beam, is attached to a SRV02 DC motor with gears and sensors. When the SRV02 gears rotate, they tilt the slave beam, making the slave ball to roll over the beam. The angular position of the SRV02 gears is measured using a quadrature optical encoder. The control objective of this system is making the slave ball follow the trajectory of the master ball as closely as possible.

B. System Specifications

The system required an MCU with at least one ADC with two analog inputs to measure the voltage of the two

potentiometers and one DAC with one analog output to actuate the motor. Both the ADC and the DAC required a resolution of at least 12-bits. The MCU must also provide digital I/O ports, embedded timers, and interrupts. Since most MCU ADCs only accept positive voltages within their reference range, it was required to design signal conditioning circuits to rescale the analog signals from the potentiometers. Another signal conditioning circuit, an LS7084 from USDigital, was required to interface the output from the quadrature optical encoder. Tables I and II summarize the system hardware specifications.

TABLE I. MCU BALL & BEAM SYSTEM SPECIFICATIONS

| MCU | Specs | Developer |
|--|--|-------------------|
| MSP430FG4618/F2013 Experimenter's Board | 12-bit DAC 12-bit SAR ADC 16-bit Sigma Delta ADC | Texas Instruments |

TABLE II. SIGNAL CONDITIONING CIRCUIT SPECIFICATIONS FOR MCU

| Circuit Type | Specs | Description |
|--------------------------|--|---|
| Span and Zero Amplifiers | $V_i = \pm 5V$ $V_o = 0$ to $2.5V$ Summing Inverter Amp $A_v = 0.25$ V/V Inverter Amp with Unit Gain ($A_v = 1$ V/V) | Used for two potentiometers. (OP07 Op-amps) |
| Differential Amplifier | $V_i = 0$ to $2.5V$ $V_o = \pm 5V$ $A_v = 4$ V/V | Used for SRV02 D.C. motor. (OP07 Op-amps) |
| Optical Encoder Chip | $V_i = 5V$ (Logic "1") $V_i = 0V$ (Logic "0") | Used to read the optical encoder. (LS7084) |

C. Matlab/Simulink Implementation

In this implementation, the BBS digital feedback controller was implemented in a virtual instrument (VI) provided by Matlab/Simulink on a PC using a WinCon interface. This is the same implementation used in the Introduction to Control Systems course. The structure of the digital controller is shown in Figure 2. It used a two-loop feedback, where the inner-loop was a proportional-only compensator used to control the SRV02 and the outer-loop was a phase-lead compensator used to regulate and stabilize the whole BBS. The dashed box in Figure 2 indicates the blocks that were implemented inside the PC. Table III contains a description of the blocks in Figure 1.

TABLE III. BLOCK COMPONENTS DEFINITION

| Component | Definition |
|-----------|--|
| R | Desired response(master potentiometer) |
| C | Actual response(slave potentiometer) |
| G_{c1} | Outer loop phase-lead compensator |
| G_{c2} | Inner loop proportional compensator |
| G_m | SRV02 transfer function |
| G_b | Ball's dynamics transfer function |

$G_m(s)$ and $G_b(s)$ in Figure 2 correspond to the SRV02 and ball's dynamics transfer functions, respectively. These are derived using *Kirchhoff's Voltage Law* (KVL), Newton's laws of motion and parameters given in the Quanser's Ball and Beam Student Handout [14].

Two control approaches were used. The first used a digital control system with the outer-loop phase-lead compensator designed in the continuous-time domain and transformed to the discrete-time domain using a *bilinear transformation* (BLT). The second had the compensator directly in the discrete-time domain using the z-Transform. The design criteria for the BBS performance were: settling time less than or equal to 2 seconds and overshoot less than or equal to 20%. The results of these two approaches were evaluated by comparing the performance of controllers implemented in Matlab/Simulink with those implemented in the MCU.

For the first approach the system transfer function was obtained in the continuous-time domain without considering sampling and hold. This function is presented in (1), where all sub-functions are all in the "s" domain. Compensators $G_{c1}(s)$ and $G_{c2}(s)$ were designed using Matlab's Root Locus Tool GUI. Since compensator $G_{c2}(s)$ is a constant gain, it was implemented directly into the digital control system but $G_{c1}(s)$ needed to be transformed using the BLT. The sampling period for this approach was set to be $T = 17.5$ ms.

$$\frac{C(s)}{R(s)} = \frac{G_{c1}G_{c2}G_mG_b}{1 + G_{c1}\frac{G_{c2}G_mG_b}{1 + G_{c2}G_m}} \quad (1)$$

The structure of the phase-lead compensator is

$$G_{c1}(z) = \frac{K_d(z - z_0)}{(z - z_p)}, \quad (2)$$

where K_d is the gain, z_0 is the zero, and z_p is the pole of the compensator. Table IV shows the resulting discrete-time compensator designed in the continuous-time domain.

For the second approach, the effects of samplers and zero-order-hold (ZOH) were considered. The transfer function is presented in (3), where all terms are in the discrete-time or z-Transform domain and analysis techniques for sampled-data closed-loop systems were used.

TABLE IV. MCU BALL & BEAM SYSTEM SPECIFICATIONS

| Inner Loop Compensator $G_{c2}(z)$ | Value |
|------------------------------------|--------|
| $G_{c2}(z)$ | 5 |
| Outer Loop Compensator $G_{c1}(z)$ | Value |
| K_d | 94.882 |
| z_0 | 0.9792 |
| z_p | 0.7595 |

$$\frac{C(z)}{R(z)} = \frac{3 \left[\frac{G_b G_m}{s} \right] (1 - z^{-1}) G_{c2} G_{c1}}{1 + 3 \left[\frac{G_m}{s} \right] (1 - z^{-1}) G_{c2} + 3 \left[\frac{G_b G_m}{s} \right] (1 - z^{-1}) G_{c2} G_{c1}} \quad (3)$$

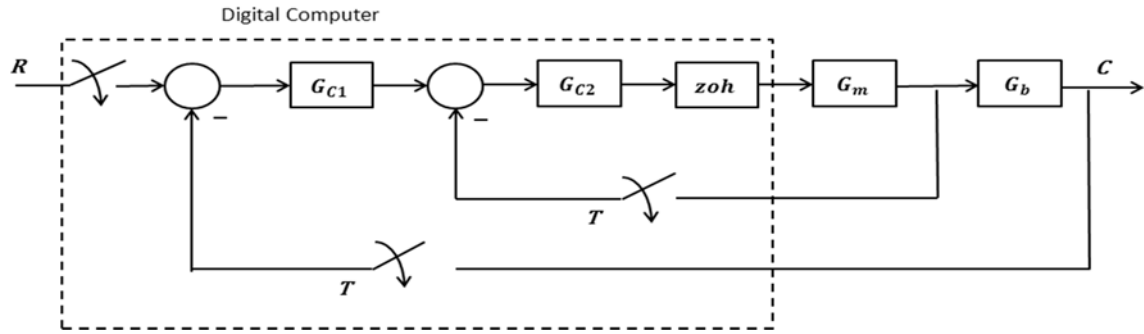

Figure 2. Digital control block diagram for the ball and beam system.

For designing controllers $G_{C1}(z)$ and $G_{C2}(z)$, the Root Locus method in the “Z” plane was used. The sampling period T for this approach was 28.6ms. The resulting compensator using this approach is shown in Table V.

TABLE V. DISCRETE TIME DESIGNED COMPENSATOR IN THE “Z” DOMAIN

| | |
|------------------------------------|--------|
| Inner Loop Compensator $G_{C2}(z)$ | Value |
| $G_{C2}(z)$ | 5 |
| Outer Loop Compensator $G_{C1}(z)$ | Value |
| k_d | 91.648 |
| z_0 | 0.9668 |
| z_p | 0.6196 |

D. MSP430 Implementation

The MCU BBS implementation consisted of two parts: the hardware components including the signal conditioning circuit; and the BBS compensators written in C-language.

The signal conditioning circuit consisted of two attenuators, one for each potentiometer; an amplifier for the motor output voltage, a low pass filter for the master potentiometer; and a quadrature clock converter to read the optical encoder. Figure 3 shows a block diagram of the hardware components. The attenuators were used to bring the -5V to 5V potentiometer outputs to the 0 to 2.5V accepted by the MCU. Since the motor operated with voltage in the range from -5 to 5V, an amplifier was necessary to raise the DAC voltage output. The low pass filter was used to reduce the master potentiometer noise output, improving the accuracy of the ADC readings.

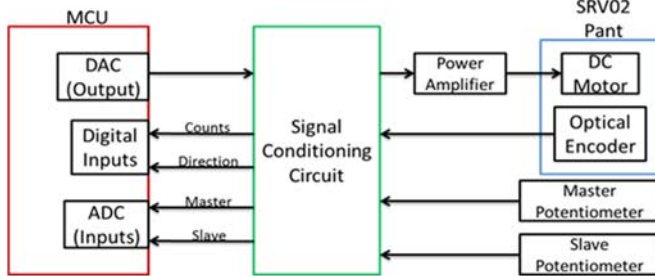

Figure 3. Block Diagram of MCU-Based BBS Implementation.

The algorithm for the software implementation was developed using the Code Composer Studio from Texas

Instruments. Figure 4 shows a flowchart of the designed control algorithm.

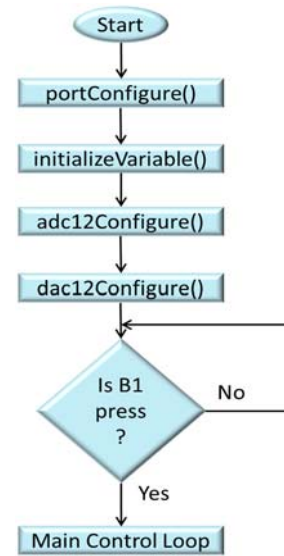

Figure 4. Control algorithm flow chart.

The program sequence is as follows: configure the necessary I/O ports, initialize the control variables, and configure the ADC to sample the potentiometers at the selected frequency and the DAC to command SRV02. The program then waits for a start button to be pressed for entering the main control loop where the sampling process and control actions take place.

In the main control loop, the algorithm starts the ADC and waits for one of two interrupts to occur: (1) ADC end-of-conversion, indicating the readings from the potentiometers are complete; (2) a quadrature encoder signal via port 2, indicating the wheel angle. Figure 5 shows a state diagram of the loop. Port2 ISR adjusts the rotation angle of SRV02 according to the sampled potentiometers' reading.

IV. COMPARATIVE ANALYSIS

Table VI shows the step-response performance characteristics for each design method and each implementation approach. Of the two design methods, the

best performance resulted from the z-Transform yielding smaller settling time and smaller steady-state error.

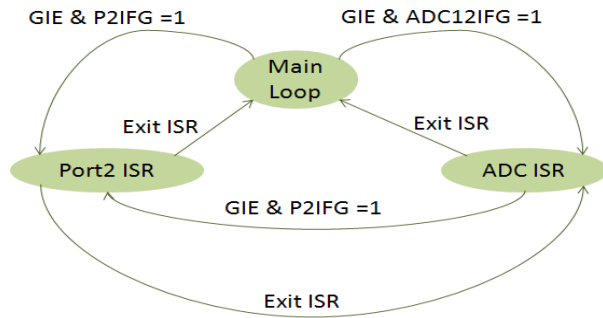

Figure 5. Main control loop state diagram.

TABLE VI. MATLAB/SIMULINK AND MCU IMPLEMENTED COMPENSATORS

| Design Method | Settling Time (sec) | | % Overshoot | | SS Error (m) | |
|---------------|---------------------|------|-------------|-------|--------------|-------|
| | MatLab | MCU | MatLab | MCU | MatLab | MCU |
| BLT | 2.59 | 1.77 | 4.78% | 1.25% | 0.004 | 0.001 |
| Z-Transf. | 2.54 | 1.50 | 3.77% | 2.72% | 0.001 | 0.001 |

A. Simulink Implementation

The step-response using the z-Transform designed phase-lead compensator running in Simulink is shown in Figure 6 where three signals are shown: (1) a step given by the master ball, representing the desired position in meters; (2) the simulated response obtained from a linear simulation of the model in Simulink, representing how the real response should ideally look; and (3) the actual response obtained from the slave ball. Neither compensator designed met the settling time requirement; but both met the overshoot and the steady-state error requirements. This suggests that the settling time requirement may have been too strict.

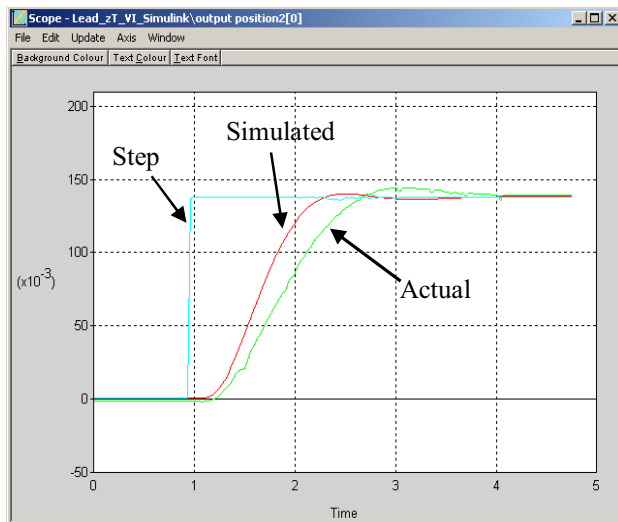

Figure 6. Z-Transform Lead Compensator Response Running in Simulink

B. Embedded System Implementation

The same compensators used on the Simulink implementation were also implemented in the embedded system through the MCU.

Table VI shows the step-response performance characteristics for the BLT and z-Transform designed phase-lead compensator running in the MCU. Both design methods accomplished the desired performance in contrast with the Simulink implementation for the same compensators. Both yielded approximately the same steady-state error and their percent overshoot was within the design requirements. The smallest settling time was achieved by the z-Transform designed compensator compared to other implementations. Figure 7 shows the step response of the system with the controller implemented in the MCU.

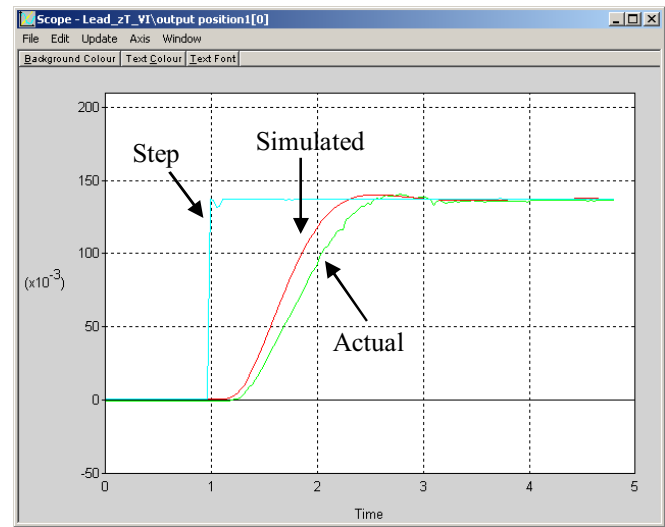

Figure 7. Z-Transform Lead Compensator Response Running in MCU.

C. Continuous-Time Domain

The first approach in both, embedded and Simulink implementations, was to design in the continuous-time domain and discretizing the compensators using the BLT. Even though the design is simpler using the BLT and similar performance was obtained, it was more difficult to accomplish the desired settling time. This is so because this approach is an approximation to the actual digital control implementation.

D. Discrete-Time Domain

In contrast to the continuous-time approach, in this method, the compensator was designed via Root Locus directly in z-domain resulting in a better performance. The performance is better because the design is done directly in the domain in which the controller is implemented.

E. Analysis

Both compensators implemented in the MCU, the BLT design and the z-Transform design, complied with all the required performance characteristics. Both simulated responses were similar; but not identical to the real

responses. The reason for this is that the simulated response comes from a linear simulation; but the real system is nonlinear.

The best performance characteristics were obtained from the z-Transform designed phase-lead compensator implemented in the MCU. The steady state-error that resulted from both implementations may be reduced even more with a lead-lag compensator; but this was not done for this project.

V. LESSONS LEARNED

A. Obstacles

The learning curve for the two students working on the project was a little slow. The project was developed in an undergraduate research setting. The students had to work with signal conditioning circuits, digital control algorithms, and MCU programming.

B. Benefits of each experience

We have had experience with the PC and data acquisition card implementation. This experience has proven to be suitable for introductory as well as for advanced undergraduate courses. However, the MCU implementation adds new dimensions to the implementation experience.

VI. CONCLUSION

We have presented several approaches for implementing digital control systems for electrical engineering projects. The Matlab/Simulink approach using PC's and data acquisition cards has proven suitable for introductory courses as well as for advanced undergraduate courses because it makes the implementation easier for the students. The MCU approach adds new dimensions to the implementation experience since it brings several new issues into the problem such as signal conditioning, digital control algorithms, and microcontroller programming. This approach is only recommended for advanced undergraduate courses such as INEL 5508. Next semester we will try the approach in the actual course with a reduced number of student teams.

VII. ACKNOWLEDGMENT

The authors would like to thank the PR-LSAMP Program for partially sponsoring this project.

Abstract – Many professors are reluctant to transform their teaching practices from "sage on the stage" to "guide on the side" for understandable reasons. Facilitating student work in a potentially unfamiliar setting has a steep learning curve and requires professors to relinquish control of their classrooms without assurance their career evaluations will benefit. However, professors who do transform their teaching practices continue to report exactly the same concerns – so how *does* the sage-to-guide shift occur? This work-in-progress paper describes early efforts in a grounded theory study whose initial participants are professors who have involved their classes in open software, hardware, and content communities, a choice which requires such a shift in teaching practices for successful student participation. Inspired by the radical transparency of the open communities our participants work with, the study itself is an open content project, creating a public compendium of teaching transformation stories that can be accessed by educators considering similar transformations to their own teaching practices.

Keywords: free and open source software (FOSS), teaching open source, storytelling, grounded theory

I. INTRODUCTION

Professors who involve their students in open communities – Free and Open Source Software (FOSS), hardware, and content projects – make an ideal population for a study on transforming teaching practices. While demographic characteristics such as institution type, discipline, and seniority vary widely between professors, the *types* of teaching practice transformations required to involve students in open projects are very similar, largely involving giving up predictability and control [1]. The radical transparency practices of open communities mean there are far fewer confidentiality issues in discussing a class's participation in a project, and some faculty members even blog or publish about their experiences [2][3][4], but the practice of "teaching open source" is new, so the literature is sparse and anecdotal. This work-in-progress paper is a first empirical investigation of the "teaching open source" faculty population that looks for themes that may illuminate teaching practice transformations in engineering education more broadly.

II. THE STUDY

A. Subjects

Our interviewees are members of teachingopen-source.org, a distributed community of practice [5] centered around an open mailing list and dedicated to supporting teachers in bringing open community participation into their classrooms. They are participating in this research voluntarily and without compensation. All participants have significantly modified their teaching practices for at least one undergraduate course (typically in STEM) without administrative mandates or departmental support. They range from new assistant professors to department chairs and teach everywhere from small private institutions to large public ones; their motivations include giving students a real-world project experience, broaden STEM participation demographics, and building student portfolios as well as their institution's public profile.

B. Research procedures

This project uses a grounded theory approach [6] to focus on shifts in teaching practice when open community participation is used in postsecondary STEM education. Each interview with a professor lasts approximately 90 minutes and is conducted in-person, taped, and transcribed. Interviewees are asked to tell the story of how they came to "teach open source" several times, focusing on different aspects with each pass: their motivations to incorporate open community participation into their courses, the concerns and challenges they faced throughout their journey and how they addressed them, the specific transformations they have noticed in their teaching practices as a result, and the resources they drew upon.

This project also uses a radically transparent research approach that mirrors the practices of the open communities our participants work with. Since our subject pool of faculty members already writes and collaborates publicly about their experiences in teaching open source, and is a non-vulnerable group already aware of research practices such as informed consent, we eschewed the usual practice of analyzing confidential, de-identified datasets behind closed doors. Instead, we assigned the copyright of interview transcripts to our interviewees, who then released "public" versions of their data under a Creative Commons license. At present, 3 transcripts have been released, with more in the pipeline for

2012. Only the public dataset is analyzed, and other artifacts of the grounded theory process such as open coding and memos are made available online under similarly open licenses, which allows participants and the open communities they work with to see – and contribute to – the “source code” of our research, allowing a broader population to engage in the project.

Participants are thus aware of each others' identities, and are prompted to refer to and compare their journeys with one another when possible, giving us multiple perspectives on an individual professor's path. Participants also pose questions they would like other interviewees to answer and respond to questions posed by prior interviewees. Responses to the radically transparent approach have been overwhelmingly positive, with participants reporting unexpected insights from going “behind the scenes” as well as changing their perspectives on the practice of research.

III. SOME PRELIMINARY FINDINGS

With only 3 interviews in the public dataset for analysis, it's too early to give definitive results; however, here are some examples of emerging codes and themes.

A. “Community” as a just-in-time enabler

Professors described the process of learning to trust that open communities will “be there” to support them and their students when problems arise, and finding that collaborative opportunism unlocked a different sort of potential in the classroom. As one participant described it, “[students] will learn so much more than if I teach them... I didn't want to be the limiting factor in learning.” This approach of instructors acting as mentors who understand (but aren't necessarily able to perform at) expert practice is common in cognitive apprenticeship models where students are encouraged to explore different directions and find “experts” themselves [7].

B. Add one new teaching practice idea at a time

The transformation process is incremental; faculty don't jump from lecturing-based instruction one semester to project-based FOSS group work in the next. The seemingly radical practice of “teaching open source” builds atop previously held values and teaching experiences. For instance, one professor's “old” class design used project-based teams and service learning, but worked with a local community rather than a distributed open one. Another used the software infrastructure of another faculty member's “open community” course before designing the use of the same tools into his own classes, and others “taught open source” to small groups of independent study students before bringing the experience into formal classes. Taking small steps can help faculty become more comfortable in working with open source communities and their working principles.

C. Accepting the tension of feeling “unprepared”

Despite holding PhDs in their field, all the professors we interviewed were concerned about not having the technical background needed to participate in open communities. Not having done *exactly* what their students were about to do was

a constant source of stress; they had to consciously adjust their expectations of themselves and their class to adapt to a teaching model where students regularly learned things the professor didn't know. Professors also wished for more time to the same learning experience similar as their students. As one said, “I will have less contributor experience [after the class] than my students do... the nitty-gritty detail is something that I would like to actually have more experience with too.” This is reminiscent Lave and Wenger's work in situated cognition, where the masters of apprentices are transformed through acting as colearners [8].

IV. FUTURE WORK

We continue to work through the grounded theory process of collecting and analyzing data and will move into selective coding, theoretical sampling, and reading of the literature over the next few months [9].

ACKNOWLEDGMENTS

We are indebted to our participants, who generously gave of their time not just for the initial interviews, but for the subsequent analysis and discussions on the practice of radically transparent research as well. We would like to thank our professors at Purdue and Olin for their support and mentorship and Purdue's IRB for being unfailingly patient with us. . Last but not least, the teachingopensource.org community continues to be a source of insight, fellowship, and inspiration; you folks are who we want to be when we “grow up.”

Stories of Change: How Educators Change Their Practice

Sally Fincher, Brad Richards, Janet Finlay, Helen Sharp and Isobel Falconer
S.A.Fincher@kent.ac.uk, brichards@pugetsound.edu, j.finlay@leedsmet.ac.uk, h.c.sharp@open.ac.uk,
Isobel.Falconer@gcu.ac.uk

Abstract - Innovative tools and teaching practices often fail to be adopted by educators in the field, despite evidence of their effectiveness. Naïve models of educational change assume this lack of adoption arises from failure to properly disseminate promising work, but evidence suggests that dissemination via publication is simply not effective. Instead of studying the adoption or rejection of a particular intervention, this paper turns the problem around. We asked educators to describe changes they had made to their teaching practice and analyzed the resulting stories to learn more about: the kinds of changes being made, their motivations for changing their practice, and the means by which they learned of pedagogical innovations. Of the 99 change stories analyzed, only three demonstrate an active search for new practices or materials on the part of teachers, and published materials were consulted in just eight of the stories. Most of the changes occurred locally, without input from outside sources, or involved only personal interaction with other educators. These results have important implications for educational developers, or researchers wishing to propagate information about new teaching materials or techniques.

Index Terms – Change of practice, Change stories, Sharing practice, Education research

INTRODUCTION

The computing community continually creates and evaluates teaching tools and techniques, but these efforts are of reduced value unless promising practices are actually *adopted* by educators in the field. In recent years there has been a growing emphasis on dissemination efforts to help bridge this gap. The solicitation for the National Science Foundation's TUES program, for example, states that "transferability and dissemination are critical aspects for projects developing instructional materials and methods and should be considered throughout the project's lifetime. More advanced projects should involve efforts to facilitate adaptation at other sites."

Unfortunately, there is little evidence that enhanced efforts at dissemination are working. A report to the National Research Council in 2008 found that "NSF- and association-funded reforms at the classroom level, however well intentioned, have not led to the hoped for magnitude of change in student learning, retention in the major, and the

like in spite of empirical evidence of effectiveness" [1]. Failure to adopt effective practices is not limited to computing or education. A meta-analysis of 743 reports, books, and articles in 2005 found that dissemination alone was not an effective implementation method in human services, education, health, business, or manufacturing. [2]

But if dissemination is ineffective, how should the computing community maximize the impact of effective tools and practices? Previous work in computing education has studied how specific tools and approaches have been adopted (or ignored) [3]-[6], and the incorporation of teaching materials from repositories [7]-[8], but much remains to be learned about how instructors decide to change their practice and how those changes are informed, implemented, and evaluated.

This paper studies the problem from the other end of the adoption process: We asked educators to describe changes they had already made to their teaching practices, in an effort to shed light on mechanisms and approaches that led instructors to those changes. We then analyzed the resulting stories to learn more about the kinds of changes being made, instructors' motivations for changing their practice, and the means by which they learned of pedagogical innovations.

CHANGE STORIES

Stories of teachers changing practice were gathered in the context of the Sharing Practice¹ project. Stories were solicited in response to the prompt:

Can you think of a time when something—an event, an article, a conversation, a reflection, an idea, a meeting, a plan—caused you to make a change in your teaching? What was it? What happened?

102 stories were collected over four weeks in February and March 2011, of which 99 were usable. Stories were gathered via a webpage, and subsequently face-to-face, both individually and via a "story-circle" held at the ACM Special Interest Group on Computer Science Education (SIGCSE) Symposium in March 2011. Each contributor provided a story of their change, gave it a title, and attached keywords. Some contributors added several stories. Additionally, some demographic information was collected

¹ <http://www.sharingpractice.ac.uk>

for each contributor, including, age, gender, length of career, and length of time in current institution.

For each story, contributors were asked to indicate how they felt about the change in the story in respect to several questions that elicited meaningful metadata about the experience. These questions were presented as *polarities*, using the concept of *opposing negatives* where “a desired or anticipated quality of the field is identified and the two end labels are provided as the thing not present and alternatively the thing taken to excess” [9]. To give an example from this study: “The change this story describes is limited to individual practice” at one end to “The change this story describes involved programmatic change (QA)” at the other.

Contributors were asked to make a mark on the scale that “best described” change in their story; polarities did not have scales marked on them, so contributors were not selecting from fixed values. Contributors were also asked to select from lists of mutually exclusive options asking them: how they felt about the story, whom they thought should pay attention to it, and how long they would remember it.

CHARACTERISTICS AND LIMITATIONS OF THE SAMPLE

Because of the situation of the project, there is inbuilt bias in the sample. Most contributors were personally solicited, either by a member of the Sharing Practice project team, or from related projects – these related projects are mentioned in several stories. The majority of the contributors (56) taught Computer Science or a closely related subject (e.g. “information systems” or “databases”) and the majority of stories (82) were contributed by someone with more than 10 years teaching experience. The great majority of contributors (80) were over 40; the largest representation is in the 40-49 age group (36). 64 contributors had taught at their current institution for more than 5 years, 34 of those for more than 10.

The type of change described was also heavily skewed to the positive. There were only thirteen stories which contributors did not feel “glad” or “enthused” about, and only one which was unequivocally negative (and about which the contributor felt “angry”). This contrasted with our (anecdotal) experience where colleagues often talk of forced or imposed change, whether instituted because of resource constraints, management dictat or departmental fashion-following. At a Share project workshop, for example, a contributor told of their forced changes “Revamp the whole thing in two weeks!. There’s not even time for people to think about how they could adopt a different approach ...or make connections from different models”³. And, over the years, we have heard several versions of “we are all doing problem-based learning now” or “everything’s agile these days”. We brought these impressions to the data, and expected to find such stories reported there.

The story corpus was relatively evenly balanced in terms of gender with 54 male and 44 female contributors,

and also for institution-type with 28 research-intensive, 36 teaching-intensive and 31 mixed teaching-and-research institutions represented.

ANALYSIS OF POLARITIES

Analysis of the polarities revealed some interesting patterns. For example, when asked who was affected by the change in their story, there were notable differences in response dependent on how long the contributor had been teaching, and on the time a contributor had been at their current institution. In both cases the longer the time, the more the response moved from the change affecting individual practice only towards affecting other colleagues and then programmatic change. (See [10] for more details on the methodology used, and additional results.)

Work from the Effective Projectwork in Computer Science (EPCoS) project suggested that educators most easily adopt small pieces of practice — things that they can implement “under the radar”, without asking others’ permission, or involving QA procedures [11]. Evidence from this study, however, suggests that the observation from the EPCoS project may be more relevant for early-career, or less experienced, teachers. As teachers become established within a department it may be that they become increasingly involved in programmatic activities, or that they are more prepared to claim programmatic influence.

We also asked how teachers themselves felt about the change described in the stories, whether they considered it *addictive*, whether they *adapted to it* or whether they *distrusted* it. There was only one story that showed strong affinity with change being addictive. Those stories most strongly associated with “distrustful” were from teaching-intensive or mixed teaching-and-research institutions. At the same time, when we asked what the source of change was — individual agency, local culture or external driver — then those who said that the source was “individual agency” were mostly from research-intensive institutions. Teachers from research-intensive institutions were also most likely to claim a limited audience for their change — “no one special”, or sometimes “the department”. This may suggest that change is more likely to be imposed on staff at teaching-intensive institutions, and that staff in research-intensive institutions are more likely to “try things out” on their own cognizance.

When we questioned the nature of the change — whether it was new to the department, new to the discipline or totally new — there was a small, continuous, effect that the older the contributor and/or the longer they had been in their career (that is, the more years of experience they had) the more likely they were to say that the change their story described was “totally new”.

ANALYSIS OF STORY TEXT

We found that we had questions of the stories that the analysis of polarities could not address. We wanted to ask what had *triggered* the change that the stories reported, we were interested in what *sort of changes* they described, we wondered how instructors determined the *details* of their

³ This quotation is from the Active Learning in Computing Workshop, December 4th 2009.

change. To look at these questions we undertook a more traditional qualitative analysis, taking the story texts as our data. Four researchers independently coded the stories, each noting aspects of interest. Three explicitly sought the catalyst for the change. A fourth researcher noted the source used to inform change and how that source was discovered. Below we report our observations based on the content of the stories. Quotations from change stories are labeled with the corresponding story number (e.g. CS86 refers to change story 86).

Seeking solutions

The first, most notable, observation was one of absence. Across all the stories, there were only three that displayed a conscious “seeking for a solution” behaviour, two of which described finding information in published materials while the third found guidance from a presentation:

I was faced with designing a new grad AI course, but I did not look forward to straightforward lecturing from the book, so I looked for alternatives. I came across an article by L. Dee Fink, “A Self-Directed Guide to Designing Courses for Significant Learning”, and I also read the book “Drive” by Pink, on self-determination theory. I followed Fink’s design exercise while applying SDT principles. [CS86]

My response was to study the various disciplines that encompass learning science. Much is known about learning, and how we can support learning. I discovered that I had not been doing a good job in the classroom. I also found that the standard textbooks for my field don’t support learning well. [CS38]

I decided to change what I was doing, and looked around for what might work. I happened to go to a session on teaching using case study and so decided to try a case. I searched for some, but in the end wrote my own, brainstorming the ideas with my colleagues. [CS9]

The absence of conscious solution-seeking may be explained by the nature of our prompting question, in that the prompt does not emphasise an existing situation, but a process of change. However, the “seeking solution” behaviour is one commonly attributed to educators. Guzdial and Fossati “...propose to think about an ideal decision-making design process of instructors as composed of three parts: 1. Making a determination that a change is needed. 2. Either finding existing solutions or creating new interventions to address the desired change. 3. Evaluating the effectiveness of the solution and deciding whether to retain it or not.” [12].

It may be that decision-making in teaching, as in other professions, does not involve a problem-solving approach of incremental consideration of each step. It may more closely represent naturalistic decision-making, where professionals make non-analytic choices in situations marked by time pressure, high stakes outcomes, inadequate (or missing, or

unreliable or ambiguous) information, team and organizational constraints, changing conditions, and varying amounts of experience [13]. Whichever construction is a more accurate representation, “seeking solutions” was an extremely uncommon change-behaviour in our data.

Revelation

Because our request was not bounded in scale or time, contributors submitted stories that described change from a single piece of work in a single course to reflections that spanned decades of an entire career. Perhaps because of this open-endedness, the catalyst for change in several stories was a clearly-recalled moment of insight or revelation, often quite a time in the past.

Coup de foudre: a thunderbolt, a streak of lightning that lit up my skies and changed forever, not only me and my teaching, but also the way in which my students learned [CS27]

In some cases, the insight was the point of a story. The title of CS85 is “An Epiphany” and contains the revelatory moment:

I remember quite clearly about two years after I started teaching; I was in London for a meeting with my old PhD supervisor. We were talking about our classes and she said “I never do lectures”. “Never?” I said. “Really, never? So what do you do?” [CS85]

Such moments were often set in relation to a status quo, a set of assumptions, or state of mind:

When I began teaching in universities a quarter of a century ago I set students essay titles, because that’s what happened when I was a student. [CS15]

... it’s just I had never seen a class taught this way when I was an undergrad. I didn’t know people could do that :-) [CS85]

There were also stories that expected, even anticipated, this sort of change where it was not forthcoming:

I started sitting in on colleagues’ classes, but that didn’t help much. I didn’t see anything they were doing that was all that different from what I was doing. But I persevered. I wish I could tell you of some epiphany that helped, but I don’t think there was one. [CS21]

Daily Bread

The most populated catalyst category was of educators initiating change in response to students: in response to something they did, or something they said, or to a close observation of their attitudes and achievements.

I found that almost all the students who had gotten the “differentiate using the chain rule” question wrong had done terribly on the exam, and almost all the ones who had gotten it right had done quite well. After that, I doubled the amount of time spent teaching the chain rule. [CS5]

On a data structure and algorithms exam, I frequently gave students recursive code to do something in a binary tree and asked them to give me the output (there was typically some numeric calculation). I would get 80% incorrect answers. I observed that students would show very little work. I changed the instructions to the problem to include showing the execution tree. Making students show their work flip-flopped the percentages. Typically 80% get correct answers now. [CS18]

What made me change my practice is a student reminding me - "I have never done this before, I don't know what you want". [CS13]

The most recent experience I have of changing my practice comes from student feedback - some formal and some informal [CS26] (The title of this story is "Module Evaluations Work!")

Although sometimes the student-focused catalyst was negative:

But when I looked into their eyes halfway through the introduction I could see that a 15 month old example was no longer topical - indeed most had never heard of something that had been a lead news item a short while ago. I rescued the class by managing to work in a more recent example. But the experience was a bit of a shock. [CS20]

I had a student come to my office during my first term teaching. She was having a hard time in her 2nd year of University, was shifting from Science to Social Sciences, and was struggling. She was in an introductory Human Geography class, and she felt lost, not connecting to the material. We were touching on international issues, and she admitted to me that she JUST DIDN'T CARE. I was stunned that she was so honest, and could not respond to her honesty with anything but compassion, even though I was at a loss to imagine how an intelligent person could be so disconnected from social and environmental injustices and suffering that were our topics. [CS31]

Other Catalysts of Change

Many stories (13) report the influence of a named individual as causing them to change their teaching. For as many (18), participation in an event, or external training, or "getting out of the classroom" made the difference although often these are not reported as intentional acts: "I attended a keynote lecture about learning preferences" [CS25], "I was reading a book and stumbled upon a quote that was written in one of the margins" [CS40], "In the toy store, wandering about, I saw some baby toys called 'bear links.' That reminded me of the linked lists I was supposed to be worrying about for class ... so I decided to get them and use them in class." [CS53]. Finally, a least populated category was "external imposition" represented by only one story, entitled "Forced to conform" [CS11].

Sources of Change Details

In all but one of the stories (the "external imposition" story above), educators were in a position to control at least some of the details of the change they described. Our earlier analysis revealed that few stories reported the sort of deliberate search for solutions that had previously been hypothesized, so how *were* educators informing decisions about pedagogical change? In just over half of the stories (50), the instructor apparently formulated the details of their pedagogical change on their own, without consulting peers or other resources.

This abundance of "local change" stories is perhaps not surprising given that "change in response to students" was found to be the most common catalyst category. One might expect these sorts of changes to occur frequently, and be relatively small in scale, making it less likely that the teacher involved would seek outside counsel. Additionally, changes made in response to student feedback are often tightly tailored to local circumstances—the constraints of a classroom or the structure of a curriculum, for example—making it less likely that a literature search would discover appropriate interventions. Published work is necessarily abstracted away from its original context in an effort to generalize a result and enhance its transferability, but the further removed the practice described is from the particulars of local circumstance, the less obviously it is relevant and the more work must be done to adapt the practice to a new environment.

All of the change stories quoted in the *Daily Bread* section fall into the "local change" category. Not all locally formulated changes were the result of student feedback, however. Eight were the result of reflection on the part of the instructor:

The original format was that the assessor would fire questions at team members about the work. I thought this approach would disadvantage anyone with limited understanding of English so I changed the format. I put more time into setting up the assessment, giving information about the areas to be assessed and asked the students to take responsibility for the walkthrough and who would be explaining sections of the documentation. [CS63]

When the instructor who normally taught the class left, we were left with no one to teach it. I was one of two professors who decided to try teaching the course. Having been trained technically as a computer scientist, I was familiar with how to teach programming, data structures, etc., but it became clear to me that teaching students about ethics and the societal impact of computing would require a completely different style of teaching. I determined that it would have to be more discussion-based, readings-based, and writing-based. [CS57]

Other changes were driven by external circumstances.

Several years ago, I taught in a classroom with no white or chalkboards. So that I could write examples for the students, I started using a tablet PC and Classroom Presenter from the U. of Washington. This has evolved into a set of "guided slides" that are partially completed that I finish in lecture, and posted soon thereafter. [CS50]

In the remaining stories, authors reported obtaining change details via interactions with other educators (39 stories) or from published materials (8 stories). The mechanisms through which these sources were located are explored in more detail below.

Transmission

As was reported above, instructors rarely searched for information when considering change. At the other extreme, 12 stories described changes resulting from chance encounters with educators who shared or demonstrated details of their teaching practice. The authors of these stories had not intended to change their practice until they were exposed to a new approach.

I never would have made this change if it weren't for a trusted friend who told me to do this and I was sort of convinced. The change was to go from more or less traditional lecture with a handful of active learning activities punctuating it, to a completely or almost-completely question-driven style with peer-instruction. [CS70]

When I started university teaching I was very 'controlled' - all "chalk & talk". It took my colleague to loosen me up! We did team teaching together and he regularly inserted activities, interactive tasks, buzz groups, video snatches for students to comment on, role play, group work etc. Basically, the 'scales dropped from my eyes' and I saw how valuable these more discursive, open-ended, student-centred approaches were; and how memorable they were to us & to the students alike. [CS99]

The change in the examples above resulted from unplanned interactions between instructors. A larger group of change stories (31) involved *primed serendipity*, where the author encountered unanticipated information but while putting themselves in situations where they could reasonably expect to learn *something* about teaching practices (e.g. attending a conference or workshop, or browsing a journal issue). In five of these stories the author drew on published materials to inform their change in practice. The remaining 26 narratives in this category involved personal exchanges with groups or individuals.

Several years ago I read a book titled "Beyond Bullet Points" by Cliff Atkinson that kept mentioning Richard Meyer's work on multimedia learning theory. I read several of his papers and his book as well. Over a summer I revised all of my CS1 slides to incorporate his multimedia learning principles. [CS56]

I participated in a course on Teaching with Technology. Although I had always used technology where I could, this course exposed me to dozens of different tools and uses for these tools in the classroom. I now incorporate many of these tools in my teaching. [CS12]

I was travelling on holiday to Italy. I had taken Jenny Moon's book on reflective practice, just to re-read I chanced on mention of a teacher who had shared his own learning journal with his students. I knew that my Soc Sci students initially had problems with reflective journalling. I thought "Why don't I share mine with them?" [CS68]

I'm a member of a science education reading group on campus. One of the papers recently was on how to evaluate your assessments (specifically tests/exams). One person in our reading group was a psychologist who researches "psychometrics" and does extensive quantitative test analysis for her courses. Based on her experiences and advice, I was inspired to go over a test I was in the process of writing for my CS0 course the following week. [CS95]

DISCUSSION

The change stories provide a valuable window into the behaviour of educators as they change their practice. Our study is novel in that it collects stories from teachers in their own words, and makes no attempt to limit the scope of the project to the adoption of any particular intervention. Stories are a relatively unusual form of data for this sort of investigation. They are not responses to direct questions (as in interviews, surveys or questionnaires), they do not represent opinions on issues, nor statements of fact. They are, however, authentic communications which illuminate complex topics, and which can provide insight into complex spaces. There is always a point to telling a story, a reason for their emergence, something the teller wants to communicate.

Stories also have an effect on the audience: "The act of listening to a story told by another person creates a ... displacement of perspective that helps people see through new eyes into a different world of truth" [14]. The power of this collection of stories is demonstrated in their content, in the things the storytellers wanted us to know. And what they contributed were stories of success, of change making an improvement, most often an improvement to student learning. They also conveyed an abiding sense of personal satisfaction, of professional pride, of overcoming challenge and disappointment, in doing a good job. And in this, the contributed stories were entirely comparable even though they were from different countries, institutional contexts and academic disciplines.

Lessons for Education Developers and Researchers

In the change stories we analyzed, instructors very rarely performed the kind of deliberate, methodical search for

educational interventions that a naïve “changing practice” model implies. This has implications for educational developers and researchers wishing to propagate information about new teaching materials or techniques.

A review of the analysis above reveals that books or articles informed change in only *eight* of the 99 stories, despite the fact that part of the solicitation was via education research mailing lists, and a number of the stories were collected at an education-related conference: In other words, the participants are exactly the kinds of instructors one would *expect* to be reading the scholarly literature. Even within the group of eight, the majority found their source through primed serendipity instead of deliberate search. That is, they encountered the information while looking for something else, or while perusing a journal or proceedings.

Over 90% of the stories described changes that were either created without drawing on outside sources, or were informed by personal interactions with other educators. The relative prevalence of personal interactions as a vector for information on teaching practices is noteworthy: Instructors reported changing their practice as the result of personal interaction with a peer far more often than after reading an article or book. Peer interactions were so powerful, in fact, that in a dozen of the stories they caused instructors to make *unplanned* changes to their practice.

Research on diffusion of innovations has found that communication is more effective between similar individuals [15]. It is possible that instructors who know one another well enough to exchange information about teaching practices are similar in key respects, which could help explain the impact of the personal interactions we see in the change stories. Peers are perhaps also more likely to have similar teaching contexts — to come from similar institutions, teach the same sorts of courses, or have similar students, for example. Information coming from someone with a similar context can more immediately be recognized as relevant, and can be implemented more easily since little or no adaptation is required to employ the practice in a new setting.

Additional research will be required to illuminate the nature of the interactions between educators, but the role of personal interactions in the stories suggests that education developers would be wise to pay closer attention to the exchange of information within personal and professional networks. As Stephen Corey said in keynote talk to the National Society for the Study of Education in 1951 “I hesitate to say so, but I believe that we pedagogues tend to exaggerate greatly the amount of change in educational practice that results from reading what other people say should be done...”

ACKNOWLEDGMENT

We are grateful to all the educators who shared their stories with us. The Share project was funded 2008-2012 by the Higher Education Funding Council for England (HEFCE) in the National Teaching Fellowship Scheme (NTFS) Project Strand, administered by the Higher Education Academy

(HEA). Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of HEFCE or HEA.

Abstract—Traditional forms of mentoring offer graduate students a support system to assist them through their education. Many times these traditional forms of mentorship can be augmented by other support mechanisms. This phenomenon is especially true in engineering education because of the interdisciplinary nature of the discipline. In this work, we explore engineering education graduate students' self-reported value in regards to their participation in a multi-institution peer mentorship program. Further, we identify if and in what ways such a program supports graduate students' development towards becoming emerging scholars in the field of engineering education.

Keywords – Graduate Engineering Education Consortium for Sstudents (GEECS), peer mentoring, graduate students, identity

I. INTRODUCTION

Graduate school is often characterized as an isolated time during students' development towards becoming academic scholars. This challenging journey is sometimes interrupted by negative experiences (e.g., failed exam, rejected article, or a discouraging advisor). While these challenges can be opportunities for growth, they often cause graduate students to doubt their ability as emerging scholars. Negative experiences may even result in an attitude shift that leads graduate students to not acknowledge past accomplishments—often referred to as imposter syndrome [1]. Imposter syndrome “is characterized by strong feelings of intellectual and professional phoniness in high-achieving individuals. According to Clance and Imes, imposters entertain these thoughts and feelings despite evidence that suggests both outstanding academic and/or personal accomplishments” [1, p. 44]. Graduate students must avoid falling into the trap of feeling inadequate if they are to become successful engineering education researchers.

The identity development of graduate students in engineering education is particularly important because the field is rarely, if at all, defined by a specific pathway to becoming a scholar. The background of current faculty who identify their main area of research as engineering education range from engineering discipline specific degrees and industry experience to education, communication, and even specific

engineering education degrees. It is, therefore, important to understand and assess interventions that may impact engineering education graduate student development from multiple points of view. We are particularly interested in an alternative approach to mentorship through peer interactions. In this study we explore the impacts of the Graduate Engineering Education Consortium for Students (GEECS) peer mentorship program on graduate students' development as emerging engineering education scholars.

Peer mentoring [2] is a program developed, implemented, and sponsored by GEECS [3]; it provides a virtual space, via monthly conference calls and an online forum, for engineering education graduate students to support and challenge one another throughout their degree program. Our study investigates the following research questions to better understand the significance of GEECS peer mentoring:

1. What value do graduate students ascribe to GEECS peer mentoring?
2. Does GEECS peer mentoring support graduate students' development toward becoming an emerging scholar?

These research questions reflect our interest in identifying how this type of mentoring supplements more traditional avenues of mentorship (e.g., advisor/advisee relationships), keeping in mind that prior research has shown peer mentoring to be a promising avenue to address issues related to recruitment and retention of women in engineering [4, 5].

In the following sections, we situate our research in the literature, explain our methods, explore the quantitative and qualitative results, discuss the findings in light of literature, and conclude with study implications.

II. PEER MENTORSHIP: AN ALTERNATIVE PERSPECTIVE TO MENTORING

GEECS peer mentoring offers an alternative perspective to traditional mentoring [6, 7]. While graduate students often engage in mentoring through a variety of avenues (e.g., advisor, faculty members, supervisors, parents, or friends),

these traditional approaches to mentorship are characterized and defined by one-on-one relationships. While these general mentoring relationships are valuable and irreplaceable, there exists an opportunity to supplement this mentoring with further support through peer mentoring.

Research in engineering about mentorship suggests a specific need and benefit for women, which has the potential to address issues related to the recruitment and retention of women in engineering [4, 5]. Chesler & Chesler's [4] work on exploring alternative mentorship for women in engineering provides three alternative models to the traditional single mentor model. In the first alternative model, they suggest that students construct a "mentoring community," "mentoring team," or "distributed mentorship" that is a composition of a range of mentors (e.g., senior and junior faculty members or industry leaders) designed by the mentee. In the second mentorship model, the authors suggest peer mentoring that "simultaneously builds community and de-emphasizes seniority and hierarchy" [4, p. 52]. In the third mentorship approach, the community takes a "collective mentoring" mindset, which is developed and implemented by the specific department or community.

GEECS peer mentoring is an example of the second approach. We focus on this approach as a promising avenue for the development of emerging engineering education researchers. Through this lens, we characterize and analyze the GEECS peer mentoring as a plausible mentorship model that has value toward professional and personal development, and supports these graduate students as emerging scholars in the field.

III. THEORETICAL FRAMEWORK

We frame our analysis of peer mentoring through the lenses of associated value and identity development.

A. Associated Value

Mentoring opportunities are designed to provide mentors and mentees with personally valuable interactions. The inherent value embedded in mentorship ranges for each individual based on how they gauge value from the activity. According to Expectancy Value Theory, behavior is a function of the value one places on achieving a goal [8]. The interest, attainment, utility, and cost associated with a given activity results in a perceived overall positive or negative sense of importance.

Initial findings from an auto-narrative analysis [2] suggest that peer mentoring for engineering education research students is a valuable undertaking. Peer mentorship increased the value participants placed on community support toward their teaching, research, service, and personal goals. We believe that strong value placed on mentorship is an important factor that can help students succeed as engineering education researchers, especially for students who lack a community at their home institution. In this way, peer mentorship also helps the growth of the engineering education research community.

B. Supporting Identity Development

There is an opportunity to examine this type of social networking beyond general characterization and potential value. The auto-narrative analysis [2] also suggested that peer

mentoring offers an environment that supports graduate students during a time in which they internally struggle with their identity both professionally and personally. Developing an identity within a field of study is an essential step in graduating to become a professional. Peer mentoring has the potential to be a supportive environment that helps engineering education graduate students grapple with identity development.

In general, various stages of graduate education can offer a variety of challenges to one's identity development. Early stages of identity development can be difficult for graduate students who often feel lost and overwhelmed as new members of their lab or research group. Graduate student reflections of their experiences suggest a feeling of being overwhelmed with high expectations for background knowledge. Mid-process students expressed anxiety and stress with qualifying exams, but also discussed peer-groups or comparable groups as a coping mechanism to commiserate with. Even in latter stages of graduate study, students expressed being challenged to compete with others for critical first step career options [9].

The overall theoretical underpinnings, consisting of associated value and identity development, meld well in providing a solid foundation to explore how a reflective activity like peer mentoring can be important to graduate student development.

IV. METHODS

In order to better understand the effects of this program, our subsequent analysis of the GEECS PEER Mentoring Program includes an assessment on the impact of perceived value and identity development. This exploratory work used an online survey to examine the value graduate students assigned to their participation in peer mentoring and the identity support students acknowledge from the experience. The following describes the peer mentoring structure, and data collection and analysis approaches.

A. Peer Mentoring Structure

In small groups (i.e., four to six participants), ten current and recently graduated engineering education graduate students participated in GEECS peer mentoring during the 2010 – 2011 academic year. Monthly conference call meetings were structured to focus on goal setting/monitoring and providing feedback on each other's work. Preparation for these sessions was augmented by participants monitoring and updating their goals in an online database (i.e., GoogleDocs spreadsheet) (see Table 1 for an example).

TABLE I. EXAMPLE GOAL SETTING AND MONITORING SPREADSHEET.

| | January Goal Setting | January Goal Update |
|-----------------|---|--|
| Research | Write the first chapter of my dissertation | Completed the first chapter and submitted to my advisor |
| Teaching | Visit a K-12 classroom once per week to teach engineering design | Participated in K-12 outreach through twice a month classroom visits |
| Service | Fulfill my role as an executive board member of the ASEE Student Division | Procured money for the upcoming conference |
| Personal | Go to the gym twice a | Visited the gym or played a |

| | | |
|--|------|-----------------------------|
| | week | sport at least twice a week |
|--|------|-----------------------------|

B. Peer Mentoring Participants

The two peer mentoring groups were each led by one doctoral-level student leader. A PhD candidate in Engineering Education at Purdue University led one group, while a PhD candidate in Human Centered Design & Engineering from the University of Washington (first author of this paper) led the other. The remaining members of the two groups included:

- four 1st year (now all 2nd year) graduate students – one Aerospace Engineering PhD student from Georgia Tech, one Engineering and Science Education PhD student from Clemson University, one Engineering Education PhD student from Purdue University, and one Engineering Education PhD student from Virginia Tech
- a 2nd year (now 3rd year) Engineering Education PhD candidate from Virginia Tech (third author of this paper)
- a recent Electrical and Computer Engineering PhD graduate from the University of Illinois at Urbana-Champaign; now post-doctoral research associate at Purdue University's Engineering Education Department
- a post-doctoral research associate at Arizona State University (ASU) with a PhD in Education from Tufts University (second author of this paper); now an assistant professor of Engineering at ASU and an assistant teaching professor of Business at the University of Missouri who is a recent Industrial Engineering PhD graduate from Iowa State University.

The current and recently graduated students all met through their involvement in the ASEE Student Division and their mutual interest in creating GEECS.

In this study consideration was paid to the influence of the researchers on the participants. The researchers in this paper were also participants in the peer mentoring groups included in the study. Special effort was made to avoid internal bias in the construction of the qualitative questions in the survey. Responses to survey questions also indicated that no significant bias as evidenced by negative critiques of the peer mentoring experience and the program. Participants were honest and unreserved in their feedback and critique. The authors also considered their own perspectives of peer mentoring and bracketed those ideas in the data analysis process.

C. Data Collection and Analysis

GEECS peer mentoring participants were surveyed after a year of participating in the program in order to understand better their experience. Two sets of data were collected using one survey to provide the primary data source for this study. The survey included fourteen fixed item questions pertaining to value and nine open-ended items pertaining to identity.

Student perceptions of value associated with the peer mentoring experience were measured quantitatively using fixed item questions. Questions were designed to address two areas of validity: 1) content and 2) construct [see 10, 11]. Content validity was addressed by framing the questions around the purpose and goals of peer mentoring. Construct validity was

addressed by designing questions that incorporated the four areas of value—interest, attainment, utility, and cost—suggested by expectancy-value theory [12-14]. Quantitative data was assessed using IBM® SPSS® Software and Microsoft® Excel®.

The fourteen items of the associated value survey were separated into three factors according to previously unpublished factor analyses. The three factors included interest/attainment value, utility value, and cost. The fixed-items were presented to students using a four-point agree-disagree scale including *completely agree*, *somewhat agree*, *somewhat disagree*, and *completely disagree*. To simplify the results, all agree and all disagree responses were separately pooled together (see Tables II – IV).

Identity questions were situated in student identity and imposter syndrome theories in order to target this dimension. The qualitative survey questions were analyzed through an open coding process [15] considering the major themes that were established in this group's prior work [2]. We used deductive reasoning to understand the participants' responses within the context of identity development and imposter syndrome. This approach confirmed what is known about peer mentoring and uncovered the theme of participants' views of peer mentoring. Once the three themes were identified, an axial coding process [14] was used to identify important subcategories to further understand participants' experiences with identity, imposter syndrome, and their view of peer mentoring within the GEECS program.

The authors' experiences as participants in peer mentoring served as confirmation of emerging themes.

V. RESULTS

This study examines students' reported experiences in relationship to associated value and identity development. These areas of interest were used to support one another. We first established a foundation using associated value to gain an understanding of the participants' peer mentoring experience. These general impressions were used to frame the relationship between peer mentoring and identity development.

A. Associated Value

1) *Interest/Attainment Value*: Interest or intrinsic value is an individual's anticipated enjoyment of engaging in a particular activity. Related to interest value is attainment value or an individual's perception of how the activity contributes to the conception of who he or she is fundamentally. Results suggest that students found peer mentoring to be motivating and helpful in effectively gaging what they've learned as graduate students. The remaining interest/attainment items produced mixed results suggesting that GEECS peer mentoring is generally interesting and beneficial to exploring who the student is, but that changes should be made to improve the program (more detail provided in the *Views of Peer Mentoring sub-section*).

TABLE II. INTEREST/ATTAINMENT VALUE RESULTS

| Interest/Attainment Value | Agree | Disagree |
|---|-------|----------|
| motivated me to do well as a graduate student | 6 | 1 |
| was an effective way to gauge what I have learned as a graduate student | 5 | 2 |
| helped me understand my own learning | 3 | 4 |
| helped me to understand the knowledge I have gained as a graduate student | 4 | 3 |
| increased my enjoyment with my graduate studies | 4 | 3 |

2) *Utility Value*: Utility value is an individual's perception of the advantages that result from engaging in the task for future goals or rewards. Results suggest that students generally found utility from the peer mentoring program. Only one aspect of the program, *representing a real world experience*, was viewed with mixed perceptions.

TABLE III. UTILITY VALUE RESULTS

| Utility Value | Agree | Disagree |
|--|-------|----------|
| will help me towards reaching my future career goals | 6 | 1 |
| was useful in my pursuit of other goals | 5 | 2 |
| increased my level of responsibility for my graduate studies | 5 | 2 |
| represented a real world experience | 3 | 4 |
| will help me towards reaching my future goals as a student | 6 | 1 |

3) *Cost*: Cost represents an individual's perception of the sacrifices required, including effort, time, and psychological impact, for successful impact of an activity. Results suggest that students generally found the peer mentoring program to cost them very little in terms of personal sacrifice.

TABLE IV. COST RESULTS

| Cost | Agree | Disagree |
|--|-------|----------|
| required too much effort | 0 | 7 |
| made me frustrated and anxious | 1 | 6 |
| required too much time | 2 | 5 |
| limited my ability to be a successful graduate student | 0 | 7 |
| required too much effort | 0 | 7 |

B. Identity and Impostor Syndrome

Within the context of peer mentoring, the results suggest that these graduate students grappled with their identity as an individual and situated within the field.

1) *Identity*: Peer mentors expressed their experience with the program on two main levels: affinity within the field and individually on a personal and professional level. Participants explained that the peer mentoring experience helped them to feel a part of the field and often motivated their desire to continue developing relationships with graduate students in

their peer mentoring group. Students discussed developing a network in the field, which assisted with understanding the diversity within engineering education and what it means to become an engineering education researcher. While students began to feel like part of a community, they were also recognizing the rapid expansion of the field, which results in competition:

"I think this field is going to be a lot more competitive than I thought it would be initially."

The students overall felt that the experience helped them make connections, some of which resulted in developing research collaborations, feeling a part of the field, and making friends in engineering education beyond their own departments. Peer mentoring was seen as a way to benefit from others in the field:

"Even though I have a large support network of people [at my own institution] in engineering education it was still beneficial to me to talk with others at different schools. It provided a unique perspective."

Individually, participants identified personal skill sets and values related to the peer mentoring experience. Participants saw themselves as mentors and wanted to contribute to others. One participant who expressed some frustration with the peer mentoring experience desired to lead their own peer mentoring group. Professional identity was also a major part of participants' discussion of the experience. A strong desire and motivation to become an excellent researcher was also a major topic of discussion:

"I am constantly learning the 'tools of the trade' for developing scholarly work in the area of engineering education. More specifically, I am learning what counts as rigorous research in this field and am dedicated to generating research that meets these high standards."

Another participant explained that the field does not provide a clear path to post graduate work. The peer mentoring experience helped them gain valuable insight into the various paths:

"I also learned that being a graduate student studying engineering education can be tough at times since there isn't always a clearly-paved road ahead."

The design of the peer mentoring program emphasizes balance as a graduate student and maintaining a personal life. Many participants felt that peer mentoring helped them achieve personal goals that are not directly related to graduate school. For example, discussing non-school related goals, such as maintaining a healthy lifestyle, spending time with friends and family, were very useful pieces of information about post-graduate work.

2) *Impostor Syndrome*: Some of the behaviors associated with impostor syndrome were overcome by peer mentoring participants. Participants' comments related to impostor syndrome behaviors were categorized as shared or similar experiences and self-affirmation. Shared experiences were related to the challenges of graduate school, such as exams, research difficulties and preparing for a career. One participant explained it this way:

"This uncertainty about what happens after graduation can, in some ways, make graduate students (studying engineering education) very anxious. This anxiety is in addition to normal stresses of graduate student life. It was not until I was part of a peer mentoring group that I saw how widely-shared this experience is."

Developing camaraderie in misery is a way to overcome imposter feelings, especially through peer mentoring groups with students from different institutions. Participants also felt more a part of the engineering education community through participation in peer mentoring, as they found others with interests similar to their own. Responses that were coded as self-affirmation referred to how students felt about their past decisions, especially entering engineering education and making an uncertain career choice. Participants also expressed increased confidence in their knowledge of engineering education.

3) *Views of Peer Mentoring:* Piggybacking off the associated value survey, participants were asked questions about their views of the peer mentoring experience. Themes of value and group accountability arose. Participants valued feedback that they gained from peer mentors as well as attempting to recreate peer mentoring groups in the future or in other contexts. In a sense, mentoring became a process involved in forming their identity. Most of the value associated with peer mentoring was related to feedback from multiple parties. One participant explained it this way:

"I once thought that my advisor (and other professors) were always the ones to go to for guidance, feedback, and insight. However, this experience has shown that my peers have a wealth of knowledge and, in some aspects, are just as capable of providing the dialogue I need."

Group dynamics and the commitment of others in the peer mentoring group was also very important to the participants, and influenced how they viewed the experience overall. For some of the participants, the need to report to others regarding goal progress was a motivator and helped increase their own accountability. Participants also felt accountability to each other to review current work and participate in meetings. Some comments indicated that groups that had lower levels of accountability or less stable participation left some wanting more from their peer mentoring experience.

VI. DISCUSSION

The results of this study suggest that engineering education graduate students found peer mentoring to be a positive experience, especially in regards to associated value, utility value, and cost. These students reported peer mentoring as an opportunity to engage in identity work. While these students generally characterized peer mentoring as a positive addition to their graduate experience, students also offered various changes and additions for potential improvement and growth of the program.

The quantitative associated value findings suggest that students generally found the mentor program to have utility and cost very little to them personally in terms of time and effort. These findings encourage the continued use of peer mentoring with engineering education graduate students associated with

GEECS, and with engineering education graduate students more generally. These findings suggest that such a program could have possible use in other disciplines where graduate students face a similar challenge of isolation (e.g., interdisciplinary programs).

Interest/attainment was not as positively scored with the quantitative data, as students seemed to have mixed perceptions as to whether the program was interesting and if it effected them on a personal level of identity. However, the qualitative data suggests an alternative perspective. Students reported that their professional identity as an individual and as a part of the field was positively influenced by the peer mentoring experience. Participants were also able to overcome self doubt and imposter beliefs through sharing relatable experiences of other graduate students in the field of engineering education. Participants deducted that the individual and group value associated with peer mentoring was accountable by the overall peer mentoring technique and indicated the intent to use the model again in the future. Participants experiencing a successful peer mentorship also expressed equal commitment to providing feedback to each other and building connections between each other for the experience to be successful.

In connecting these results back to our theoretical framework, peer mentoring is a promising mechanism through which to support graduate student development throughout their program. In relationship to Expectancy-Value Theory these results indicate that students' behavior towards individual degree progress and community situatedness grew in the positive direction. In relationship to identity theory, these results connect to both the development of one's identity personally, as well as one's identity situated within the community.

VII. CONCLUDING REMARKS

Our initial findings suggest that the reflective activity of peer mentoring leads to engaging in identity construction. For example, these participants began to recognize themselves as capable academics, and in some cases began grappling with and even overcoming their feelings of being an impostor. Through interactions with peers at various stages in their graduate education, these students were able to validate one another's accomplishments.

While this program is a strong initial step towards supporting engineering education graduate students, there were clearly areas for improvement. For example, the program can be strengthened through more consistent communication. Initial logistics of planning meetings often led to a delay in peer mentor opportunities. Furthermore, groups became quite dependent on the group leader/organizer. The group often struggled if and/or when this person became too overcommitted with other graduate student responsibilities.

Our results suggest that GEECS should maintain peer mentoring efforts with an eye towards checking-in at least annually with all participants. Growth of the program will require additional monitoring to ensure that the experience is valuable for all involved. It will also need leadership to think broadly about the associated benefits. One suggestion is to have larger departments develop a peer mentoring type of program

within institutions and across institutions as part of the GEECS program. The more students that we can involve and associate with GEECS peer mentoring will mean sustainable success for the program in the future.

The findings in this study can guide future program development in several ways. Participants indicated that the program did not necessarily help them in understanding their own learning. The structure of peer mentoring goal setting may need to be adjusted in the future to better help participants understand their own learning, especially in the early phases of their graduate career. Participants also indicated that peer mentoring did not represent a real world experience. While peer mentoring often does not formally at some institutions, participants may be gaining skills to continue this type of mentorship into their career. Peer mentoring can be a useful method, but emphasis on the possibilities of the program beyond graduate school will need to be increased to identify applicability during pre-tenure and as a pedagogical strategy. The continuous improvement model being implemented with peer mentoring movies designed to help participants as they move into faculty and other professional roles in their careers. In the future this group will examine the longitudinal effects of the program on participants and their use of the strategies gained in other contexts.

ACKNOWLEDGMENT

The authors would like to thank the remaining members of the peer mentoring groups for their participation.

Implementing & Evaluating Undergraduate Research in Renewable Energy at Colorado School of Mines

Chuck Stone and Scott Strong

Colorado School of Mines, cstone@mines.edu, sstrong@mines.edu

Abstract - In 2011 Colorado School of Mines hosted 20 students in a Research Experiences for Undergraduates (REU) program in renewable energy. Students participated in weekly technical seminars, professional development sessions, laboratory tours, social activities, and an end-of-summer poster session with other nearby students in the National Nanotechnology Infrastructure Network program at the University of Colorado, Boulder. The REU also joined the 2011 cohort of the Cornell Office for Research on Evaluation (CORE) Evaluation Partnership program, which stressed intensive modeling centered on stakeholder interviews. A CSM faculty member led this modeling effort and determined that diversity and integration of community members were as important as an individual's research experience. Moreover, it was thought that successfully controlling these REU parameters would lead to a better understanding of what role community plays in student attitudes and could inform a set of best practices for arbitrary REU communities. From this perspective, a set of mixed-method measures was constructed leading to an introductory evaluation of program aspects. This paper provides an overview of the Colorado School of Mines' renewable energy REU, the evaluation protocols applied to the program, and their implications that will be integrated into the second year of the project.

Index Terms – renewable energy, research experiences for undergraduates, REU evaluation, REU implementation.

IMPLEMENTATION

The following section discusses the implementation of the renewable energy REU summer program at Colorado School of Mines (CSM).

I. NSF REU Site Grant

In January 2011, the National Science Foundation's (NSF) Division of Materials Research awarded CSM a 3-year grant [1] for \$270,000 to establish a Research Experiences for Undergraduates (REU) Site to support 8 students a year in a renewable energy REU program. Consistent with NSF's mission and purpose, the goals of this REU are to

- provide participating students with high quality research experiences in renewable energy, and
- increase undergraduate students' interest in pursuing advanced degrees in the discipline.

The following objectives target the first goal: a) introducing talented undergraduate students to the excitement of discovery through participation on a vibrant research team; b) enhancing

undergraduate students' technical expertise by providing them with a rich and engaging research experience; and c) providing undergraduate students with training and independence in a research environment. Increasing female, underrepresented minority, and non-traditional students' interests in pursuing advanced degrees in renewable energy achieve the second goal. Table I lists the funds budgeted in our NSF REU Site Grant [1] to support one student in our 10-week summer program.

TABLE I
COST TO SUPPORT ONE STUDENT IN 10-WEEK 2011 REU PROGRAM

| Description | Cost |
|---|----------------|
| Stipend (\$11.25 per hour) | \$4,500 |
| Roundtrip Travel from Home to REU, then REU to Home | \$500 |
| Housing in Campus Apartments | \$1,190 |
| Weekly Meals | \$750 |
| Working Meals | \$100 |
| Materials and Supplies | \$60 |
| Publication / Documentation / Dissemination | \$75 |
| Hotel, Registration, Travel (to present at future conference) | \$1,250 |
| Subtotal | \$8,425 |
| Administrative Allowance (25% of Stipend) | \$1,125 |
| Grand Total | \$9,550 |

As shown in Table II, the REU Site Grant supported 8 students, while a variety of other funding sources supported 12 additional students, allowing us to host a total of 20 participants in our 2011 REU program.

TABLE II
FUNDING SOURCES FOR 20 PARTICIPANTS IN 2011 REU PROGRAM

| Funding Source | # Supported |
|--|-------------|
| CSM Sources | |
| Louis Stokes Colorado Alliance for Minority Participation – Bridge to the Doctorate Program [2] | 0.34 |
| Multicultural Engineering Program [3] | 2.00 |
| Office of Graduate Studies [4] | 0.33 |
| Oil Shale Symposium Sponsorship [5] | 1.00 |
| Renewable Energy Materials Research Science and Engineering Center [6] | 4.33 |
| Research discretionary funds from physics professor | 1.00 |
| NSF Sources | |
| REU Site Grant [1] | 8.00 |
| Supplement to NSF Award DMR-0907409 [7] | 1.00 |
| Other Sources | |
| Center for Revolutionary Solar Photoconversion [8] | 1.00 |
| Pat McAdam Scholarship in Chemical and Bioprocess Engineering from University College Dublin [9] | 1.00 |

II. 2011 REU Participants and Mentors

Due to overwhelming campus support, our 2011 REU hosted 20 students from 14 different institutions (12 national, 2 international) in a 10-week summer program that strove for

gender balance (11 females, 9 males) and diversity (3 underrepresented minorities, 1 non-traditional student), as well as a balance between participants from research institutions and from institutions where research opportunities for students are limited. Table III displays features of our student population, while Table IV lists student's home institutions.

TABLE III
FEATURES OF 20 STUDENT PARTICIPANTS IN 2011 REU PROGRAM

| Demographic Profile | |
|-----------------------------|-----------------------------------|
| Age | 19 to 28 years old (one over 25) |
| Citizenship | France (1), Ireland (1), US (18) |
| Disability | None |
| Ethnicity | Hispanic (2), Not Hispanic (18) |
| Gender | Female (11), Male (9) |
| Race | Black/AfricanAm (1), White (19) |
| Diversity Profile | |
| Non-Traditional Students | Age over 25 years old (1) |
| Underrepresented Minorities | Black/AfricanAm (1), Hispanic (2) |
| Scholastic Profile | |
| Average Grade Point Average | 3.69 |
| Graduate School Plans | 17 of 20 |
| Representation | 14 Institutions / 8 Majors |
| Year of School Completed | Fr (3), So (6), Jr (9), Sr (2) |

TABLE IV
HOME INSTITUTIONS OF 20 STUDENT PARTICIPANTS IN 2011 REU PROGRAM

| Home Institution | Participants |

| University of Colorado – Boulder, CO | 1 |
| International Schools | |
| Ecole des Mines – Albi, France | 1 |
| University College Dublin – Dublin, Ireland | 1 |

Faculty mentors and research staff provided valuable roles in shaping the behavior, beliefs, communication skills, laboratory talents, presentation abilities, safety habits, and work ethic of our REU students as they developed as professional researchers. Each REU student was assigned a primary faculty mentor and a primary student contact within their research team. Both the primary faculty mentor and the primary student contact were available throughout the program to support the REU student. The primary student contact acted as a “near-peer” role model and as an approachable resource, and was either a graduate student or an undergraduate alumnus of the REU program. As novice researchers, many undergraduate students hesitate to ask scientific questions of their faculty mentors, fearing that the topic is something they should already know. The availability of another student addresses this concern. Additionally, our student contacts had considerable knowledge and experience within the university environment; they were aware of social events and activities that were available and appealing to college-age students, and knew how to work with the various “systems” in and around campus.

Table V lists the number of faculty, staff, and scientific mentors that contributed to the success of our 2011 REU program.

TABLE V
FACULTY, STAFF, AND SCIENTIFIC MENTORS IN 2011 REU PROGRAM

| Group | Mentors |
|--|---------|
| CSM Faculty | |
| Applied Mathematics and Statistics | 1 |
| Chemical and Biological Engineering | 6 |
| Chemistry and Geochemistry | 3 |

| External Collaborators | |
| National Nanotechnology Infrastructure Network at University of Colorado – Boulder, CO | 2 |
| National Renewable Energy Laboratory – Golden, CO | 4 |

III. 2011 REU Program Elements

An interdisciplinary team of ~ 40 engineering and science faculty at CSM, as well as staff from the Colorado Energy Research Institute and the National Renewable Energy Laboratory (NREL), mentored 20 students in renewable energy research projects. These projects addressed the performance of next-generation photovoltaic devices; microstructural design of composite membranes; hydrogen storage in clathrate hydrates; social and ethical implications of climate change, renewable energy, sustainability & education; hybrid energy systems for oil shale production; and optimizing computational tools for energy science.

Students attended weekly technical seminars that spanned photovoltaics, energy storage materials, the role of catalysts in fuel cells, computational energy science, and challenges & opportunities with biofuels. These technical seminars exposed the students to a renewable energy curriculum that provided them with appropriate depth and breadth in the subject. Students demonstrated an appreciation for how and why an advanced degree in an engineering or science discipline is beneficial to further advances in renewable energy. Professional development sessions covered Ethics and the Responsible Conduct of Research; Learning, Teaching, & Working Across Generations; Being a Role Model, Finding a Mentor; Careers in Renewable Energy; and Graduate Schools & Fellowship Opportunities. Student “Snapshots” Sessions allowed participants to informally share their research results in a weekly open-learning environment.

After a mandatory laboratory safety training program, students enjoyed field trips to the National Nanotechnology

Infrastructure Network (NNIN), NREL, and the Renewable Energy Materials Research Science and Engineering Center. Each program included facility tours; lunch with other REU students; workshops on graduate studies, renewable energy careers, and laboratory jobs; networking with scientific leaders; and technical seminars with respective lab directors.

Nine NNIN REU students joined our 20 REU students in an end-of-summer Poster Session held at CSM. About 150 people attended including students, faculty, post-doctoral scholars, research staff, upper-level campus administrators, and NREL scientists. Judges awarded prizes for Best Presentation (acknowledging one student that best communicated the nature, impact, and results of his or her research) and Best Technical Achievement (recognizing one student's remarkable scientific results).

Social activities included an Orientation Day, a trip to the Teva Mountain Games, two barbecue dinners with CSM's Society of Physics Students, a Coors Brewery tour, a tour of a local Catholic shrine, a picnic at a local mountain park, attending a major league baseball game, a tour of "The Sustainable Museum of Sustainable Transportation", and an outdoor concert at Red Rocks Amphitheatre.

IV. 2011 REU Student Achievements

At the end of our program, videos [10-12] of three students' research projects were recorded to provide the general public and prospective applicants insights on our REU. Each video features a different student (KS, AS, DF) describing his or her renewable energy project in the context of one's academic background and summer experience.

In fall 2011, three other students presented their research results at national scientific conferences. One student (JTF) presented his work "Recovery of Iodine from Produced Water Through Anion Resin Exchange" at the Joint Meeting of the National Society of Black Physicists and National Society of Hispanic Physicists held September 21-24, 2011 in Austin, TX. Two other students (JC, SG) presented their results on "The Effect of Environmental Aging on the Mechanical Properties of PMMA Material Used in Concentrating Photovoltaics" and "Characterization of Defect Density of Varying Crystal Volume Fraction in Nanocrystalline Silicon" at the Conference of Research Experiences for Undergraduates Student Scholarship, hosted by the Council on Undergraduate Research, held October 16-17, 2011 in Arlington, VA.

A seventh student (MJ) won the Student Poster Competition at the Front Range High Performance Computing Symposium held September 23-24, 2011 in Golden, CO for his REU research on "High Performance Computing Applications for Material Physics." He also received an all-expenses paid trip to the SuperComputing 11 Conference held November 12-18, 2011 in Seattle, WA.

An eighth student (HH) won third place and \$1000 for her REU research on "Molecular Monolayer Optimization of the Interface in Nanostructured Organic/Inorganic Composites" in the University of Notre Dame's *NDConnect Undergraduate Nanoscience and Nanoengineering Research Competition* on September 30, 2011.

EVALUATION

The following section discusses the role of the Cornell Office for Research on Evaluation (CORE) Evaluation Partnership (EP) program on our renewable energy REU.

V. CORE Systems Evaluation Protocol (SEP)

Throughout 2011, one of the authors (Strong) was trained in the CORE Systems Evaluation Protocol (SEP) [13]. The SEP is intended to serve several purposes: it is first and foremost designed to be a step-by-step guide for evaluation professionals who wish to integrate a systems evaluation perspective into their work with organizations in order to enhance the quality and appropriateness of program evaluations. This Protocol was specifically created in the context of education and outreach programs generally and specifically for programs in Science, Technology, Engineering, and Mathematics (STEM) education and outreach sponsored by NSF and in programs sponsored by Cornell Cooperative Extension [13]. This SEP training and corresponding work effort helped us design a Logic Model [14] (that outlined our program's inputs, activities, outputs, outcomes, context, and assumptions) and a Pathway Model [14] (a graphical representation of the activities and outcomes that make up a program and how they are interrelated), resulting in a comprehensive model of our REU along with an associated evaluation plan. Collectively, these models revealed the important role *community* plays in the overall success of our REU. This evaluation section discusses how we applied the SEP to our REU to develop our Logic and Pathway Models, how we plan to use these elements to evaluate our 2012 REU, and how these results might be extended to other programs.

VI. SEP Phase I (Evaluation Planning)

Thoughtful evaluation plans can help long-term programs efficiently and meaningfully evolve. As an example, directors wishing to sustain or grow their programs must allocate their limited resources to those areas that need improvement or are critical to program outcomes. These areas may be obscured by microscopic and macroscopic struggles within the program, as well as human attachment to the status quo. Secondly, program resources are typically secured through benefactors or funding agencies that need to understand the program and its outcomes. In order to assure these stakeholders of the program's capabilities and vitality, they must clearly understand the program's structure so their involvement is as transparent as possible. While these are compelling reasons for a robust evaluation plan, a lack of resources and trained evaluators often force programs to adopt improvised or rudimentary evaluation schemes.

CORE developed SEP to enhance STEM program evaluation, placing an emphasis on program modeling. SEP includes three broad phases, subdivided into stages [15]:

- Phase I (Evaluation Planning): Stage 1 – Preparation, Stage 2 – Modeling, Stage 3 – Evaluation Plan Creation
- Phase II (Evaluation Implementation): Stage 1 – Implementation Preparation, Stage 2 – Data Collection and Management, Stage 3 – Data Analysis
- Phase III (Evaluation Utilization): Stage 1 – Reflection and Plan Revisions, Stage 2 – Reporting

During 2011, our REU evaluator completed Phase I, Stages 1 and 2, and is now completing Stage 3 in preparation for our 2012 REU program. CORE investigators have not yet finished developing Phases II and III of the Protocol.

VII. SEP Phase I, Stage 1 (Preparation)

The Preparation stage acquaints evaluators with the SEP and the CORE EP arrangement, and helps them identify current evaluation resources. Preparation involves (1) connecting with key program decision makers to discuss the evaluator's expected commitment to the EP and expected deliverables; (2) developing a *Memorandum of Understanding* that describes the roles and responsibilities of participants in the EP and a timeline of project activities and completion; (3) identifying internal stakeholders (program personnel who should be involved in evaluation planning); (4) identifying working group members (program personnel who will play a key role in developing the evaluation plan); and (5) assessing the program's evaluation capacity. Our evaluator completed these Stage 1 activities in early 2011.

VIII. SEP Phase I, Stage 2 (Modeling)

The Modeling stage enhances the evaluator's knowledge of evaluation concepts and provides aids to help identify how one's program "works." This stage requires the evaluator to produce program Logic and Pathway Models that are used to guide Stage 3 (Evaluation Plan Creation). The Modeling stage involves ten steps summarized as (1) performing a **Stakeholder Analysis** to determine the potential people and organizations that may have a stake in the program; (2) an introduction to the **Program Model Development Process** (the core evaluation concepts that will be needed to complete the SEP); (3) a primer on how to perform a **Program Review** to gain a firm understanding of the components and characteristics of one's program, including how it operates and whom it serves; (4) a **Program Boundary Analysis** to determine the conceptual limits of the program; (5) a **Lifecycle Analysis** to determine the maturity of the program and how its level of evolution influences evaluation capacity and method choices; (6) the production of a **Logic Model** (that includes the program's assumptions; context; inputs; activities; outputs; and short-term, medium-term, and long-term outcomes); (7) the generation of a **Pathway Model** that articulates clear and direct linkages between program activities and outcomes; (8) formulating an **Evaluation Scope** that determines the specific components of the Pathway Model that will be the focus of the upcoming evaluation cycle; (9) developing **Program-System Links** which introduce tools and strategies for finding similar programs and shared outcomes; and (10) a **Program Logic Model Synthesis** that finalizes the Logic and Pathway Models and assesses these from the perspectives of key stakeholders while staying within the guidelines established by the Program Boundary and Lifecycle Analyses.

Performing the Stakeholder Analysis is the first step in developing the Logic and Pathway Models. The evaluator identifies all entities having a stake in the program, their associated investment and interconnections, and through them, seeks to define the program. This provides an overarching view

of the program, but not specific elements critical to more heavily vested stakeholders. The evaluator seeks to interview stakeholders that have an understanding of "how the program works" so the evaluator can understand the subordinate parts of the program (for example, how these parts operate and who they serve). Four stakeholders (the REU Director, the REU administrative assistant, an REU senior faculty mentor, and the Chair of CSM's Committee on Diversity) were interviewed and asked the following open-ended questions:

- What does the REU do, and what do you want it to do?
- Where do you see the REU in three years from now?

An analysis of these interviews defined four general themes: (1) deliver a high-quality research experience, (2) devise a generalized REU construct, (3) maximize student diversity, and (4) enhance the local and regional scientific community. The first theme was expected, and though the second theme was not expected, it remains as a long-term goal of both the REU and its evaluation. The third and fourth themes emerged in all four interviews and were, to the evaluator, unexpected. Central to both themes (3) and (4) is the idea of an REU *community*, which struck the evaluator as extremely significant because evaluations from two renewable energy pilot REUs (offered during 2009 and 2010) [16-17] identified a lack of community. Increased focus should be paid to this important program aspect, and at this point, it is likely that this data will broadly and deeply define both the nature of the program evaluation and its elements. Thus, it is important to complete these preliminary Modeling steps by determining the program's conceptual limits.

As an example of Program Boundary Analysis, consider that K-12 STEM outreach seeks to "close the loop" by injecting higher-education system program gains back into the K-12 system. While some stakeholders may identify the effects and outcome such a program has on the parents of K-12 students, the evaluator must consider whether parents are participants of the program and if unique outcomes are connected to specific program activities. Analyzing such matters defines programmatic boundaries and helps to identify the statements and claims central to the evaluation. As a result, Program Boundary Analysis serves to define the program with respect to the evaluation, and does not necessarily include or exclude stakeholder-defined elements. Once stakeholder data is analyzed, the evaluator may step in and define the evaluation boundaries for the program, which makes the accumulated data manageable. Regardless of whether an element falls into or out of these boundaries, it will find a place in the overall program model. In the case of the renewable energy REU, the evaluator chose to create boundaries that would include the student participants but exclude the faculty, staff, and scientific mentors listed in Table V, even though they play important roles in the REU.

With a clear picture of both the overall mission and the internal elements of the REU, the evaluator's next task is to develop the Logic Model that captures these findings. Most program elements fall into four categories: inputs, activities, outputs, and outcomes [short-term (ST), medium-term (MT), and long-term (LT) outcomes]. Elements that do not fall into one of these four categories are listed as program assumptions or context. As the program evolves, topics from these

assumptions and context areas may find their way into program elements, so it is important to include them in the model development process. The Logic Model evolves as the evaluator frames the program and clarifies the evaluation scope. When completed, the Logic Model simply communicates program elements. Figure 1 shows an image from Netway [18], a CORE-developed online tool that helps evaluators build program logic models. The model in Figure 1 includes elements important to the community aspects of the renewable energy REU and constitutes a portion of the larger, overall REU Logic Model. Absent from Figure 1 are the context and assumptions which includes the faculty, staff, and scientific mentors listed in Table V (context), and an organized NSF-funded REU site (assumptions).

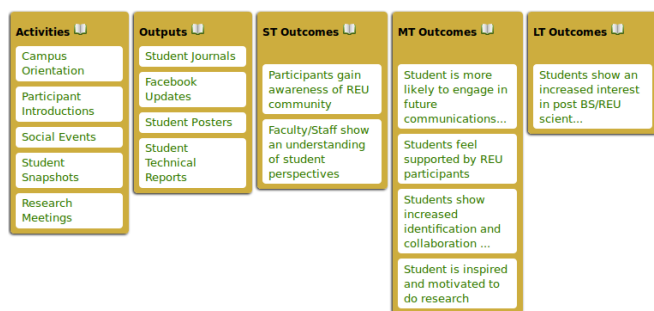

FIGURE 1
LOGIC MODEL FOR 2012 REU PROGRAM

Once the Logic Model is constructed the evaluator seeks to establish interdependencies between the activities and short-term outcomes. From this point, short-term outcomes can be connected to one another and to medium-term outcomes. This continues until specific long-term outcomes are established as terminal outcomes. The principle focus here is on the interconnections between program elements – the evaluator must consider the logical connectedness of the elements and whether an outcome is observable. For instance, broadening the K-12 STEM outreach example previously mentioned, it is expected that higher-education outreach into K-12 education will equip educators with STEM skills. However, no one would believe that a classroom demonstration constructed in higher-education and delivered to K-12 educators and students would manifest a radical improvement in the educators’ STEM skill-set. Instead, it is more likely that several such short-term demonstrations, in conjunction with several medium-term activities, will elicit the desired long-term outcome.

Careful analysis of these interdependencies creates a natural flow within a Logic Model whose graphical representation is called a Pathway Model. The Pathway Model tells the story of how the given program “works,” and it is at this point an evaluator sees the fruits of his or her modeling labor. Figure 2 is the Pathway Model created by Netway [18] that is associated with the Logic Model for the 2012 REU program shown in Figure 1. This Pathway Model describes only a portion of the larger, overall REU Pathway Model. The analysis and description of these larger, overall REU Logic and Pathway Models is beyond the scope of this paper. Suffice it to say that this is yet another point in the SEP where the evaluator

must again scrutinize the program model and separate essential from non-essential elements.

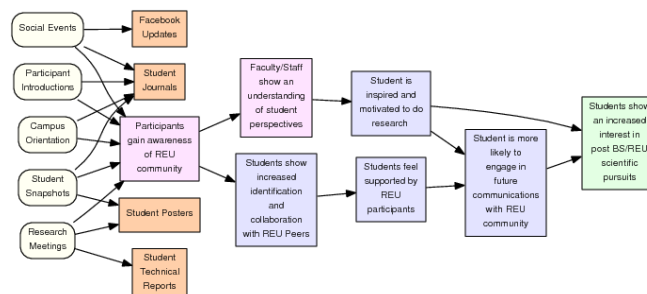

FIGURE 2
PATHWAY MODEL FOR 2012 REU PROGRAM

While the outcomes of the Pathway Model define those quantities an evaluator could measure, it does not say what should be measured. A program’s Lifecycle Analysis informs the decision on what should be measured. For relatively new programs the evaluator should concentrate on developing evaluation questions associated with short-term outcomes, and as the program evolves, so should the evaluation questions. This serves to define the scope of the evaluation and places the evaluator in a prime position to construct an effective evaluation plan.

IX. SEP Phase I, Stage 3 (Evaluation Plan Creation)

The Evaluation Plan Creation stage focuses on the development of an evaluation plan that will guide the implementation of the evaluation. This stage requires the following 9 steps: (1) introducing the concept and components of an Evaluation Plan; (2) developing evaluation questions based on the Logic and Pathway Models, Lifecycle Analysis, Stakeholder Analysis, and program insights (these evaluation questions will function as the core determinants of all the evaluation plan components and enable the evaluator to develop an Evaluation Purpose Statement); (3) developing a Sampling Plan that defines the population of interest, sampling frame and sample, and the sources of the evaluation data; (4) identifying measures already being used in evaluating the program and assess them for quality and feasibility; identify other existing measures that might fit the program evaluation needs; and/or develop any new measures that are needed; (5) developing an Evaluation Design that describes how the samples, interventions, and measures will be coordinated over time; (6) developing an Analysis Plan for analyzing evaluation data and describing how data will be managed; (7) developing an Evaluation Reporting Plan for reporting the results of the evaluation to key stakeholders; (8) developing an Implementation Plan and Schedule for the evaluation and key implementation milestones; and (9) generating a Final Evaluation Plan to share with leaders in the program and other relevant stakeholders.

The CORE EP occurred concurrently with the 2011 REU program. Consequently, much of the evaluation plan described here did not make it into the 2011 evaluation. That said, it was seen in the 2011 evaluation that a wealth of information was contained within the qualitative data associated with bi-weekly student updates. Specifically, students updated their progress to

the evaluator by responding to open-ended questions concerning the status, direction, and impediments of their research. At the same time, quantitative data was acquired via surveys that charted frequency and types of student-student interactions. Journaling exercises provided texture that complemented the previously described data. In summary, it appeared that success in the REU was correlated to overall student engagement. However, since the evaluation had not been focused on this engagement, a clear conclusion could not be drawn.

Our experience with two renewable energy pilot REUs (offered during 2009 and 2010) [16-17] enabled our 2011 NSF-funded REU Site to begin as a generally mature program. However, the evaluation of its community aspects is relatively new, and we can only hope to meaningfully measure short-term outcomes with our Pathway Model. We expect these aspects to be difficult to quantify and are again planning on exploiting the data found in student journaling. Specifically, we seek to address how REU participants characterize their interactions with their research groups and with each other. In order to increase the relevance of the information contained within their journals, we plan to add an additional question specifically asking them about their research group and REU interactions. The evaluator will analyze the qualitative data coming from these journals for themes important to the REU community. Also, the students will be asked to self-report their data in the form of an REU summary sheet, which will outline for each student memorable events and interactions of their REU experience.

SEP applied to our renewable energy REU has led to a detailed model of the program and revealed the importance of community in the developing scientist. If we wish to nurture this in our students, then we must well-understand its mechanisms. To accomplish this, the 2012 implementation of our Evaluation Plan seeks to investigate this from the students' perspectives. Surveys, the backbone of many evaluations, will be used in conjunction with journaling exercises to triangulate quantitative survey data. These journals will be analyzed thematically and also provide the basis of student self-reports. Our hope is that this data will not only inform the 2013 REU Evaluation Plan, but also begin the process of constructing a set of best practices en route to the development of a general REU construct.

SUMMARY

In 2011 Colorado School of Mines hosted 20 students in an NSF-funded REU program in renewable energy. To provide a measure of program evaluation, the REU joined the 2011 cohort of the Cornell Office for Research on Evaluation that trained an evaluator in Phase I (Evaluation Planning) of its Systems Evaluation Protocol. With a clear picture of both the overall mission and the internal elements of our REU, the evaluator developed Logic and Pathway Models that informed the creation of an evaluation plan that will be used in our 2012 REU program. Student success and satisfaction in our 2011 REU were closely linked to overall student engagement and a sense of community within the program's research and social environments. To better understand and nurture this sense of community, our 2012 Evaluation Plan will use journaling

exercises to triangulate quantitative survey data. The Cornell partnership has enhanced the evaluation skills and leadership of our REU Site, and built our capacity for extending our evaluation method to additional on-campus research programs.

ACKNOWLEDGMENT

NSF has generously supported renewable energy education at CSM through its awards NSF DMR-1063150, *REU Site: Research Experiences for Undergraduates in Renewable Energy* [1] and NSF DMR-0820518, *Renewable Energy Materials Research Science and Engineering Center* [6]. In January 2011, our REU Site was selected as one of five to participate in the 2011 cohort of the Cornell Office for Research on Evaluation (CORE) Evaluation Partnership (EP) project supported by NSF DRL-0814364, *A Phase II Trial of the Systems Evaluation Protocol for Assessing and Improving STEM Education Evaluation* [19].

The Effectiveness of Undergraduate Research Programs: A Follow-up Study

Linda S. Hirsch, Angelo Perna, John Carpinelli and Howard Kimmel
New Jersey Institute of Technology, Center for Pre-College Programs
Newark, New Jersey, USA

lhirsch@adm.njit.edu, perna@adm.njit.edu, carpinel@adm.njit.edu, kimmel@adm.njit.edu

Abstract—Graduate work, especially the Ph.D., requires extensive research, a skill not often emphasized in undergraduate programs. Although not much is known about all the factors that influence undergraduate students' decision to pursue or not pursue graduate studies, particularly in science, technology, engineering and mathematics, recent research indicates that many undergraduates feel unprepared for graduate studies and view the research requirement as a deterrent. Opportunities for undergraduates to engage in research have increased recently as a result of federally funded programs including Research Experiences for Undergraduates (REUs), McNair Achievement Programs and Bioengineering and Bioinformatics Summer Institutes (BBSI). Students work in research laboratories during the summer, interact with faculty and graduate students, learning hands-on how to do research. The Attitudes toward Graduate Studies Survey was developed to help evaluate the effectiveness of these programs at New Jersey Institute of Technology. Students who participate in these programs show increases in their attitudes toward graduate studies and have significantly higher attitudes than students who do not participate. Often students indicate confidence in their ability to pursue graduate studies but only a small percentage think that they will have the skills necessary to begin a Ph.D. program when they complete their undergraduate degree. A possible conclusion is that even though students feel confident in their academic abilities they do not feel confident enough about their research skills to complete a Ph.D. program, making research programs such as REU's, BBSI and McNair, necessary. A follow-up study of students who attended these programs at NJIT over the last decade has found that participation in these programs increases attendance in graduate programs.

Index Terms— Attitudes toward Engineering, Attitudes toward Graduate Studies, Research Experiences for Undergraduates (REU), BIOMEMS, McNair.

I. INTRODUCTION

The need for a more highly qualified workforce continues to grow rapidly [1] but the number of students entering college programs in technological fields including science, mathematics and engineering (STEM) has only recently begun to increase [2]. Considerable research has been conducted to develop effective methods of encouraging more students to pursue careers in STEM, particularly engineering [3-7] so this increase has been expected, but there does not appear to be a corresponding increase in students engaging in more advanced, post-graduate studies, especially in engineering.

Research has shown that most students lack basic knowledge about what engineering is what engineers actually do [8]. Research has also shown that many students develop negative attitudes towards engineers and the field of engineering [9-10] and do not see the connections to their science and mathematics lessons. One approach has been to determine how the presence of engineering can be increased in K-12 school curriculum [11] and more recently greater attention has been given to students' attitudes toward STEM and engineering in particular, in an effort to steer more students into undergraduate engineering programs [12-13] and careers in engineering.

The factors that influence students' decisions about whether to attend college, which college to attend and their choice of career paths have also been studied [14-17]. However, far fewer studies have investigated the factors that influence undergraduate students' decisions to pursue or not pursue graduate studies, or their attitudes toward graduate studies, which could be an important factor in undergraduate engineering students' decisions of whether or not to pursue graduate studies [18-20].

Among the many reasons found for why undergraduate students decide not to begin graduate studies are the desire to get some practical experience first and being tired of attending school. Many students also indicate that although they believe the research requirements for a graduate degree would be beneficial in a STEM career, especially engineering, they admit the research requirement necessary to complete a graduate degree, a skill not often emphasized in undergraduate engineering programs, is a deterrent [19-20].

Another troubling fact is that while most students will agree they are confident in their ability to pursue graduate studies only a small percentage think that they will have the skills necessary to begin graduate studies, particularly a Ph.D. program by the time they complete their undergraduate degree [19-20]. One conclusion is that even though students feel confident in their own academic abilities they do not feel confident enough about their research skills.

Research opportunities for undergraduates in the United States have expanded over the past several years with the initiation of federally funded programs such as Research Experiences for Undergraduates (REUs) funded by the National Science Foundation (NSF) [21], the Ronald E. McNair Post-baccalaureate Achievement Program (McNair) funded by the Department of Education [22] and

Bioengineering and Bioinformatics Summer Institutes (BBSI) [23] funded by NSF and National Institutes of Health (NIH). Research programs such as these are intended to prepare students for graduate studies by teaching many of the necessary skills, but primarily research. Students work in research laboratories throughout the summer, interacting with faculty mentors and graduate students, learning hands-on how to do research. Students are required to make a presentation of their experience and participate in conference-style poster sessions. Often these programs extend into the academic year where students attend seminars, receive help in resume writing, interview skills and graduate school applications.

II. ATTITUDES TOWARDS GRADUATE STUDIES

Over the last decade New Jersey Institute of Technology (NJIT) has hosted the McNair program consistently, several different NSF funded REU programs across multiple years and the BBSI program [26] funded by NSF. Although these programs typically include students from other scientific disciplines, a majority of the students who participate in these programs at NJIT are engineering majors. As part of the effort to evaluate the effectiveness of these programs, the Attitudes toward Graduate Studies Survey (AGSS) [19-20, 24] has been developed to measure the impact the research experience has on students' attitudes towards pursuing graduate studies, especially a Ph.D. degree. The AGSS, the psychometric properties of which are published elsewhere [20], uses Likert-type attitudinal scales to measure undergraduate students' attitudes toward graduate studies, their engineering skills self-efficacy, and their level of school-related self-confidence.

Students participating in REUs and the McNair programs at NJIT during the last seven years complete the Attitudes to Graduate Studies at the beginning and end of the program to evaluate the impact of the research experience on their attitudes toward pursuing graduate studies [19]. Students indicate the degree to which they agree or disagree with a total of 30 statements about careers in engineering, the benefits and or disadvantages of graduate studies, their desire to pursue graduate studies and the obstacles students face in pursuing advanced degrees. Agreement is measured on a five-point scale where 1 indicates strong disagreement and 5 indicates strong agreement. For example, one item states "The research requirements necessary to complete a graduate degree are undesirable". Since students typically participate between their junior and senior years students are also asked whether they have applied or intend to apply to graduate school to see if participation in the program influences their immediate plans.

Over the past few years, the survey has also been given to a large heterogeneous sample of other students at NJIT and students in REU programs at other universities in addition to the students in the REU, BBSI and McNair program at NJIT [20, 24]. Overall, less than 25% of all students who responded to the AGSS indicated they were considering advanced graduate studies. Many students expressed financial concerns or a desire to get out into the world and gain experience. Many students felt that they were not adequately prepared to pursue an advanced degree, particularly a PhD. in engineering.

In contrast, the students who participated in one of the summer research programs were found to have significantly more positive attitudes toward graduate studies, appeared more confident in their abilities and indicated they felt more prepared for graduate studies at the end of the program than they did before beginning the program [24, 25].

A. Difference between Male and Female Students

Some interesting significant differences have been found between male and female students, consistently. There are several items on the survey intended to measure gender equity including but not limited to; "To be successful, it is more important for women to attend graduate school than for men", "Women can succeed in a STEM career as easily as men of similar ability" and "Women are more likely to be accepted into competitive graduate programs than men of similar ability".

Female students agree more strongly that women could "succeed in a STEM career" than the male students. And although females students agreed more strongly than the males students that it was "more important for women to attend graduate school than for men", male students more strongly agreed that "Women are more likely to be accepted into competitive graduate programs". From this it is possible to conclude that most female students feel they are equal to male students and are being evaluated equally while male students do not think women are equal even though they feel women are accepted more often into competitive graduate programs.

III. FOLLOW UP

An alumni version of the survey for students who have completed their undergraduate degree has been developed to begin collecting information about what students actually do during the years immediately following graduation, how working or attending graduate school may affect students' attitudes, and how their attitudes toward graduate studies may be different from students who have not yet graduated.

The alumni version of the AGSS has been sent out to students who participated in the REU, BSSI and McNair programs at NJIT and a random sample of alumni who did not participate in any of these programs for comparison purposes. The response rate has been very slow and because students often relocate, large numbers of survey are returned as undeliverable.

Preliminary results from the small number of students who have responded to date indicate that 30% are enrolled in Ph.D. programs most of which are students who participated in one of the research programs but the sample is too small to draw strong conclusions. The authors need to wait for more responses and find other ways of locating the desired students before completing the final analyses including a summary of the attitudinal responses. Perhaps a follow-up reminder letter needs to be sent out to help increase the responses rate.

In an effort to get a more immediate estimate of how many of the students who attended the research programs are currently enrolled in or have completed graduate programs the authors traced the academic status of students who attended an REU, BSSI or McNair programs at NJIT during the period from

1999 through 2010, using the National Student Clearing House. The McNair program began at NJIT during 1999 and has run continually. Seven different REUs, some concurrently, were run during the years from 2006 through 2009 and the BSSI ran from 2003 through 2009. Because students typically attend these types of research programs prior to their senior year most students who attended through 2010 would have completed their undergraduate degree and had an opportunity to apply to or begin a graduate program. Those who attended in 2011 would not be expected to even complete their undergraduate degree until 2012.

Seventy-one undergraduate students attended an REU, 63 attended the BSSI and 121 were enrolled in the McNair program at NJIT during the time period from 1999 to 2010 for a total of 255. There were four students who could not be located through the National Student Clearing House, therefore the summary of students' post undergraduate activity in Table I is for the 251 students that information was available for. Across the three programs the ratio of females to males was 36% to 64% which is higher than the 27% to 73% reflected in the current STEM workforce [1].

TABLE I. SUMMARY OF POST-GRADUATE ACTIVITY

| Program | Withdrew | Currently Enrolled | Completed | Percent |
|----------------|-----------|--------------------|------------|------------|
| None * | | | | 25% |
| Masters | 3% | 5% | 31% | |
| Ph.D. | 6% | 20% | 3% | |
| Medical Degree | - | 4% | 2% | |
| Law Degree | - | <1% | 1% | |
| Total | 9% | 29% | 37% | 25% |

* No post-graduate activity was found

Based on the 251 students identified through the National Student Clearing house, 25% terminated their education with a bachelors degree and 75% began a graduate program, although 9% withdrew after beginning. Therefore, to date 66% of the students who attended one of the summer research programs at NJIT is either currently enrolled or complete a graduate degree; 29% are currently enrolled and 37% have completed their program, a percentage that is much higher than for those students who do not attend such programs [1, 27].

Five of the 31% who completed their Masters degree had begun a Ph.D. program but withdrew with a Masters degree. Another 6% began a Ph.D. program and withdrew with no degree. From this one can conclude that even though only 23% are currently enrolled or have completed a Ph.D. (20% + 3%, see Table I) 34% of the students at least began a Ph.D. A smaller percentage of students who began a Masters Degree program withdrew without completing their degree. A follow-up study to determine why students begin but do not complete their degree could be informative.

All but one of the students who are attending or attended either Law School or Medical school received their bachelors degree in Biomedical engineering the other in Chemical

engineering. The two students who have completed their Law Degree received their Juris Doctor in Patent Law.

Several students complete more than one Masters Degree rather than a Ph.D. One students' second Masters Degree was in Education which is encouraging in that this student probably went into education and might help advance STEM education in this country.

Many of the students who are still currently enrolled in graduate programs did not begin their programs immediately after completing their undergraduate degree but rather 2 or 3 years later. This fact is consistent with the high frequency with which students who responded to the Attitudes to Graduate Study Survey indicated they "thought it was a good to work for a couple of years to gain experience".

IV. DISCUSSION AND CONCLUSIONS

Research into undergraduate students' decisions of whether or not to pursue graduate studies, especially in engineering has found that less than 25% of students consider advanced graduate studies by the end of their junior year [19-20, 24]. Many students express financial concerns or a desire to get out into the world and gain experience, but more often indicate that they do not feel they are adequately prepared to pursue an advanced degree, particularly a PhD.

In contrast, students who participate in a summer research program, such as an REU, the BSSI or McNair appeared more confident in their abilities and felt more prepared for graduate studies at the end of the program than they did before beginning the program [19, 24-25]. Further research is necessary to explore more fully the reasons students do not feel they are prepared for graduate studies or why they withdraw after beginning a program (i.e. are there other reasons besides inadequate research skills?).

Female students in STEM programs appear to see themselves as more capable than the male students perceive them to be. Male students seemed to think it is more important for female students to attend graduate school to be successful and that female students are more likely to be accepted into competitive graduate programs. Future research on engineering students' attitudes to graduate studies should include a more in-depth examination of the differences between male and female students and possible explanations for the differences.

Location of students through the National Student Clearing House has been informative in allowing us to estimate the proportion of students who attended summer research programs at NJIT have either entered or completed graduate programs after completing their undergraduate degree; 64% which is much greater than for students who do not attend such programs. Although tracking these students provides confirmation that there programs are effective in encouraging and preparing students to pursue graduate studies it has also led to more questions, such as why students withdraw after beginning or why they take several years to begin their studies?

The authors intend to step up efforts to reach the students who attended REUs, the BSSI and McNair personally and ask

them to complete the Alumni version of the Attitudes toward Graduate Studies Survey. Perhaps an incentive to answer is necessary. The response rate should also improve since location of students through the clearing house has provided more current contact information for students whose original surveys were returned as undeliverable.

ACKNOWLEDGMENT

The Research Experience for Undergraduate programs and the development of the Attitudes toward Graduate Studies survey have been supported by the National Science Foundation (NSF) under Grant No. 0552483. The BBSI program was supported jointly by NSF and NIH under Grant No. 0234132 and 0609334. Any opinions, findings, and conclusions or recommendations expressed in this paper are those of the authors and do not necessarily reflect the views of the National Science Foundation or the National Institutes of Health.

Abstract—Information technology (IT) forms a crucial foundation for designing, building and managing future sustainable cities. This paper proposes a model to innovate the engineering and computing curriculum to include sustainability and IT topics in order to develop the skills and competencies that future professionals will need to design, build and manage future cities. Rather than developing a new program, we propose a curriculum model – called SustainIT – adapted from the successful 2006 US NAE Gordon Prize engineering curriculum innovation, The Learning Factory – as a possible roadmap to reform and complement existing Bachelors of Science (BS) degrees in engineering. By providing a series of guided electives, any engineering program may offer engineering, and/or computer science students the opportunity to learn about and become specialized in IT for Sustainability. Multidisciplinary topics include traditional ecological engineering; life-cycle design; design and application of resource microgrids; pervasive sensing and data aggregation; knowledge discovery, data mining and visualization; and, policy based control and operation for resource provisioning.

Keywords - curriculum innovation, engineering education, BS, sustainability, information technology (IT), future cities.

I. INTRODUCTION

A. Motivation

Environmental sustainability is top-of-mind for many university faculty and administrators today, as well as for countries, industry and citizens. Growing concern, both in the developed and developing world, regarding the impact of resource consumption challenges stems from various drivers. The world's population is expected to reach 9 billion by 2050 [1]. How do we deal with the increasing strain that the economic growth is placing on our dwindling natural resources? Can we expect to meet the needs of society by solely relying on replicating and extending the existing physical infrastructure to cope with economic and population growth? Indeed, anecdotal evidence of the strain that society is placing on the supply side—the resources used for goods and services—is apparent: rising prices for critical materials, such as copper and steel; the dramatic reduction in petroleum output around the world; and limitations in city scale waste disposal. Increasing costs for basic resources required for population growth and social services will have a negative impact on economic growth in many geographies. Furthermore, externalities such as environmental pollution, natural disasters and military conflicts are increasingly becoming a burden to society. As many of the costs for environmental externalities are being imposed, consumers and producers are being forced to internalize and allocate the environmental costs associated with their consumption and production. We cannot expect to meet the future needs of society

simply by extending existing infrastructures or conducting business as usual with a reactive stance towards environmental concerns. Finally, extensive literature around the world cites the constant need of renovating existing engineering curricula to better respond to stakeholder needs. We still have learning systems that were developed in the 18th century with little change in content and student learning experiences.

B. Urban Transformation and Sustainable Cities

The concept of “cities of the future” sparks the human imagination. From Orbit City and aerocars in the Jetsons cartoons to fantastical real-world constructions in modern Dubai, our vision for urban architecture and infrastructure has driven amazing innovation. But while our imagination is abundant, the earth's energy and physical resources are not. As a result, we may no longer simply ask, “is it faster, more capable, more powerful?” but rather, we must consider the global environmental challenge and ask, “is it part of the problem...or part of the solution?”

Our very definition of breakthrough innovation for future cities must evolve [2]:

- to apply the experiences of our ancestors, who in the days before mechanized mass transportation, built cities that utilized local resources (the supply side) to meet the demands of their inhabitants;
- to gather lessons from ancient cities to assimilate traditional engineering knowledge;
- to apply fundamentals of social and physical sciences; and
- to examine the role of information technology, using ubiquitous connectivity for the collection of data, data mining, and its analysis for effective and efficient decision making.

Planning of future cities will require the integration of the IT ecosystem into the fabric of a city's infrastructure to enable necessary societal and business activities to take place without unduly taxing the supply side and the environment. Consider, for example, the supply side physical infrastructure made up of roads and vehicles. We cannot expect to meet the needs of the society (the demand) by solely relying on extending the physical infrastructure to cope with population growth. Thus, as populations increase and resources dwindle, how will we design and build fully sustainable cities of the future? We must apply tools and methodologies that enable systemic analysis, design, and management based on integrated management of supply and demand [2]. Section II. B discusses a possible framework to address these challenges.

II. ROLE OF IT IN SUSTAINABLE CITIES

According to Infolific (www.infolific.com) information technology in the broadest sense “refers to both the hardware and software that are used to store, retrieve, and manipulate information.” Moreover, we are experiencing a fundamental shift from focus on the “technology” to the “information.” The new value chain in human information spans from sensing – physical, personal, and social – to storage, to analysis, to visualization; to the ability to securely access and share information and insights. We believe that information technology can transform future cities along the following two axes:

- **IT Services:** Driving the next generation of IT services will be the millions of citizens who will avail themselves of IT services to address their fundamental needs and improve their quality of life. We have the opportunity to transform the world by deconstructing conventional supply-chains and replacing them with sustainable IT services. This transformation can be delivered by an ecosystem made up of trillions of sensors, billions of handhelds and printers, millions of systems, thousands of data centers and print factories [18], [19], [20].
- **Management of Resources:** With data centers at the hub, and pervasive connectivity, the IT ecosystem can enable integrated supply-demand management of critical resources such as power, water, waste, etc.

Interestingly, the IT-led transformation noted above can only occur if IT itself is sustainable. As an example, as energy drives the total cost of ownership of a data center, there is a need for a new paradigm in design and management of the data center that minimizes energy used across its lifetime – from “cradle to cradle”. The need for a “least lifetime energy data center” is further compounded as a result of the projected increase in cost of energy [3] and imposition of regulations that address environmental externalities. An architecture for a sustainable data center that delivers on total cost of ownership goals and has the long-term view of addressing the environmental externalities such as carbon dioxide emissions is needed. Indeed, the authors contend [2] that contrary to the oft held view of sustainability as “paying more to be green”, sustainable data centers – built on a framework that focuses on supply and demand management - are the lowest cost data centers.

A. HP Labs Research on Sustainable Data Centers

Recent studies indicate data center and associated facility energy use currently account for approximately 1.3% of global energy consumption. In the US alone, this share of consumption increases to approximately 2% [17]. The massive-scale, intelligent infrastructure required to power modern business can and should be sustainable. A sustainable data center is one in which end-to-end resource consumption, from material extraction and manufacturing, to operation and end of life, is minimized. Since data centers provide useful services, a sustainable data center must also satisfy the performance requirements - known generally as Service Level Agreements (SLAs) - of the hosted services, while reducing the Total Cost of Ownership (TCO) and emissions.

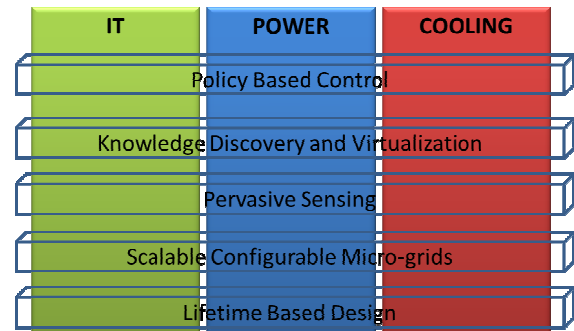

Figure 1. Architecture of Sustainable Data Centers

As shown in **Figure 1**, at HP Labs we have identified five principal areas for integrated design and management to enable a sustainable data center [18]. Each of the five subject areas span the three primary infrastructure components found in data center designs: IT infrastructure (including compute, storage and networking), power delivery infrastructure (including backup power generation and storage, transformers, UPS etc.) and cooling infrastructure which is responsible for removing the heat generated by the IT and Power infrastructures and conditioning the thermal environment for reliable operation. Recently, we’ve shown how this architecture can be used to design and operate data centers using renewable resources in a manner that consumes no net energy from the public utility grid [19],[20]. Such “net-zero energy” data centers represent the future of sustainable computing. Given the diverse expertise required for designing and operating of each infrastructure element in Fig. 1, multi-disciplinary teams are required for research, design and operation of such facilities. In the sections below, we first elaborate on the content of the curriculum (the five principal subject areas), then on the skills engineering students should possess, to finally propose a learning model.

- **Lifetime Based Design.** Existing data center design approaches are focused on assimilation of discrete components into an operational infrastructure that meets runtime objectives, such as performance and cost targets. From a sustainability perspective, however, the environmental impacts are distributed across the lifecycle of the data center – including the extraction of raw materials, manufacturing of the components and building, transportation, operation, and end-of-life. An integrated approach is needed that incorporates Design for Environment (DfE) principles across the lifecycle, while allowing the data center designer to evaluate the necessary runtime objectives. Such an approach requires expertise in subjects like the environmental sciences as well as software development.
- **Scalable, Configurable Resource Micro-grids.** The data center is built with flexible components within each infrastructure that provide the ability to vary resource use dynamically according to demand. Examples include variable speed fans and pumps in the cooling infrastructure, and virtualization in the IT infrastructure. Necessary subject-matter expertise spans mechanical and electrical engineering to computer science.
- **Pervasive Sensing** continuously monitors the entire data center. There are many measures of interest in a data center - measures that are required to gauge and affect demand-side usage.
- **Knowledge Discovery and Visualization.** Knowledge discovery and visualization (or visual analytics) is a family of mathematical tools for detecting, predicting and visualizing

patterns and anomalies, and can provide better insight to the administrators and agents that manage a data center [4],[5]. Subject matter expertise ranges from data mining and analytics, to domain knowledge.

- **Policy-Based Control.** There are some decisions that must be made too frequently or that are too complex for humans to be effective arbiters. A policy-based control system enables real-time control of data center infrastructure components – IT, power and cooling – based on control theoretic techniques. It utilizes each of the previous layers to control and provision resource use across the data center based on sustainable operating policies (like minimization of energy consumption or emissions). Subject matter expertise includes control theory and domain expertise from mechanical and electrical engineering to computer science.

B. Beyond the Sustainable Data Center: Sustainable Cities Enabled by Supply and Demand Management

Just like the sustainable data center, resource management in urban infrastructure relates to holistic management of physical infrastructure at city scale through IT technologies. Unlike industrial age generations, where cities were built predominantly focusing on cost and functionality desired by inhabitants, sustainable cities will require a comprehensive life-cycle view, where systems are designed not just for operation but for optimality across resource extraction, manufacturing and transport, operation, and end-of-life. However, like ancient cities, we suggest a return to traditional engineering knowledge as a foundation of new cities but strengthened with sustainability and IT learning experiences. Indeed, researchers such as S. Ramakrishnan (2001) refer to this as “traditional ecological knowledge” [6] and explore the riches of tribal knowledge in North East India. Examples abound in historical monuments: the Amber Fort in Jaipur, Rajasthan, India, for example, is in an arid region and was built with intricate water harvesting to enable a local micro-grid of water [7].

Our **supply side perspective** calls for using pools of resources of available energy, alongside design and management that minimizes the energy required to extract, manufacture, mitigate waste, transport, operate and reclaim components. This suggests creating numerous “micro-grids” that incorporate various sources of locally-sourced energy, such as solar electricity or wind turbines, that complement centrally-sourced electrical energy. Indeed, seeking available energy in waste streams to augment the distributed energy resources is key to improving efficiency, e.g. using methane from waste water, or methane derived from manure in local farms [8]. These micro-grids need to be scalable and flexible in order to enable a balance in supply and demand.

The **demand side perspective** requires provisioning resources based on the needs of the user by applying sensing, communications, knowledge discovery and policy-based control to the flexible building blocks. Akin to the sustainable data center, the flexible building blocks are micro-grids and other means for generating and distributing resources in the city. An integrated supply-demand system can enable a city to operate and maintain an optimal balance of demand and supply [2].

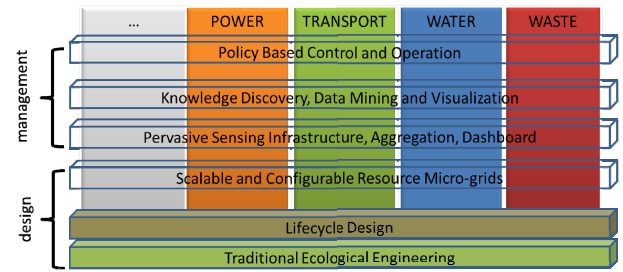

Figure 2. IT-Enabled Architecture for Sustainable Cities

Given this framework, we need a new breed of engineering professionals trained in the engineering fundamentals and the role IT plays in the challenge of building the sustainable cities of the future. In addition, these engineers need to have learning experiences on how work in multidisciplinary teams and are capable of optimizing solutions with input from many perspectives, including those not technically related, like social, historic and economic issues.

III. IT AND SUSTAINABILITY CURRICULUM

A Google search on the keywords “sustainability and IT curriculum” yields over 13,200,000 resultsⁱ covering a wide spectrum of answers covering all levels of education. One can also find extensive dialogue and discussions regarding ‘sustainability across the curriculum’ aiming at integrating the theme/topic into existing curricula [9]. Yet, among the first few dozen results, none address the curriculum needed to develop the engineering/technical professional in which IT and its role in sustainability are part of the learning experience.

Nevertheless, there is a significant amount of activity in curriculum development and innovation around the world to address sustainability issues. We present a detailed review of existing programs in our prior work [10]. Curriculum development was one of the key topics presented and discussed at the inaugural meeting of the European Platform of Universities Engaged in Energy Research, Education and Training (EPUE), held in TU Delft, in the Netherlands in February 2012. Again, none of the presentations included the topic of IT as fundamental for curriculum innovation.ⁱⁱ Yet, of the hundreds of papers presented in this year’s ASEE Annual Conference, there was only one (1) session pertaining to integrating sustainability into the curriculum [11].

Our key findings are that while high-quality sustainability curricula already exist today, the majority are focused on environmental or social issues and are housed in departments such as Environmental Engineering or Urban Planning. Few incorporate coursework related to computing or IT for sustainability.

We believe that IT is among the very basic disciplines required to design, build and manage cities of the future. Moreover, to build, manage and make effective decisions, a unique professional

ⁱ Google search conducted January 19, 2012

ⁱⁱ <http://www.eua.be/events/past/2012/epue-inaugural-event/presentations.aspx>

is needed: one with a blend of knowledge and skills in computer science, mechanical and electrical engineering, economics, social and environmental sciences, and economics, among others.

A. Innovating the Curriculum

The curriculum is one of the many variables that help universities achieve their mission and comprises the set of experiences a student has to go through to acquire knowledge and develop skills, in other words, competencies.

We believe innovating or reforming the curriculum is a more efficient approach to respond to ecosystem needs than developing a new curriculum from scratch. In this paper we propose a very well known, effective and efficient process to be used by engineering and computing educators to undertake curriculum innovation: applying the engineering problem solving approach to innovate the curriculum. We provide a more detailed discussion in our prior work [10],[11], including an overview of the *Learning Factory* curriculum innovation model, co-developed by one of the authors of this paper (Morell), and which won the US National Academy of Engineering Gordon Prize of 2006 [13],[14]. This multidisciplinary curricular innovation was successfully conceptualized, developed and implemented in three major US universities in a record time of 2 years. The program was designed and implemented in response to industry needs for an engineer with focused knowledge of product design and manufacturing. It involved course development, learning/laboratory facilities for student hands-on practice based activities, industry collaboration and outcomes assessment. Since its creation, the Learning Factory model (or some of its components) has been adopted by other disciplines in many institutions around the world.

B. IT and Sustainability Curriculum – The Need

The first step in curriculum innovation is establishing the need. As we described in section II, IT will become a fundamental tool for the efficient management of scarce resources that have an impact on society, such as water, energy, waste management, or transportation. But as we begin to understand the technical requirements of such a holistic solution for the development of sustainable cities, the need for engineers trained in the disciplines required for each of these competencies becomes apparent. The need for multi-disciplinarity and knowledge of disciplines outside the traditional engineering discipline realm also becomes apparent.

In **Figure 2**, we illustrate how the supply- and demand-side framework of design and management principles developed for Sustainable Datacenters may be applied to sustainable cities as horizontal activities that, in turn, can be used to optimize city “vertical” services such as power (energy) or transportation. Each of these **horizontal and vertical activities** will require engineers that are trained in a set of distinct competencies:

- **Policy-Based Control and Operation:** Control theory from a Mechanical and Electrical Engineering point of view; Industrial Engineering to understand operations and optimization at multi-megawatt scales; understanding of electrical power design; and understanding of mechanical design. This implies a “control systems thread” taught by an Electrical Engineering department or Mechanical Engineering department that combines Computer Science, Mechanical Engineering and Industrial Engineering.
- **Knowledge Discovery, Data Mining, Visualization:** Analytics of this form will become the backbone of many solutions in the sustainability age. The learning will be derived from Mathematics (Advanced Statistics); Computer Science with a focus on data mining and visualization for

analytics; and Machine Intelligence. In addition, as many of the devices that will be addressed will be made up of fluid movers, compressors, and so on, knowledge of fluid mechanics and thermodynamics will be important.

- **Pervasive Sensing Infrastructure, Aggregation, Dashboards:** Electrical and Mechanical Engineering principles will be required to understand a variety of methods for sensing and calibration. These will need to be combined with communications to gather data using both wireless and wired networks. Overlapping with Knowledge Discovery, students of this area will specialize in data aggregation leveraging a variety of data mining principles in their “toolkit”. Knowledge of the current generation of software methodologies for creating user interfaces will also be necessary to build usable dashboards for network operations centers.
- **Scalable and Configurable Resource Microgrids:** Fundamental principles of Mechanical Engineering and Electrical Engineering, specifically power systems, will drive this area. In addition, strong knowledge of Thermodynamics, Principles of Electricity and Magnetism will be needed to understand energy conversion. Mechanical and Electrical design principles will be needed to understand how to make power grids flexible. Computer Science and Electrical Engineering principles will be needed to understand the means of communication with the physical grids.
- **Life-cycle Design:** This area will require personnel trained in Engineering Economics, Environmental Economics, Materials Science, and Principles of Mechanical Engineering. All these areas will need help from Computer Science learning to build design tools e.g. software and database solutions.
- **Traditional Ecological Engineering:** This foundational area will require understanding of Social Sciences, Environmental Economics and a new area of traditional knowledge gleaned from textbooks of the past. Understanding of Anthropology, Botanical Sciences and Agriculture will be critical. While not specifically addressing traditional engineering, an understanding of the evolution of environmental policy matters over the years will also be crucial for future professionals.

In addition to this list of knowledge, engineering students will also need to continue to develop professional skills that have been identified by accreditation agencies such as ABET [15] and professional societies. These include skills like working in multidisciplinary teams, ability to communicate effectively, awareness of business and environment needs, agility and flexibility, among others. These skills become ever more important for engineers in the sustainability area.

IV. SUSTAINIT: A PROPOSAL TO INNOVATE THE BACHELOR IN SCIENCE IN ENGINEERING (BS) DEGREE

We propose opening a dialogue among the computing and engineering education community focused on the development of a curriculum for the sustainability age at the BS level. We present the first two phases of the process: needs identification and curriculum design. Implementation and outcomes assessment, important components of the process – would need to be considered at a later stage.

A. The Sustain IT Undergraduate Curriculum

First, at the undergraduate level, the **SustainIT** curriculum relies on engineering fundamentals in the various engineering

disciplines. Degree programs naturally inclined to provide fundamental coursework towards this specialization (with their respective required technical courses), include:

- **Computer Science and Engineering:** Software Development; Programming; Operating Systems; Databases; Systems Architecture; Data Storage; Networking;
- **Electrical and Electronics Engineering:** Power Generation; Grids and Micro-grids; Power Transmission; Failure Analysis; Semi-conductor Physics; Chip and System Packaging; Control Theory;
- **Mechanical and Civil Engineering:** Thermal Sciences; Engineering Design; Solid Mechanics; Structures; Manufacturing; Statics and Dynamics; Quality and Reliability;
- **Environmental Science and Sustainability:** Sustainability Basics; Macroeconomics; Microeconomics; Environmental Accounting; Development Theory; Waste Management; Public Policy and Standards; Introduction to Anthropology;
- **Industrial Engineering:** Supply Chains; Operations management; Engineering Economics; Optimization.

Second, students wishing to earn a specialization in *SustainIT* would then be required to take a series of guided electives offered across the program, as well as complete other requirements described below. Following the components of the Learning Factory, the *SustainIT* curriculum would have the following three features: 1) an IT and Sustainability specialization, track, minor or optionⁱⁱⁱ within existing engineering disciplines (consisting of a series of *Sustain-IT* electives available to all engineering students to be taken across the program); 2) hands-on learning experiences that would include industry-based projects and could entail an internship in industry or a government facility; and, 3) a multidisciplinary capstone design project focused on an IT for Sustainability theme.

In keeping with the IT-enabled architecture for sustainable cities described in **Figure 2**, the following is our recommendation for a series of guided multidisciplinary electives in the *SustainIT* specialization:

1. Fundamental course in IT and Sustainability that would be required for all students wishing to complete the specialization in each of the disciplines.
2. Six directed multidisciplinary electives focused on IT for Sustainability, available to all engineering disciplines:
 - a. Policy-based Control and Operation
 - b. Knowledge Discovery, Data Mining and Visualization
 - c. Pervasive Sensing Infrastructure, Aggregation, Dashboards
 - d. Scalable and Configurable Resource Microgrids
 - e. Life-cycle design
 - f. Traditional Ecological Engineering
3. Other optional electives such as: History of Urban Development, Ecological Engineering, and/or other relevant social science courses in economics, public policy, anthropology, or demographics.

This proposal acknowledges the uniqueness and particularities of each institution. We propose a framework to innovate the engineering and computing curriculum. Each institution or program has the flexibility to develop these (and other courses)

ⁱⁱⁱ Curriculum innovation alternatives are dependent on each university/program's regulations.

that might address the need, and to adapt the ideas presented here to their particular needs and regulations.

For example, engineering disciplines at University X would determine the minimum credits (and number of courses), student experiences, capstone design projects, etc. needed for the minor. The Mechanical Engineering program might suggest the following sequence of courses and experiences to students wishing to earn the *SustainIT* specialization:

1. Fundamental *SustainIT* course (3 credits)
2. Life-cycle design (3 credits)
3. Traditional Ecological Engineering (2 credits)
4. Scalable and Configurable Resource Microgrids (3 credits)
5. *SustainIT* focused Capstone Design Project (3 credits)

Similarly, Computer Science/Engineering might suggest the following sequence:

1. Fundamental *SustainIT* course (3 credits)
2. Policy-based Control and Operation (3 credits)
3. Knowledge Discovery, Data Mining and Visualization (3 credits)
4. Pervasive Sensing Infrastructure, Aggregation, Dashboards (3 credits)
5. *SustainIT* focused Capstone Design Project (3 credits)
6. Industry internship (2 credits)

Figure 3 illustrates the various components of the *SustainIT* curriculum model. As with the Learning Factory model, teaching/learning methods must also be reformed to center on the student's learning and skills development. Hands-on practice-based activities, industry projects, and other activities should be designed and integrated into the learning experience. Finally, and as mentioned earlier, tools and rubrics to assess student learning will also be required to continuously enhance the quality of the program.

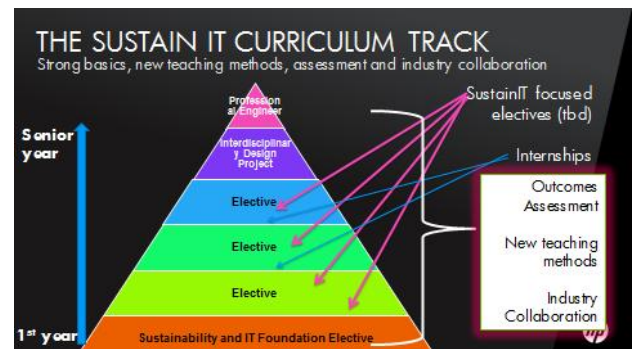

Figure 3: Sustain-IT Curriculum Track

B. Industry-University-Government Partnerships

The *SustainIT* curricula require students to have hands-on, practice-based experiences, as well as participate in real life industry-based projects. These are a crucial component for developing the kind of engineers that future cities will need.

Industry and governments have a vested interest in collaborating with academic institutions in developing these types of curricular innovations. They will need talent to help design, build and manage future cities. Therefore, collaboration among industry, government, and non-profit organizations is at the heart of the proposed model. They can assist professors in defining the desired profile of the graduating student; provide students with real life projects and provide students and faculty with internship

opportunities in real-life engineering settings; and share state-of-the-art technologies being developed in research labs that could influence curricula [16].

V. CONCLUSIONS AND RECOMMENDATIONS

Higher education is responsible for formally preparing the next generation of business leaders, technical professionals, government officials and educators, and plays a central role in our increasingly technology-based societies and in addressing local, regional and global challenges. The education of computing professionals and engineers must prepare them for the multi-disciplinary nature of the problems they will face.

IT is an important foundation to design, build and manage cities of the future. There is a need to initiate a dialogue around the globe to develop the human resources desired to address future requirements in these areas. As a first step in curriculum innovation, the authors have described the needs for curriculum innovation for the sustainability age and propose a roadmap for innovating the engineering and computing curriculum at the Bachelor's level, called *SustainIT*. This paper is intended as a baseline and foundation for dialogue among the engineering education community of stakeholders. We encourage not only dialogue around the creation of a novel curriculum model such as the one we describe here, but also a dialogue around a re-emphasis on fundamental engineering principals that includes hands-on learning experiences and experiments that teach problem solving and design, and that provide a solid basis for multi-disciplinary engineers who can integrate traditional engineering with information technology to address the new sustainability challenges facing our society.

The authors recognize that more in-depth research around the world must still be done on 1) integration with existing sustainability and IT curricula and, 2) current and future employers' needs. In addition, curriculum options in sustainability and IT should be developed at the Philosophy Doctorate (PhD) and Masters (MS) degree levels to complement the Bachelor's (BS) degree proposed herein. The latter will be critical to advancing this burgeoning research innovation agenda.

[†]Corresponding author. Email: reillycf@utpa.edu

Abstract—We examine the impact of using lab exercises based on real–world topics in the CS1 course at the University of Texas – Pan American. In Fall 2010 and Spring 2011 we used drill style exercises. For Fall 2011 and Spring 2012 we created a new set of lab exercises that are based on real-world problems. In this paper we examine impact of the new lab exercises on the number of students who complete the exercises, on the students’ grades on the exams, and on the final course grade. For the new lab exercises, the students are provided with an example program that contains extensive comments describing the skills targeted in that lab. Then they complete a similar program on their own. Whenever possible, we used games for the programs. When we could not devise a game exercise, we used problems that the students are likely to encounter in the real world. Sometimes we reused the same game/problem in multiple exercises. We found that many more students completed the lab exercises and the overall course performance improved when we used the new labs.

I. INTRODUCTION

The University of Texas – Pan American (UTPA) is a Hispanic serving institution located in South Texas. There are over 19,000 students enrolled at UTPA, with 88% of those students being Hispanic, and 68% of the students being first generation college students. The university as a whole is pursuing student retention initiatives in order to increase the percentage of students who graduate in six years, which now stands at 42%.

In 2011 (spring and fall combined) 13 Computer Science and 15 Computer Engineering students graduated from UTPA. Our Engineering Computer Science I (CS1) course, which focuses on introductory programming in C++, is required for both the Computer Science and Computer Engineering majors. Each section of the course usually has between 25 and 35 students enrolled. In the fall semester we usually offer three sections of CS1, and we usually offer two sections in the spring semester. We note the significant difference in the number of students entering the majors with the number graduating. There are non-majors who take CS1, but there are usually only a few per section because we have a separate introduction to programming course for non-majors.

Like many other schools, our introductory computer science courses have a high fail/drop rate and we are actively seeking solutions for this problem. We observed that because the laboratory portion of the course contributes to 30% of the course

grade, those students who were not completing many lab exercises were less likely to succeed in the class. Additionally, the students who do not complete lab exercises do not get the programming practice provided by these exercises and may have poorer performance on the more complex programming assignments and exams.

In this paper we present an initiative to increase participation in the laboratory component of the course by creating lab exercises that focus on topics that we think would engage student interest. We used games for the lab exercises as much as possible, and used other real–world problems for the remaining exercises. Although we focus our study on the CS1 course, we encourage others to study the impact of using real–world topic assignments in other computer science courses, and in engineering courses in general.

This paper is organized as follows. In Section II we describe other research that is related to our work and that provided the inspiration for our study. We then describe the lab exercises we designed in Section III. The comparison of student performance in the course when we used the original labs versus when we used the new labs is presented in Section IV. Finally, we conclude our study and discuss avenues for future work in Section V.

II. RELATED WORK

It has been widely acknowledged that using game-themed assignments in introductory programming classes helps to engage students. When using games in introductory programming classes, students should be learning computer science concepts through the use of games, as opposed to learning how to program games or about game related algorithms [1]. Some of the prior research has examined the use of video-games as CS1 assignments, while others have used board games. The research generally acknowledges that graphical games are better than text-based games in engaging students, but that the graphical games can require significant development time on the instructor’s behalf. A major motivation for using game-themed assignments is that students can easily relate to the topic [2].

Drake and Sung [3] examined the use of board games for programming assignments in CS1 and CS2. They used well known games such as tic-tac-toe, hangman, and backgammon,

TABLE I
COMPONENTS OF CS1 COURSE GRADE

| Component | Weight |
|-------------------------|--------|
| Class Participation | 10% |
| Programming Assignments | 20% |
| Exams | 40% |
| Lab Exercises | 30% |

as well as more obscure games, including European board games that are gaining in popularity in the United States. They provide suggestions for the right type of game to use as a programming assignment. The game should have simple, but not trivial, rules. Games where the boards form complex graphs or that involve many different pieces should be avoided. The game should take five to fifteen minutes to play, and it is best to use games that require two players. Because both players will be sharing the same computer screen, games that require hidden information, such as a hand of cards, should be avoided. All of the games presented in their paper can be implemented using a text-only interface, but the authors acknowledge that students generally prefer a graphical user interface. They provide a Java library that supports both text-based and GUI programs. They utilized the board game assignments in a CS2 course at a small liberal arts college and received many positive comments about these assignments on the student evaluations.

While GUI-based games are thought to be more engaging to students than text-based console games, it is also acknowledged that GUI-based games require extra effort and knowledge from the faculty member. Some libraries have been developed for GUI-based games in Java [3] and in C# [1]. There is an introductory C++ textbook that uses games and graphics [4]. Most of the assignments in this textbook that we could use for our CS1 course are ones where the students write programs that draw rudimentary graphics on the screen and do not involve interactive play.

III. DESCRIPTION OF LAB EXERCISES

The CS1 course at UTPA has a co-requisite lab course. The students attend lab one day per week for two hours and forty minutes. The students' task during the lab class is to complete programming exercises. There are teaching assistants on hand to describe the programming exercises and to assist the students while they work on the exercises.

For grading, we treat the three credit lecture course and one credit lab course as a single four credit course by assigning a student the same grade in both courses. The grade is calculated as a combination of the exams, major programming assignments, class participation, and the labs, as shown in Table I. Because the labs count as 30% of the course grade, they contribute to a major portion of a student's grade.

A. Original Lab Exercises

In Fall 2010 and Spring 2011 we assigned lab exercises that are formatted as drills where the students are given certain skills to practice. The students are given a C++ program to

complete. The program contains a demonstration of the types of skills students will use to complete the lab. For the most part, these lab exercises do not have a specific topic or goal for the program. The purpose of the programs is for the students to practice and demonstrate the specified skills. All of the description and documentation for the lab exercise is contained within the provided code skeleton. Some of the example code in the exercises contains skills that the students have not yet learned. Note that the original lab exercises were not written by the instructor who was using them. The instructor who wrote the labs may have taught topics in a different order, or briefly introduced more advanced topics earlier in the semester.

The students completed a total of 24 lab exercises, usually two per week. We provide some examples of these exercises, chosen for the purpose of comparison between these original and the new lab exercises:

- **Lab 1 (week 1) - Hello World and simple math:** The demonstration code first uses basic console I/O to interact with the user. Then, based on user input regarding the student's projected course grade, it uses if-else statements to print the corresponding letter grade. Note that our students had not yet been exposed to decision making statements. Finally, the lab demonstrates basic addition and then asks the student to write code that performs subtraction, multiplication, and division.
- **Lab 3 (week 2) - Type conversion, named constants:** The demonstration code shows integer division, casting, overflow, and underflow. Then the students are asked to use a named constant to compute the area of a circle with a user supplied radius. The code supplied to the students uses a function to generate a menu where the user chooses which operation they would like to demonstrate, if statements to perform the chosen operation, and uses an infinite for loop to continue the program until the user chooses to quit. At this point in the semester, we had not covered the use of functions, decision making, or looping.
- **Lab 6 (week 3) - if statements:** In this lab, the student is asked to input their score in the course, and the code uses if statements to determine the corresponding letter grade. The lab consists of three steps: using only if statements, using if-else statements, and using nested if-else statements. For each step, the student is provided with example code that determines the score that corresponds with the grades A and B, and the student completes the code for the remaining letter grades.
- **Lab 7 (week 4) - switch statement vs. if-else:** In this lab, the student is provided with code that asks the user to input a letter between a and d, and shows how if-else statements can be used to print a different phrase for each letter that the user could enter. The student is then asked to re-write the code using switch statements with an integer condition that selects what to print. Then they are asked to re-write that switch statement as a series of if-else statements. Note that the example code uses an infinite while loop to keep repeating the user

selection until the user chooses to quit (at which point it executes a break statement). At this point in the semester the students had not yet learned about looping.

- **Lab 14 (week 7) - Functions:** The example code for this lab demonstrates writing and calling both value returning and void functions, with and without parameters. The functions take the sum of two numbers, sometimes obtaining the numbers as parameters and other times retrieving the numbers from user input. The students are then asked to write similar functions that ask the user for their first and last name, then print the name.

B. New Lab Exercises

For Fall 2011 and Spring 2012 we implemented new lab exercises [5] where the students were asked to use particular skills to solve a given problem. Our goal when designing these labs was to make them something that the students could relate to and that they would be more likely to be interested in completing. Whenever possible we used games for the programming exercises. When we were not able to devise a programming exercise using a game, we focused the exercise on a problem that the students are likely to encounter during their daily lives.

The lab exercises are all console-based programs. We chose this format because we are not familiar with graphical programming in C++. We wanted to quickly develop new lab exercises so stayed with the format we are familiar with. As discussed in Section II, it has been shown that using graphical programming assignments engages student interest and we will consider exploring the use of graphical programs in the future.

All of the labs have a similar format. The lab is described on a web page that contains links to example programs and the program skeleton for the lab exercise. First, the students are given an example program to review. The example program demonstrates the skills the students are practicing in this lab and contains extensive comments describing these skills as they are encountered in the example program. Then the students are asked to complete their own program. For most labs, they are given a skeleton of the program with preliminary code and comments that guide them on how to complete the lab. They are also provided with sample output from the correctly completed lab exercise.

The students completed a total of 21 exercises. In the early part of the semester, they completed two or three exercises per week. From the middle of the semester onward, an individual lab exercise was generally more complex than those from earlier in the semester and the students completed one exercise per week. We have chosen a sample of the lab exercises to present in this paper, generally those that provide a good illustration of our design or those that are a good comparison with the original lab exercises.

- **Lab 1 (week 1) - First C++ program:** The purpose of this lab is to teach the students the basic principles of using Visual C++ (the IDE we use) and running a simple “Hello World” type program. The example program is “Hello World”, and the students complete a program

where they print their name. The only C++ skills required for this lab are basic statements and console output.

- **Lab 2 (week 1) - Basic Debugging:** In this lab, the students are provided with a version of the “Hello World” program that will not compile. They must identify and correct the missing quotation marks around the output text and insert a missing semicolon. The description for this lab shows students how to interpret the compile error messages, how to use the compile error message to find where the error is in the program, and to address each compile error one at a time.
- **Lab 3 (week 2) - Basic Math:** This lab adds basic math skills (addition, multiplication, division, and modulus) to the skills covered in previous labs. The example program uses an equation to calculate the “Dateable Age” for the user (the youngest age they “should” date based on the user’s age) using a formula that involves addition and integer division. The instructions point out that dividing two integers results in an integer, which is the correct result in this case. The students then complete a program that calculates a “magic number” using a formula that involves multiplication and modulus.
- **Lab 4 (week 2) - Console I/O and random numbers:** This is the first lab where we found games suitable for the content to be demonstrated. The example program simulates a coin toss by generating a random number between 0 and 1. The student’s program is the beginning of the development of the Pig dice game [6], a game they will continue to develop as the semester progresses. In this lab they ask the user to enter his or her name, roll the die once (generate a random number between 1 and 6), and print the value that was rolled. In this lab the students use a random number generation function that is provided in the lab skeleton code, and use the getline function from the string library. The use of pre-defined functions had also been discussed in class at this point of the semester.
- **Lab 6 (week 3) - if statements:** The example program for the if statements lab simulates a drive-thru restaurant where the customer chooses their menu item by number. Based on the number entered by the customer, the program uses if-else statements to determine the amount to charge for the order. The program that the students complete simulates the Magic 8-Ball toy (a fortune telling toy). The students must generate a random number then use if-else statements to pick the corresponding answer from the Magic 8-Ball. Note that nested if statements are covered in a separate lab.
- **Lab 9 (week 4) - switch structure:** The example program and student program are the same topic as the if statements lab, but now the selections are made using a switch structure. The instructions encourage the students to compare the switch solution with the solution from the if statements lab.
- **Lab 15 (week 7) - Functions:** The example program asks the user to input the price of an item in two consecutive

years and calculates the inflation rate for that item. It uses functions for user input, calculating the inflation rate, and printing a number with two decimal points followed by a percent sign. The students' program continues to develop the game of Pig [6] that we had started in earlier labs. The students are provided with a program that plays the Pig game for a single player. Their task is to create a two-player version of the game. The students must write a value returning function that gets user input (checking for correct input), a value returning function to play a single turn of the game, and a void function to print the output in a specified format. They must also complete the main function by calling the functions that they write.

C. Discussion of Original and New Labs

Both the original and new labs provide demonstration code then ask the students to complete a program. The new labs provide a more complete description of the task at hand, and generally focus solely on a single new skill. Some of the examples in the original labs contain code that the students had not yet learned in class, while the new labs restrict the code in both the example and student's program to code that has been covered in class. One benefit of the original labs is that they are very complete in covering the various skills and often directly identify these skills. The new labs do not cover the skills in such detail, but do discuss the skills that are covered in the comments in the example programs.

IV. COMPARISON OF STUDENT PERFORMANCE

We compared the performance of students in four semesters of CS1 that were taught by the same instructor. In Fall 2010 and Spring 2011, the students completed the original lab exercises. In Fall 2011 and Spring 2012 the students completed the new lab exercises.

A. Lab Completion Rate

The first metric examined was the total percent of labs that were completed in each semester. This number was derived by taking the sum of the number of labs that were completed and dividing that sum by the number of labs that were assigned. As shown in Fig.1, in Fall 2010, 71% of labs were completed, in Spring 2011, 66% of labs were completed, in Fall 2011, 82% of labs were completed, and in Spring 2012, students completed 81% of the labs.

There is a dramatic increase in the number of labs completed when the new lab exercises were used. We take this result as an encouraging sign that students might be more engaged by the new lab exercises and therefore decide to complete more of the exercises. Another possible reason for the increase in lab completion is that the instructor emphasized the impact of the labs on the course grade (labs contribute 30% to the course grade) more in Fall 2011 and Spring 2012 than she did in Fall 2010. However, she did also emphasize the importance of the labs to the students in the Spring 2011 class, which had the lowest lab completion rate.

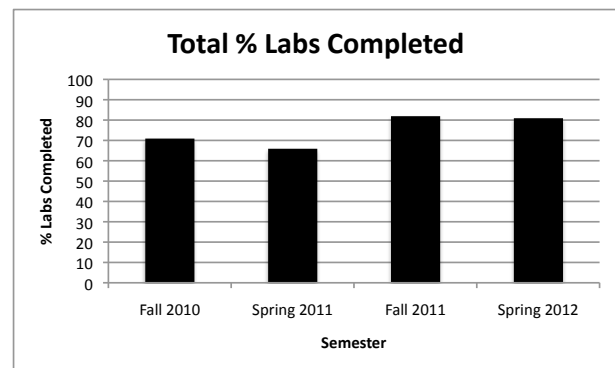

Fig. 1. Lab Completion Rate per Semester

B. Exam Grades

We are also interested in examining if the new labs had any impact on the students' exam grades. It is possible that by completing more of the lab exercises and, therefore, getting more programming practice, the students will perform better on the exams. Fig.2 shows the grades on the three exams for each of the four semesters. Each set of bars in this figure represents the grade on one of the exams for each of the four semesters. The average grades are presented both excluding and including zeros. As is especially evident in Spring 2011, there are students who stop participating in the course and decide to accept a grade of F instead of dropping the course. Because of changes in financial aid rules with regard to failing grades that were implemented in Fall 2011, we expect that fewer students will simply stop participating in the course in future semesters.

For this discussion, we focus on the average of exam grades excluding zeros because the students who received a grade of zero on the exam were most likely also not participating in lab. For all three exams, Fall 2010 has the lowest average (61, 67, and 65 for Exams 1, 2, and 3, respectively). Spring 2011 has the highest average score of 80 for Exam 1, but has the second lowest scores for Exams 2 and 3, of 71 and 75, respectively. The highest grades on Exams 2 and 3 were achieved in Spring 2012, with averages of 79 and 78, respectively. In Spring 2012, the average for Exam 1 was 75. In Fall 2011 had the average score was 77 for all three exams.

With the exception of Exam 1, the students in Spring 2012 performed better on the exams than students in the other three semesters, followed by the students in Fall 2011. This supports our hypothesis that getting more programming practice through completing more lab exercises leads the students to perform better on the exams. However, in the absence of a controlled study we are unable to confirm this hypothesis.

C. Course Grades

Completing more lab exercises has a direct impact on a student's grade in the course because the lab exercises contribute to 30% of the course grade. Most students receive a high grade on each lab exercise, with many receiving grades of 100% on each exercise. Therefore, we expect that by

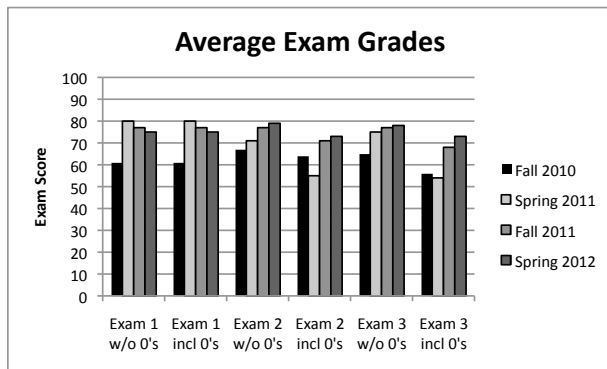

Fig. 2. Average Exam Grade per Semester

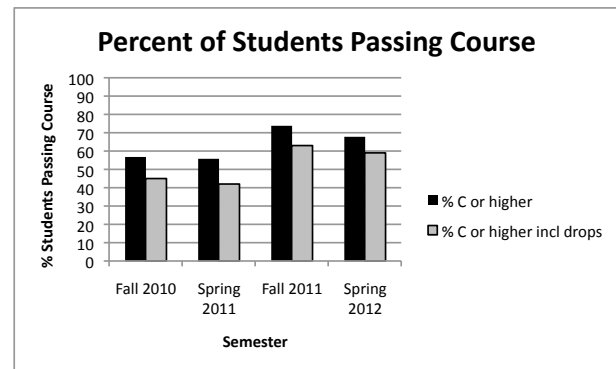

Fig. 4. Pass Rate per Semester

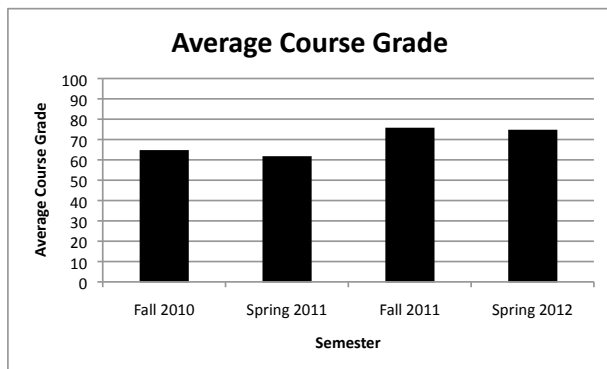

Fig. 3. Average Course Grade per Semester

completing more lab exercises, students will earn a higher grade in the course. This expectation is confirmed by our data, shown in Fig.3. Students in Fall 2011 had the highest average course grade of 76, followed by Spring 2012 with an average of 75. Fall 2010 and Spring 2011 had the lowest course grades of 65 and 62, respectively.

D. Pass Rate

We examined the proportion of students in each semester that passed the course. Students must receive a grade of C or higher in order for CS1 to count in the Computer Science or Computer Engineering curriculum. Fig.4 shows the pass rate of students in each semester, with the left side bar for each semester representing the percent of students who received passing grades at the end of the semester, and the right side bar including those students who dropped the course in the number of students who failed the course.

Our results show that the students in Fall 2011 and Spring 2012, when the new labs were assigned, had a higher pass rate than those in the previous two semesters. By completing more labs the students directly increase their course grade, as discussed above in Section IV-C, leading to more students passing the course when there are more students completing the labs.

V. CONCLUSIONS AND FUTURE WORK

Our conclusion is that the students perform better in the course when they complete the game/real world problem based lab exercises. However, we cannot draw a correlation between implementing the new lab exercises and the students' overall performance in the course. One reason for the higher course grade is that by completing more of the lab exercises, the students are directly increasing their grade. The fact that the students in Fall 2011 and Spring 2012 performed better on all but the first exam may indicate that more programming practice results in better retention of the material. Another factor that may affect the students' performance that the instructor did not have much teaching experience prior to Fall 2010. Despite the fact that we cannot draw a correlation between the new lab exercises and the students' course performance we are encouraged by the increased participation in the lab and by the large increase in the course grades.

As of the time this paper was written, we had not yet received the student comments from the student course evaluations for Fall 2011 or Spring 2012. Therefore we are unable to report on student opinions of the new lab exercises. Other sections of CS1 courses at UTPA, including the version for non-majors, utilized some or all of the new lab exercises. Feedback from the professors who taught these courses was very positive. We will continue to monitor student performance in CS1 when these new labs are used to determine if the improved student performance will be seen in future semesters.

We plan to continue refining the new lab exercises. In the future, we would like to explore the possibility of implementing exercises in C++ that involve a graphical user interface. We would also like to work on replacing the non-game topic exercises with game-based exercises.

Abstract—The application of problem-based learning (PBL) to undergraduate engineering education has emerged as an area of research interest over the past few decades, although it does not appear to be the dominant pedagogy for most engineering programs. A related form of active learning is project-enhanced learning (PEL), specifically designed to enhance but not replace traditional teaching methods in engineering science courses. The perceptions of instructors who attempt PEL were examined using extended-term mixed-method approaches, seeking to examine perceived benefits and barriers to PEL as an intervention for improved student learning. Instructors expressed satisfaction with improved student motivation, interaction, and socialization, which may help with student success and retention in engineering. Instructors also expressed concern about losing focus on the challenging analytical course topics, but were able to achieve appropriate balance by designing project tasks to align well with the topics and limiting non-aligned project activity.

Keywords - problem based learning; project-enhanced learning; engineering science; engineering education

I. INTRODUCTION

This paper represents the initial findings of the NSF-funded study “Implementation, Dissemination, Barrier Identification and Faculty Training for Project-Enhanced Learning in Gateway Engineering Courses” and highlights faculty perceptions of the use of Project-Enhanced Learning (PEL) strategies specifically in sophomore and junior-level engineering science courses. PEL is defined as an integrated project within a traditional lecture-based course that can be implemented in a gradual and transferable way and across multiple sections and instructors [1]. As many undergraduates perform poorly in early engineering science courses that are primarily lecture-based, attention to pedagogical innovation may present an opportunity for increased retention. Additionally, surveys, and classroom assessments indicate that many students completing these courses did not really understand the fundamentals, even if they could apply the ‘formulae’.

The guiding research approach for the project follows the Extended-Term Mixed-Method (ETMM) design [2]. This design includes five inter-related principles: (a) developing a long-term time-line, (b) using theory and data to inform decisions, (c) paying attention to formative and summative components of the study, (d) creating sharply focused causal questions regarding impact of the program, and (e) using a variety of quantitative and qualitative evidence to support claims. Workshop observation, qualitative interviews, and a constant-comparative analysis [3] were utilized in the research design.

The participants in this project have designed and implemented project experiences in three different ‘gateway’ engineering science courses, based on initial experiences in a course on *Thermodynamics*. We refer to the first courses in the engineering major as ‘gateway’ engineering courses, specifically courses in engineering sciences. In Fall 2011, PEL was introduced in two other courses: *Probabilistic Methods In Electrical And Computer Engineering*, and *Dynamics* in the mechanical engineering curriculum [4]. One or two major projects based on authentic systems, objects, or activities are designed and assigned to apply key course topics. The goals include increasing student motivation, provide realistic application of abstract concepts, and long-term learning retention. Teamwork, increased communication with Engineering faculty and professionalism were also emphasized. Significant findings include faculty perceptions of both the value of and barriers to implementing a PEL component in gateway engineering courses and an underlying understanding of the need for increased student engagement in the engineering curriculum.

II. LITERATURE REVIEW:

For most college majors, the first year is the most critical for persistence in college. Tinto [5] observed that almost one-half of students entering two-year colleges and more than one-fourth (28.5%) of students entering four-year collegiate institutions leave at the end of their first year. However, a significant fraction of students who decide at that point to persist in engineering, nonetheless leave engineering in the

middle years of college [6]. Practitioners and scholars seek explanations, whereas college and university administrators desire to manage their student enrollments by reducing such rates of departure. The findings [6] indicate that faculty classroom behaviors in general and active learning in particular (of which PEL may be considered a form) may constitute an empirically reliable source of influence on social integration, subsequent institutional commitment, and departure decisions.

A large body of research affirms that active learning enhances student knowledge and understanding of course content [7-10]. Moreover, students who frequently encounter active learning in their courses *perceive* themselves gaining knowledge and understanding from their course work. As a consequence of this self-efficacy, such students may be more likely to view their collegiate experience as personally rewarding [11]. Students who frequently experience active learning in their classes may also have more time available for participation in collegiate social communities because they feel that they are able to spend less time on course preparation and studying for examinations. Thus, active learning course practices may directly influence social integration and indirectly affect subsequent institutional commitment and student departure decisions. Tinto [5] presents findings on the role of active learning in influencing student persistence/departure decisions.

The research conducted by Southeastern University and College Coalition for Engineering Education (SUCCEED) provide a unique snapshot of engineering education at a transitional moment in its history [12]. The major component of this study is the design and implementation of a faculty development program. The objectives of this program were: (1) to promote faculty adoption of non-traditional instructional methods and materials that have been proven effective by classroom research studies and (2) to improve institutional support for teaching at each of the eight SUCCEED campuses. The study finds that the percentage of responders giving required team assignments vary from a low of 35% at one institution to a high of 72%. Assistant professors are more likely than associate or full professors and female professors are more likely than male professors to use in-class group activities and the internet in their teaching, and the assistant professors and female professors are more likely to believe that teaching is devalued in the faculty reward system. In short, there is general agreement that active learning approaches such as PEL have positive outcomes for students but there is great variance in faculty perceptions of non-traditional instructional strategies and the benefit/rewards for increased faculty implementation.

The application of problem-based learning (PBL) to undergraduate engineering education has emerged as an area of research interest over the past few decades, although it does not appear to be the dominant pedagogy for most engineering programs. Educational studies often use lecture as the default style to compare alternative methods to, such as PBL or active learning [13-15]. An evidence-based comparative study examining the effectiveness of PBL versus lecture-based learning in an introductory engineering course revealed that students retained more knowledge when instructors used a

PBL approach [13]. Research in engineering education has shown that building a sense of community and hands-on learning (which is often seen in PBL) contribute to increased student retention and motivation [16-17]. In many instances PBL is used as a partial strategy or in addition to traditional curriculum in engineering courses [18-21].

Conventional teaching methods for engineering courses are often lecture-based and emphasize deductive learning in the engineering science courses that students encounter early in their major. Projects are typically a component of engineering design courses, which are usually separate from engineering science and are more likely though not all at the upper level. Problem-based learning and project work share some similarities such as being multi-disciplinary, collaborative, and self-directed, but the two approaches differ slightly in their focus and method of implementation [21]. In problem-based learning, students are given a real-life problem to solve as a team and the teacher is seen as a facilitator in the process, rather than a lecturer. The process is self-directed and the students' goal is to refine the problems [22]. Problem-based learning is geared toward acquiring knowledge, whereas project-based learning is directed toward applying knowledge. Project-based learning tends to be more focused on real-world applications and attempts to mimic professional work. Project work tends to take a longer period of time than the tasks in problem-based learning because the projects are more complex and closer to professional reality. Students also tend to produce a concrete product in project work (Table 1).

The suitability of problem-based versus project-based learning for engineering education was compared in [23]. In their review of university engineering programs, they concluded that a mixed-mode approach in which students took more traditionally lecture-based courses covering the fundamentals of engineering combined with project-based components was best for preparing students for the workforce and would be more familiar to instructors than problem-based methods. Perrenet et al. [21] concluded in their review of the literature and in comparing programs that implemented PBL as a partial strategy, that some direct instruction of core concepts is necessary and PBL and project work have some advantageous aspects, such as motivating students as well as being more cognitively engaging than conventional instruction.

The trend of combining or mixing elements of PBL and traditional "topic" focused instruction is also seen with project enhanced learning, as described in [24]. The authors make distinctions between project-enhanced versus project-added implementations. Barroso and Morgan [24] describe project enhanced learning as the implementation of projects in engineering courses that utilize open-ended problems and allow abundant opportunities for students to make decisions in the design and assessment of their work. This is in contrast to a project-added implementation, in which projects are often viewed as an additional lengthy homework assignment and have well-structured problems with clearly defined solutions and outcomes (Table 1).

TABLE I. FOCUS AND COMPONENTS OF SELECTED TEACHING METHODS [24]

| Problem-based learning (PBL) | Project-based learning | Project-enhanced learning (PEL) | Project-added implementation |
|--|--|---|--|
| <ul style="list-style-type: none"> Acquisition of knowledge Students solve real-life problems as a team Teacher is seen as a facilitator in the process Students' goal is to refine the problems | <ul style="list-style-type: none"> Application of knowledge Students create projects with real-world applications Mimics professional work Projects take an extended period of time (up to several months) | <ul style="list-style-type: none"> A project is integrated with a traditional lecture-based course Can be implemented in a gradual and transferable way over time and among multiple sections and instructors | <ul style="list-style-type: none"> Projects are an added course component that can be seen as a larger and more complex homework problem Well-structured problems with clear instructions for completion Well-defined project outcome |

Krishnan and Nalim [1], offer their own unique approach of project-enhanced learning (PEL), which integrates a major project with a traditional lecture series. In their conceptualization of PEL, core topics are introduced early in a course in relation to a project so that students anticipate what they will learn in lecture. This model is designed for implementation at the early stages of an engineering student's coursework, such as the sophomore year when students take many gateway courses, rather than waiting until content is mastered to begin project work. PEL introduces core concepts early in an engineering program with the integration of a term-long project, and the learning is thought to be transferred over time with this method. The current study adopts this interpretation, contrasting PEL with the more student-created project-based learning, but not making it sharply distinct from project-added implementation. The accommodation of PEL within a traditional lecture-based setting is deliberately intended to ease this intervention into courses where traditional methods are most entrenched. Some benefits of this model have been identified, such as increasing the motivation of students, but more research is needed on PEL. Krishnan and Nalim recommend future studies looking at the longitudinal impact of PEL on student retention in engineering programs, student performance, and students' professional outcomes.

III. RESEARCH DESIGN

The research project follows a formative case study design to explore the implementation of PEL in gateway engineering courses. The research team has been conducting the evaluation, consisting of process observations, qualitative data collection, and a satisfaction survey. The evaluation results, considered existing data that the research team then used to inform the ongoing design of the proposed research project.

One group of participants in the case study includes instructors who teach gateway engineering courses at Indiana University – Purdue University Indianapolis (IUPUI), University of Illinois Chicago (UIC), and Virginia Commonwealth University (VCU). The participants all agreed to attempt PEL, and some had begun implementation of PEL in their courses. The current study does not include instructors

who declined to attempt PEL. The team conducted interviews focused on instructional planning and reflections on PEL as a pedagogical strategy. In addition, instructors were recruited to participate in a series of professional development activities and focus group discussions occurring at various points throughout the ongoing project.

All individual participants were contacted initially by a member of the research team via email or a phone call, and face-to-face during the interview phase. Consent statements were collected for participation in the research and evaluation following all appropriate requirements of Human Subjects Research via Indiana University.

A. Research Team

The research team, led by Robert Helfenbein, professor in the School of Education at Indiana University - Indianapolis, includes two graduate assistants from the Center for Urban & Multicultural Education (CUME) involved in literature review, data collection, and preliminary data analysis. The guiding approach for the processes and products of the project follows the Extended-Term Mixed-Method (ETMM) design [2]. This design includes five inter-related principles: (a) developing a long-term time-line, (b) using theory and data to inform decisions, (c) paying attention to formative and summative components of the study, (d) creating sharply focused causal questions regarding impact of the program, and (e) using a variety of quantitative and qualitative evidence to support claims.

B. Research Questions

1. How are instructors implementing (or not) PEL in their classrooms?
2. How does the implementation of PEL in gateway engineering classrooms follow "best practice" as identified by the research?
3. How supported (by all stakeholders) do instructors feel during the PEL implementation process?
4. What are the challenges to implementing PEL in engineering classrooms?

C. Methods and Instruments

1) *Observations.* Using qualitative inquiry and ethnographic methods [25-26], team members have conducted a series of observations of PEL instruction, professional development, and coaching. An ethnographic approach is appropriate for building a detailed account of how the implementation process unfolds within the context of a classroom and school, and illuminate some of the strengths and challenges of individual instructors as they move through the implementation process.

2) *Focus group discussions.* Team members conducted focus group discussions with the gateway engineering faculty. These were used to check the data collected through the surveys. Sample focus group probes are: "What kinds of support have you been given during the implementation process?"; "How have colleagues helped or hindered your

implementation of PEL?” and “How has PEL affected student learning?”

3) *Interviews.* Team members have interviewed faculty members (n=5) about support structures within the School of Engineering & Technology and about their perceptions of how the implementation process is going overall. Sample interview probes are: “What kinds of support have been provided during the implementation process?”; “How have students responded to PEL?”; and “How has PEL affected student learning?”

4) *Document review.* The research team is collecting lesson and unit plans including entry documents and other PEL-related planning materials, assessment rubrics, samples of student work, and teacher reflections in order to understand PEL implementation processes and evaluate the objectives. These data were analyzed using content analysis [27].

5) *Survey.* Implementation surveys were disseminated to all participants at the end of the relevant semester. These asked participants a series of questions about their implementation of PEL in their classrooms as well as some of the challenges they have experienced in implementation. Results were compared to the existing data from the PEL evaluation to see how and in what ways teachers have followed through with their plans to implement PEL in their classrooms.

D. Qualitative Analysis

The constant-comparative method [28] was employed to allow researchers to use the initial results of one method to extend or clarify the results from another method. As data sets from each of the various sources are obtained, they were initially coded to determine common patterns within the data and develop overarching themes. Throughout subsequent data collection activities, researchers built upon existing data to inform the collection process. Additionally, data previously collected and analyzed was shared with stakeholders including participants for member checking in order to solicit feedback on analyses to date.

IV. FINDINGS

A. How are instructors implementing (or not) PEL in their classrooms?

Implementation of PEL and other active learning strategies varies among the engineering faculty participating in this study. Differences in approach relate to the educational experiences of the faculty themselves as frequent responses related their teaching approach to the ways in which they experienced engineering education at various points in their career. Typically, the PEL projects followed the model suggested by [1] and included a semester-long supplemental assignment that attempted to provide an authentic application of course concepts.

Faculty report that “best practices” of implementing PEL projects include providing time for project development, advance notice for students to ensure clear expectations, and

projects that are designed to be semester long to include a variety of course concepts. One faculty member suggests that it is best to assign the project early in the semester “so that they can get thinking on a concrete example[s].” This additional time allows groups to review the project concept several times as a group and turn to instructors throughout the semester for clarity. Due to the weight and length of the project groups are often strategically composed to provide an intellectual balance in the hopes of peer-to-peer instruction and added camaraderie. However one instructor commented that his approach to assigning teams varies. Commenting on issues that face PEL he states: “some of the issues of course have to do whenever you have a team project as to how you form the teams and whether a student likes their partner...I let them choose their own partner, but [I] put some constraints on that because I wanted to make sure that the teams would not [be] very unbalanced in the [intellectual] composition...”

B. How does the implementation of PEL in gateway engineering classrooms follow “best practice” as identified by the research?

Faculty who attempted PEL perceives significant benefit to implementing PEL in engineering education and cites increased student motivation as the most significant outcome. One participant noted the dual nature of benefit to students “the benefit is that students will have an immediate application of the theory that they are learning-something that is quantifiable [and] something that is physical and that they can relate to.” Succinctly put, one faculty member states that PEL provides “an immediate application of the theory that they are learning.”

Interestingly, faculty reported that increased contact between instructor and student as an unanticipated positive outcome as an increased number of students attended office hours and engaged faculty outside of class. One subject recalled that time spent processing the project prompted students to “come and discuss the project with me when they’re having difficulties [or] when they have questions and I have office hours outside the classroom, but I always make sure that if they [can’t] come at that time that I was available to discuss any questions they had on the project.” Faculty reported that these interactions expanded beyond the assignment and provided an opportunity for professional mentoring and socialization to the life of an engineer. This increased sense of community follows the research that suggests a positive relationship with retention and degree completion efforts.

C. How supported (by all stakeholders) do instructors feel during the PEL implementation process?

Faculty report that the support for active learning approaches including PEL is beginning at IUPUI. The time provided through the NSF grant to work together on the generation of projects and sharing of tips and techniques is seen as beneficial for faculty to adopt these practices. It would seem that creating further opportunities for faculty to collaborate would have positive impact on the level of implementation and the possibility of compiling a collection of projects across curricula could be advantageous.

D. What are the challenges to implementing PEL in engineering classrooms?

Faculty had strong feelings regarding the barriers to implementing PEL and other active learning strategies in engineering instruction. While it is clear there is an intention on the part of engineering instructors to use PEL to advance the curriculum, there is significant concern that its adoption not be used to the detriment of the content instruction or student growth. PEL, as one instructor states, can be used to fool students into thinking that engineering is "fun" or likened to a science fair that ultimately waters down foundational concepts. Conversely, one participant noted that "the project should not be burdened with a lot of additional busy work that might actually be realistic in terms of what an engineer has to do in a real project, but is not helpful in the learning process." Here the point is made that there needs to be a balance between the authentic tasks of engineers and the larger conceptual goals of the course. Faculty members see the projects as helping students bridge concepts built around mathematical equations to real life applications in the field. It was also suggested that projects can also be used after the course as a way to enhance a student's resume or demonstrate knowledge during job interviews.

Obstacles to implementation can include an instructors level of comfort with the project's purpose in the course (i.e. they will not have a project just to have a project or for the sake of saying they are practicing PEL) and the time required for faculty to create and assess projects in a research-intensive university. Faculty reported some concern with the level of student comfort or prior experience with PEL or active learning approaches as it is possible that some students prefer a more traditional instructional approach. As some courses are shared enrollment with other subfields in science education (i.e. students from various fields outside of engineering), one instructor reported sacrificing or adjusting a project in order to meet the needs of class as a whole, rather than just a portion.

Although instructors who declined to attempt PEL were not interviewed formally, some reasons given for declining are noted: (a) The class size is too large, and the burden of grading a large number of projects is unacceptable; (b) The effort to create a meaningful project is beyond what a tenure-track instructor can accomplish, given pressing research goals; and (c) The best way for students to learn difficult engineering science fundamentals is to work hard on more homework problems. There also appear to be interesting differences between the concerns of experienced, perhaps more conservative, instructors, and younger, novice faculty members. We may generalize from these observations that an incremental approach to introduce PEL that also anticipates these perceived barriers may in the long term lead to more successful transformation of the student's learning success in gateway courses in the engineering curriculum.

V. CONCLUDING THOUGHTS

An on-going study of faculty perceptions of project-enhanced learning in early engineering education is reported in this paper. There are well-researched and demonstrated benefits of active learning strategies in engineering education,

including the use of projects. PEL is a carefully calibrated approach to active learning using projects that seeks to retain and enhance traditional lecture-based instruction.

Instructors who agreed to attempt PEL expressed satisfaction with student learning outcomes, despite reservations about workload and potential dilution of academic rigor. They were particularly impressed with increased student motivation and with the immediacy of application provided by the project, as well as the socialization of students into the community and culture of engineering. They also noted the increased interaction of students with each other and with instructors.

Instructors expressed concern about misleading students about the challenges and rigor of engineering education by focusing on the project perhaps at the expense of more analytical tasks essential to the course topics. They achieved a balance between project benefits and course goals by designing project tasks to closely align with specific learning outcomes of the course, and whittling down less relevant activity.

Support from an NSF grant allowed instructors some time for creation of projects and preparation for teaching. For some instructors, PEL materials were already available and had been used in their course previously. Using ETMM to study PEL perceptions, utilizing multiple scholarly sources and research approaches over a long-term time-line, allowed the research team to delve deeply into multiple facets of PEL. Insight provided in this research embarks on a discovery on not only how pedagogical practices in engineering influences student learning, but how administering it impacts the professoriate. This study does not investigate whether instructors would attempt PEL without such assistance. This study has also not examined the thinking of instructors who either ignored the PEL activity or specifically declined to attempt PEL. These questions would be fruitful areas for future research.

This paper points to several conclusions about PEL and faculty implementation. As an active learning approach, PEL provides increased opportunity for faculty/student interaction and enhances traditional lecture-based instruction with authentic application of engineering concepts. Faculty report positive increases in student motivation, socialization to the field, and learning outcomes as a result of implementation. Faculty satisfaction was a direct result from intentional project design that incorporated specific learning outcomes within courses and minimized "busy work." While the need for more research is clear, this project suggests that the positive impacts of PEL may go well beyond course enrollment numbers by increasing engineering faculty and student satisfaction and broadening instruction experiences in engaging ways.

Unveiling Fieldbus Network Technology through Project-based Learning

Samuel E. de Lucena and Omar Mogames

Department of Electrical Engineering
Unesp – São Paulo State University
Guaratinguetá, Brazil
{sdelucena; omarmog}@gmail.com

Abstract—Fieldbus communications networks are a fundamental part of modern industrial automation technique. This paperwork presents an application of project-based learning (PBL) paradigm to help electrical engineering students grasp the major concepts of fieldbus networks, while attending a one-term long, elective microcontroller course.

Keywords - Hands-on education; projec-based learning; automation; networks; fieldbuses; microcontrollers.

I. INTRODUCTION

Modern industrial automation systems rely heavily on field control systems (FCS), such as temperatures controllers, pressure controllers, and level controllers, to name but a few systems, that are distributed over the plant area and interact and communicate with each other by means of industrial communications protocols [1]. FCS evolved from discrete control systems (DCS) over the last decade to bring the control of the process the nearest possible to the locus of sensors and actuators, thus reducing wiring, easing troubleshooting and lowering maintenance cost of the industrial control network [2].

Controllers, sensors and actuators are networked on the factory floor by means of a fieldbus, which is a local area network (LAN) featuring digital, serial, bidirectional and multidrop communications technology. Despite the enormous importance of fieldbus communications networks, researchers

have shown that there is still a great need to integrate fieldbus topic with hands-on experiments into undergraduate engineering and technology curriculum [3].

Whilst engineering education research has shown that traditional lecturing is far from being an efficient instructional pedagogy [4], project-based learning (PBL) has proved a powerful learning strategy, capable of engaging students and fostering their learning enthusiasm [5].

This paper presents the design, development and test of a fieldbus communications network by senior year students of electrical engineering of our university. PBL was chosen as the learning paradigm.

II. PROPOSED APPROACH

A. Project Specifications

Fig. 1 shows the general block diagram for three controllers assigned to the students for networking. The controllers are based on an 8-bit microcontroller manufactured by Microchip Inc. (PIC18F4550). As Fig.1 makes it clear, though the controllers feature basically the same hardware, each unit has received a special function, namely: controller 1 incorporates a real-time clock (RTC); controller two encompasses a temperature sensor; and controller three includes a 110-V ac motor and its relay-based driving circuit.

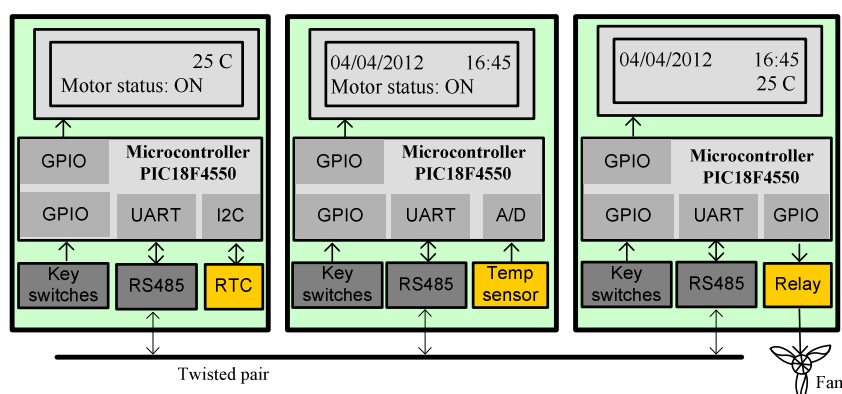

Figure 1. Three controllers networked by students.

This work was supported in part by Capes and Fundunesp (Brazil).

At our campus, microcontrollers is a 45-hour long elective course offered to the senior-year students of electrical engineering. A 150-hour long microprocessors systems course is the prerequisite. This is a comprehensive course on the design of microprocessor-based systems and their programming in assembly language. Theoretical and practical topics include CPU interfacing with ROM and RAM memories, memory map and address decoding techniques and circuits, interfacing of digital and analog input and output ports, synchronization techniques (polled i/o and interrupt driven techniques), and serial communication techniques (UART). Additionally, students have taken a 150-hour long course on C language during their freshman year. At the edition this project refers to, a group of 10 students enrolled in this discipline. The lecturer used the first two weeks to swiftly introduce students to the microcontrollers' world, in especial to the brand they were about to begin working with and to a corresponding professional integrated development environment (IDE). Eventually, the lecturer addressed more topics as students demanded or needed. Students were grouped into three different teams. Each team developed the needed programs for the specific controller, while all groups collaborated to develop the fieldbus (LAN) protocol. All programs were developed in C language. The students were assigned as major task networking the three node controllers so that every individual node controller could obtain information from any of the other controllers on the bus at any time and under request. Therefore, daytime, room temperature and the motor status (turned-on or turned-off) are available to all controllers at any time. Moreover, simple messages can be edited in any controller and sent to any other on the bus. In this case, the targeted controller must display on the LCD the received message.

B. Network Topology

Fig. 2 shows six types of network topologies that are commonly used in industrial data communications systems [6]. There are advantages and disadvantages to each type of topology. The bus topology is one of the most common on industry floor due to its simplicity and the fact that a failure of any node (controller) to operate should not prevent other nodes (controllers) from communicating, a feature that is crucial to industrial automation. As can be seen in Fig. 1, the controllers of this project were connected to form a bus.

C. International Standard Organization's Open System Interconnect (ISO's OSI) Reference Model

ISO's OSI is perhaps the most robust and generic standard and model that has been proposed for data networking. And though OSI is a seven-layer reference model for computer networking, it is applicable to any type of network wherein the processing elements communicate over a common path. Most fieldbus networks specify only the first three or four initial layers, which are the most basic ones [6], [7]. As illustrated in Fig. 3, in this project, only the first three layers have been implemented.

- Unshielded twisted pair (UTP) and ubiquitous RS485 were used to implement the physical layer of the network. The RS485 transceivers (DS75176B) enable

up to 32 devices to communicate over UTP whereas controllers may spread over a distance of up to 1200 m. This formidable performance is a result of the high noise immunity of the differential voltage signaling provided by RS485 transceivers.

- Universal asynchronous receiver/transmitter (UART) has been adopted to implement the data link layer. Fig. 4 depicts the serialization of one data byte by the UART. Every data byte is preceded by a start bit and followed by a stop bit. A bit rate of 9600 bits per second (bps) has been selected. Parity bit has not been used.

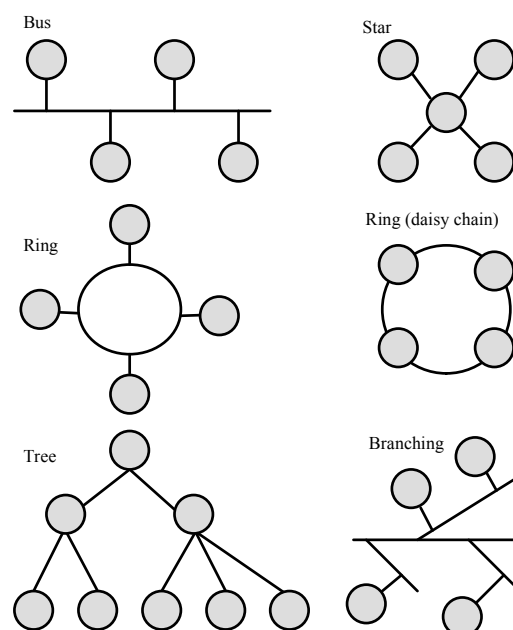

Figure 2. Network topologies.

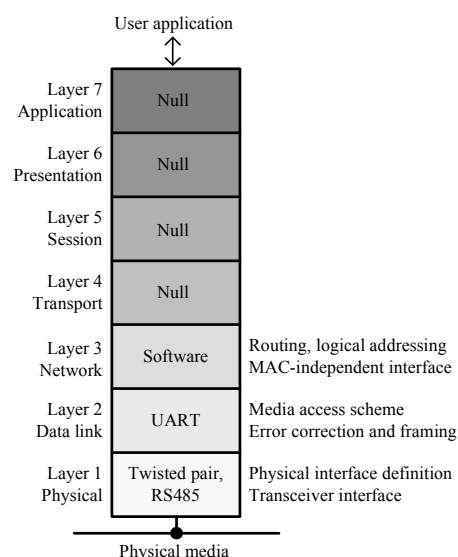

Figure 3. The OSI seven-layer reference model as used in this project.

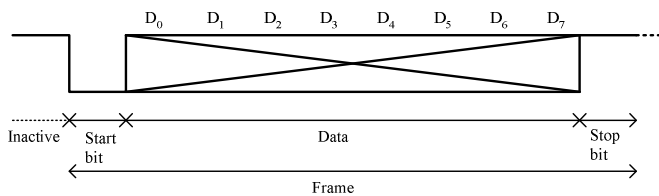

Figure 4. Data frame standard used by UART.

- The network layer has been implemented in software. The LAN protocol includes a medium access control (MAC) which uses the “listen before transmit” principle to access the medium, detect and avoid collisions. LAN frame structure employed (Fig. 5) resembles that of Ethernet and contains several fields as preamble, destination address, source address, message type, data length, payload (application data), and a frame check sequence. This last field allows for error detection and correction.

III. RESULTS AND DISCUSSION

The two upmost pictures of Fig. 6 offer a view of the three implemented controllers and a close-up of the third controller and its fan load, respectively. Though much of the hardware was designed and mounted by the professor (one of the authors) who was in charge of the course, students had the opportunity to deal with (and explore) the controllers’ hardware during the whole semester. They used oscilloscopes to measure signals and to make sure that the hardware was operating appropriately. Then they dedicated their course time to write and test software to the controllers. Weekly, the teams discussed their progresses and drawbacks and planned common actions. Needless to say, they shared all conquests that could interest any specific team.

Student teams were provided with a couple of basic functions to deal with the LCD and key-switches. The functions to work with the RTC were handed only to the team who needed it. One of the authors had developed these functions earlier. This “helping hand” aimed at getting the teams tackling the main problem as soon as possible. In other words, they had to discuss, plan, write and test software to put the controllers up and running on the bus. This is far from being a trivial task and many work hours were spent before the controllers could change the first messages through the bus. It is noteworthy that a seemingly humble twisted pair cable problem fooled the teams with an intermittent flaw that lasted for weeks. Owing to the nature of mixed hardware and software-made functions, it is quite challenging to pin point fast the problem source and nature in an intermittent malfunctioning system. This, however, may turn out to be an extraordinary opportunity to educate future engineers on the challenges they will face during their careers while dealing with real-world application. As a matter of fact, this kind of environment is what makes PBL so powerful an instructional methodology.

The three lower picture of Fig. 6 are snapshots of the three controllers’ LCDs. Controller 1’s LCD is showing the room temperature which was measured by controller 2 and sent to

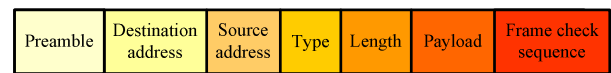

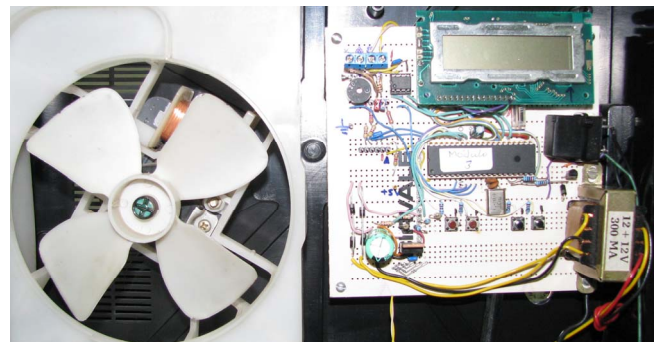

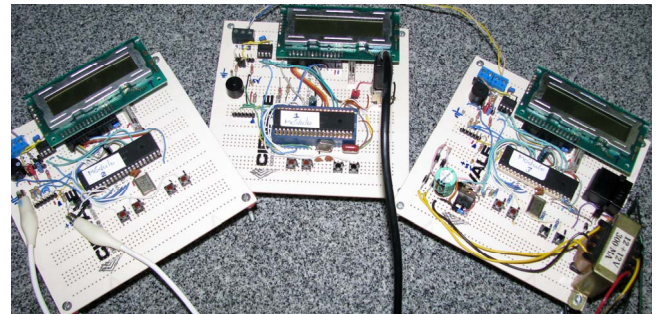

Figure 5. Frame format used by the network layer.

Controller 3
(Motor)

Figure 6. From top to bottom: picture of the three controllers used by student teams; a close-up of controller 3 and its fan; LCDs’ screens of the three controllers at a given time.

controller 1 over the fieldbus upon request from the latter. Additionally, controller 1’s LCD shows the motor status (on, at the time of the snapshot) which is ultimately governed by controller 3. This information was transmitted by controller 3 to controller 1 over the fieldbus, following a request for this information from controller 1 to controller 3. Likewise, controller 2’s LCD presents a message sent to it by controller 3. Finally, controller 3’s LCD is populated with the message it sent to controller 2 and with date and time information the former received via the fieldbus from controller 1.

This is to illustrate that controllers networked via a fieldbus can exchange information easily and conveniently. For instance, controller 3 can turn the motor on or off, based on

temperature information that it gathers via the fieldbus. The temperature sensor and the corresponding controller may be located in far apart plant locations.

Shown in Fig. 7 is a collection of oscilloscope records for the differential signal on the fieldbus network as registered at different points and during active and inactive bus state. Two oscilloscope channels have been employed, for the bus uses a differential signal. The bottom signal was recorded when no information was propagating over the bus. This is easily noticed by the absence of relative inversion between the two signals. Signal wanders owing to bus wire fluctuations, i.e., all controllers are in the “hearing” mode and this effectively fluctuates the bus until a transmitter puts some information on it. The second oscilloscope screen shows a beautiful differential signal captured on the bus at a point near a transmitting controller. The not-so-beautiful signal of the third record illustrates how the signal is degraded as it propagates over the bus, as the record was taken at a point away from the transmitting controller. Nevertheless, from a differential receiver viewpoint, this is a very good signal, given that the signal-to-noise ratio is very high. In other words, subtracting one signal (channel 1) from the other signal (channel 2) would surely result in a quite clean single-ended signal. The top screen is just to illustrate the fast settling of the differential signal on the bus, as can be noted by the horizontal settings of the oscilloscope.

Not surprisingly, students were observed to feel significantly more enthusiastic about the course than those who took the same course the year before but under traditional lecturing scheme. Likewise, professor dedication to students was quite bigger as was the students’ dedication to the project.

Weak points noticed include asymmetries in task planning and execution inside teams. It was crystal clear that in each group a leading student assumed the team’s task as his (her) sole task. Maybe this stems from the fact that almost all students were quite involved in their internships in industrial plants and with an eye in their first jobs as engineers (of course, in occupations not related directly to either microcontroller applications or industrial networks area). Assessing students in PBL-based courses in quite challenging, given that team work and peer-to-peer instruction are pillars of this strategy that would be broken if projects were assigned to students individually. Moreover, this could be impractical whenever a great number of students got enrolled (not the case in this course edition).

IV. CONCLUSION

Traditional lecturing fails to motivate engineering students. The result is that retention and engagement of students are jeopardized. The lack of engagement leads to graduates with “less-than-expected” understanding of engineering basics. This, in turn, can compromise career and hiring, on the individual side, and innovation rate and industrial competitiveness, on the social side. The solution to this crucial problem is neither easy nor cheap. Research on engineering education (and on learning overall) over the last four decades has led to a much better understanding of learning mechanisms. This has open a door leading to different teaching strategies

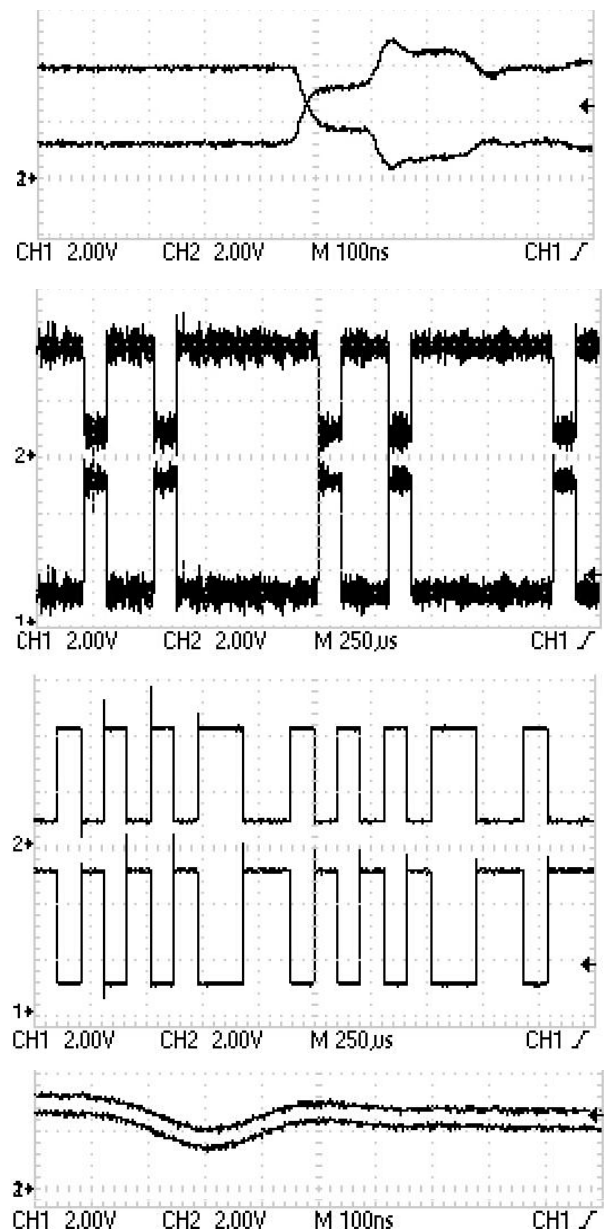

Figure 7. A and B (differential) signals recorded on the bus, from bottom to top: when no transmission is occurring through the bus; near an active transmitter; near a receiver; fast trace near an active transmitter.

that have been shown far superior to traditional teaching methods. The different approaches of “active learning” (e. g., problem-based learning, project-based learning, service learning, scaffolding, peer-to-peer mentoring, hands-on training, etc), as opposed to traditional lecture-based “passive learning”, put the focus on the students (the learners) rather than on the subject-matter itself. As students play an active role in the learning environment, they naturally work with the superior mental structures required by goal planning, decision making and prediction. These activities are crucial to definitive knowledge acquisition, and contrast with “knowledge” apparently gathered through simple memorization. The latter vanishes fast as experience has shown.

In traditional lectures, students do not see a connection between the subjects they are required to learn and the real world experience, notably the world of their daily lives. Students are passive “learners” (listeners) during the lectures and passivity does not leverage learning. Additionally, in traditional instructional methods students-faculty interaction is admittedly weak, though this relationship be recognized as an important student engagement, retention and motivational tool.

This paper presented an application of the project-based learning paradigm to the difficult task of teaching electrical engineering students the fundamental concepts of industrial network technology. There are a myriad of details embedded in this theme and, worse, abstraction is almost inevitable, what renders it a highly tough subject to tackle with traditional classes.

Our approach was to use a couple of homemade controllers and assign students the global task of networking them. While pursuing the global objective, students had to deal with some mundane, but “must-know”, microcontroller-based human-machine interfacing techniques, such as key-switch monitoring and decoding and writing messages to an LCD. Some basic and minimum knowledge about fieldbus network were presented and incorporated by students into their projects over the semester.

Developing and testing the software to implement the data communications protocol for the network layer of ISO’s OSI reference model was a much challenging design goal that required the students to use the most their creativity and theoretical understanding of the topic. This is a premium example where theory and practice must walk hand in hand to meet a design specification.

It was felt that student assessment is much complicated than in traditional lecturing, as expected. Also, instructor and students’ dedication to course is far higher than in conventional methodology. Despite these difficulties, the power of PBL to promote student mastering of fieldbus network technology is undeniable, as results of the projects carried out by the student

teams made it clear. By the end of the course, students demonstrated proficiency in navigating through the IDE and in developing and testing programs in C to the target microcontroller. To achieve the project goals, they utilized several microcontroller resources (e.g. timers, interrupts, serial ports, and general purpose input/output pins), and used programming techniques as modularization and top-down design approach, thus fulfilling the main course requirements. The students’ enthusiasm and engagement observed during this experience, besides effective mastering of key subjects by students, have definitely changed our minds, leading us to decide to adopt PBL methodology in all future editions of this course. Nevertheless, some improvements should be implemented, as closer follow-up of groups, through for instance a quarterly presentation of achievements, and assignment of rotating roles such as team leader and spokesperson for every team.

Work in Progress: Hands-on Biomechanics Lab for Undergraduate Universities

Deborah Schenberger Munro, Ph.D.
Donald P. Shiley School of Engineering
University of Portland
Portland, United States
munro@up.edu

Abstract—This paper discusses the development of a biomechanics lab course suitable for use at undergraduate engineering institutions who wish to expand their elective offerings or move towards developing a bioengineering degree program. The labs are designed to be low cost and feasible in a teaching environment with groups of students rotating through stationary lab setups. The biomechanics course at the University of Portland has nine labs. The six stationary labs are 1) Gait Force Profile Analysis, 2) Basketball Freethrow Arm Angle Analysis, 3) Biomechanical Arm Muscle Analysis, 4) Muscle Fatigue Analysis, 5) Occupational Biomechanics Glove Fatigue Analysis, and 6) Breathing, Heart Rate, and Knee Motion Analysis. The three labs performed as a class are 7) Sprint Acceleration and Terminal Velocity Analysis, 8) Auto Collision Analysis, and 9) Orthopaedic Implant Mechanical Testing. The remainder of this paper is a detailed description of each lab, its learning objectives, and how it was implemented. Other aspects, such as final projects, research reports, and student opinions of the course will also be discussed.

Keywords- *biomechanics, hands-on laboratory experiments, undergraduate engineering, bioengineering*

I. INTRODUCTION

In recent years, undergraduate engineering programs across the country have seen marked increases in enrollment, with the enrollment increasing 15% between 2006 and 2009, bringing enrollments to the highest level since 1982 [1]. Mechanical engineering has seen the greatest increases, but bioengineering is rapidly growing in popularity, and it's no wonder, as the US Department of Labor and Statistics predicts a 72% growth in jobs between 2008 and 2018 in bioengineering fields [2]. Traditionally, bioengineering was only taught at the graduate degree level, but the last ten years has seen a tremendous increase in the number of undergraduate institutions offering bioengineering degrees. Developing a full-fledged bioengineering program is a long, involved process with multiple considerations that the institution must take into account, and yet students want to learn about bioengineering now, during their brief four year tenure. As educators, we have the opportunity to introduce students to the field of bioengineering through special courses and electives that will give them the exposure they need to pursue careers in this field. One such course is Biomechanics, which has been developed in the Mechanical

Engineering program at the University of Portland (UP). This combination lecture and lab course is designed to expose students to the very broad field of biomechanics. The purpose of this article is to clearly outline the lab component of a course developed at UP and to provide enough detail that other undergraduate engineering programs could implement a biomechanics course in their curriculum at low cost.

The target audience for Biomechanics is engineering students who have taken Physics, Statics, and Dynamics. It is helpful if they have also taken Strength of Materials and some kind of lab in signal measurement, but not required. Most engineering students will not have taken any biological sciences, such as Biology, Physiology, or Anatomy. Students interested in the bioengineering field should be encouraged to take such courses to fulfill science requirements or as electives, as this will only improve their understanding of the field. Students will also not have had exposure to testing with human subjects and how to analyze data gathered from human subjects. Knowing these restrictions, the build-up of the course requires some foundational knowledge.

The course at UP is offered three days a week, with two hours of traditional lecture and one hour of lab. The syllabus covers several broad topics: Anatomy & Physiology, Biomechanics: Statics, Biomechanics: Kinematics (Dynamics), Lower Body Performance (Hips, Legs, & Knees), Muscle Tissue Mechanics, Bone Tissue Mechanics, Fatigue, Occupational Biomechanics, Sports Biomechanics, Accidents and Injuries (Vehicles, Consumer Product Failure, Slip & Fall), and Orthopaedics. These topics are all subjective, and any of them could be eliminated, replaced, or emphasized depending on the instructor. Also, some of the topics are covered through a combination of guest speakers from local industry and field trips. UP is located near a biomechanics research lab, a prosthetic upper limb manufacturer, an athletic shoe company, and an orthopaedic implant company. However, any local industry could be substituted that has some relativity to the field of biomechanics.

Laboratory experimentation is an important component of this course in biomechanics. Dealing with human subjects and the ability to gather meaningful data for analysis is one of the key challenges in biomechanics. Unlike other

engineering disciplines, bioengineering is extremely dependent on test setup conditions. Thus, graduates need hands-on experience with research techniques in biomechanics, and how to present those results to an audience of their peers. Human performance is influenced by fitness, age, gender, diet, fatigue, prior activities, time of day, and countless other variables that cannot be controlled. Generated data is noisy and can be altered by placement of electrodes, movement of the body, clothes worn, stance, temperature of the room, air flow, etc., so it is very difficult to compare results from laboratory experimentation to published literature, as it is virtually impossible to recreate the same conditions. In order for students to be successful performing biomechanical research in their field, they need to have firsthand knowledge of the challenges and limitations so that they can properly interpret their results. The course at UP has eight to nine laboratory experiments. This number can be increased or decreased at other institutions as needed to fit the curriculum, and the exact types of experiments can also be adjusted as needed to give students the exposure desired. At UP, six of the labs are stationary, and the student groups rotate through them every two weeks. The first week is used to read about the lab and learning objectives and to practice with the data collection equipment. Technical journal articles on the subject of the lab station are posted online, and those are also read by the students prior to performing the lab. Many of the labs also require the student volunteer to wear particular clothing or shoes, so this gives the groups time to prepare for data gathering the second week. Three additional labs are performed outside of the classroom, and all groups participate in the lab at the same time. The six stationary labs are 1) Gait Force Profile Analysis, 2) Basketball Freethrow Arm Angle Analysis, 3) Biomechanical Arm Muscle Analysis, 4) Muscle Fatigue Analysis, 5) Occupational Biomechanics Glove Fatigue Analysis, and 6) Breathing, Heart Rate, and Knee Motion Analysis. The three labs performed as a class are 7) Sprint Acceleration and Terminal Velocity Analysis, 8) Auto Collision Analysis, and 9) Orthopaedic Implant Mechanical Testing.

First, it is important to emphasize that this is an introductory, broad overview biomechanics course developed for undergraduate mechanical engineering students. Since UP is a teaching institution, funding for the development of this course came from the School of Engineering and from an internally awarded Butine Grant. Funds were thus very limited, and state-of-the-art data gathering equipment was not the objective. Instead, low cost ways of gathering the type of data desired was purchased, and much of the instrumentation came from Vernier Software & Technology, a company that specializes in science education instrumentation [3]. Many other pieces of equipment are standard, commercial sports equipment, tools, and electronics. Concepts learned in this course, however, are easily transferrable to more sophisticated tools the students may encounter in the future. The total cost for all equipment used in this course was about \$4000, purchased over a period of three years.

In this senior level course, students have already been exposed to numerous writing and presentation experiences, but they have not learned how to present their work in a format suitable for journal publication. As such, these laboratories are designed to give students skills in experimental design, hypothesis testing, and journal publication writing. At the beginning of the semester, each student performs a clinical literature review on a biomechanics topic of their choice, which they then submit in typical journal format, with Abstract, Introduction, Methods, Results, Conclusions, Discussion, and Works Cited. They must cite a minimum of five peer-reviewed references, using library resources to obtain the full articles. They summarize the articles and then analyze the similarities and differences between opinions and draw their own conclusions. This journal format is then used for all group laboratory reports.

At the end of this course, student teams conduct student-designed experiments on any area of biomechanics. Topics have ranged from baseball swing analyses to vehicle-pedestrian accident reconstruction analyses. Again, these reports are written as journal articles, and each team must present their findings to the class. This has led to lively discussions, and students really enjoy the opportunities to define their own experiments.

The remainder of this paper is a detailed description of each lab, its learning objectives, and how it was implemented at UP. As the goal was to provide a forum for students to become better experimental researchers, outcomes for the laboratories were not defined. Each lab station had a set of equipment and a handout. The handout gave an overview of how to use the equipment and the learning objectives of the lab. It then provided a series of open-ended questions to answer. Students could choose to answer one or more of the provided questions or create a hypothesis of their own. As each lab was conducted over a period of two weeks, the first week the students familiarized themselves with the provided equipment and decided as a group what their hypothesis would be. The second week, a student volunteer would arrive appropriately attired, bringing any necessary props or equipment, and the team would collect the data during the lab period. They then had one week to analyze their results and submit their journal-formatted report.

II. LAB EXPERIMENT DETAILS

A. *Gait Force Profile Analysis*

In this lab station, students gained an understanding of how shoes affect the motion of the foot. They were directed to walk and jog across a force platform in athletic shoes, rigid sole boots, and barefoot. They had a choice of collecting all the data for one foot or alternating feet. They were equipped with two force plates by Vernier Software & Technology. The force plates were connected to a Vernier LabPro interface. The LabPro was connected via a USB cord to a Windows XP computer. The software used to read the input was Vernier's LoggerPro for real time graphing and analysis. The two force plates were summed within LoggerPro and the output was exported for later spreadsheet analysis, using Microsoft Office Excel 2010. Like much of

the equipment used in this course, the force plate has limitations. It can only gather force in the z-direction, perpendicular to the floor. This is a significant limitation, but a lot of good data can still be collected with this device. Three axis force platforms are very expensive and must be installed flush with the floor, which was not an option in the lab at UP. The Vernier force plate looks similar to a bathroom scale, and since it is not flush with the floor, early attempts to use it for walking force profiles were unsuccessful. First, the student volunteer had to step up onto the force plate and then back down. The step up motion altered their gait and made it difficult to compare changes in walking profile. Second, the force plate was small, and students had a hard time adjusting their stride to land their foot squarely on the force plate. To overcome these challenges, a ramp was built to allow a gradual change in inclination. The ramp was built wide enough for both feet, and two force plates were placed under a wood cover to give an extra long striking surface for running. This new ramp was student-built from plywood and was designed to be modular for easy storage when not in use.

Recently, barefoot running has become popular. Biomechanically, there are several advantages to barefoot running, especially the more natural gait. In an athletic shoe, a runner will stride out and strike heel first. This leads to larger forces in the knee joint and thus a higher probability of injuries. However, barefoot running is not necessarily the answer, as most runners now run on paved surfaces that are much harder than natural surfaces, and these surfaces are often strewn with sharp objects and fluids that could infect the foot. Thus, shoe manufacturers are now marketing so-called barefoot running shoes. The goal of the lab is to compare the walking and running force profiles with different footwear. Like all of the labs, the data gathered depends upon what the student group decides they want to analyze. For each lab station, a series of open-ended questions were asked to promote the students to think about what they should observe. These questions are based around the learning objectives of each lab. For this lab, the questions were: 1. How does the shape of the force profile change for shoe type? 2. How does the magnitude of the impact force change for shoe type? 3. How does the force profile change for running versus walking?

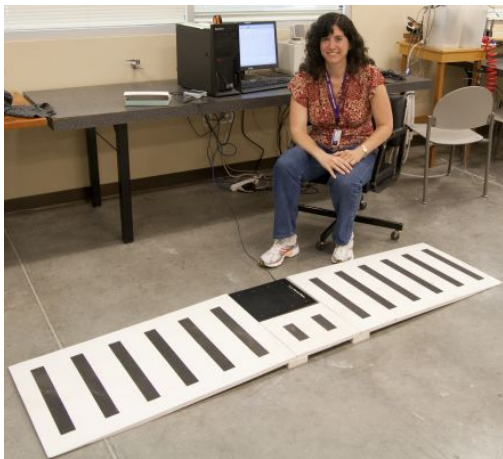

Figure 1: Wooden ramp for force plate

B. Basketball Freethrow Arm Angle Analysis

In this lab, students made a video recording of a volunteer shooting basketball freethrows. They were directed to capture the angle of the arm at ball release and to correlate this with the success or failure of the shot. The lab station was equipped with a Panasonic video camera with 40 gigabyte hard disk drive and a tripod. Within the lab, a standard basketball stand with a reduced rim height of seven feet is set up on its rolling base. The base is filled with water to counterbalance the weight of the stand. Part of the safety training for the lab explains the dangers of having a water-filled base. If a student were to hang from the rim, the stand would come over, and the mass of the water flowing towards the front of the base would accelerate that motion. The lab station also has a regulation size basketball and a ball pump. To facilitate finding the arm angle, the volunteer's shoulder, elbow and wrist are marked with black permanent marker. Within LoggerPro, video input can be analyzed. LoggerPro has a video utility that advances the movie file frame by frame. Marks can be added at each frame and plotted as desired in real time. The students advance to the frame of ball release and mark each joint with X-Y coordinates and determine the vector between elbow and shoulder and elbow and wrist. Using the dot product, they can then calculate the included angle. The angle can be correlated with the success or failure of the shot, with most student groups recording "swish", "backboard make", "rim make", or "miss" for a total of 30 shots. Questions for this lab were: 1. How far off from ideal does this angle have to be to miss the basket? 2. What does the shot look like if the arm angle is oblique versus acute? 3. Is there a significant difference between a "swish" and a backboard shot in terms of arm or body profile? 4. Besides arm angle, what other factors influence the success of a basketball shot?

C. Biomechanical Arm Muscle Analysis

For this lab station, the students investigate mechanical advantage of muscle attachments using either a biomechanical arm or leg developed by Denoyer-Geppert [4] and a dual force sensor and low G accelerometer from Vernier Software & Technology. The biomechanical arm apparatus has attachment points that allow the biceps muscle to be simulated with the dual force sensor. Weights are placed in the hand of the biomechanical arm, which causes the arm to rotate downwards about the elbow joint. The tension in the biceps is adjusted until the forearm is once again horizontal. This is repeated for multiple weights in the hand and two different biceps muscle attachment points on the forearm. The sensors are attached to a Vernier LabQuest Mini unit, which is a simplified version of the LabPro, with four input/output ports. The LabQuest Mini is connected to a Lenovo Windows XP computer and the sensor input is analyzed using LoggerPro.

The goal of the lab is to demonstrate how human muscles act at a mechanical disadvantage in favor of increased range of motion. The LoggerPro software has many built-in mathematical functions, so the low G accelerometer signal can be integrated twice to get position, and this can be used to make the arm horizontal. Most student groups, however, simply use the protractor scale on the elbow joint to

determine horizontal. The output result should show that at the nearer attachment point for the biceps muscle, the muscle is producing about eight times the force in the hand; whereas, at the further attachment point, the muscle is only producing about three times the force in the hand. The questions for this lab were: 1. What is the mechanical advantage (multiplying factor) for the far muscle attachment point versus the near muscle attachment point? 2. Why are muscles attached so closely to the joint? How does this influence the design of muscles and bones? 3. How could biomechanics of the arm be improved externally (with tools and sports equipment)?

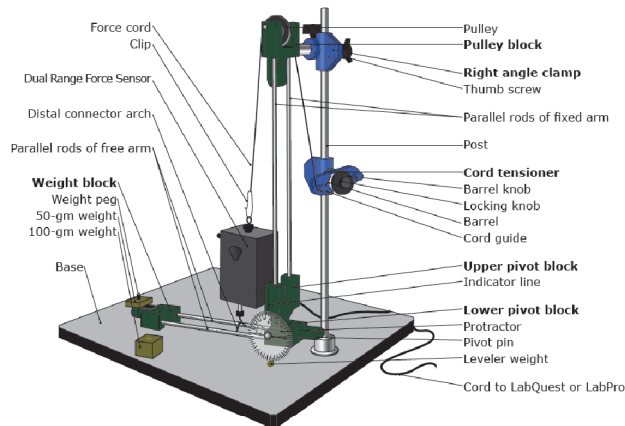

Figure 2: Denoyer-Geppert biomechanical arm [4]

D. Muscle Fatigue Analysis

This lab introduces the use of electromyographic signals (EMG) to capture electrical signal from muscles. EMG signal is extremely noisy and highly dependent on electrode placement, so the students get to learn what EMG signal can be used for and what it cannot. The volunteer performs three exercises, first wrist extensions with a light weight with electrodes on the forearm extensor muscles, then they flip their arm over and perform wrist flexions. The extensor muscles have baseline potential voltage noise, but they only "fire" when the wrist is extended. After gathering this data, the volunteer moves the electrodes to the biceps muscle and does biceps curls with the maximum amount of weight they can lift. These are repeated until the volunteer cannot produce any more repetitions, at which point their team begins cheering for them forcefully. With cheering, the volunteer finds they can do multiple additional repetitions. Throughout the exercise, the EMG signal changes, first decreasing in overall amplitude, then increasing in firing frequency. When cheered, the muscle EMG signal does not improve, allowing students to consider what is happening, such as other muscle recruitment. The questions for this lab were: 1. When the muscle is being activated versus not activated, how does the EMG signal differ? 2. How does placement of the electrode affect the EMG signal? In other words, what can you infer and not infer about the muscle based on the signal amplitude? 3. How does EMG amplitude change with fatigue? 4. How does cheering (brain stimulus) affect performance? 5. What is happening to the EMG amplitude when the volunteer is fatigued yet being cheered on to perform more reps? What is happening biomechanically in the muscles?

E. Occupational Biomechanics Glove Fatigue Analysis

Many professions require the use of gloves, which protect hands from the elements and harsh conditions, but also decrease feedback on grip force. Thus, workers must increase their grip force when wearing gloves, and this accelerates fatigue. For this lab station, the students are provided a Vernier hand dynamometer, a LabQuest Mini unit, a Windows XP computer, and a variety of work gloves. They first grip the dynamometer barehanded and record their maximum voluntary contraction (MVC). Then they record the amount of time they can hold within 75-80% of their MVC barehanded. Then, they don a glove and try to hold 75-80% of their MVC for as long as possible. This is repeated for both hands for all gloves, as well as for pinch force. The students are surprised to see the effect of gloves on their performance. They are also surprised that pinch force is improved by wearing gloves. The questions for this lab were: 1. How do gloves affect grip and pinch forces? 2. From an occupational biomechanics viewpoint, what are the advantages and/or disadvantages of using gloves for various tasks? 3. How could the effects of gloves be minimized? In other words, for a particular task that requires a certain type of glove, how should the glove be designed to minimize fatigue?

F. Breathing, Heart Rate, and Knee Motion Analysis

For this lab, a student volunteer rides a stationary bike for 30 minutes then stopping for 5 minutes while breathing into a Vernier spirometer and wearing a heart rate chest strap or wristwatch. The respiration rate and heart rate are recorded frequently for the first few minutes, then every minute for the remaining time, then frequently again during the rest period at the end. The goal is to determine whether heart rate or respiration increases first and which one decreases first. In the future, the hope is add a carbon dioxide sensor to the spirometer to see the oxygen flow rate.

Also for this lab, the students video record a few pedal rotations of the knee and import the motion into LoggerPro for analysis. Both the angular velocity versus time and the angular velocity versus angular position are analyzed to show the interesting kinematics of the knee. The questions for this lab were: 1. What do the knee path profiles look like during cycling? Why is this significant? 2. How do heart rate and respiration rate change during exercise? Which increases first? Do they reach steady state over time? Which decreases first? 3. How do revolutions per minute and "aerobic threshold" affect heart rate and respiration? 4. How do seat position and body posture appear to affect the biomechanics of motion, heart rate and position?

G. Sprint Acceleration and Terminal Velocity Analysis

For this lab, an indoor or outdoor running space is needed where the student volunteers can safely run 100m without having to slow down at the end of their sprint. Timers with stopwatches are located at each 10m interval, and everyone starts their stopwatch at the same moment. Using an inexpensive high speed camera from Casio, video of the start is captured at frame rates up to 1000 frames per second, although 30 frames per second is sufficient. Each volunteer runs two trials, and the results are averaged. The goal is to

demonstrate that terminal velocity is not as significant as acceleration rate and time in determining a person's finishing sprint time. Thus, a "fast" runner is one that accelerates to full speed in the shortest period of time. No questions were provided for this lab.

H. Auto Collision Analysis

For this lab, UP has constructed two buggies that ride on rails. The buggies were built from garden wagons and modified to have windshields and rail wheels. They have child booster seats on them and shoulder harness seatbelts from a salvage yard. In the seats are two large teddy bears. Students push the two vehicles toward each other over a distance of 30 feet, then release them just prior to impact. A high speed video camera is used to capture the release and impact for analysis of deceleration of the passengers. The vehicles are inspected for damage, and sheared bolts are located and dent depths are measured. The experiment is then repeated without the seatbelts. This experiment has evolved over the years to something that can be done precisely and indoors. In a lecture on accident reconstruction, forces on the body due to automobile collisions is discussed and physics is used to determine impact forces. In the future, it is hoped that the teddy bears and vehicle could be outfitted with accelerometers to capture additional data, but the G forces are too high for the sensors currently owned. No questions were provided for this lab, as it was intended that all groups would determine the speed of the two buggies, their impact force, and anecdotally discuss the effects of the seatbelts. Due to delays in the fabrication of the rails for the buggies, there was not enough time to write reports before the end of the semester, so this lab was discussed by the class as a group. Slow motion videos were played on the digital projector, and students discussed the pros and cons of how the data could be analyzed.

I. Orthopaedic Implant Mechanical Testing

One major field in biomechanics in orthopaedic implants. These implants must survive at least ten million cycles of wear testing, at physiologic worst case loads. There are dozens of standards for how the tests must be performed. One test that can be performed is on the spine. Spinal fusion surgeries are performed hundreds of thousands of times per year in the United States. On the posterior spine, four pedicle screws are fastened to adjacent vertebrae, and then rods or plates are positioned over two screws on adjacent vertebrae and anchored in place. This constructed can then be mechanically tested using a fatigue test machine, or more simply with strain gages on the hardware in a standard tensile test machine. For this lab, a sheep spine double loin is purchased from a local butcher. Using scalpel blades, all the excess tissue is removed and disposed of in a compost bin. Using a standard cordless drill, hardware donated by an orthopaedic spine company is installed on the sheep spine, and it is mounted in the test stand to gather some data. This is an easy lab to do, especially if no testing is performed. Much biomechanical testing is done on animals and cadavers, so exposure to the process of dissection is a valuable skill. Performing "surgery" on the spine also helps the students learn, as many will end up being present during surgical procedures, either to learn more about the challenges

of current devices or to test a device they have designed. This year's class did not get to prepare the spines themselves, and testing was only discussed with the class as a whole, as it was conducted late one evening in order to finish it by the end of the semester. New dynamic fatigue test equipment and better planning will allow this lab to be more hands-on in future years.

III. CONCLUSIONS

Implementing a biomechanics course at an undergraduate university is a feasible option for engineering programs that would like to offer electives, tracks, or majors in the bioengineering field. This paper has outlined how such a course with a full laboratory experience was developed at the University of Portland at very low cost. Other educators have discussed the importance of teaching experimental design at the undergraduate level, specifically in the area of biomechanics [5-9]. Gefen provides a list of equipment available to students in his undergraduate course, along with guidelines for using the equipment. Like the course at UP, he avoids providing "recipes" for the students to follow. He also places students in groups of three to four and has them conduct literature reviews prior to each laboratory. They are required to prepare a protocol in advance of the lab, which is then approved. For his course, there are six lab topics: tissue mechanics, biomaterials, posture, gait, heart valve, and exercise biomechanics. UP offers a separate course in biomaterials, so only four of the six labs are similar. Gonzalez works at a university that built a laboratory equipped with modern research equipment, specifically for the use of undergraduates for education and research [6]. Again, the equipment is meant as "tools" for students to answer their own research hypotheses. The goal of Gonzalez is to teach students to observe phenomena, formulate a hypothesis, develop an experimental methodology, and gather data for analysis. Results are presented as a poster or conference proceeding paper. He states that experimental methods are as important as analysis and design in the engineering curriculum, and agrees that biomechanical labs should be the focus of the course, not a supplement to lectures, if we hope students to develop skills in independent scientific inquiry. His laboratory is equipped with very high quality equipment, such as a 5 camera motion analysis system and a six degree of freedom force plate. His setup requires extensive software as well, which makes the cost of such a laboratory well beyond the means of smaller, teaching universities. His course has three defined topics and two independent design experiences. The three topics are maximum vertical jump analysis, hand dynamometer output with EMG, and arm stiffness measurements. The independent experiments are designed by the students, conducted in the laboratory, and then presented. He notes that several of these independent experiments have led to undergraduate research investigations. Cluss describes a low-cost method to measure the biomechanical forces in a moving human body [7]. She uses a 2D video analysis and software from Vernier, Inc. called VIDEOPOINT to evaluate the vertical jump of ballet dancers. With the software, students calculate the center of mass of the various body parts and deduce the accelerations and thus forces in the

joints. She states that many state-of-the-art video analysis systems cost upwards of \$250,000, but with a simple video camera, or even a cell phone with video function, and some low-cost 2D software, meaningful results can be obtained. This compares well with the experiences at UP. Using regular and high speed cameras (purchased for less than \$300), we are able to analyze many complex motions, including basketball freethrows, sprinting acceleration, golf swings, baseball swings, and simulated auto collisions. With software, it is simple to determine the acceleration and velocity, from which many parameters can be calculated, depending upon the hypothesized question. Zapanta also discusses the importance of laboratory courses in bioengineering and how his university has developed an introductory course to cover the five areas of biomedical engineering offered at his institution: cellular and molecular biotechnology, bioinstrumentation, bioimaging, biomaterials, and biomechanics. He uses EKG to study the heart and EMG to study force generation by limbs for movement. For the EMG labs, he has two experiments. The first is fatigue of the bicep muscles, using a weight held stationary in the hand for 60 seconds. The Fast Fourier Transform is analyzed. The second EMG lab is done in conjunction with a force plate to study the phases of jumping. This is analyzed using MatLab. His course also includes a research project, which culminates in a poster presentation with a written report. Student feedback is very positive for his course, and students liked the breadth of coverage. Some complained that the MatLab was too hard, and some students wanted more depth. At UP, MatLab is covered in a one credit hour computer science course, so all students have excellent MatLab skills, but the Vernier LoggerPro software is quite comprehensive, so no students have used MatLab to complete their analyses. Barr discusses a series of virtual labs developed by VaNTH that evaluate student outcomes based on pre and post tests and surveys administered to the students [9-10]. These biomechanics lab modules cover a variety of topics, including Iron Cross muscle strength, various gait analysis exercises (center of gravity, force generation, and EMG of quadriceps muscles), jump height experiments, and the performance of the ACL during knee extensions. Although the data is provided to the students, the modules are quite thorough and provide a series of videos, relevant literature, and analysis tools to the students. If implementing a physical lab experience is not feasible, this may be another low-cost option for some universities. The course is broad enough to cover a wide variety of biomechanics topics, while still having plenty of depth for students to understand how and where these concepts could be applied.

For the course at UP, student evaluations have been overwhelmingly positive. The overall score was 4.73 out of 5. When asked what students liked best about the course, comments included, "The labs were really interesting and fun.... It is nice that we can infer what we find most interesting from the labs and have some freedom to do them as we want. I learned about new programs and ways of analyzing which I liked as well." Also, "This course is a great opportunity for those looking to go into biomedical engineering. It really gives a well-rounded opportunity to learn about every aspect of biomechanics. The material

learned could be used in many different ways. The labs were also a great experience.... The reports helped the students really look into the background of what they were doing and then really how to evaluate the data they just collected."

Based on this feedback, the open format of the course and lab exercises will not be changed, but students were disappointed that we did not get to do the orthopaedic dissection and testing as planned. This summer, UP is receiving a dynamic fatigue test machine, which will provide a much-needed testing resource for biomechanical experimentation. Labs based around this new test machine are planned for the upcoming year. Also, Gefen's requirement of a test protocol in advance of data collection is intriguing and will be tried [5]. Gonzalez's formal approach to scientific inquiry was similarly intriguing, and I intend to add a stronger emphasis on development of the experimental method [6]. And Zapanta's use of Fast Fourier Transfer and MatLab to further analyze results are excellent low-cost options for UP that I intend to incorporate into the set of skills I provide to the students [8].

ACKNOWLEDGMENT

With special thanks to John Melville of Vernier Software & Technology for his continued support in the development of this course.

IT Experiential Learning: The Living Lab

Connie Justice, Liem Do

Indiana University Purdue University Indianapolis, cjustice@iupui.edu, liedo@iupui.edu

Abstract - In today's competitive job market, businesses will hire people with the relevant work experience, which creates quite a challenge for graduating students. Thus, graduating students also need experience to go with their degrees in order to be competitive in current job market. To better prepare our students, the Computer Information Technology program developed an experiential learning program called the "Living Lab". The Living Lab provides real world experience in all aspects of information technology to students by assigning various projects in a real work environment. This allows students to apply their classroom learning and develop the skills and experience needed to prepare them for today's competitive job market, which is the mission of the Living Lab. Just like the name, the Living Lab experiences remain ever evolving and complicated; thus, finding ways to effectively assess learning persists as a challenge. In this paper, we will show how the Living Lab evolved and the organization, management, and assessment tools used in order to provide students the best experience to assist in their obtaining jobs. Further discussions will show our findings and the innovative ways the lab evolved to take into account the blending of processes, business practices, and academic rigor.

Keywords - *experiential learning; IT; living lab; service*

I. INTRODUCTION

According to Ferrara's research [6], the unemployment rate at 9.9% makes the current marketplace even more competitive, which adds more pressure for college graduates. Furthermore, the CareerBuilder survey concludes that less than half of employers prefer to hire recent college graduates in 2010 [6]. Therefore, without work experience, students will have a lower chance of getting a job. In order to help students overcome this difficulty, the Computer Information Technology (CIT) program in the Purdue School of Engineering and Technology at Indiana University Purdue University Indianapolis (IUPUI) developed an experiential learning program called the "Living Lab" (<http://cit.iupui.edu/citnet>). The Living Lab's mission is to provide experiential learning for students in the Information Technology and Security discipline. It immerses students in a real technology business environment and expands their knowledge and experience beyond the typical classroom environment. The goal of the Living Lab is to promote learning through challenging real-life hands-on experiences that are supervised by faculty, students and staff. Not only do the students improve their hard skills, but they are also taught soft skills.

Just like the name, the Living Lab experience remains ever evolving and complicated; thus, finding ways to effectively assess learning persists as a challenge. Furthermore, because the Living Lab is still so new, being able to organize and

manage it won't be an easy task. With the efficient organization and management tools, the Living Lab's foundation will be greatly enhanced. It is necessary to assess student's learning, and to find the way to improve the organization and management of the Living Lab in order to ensure the validity of the course and provide students with the best experience to assist in the process of life-long learning and the ability to gain employment.

II. BACKGROUND

A. Literature Review

Experiential learning – or learning by doing – is an important factor in education improvement. The purpose of experiential learning is to fill the gap between theory and practice. Consequently, many researchers such as Walker [7], Krane [3], and McCarthy [4] have shown interest in experiential learning, which was proven to be a valuable asset in education. All of these authors believe that it is important to bring theory which was studied in class into a real-life situation where the students can apply what they have learned to solve problems. They agree that experiential learning plays a significant role in education improvement. In their research, they explained the link between theory and application as well as the necessity of experiential learning. However, each of them expressed their ideas in a unique way.

Walker [7] described the process of experiential learning, and how students adapted to this process. Unlike Walker [7], Krane [3] implemented a self-directed learning course and showed its result. McCarthy [4] took a different path and focused on comparing an example of experiential learning and traditional learning. According to Walker [7], the process of experiential learning moved students from passive recipients of information to learners who observed and experienced phenomena in the workplace; as a result, the students were better equipped to implement the principles they learned from class in the marketplace. While Walker [7] showed a general process of experiential learning, Krane [3] applied it to a specific area such as physiology. He realized that there was a disconnection between what information was retained in the laboratory exercise and its application in a practical setting. According to Krane [3], students tended to memorize information in a static pattern rather than process information and formulate strategies for truly understanding the dynamism. Krane [3] created a course which was designed to extend the individual lessons performed in the laboratory course with self-directed learning through the contextual application of information. He also showed that the students' responses were overwhelmingly positive despite a small number of students expressing disappointment due to schedule conflict or an

unexpected event. On the other hand, McCarthy [4] didn't apply experiential learning to any specific area, but compared between case study method which was popularly used in a class and job shadowing method which was integrated into a business course. McCarthy [4] said that direct learning forced students to make their own decisions when facing a real-life problem. When students engaged in tasks, it fostered the development of their skills. McCarthy [4] incorporated job shadowing in a junior-level business communication course. Students who took this course would need to write a research paper, orally share experience with each other and complete a survey. After that, she evaluated all activities, and used paired-samples t test for job shadowing and cases. With the t test in 95% confidence level, she concluded that experiential learning was preferred over traditional learning.

In the same way, Massachusetts Institute of Technology (MIT) developed a similar program called "Action Learning" (<http://actionlearning.mit.edu>). MIT Action Lab said "Our approach integrates theory, real world practice, and personal reflection to develop principled, innovative leaders who solve complex problems and produce systemic changes" [5]. For this reason, Action Learning offers many opportunities for students such as China and India Lab, E-Lab, Global Health Delivery Lab, Global Entrepreneurship Lab, i-Teams, L-Lab, P-Lab, and S-Lab. Each of these labs encloses a different segment of learning perspective. China and India Lab focus on international cooperation while E-Lab focuses on local internship. Global Health Delivery Lab helps students learn about healthcare perspective. The i-Teams (short for "Innovation Teams") lab teaches students the process of science and technology's commercial potential. And Global Entrepreneurship Lab, L-Lab, P-Lab, and S-Lab focus on business perspective.

In short, all of these researchers have proven the important role of experiential learning. Walker [7] showed a general process of experiential learning which consisted of four stages, whereas Krane [3] actually implemented experiential learning to a specific area such as physiology. On the other hand, McCarthy [4] compared between case study method and experiential learning method. Furthermore, MIT University realized the advantage of experiential learning and developed the "Action Learning" program [5]. In other words, experiential learning was an excellent supplement to the classroom environment, which allows student's learning to extend past classroom walls and into the real world environment. Experiential learning presents students the opportunities and problem solving skills which are usually encountered in the workplace so that it required them to think and apply theories to solve problems. It also helps them experience teamwork and expand their learning. Walker said: "This process is indeed a necessary tool in which students expand their abilities to analyze, reflect, and make adjustments" [7]. However, Walker [7] showed a general process of experiential learning but didn't show the application of the process. Krane [3] applied experiential learning to a specific area such as physiology, but didn't actually assess student's learning in depth. McCarthy [4] analyzed and compared experiential learning with traditional learning, but she didn't analyze for the actual improvement of student's learning. Moreover, MIT "Action Learning" program

[5] is too general and doesn't focus specifically on Information Technology. Most of their labs are on external sites and are optional for students whereas "Living Lab" is an in-class and required course which students have to take before graduation. The "Living Lab" is a true experiential program and focuses on a student's true immersion into the business environment.

B. Living Lab Genesis and Organization

It is all started back in 2001 when the CIT faculty needed a server that ran Microsoft's IIS 4.0 for their courses. However, due to security risk, University Information Technology Services (UITS) would not install it in any of their labs. Therefore, the CIT program acquired their own servers starting with two machines. The servers continued to grow, not only to be used for courses, but also to support faculty for their testing space. The first recruited CIT student was able to maintain, monitor and administrate the servers. Meanwhile, the program coordinator was also trying to design hands-on laboratory for networking courses. From there, the idea grew and the Living Lab was born.

The course requires no previous work experience and students that have completed the introductory networking courses are eligible for the Living Lab. The students work under the supervision of faculty and/or staff, supporting CIT's web site, database, security, and networking labs. The internal projects vary from being simple to being complex such as server management. When their level of experience and expertise grows, students are ready to work on external projects in other companies who cooperate with the Living Lab such as Simon Properties Group, Inc.

The first Living Lab roster started with 6 students and grew to 24 students in the fall of 2010. Currently, there is an average of 14 students attending the Living Lab each semester. The CIT program utilizes two student classrooms (ET005 and ET007) to support the lab work for networking and security classes. Today, the Living Lab has expanded to include support for other departments at IUPUI. There are 15 workstations in the room ET005, 30 workstations in the room ET007, and 32 servers in the server room (ET005A). These labs are isolated from the campus network, and give the students administrator access to the workstations, which provides a realistic working environment without a risk of security breach on the campus network. As a result, it offers instructors in the security courses a chance to introduce vulnerability and risk assessment tools for the students. Moreover, the Living Lab provides firewalls, switches, routers, etc. as class materials to students. Therefore, the students get some hands-on experience using equipment and software as part of their class work. Students who complete the Living Lab gain even more experience by maintaining the labs and completing assigned projects. Furthermore, all of the classes taught by the CIT program have the ability to host applications and websites on the Living Lab servers. These servers are also built, administered and maintained by students in the Living Lab. Fig. 1 shows an overview of the Living Lab organization.

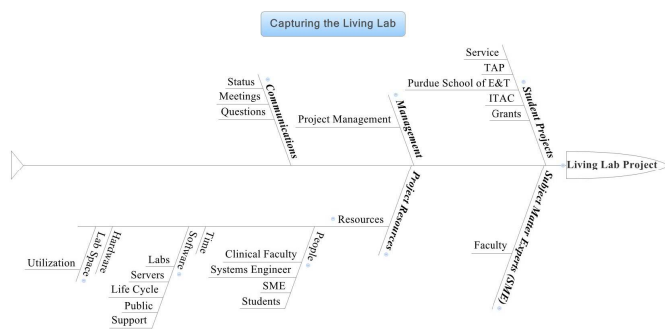

Figure 1. Living Lab overview.

III. MANAGEMENT

To qualify for the Living Lab, students must have successfully completed the first two semesters of courses in the curriculum. It is a required course before the students graduate.

All members are required to attend weekly meetings, including supervising faculty. In the weekly meeting, each student must report on their project work. These meetings are conducted similarly to status meetings in a corporate environment, which provides each student with real world experience. In addition, students are present in the Living Lab on Fridays and Saturdays from 9am to 5pm during the semester (supervised by systems engineer). Supervising faculty and staff have weekly planning meetings as well. Project management tools are used to track the progress and document milestones for each project. The project management tools provide a roadmap for the students to make sure deadlines are met. Projects being assigned to students include technology projects for the department, external service learning projects, university-wide projects. Recognizing the role of reflection in extracting learning from experience, each student in the Living Lab is required. Students keep track of their projects during the semester by writing status reports and journals. Status reports document all the project milestones. Journals document project activity as well as any processes helping to accomplish a particular task in the project with personal reflection. As a result, journals offer students a chance to reflect on what they have been learning and how it relates to the theory they memorized from courses taken before. Likewise, students also need to create documentation (how-to) by recording their processes, procedures and fixes. This is extremely important. Not only does it help students to have a best practice, but also makes the process easier. If a similar situation arises, other students can look at the documentation for help. As the students reflect and document on their project work, they gain confidence in their ability to accomplish any IT project or task that they are given. It is amazing to see students without experience come into the Living Lab as uncertain neophytes and leave with confidence in themselves and their abilities. Fig. 2 illustrates the Living Lab methodology.

Figure 2. Living Lab methodology.

The project opportunities for students are wide-ranging. Projects can come from the CIT program itself, other university-wide departments, or even externally from other companies, and nonprofit companies. Here is a list of some projects, which were assigned to students in the Living Lab. More information about Living Lab projects can be found via our website at <http://cit.iupui.edu/citnet>.

- Living Lab web site development
- SharePoint server / Oracle server setup
- Secure media sanitization
- Bacula Backup Project
- Dell OpenManage Server Admin
- Symantec Ghost implementation
- Encryption protocols implementation
- Nagios setup and configuration
- Forensic projects: Encase, FTK
- External projects: Simon Property Group, Inc., Avon Church

At the end of semester, students are required to submit all deliverables for grading: project report, presentation, poster, weekly status, and journal. The project report is an overall summary of all the project work, including what students have accomplished over the semester and, more importantly, what the Living Lab experience has meant to them. They are expected to clearly state what kind of projects they did, the purpose of each project, how this experience related to their course work, and how it may help them with future employment. To summarize, Fig. 3 shows the flowchart of Living Lab processes.

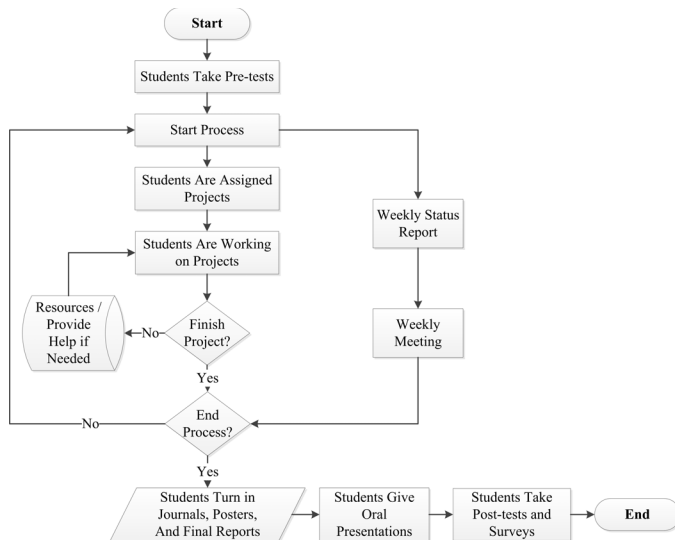

Figure 3. Flowchart of Living Lab processes.

IV. ASSESSMENT OF STUDENT'S LEARNING

Many researchers such as Brinke & Jochems [1], Koriati & Bjork [2] think that student's learning needs to be evaluated. Not only does it help to know whether the student's learning improves during the course but also helps to identify any problem and find a solution for it. Therefore, learning assessment was also an important factor in this picture. It helped to evaluate the student's learning outcomes. Without student's learning assessment, we would not know if students are learning or meeting the course expectations. And the main question is: "Will student's learning increase or remain unchanged after they complete the Living Lab?"

A. Participants

Since this study was intended for the Living Lab, the population of this study was all students participating in Living Lab. Students in the Living Lab between Spring 2010 to Spring 2011 served as the sampling frame (see Table I). That was small enough so that all students in the sampling frame would be included. The advantage of this is the ability to test all the individuals in the segment of the population in order to obtain reliable, valid and accurate results.

TABLE I. SAMPLING FRAME

| Semester | Number of students |
|-------------|--------------------|
| Spring 2010 | 13 |
| Fall 2010 | 16 |
| Spring 2011 | 7 |
| TOTAL | 36 |

B. Materials

In this study, the quasi-experimental approach was utilized to obtain a general overview of the student's learning performance. Single-Group Pretest/Posttest design was used. A skill assessment test was developed and designed based on general knowledge about Computer Information Technology. It

was divided into 9 different areas of knowledge, all of which were necessary for students to know in order to be able to get a job. Also, a course evaluation survey was used to ask for students' opinions and suggestions about the course and the skill assessment test.

C. Procedures

The students took the skill assessment test at the beginning and the end of the Living Lab through an electronic testing tool in the university learning management system. These tests were graded based on a grading checklist with a total of 100 points. The two measures of the pretest and posttest could then be compared, and any differences in the measure were assumed to be the result of the course. Furthermore, at the end of the Living Lab, the students took a course evaluation survey. The surveys were also collected for future reference.

V. RESULTS

By completing the Living Lab, students learn to develop self-directed learning ability in a real-world environment as well as to integrate knowledge studied in the classroom with practical application. They learn to manage projects effectively, work in a team, and communicate their synthesis and interpretation of the experience in both written and oral presentations.

To test for whether student's learning increases or remains unchanged after they complete the Living Lab, pretest and posttest scores were examined. Pretest and posttest scores were collected from 36 students in 3 semesters. Table II shows the mean test scores of pretest and posttest by semester.

Before doing any analysis, the null and alternative hypotheses were defined. The null hypothesis was that student's learning remained unchanged after they completed the Living Lab; and the alternative hypothesis was that student's learning increased after they completed the Living Lab. A paired-samples t test was conducted to determine if there were any significant differences among the pretest and posttest scores. In addition, the result in Table III indicates a significant difference at the 0.05 level of significance among the means of the pretest and posttest scores.

A paired-samples t test was calculated to compare the mean pretest score to the mean posttest score. The mean on the pretest was 22.7597 (sd = 12.35004), and the mean on the posttest was 36.8872 (sd = 21.72411). A significant increase from pretest to posttest was found ($t(35) = -3.675, p < 0.001$).

TABLE II. MEAN TEST SCORES

| Semester | N | Pretest Mean | Pretest Std. Dev. | Posttest Mean | Posttest Std. Dev. |
|-------------|----|--------------|-------------------|---------------|--------------------|
| Spring 2010 | 13 | 19.66 | 0.11 | 37.65 | 0.212 |
| Fall 2010 | 16 | 27.22 | 0.137 | 40.59 | 0.186 |
| Spring 2011 | 7 | 18.34 | 0.091 | 27.00 | 0.289 |

TABLE III. PAIRED-SAMPLES T TEST

| Paired Difference (Pretest – Posttest) | t | df | Sig. |
|--|---|----|------|
|--|---|----|------|

| Paired Difference (Pretest – Posttest) | | | | t | df | Sig. |
|--|--------------------|---|--------|--------|----|------|
| Mean | Standard Deviation | 95% Confidence Interval of the Difference | | | | |
| | | Lower | Upper | | | |
| -14.128 | 23.062 | -21.93 | -6.324 | -3.675 | 35 | .001 |

As a result of the paired-samples t test, we rejected the null hypothesis. Student's learning did increase significantly after they completed the Living Lab. Fig. 4 illustrates the pretest and posttest scores per students.

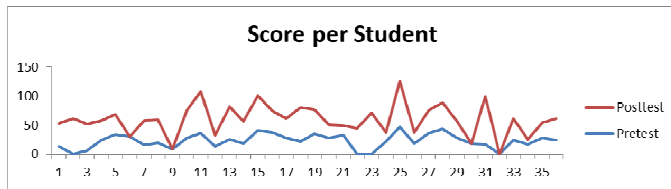

Figure 4. Pretest and posttest score difference among the students.

On the other hand, Fig. 5 illustrates the pretest and posttest score per semester.

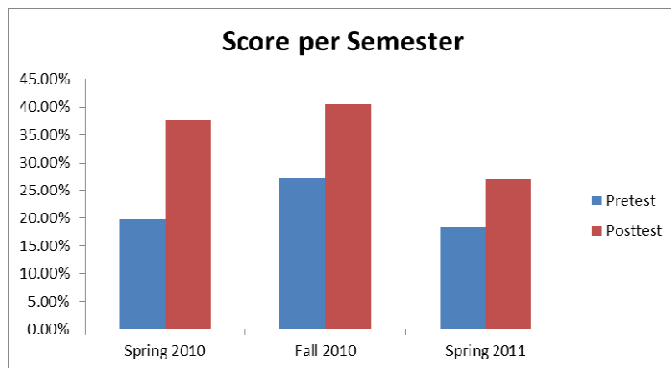

Figure 5. The pretest and posttest scores per semester.

VI. DISCUSSION

The Living Lab aligns with the mission of the CIT program by helping students to develop modern technological skills, effective oral and written communication skills, and the ability to perform well in teams. The program has produced experienced students who can function in the IT space with confidence. Buoyed by its success, and to continue to help prepare our networking students to meet the needs of today's employers, we have recently added a mandatory IT experience for all students in the entire CIT curricula. The Living Lab is one way to meet this requirement. Furthermore, we try to expose students as many different projects possible so that they can experience a variety of skills. Besides receiving many projects from other department or external organizations, we also focus on experiential services such as volunteering projects for churches, charities, etc. Along with the process, there are some challenges that we has faced.

A. Challenges

The Living Lab has faced several challenges over the years, primarily how to accommodate the numbers of interested students, and projects to work on, processes of taking project from initial to final stages, and assessing student work. To be effective, each student or student team must have at least one project that he or she can research, implement, and maintain each semester. Furthermore, Living Lab business hour in the lab for the students to do their work was also a problem. Since the labs and servers supported by the Living Lab are used almost nonstop during the week for CIT courses, business hours for the Living Lab had to be on Friday and Saturday from 9am to 5pm. However, this schedule is not always conducive for those students who work weekdays. In order to solve that problem, students work any other weekday or offsite in the evenings to complete their projects.

B. Assessment Evaluation

Living Lab successfully integrated the work environment into the academic environment. Rapid project completion inside of the Living Lab raises the need of student's learning assessment. It is necessary to perform an assessment on student's learning in order to determine whether students actually learn after completing the Living Lab. Using comparative means analyses, we found that there was a significant difference among the pretest and posttest scores. This can suggest that student's learning did increase after they completed the Living Lab. Surprisingly, as showed in Fig. 5, we could see a slight increase from Spring 2010 semester to Fall 2010 semester, and a significant decrease from Fall 2010 semester to Spring 2011 semester. This change is due to the number of students completing the Living Lab (see Table I). This result suggests that the more data collected, the more accurate the hypothesis test would be.

Because the pretest/posttest design includes only one group, there is a limitation in this study. Testing effect confound might affect the results since experience with previous test may change performance. It occurs when taking a pretest influences students' behavior on a posttest; for example, students would be more relaxed on the posttest because it is now a more familiar testing situation, or taking the pretest allows them to have practice with the particular types of items on the test. The design does not control for potentially confounding extraneous variables such as testing effect; so it is still difficult to identify the effect of the "Living Lab treatment" condition. Furthermore, this study lacks a comparison group. With no comparison group, we do not know whether any observed change in student's learning is due to the "Living Lab treatment" or to something else that may have happened during the time of the study. For example, maybe the students got a job while taking the course. Therefore, the students might have scored higher on the posttest regardless of whether they completed the Living Lab or not.

Further research requires a control group, thus minimizing confounds and ensuring the validity of this study. In addition, the skill assessment test can be re-edited in order to keep the

testing questions updated. A feedback system will be developed to collect the future success of students who took the Living Lab. With this information, we can evaluate how effective the Living Lab is in helping students acquire work. Despite the limitation, the data analysis revealed that student's learning increased significantly after they completed the Living Lab.

VII. FUTURE WORK

During the Living Lab development, we found several innovative ways to evolve the lab while taking into account the blending of processes, business practices, and academic rigor.

A. Project Management

In future work, we will implement a SharePoint server incorporating with Microsoft Project to manage the students' projects, documentation, research, and many more. This will be our main base of collecting and storing information. All the incoming project opportunities will also be managed through this server. Furthermore, all the communication between students and staffs or between students and their projects will happen through server services. Therefore, we will have a controllable and centralized system which helps to keep track of students' deliverables, work hours, documentation, etc. This will significantly enhance the Living Lab organization.

B. Assessment Process

In order to improve the assessment process, all the questions in the assessment test need to be revised and restructured. Because the assessment test will measure student's learning through Living Lab process, it needs to cover as many standard skills as possible. Despite that, the assessment can't be too long. Fig. 6 and 7 show an overview of the assessment test which we had used. Furthermore, because each student has a different skill set, it is hard to test him or her based on only one general test. Figure 8 show the new assessment test and includes two parts: general questions and project-based questions. The general questions include all the basic concepts of computer techniques, e.g., shortcut keys, simple command line, standard knowledge about computer information such as policy, network, computer process, etc. The project-based questions will include more specific knowledge of many different areas of IT. Depending on students' background, they will take a different part of the assessment test. As a result, the learning process of students with different majors can fully be assessed.

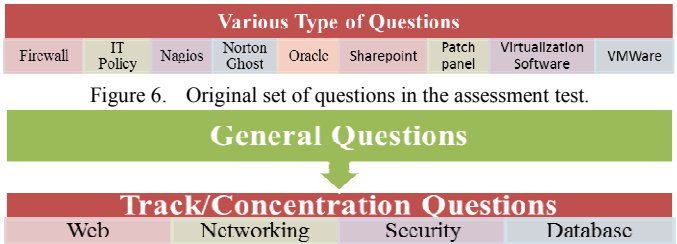

Figure 7. The 2nd generation of the assessment test.

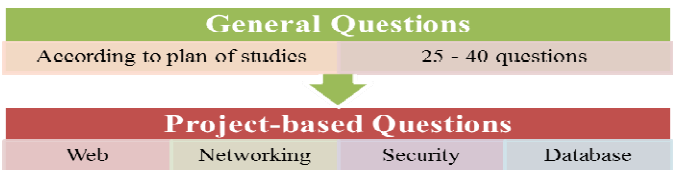

Figure 8. The future of assessment test.

The Living Lab process consists of two aspects, academic and business. The academic portion is based on course outcomes and is graded by a students' performance and final deliverables. The business side, is based on IT current and new project opportunities as well as grant and support. In order to maintain a balance between academic and business, a clear process needs to be defined. Figure 9 demonstrates the interaction among these components.

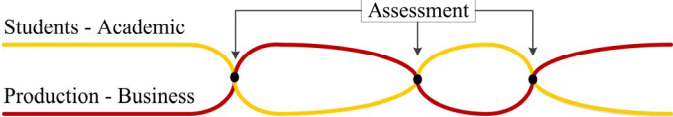

Figure 9. Living Lab streamline.

In conclusion, although the Living Lab is still a new concept, it successfully fulfills its mission. According to the student's learning assessment, the Living Lab significantly helps students improve their skills through the experiential learning process. Furthermore, feedback from the students who took the Living Lab is positive. With constant ongoing innovation, the Living Lab will continue to evolve. It is a very powerful tool of which every educational institution needs to take advantage. Not only does it equip students with knowledge and experience, but it also gives them a solid direction in the way of their professional quest. It is truly one of a kind. It is hoped that this analysis shows the value of the Living Lab, and encourages more institutions to adopt this course.

Abstract—The impact of the computing field is becoming more profound everyday in all facets of modern society. Despite significant efforts from academia and relatively high demand for computing, technology producers are needed more than ever. This has been corroborated by a recent NSF Press Release [1], stating that computing is the only STEM discipline with more job openings than college graduates to fill them up. A major responsibility for such an outcome rests upon educators' ability to produce professionals capable of handling ever more complex technical challenges.

In this challenging environment, the importance of practical work in science and engineering, supported by lab exercises, is widely known. While it is desirable to create physical laboratories for teaching these technologies, it is not always possible nor desirable. In this paper, we present an effective alternative approach, in the form of an affordable, virtualized laboratory environment that can be used in a variety of computing and engineering courses, as well as in other fields, in lieu of physical labs.

Results of a survey supporting the validity of this approach are also presented. Students in four different classes were surveyed concerning the effectiveness and desirability of this virtual laboratory approach. The survey results indicate that student response to and interest in the virtual environment is very strong.

I. INTRODUCTION

Computer hardware and software continue to evolve into increasing levels of sophistication and maturity, which have allowed computing devices to gain a greater integration into many aspects of human society. Correspondingly, the role and importance of the computing disciplines have increased, with a similarly higher demand for technologically competent information technology professionals in the workforce. A major responsibility for the production of such capable professionals rests in the hands of the computing education community. It is notable that (as reported by NSF [1]) computing is the only discipline among Science, Technology, Engineering, and Mathematics (STEM) with more job openings than graduates.

For the computing educator, an additional complexity is to keep up with the rapid pace of change, advances and new developments in the field. Educators must be able to translate the complexities imposed by rapidly changing technologies into fundamentally sound and practically effective curricula, so that graduates are properly prepared to enter their professions. In other words, computing educators must frequently update curriculum to cope with the dynamics and developments.

These exacting circumstances require educators to be flexible, up-to-date, and able to offer their students practical

experience with continually changing computing technologies. The importance of practical work in science and engineering, supported by lab exercises, is widely known. While it is desirable to create physical laboratories for teaching these technologies, it is not always possible nor desirable. Cost, availability, and environmental effects of physical space represent constraints on building physical laboratories. Additionally, cost effectiveness is becoming increasingly more important, and purchasing a specific technology offers no guarantees that it will not soon become obsolete.

Due to the aforementioned dynamics, it is highly important that undergraduate students are exposed to practical experiences, such as relevant lab exercises [2], [3], [4], internships, and other avenues of practice. Recent advances in high-performance server architectures and virtualization technology allow us to not only avoid the pitfalls of building physical laboratories, but also to introduce significant developments to and expansions of the curriculum. Virtualization enables decoupling of applications, information, and provisioning of resources from the complexities of the physical assets of the computing laboratories. It can also be used to improve exercise repeatability, safety, and flexibility while reducing the overall cost and carbon footprint on the environment.

This paper presents a description of an affordable, virtualized and green laboratory environment that can be used in a variety of computing and engineering courses, as well as in other fields, in lieu of physical labs. This environment allows instructors and students to build more complex environments than are typically available in physical laboratories. The virtualized infrastructure is easier to administer, provides consistent and repeatable setup, and notably frees instructors from technical hurdles that often burden physical systems. To date, the environment has been used for courses in computer networking, operating systems, database, programming, and security, with plans in place for use in additional advanced computer science and information systems courses. In addition to its description, we also present examples of use cases from several classes. The advantages and disadvantages of the virtual approach are discussed, along with the possibilities of augmenting existing pedagogical approaches.

A validation of the approach, in terms of the results of student surveys from four different classes, is also presented. The survey results indicate that student response to and interest in the virtual environment are very strong. Students enjoy

the virtual lab environment and exercises, and in general they find that it presents realistic and practical exercises in a safe environment. Students also report that the exercises present a good value and are applicable to the real world. The virtual lab environment is regarded as safe, cost effective, and environmentally-conscious. It allows students to make mistakes without worrying about breaking anything or breaching security. A practical benefit is that one single server replaces hundreds of physical machines, with enormous power savings. Another benefit is manifest in increasing the quality of experience for distance learners to bridge the learning environment gap with in-class students.

The statistical analysis of survey results shows that the respondents clearly and overwhelmingly agree that the lab infrastructure is an effective tool for improving their learning experience. While the approach is not without its shortcomings, it appears to be very promising for adoption in a wide range of courses, including those outside of the computing and engineering curricula.

The rest of the paper is organized as follows: Section II presents related work. Section III presents technical details of the virtualized laboratory setup. Synopses of several labs we have offered using this infrastructure are given in Section IV. Section V provides a qualitative and quantitative assessment of the effectiveness of this approach. Finally, section VI presents conclusions and future directions for our work.

II. RELATED WORK

In academia, virtualization is mostly used in networking classes of computer science programs, as it naturally lends itself to the curricula of such classes. As we posit in this paper, virtualization shows great promise for other computing classes, as well as many engineering disciplines and other programs of study in which computing labs are inherently needed and used. Since the networking subfield dominates the virtualization literature, we primarily concentrate on this area in the following discussion.

The classic way of realizing networking labs is by means of physical infrastructure, and there are numerous examples in the literature. For example, [5], [6] briefly mention such a lab setup. Similarly, some high-level descriptions (with limited technical content) are presented in [7], as well as [8] and [9].

Tele-Lab [10], [11], [12] introduced a high-level abstraction, in which Linux-specific security labs were virtualized on top of User Mode Linux (UML) [13], [14]. The set of labs are restricted to Linux system administration tasks. Another set of labs specific to older network security techniques are mentioned in [15]. The approach in [16] focused on the fast reconfigurability of lab infrastructure that may be shared by many classes. Other limited networking labs are presented with brief descriptions in [17].

Network security labs can place the students in the role of attacker [18] or defender [19].

The alternative to the classic way of developing networking labs under a physical base is to develop them by means of *virtualization*, which has a rather large scope in terms of its

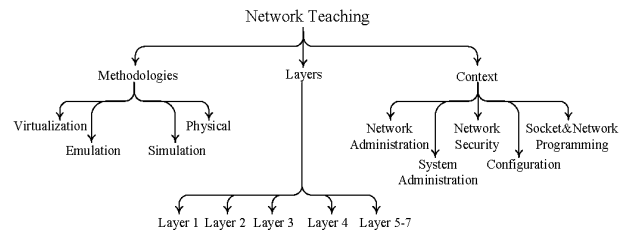

Fig. 1. A classification of teaching networking topics.

applicability and definition. In this project, by virtualization, we refer to the *full platform virtualization* that separates an operating system from the hardware resources underneath it.

Virtualization was first introduced by IBM in the early 1980s [20], [21]. The demise of mainframe computing and rise of peer-to-peer computing, followed by server-based virtualization, has prevented it from gaining much attention. Within the last decade or so, to reduce the cost of IT infrastructure, a centralized approach has gained a lot of attention and has become a useful technique for software testing, dynamic provisioning, real-time migration, high availability, and load balancing [22]. The benefits of virtualization are succinctly summarized in [23]: better security, higher reliability and availability, lower cost, improved adaptability to workload variations, more efficient load balancing, and the ability to run legacy applications in newer, incompatible platforms.

One of the first virtual network labs is presented in [24], which focused primarily on multimedia. The use of Microsoft Virtual PC virtualization for labs on application layer services is presented in [25]. The Open Network lab is introduced in [26] to study protocol performance issues rather than the more practical issues of network design, configuration and maintenance. Another conceptual approach to make use of virtualization is published in [27], where QEMU [28] is used as the underlying machine emulator and virtualizer.

A recent approach most closely related to ours is reported in [29]. However, the usage reported therein is limited to system administration and some security topics, even leaving out many important networking concepts such as layered protocols, programming, performance evaluation, etc., as shown in Figure 1. Further, the authors in [29] did not report any assessment of their environment. In contrast, we conducted an assessment study, presenting a statistically significant analysis of the validation of our environment. Furthermore, our philosophy intends to give a much broader focus to our virtualized lab infrastructure, to include other STEM disciplines, as well as other computational non-STEM disciplines.

III. TECHNICAL DETAILS

Our virtualized lab infrastructure consists of a Virtual Computing Environment (VCE) [30], using high-capacity servers capable of hosting many instances of virtual machines in software. We use VMware vSphere, ESX 4.1, vCenter Server, vMA (vSphere Management Assistant), and vCenter Lab Manager 4.0.2. The price of creating a physical machine used for virtual infrastructure was \$7,943.08 per server; each server has 8 cores, 128 GB of physical RAM, and 2.5 TB of physical disk

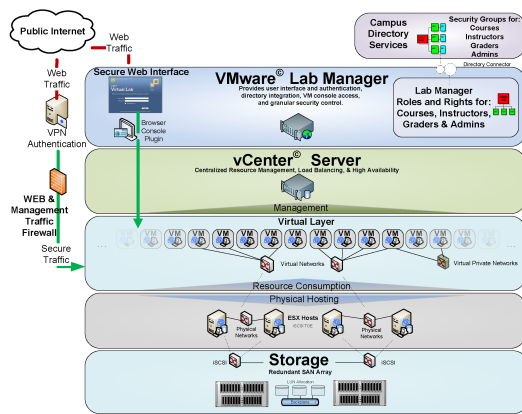

Fig. 2. A sketch of our virtualization infrastructure.

Fig. 3. Log into interface of virtualized infrastructure.

space configured in a RAID-10 array¹. The cost of VMware software through its Academic licensing is nominal. Figure 2 shows a high-level layout of our virtualized infrastructure setup. In the Fall semester of 2011, one of the servers was running about 250 student virtual machines simultaneously, eliminating a significant source of energy waste compared to an equivalent physical infrastructure.

A high-level description of the lab environment is as follows: students log into the host server through a web interface, as shown in Figure 3. This portal provides a management interface, as well as a console interface to let users create virtual machines from cookie-cutter style templates (as depicted in Figure 4) to significantly reduce deploying *sandbox*-style lab infrastructure for a variety of curricular topics. Labs are served for numerous courses in our department, with a current focus on networking classes in two separate programs (computer information systems and computer science). Additional labs have been hosted in operating systems, database, security, and distributed systems classes, and there are plans to integrate the virtual labs in system administration, parallel computing, and mobile computing classes.

IV. LAB SYNOPSIS

The Virtualized infrastructure is currently used in 6 different classes, involving a number of different lab exercises. Below,

¹Considering the ever decreasing per-unit costs of computing, the specific costs and configuration are simply presented to give an approximate idea.

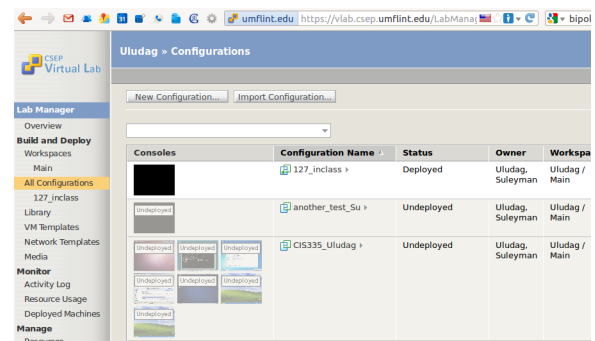

Fig. 4. Management Interface to create new machines.

we present general and concise descriptions (due to page limits) of representative lab exercises and the classes in which they are presented.

Computer Networks: There are four networking classes, including three undergraduate courses in computer science and information systems, as well as one graduate course. In these courses, students are required to configure linux and/or windows machines in a networked environment. Lab exercises require students to configure network hardware and software from the data link layer up to the application layer. Students begin by learning the basics of hardware and software configuration of network interfaces. They continue with exercises in routing, followed by transport-layer experiments. Application layer exercises include Network Address Translation (NAT), web server configuration, Domain Name System (DNS), and security.

Operating Systems: One particularly informative lab is related to kernel configuration and the creation of a new system call as a part of the kernel. System calls are an important early concept in the presentation of operating systems. They simultaneously illustrate several important OS concepts, as well as aspects of software engineering, such as the roles of encapsulation, the separation of interface and implementation, and the operating system's role in managing resources and abstracting the underlying architecture. As such, exercises involving system calls help to illustrate these concepts to the student. This particular lab exercise required the students to download and extract the source for a version of the Linux kernel, add a new system call to the kernel source, and compile and install the new kernel. On rebooting the virtual machine into the new kernel, the students are able to write a small test program that calls the system call and to observe the effects by examining the kernel's ring buffer using the `dmesg` utility program.

V. ASSESSMENT

Table I presents the questions that were asked in the surveys. We have given these questions to all the students in 4 classes: CIS335 (Telecommunication and Computer Networks), CSC336 (Computer Networks II), CSC377 (Operating Systems), and CSC535 (Advanced Computer Networking). The number of students were 22, 14, 18, and 24, respectively,

TABLE I
QUESTIONS OF THE SURVEY

| | |
|----|--|
| 1 | The virtualization infrastructure enabled me to relate some concepts of the course with a realistic and remotely accessible setting |
| 2 | Labs on the virtualization infrastructure helped me to go beyond class discussions and readings to gain practical experience. |
| 3 | Labs on the virtualization infrastructure provided me a safe and secure environment for a variety of experiments |
| 4 | The virtualization infrastructure has more potential to reinforce fundamental course concepts and relate the theoretical topics to a real-world product, if more similar labs are developed and if the lab is more intensely incorporated into the curriculum. |
| 5 | Virtual labs enabled me to have anytime, anyplace individual access with only an Internet connection and a browser. |
| 6 | Virtual labs enabled me to build experience without risking damage to the equipment or infrastructure. |
| 7 | As a result of the Virtual labs, I am more comfortable about approaching course technologies and utilizing them in my professional career and personal life. |
| 8 | Labs on the virtualization infrastructure provided me an opportunity for hands-on experience with several computing technologies. |
| 9 | Virtual labs helped me see how the theoretical principles apply to practical applications. |
| 10 | Virtual labs enhanced the value of this course. |
| 11 | Virtual labs provided me a rich and compelling interaction with realistic technology. |
| 12 | Virtual labs have helped me achieve mastery on custom application(s) or on specific IT skills |
| 13 | I would love to have more time spent on Virtual lab exercises as part of the course |
| 14 | Virtual labs helped me save costs associated with travel, administration and other purchases for a physical lab. |
| 15 | I believe virtualization-based laboratory experiences contributed to my knowledge retention. |
| 16 | I would love to do a project or extended lab on the virtualization infrastructure. |

giving a good statistical significance to our analysis below².

A categorization of the questions in terms of their general areas of assessment is shown in Figure 5. The six major

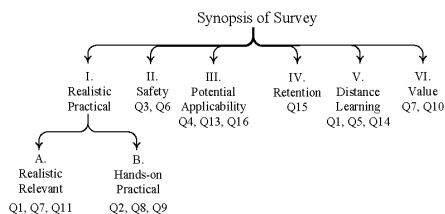

Fig. 5. Categorization of the end-of-term Survey questions.

categories are those addressing whether the labs represented realistic/practical applications, how well they ensured safety, the applicability of the exercises to their career, whether they addressed student retention, how compatible they were with distance learning, and their overall value. In terms of the *realistic* questions, they were also sub-categorized into whether the exercises were relevant to students' career, as well

²The questions related to course content were slightly modified for the operating systems course.

as how practical the exercises were³.

A. Quantitative Analysis

Figure 6a shows the aggregate percentages of students who have responded favorably (Strongly Agree and Agree in the Likert Scale) to the survey questions for each category (see Figure 5 for the classification) for the four courses. On the other hand, Figure 6b plots the the percentages of the students who have not been completely satisfied with the virtualization infrastructure. The results of these two graphs clearly indicate the overwhelming positive reaction of the students across these courses. In particular, they show that the number of students overall who agree to strongly agree is above 70% across all courses, while the number of students who found little value in the exercises is nearly universally a small minority, below 10%. In particular, students in one of our networking courses found high value in the exercises, often in 100% agreement with the questions in categories related to safety, applicability, and retention. These graphs illustrate that there were strong opinions either way on the part of the students, with relatively fewer neutral responses. Moreover, they show that the number of actual negative responses was in fact in a tiny minority.

From another perspective, a plot for a measure of dispersion in terms of an error plot is provided in Figure 6c. The y-axis is the quantized values of the Likert Scale responses, i.e. Strongly Agree = 2, Agree = 1, etc. A low variation of the results is obvious, which are concentrated in high positive averages.

Another statistical analysis of the results is provided in Figures 7a-f as aggregated pie charts of all categories for all courses combined. Pie charts depict the pattern of the student responses that indicate that majority of the students perceive the infrastructure positively.

Finally, Figures 8a-d show the individual course assessment results in terms of the absolute responses, rather than percentages as in the previous plots.

As can be seen from the Figures 6-8, despite the different dicing and slicing of the data from multiple perspectives, the results are consistent, clearly concluding that the students overwhelmingly approve the efficacy of the virtualized infrastructure.

B. Qualitative Analysis

The quantitative analyses presented above support the assertion that students like the environment and they believe it is helpful. There is also a qualitative analysis to present, as we have found that the approach of using a virtualized environment has advantages and disadvantages that are not completely revealed by the numerical results. Some of the advantages have already been highlighted, but we reiterate all of them here. One primary advantage may be in cost savings of various sorts. Use of a virtual environment requires the purchase and maintenance of a small number of server machines, with no need for administrative walk-up (i.e., physical

³Question 12 was omitted from the categorization as it did not fit into any of the other ones and we realized during the analysis that it was too strongly worded, i.e. *mastery on custom applications*.

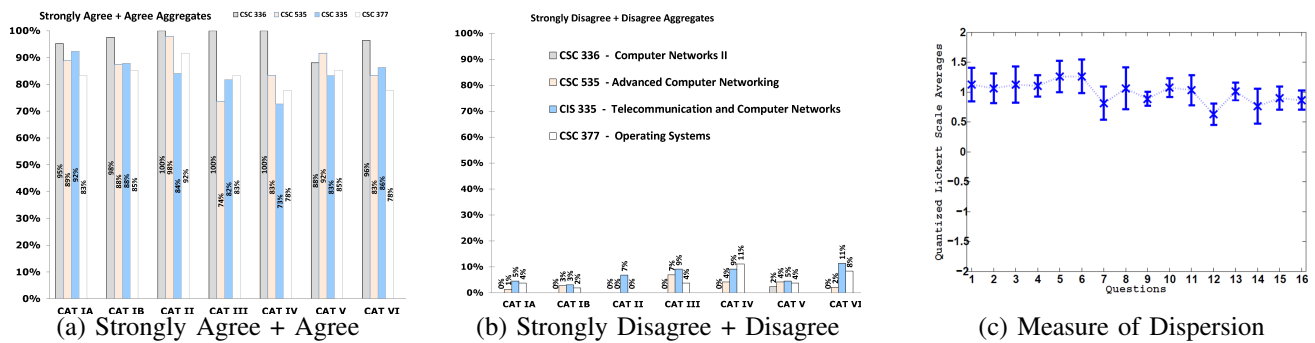

Fig. 6. Aggregate histograms and error plots of the assessment results for all four courses.

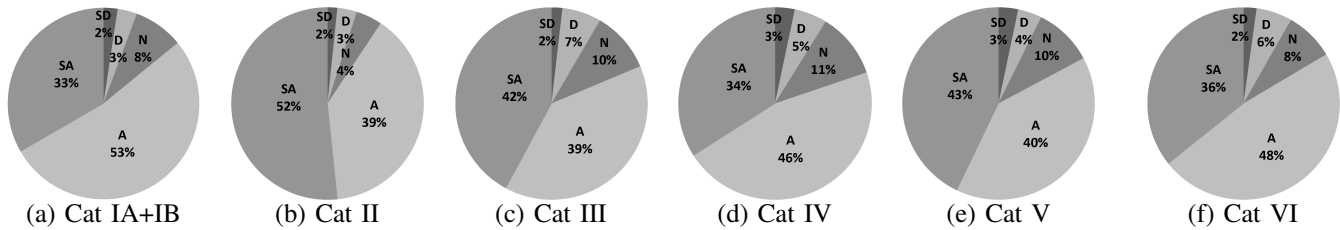

Fig. 7. Pie Charts of the assessment data for all four courses combined in terms of the aggregate percentages for the categories.

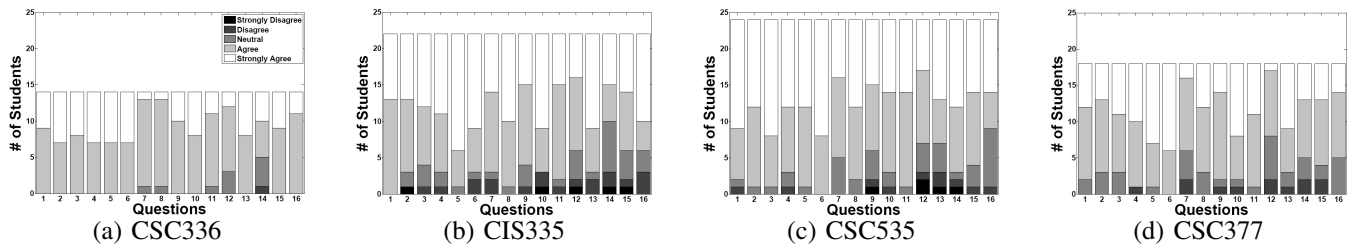

Fig. 8. Individual plots of the four courses in terms of the absolute value of respondents. Note that the legend given in (a) is applicable to all.

maintenance of laboratory PCs, switches, wires, etc.), ease of configuration, provisioning and de-provisioning through virtual machine software, and repeatability due to the ability to save correctly configured environments as images within the virtual machine software. Another cost savings is related to the fact that students may create as many copies of machines as required by their labs. For example, if a student happens to need 5-10 machines, then he/she can create them quickly in the VLAB, and just as quickly, they can be removed.

Another primary advantage is safety, due to the fact that these machines are created within a virtual *sandbox* environment. Indeed, the environment is shielded from the greater Internet by our university network, which filters access in a highly controlled fashion. Furthermore, the machines themselves can be configured in virtual networks such that they never have access to the outside Internet.

Flexibility is another fundamental advantage. As long as we have images of various operating systems available on the primary server, we are able to create as many variants of different configurations as we need. Our system is currently configured to support about 15 versions of Linux and about 7 versions of Microsoft Windows. Images for different classes can be pre-configured for the computational environment needed, so that students can jump right into the actual exercises without any hassle.

As we have also mentioned, this environment is highly compatible with online education. The VLAB interface is presented through a web page, and students may access it via any computer on the Internet, as long as it has the correct software installed as plugins in its browser.

Another side benefit of this approach is that it introduces our students to virtualization software. Although this is not a concept widely taught in our curriculum, it is a highly practical technology that is growing in its usage in the IT field.

A primary disadvantage of this environment is the fact that it is not 100% hands-on. For example, one exercise we have employed in our physical labs involves students manufacturing, testing, and measuring CAT-5 Ethernet cables. In the VLAB environment, it is impossible to create virtual *build a cable* exercises; nothing in this environment is an adequate substitute for the physical process of stripping CAT-5 cables, aligning the wires, crimping the RJ-45 ends, etc.

Another disadvantage is as alluded to in a preceding paragraph. We have found that the virtual software only supports a limited subset of web browsers, although we will consider three commonly used browsers: Firefox, Internet Explorer, and Chrome. Firefox must be confined to a relatively out-of-date (and soon to be obsoleted) version in order to support the plugin required to deliver the X-windows console of virtual machines through the web browser. Internet Explorer works,

but there are issues with configuring it to run in some versions of MS Windows. Chrome is simply not supported. Related to this, the browser plugin introduces a latency over and above network latency in the interactions. Consequently, students accessing their virtual machines from across the network must be patient.

VI. CONCLUSION AND FUTURE WORK

The relevance and importance of computing is likely to remain high, or even to increase in the future. Yet, diffusion of best practices for teaching computing courses seems to be taking longer than the demand emanating from industry. To reduce the gap between the demand for qualified computing degree graduates and its supply, or at least prevent further deterioration, innovative and effective best practices of educational approaches need to be devised. One such approach is briefly outlined in this paper to draw attention to the affordable and easy, yet very promising, method of delivering and complementing computing courses by means of a virtualized infrastructure. Our methodology seems to be equally beneficial and applicable to a wide variety of computing, engineering and other curricula where computing labs are used. The adoption of our virtualized infrastructure by faculty teaching a variety of courses is underway in our department. We have also provided a formal and rigorous evaluation of the efficacy of our approach with a clear conclusion that students overwhelmingly support and benefit from the infrastructure. A description of technical details in a *how-to* type document is a future work to facilitate easier dissemination and replication of our infrastructure for universities.

As for other future work, here are some ideas we are planning to work on: we have not yet examined some more direct assessment related to other manifestations of effectiveness of the virtual lab. In the future, we wish to explore the effects of the VLAB environment on our students' grades. With the premise that experiential learning will improve various aspects of the student experience, but most importantly, their knowledge retention and ability to apply the knowledge, we intend in the future to explore how well the VLAB facility correlates with student performance.

Another avenue of future work is to examine the effectiveness of this environment for use in a variety of other computing courses, which are adopting the infrastructure now. Our campus has historically been a commuter campus, and although we are growing our on-campus student population, it is true that the number and variety of online courses is also growing on our campus. There is a desire to explore offering a greater variety of online courses. It will be interesting to expand the assessment to include these other online and traditional in-class courses.

Abstract—White privilege is an important concept when considering issues such as social justice, the internal “culture” of engineering education and systematic change in engineering education. However, it is not well understood by most engineering educators. This Special Session will help participants explore the idea of White Privilege within the context of engineering education. Through an interactive format, participants will learn some theory and develop some ideas for addressing White Privilege in engineering learning environments. The related idea of stereotype threat will also be discussed.

Keywords—White Privilege; underrepresented minorities; social justice; engineering culture; stereotype threat

I. SESSION GOALS

Participants will leave this session with

- a working definition of White Privilege.
- at least one idea of how to address White Privilege in the engineering learning environment.
- a more complete understanding of stereotype threat in engineering education

II. SESSION DESCRIPTION

Sociologist Michael Kimmel [1] uses the metaphor of wind to describe the subtlety of privilege. If you are walking into the wind, the force of the wind holds you back, it makes you walk more slowly, you squint your eyes; it can be chilly. By contrast, if the wind is constantly at your back, you hardly notice it. It puts a lift in your step, you walk seemingly effortlessly, you reach your destinations more quickly; no force holds you back.

In engineering, to be White and male is to have the wind at one's back; such a person does not have to think much about the natural forces that sustain and allow him to feel comfortable with relative ease. A White male can make mistakes without people attributing it to his race or gender. He can ask questions

or draw attention to himself without worrying if people will make judgments about him based on race or gender. When with other engineers, he can easily find many others who look similar to him. His speech and accent, the jokes he tells, the food he eats, and his social habits seem normal. People do not question his academic abilities on a regular basis, or wonder if he is an “affirmative action” token. A white male can move along fluidly through engineering education as his race and gender seem invisible.

The purpose of this special session's activities were to help the participants gain a better understanding of how White Privilege shapes the experiences of our engineering students and of engineering faculty. In addition, participants left with more strategies to manage White Privilege in the engineering learning environment.

III. SESSION AGENDA

The session organization was as follows:

- **Introduction and Goals** (10 minutes)
- **Kites of Inequality** (15 minutes)
 - Each group is given materials to make a simple object such as a kite. The participants do not know that the materials are stratified so some groups have abundant materials while others have increasingly fewer supplies.
 - After 10 minutes, the groups with the most resources present their work first, followed by the other groups.

This work was supported in part by a collaborative grant from the National Science Foundation (NSF) Gender in Science and Engineering Research (GSE-RES) program (0734085 & 0734062). The opinions expressed in this work are those of the authors and do not necessarily reflect the views of NSF.

42nd ASEE/IEEE Frontiers in Education Conference

- (15 minutes) **Discussion/Debriefing of Kites of Inequality Activity**

- After all groups have presented, we facilitated a discussion. Someone will likely point out that groups seemed to have varying amounts of materials. The impoverished groups are usually the most vocal, describing it as “unfair” and that they were keenly aware that they did not have enough to complete the project easily. By contrast, groups with the most supplies will likely describe that they did not realize their abundance.
- The goal of the activity is to have participants understand stratification, recognize how privilege operates, understand the effect of low resources on students in our educational system, and identify how power operates “invisibly”. By inhabiting a space of discomfort and frustration, participants begin to understand how marginalization feels. The “rich” participants reflect on how they were unaffected by others’ problems, because they were absorbed in their task.

- **Read White Privilege: Unpacking the Invisible Knapsack by Peggy McIntosh [2] (10 minutes)**

- **Develop White Privilege Strategy Posters (15 minutes)**

In small groups, participants discussed *Unpacking the Invisible Knapsack*. The presenters provided a set of discussion questions and materials for presenting responses. Participants were asked to provide

- examples of how White Privilege manifests itself in engineering education.
- strategies for how to manage White Privilege in engineering education.

- (10 minutes) **Mini Poster Session – Report Out**
Participants will move around the room to learn strategies developed by other groups.

- (15 minutes) **Wrap Up and Next Steps**

- The facilitators provided a list of strategies that were covered depending on what ideas the participants presented.
- The facilitators introduced the related concept of stereotype threat in engineering, along with strategies to address it. “Stereotype Threat” is the experience of heightened anxiety in a situation where a person has the potential to

conform to a negative stereotype about their social group (e.g. race, gender) [3-4].

- The facilitators provided a list of relevant literature
- Contact List, Evaluations and Brainstorm Cards for next steps were circulated.

IV. ANTICIPATED AUDIENCE

The expected audience for this session is engineering educators who are interested in exploring more deeply the implications of their own privilege on their teaching.

V. EXPECTED OUTCOMES

We hope that this session will begin a dialog in the engineering education community about the issues raised. Specifically, we hope to see presentations at future FIE conferences related to White Privilege. White Privilege is an important concept when considering issues such as social justice, the internal “culture” of engineering education and systematic change in engineering education.

VI. SPECIAL SESSION JUSTIFICATION

To our knowledge, there has never been a session at FIE addressing the issue of White Privilege. Given that the majority of engineering educators are White and that there is a desire to increase the racial diversity of engineering students and educators, it seems imperative that those in the majority learn more about themselves and how they can make a difference. This topic is difficult to address in a non-interactive setting. Thus a special session format provides a preferred venue for exploring White Privilege in engineering education.

Understandings of Value in Engineering Practice

James Trevelyan

The University of Western Australia
james.trevelyan@uwa.edu.au

Abstract— This paper draws on a large body of empirical data from interviews and field observations to suggest that many engineers, even some professional organizations, have difficulty explaining the commercial value of engineering work. This difficulty could contribute to a public and employer perception that marginalizes the significance of engineering work. Research data came from qualitative interviews with engineers in Australia and other material. Data from individual engineers and other studies contributes to a description that educators and engineers could draw on to better explain the value of engineering to students, firms and the community at large. This paper presents a limited sample of the evidence behind this research.

Keywords- *Engineering practice; engineering education; community perceptions of engineers*

I. WHY WOULD A FIRM EMPLOY AN ENGINEER?

What value can an engineer contribute? These are important questions, yet there are few if any useful answers in the literature of engineering education that would help engineering graduates respond quickly with a meaningful reply. The concept of value itself has many different meanings. Looking at economic benefits for different stakeholders is just one of many possible avenues to explore the value that can emerge from engineering.

Why is this discussion important?

First, it raises issues lying at the core of shared identity in the engineering community and the profession. Historical studies have shown how the value of engineering has been articulated at the societal level in terms of building the nation state, maintaining military strength, or advancing industrial competitiveness.[e.g. 1] However, this literature requires careful study for a reader to be able to explain the value of engineering in meaningful terms at the level of a single firm or small engineering enterprise.

Second, young professionals who can easily explain the relevance and value of their work in their community are much more likely to feel respected and valued. There are many indicators that expose continuing concerns among engineers at the relatively esteem in which they are held in comparison to other professions such as law and medicine. The lack of community understanding about engineering can be linked with the lack of discussion on this topic within the engineering community itself, and campaigns to reassert a public image for engineers. A large survey of ASCE members in 2006 revealed a widespread perception that they were undervalued, wanted more respect from the public, and more opportunities to lead project teams [2]. There have been calls for more public awareness in the several countries [3, 4].

Notwithstanding efforts across the professions to raise the profile of engineering, a brief survey of the public advocacy sections of ASCE, ASME, IEEE and EA web sites at the time of writing revealed neither a useful description of engineering nor its social or economic value. None described engineering work. Most emphasized creating new technologies, particularly IEEE and ASME who prominently displayed an iPad on its technology and society page. ASCE emphasized building water and power systems, for which a literal interpretation would be misleading because engineers seldom build anything themselves.

Third, research on engineering practice has revealed many instances in which engineers have had difficulties in understanding the relative priority of different aspects of their practice because they have limited understanding about the value created by their work. This leads to frustration, delays and added costs. The CEO of a large engineering enterprise expressed his frustration in these words:

"Our engineers don't understand the business imperative of this organization. They simply don't get it and it frustrates me immensely."

Similar frustrations from a different viewpoint have emerged from engineers in our research and other studies. Several have alluded to non-engineers in senior management with a limited understanding of engineering issues, for example

"This company is run by f---ing accountants! They just don't understand even the simplest ideas in engineering."

This study has revealed that while engineers have a solid understanding that their work contributes great value, this understanding is not easily articulated. Many engineers seem to have rather simplistic ideas about the economic value that their work creates, possibly placing them at a relative disadvantage in the contemporary post-industrial world of work. A recent US-based qualitative study revealed engineering students' notions of engineering in which economic considerations are not core to engineering as such, although they are key considerations in the working world [5].

The first half of the 20th century perhaps represented a golden era for engineers in the industrialized world. They were regarded as public heroes, providing great advances in material living standards. In the 21st century, engineering is taken for granted and has receded from the public eye. An ordinary person in the industrialized world today can switch on a light, turn a tap, or start a car without any concern that the electricity, water supply will not be functioning, or that the car won't start. The value of engineering, therefore, is much less apparent.

II. ENGINEERING VALUE IS MORE CONSPICUOUS WHEN IT IS ABSENT

The backstreets of South Asian cities provide an opportunity to appreciate the real significance and social value of effective engineering because it is conspicuously absent. We take good engineering for granted in Australia where potable water is piped 24 hours a day to kitchen and bathroom taps and usually costs less than US\$2 per tonne including connection charges. In most South Asian cities, water flows from pipes for an hour or so every other day and it is almost certainly unsafe to drink. Potable water has to be prepared or often carried by women, with the result that the real economic cost is many times higher than in Australia *in equivalent currency terms per ton*. A copious amount of potable water for a house and garden in Australia costs only about 1% of a family income. Obtaining and preparing a minimal 10 liters daily per person can be represent 20–40% of an average family household's economic capacity in Pakistan [6, 7]. For locals, most of these costs are invisible: there is no charge for water from public purification plants and women's labor is regarded as a free household commodity. Indeed, the notion that basic goods could be far cheaper in a wealthy country seems beyond comprehension. The cost of other services that rely on engineering (such as electricity supply and construction), taking into account total costs and comparable end-user service quality, were also much higher than in Australia, though the difference was not as great as for potable water which is heavy to transport.

For people in an industrialized country, many of whom have experienced low cost back packer holidays in the developing world, the notion that essential services they take for granted at home could be so much more expensive for people who have to live there also seems counter-intuitive.

Here is a startling illustration of the economic and social value of a reliable city water supply system providing potable water at high pressure 24 hours per day. Water supply utilities are large engineering enterprises. When they work well, engineering enterprises provide the products and services needed to maintain a civilized society at much reduced cost in terms of human effort and material resources. In other words engineers provide the means to achieve high levels of productivity. This frees up economic resources for all the other human activities that support a civilized society: law enforcement and security, justice, good governance, education, health care, and social services.

I had practiced and taught engineering for more than two decades, and until then I had never questioned the social and economic benefits of engineering. It was only when confronted by the absence of effective engineering that I began to understand the real value that it contributes to a society.

I was employing engineers in Pakistan and I became aware that I had to completely recalibrate my expectations for engineers' performance there, compared with my experience in Australia. I hypothesized that differences between Australian and Pakistan engineering practice might be a significant contributing factor. The near complete absence of research on engineering practice [8, 9] exposed the need for research to establish a body of evidence on practice in Australia and developing countries in order to test this hypothesis [10-12].

The research consisted of a series of mostly qualitative studies on engineering practice in Australia and South Asia informed by a combination of interviews, field studies and research visits.

III. STUDIES ON THE WORK OF ENGINEERS

In the 1970s and 1980s there were studies of engineers using the job analysis method revealing survey data showing, for example, that engineers spent about 60% of their time interacting with other people [13]. Several later studies of engineers explored social relationships between engineers and the wider structures of industrialized societies [e.g. 14, 15]. The rapid economic ascent of Japan relative to other industrialized countries during the 1980s motivated a series of comparative studies [e.g. 16, 17]. Sociologists interested in the details of daily practice have described many difficulties in studying engineers, such as technical jargon and the intellectual nature of critical aspects of the work which cannot be directly observed [18]. Most studies have been written for science, technology and society specialists (STS) and few are easily accessible for engineers or their educators, our primary constituencies. While these studies have contributed to our understanding of engineering practice, our knowledge of technical occupations remains tenuous and it is only recently that a comprehensive understanding of engineering practice with validity in a wide range of disciplines and settings has begun to emerge [e.g. 10].

Research literature on the social and economic value of engineering is even scarcer. A survey of introductory texts and engineering education research literature has exposed the near complete absence of any explanations that could be useful for students [19].

Recent research to build a comprehensive understanding of engineering practice has relied on observations of engineers in their workplaces [e.g. 10, 20-23]. Data from these observations could yield valuable insights on how engineers perceive the value of their work.

IV. RESEARCH METHOD

Qualitative research contributes rich data for an exploratory study of the ways in which people think about ideas. This approach has yielded valuable insights from systematic investigations of engineering practice. This study draws on evidence collected for earlier studies of engineering practice {Trevelyan, 2010 #1045}. Semi-structured interviews with a total of 120 practicing engineers in Australia lasting 90-120 minutes explored their careers, most aspects of their current work, and perceptions related to job challenges and achievement satisfaction. Some interviews included questions on dishonest behavior (of others), checking, and mistakes. In some instances, circumstances required small focus group discussions with up to three participants instead of interviews. Transcripts were prepared from recordings (with participants' consent) or notes (checked by participants). Several students contributed interview data using the same protocol with minor variations to suit their research on slightly different aspects of practice. Some also contributed field study data to triangulate the interviews. Training, joint interviews, and reviews of the recordings and transcripts helped ensure consistent data.

The sampling was partly opportunistic and partly purposeful for maximum variation to include engineers in all major disciplines, experience levels, and types of business (except defense). 6% were female and most had engineering degree qualifications.

Analysis followed standard ethnographic analysis techniques and also drew on the author's extensive first-hand experience of practice. Some recently published accounts from other research teams also helped triangulate data.

Instances of the word "value" and "benefit" in transcripts and field notes yielded a variety of perceptions that engineers have relating to value in engineering. This paper only presents a limited selection of the evidence analyzed for the research leading to this paper.

V. FINDINGS

Value can be a confusing idea, especially for engineers, even more for non-engineers listening in to an engineering conversation.

Many engineers use the word most often to refer to a number, the particular value of a variable quantity. Often the number represents an amount of money, for example 'dollar value' that might represent the total amount of money needed to purchase a machine.

Occasionally engineers referred to 'values' in the sense of personal integrity and honesty. This too can be confusing as many organizations now promote their 'values', building on the work of identity economists [24], because people whose identity aligns better with organizational values are more likely to display higher levels of motivation and loyalty.

Engineers often used the words 'value' and 'benefit' interchangeably to describe positive learning experiences for themselves or colleagues. Here a young engineer talks about the need to seek help from more experienced engineers:

"You can ask the most stupidest question it doesn't matter.. cause at the end of the day you are the one who is going to benefit from it...it is always good to stop and ask questions"

He has used the notion of 'value' or 'benefit' to refer to the personal acquisition of knowledge. Several engineers connected the word 'value' with detailed technical knowledge or information, or greater certainty, and in these cases the word 'benefit' was not used at all. Here is a process engineer talking about the earliest stages of engineering design:

"And then you move through to say a pre-feasibility, where you do a bit more engineering, solving some of the issues, defining some of the ideas and concepts and adding a bit more value to that number."

Here we see the word 'value' being used in association with 'number' but with an entirely different meaning from the notion of a number as a particular 'value' of a variable quantity. Here 'adding a bit more value' refers to the reduction of uncertainty in a number that represents an estimated technical quantity, in this instance the production capacity of a process plant. Engineers work with ever-present uncertainty from natural causes, the limitations of engineering science in predicting behavior of artifacts, and from the uncertainties of

human behavior. Reducing uncertainty, 'controlling risk' is a deep-seated value for engineers, as we shall see later. Safety, or the ability to reduce the chance of events that can cause harm to people, is also part of this engineers' concept of value, as the next quotation from a mechanical services engineer illustrates

"Ensuring that you select the appropriate equipment and appropriate way to develop the project that maximizes the value. It's safe and is efficient and conforms with ... (pause) ... engineering practice."

Although all engineers were asked to comment on discussions with clients or project sponsors, only three out of around 100 interviewed for earlier studies mentioned the idea of value in this context. All of these were the most senior engineers in their divisions of their firms. A senior software engineer talked about his difficulties in keeping design focused on the appropriate requirements:

"We have to make sure that the client's people understand how our systems will help them in their business. It's so easy for their ideas and ours to diverge, for our people to lose track of their needs and you end up with a system that produces little real value for the client. It's a constant struggle."

His understanding of value, in contrast to nearly all the other engineers, was firmly based in terms of the way the software behaved to produce economic value for the client.

One of the engineers who mentioned value in the economic sense identified that reducing uncertainty, usually described in terms of 'risk', was important in their work. This engineer linked 'value' with 'driver' to convey the notion of an important aspect for the economic performance of the project:

"One of the key drivers for the project – value drivers – was reliability."

In this particular project, failures would lead to extremely expensive production interruptions, both because of the cost of purchasing product from competitors to meet contracted customer delivery schedules, and the high cost of repairs to the equipment. This was translated into a need for high reliability from engineered systems being created by the project team.

The realization that describing the value that arises for their work could be a challenging task for many engineers led to two focused studies in a variety of firms. Twelve engineers described the relevance of business-related aspects of their work, including the economic value they create through their work. All found this issue difficult when it came to expressing it in words.

Two focus group discussions with five engineers in a technical consultancy revealed the difficulties that most engineers have with expressing notions of economic value emerging from their engineering work. When asked how they would describe what engineers actually do, one paused with a puzzled frown for several seconds, and then, when prompted that it might have something to do with "problem solving" that was a prominent feature of a company advertising poster displayed in the meeting room, he said:

"Yes, problem-solving, analysis... analyze systems... to make

things better, to make things more efficient."

When asked about the value created by the work they performed, there was another long pause. Finally, another engineer hesitantly said:

"Well, I guess the thing that the client wants most is the results so the value of my work is getting the results from out in the field."

Some of the engineers offered long-winded explanations that ended up at the same point: ultimately the client pays for a report or data. That, they said, would explain the value that emerged from their work.

The second study involved interviews with seven engineers at different firms, this time with more emphasis on business-related aspects of practice. Participants were asked about several aspects of commercial practice including value, negotiations and how they learned about business issues. Three of the participants had studied commerce in addition to their technical engineering degree course. All had difficulty expressing how commercial value emerged from their work. This chemical engineer firmly switched the focus on value back to technical certainty:

"For me, I don't really see value as a massive buzz word. I think there are better words. The word we always focus on is quality, which is basically how well you are able to deliver or exceed what someone is expecting of you."

Others mostly expressed commercial value only in terms of direct costs or time, or in achieving the project objectives without further elaboration. For example a graduate engineer with a few months of experience described value creation in these terms:

"It's making sure that the company does what it wants to do in the budgeted time and the budgeted amount of money, and ensuring that the skill set that I bring ensures that happens."

They also closely connected achieving objectives with 'enhancing shareholder wealth.' They also connected value with safety, a primary concern due to the high risks associated with their work, as seen in the following comments made by an oil field engineer (after the Macondo disaster in the Gulf of Mexico).

"Higher value is when you deliver something that's timely, it's what they wanted and it's been done without any safety problem or anything like this. I guess for me, in my job, the most important thing for me is safety. We work in an industry where there's a lot of potential for things to go wrong."

In discussing the concept of value, only one of the seven engineers in this second focused study specifically identified risk as a factor, a maintenance engineer with four years experience:

"What does the company stand for? It's adding value to the shareholder. I see that as two things: a finance return, i.e. making more money, or a reduction in risk because, if you think about it, all investors have a particular risk profile,

right? So if you can continue to reduce the risk that a shareholder has, whilst keeping the same rate of return, then obviously that's more attractive to more people."

He later confirmed that his understanding of risk and return in relation to investor preferences had been developed through his commerce studies. None of the other engineers with a commerce background made this connection.

In the earlier phase of the study before the focus on business aspects, only the most senior engineers had been able to connect technical work with creating value for clients. One cited an extensive design study for a mine in a pristine tropical location:

"I had to review the work done in the previous year. They had spent tens of millions on engineering, but they had added no value because they had not dealt with any of the ten showstoppers: risks that could cause a major release into the environment, mostly from flood events."

This engineer has directly connected the elimination of risks with increasing the project value for the client who was still seeking finance to implement the project. Yet the engineers working on the project seem not to have understood the link between the need to eliminate major risk factors and the availability of finance to develop the project.

VI. DISCUSSION AND LIMITATIONS

The data reveals that the notion of 'value' posed evident difficulties for the engineers interviewed in this research because of the number of different meanings that appeared in different contexts. These included the value of a variable, namely a precisely defined number, a notion of technical quality, an attribute of technical investigations that helped to clarify an appropriate choice from several different options, reduction of uncertainty, a personal attribute such as integrity, even an attribute that denoted useful learning from a personal experience. This last association was the main one that engineers associate with 'benefits'. Among these, the ultimate value of engineering work for a client or end-user is remote from the day-to-day considerations for most engineers: for most this value is associated with direct cost savings such as reducing the energy needed for a process, or the amount of labour needed, or simply achieving stated objectives. While most engineers see the reduction of uncertainty, usually conceived as the notion of risk, hazards, or threats to human safety, as a useful end in itself, only a few connect this idea with increasing the apparent value for an investor, client or end-user. Studying commerce can help engineers to see this connection, but does not seem to make it obvious. Even the entirely technical links between levels of uncertainty, design safety factors, and additional material weight and cost never emerged in interviews with engineers.

Another illustration that complements the data analysis came from an unexpected source. Engineers Australia are revising statements of competency [25] used to evaluate whether young engineers are ready to be admitted to chartered engineer status, the capacity for independent, unsupervised practice. Engineers Australia have used competency standards for this assessment since the 1990s. A near final draft released

for public comment in February 2012 after extensive consultation devoted an entire section to “creating value” in terms of advanced engineering knowledge – applying advanced theory-based understanding of engineering fundamentals, applying local engineering knowledge, investigating and analysing engineering problems, developing creative and innovative solutions, and evaluating the outcomes of engineering activities. While one of the suggested indicators that an engineer could use to demonstrate attainment of these competencies was “develop and apply new and emerging technologies, engineering applications and systems to create value for customer” the analysis presented earlier in this paper demonstrates that engineers are likely to interpret ‘value’ in this context in terms of technical quality rather than economic value.

As suggested in the introduction, a better understanding of economic and social value created by engineering work could help resolve several issues currently facing professional engineers.

Engineers enjoy a great deal of autonomy in their work. At the same time, engineers are often faced with open-ended tasks such as risk assessment and fault tree analysis that can never be fully explored in the time available. Engineers need to judge how far to pursue these investigations. Expectancy value theory [26] in its simplest form explains how choices to engage in activities are shaped by competency and value beliefs. In other words, engineers who perceive value in terms of technical quality and precision are likely to engage their technical competency in pursuit of quality and precision. This was observed by an engineering manager describing the difficulties of a project that was well behind schedule:

“the engineers were too involved in the design, the paper system, where the endgame is a railway product which has to be delivered”

An equally potent illustration arose from two studies on design checking and review in separate firms with demanding quality assurance regimes [e.g. 27]. The engineers regarded checking as “non-productive” and “work that added little value to the design”. Checking work was delegated to junior engineers, deferred, or relegated to the lowest priority. Some engineers complained that they did not have time for checking. As a result, engineers failed to detect mistakes in design documents leading to schedule slip, additional cost and time for rework and the risk of premature termination of a project. These unnecessary risk factors significantly affect the commercial performance of projects, yet this connection was not apparent to these engineers.

In both these instances, a better understanding of the economic value of technical engineering work might be helpful in refocusing the attention of engineers on tasks that are likely to contribute useful economic value. While the engineers in the studies reported above were often devoting attention to the reduction of risk, they were less able to perceive commercial opportunities and financial constraints on projects such as the amount of finance available, cost of the finance, and payback period, all of which strongly depend on investors’ perceptions of risk.

A training course for junior engineers based on analysis of the interview data ran into unexpected difficulties with their ability to understand the commercial connections with their technical work. They were keen for their company to invest in their technical ideas, yet were unable to build a commercial case for their ideas based on risk perceptions. A discussion late in the course centered on the reasons why a client might employ a technical consultancy to perform a structural integrity review at a significantly higher hourly rate. Even though the facilitator provided considerable help, only one of ten engineers on the course finally managed to realize that a smart consultant could devise low cost ways to reduce failure risks, saving the client several times the total fee for the work. A careful review of the possible reasons for this difficulty after the course led to a decision to review engineering education curricula and texts. This review showed that the relevant technical and commercial issues were not addressed at all in most engineering programs [19].

Helping engineers to create more economic value from their work could also help with another issue perceived by many engineers: remuneration. Labor market economics predicts that remuneration is driven by marginal product, the value that workers contribute. It is possible that difficulties experienced by engineers in perceiving the economic value of their work, and hence engaging in tasks likely to contribute useful economic value, might be related to the widely reported steady decline in engineering remuneration relative to other professions.

Professional associations could help to develop an improved understanding of economic and social benefits provided by engineers working mostly out of sight, providing clean water, ubiquitous sanitation, adequate supplies of healthy processed food, telecommunications (without which most ‘technology’ would be merely of curiosity value), transport systems, robust buildings, healthcare and many other services. Some of the evidence presented in this paper might provide some useful ideas to publicize the social and economic contributions of their members.

The low rate of female participation in engineering in most industrialized countries is an issue that concerns many engineers. Female engineers have to tolerate direct and indirect discrimination to pursue their careers. Perhaps most women contemplating a professional career would prefer a profession with a clearly articulated social contribution. Lawyers fight for justice and doctors deliver healthcare. While engineers contribute to both, their contributions are mostly invisible and unrecognized. A better understanding of the social and economic contributions of effective engineering could help to change these perceptions.

Even though notions of value lie at the core of professional practice, the diversity of meanings and lack of coherent understandings on value in engineering discourse emerged late in this study. Further investigations focused on this issue may produce results that could answer questions raised by this research. One is the degree to which female participation in engineering is affected by espoused and implicit professional values. Ways to locate ideas on the value created by engineering at the core of curriculum require further investigation and experimentation.

VII. CONCLUSIONS

Analysis of interview data suggests that engineers' perceptions of value in their work primarily relate to technical quality and precision. To the extent that they perceived economic value, their perceptions are almost entirely limited to direct cost savings. In engineering practice, the word 'value' has a range of different meanings: it is easy for engineers using the English language to confuse the notion of 'value'.

Educators have a central role to play in helping engineers develop the ability to understand the economic and social value arising from their work. While social justice and caring has received increasing attention from engineering educators recently, one can argue that engineering must first produce tangible economic benefits before discussing how they might be shared between different stakeholders.

Educators could help young engineers appreciate that there would be few opportunities for engineers without investors who are prepared to entrust engineers with their money in the expectation of future financial and economic benefits. The evidence presented in this study suggests that studying commerce alongside engineering is not sufficient to enable engineers to understand the relationship between risk perceptions and financial constraints. Educators need to find ways to integrate an appreciation of uncertainty, risk perception, finance and the appropriate selection of technical options. Researchers need to rectify a lacuna of evidence in this aspect of engineering.

For most of the 20th century, the value of engineering in developing the power of industrialized societies and economies was unquestioned. Governments invested large resources in engineering enterprises though they demanded strict financial controls. [e.g. 28] By the end of the 20th century, however, economics had displaced political ideology as the primary determinant in political decision-making. Governments in most industrialized countries divested themselves their engineering organizations and now outsource their engineering from private sector providers. The commercial imperative now governs engineering priorities. This study suggests that engineers at the working level could benefit from a much clearer understanding of the links between their work and the perceptions of investors that make it possible.

VIII. ACKNOWLEDGEMENTS

The author acknowledges the work of Michael Crossley that contributed to this paper, and also students, colleagues and all the engineers who contributed their time and patience.

Work in Progress: Engineering Education and Pragmatism:

Imagining an Undergraduate Engineering Course based on the Educational Philosophy of John Dewey

Abstract—In this paper, we attempt to envision -- in the spirit of a mind experiment -- a specific and practicable engineering course (an engineering studio) using as our guide the basic principles of John Dewey's educational philosophy, which continues to influence all levels of American education (as can be seen, for example, in references to his ideas on education in the Boyer Report).

Keywords—component; philosophy of engineering; pragmatism and engineering; Dewey and engineering; engineering synthesis; open design

I. INTRODUCTION

The paper first situates Dewey's educational philosophy as one articulation of American Pragmatism, which itself represents one set of responses to traditional or Platonic philosophy. In all currently viable philosophical currents responding to that traditional philosophy, "practice" has become the central epistemological trope. However, despite this tectonic philosophical shift and despite the emphasis on "practice," engineering education continues to justify its curricular choices and pedagogic practices in Platonic terms. This paper attempts to envision a course that envisions those choices and practices in terms of John Dewey's articulation of Pragmatism.

A starting point of pragmatic educational philosophy is its refusal to see thought (and ideation) as fundamentally opposed to practice. This opposition is most visible in the popular image of the "doing engineer" who competently solves the problems of the "thinking boss." In Deweyan educational philosophy, the goal of education is freedom, that is, the student's ability to formulate intelligent purposes^[1-6]. Thus, students cannot be presented with unchanging goals of their education, unchanging results of other people's inquiries as "knowledge," and unchanging paths to achieving those results as "method," and then expected to become inquirers.

Dewey would insist that students must participate in formulating the ends and means of their educational activities, that is, engage in rational assessment of values, whether accepted values (standards) or pursued values (goals), at every stage of their education: By formulating their goals and interests, by critiquing them from multiple angles, by settling on some goals, by actively thinking about the routes to achieving those goals, and by always being

open -- given the resources available -- to revising both the paths and the goals.

In a previous article, the authors proposed a re-framing of the epistemological basis of engineering education in pragmatic terms^[7]. In this work, we would like to offer a mind experiment imagining a concrete, practical engineering course or set of courses based on Dewey's educational philosophy.

Dewey's educational philosophy revolves around the idea of inquiry, that is, an activity (practice) that people engage in when they come out of balance from their environment. Dewey divides this idea into five parts: "(i) a felt difficulty; (ii) its location and definition; (iii) suggestion of possible solutions; (iv) development by reasoning of the bearings of the suggestion; (v) further observation and experiment leading to its acceptance or rejection; that is, the conclusion of belief or disbelief"^[3].

The following aspects of Dewey's idea of inquiry are important for the discussions in this paper. According to Dewey, all thinking begins with a problem. The problem itself arises from already ongoing activities of the inquirer, which are based on the interests, identities, and the values adopted from the social world of the inquirer.

II. DEWEYAN EDUCATIONAL PHILOSOPHY

For Dewey, the goal of education is freedom, "power to frame purposes," to judge wisely, to evaluate desires by the consequences which will result from acting upon them; power to select and order means to carry ends (purposes) chosen by the student into operation. The final goal is creating of conditions of growth both for the student and for society.

Modern theories of knowledge have several pedagogic implications. We will mention some that will be relevant to this work: i) Knowledge remains theoretical, subject to change and revision. ii) The learning environment must demonstrate its openness to change: Instructors may have to change their syllabi, their projects, their overall teaching strategies, etc. iii) Teaching of facts should primarily take place within the context of inquiry

If the curriculum is to succeed in creating conditions in which an accelerated process of real inquiry (an inquiry that matters to the student in that the student has ownership over the problem the theory tries to solve), then of course the student should also be encouraged to doubt and question the theory.

There are many ways in which the Deweyan educational philosophy can be incorporated in engineering curricula. We believe one of the best entry points is the engineering laboratory and engineering design. In the next section, we will briefly look at the role of engineering laboratory and engineering design and discuss how they might be modified to accommodate the principles of Deweyan educational philosophy.

III. ENGINEERING LABORATORIES

A. Laboratories

Laboratories in engineering have always had two purposes. First, focus has been to show, teach, and allow students practice with the known standards, trade know-hows, instrumentation, measurements, and basic blocks of engineering and engineering design. Second, to allow students to practice the art of engineering from identifying a problem, to research the problem, to identify specifications, objectives, and to go through the iterative process of engineering design (Synthesis of their knowledge).

IV. OUR COURSE AND CURRICULAR ISSUES

In order to help engineering students to grow into thinking and educated members of society who can systematically face challenges and push the knowledge base and possibilities to new levels we need to have more integrated forms of synthesis and coaching of our engineering students. We propose a new engineering studio class where a group of student together with a group of faculty, teaching assistance, and student mentors interact. We believe such classes can be most effectively modeled to a Deweyan class. While studio classes are proposed and have been implemented, we believe a Deweyan based studio classes will be most effective for engineering students^[8, 9].

A. Standard Studio Classes

One way to achieve this is to create a modified version of the "studio" class for engineering students. Studios are routinely used in architecture and design programs. Studio classes are less regimented than regular classes and more focused on group work. Class activities include some or all of the following: i) Research, experimentation, hands-on shop work, and other opportunities to learn from failures. ii) Collaboration involving discussion and debate; iii) Ongoing group presentations iv) Documentation of the process for creating a final product (which can be research work, analysis, or final design of a physical product); v) Presentation of the idea, processes, and the product to a review team.

The Studios that are coached by faculty (and at time by a group of faculty) provide such an environment. Faculty will spend more time discussing, listening, coaching, and inspiring students in small groups, and will see and help students progress at all levels. Studios and open labs provide progressive steps and challenges that help students grow in their: i) knowledge integration, ii) active, on-going

learning, iii) team work, iv) learning from trial and error, v) perseverance, and presentation.

V. STUDIO MODEL ADAPTED TO DEWEYAN EDUCATIONAL PHILOSOPHY

The modified studio faces the problem of how to incorporate flexibility in how the ends and means of the course are envisioned. There can be many different venues of effective projects. In general projects with practical goals with some open-ended possibilities and approaches are ideal for such a class. By choosing open ended engineering problems that start with an engineering challenge and following Deweyan knowledge inquiry process, we can create environments that help student growth, emphasis scientific method, democracy, and communication, help decentering the disciplinary authority and reach specific disciplinary goals.

VI. FINAL REMARKS

In this paper we explored some of the ways in which the ideas of John Dewey could help enhance engineering education. By adapting the studio model to Dewey's ideas, students will be presented with more flexibility, diversity of perspectives, and open problems, as well as opportunities for collaboration to enhance students' ability to use their creativity and to synthesize their learning.

This research was supported partially by National Science Foundation DUE0837314.

Work in Progress: Phenomenographic Perspective on Engineering Students' Experience of Interdisciplinary Learning

Ming-Chien Hsu

School of Engineering Education, Purdue University, West Lafayette, IN, USA
mhsu@purdue.edu

Abstract— With challenges engineering education faces in meeting societal needs, learning in an interdisciplinary setting has the potential to provide engineering students with opportunities to consider alternative perspectives and engage in deep learning approaches. Few empirical studies have explored interdisciplinary learning situated in other learning literature. This work-in-process explores the variance of students' experience of interdisciplinary settings. A phenomenographic framework is used to guide the methodology of the study. Maximum variation sampling is employed when collecting data using semi-structured interviews with 20-30 engineering students about their concrete experience of interdisciplinary learning. The literature and research on interdisciplinarity as well as adult learning inform the construction of the phenomenographic study and will provide ways to interpret and situate the results. The interpretive framework includes elements from theories of transformative learning, encountering others, and interdisciplinary topology.

Keywords—interdisciplinary learning; phenomenography; encountering others

I. INTRODUCTION

Interdisciplinarity has been described as “a process of answering a question, solving a problem, or addressing a topic that is too broad or complex to be dealt adequately by a single discipline or profession... [which] draws upon disciplinary perspectives and integrates their insights through construction of a more comprehensive perspective [1].” One reason to include interdisciplinary learning opportunity in the engineering curriculum is that real world problems are inherently complex and understanding and solving those problems requires different knowledge and perspectives, and team design projects are often used in engineering curriculum to provide engagement with real world problems. Proponents of interdisciplinary learning have also argued that students are more likely to engage in deep learning approaches in such contexts [2].

Existing literature on interdisciplinary learning identified process, outcomes, and barriers of interdisciplinary learning. Nikitina concluded from interviews with teaching professionals and from classroom observation that contextualizing, conceptualizing, and problem-centering are three strategies used in interdisciplinary curricula [3]. Frutchter and Ritcher proposed that becoming interdisciplinary

is a journey from the state of *islands of knowledge* to *understanding* [4]. Schaffer, Lei, and Paulino have also identified the process of *identification*, *formation*, and *adaptation* as a framework to understand interdisciplinary learning and teamwork [5]. Additionally, Adams et al. found that engineers experience interdisciplinary practice in qualitatively different ways, and two of those include *working together* and *intentional learning* [6]. However, Ritcher and Parretti found that students often failed to connect the problem at hand to their identified fields of expertise and to value the contributions of multiple fields [7].

Other studies explored factors associated with interdisciplinary learning. Gender and disciplinary association are found as factors influencing how students frame an interdisciplinary design problem [8]. Additionally, class standing is associated with improvement in self-efficacy of interdisciplinary learning in project-based teams [9].

II. PURPOSE

No study has explored the nature of student learning experience in different interdisciplinary settings. To address the need, this proposed study seeks to examine the qualitatively different ways engineering undergraduate students experience learning in interdisciplinary environments.

III. METHODOLOGY

The design of the study is shaped by a number of frameworks. A phenomenographical framework is chosen as the methodological framework since it allows the exploration of critical variation among students' experience. Phenomenographic studies usually use interviews as the primary mode of data collection. A semi-structured interview protocol is used to probe concrete experience of interdisciplinary learning. Most phenomenographic studies include 20 to 30 participants. Data analysis is done at the transcript level, meaning no experience can be understood without others [10]. The outcome space of a phenomenographic study is a critical variation in the experience called “categories of description” and that has an “inclusive structure” relating the different categories forming a hierarchical structure [10]. The categories should emerge from the data instead of being pre-determined. Data collection will

be ongoing until no more new categories emerge. The outcome space provides a way to look at the collective experience of interdisciplinary learning of engineering students.

The literature and research on interdisciplinary learning and teaching topology [11], transformative learning [12], and engagement with others [13] also guides the design of the phenomenographic study in terms of sampling. These frameworks might also be able to help situate the results of the study once the categories of description emerge from the data.

IV. STUDY DESIGN AND PARTICIPANTS

Participants are recruited from engineering undergraduate programs at a Midwestern university. A purposeful maximum variation sampling is used to recruit participants of the study. A pre-interview survey is filled out by prospective participants to ensure participants have a wide range of interdisciplinary learning experience. Instead of only considering participant attributes such as gender, race, academic class, and discipline affiliation, we recruit participants with experience and coursework reflecting variations of the following characteristics:

A. *Topology of Interdisciplinary Learning Experience [11]*

- Informed interdisciplinary (courses and projects informed by other disciplines), such as cross-listed courses
- Synthetic interdisciplinary (courses and projects combining identifiable disciplines), such as a course that analyze an event from the perspectives of engineering, sociology and art
- Transdisciplinary (courses and projects no longer associated with single disciplines), such as the Africa water supply project and haptics project

B. *The Degree of Engagement with Others [13]*

- No partners or clients
- Projects with team members and local clients
- Projects with team members and remote clients

C. *The Extent to which Experience Reflects Elements of Transformative Learning [12]*

- Different degrees of instructor support and scaffolding

Prospective participants are recruited from programs and courses that satisfy the described criteria. Some of these courses and programs include the global engineering program, a service-learning program, an engineering undergraduate summer research program, and cross-listed courses.

V. INTERVIEW PROTOCOL

A phenomenographic interview focuses on discussion of concrete experiences in order for the participants to share their understanding about a specific aspect of the world. The

interview protocol is semi-structured beginning with participants' background information. Then, participants are asked to describe one concrete experience involving learning in an interdisciplinary setting. Afterwards, they describe another interdisciplinary learning experience and explain how it differs from the first experience. Finally, participants are asked questions that are intended to probe meanings they associate with interdisciplinary learning. The interview is meant to provide reflective data situated in concrete experiences.

VI. IMPORTANCE OF THE EDUCATIONAL COMMUNITY

All accredited engineering programs include interdisciplinary learning opportunities of team-based design project as part of their curricula. However, being in a team does not guarantee students can learn to function in a team and learn to work with other perspectives. By capturing the critical variations of student learning experience of interdisciplinary courses and projects, this study seeks to provide insights on the design and structure of these learning opportunities. The outcome space will also provide a developmental perspective of increasing comprehensive view of interdisciplinary learning.

VII. PROJECT STATUS

Interviews are currently being conducted and will be ongoing until categories of description saturate. Analysis is being conducted concurrently. Participants encountered differences in instructor coaching style and team dynamics which influenced how they experienced learning. So far, all participants chose to talk about their formal education experiences in classrooms when they are asked to describe an interdisciplinary learning experience, but when asked to describe another interdisciplinary experience, some participants drew from less formal experiences such as residential life, internships, and entrepreneurial competitions.

Results of a phenomenographic study are only meaningful when the comparison of all transcripts is completed. Preliminary results of the outcome space on interdisciplinary learning will be available at the time of the conference.

Applying philosophical inquiry:

Bringing future engineering education researchers into the philosophy of engineering education

Robin S. Adams, Alice L. Pawley, Brent K. Jesiek

School of Engineering Education

Purdue University

West Lafayette, IN, USA

rsadams@purdue.edu, apawley@purdue.edu, bjesiek@purdue.edu

Abstract—An ability to apply philosophical inquiry to both create and critique arguments about the current and future state of engineering education is a critical capability for future engineering educators to develop. However, there are few, if any, examples of how to do this. In this paper we describe a course that we have been offering for four years at Purdue University, *History and Philosophy of Engineering Education*, as an example of how to address this gap. We describe the learning objectives, conceptual frameworks used, learning and assessment activities, and examples of course assessments that illustrate learning outcomes.

Keywords – philosophy; epistemology; graduate education; professional development; engineering education research, history

I. INTRODUCTION

The philosophy of education is the study of education problems such as the goals of education, access to education, the process of education, and the role of government in education [1]. Philosophers of education draw on a variety of tools to examine and critique these problems, in particular philosophical inquiry. Philosophical inquiry involves exploring positions, or “arguments”, about what is and should be, critiquing the likely outcomes or consequences of these arguments, and persuading others that these consequences should be valued [1]. As such, philosophical inquiry can guide education transformation initiatives and play a critical role in shaping new fields or disciplines. Therefore, an ability to apply philosophical inquiry to both critique and produce arguments about the future of engineering education in postsecondary institutions is a critical capability for future engineering educators to develop [2].

In this paper we describe a novel and unique course that we have been offering for four years at Purdue University, *History and Philosophy of Engineering Education*, as an example of how to prepare future shapers of engineering education. The course may be viewed as an example of “scalable scholarship” [3] for training the next generation of engineering education scholars. The course is considered unique because of its specific focus and approach for preparing engineering education professionals, and the interdisciplinary effort to bring together scholarship from educational philosophy, history of higher education, science technology and society studies, and philosophy of science, engineering, and technology. This involves integrating research from a variety of professional communities, journals (e.g., *Engineering Studies*, *Research in*

Higher Education, *Technology and Culture*, and *Studies in History and Philosophy of Science*) and conferences (e.g., Philosophy of Engineering¹ and the Forum on Philosophy, Engineering and Technology², and the American Society for Engineering Education). In the following sections, we describe the course objectives, structure, frameworks, and topics and content. We also provide examples of student evaluations and coursework that illustrate some of the insights students gain through the course, as well as challenges they face as they encounter paradox, ambiguity, and competing paradigms.

II. COURSE BACKGROUND

In this graduate-level course, we examine the history and philosophy of engineering education through tools that guide critical analysis of philosophical, epistemological, ontological, and historical arguments such as: what is (and should be) engineering, what is (and should be) the purpose and process of engineering education, who gets to be an engineer (and who should be), and what shapes these decisions (and what should shape these decisions). Learning objectives focus on developing a culture of critical reflection and a tolerance of ambiguity, identifying and understanding tools to inquire into the history and philosophy of engineering education, using these tools to form arguments for oneself and for others about engineering education, and developing a perspective or identity as an engineering education scholar.

This course is taught during the first term of the graduate program and represents a foundation course required of all graduate students. As a foundation course, it sets students on a pathway of inquiring deeply, early, and often into critical questions about engineering education that shape choices about research goals, questions, designs, and impact plans. It is also an entry point for students to learn how to understand and value multiple perspectives or new ways of thinking, and to link their personal professional goals with what it means to be an engineering education scholar and change agent.

Inquiry tools used in the course include (see Appendix): (1) reflective practice and “sitting comfortable with paradox”, (2) drawing on insider (engineers) and outsider (those who study engineers) perspectives to reveal what engineers know and how they know it, (3) philosophies of education that argue for particular aims, purposes, and processes of education, (4)

¹ <http://www.raeng.org.uk/societygov/philosophyofeng/default.htm>

² <http://philengtech.org/>

archival research and historical documents that reveal enacted philosophies of engineering education, and (5) boundary work metaphors to understand the managing and policing of ideas about the aims of engineering education, the nature of engineering knowledge (epistemology), and the nature of engineering being (ontology).

III. COURSE STRUCTURE

The course is three credits in a 16-week semester system, offered for the last four years in one three hour class period held once a week. The course is set at the 500 level, as an introductory graduate-level course primarily for engineering education graduate students. Graduate students in other programs have been encouraged to enroll, and each year the course tends to include students from other engineering and education disciplines, as well as students from technology and psychology.

Four course tasks support the course's learning goals:

- Weekly discussions on readings in class. We have used Nel Noddings' *Philosophy of Education* [1] as a key reference text, and have produced a reading list of articles and book chapters to provide additional breadth and depth (see Appendix). Class periods usually entail a mixture of individual reflection, group discussion (in small groups and amongst the whole class), specialized activities, and peer review opportunities.
- Reflective essays students share with each other on a course blog or protected discussion page. The purpose of the reflective essays is to help students prepare for class discussion, develop reflective practice skills, and gain confidence with actively participating in discussions whether they be in class or in public communication forums.
- Three short synthesis papers in which they receive peer and instructor feedback and on which they can iterate. The papers parallel the course content: What is engineering? What is education? What is engineering education? Papers are evaluated on the quality of the arguments they make, their completeness (whether they address the overall guiding questions), whether they are grounded in the literature we have discussed in class (or additional literature), and whether they are well-organized (both macro and micro-structure), clearly written, and engaging. The last essay, treating the question of "what is engineering education?," is expected to be of the quality that students could include it in a portfolio of their graduate work.
- A YouTube video, produced in groups of 3 or 4, that presents a philosophy for the future of engineering education. The YouTube project was designed to provide opportunities to reflect on course ideas and to translate them into action in a way that may engage the broader engineering education community. The YouTube video project has been presented in more detail elsewhere [4], and are publicly available on YouTube at <http://tinyurl.com/ene502-youtube>.

Course assessments include an end-of-course evaluation, open-ended student feedback at multiple times through the course, and feedback forums through our Graduate Student Association.

IV. COURSE FRAMEWORKS

Choices regarding frameworks for designing the learning experience were made based on insights from engineering education research capacity-building programs [5-6] and efforts to help students connect the course objectives to the graduate program as a whole and to the broader profession. A particular challenge was helping students move from a problem solving mindset to a problem framing mindset that involves developing persuasive arguments about the past, the present, and the future. Over the multiple offerings of this course, it became clear that students would experience questions such as "what is engineering" as something that has a correct answer, rather than something that might have many plausible answers. As such, it was important to help students become comfortable with ambiguity and living with paradox.

Other work illustrates the challenges of transitioning from disciplinary to cross-disciplinary mindsets, learning and valuing new language and ways of thinking, navigating the existing literature, dealing with the complexity and ambiguities of education research particularly qualitative research, and evolving interdisciplinary identities [5-10]. Efforts to alleviate or address these challenges involve supporting a community of practice through group projects and peer feedback on course reflections and essays, attending to language and epistemological differences in course readings, focusing course essays on synthesis and identity formation, and scaffolded instruction on difficult concepts such as "what is an argument" and "what does it mean to ground an argument".

To help students connect their learning to the graduate program as a whole, we mapped the course objectives to the School's competencies required for student graduation³. We also used Shaffer et al's [11] epistemic frame structure of knowledge, skills, identity, values, and epistemology to communicate course objectives as a broader set of professional lenses.

V. COURSE TOPICS AND CONTENT

The course has been structured into three key questions for students to consider:

- What is engineering?
- What is education?
- What is engineering education?

These have been addressed in different orders over the various iterations of the course, with the most recent iteration in the order given above.

We begin the course with a discussion about "tools for thinking" that we use throughout the course: reflecting in and on action [12], paradoxes, and sitting with tension [13], boundary work [14-15], and classification as a political act

³ <https://engineering.purdue.edu/ENE/Academics/Graduate/competencies>

[16]. To discuss “what is engineering,” we treat engineering as a science and as a profession [17-19], as design [20-22], and as sociotechnical practice [23-24]. We also explore how engineering is viewed by outsiders compared to insiders [25-26], using the tool of boundary work to help us position ourselves.

To discuss “what is education,” we work through the majority of a text by Noddings [1], regularly taking time to collectively synthesize the arguments she represents through tables on the shared discussion board on Blackboard, allowing us to summarize different goals/aims/purposes of education as represented by various philosophers of education, who they think should be educated, and what the consequence of this philosophy has been on modern US educational systems.

The topic of “what is engineering education” is treated in more depth than the previous two. We spend two class periods looking at historical perspectives on engineering education, both reading engineering education reports [e.g. 27-28] as primary sources, and scholarly works [e.g. 29-30] describing different historical aspects of US engineering education. We particularly look at how engineering education systems have explicitly and implicitly excluded women and people of color except in times of national need [e.g., 31-33]. We then shift to more contemporary perspectives on engineering education [34-36], including some of the more recent reports on engineering education reform. In the most recent iteration of the course, we broadened perspectives from the US-centric perspective to incorporate more cross-national perspectives [37-38]. We also have added an explicit discussion of engineering education research as a topic, again treating this from a US perspective [39-43], then cross-national perspective [42-44]. We end the course with a final activity to help students synthesize key ideas discussed, and the YouTube Extravaganza where students present their videos to their peers and the broader community.

VI. COURSE EVALUATION AND STUDENT WORK

Course evaluations were conducted at the course and program level. Each year students complete an end-of-term survey that includes questions about the overall experience and questions targeted towards specific aspects of the course. In particular, some questions ask students to rate the quality of the learning environment (i.e., clarity and organization of course, quality and balance of assignments, collaborative learning, team teaching, and supportive and respectful culture), and others ask students to rate the impact of the course on their learning (i.e., contributions to personal and professional growth, improved critical and reflective thinking, improved synthetic reasoning abilities, and broader perspective). The overall course evaluation has consistently been 4.7 out of a possible 5.0, and students’ average rating of the extent to which instructors “ask questions which challenge me to think” was 4.9 out of 5.0. An example of course evaluations from one offering is provided in Table I.

Course evaluations also include open-ended questions. Students often comment about how the course helped develop a tolerance for ambiguity and multiple perspectives, and provided tools to inquire into engineering education issues that they can use now and into the future. Some examples of these are provided below:

“...before this class, I was not a huge fan of history OR philosophy. However, thanks to this course I have come to appreciate these subjects and plan to go back over some of the readings at a later time. Thanks for making the content interesting and showing how it applies to ENE. The engineer-in-me loved the practical element of this course.”

TABLE I. COURSE EVALUATIONS , FALL 2010, N=15

| Evaluation Survey Questions | Mean out of 5.0 |
|--|-----------------|
| CLARITY AND ORGANIZATION OF COURSE | |
| Course requirements are clear. | 4.6 |
| Required course activities are consistent with course objectives. | 4.4 |
| The course appears to be well organized. | 4.6 |
| QUALITY AND BALANCE OF ASSIGNMENTS | |
| This course strikes a good balance between reading, discussion, and writing. | 4.5 |
| Assigned readings help me understand concepts discussed in class. | 4.5 |
| Course assignments help me learn on my own. | 4.4 |
| This course helps me clarify my ideas through writing. | 4.5 |
| One real strength of this course is the classroom discussion. | 4.3 |
| Class discussions are helpful to my learning. | 4.3 |
| This course provides an opportunity to learn from other students. | 4.6 |
| COLLABORATIVE WORK AND TEAM TEACHING | |
| Collaborative work is a valuable part of this course. | 4.5 |
| The group work contributes significantly to this course. | 4.1 |
| The teaching methods used in this course enable me to learn. | 4.3 |
| Team teaching is effectively used in this course. | 4.5 |
| Team teaching provides insights a single instructor cannot. | 4.4 |
| SUPPORTIVE AND REFLECTIVE CULTURE | |
| When I have a question or comment I know it will be respected. | 4.7 |
| I am free to express and explain my own views in class. | 4.5 |
| Class sessions were interesting and engaging. | 4.5 |
| CONTRIBUTIONS TO PERSONAL AND PROFESSIONAL GROWTH | |
| This course builds understanding of concepts and principles. | 4.4 |
| This course contributes significantly to my professional growth. | 4.4 |
| This course gives me an excellent background for further study. | 4.4 |
| My work is evaluated in ways that are helpful to my learning. | 4.5 |
| IMPROVED CRITICAL / REFLECTIVE THINKING, SYNTHETIC REASONING, AND BROADER PERSPECTIVE | |
| This course effectively challenges me to think. | 4.7 |
| This course has been intellectually fulfilling for me. | 4.4 |
| This class provides a meaningful learning experience. | 4.5 |
| This course stretches and broadens my views greatly. | 4.7 |
| My critical thinking skills improved because of this course. | 4.3 |
| This course helps me synthesize information from several sources. | 4.5 |

“Instructional team was excellent at facilitating the class as a whole through a fairly intense learning process. They both did an excellent job of balancing our need for reassurance and comfort with their demand for excellence and high-level, synthetic thinking.”

“I really believe I walked into a class that was designed

to intentionally grow students in a way that balances self discovery and instruction. Concepts were linked without the information being forced, students can trace the connections on their own...I felt pushed at times, given an adequate break at other times, and important topics came full circle in the end....The dialogue was also appreciated and huge part of my learning, it could also be that I come from a discipline where dialogue does not happen very much and this all very exciting and new."

"I thought this class was exceptionally difficult, but I can't recall a time where I feel like I made so much progress in such a short period of time."

"Great at asking questions that cause me to pause and think. I need more of that type of questioning perspective."

In addition, in the spring of 2009 our graduate students conducted a full program review where more than half of the student body participated in two 1.5 hour discussions on what is working well in the program and opportunities for improvement. This was designed and led by our Graduate Student Association, who synthesized the discussion and submitted a report to the Graduate Committee. Regarding the course discussed in this paper, there was strong support for the iterative assignments and how they help students develop over the course of the semester. When asked to describe how the course prepares them for the future or fits within the rest of the program, students responded: "This course works to shift our thinking beyond our preconceptions and assumptions about engineering and engineering education" and "helps build a community of intellectual questioning and discussion that can be used throughout the curriculum."

Finally, the YouTube project videos are developed to be public, and are showcased at an end-of-semester celebration open to the school, college, university, and community. They are posted to YouTube and collected into a playlist (<http://tinyurl.com/ene502-youtube>). Readers of this paper are encouraged to review and critique students' YouTube videos and the ways they demonstrate students capabilities to inquire into the history and philosophy of engineering education and the extent to which they can present arguments that are clear, organized, grounded, and engaging.

VII. CONCLUSIONS

Drawing on the work of Gramsci, Downey uses the term "scalable scholarship" to describe how academic teachers and researchers might critically participate in worlds of practice. Situating his remarks at the productive intersection of science and technology studies (STS) and engineering education, he explains: "[S]caling up involves inquiring into what is taking place when scholars not only conduct research on engineers and engineering but also design and teach courses for engineering students, serve on official panels and advisory committees, offer presentations to engineering audiences, and help build a new discipline focused on engineering education" [3]. When one embraces scaling up, it requires showing how critical, theoretical analyses of practice have meaningful implications for practice, all the while remaining wary of the dangers of co-optation, resistance, or worse - being ignored.

Classrooms can help open up new spaces of opportunity for relating ideas to life, and linking critical inquiry to concrete action. By engaging foundational philosophical questions about what counts as engineering, education, and engineering education, the course described in this paper encourages graduate students to undertake critical self-reflection, which may in turn place them on transformative learning pathways [45-46]. In part, we are successful when we are able to help people see the world in new and different ways, including through productive dialog with both one another and the ideas, texts, and authors explored in the class. Yet ultimately, the real test of our labors is whether our students are able to carry the course with them into future situations and contexts, using it as a foundational scaffold to proactively interrogate and transform dominant practices in engineering education and professional practice. Such is the spirit of scalable scholarship.

ACKNOWLEDGMENTS

We'd like to acknowledge the contributions of Karl Smith, who helped design the first offering of the course, and Holly Matusovich, who was an Apprentice Faculty for that first offering. We also thank the students who have taken this course over the last few years and contributed to its iterative development.

| 10 | What is engineering education? Historical perspectives on engineering education, Part 2 Assignment: "What is education?" essay due Reading, references: [30, 31, 32], and Bix, Amy Sue. (2005). "Engineering National Defense: Technical Education at Land-Grant Institutions during World War II." In Alan I. Marcus, Ed., <i>Engineering in a Land-Grant Context: The Past, Present and Future of an Idea</i> , pp. 105-133. Purdue University Press. |
| 11 | What is engineering education? Contemporary perspectives → Tools: Boundary work Assignment: "What is Engineering Education?" essay assigned Reading, references: [14, 33, 34, 35], and ASCE. (2008). Civil Engineering Body of Knowledge for the 21st Century Preparing the Civil Engineer for the Future (Second Edition). Executive Summary and Chapter 1. |
| 12 | What is engineering education? Cross-national perspectives → Tools: Historical ethnography Reading, references: [36, 37] and ONE additional paper/chapter focused on a specific country (see Blackboard). |
| 13 | What is engineering education research? Origins and American perspectives Assignment: Draft design of YouTube videos for peer review Reading, reference [2], Chapter 7 and references [38, 39, 40] |
| 14 | HAPPY THANKSGIVING – no class! |
| 15 | What is engineering education research? Cross-national perspective and current trends Reading, references: [41, 42, 43] |
| 16 | Synthesis of the course Peer review of engineering education synthesis essays done in class |
| Finals | Final presentations: YouTube videos and rationale Electronic copy of "what is engineering education?" essay and YouTube rationale due |

A Philosophy Driven Curriculum: the Example of an Engineering Science Course in England

John Heywood
Trinity College Dublin
Ireland
heywoodj@eircom.net

Abstract

During the last thirty or more years a number of articles about engineering education have suggested that one of the reasons why the goals of engineering have not been achieved is the lack of a proper philosophical base to provide the guidelines needed. At the same time a number of those involved in engineering course design have found it necessary to use the term philosophy when talking about the rationale for their courses. Inspection of such descriptions suggests they are describing a “naïve” philosophy rather than a curriculum that has an “operational” (working) philosophy that drives curriculum design, implementation and evaluation.. This paper describes a course in engineering science at ‘A’ level for university entry in England and Wales that was epistemologically driven, and examines the extent to which it achieved its goals.

The discussion is prefaced by a short description of the system of selection to universities in England at the time of the development. At that time students seeking admission to university engineering departments were expected to have performed well in examinations that corresponded to first and or second year university courses in other parts of the world in physics, and pure and applied mathematics taken as separate subjects. It was proposed that physics should be replaced by engineering science. A major reason for this was the well documented attraction that students had for physics as opposed to engineering. It was argued by the product champion that more students would be attracted to engineering if they understood that it was a different way of thinking to physics. Thus the examination had to be equivalent to physics yet encourage a different way of thinking. It was found that in order to achieve this goal, different approaches to examining and assessment had to be introduced. It was also found that for curriculum goals to be achieved assessment had to become an integral part of the teaching-learning process rather than an afterthought. The paper describes the introduction of this examination as an alternative to physics and considers what it achieved, and why over a twenty year period it eventually failed.

Key words *Assessment; Curriculum development; examinations; operational(working) philosophy; syllabus*

INTRODUCTION

There has been increasing interest in the philosophy of engineering and engineering education since Bucciarelli [1] and Koen [2] made major contributions to these topics in 2002. Since 2006 conversations have taken place in a series of international workshops focused on the philosophy of engineering [3], and separately through special and paper

sessions at successive Frontiers in Education Conferences that focused on the role of philosophy in engineering education. These culminated in a workshop at the 2011 Conference sponsored by the ERM Division of ASEE, the IEEE Education Society, and NSF. The associated bibliography and accompanying commentary [4] did not develop the concept of “operational (working) philosophy”, or find examples of curriculum that were philosophically driven. As a contribution to these discussions this paper presents an example of the development of an engineering science curriculum in the UK that was philosophically driven.

In the context of education operational (working) philosophy describes the value (belief) system that drives a particular curriculum, syllabus (detailed list of content), course or teaching session. It is the personal motivation of individuals that sustains them or drives them to change or seek change. It is analogous to the working capital required for a firm to keep functioning. Sometimes the statement that emerges is so brief as to be meaningless; at other times it is substantive. The need to define a philosophy seems to be felt when new courses are proposed and the new course needs to be justified. A basic need has been to establish what is distinctive about engineering education when compared with physics. Is engineering education simply the application of physics or is it something more? [5] This paper describes the operational philosophy and its effects on the development of a public examination for university entry in engineering science intended as an alternative to physics in England for university entry. It had a profound effect on the design of the examination and assessment, and also led to an epistemology of practical work in engineering. A major innovation was a statement of attitudes, motives and interests that the curriculum should foster. This innovation continues to be of interest because it illustrates problems in the process of curriculum design and evaluation, and it is the progenitor of the model that a committee of the US National Research Council used to illustrate balanced system of school and national assessment [6], [7]. The paper complements the semi-official history of the development [8].

II THE SYSTEM OF ENTRY TO UNIVERSITIES IN ENGLAND AND WALES CIRCA 1965

A very small percentage of students in 1965 entered university from state funded schools. These came mainly from grammar schools. The principle requirement for entry was that students

at the end of their schooling (aged 17 or 18) they should have obtained good grades in three or four subject examinations nicknamed 'A' levels (General Certificate of Education-Advanced) [9]. University departments specified what 'A' levels a student should offer. Engineering departments required all students to take physics and mathematics (pure and applied – or taken as separate subjects). If pure and applied mathematics was taken as a single subject departments would ask the candidate to offer another science subject such as chemistry. 'A' levels were considered to be of the same standard as first year courses in four year programmes offered by universities in the English speaking world [10]. These examinations were set by matriculation boards [11], and the examination for each subject consisted generally of two three hour written papers, and in the sciences some form of practical (laboratory) work. This paper is about the development of an 'A' level syllabus in Engineering Science by the Joint Matriculation Board (JMB) as an alternative to physics for entry to university engineering departments. A major purpose of some of the players was to attract a better quality of student into university departments of engineering. Others were concerned with the educational possibilities on offer.

III ENGINEERING SUBJECTS AND THE JOINT MATRICULATION BOARD CIRCA 1965

The functions of these examining authorities were to issue syllabuses (statements of required content), which they designed, implemented and examined. It was a stated principle that they did not interfere with the way the subject was taught. This was the responsibility of the schools and their teachers. Most schools in the north of England took the examinations set by the JMB.

Between 1956 and 1965 there was a continuing debate about the need for examinations in the general area of engineering at 'A' level within the JMB. Nothing had come of various suggestions but a syllabus for Engineering Science at A level had the conditional approval of The Schools Council, a body delegated by the Ministry of Education to regulate the system. The Council was concerned that the extensive coursework required would only be used as a hurdle and not graded. Concern was also expressed by one of the JMB's constituent universities that the syllabus would not be acceptable for admission to university departments.

At this stage the Dean of the Faculty of Engineering Science at the University of Liverpool suggested a major re-appraisal of the syllabus which took two years. During this time Professor Edels became the product champion of new syllabus, which began the emergence of the philosophy to be discussed [12].

IV THE EMERGING PHILOSOPHY

Edels believed that able high school students preferred physics to engineering because they did not understand what

engineering was about. He felt that in high school pupils should be exposed to the engineering habit of mind [13]. This was the purpose of replacing physics with engineering science as an entry requirement to university engineering departments. At the same time it would have to be seen to be the equivalent of physics, if university admissions officer were to select candidates with good grades in engineering science. Thus the examination had to be firmly based in science (physics) and at the same time convey the essence of engineering. Edels had to campaign among his colleagues and school teachers that the habit of mind was as important as the principles, but those principles would not be sacrificed if this approach was adopted. This approach placed a major constraint on the development of the syllabus. This was acceptable to the progenitors since they understood engineering to be the application of science to practical problems.

V ORGANIZATIONAL HELP

The JMB was advised that teachers who were likely to be physicists may need considerable help to adjust to the philosophy and delivery of the subject. Accordingly it created a co-ordinating committee in December 1966 with a remit to supply extensive resource material. At the same time with the support of the Schools Council Project Technology it was able to finance an education officer for four years, to advise schools about the subject and service the committee. This was a major policy departure for the Board. It meant that the syllabus could be developed independently of a subject committee, in this case either physics or craft and technical subjects, and the committee could engage, with some limitations, in curriculum development. It established four working groups. (1) A teacher training group engaged with teachers through regular meetings, usually of a day's duration. (2) A group to write textbooks for each of the sections of the syllabus - were Mechanics, Materials Science, Transport Phenomena, Wave Phenomena, Field Phenomena, Basic Systems Analysis, Electron Physics and Devices, and Thermodynamics. The texts and teaching were to be written and conducted on the basis that "many physical and engineering concepts and processes are analogous and that concurrent study of such analogues would develop the integration and synthesis of thought required in the solution of relevant engineering science problems" [14]. (3) A Laboratory and Project Group; and (4) A Validation group that had the task of developing assessment procedures that would ensure the philosophy was met. Only through assessment could a "distinctive Engineering Science flavour that was not substitute for, or extension of, a pure science subject" [15] be achieved. It is the perceptions that students have of the requirements for assessment that governs student learning in assessment-led-for learning systems of public examination [16]. They had to take into account an edict "That, the course of study should provide an understanding of the constraints which operate in real life engineering situations" [17].

VI THE EPISTEMOLOGY OF PRACTICAL WORK

Early in the deliberations of the working parties a memorandum from two members pointed out that no attempt had been made consider the implications for the development of students as engineers that were a consequence of the original philosophy [18]. There was a need to consider the factors that lead to “the development of certain features characteristic of the personalities of engineers and physicists”. These differ because the approach to solving engineering problems is fundamentally different to solving physics problems. They distinguished between two types of student. The first was an engineering scientist who dealt with the physics of engineering, and the second was an engineering scientist who dealt with design. They argued that the first document on practical work favoured the first type. They thought it should be re-balanced.

To reinforce their point they gave operational definitions of engineers and physicists. They went on to argue “the balance and ordering of cognitive skills seems to be different between the two, thus physicists probably need more skill in comprehension and analysis (Bloom’s Taxonomy), whereas engineers require greater development of the skills of synthesis, application and evaluation”.

They believed that this could be rectified through the emphasis of design in the 50 hour project and the inclusion of short design projects for training for the compulsory project. (It had been approved that during the two year programme a student would complete a project investigation chosen by h/herself, to be completed in 50 hours of laboratory time).

They argued for greater flexibility in teaching and assessment, and supported their case with a substantial appendix of research carried out by Price and his students. In the event one of the six assessment categories was for design, and when the objectives for the whole syllabus were declared in the 1972 syllabus “synthesis” was linked with “design” (see exhibit 1) [19]. Examples of projects that had been undertaken by students in the previous three years were given in the 1972 Notes for Guidance on the subject. Most of them were prefixed with instruction “Design” (see exhibit 2) [20]. Prior to beginning a project students were required to demonstrate to their teachers and moderators that their chosen project would meet the requirements of a criterion referenced assessment system base on the abilities listed in exhibit 1 and other abilities stated in the syllabus. The candidate was provided with a quite specific list of questions that the project plan had to give answers. As indicated below the design debate did not go away. The 1972 syllabus also included a statement of attitudes, motives and interests.

VII ATTITUDES, MOTIVES AND INTERESTS

In a major departure from practice, one that was hotly debated in the Board the 1972 and subsequent syllabuses (published annually) included a statement of attitudes, motives and

interests [21]. The co-ordinating committee recognized that there were a group of aims that were associated with the “outlook and personality of the individual”. They did not believe that they could be measured directly but could “be detected in the way students tackle problems based both on syllabus content and on coursework. They published a list that was intended to help students develop an “engineering attitude to its highest level”. The list is shown in exhibit 3.

D. Knowledge, understanding and abilities to be tested
[...]

4. Synthesis and design

The ability to

- (a) Design the manner in which an optimum solution may be obtained efficiently and to propose alternative solutions taking into account the restraints imposed by material, economic and social considerations.
- (b) Make a formal specification, having decided on the design or scheme.
- (c) Make a plan for the execution or manufacture of the design or scheme.
- (d) Use observations to make generalizations or formulate hypotheses.
- (e) Suggest new questions and predictions which arise from the hypotheses formulated.
- (f) Suggest methods of testing these questions and predictions.
- (g) Find the optimum solution to an engineering design or other problem and give valid reasons for the rejection of alternatives.

Exhibit 1. The Synthesis and Design category in the Statement of knowledge, Understanding and abilities to be tested pp 3 and 4 in *General Certificate of Education. Engineering Science Advanced: Syllabus and Notes for the Guidance of Schools. Manchester, Joint Matriculation Board* [19]. The other categories were, knowledge and understanding; comprehension, communication; analysis; and evaluation and judgment. At the time it was thought these were hierarchically ordered.

VIII AN EXPERIMENTAL EXAMINATION

The freedom provided by this committee structure enabled the validation group to have a proposal for an experimental examination undertaken in four schools that had indicated they would enter students for the first sitting of Engineering in 1969. Set in 1968 the experimental examination broke with the convention of having two three hour papers of questions requiring long and short answers. Its authors were influenced by Furneaux’s study of engineering examinations at Imperial College [22], the *Taxonomy of Educational Objectives* [23], and a JMB examination in General Studies that tested the categories in the *Taxonomy* [24]. Furneaux had found that there was only one major factor tested in each of the written examinations. He suggested that it reflected an ability to pass examinations. An alternative explanation suggested that the factor was a particular form of mathematical analysis [25]. The Taxonomy showed that there were other important objectives

The design construction and evaluation of a model homopolar motor.
 The design and construction of a remote control land yacht
 The design and construction of a suspension and propulsion system for a chassis containing an electric motor for a mono-rail system with selected nylon track.
 The design of a roller towel machine.
 To design, construct and investigate a polariscope.
 To design, construct and test a vortex tube for amplification in a fluidic system.
 To design and construct a machine to record vehicles entering and leaving a car park.
 To design and construct an automatic level crossing for an "00" gauge model railway.
 Design a simple pile driver and investigate the forces acting during its operation.
 Development of a demonstration gyroscope.
 To design and construct a teaching aid for the demonstration of mechanical resonance and damping.

Exhibit 2.. Examples of projects completed by students cited in the 1972 *Notes for the Guidance of Schools*. Pp 29 and 3 [19].

(outcomes) that should be tested. Therefore, an examination was designed that would test specific domains (skills) related to what it was thought engineers would need in the workplace. They designers understood that this examination could have a profound effect on teaching.

The first part of the examination was of the traditional kind requiring short (10 minutes) and long (30 minutes) answers to the questions set.. The second part, together with coursework, attempted to meet the philosophical challenge of causing and engineering way of thinking or 'habit of mind'. Section 1 of this part was a "comprehension" exercise; Section 2 was a "design-problem formulation and reasoning exercise", and Section 3 was an exercise in "engineering reasoning". Although not well done, both students and teachers wanted questions of this type included in the public examination.

The Board acceded to this request and in 1969 a multiple-objective (later called strategy) examination was set. This comprised of one traditional three hour paper with short and long answer questions that focused on problem solving (application and analysis) in the applications of science and some questions of the engineering reasoning type of question that dealt with commonly used artifacts. "The aim of this question was to see to what degree candidates could analyse the physical principles employed in a common piece of equipment, in this case an electric kettle and to analyse the important features of design from the point of view of the user, manufacturer and the supplier. In other words this question extends the Engineering Science into other aspects of engineering design" [26]. The need for instruction in how to approach this type of question and the depth of understanding required was revealed, as many answers were not of the depth sought. This illustrated how assessment could improve

"The recognition of the need for a method which is organised, careful and intellectually honest-particularly in respect of experimental observation".

"The acceptance of the need to consider parallel social and economic bases of engineering".

"An awareness of the advantages of deriving the more particular relationships from basic concepts".

"An awareness of the advantage of seeking parallels in other fields to relate one kind of phenomenon to another".

"An awareness of the advantage of attempting to reduce a social, economic or scientific situation to a simple system".

"The recognition of the fact that it may be necessary to exercise judgment as well as reason when dealing with a problem".

"The recognition of the fact that a perfect answer to a problem may not exist, and that the best available answer must be sought".

"The recognition of the fact that not all the information necessary to tackle a problem may be available, and that some which is available may not be relevant".

"The acceptance of the fact that more than one way of thinking exists, and that different ways may be more appropriate to different problems or different stages of the same problem".

"The recognition of the fact that the required exactness of calculation may vary from case to case (for example, from preliminary, quick 'order of magnitude' estimate to precise forecast of performance".

Exhibit 3. Statement of relevant attitudes in the 1972 *Notes for the Guidance of Schools* [19].

learning and in consequence this type of question was set in subsequent papers.

The other three hour paper included a one hour objective test designed to assess knowledge of concepts and principles across the syllabus with some short-chain problem solving. A one hour 'comprehension test', but set against an article from an engineering magazine rather than newspaper article, and a project design and planning exercise of one- hour duration. As indicated above it was designed to replicate the exercise that a student would have to carry out for the 50 hour laboratory project required of coursework. A candidate was not allowed to proceed with a project unless h/she could demonstrate to h/her teacher and the moderators that the project was viable and would meet the requirements of assessment. The

examiners described the philosophy (purpose) of this question to the Validation working party as follows;

“The aim of this question was to test the candidate’s ability to undertake a design problem of a similar nature to that facing him when presented with a project. The nature of the problem is of secondary importance and will determine the form of the answer [...] In this particular case a common mechanical component was given and the candidates were required to set up an investigation to determine, as fully as possible, the properties and behavior of the device. This type of problem is reasonably common, except that in the majority of cases the approach would be reversed, i.e. the design of the piece of equipment would call for a device of particular properties and the task of the designer would be to find or produce a device most nearly corresponding to his need. This inversion of approach is not of major importance however. Even in the situation now being considered, standard components are often used and it is therefore important to know as much as possible about the behavior of these components. [...] The component under consideration was a small spring requiring a tensile force of approximately 10 N to double its length” [...] In an endeavour to assist the candidate the task was divided into four parts and clear guidance was given on the aspects of design the examiners were looking for. The candidates were asked to list five mechanical properties of the spring to be determined and to sketch-design the apparatus that they would use to determine each of these properties and to outline the experiments to be carried out. Finally they were asked to draw up a time-table of operations. Attention must be drawn to the last sentence of the question which stated “It is very important that where possible and relevant you should explain the reasons for your choice of design apparatus or procedure” [27].

IX THE ENGINEERING DESIGN DEBATE

It was expected that there would be a high correlation between scores for the 50 hour project and the written planning exercise since incorporated in those scores was a project planning exercise for the actual project. This turned out not to be the case and this led to a debate between the proponents for a separate section on engineering design in the syllabus and those who thought that it would overload the syllabus [28]. Although the proposal was overturned a note was included in the 1972 *Notes for Guidance* [29] that said, “It is strongly recommended that the students familiarise themselves with the book *Introduction to Engineering and Engineering Design* by Krick (New York, John Wiley)..

X SOCIAL STUDIES IN THE ENGINEERING DESIGN CURRICULUM

From the beginning it was recognized that engineering had social consequences for society. How that should be accommodated within the engineering science programme was problematic. J. F. Gamlin, the Education Officer produced a

substantial document on the problem [30]. He suggested core material for the syllabus. While this was rejected some of his ideas were accepted. From time to time some of the comprehension exercises and projects included a strong social content.

On the basis of an experimental course in industrial studies that integrated organizational behaviour, economics and the history of technology given to participating students at one of the schools Heywood proposed an ‘A’ level syllabus in Industrial Studies [31]. While it received support from the co-ordinating committee it did not progress within the Board. The problem was never satisfactorily resolved.

XI COMPETITION WITH PHYSICS AND THE DEMISE OF THE SUBJECT

In spite of the small numbers taking the subject annually, the subject was retained by the Board for more than twenty years. In the semi-official report it is argued that its demise could have been predicted [32]. There were three reasons for this remark. The first was that it was already apparent that the demand for a qualified technological workforce was declining. The second and more significant was the competition with physics. From the nineteen seventies there were continuing discussions with the physics subject panel, and attempts were made to integrate some of content.

The third reason for its demise was the failure of the senior engineering professoriate to give full support to the subject and recommend that schools should encourage intending entrants to engineering departments to take engineering science rather than physics. Beliefs that engineering was simply the application of physics were deeply embedded and an objective evaluation was never undertaken by this key group in spite of the fact that evaluation data had begun to be made available as early as 1972 [34].

However, the semi-official report shows that the subject boxed well above its weight. It discussed the influence of the subject on the Board.. If it had been written fifteen years later it would have been able to record that in the United States the Committee on the Foundations of Assessment of the National Research Council in its report, *Knowing what Students Know?* -called for “balanced” systems of assessment to be struck between classroom and large scale assessment [35]. The principles enunciated seem to apply to any system of assessment. The nearest example found of such a system was the Physics B syllabus that Kelly accounted for above for which engineering science had been the progenitor. Elsewhere it has been shown that the principles of enunciated are directly applicable to the assessment of learning in engineering.

XII ACHIEVEMENTS AND DISCUSSION

Furneaux’s findings challenged the designers of the engineering science examination to question the validity of

what they were trying to achieve. Rather than have two papers that tested the same ‘thing’ their written examination comprised 4 components that could clearly be differentiated by the abilities they sought to test. Repeated analyses of these yearly examinations led them to conclude, that in addition to a factor that isolated the whole of coursework, they were measuring different qualities in each of the sub-tests. Their general evaluations clearly showed the impact that assessment had on learning and teaching, and the importance of integrating assessment into the curriculum process. This led to the design of curriculum process models that took into account assessment and at the same time indicated the dynamic nature of the process [36]. Within that framework an integrated philosophy of curriculum and assessment was developed [37]. Unfortunately there is little evidence to show that curriculum is understood to be an integrated process and assessment remains an afterthought of the educational activity. This is the challenge that continues to face engineering educators.

A serious weakness in the evaluations was that they focused primarily on the effectiveness of the examination and assessment procedures rather than on the effect that the subject had on the perceptions that students had of engineers and how they think and act in the workplace situation. There continues to be a need for investigations that explore these perceptions and the impact that teaching has on them.

This model was severely criticized at the time by industrialists because it was based on beliefs rather than facts about what engineers actually did. Studies of the kind initiated by the criticism [38] are rare even to this day. In any event the focus was on abilities rather than knowledge required to do the job which is where research should now be directed

Much of what was discussed over forty years ago is being discussed today in the various discussions on the role of philosophy in the development of engineering education. In this context the experience of engineering science continues to be relevant and it is fortunate that much of the documentation is extant

Abstract— The Australian higher education sector has accepted that increasing work-related stresses can have a negative impact on the quality and productivity of academic life. Workplace stresses can have significant financial impact both on university budgets and the overall economy due to poor decision-making, health issues and accidents resulting from illness. Engineering academics that teach and/or research within higher education institutions have been reported anecdotally to have a high prevalence of stress. The actual (self-perceived) level however has been largely unquantified. The research reported in this paper was conducted to assess self-perceived stress levels and identify the stress factors within a cohort of engineering academics at the University of Southern Queensland (USQ), a small regionally based Australian university renowned for its distance education. The questionnaire was applied using a mix of validated and non-validated survey instruments and incorporated a set of questions previously applied at the University of Adelaide (UoA). Findings from USQ are broadly in line with those independently reported elsewhere for Australia and the UK, with some minor exceptions. In summary the USQ project indicates that engineering academics have higher perceived stress levels than the validated health threshold, with significant variation based on age, academic type (teaching-research), and for staff with English as a second language. The results from both universities also indicated that there are significant stress contributors related to the pressure to obtain grants and to publish and to the (low) resultant levels of recognition from employers for any success. More specific to distance education providers (such as USQ), there are stress contributors related to servicing and dealing with the external mode of course design, delivery and lecture preparation.

Work-related stress, workplace practices, faculty development, academic development.

I. INTRODUCTION

Academics in today's competitive workplace must work in an increasingly complex and stressful environment. The

Australian higher education sector and universities internationally have accepted that increasing work-related stresses can have a considerable impact on the quality and productivity of an academic's professional life. Workplace stresses can have significant financial impact both on university budgets and the overall economy as outcomes from poor decision-making, health issues (such as obesity, cancer, and heart disease) and accidents resulting from illness such as stroke and heart attack. This environment generally encompasses a variable blend of teaching, research and service responsibilities. Engineering academics that teach and/or research within higher education institutions have been reported anecdotally to have a high prevalence of stress.

Research from Medibank Private and the Australian Productivity Commission [1][2][3][4] reveals workplace stress costs the Australian economy more than \$14 billion a year. Absenteeism, and "presenteeism" where staff are present, but not productive, cost more than \$10 billion a year. The impact of negative workplace stress includes poor decision-making, an increase in selfishness (including a greater reluctance to help co-workers or customers) and an increase in workplace accidents

Unhealthy employees take up to nine times more sick leave than their healthy colleagues and healthy employees are nearly three times more productive than unhealthy employees. Prolonged stress can cause or contribute to all manner of health issues including obesity, cancer and heart disease. At its most extreme, workplace stress can cause sudden death via stroke, heart attack and suicide. The Japanese have a word for workplace stress, "karoshi", which literally translates as death from overwork.

The tertiary education sector in Australia is a significant contributor to Gross Domestic Product [5], and was valued at AUD \$18.6 billion in 2010 [6]. However, the impact of workplace stress on academics in research and teaching

environments does not appear to be widely understood or acknowledged [7][8]. In light of the introduction of a market driven, post-Bradley Review [9] deregulated higher education sector environment it is paramount to review the “health” of the tertiary education sector, in terms of workplace stress. Current studies that are being undertaken nationally include “Work and Careers in Australian Universities” by Griffith University and University of Queensland funded by the Australian Research Council [10].

In this research a study was conducted within a regional Australian university in the Faculty of Engineering and Surveying. This study mirrored a similar conducted at the University of Adelaide (UoA), considered to be a research intensive university [11]. This study aimed to assess the level of stress and identify individual stress factors (stressors), and stress variables that are unique to distance education (or online education) providers for engineering academics that have teaching-only and teaching-research responsibilities. Furthermore, it is envisaged that this study will inform further studies that aim to investigate the correlation between stress levels and perceived performance of academics in their duties.

II. METHODOLOGY AND METHODS

A. Methodology

The methodology adopted was a quantitative research approach; a systematic empirical investigation of social phenomena via statistical techniques [12]. Though the approach is far from a positivist framework or explanative in nature, it is intended as a pilot study with a limited cohort to inform the development of a larger multi-disciplinary study. The hypothesis for any future studies is that there is an empirical relationship between the levels of stress (and the stressors) and performance.

While the study is probably not extensive enough to generalize the findings, it will be useful to help inform further studies and university managers of distance education providers within an Australian context. The study is also an opportunity to solicit further insights into the specific experience of engineering academics.

B. Methods

There are 3 parts to the questionnaire developed for this study using a combination of validated and non-validated instruments. Part 1 is a validated instrument “General Health Questionnaire (GHQ-12) consisting of 12 questions [13] with Likert scale for responses. Question responses were assigned a score value of 0 to 3 to give a possible total Likert score of 36 which represent the highest stress level. The health threshold for unhealthy stress is a Likert score of > 12 [13].

Part 2 consisting of 15 questions was developed for the purpose of identifying individual stress factors (stressors) of which were created and piloted within a small interfaculty group [11] at the UoA, and is not validated. This part is designed to specifically solicit insights to highlight stressors of concern. The questions were divided and categorized as Tier A, B and C.

Part 3 consisting of 8 questions are stress issues that could be considered to be unique to USQ as a regionally based

distance education or online teaching provider with majority of students studying off-campus, and is not validated. The questions were divided and categorized as Tier A and B.

The survey instrument was applied using SurveyMonkey® to academic staff within the Faculty of Engineering and Surveying at USQ. Ethical clearance was applied for and approved for the study.

III. RESULTS

The survey was carried out between 10th Oct and 4th Nov 2011. A total of 39 staff responded out of a possible 70 academics equating to a response rate of 56%. This reduced to 34 valid responses which included 30 male and 4 female academics equating to a response rate of 49%. In comparison to the UoA’s study as illustrated in table 1, there seems to be a consistency across a number of indicators. This includes age and gender variables, in that academics are more likely to be more stressed if they were “mid-career” in terms of age and/or female. Overall mean GHQ-12 scores are fairly consistent between the two institutions, though UoA is slightly higher if Teaching-only staff was included. However, both institutions have higher stress scores against the GHQ-12 threshold (>12), indicating unhealthy levels of stress. Interestingly, the UoA’s study suggested that there is a stress trend decrease as age increases. This was not reflected in the USQ’s study though there is consistency in stress levels between the ages of 40 to 60.

TABLE I. COMPARISON OF USQ STUDY VS UoA STUDY

| Items | USQ | The Univ. of Adelaide |
|--------------------------|--|---|
| Participations | 34 Male | 49 Male |
| | 4 Female | 9 Female |
| Response Rate | 48% | 38% |
| Stress under 60 Year old | >12 | >12 |
| Female Stress | > Male | > Male |
| Overall Mean Score | 15.1 | 14.7 (16.1 including Teaching Only Academics) |
| Stress Trend | Not very clear. Stable among age groups between 40-60 years old. | Mean Lickert Score decreases as the age increases |

Figure 1 provides the GHQ-12 stress scores (mean, maximum, minimum) against age of the engineering academics surveyed. The 30-60 years age groups have stress levels higher than the GHQ-12 threshold of 12. The 51-55 years age group has the highest value of 18, followed by 56-60 at 17.8, and then 61-65 at 17.7. The deviation between maximum and minimum scores is the widest within at the 61-65 age groups

Figure 2 illustrates that female engineering academics (GHQ-12 score of 20) have significantly higher stress levels than their male counterparts (GHQ-12 score of 14).

Figure 3 illustrates that engineering academics from an English as-a-second-language background (GHQ-12 score of 16.2) have moderately higher stress levels than their English as a first language counterparts (GHQ-12 score of 13.2).

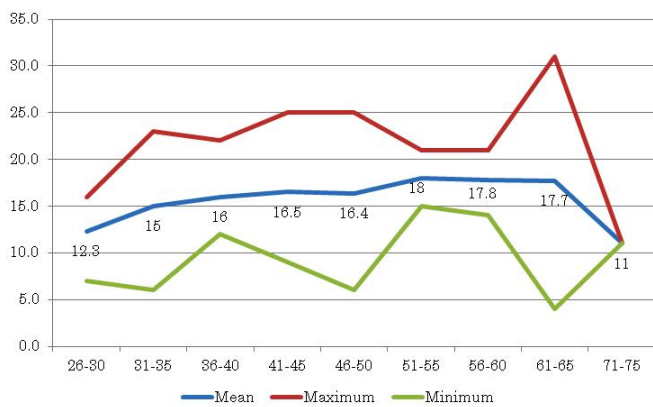

Figure 1. GHQ-12 Stress Likert Scores vs Age of academics surveyed

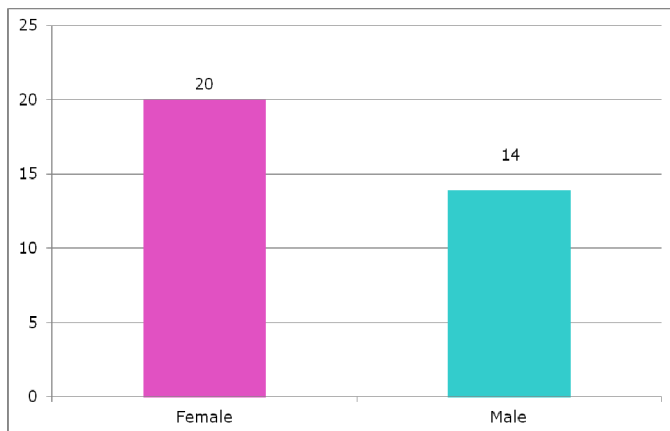

Figure 2. GHQ-12 Likert score averages of Female vs Male academics surveyed

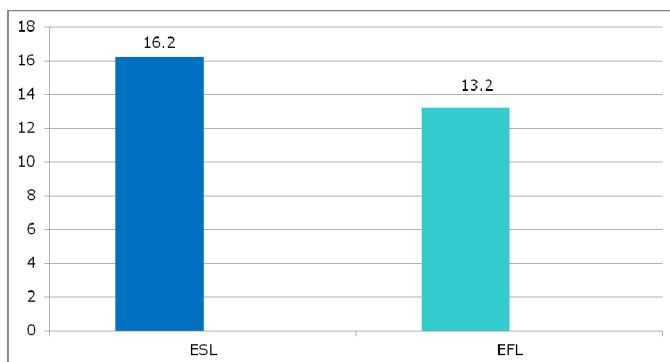

Figure 3. GHQ-12 Likert score averages of English second language vs English first language academics surveyed

Figure 4 shows that engineering academics with Teaching-only responsibilities (GHQ-12 score of 20.5) have significantly higher stress levels than academics with Teaching-Research responsibilities. This trend is consistent with the UoA's study.

Figures 5 to 9 highlight the sensitivity of the engineering academics to the different types of stressors, of which figure 8 and 9 are unique to distance education and/or online teaching providers.

Figure 5 illustrates that engineering academics are perceived to be highly stressed by the pressure to obtain

research funding, and to publish research outcomes. There were also stress issues arising from the commercially driven attributes of modern universities, resultant lack of confidence in its strategic direction, a perceived lowering of recognition, and lack of opportunities for genuine scholarship.

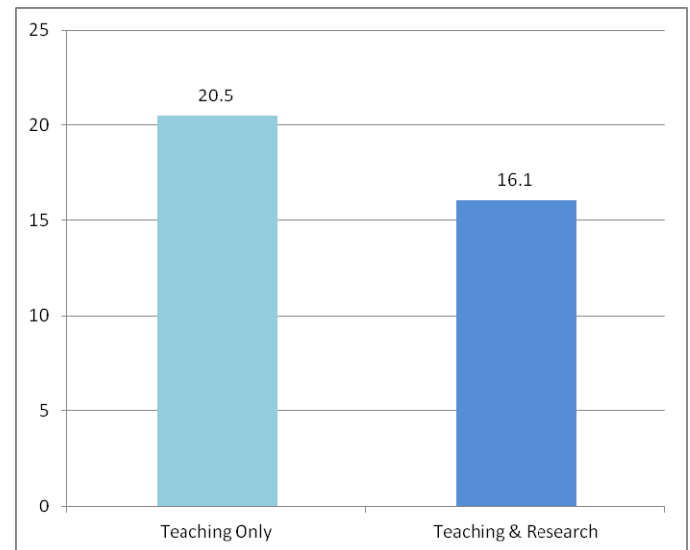

Figure 4. GHQ-12 Likert score averages of Teaching-Only vs Teaching-Research academics surveyed

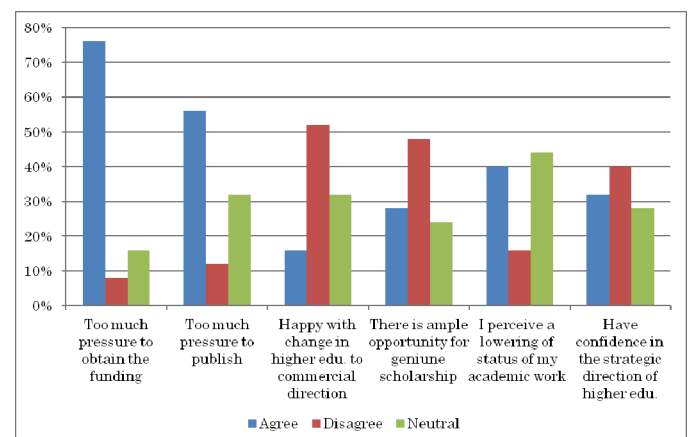

Figure 5. Responses for Stressor identification (Tier A)

Figure 6 shows the divide in the engineering staff profile in terms of stress associated with work-life balance, but there are some concerns with the administrative workload that are required for engineering academics. The results indicate that there is adequate support for teaching and maintenance of quality in the education the institution provides.

Figure 7 illustrates that original research is valued by the institution and expectation of academics' responsibilities are clear. Engineering academics surveyed think that class sizes are manageable and are not threatened by the possibility of job redundancies (within a commercially driven context as identified earlier).

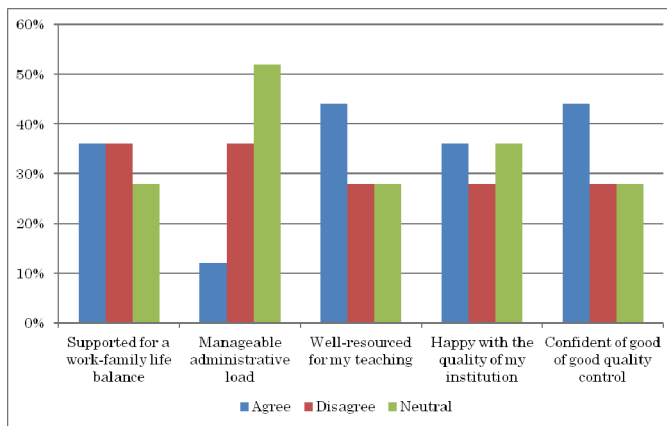

Figure 6. Responses for Stressor identification (Tier B)

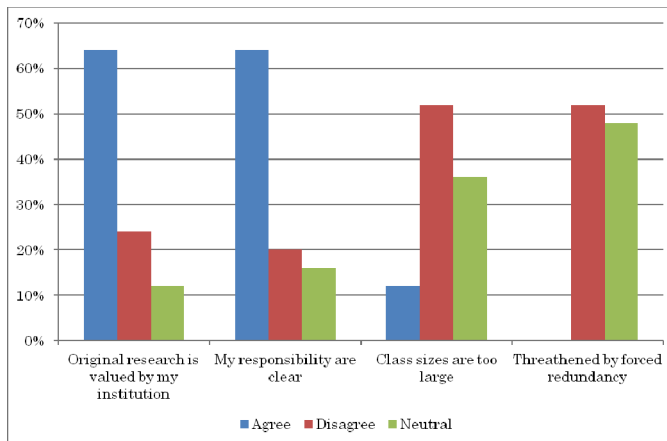

Figure 7. Responses for Stressor identification (Tier C)

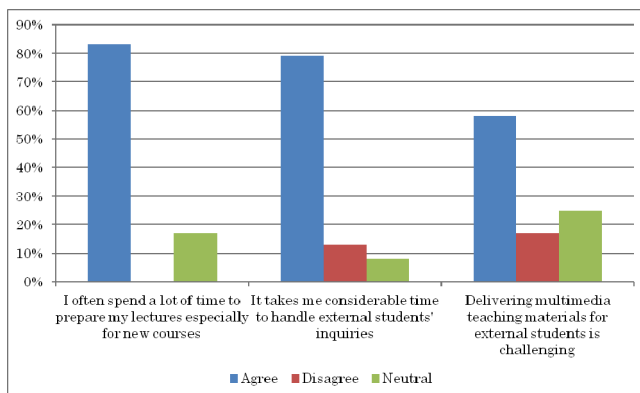

Figure 8. Responses for Stressor identification unique to USQ (Tier A)

Figure 8 illustrates there are stress issues around the preparatory requirements associated with development of “new” courses for teaching into on-campus and off-campus modes, but importantly, considerable effort is required to support off-campus students. This is in addition to the stress issues around the development and delivery of multimedia learning and teaching resources to both cohorts.

Figure 9 illustrates that there is stress issues associated with a moderate proportion of engineering academics that are finding it difficult to balance teaching and research pressures,

though they have an optimistic view of their career future, and are not overly concerned with impact of the levels of teaching commitments on overall quality and productivity on academic work. Small class sizes are not considered as a stress issue in terms of productivity of engineering academics.

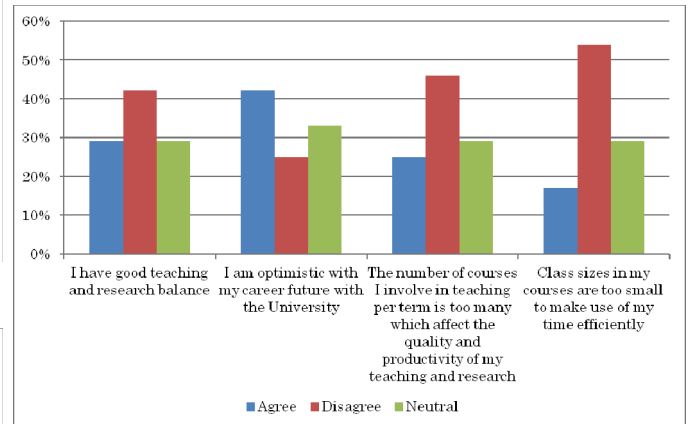

Figure 9. Responses for Stressor identification unique to USQ (Tier B)

IV. DISCUSSION

Though the response rate was significant within the cohort being investigated, the outcomes cannot be generalized across the tertiary sector. However, it is useful as a reference for further broader studies across disciplines or universities. The question of validity is confined to the faculty being studied with its associated influences; e.g. regionality, multi-teaching modes, online learning environment, male biased sample, and the Australian academic context.

The results have indicated that the overall self-perceived stress levels of engineering academics within the Faculty of Engineering and Surveying at the USQ are above the GHQ-12 threshold, and that “mid-life” age grouped and/or female engineering academics are significantly more stressed than other colleagues. It is also noted that the academics whose English is their second language are more stressed. Also teaching-only academics are more stressed than teaching-research academics. It may be that there are relationships (hypotheses to be tested) of perceived higher stress values evidenced in the surveys linked to:

- Gender imbalance within the faculty and the pressure associated with performance as a minority group;
- Difficulties experienced and lack of confidence in communicating effectively with colleagues and students in the English language. This is somewhat associated with performance as a minority group within a wider context in the community.
- Lack of time flexibility associated with Teaching-only workload allocation (eg. research activities are not tied to timetabled classes).
- Lower tolerance for functional and performance-related changes as age increases.

The study also provides insight into the growing pressure of engineering academics to obtain research funding and

publish research outcomes within the faculty. This is perhaps an indirect impact of the discourse and policies within the faculty to encourage engineering academics to pursue external funding and to publish extensively. However, this contradicts the finding that there is a perceived low level of resultant recognition of any success from the employer. Hence, the discourse and policies within the faculty and university may need to be explicit (rather than implicit) in recognizing significant achievements in both grant successes and publication achievements. Self perception of the value of academics' research output may also be a contributor to this contradiction but is not part of the scope of this research.

The study indicates there is a perceived lack of opportunities for genuine scholarship. Hence, it does suggest the growing financial discipline (including tightening workload based on activity-based costing) within a commercial-driven academia is affecting the traditional flexibility and affordability that were available to academics to experiment and explore scholarship within their respective discipline. This is perhaps an expectation that academics have retained their value system but felt constrained in the new competitive and commercially driven environment. This is supported by the finding that the respondents have a lack of confidence in the strategic direction, and are unhappy with the environmental changes in higher education.

The study shows there is a divide between those engineering academics who are satisfied with a work-life balance and those that are not. The cause of this divide is worth investigating further. However, it may be deduced that overall higher administrative workloads have played a significant part (whether it is from general, teaching and/or research related activities). It does suggest that the increased pressure to source funding and to publish may have played a part in creating this divide. However, it is worth noting that, overall, respondents are satisfied with the resources provided for "teaching", though it is unclear whether this response included administrative duties associated with teaching. This observed divide also explained the divide seen in the evaluation of quality of oneself and the institution. About a third of engineering academics surveyed felt the quality of their research and/or teaching "artifact" are compromised in some ways due to the time pressures.

Despite the pressure to source funding and to publish, original research is perceived as highly valued within the institution. This does indicate that the rewards or incentives are adequate, but that "value" could be better linked to public recognition (explicitly as mentioned before). Perhaps there is a systemic disconnect between the financial reward system within the Faculty and the university promotion system. It is seen that respondents are clear in their responsibilities in teaching and/or research. The issue then is if the expectations of academics were clear and that original research was highly valued, why is it that respondents felt they are not adequately recognized? Perhaps the university hurdles for academic promotion may be the cause, and worth investigating further in future studies.

Respondents felt that class sizes are not too large, indicating that the administrative burden identified earlier may

not be directly associated with teaching activities, but rather with either general or research activities. The stress issues around forced redundancy were not of concern for respondents indicating the value system associated with traditional academia are still strong and have not been affected by evolution towards a more commercially driven context.

Unique to USQ and possibly other distance/online educators, most respondents agreed that preparation and servicing students from both on- and off-campus modes takes considerable effort. This was of special concern when dealing with the multimedia expectations of teaching resource materials and servicing off-campus student enquiries. In some ways, this explained that traditional academia values have not caught up with technological and environmental changes within the higher education system. It may also be that the workload expectations for preparing and servicing off-campus teaching are not accurately reflecting the actual effort required. This may also explained the divide between respondents in that some prepare and deliver courses with larger off-campus student cohort than on-campus; or, co-exist in large teaching teams (hence smaller and targeted responsibilities) than small teaching teams (all teaching and administrative responsibilities) when teaching into courses. This finding (along with "teaching" being well-resourced and class sizes are not large) indicates that there is possible stress issues around the administrative workload (rather than direct teaching workload) associated with preparing and servicing off-campus student cohorts.

V. RECOMMENDED FURTHER WORK

Further work in the form of a qualitative study with semi-structured interviews should now be conducted to investigate the reasons for the causes of stressors. This will assist to help confirm some of the discussion points and generalizations made in this paper. In addition, further work in a broader cross-faculty study should be conducted within USQ, and possibly a much wider national or international study of engineering and science-related faculties across institutions in Australia with some international input.

VI. CONCLUSIONS

The Australian higher education sector has accepted that that increasing work-related stresses can have a negative impact on the quality and productivity of academic professional life. Workplace stresses can have significant financial impact both on university budgets and the overall economy due to poor decision-making, health issues (such as obesity, cancer, and heart disease) and accidents resulting from work related illnesses such as stroke and heart attack.

Engineering academics that teach and/or research within higher education institutions have been reported anecdotally to have a high prevalence of stress. The actual self-perceived level however has been largely unquantified. The research reported in this paper was conducted to assess self-perceived stress levels and successfully identified some of the stress factors within a cohort of engineering academics at USQ, a regional Australian university renowned for its distance education.

The questionnaire was applied using Survey Monkey with a response rate of 56% with a mix of validated and non-validated

survey instruments and incorporated a set of questions previously applied at the University of Adelaide (UoA), a more research intensive university. Although the scope of the study was focussed on USQ the findings correlated well with those from the UoA and should be useful to help generally inform academic managers across the sector. Findings from USQ are broadly in line with those independently reported elsewhere for Australia and the UK, with some minor exceptions.

In summary the USQ project indicates that its engineering academics surveyed have higher perceived stress levels than the validated health threshold, with significant variation based on age, academic type (teaching-research), and for staff with English as a second language. The results from both universities also indicated that there are significant stress contributors related to the pressure to obtain grants and to publish and to the (low) resultant levels of recognition from employers for any perceived success. More specific to distance education providers (such as USQ), there are stress contributors related to servicing and dealing with the external mode of course design, delivery and lecture preparation.

The findings in this study, supported by the earlier UoA study should be useful for academic managers such as Executive Deans, as they highlight some of the challenges and difficulties faced by their staff in an increasingly competitive and complex higher education sector.

ACKNOWLEDGMENT

The authors would like to acknowledge the support of the Faculty of Engineering and Surveying, University of Southern Queensland, and their engineering academics who participated in the study.

Abstract— This work addresses a gap in the professional development of engineering faculty: student advising. The development and assessment of the Designated Faculty Advisor program is described, including training components, student and faculty responses, and future plans.

Keywords- advisor; advising; mentoring; faculty development; four-player model

I. THE MISSING CONVERSATION

It is widely agreed that challenges exist in the education of future engineers [1]. In California, Silicon Valley employers are concerned about the supply of “home-grown” engineering talent and urge K-12 and higher education sectors to promote STEM education to young people [2], and the nation’s demographics make it clear that tapping into the large pool of underrepresented minorities as well as women is a wise investment for increasing the number of future engineers. Review of many conference programs and journal issues in the engineering education domain shows how much effort the community has invested in bringing into, and retaining, non-traditional students in engineering programs through K-12 outreach, improvement in the effectiveness of classroom teaching, first year programs, awareness of diversities of learning styles, and summer research opportunities, to name a few. However, discussions of the quality of engineering faculty advising have not been widespread. This paper describes efforts to examine and improve this quality.

In the context of undergraduate engineering education, the term “faculty advisor” can refer to the intellectual advisor to a senior project, research experience, or other curricular-related project or activity; to the organizational advisor for a student section of a professional society; or to the academic advisor, with the primary role of helping students select courses and complete the prerequisite chain, and the secondary role of performing career mentoring and resource referral. The focus of this discussion is on the latter role of academic advising, specifically as practiced by engineering faculty.

Academic advising and mentoring share traits related to promoting student success but are not identical, as academic advising includes elements of curriculum and scheduling assistance that may be absent from mentoring situations. Mentoring also may involve a more intentional effort to role

model for students. There is a robust literature on mentoring in academic contexts, much of it aimed at faculty-student interactions related to research environments [3]. Some recent work has focused on the need to improve engineering faculty professional development in the mentoring arena [4]; one project, Engage [5], has identified faculty-student interactions as a key area on which to focus, developing workshop training materials for improving such interactions and exploring ways to efficiently embed best practices, based on research, into engineering colleges [6]. Muller has deeply examined both the need for, and the barrier to, more effective faculty-student mentoring interactions [7]. There is also a significant literature on academic advising for professional staff, with much recent focus on First-Generation students, under-represented student populations, and developmental student populations [8]. However very few published conversations about the significance of the faculty academic advisor role have occurred in the engineering education community [9].

Student advising involves a blend of direct teaching and indirect mentoring, and is frequently mistaken by both parties as a simple transaction. Consequently training for faculty advisers is often ad hoc, and the advising role may be seen as an unimportant part of a faculty member’s service component, not worthy of serious training or effort. However, for faculty to be effective advisors, they require explicit instruction in the policies and practices of the institution, in the mechanics of the institution’s processes and information systems, and to some extent in the theory of student development. They may also need practice in techniques for effective dialogue.

II. THE NEED FOR ADVISOR TRAINING

In the terminology of academic advising, there are two general styles: prescriptive and developmental advising [10]. Engineering faculty frequently engage in prescriptive advising, a model in which the student is the “patient”, the advisor is the “doctor,” and the “prescription” is a set of courses. The relationship is unilateral, transactional, unequivocal, and there is an implied contract stating that if the student takes the “medicine,” (i.e. enrolls in and passes the courses), the outcome will be positive (i.e. a degree will be earned). The prescriptive style is attractive because it does not require any training of the advisor beyond rules, policies and curricular roadmaps. The “doctor” needs to know his meds, but doesn’t

need any “bedside manner.” This style of advising may be effective for some students, particularly those who are highly self-motivated, come prepared to advising sessions, and do not have any personal, emotional, financial, academic or other barriers to a smooth academic path. However, even for the most well-prepared students, mentoring opportunities will be lost by using only the prescriptive style in all situations.

Given the complexity of our actual student population, the developmental style of advising is likely to be more effective; but this style requires a deeper understanding of student development, and also requires training of the advisor in the art and science of dialogue. In addition to a comprehensive understanding of all of the policies, programs and resources available on campus, the advisor needs to understand our students and their challenges and contexts, which are often far outside of the advisor’s own experience. Professional advising and counseling staff are expected to gain pertinent skills and knowledge in their masters-level, pre-professional training or through professional development, but faculty may be assigned an advisor role without being offered opportunities to gain these skills. This is unfortunate, particularly at public institutions, because as academic budgets shrink, as the reliance on part-time adjuncts increases, as accrediting bodies look more closely at graduation rates, and as the student body becomes increasingly more diverse and less traditionally prepared, the lack of attention paid to faculty advising is emerging as a serious issue.

The idea of offering faculty development related to advising skills is not unlike the issue of training faculty to teach more effectively. Over the last 25 years, awareness that engineering doctoral programs generally train faculty in research methods, but not in teaching methods, has given rise to thousands of articles and hundreds of faculty training seminars, workshops and conferences on effective teaching strategies [11]. The expectation that a new faculty member will come either prepared to teach effectively, or will attend professional development opportunities in order to become effective, has become the norm, particularly at undergraduate institutions.

Engineering has a significant dependence on faculty advisors rather than professional staff advisors, due to the complex nature of the disciplinary training. In addition, part of our responsibility as educators is to turn students into novice professionals. This task is not easy – and it mostly happens outside the classroom. The notion of academic mentoring for undergraduate students, much of which needs to take place in a one-on-one setting, particularly for more vulnerable students, is not commonly on the syllabus of professional development for engineering faculty. This work describes a first step in building a syllabus for faculty advisor professional development.

III. THE DESIGNATED FACULTY ADVISOR PROGRAM

A. Context for the Development of the DFA program

SJSU is part of the 23-campus California State University system and the 7th largest in terms of undergraduate population with nearly 25,000 students. The Charles W. Davidson College of Engineering serves approximately 2500 undergraduates and

1500 masters’ students, and awards almost 350 bachelors’ degrees and 600 engineering masters’ degrees annually (average of 2008-2012 data). Fall 2011 data show our engineering undergraduate population as about 14% women; 41% Asian-American/Pacific Islander, 18% Hispanic, 23% White, 3.3% Black, 0.2 % Native American, 6% international and 7% other or decline to state. About 40% of our undergraduates enter as junior transfers, primarily from the California Community College system. About 35% of incoming engineering freshmen place into calculus, while the remainder place into either pre-calculus, college algebra or developmental math. Helping students complete the degree in a timely manner is a high priority of the University, thus faculty advisors have responsibility for the challenging endeavor of helping students remain on the pathway to success.

The College is a major supplier of engineers to Silicon Valley employers and most of our alumni stay in the area. We have eight ABET-accredited undergraduate degrees, as well as degrees in Industrial Technology and Aviation; the faculty comprises 62 tenured or tenure-track faculty along with about 150 part-time lecturers. The Engineering Student Success Center staff includes the executive director, five peer mentors, one student support staff, and two FTE academic advisors who focus on general education and probation advising. Engineering students are also required to see a faculty advisor in their major every semester (enforced by a registration hold until advising is complete). Improving the effectiveness of faculty-student interactions in the advising domain (and by extension in the classroom domain) is a priority for the University and for the College.

For the past three years, the College of Engineering has been engaged in a significant effort to improve faculty advising [12]. Beginning in AY 2009-10, the College brought together faculty advisors from the eight departments to share best practices and to establish new academic policies on progress to degree. It soon became clear that to reach convergence on new college-wide advising practices, a program with faculty support and recognition was needed. Consequently in AY 2011-12, the College launched the Designated Faculty Advisors (DFA) program, for which the Dean and the Provost provided funding for one course release time for 16 faculty advisors. The components of the program are described below.

In addition to this program within the College of Engineering, the University also launched various programs to bring together advisors all over campus, including the Faculty Advising Liaisons, the Advising Council, which includes administrators from both Student Affairs and Academic Affairs, and a campus Advising Coordinator who maintains the online Advising hub and communicates campus-wide about events and presentations of interest to advisors. In addition, over the last four years, Student Success Centers have been opened in four different colleges including Engineering. The campus-wide increased focus on student success has raised the bar on expectations for faculty contributions both inside and outside the classroom.

The 2011-12 DFA cohort included 16 funded faculty advisors, chosen by department chairs. Some had been advisors for many years, while others were new to the activity.

All advisors were given one course release time for both semesters; some department chairs participated in all or some of the program, which consisted of an all-day retreat in August, and three meetings each semester in Fall 2011 and Spring 2012.

B. Components of the DFA program

A description of the Designated Faculty Advisor (DFA) Roles and Responsibilities are provided to the faculty before their selection for this program. DFA faculty are required to attend an Orientation Training in August (see Table I), as well as monthly DFA lunch meetings. The yearlong syllabus for faculty advisor professional development includes speakers, workshops and discussions on topics related to policies, practices, theory and mechanics of student advising. Each of these areas is discussed briefly below.

1) Policies

Academic policies on campus change frequently, especially during times of budget cuts and enrollment limits. Thus it is critical for faculty advisors to be kept up to date on policies, as well as to help develop specific policies for the College of Engineering. Working together towards college-wide practices prevents departments from diverging too widely in their academic policies, which in turn prevents confusion among students. For example, over the last two years a new College policy on Progress to Degree was formulated, adopted and implemented, after six months of consultation with advisors regarding curricular roadblocks, advising issues, and improvements to advising processes.

2) Practices

Documentation of student advising sessions is important for many reasons, including accreditation. Sharing best practices and developing new uses of technology in advising is an important benefit of having college wide advising group. When the University instituted new restrictions on change of major, the College was able to respond quickly by developing effective practices to help students navigate the new requirements while still making progress towards degree.

3) Theory

Engineering faculty have rarely had the opportunity to study the field of student development. The program includes a series of presentations by on-campus experts called "Knowing our Students Better," which includes topics such as cultural expectations and differences between various ethnic groups, special issues facing veterans and students with hidden disabilities, and general topics regarding student development.

4) Mechanics

DFAs are encouraged to use a variety of on-line tools to improve advising including the Student Administration database on Peoplesoft, as well as the **Advisor Blog**, an on-line discussion group site (built on BuddyPress) which provides a confidential location for faculty to ask difficult advising questions and serves to build the advising community. A **google group** is used primarily for communication about upcoming meetings, opportunities for professional development, and dissemination of policies and changes. Almost all departments now use an **online appointment system**, making it easier to get students to come in for advising

well before registration opens. A group of students and faculty are developing **mobile advising apps** and online **FAQs** for Engineering students.

IV. FIRST YEAR ASSESSMENT OF THE DFA PROGRAM

The development of the DFA Program was based on the twin hypotheses that (1) more effective faculty advising would result in improved student outcomes, and (2) that engineering faculty could be trained to be more effective advisors.

Student outcomes of interest include increased student satisfaction with their SJSU experience, higher retention rates, reduced time to graduation, and attainment of early professional success after graduation. First-year assessment of the program included measures only of student satisfaction. Assessment of the other outcomes is complex and compounded by many factors.

Much of the first-year program assessment examined whether faculty did become more effective advisors. The assumption was that by providing faculty with knowledge and skills, and by building an advisor community, "better" advising would result. The effects were measured in terms of faculty perception of personal change and student perception of their advising experience.

In order to assess the effectiveness of the first year of the DFA program, we used four instruments: a DFA orientation assessment survey, an online student survey administered during Fall 2011 and Spring 2012, a yearlong online faculty Reflections Log, and an online faculty survey at the end of the academic year.

A. Faculty Perspectives on the DFA Program

The DFA Orientation training components were assessed by an online survey immediately after the event. Formative assessment and perspective was gathered from the Major Advisors throughout the year by inviting them to submit reflections on their advising experience to an ongoing Reflection Log. A total of seventeen log entries were submitted. Since the entries were anonymous and since multiple submissions were encouraged, it is not possible to determine how many of the 16 or so different Major Advisors contributed to the log. A faculty survey was administered online at the end of the academic year, sent to all the DFAs as well as their department chairs. Fifteen individuals completed the survey, including 11 faculty advisors, 2 department chairs, and 2 chairs who also serve as DFAs.

The DFA August orientation agenda is shown in Table I. The training session was very well received; one respondent commented: "Great meeting – well organized, easy to understand. I learned a lot – thank you." The DFA Orientation was the first time many of the College advisors had met as a group, or met with the Engineering Student Success Center staff, and also the first time many of them had met professional staff from campus student support units such as counseling services, the disability resource center, and the University advising center.

A large majority of participants (88%-94%) found nine of the ten training components to be "useful" or "extremely useful." The toolkit training component was rated by the

largest number of participants as “extremely useful”. It was also noted that the use of advising tools is very uneven across the tools and across the group of advisors. There is thus an opportunity to increase both awareness and use of these tools. Participants also selected among six proposed themes for additional training, and identified very clearly as their top choice “informal discussions about effective Major Advising sessions,” which can be interpreted as an expression of the desire for community among advisors, reflected in later feedback about the program as well.

In addition to expanding their advising repertoire, the presence of engineering faculty from every department lent legitimacy to the advising activity, positioned advising as an important contribution, and encouraged the untenured faculty that advising would be considered a significant aspect of their faculty portfolio.

TABLE I. DFA ORIENTATION AGENDA

| Policies, Practices, Theory and Mechanics of Student Advising | |
|--|---|
| College of Engineering Faculty Advisor Program 9 am - 5 pm, August 17, 2011 | |
| 9am | Moving Towards Excellence: A Look at the Data |
| 930am | Who Are Our Students? Student Development/Student Involvement 101 |
| 1030am | Knowing When to Make Referrals to Counseling and Disability Resource Center |
| 1130am | Advisor Toolkits: Peoplesoft/Custom CoE Advisor Toolkits/Case Studies |
| 1pm | How Do We Know We're Getting Better? Assessing our Work |
| 2pm | Policy and Process: Probation/DQ/Reinstatement/Change of Major Processes |
| 3pm | Working Together for Student Success: Coordination of Campus Advising Resources |
| 4pm | Meeting Graduation Requirements: Requirements, Substitutions, Mechanics of Transfer |

In their Reflection Log entries, several DFAs comment that they believe the quality of advising is increasing and point to the value of belonging to a community of advisors. “It is great for the faculty because we are building a community of excellence in advising, and you don’t feel you have to walk a hard path alone,” one Major Advisor notes. Another indicated, “I think the [DFA] meetings are very important for the following reasons: 1) We get to know each other. This makes interacting to solve student problems smoother. 2) Everyone is on the same page (at least in theory) and is informed of the rules and challenges. 3) It raises the profile of advising to a higher level.” The importance of quality advising is expressed in another log entry: “I am much more comfortable with the quality of academic advising that I know students are getting now than I was before the pilot started.”

Several of their comments expressed satisfaction about having dispensed advice that made a difference. “There were many sessions where I felt my input was very helpful for charging an efficient and personalized education plan,” one advisor noted. Another expressed satisfaction at “...letting

them know the department cares that they succeed, and pointing them toward behaviors that will work for them and resources for help really feels like a good thing.”

Table II shows some of the responses from the end of year faculty survey. Of note is that more than half the respondents indicate change in the content of their advising session conversations. One advisor noted, “Now the questions change depending on what stage the student is at. New questions: What do you want to do with your EE degree? What is your favorite class? How are things going?”

TABLE II. SELECTED FACULTY RESPONSES TO YEAR-END SURVEY

| Since the start of the DFA program have you... | | |
|--|---|--|
| | Effectiveness of your advising increased? | Accuracy of your advising improved? |
| Yes | 40% | 33% |
| No | 27% | 47% |
| Not sure | 33% | 20% |
| | Expanded the referrals you propose? | Changed the content of your advising sessions? |
| Yes | 57% | 56% |
| No | 36% | 25% |
| Not sure | 7% | 19% |
| | Getting to know students better? | Feel part of an advising community? |
| Yes | 43% | 100% |
| No | 43% | 0% |
| Not sure | 14% | 0% |

Advisors noted changes in students as well, “I feel students have accepted our intent to have a quality program built on fundamentals. I feel that it is much less likely that at-risk students will be overlooked,” while another observed “The students are better prepared, and less likely to get into problematic situations. The path to success is clearer, and the failure modes better identified.” Another notes that “more students are coming in to ask about program/career...Also, I'm observing students stopping by to just share information about how their job search or internship search is going.”

B. Student Perspective on Advising

Assessment of student perception of advising effectiveness was accomplished by means of an on-line survey conducted with students after they met with their major advisor. The survey was designed to generate information that would address the following evaluative questions: How satisfied are students with the major advising? What do they like and not like about the major advising? What suggestions do they have for improvements?

A draft survey design was distributed for review and comment at the first professional development session for the

Major Advisors. Input received from the group was incorporated into a revised version which was tested with a group of students. After final revisions, the survey was introduced and first disseminated about 5 weeks into the Fall 2011 semester. Each week every department provided lists of the email addresses for students who had seen their Major Advisor that week, and the Dean's Office staff emailed the survey link to students as soon as possible following their major advising session. The email that arrived in each student's mailbox was introduced by a letter from the Associate Dean, encouraging students to participate and ensuring them that their responses were anonymous. Incentives in the form of \$20 gift cards were used to increase the response rate. A similar protocol was followed for the Spring 2012 survey, after it was revised and some new questions designed and tested. Some departments were more diligent than others in providing lists of appointments, so not every student who saw an advisor received a survey.

A total of 434 students responded to the Fall survey and a total of 590 in the Spring, giving a 27% response rate in Fall, and a 36% rate in Spring. The respondents represent 14% of the Fall undergraduate enrolled student population, and 21% of the Spring. The survey respondents matched other college data in terms of the gender distribution, the ratio of native versus transfer students, and the self-reported GPA distributions.

TABLE III. STUDENT RESPONSES: ADVISING TOPICS

| Advising session topics: | % discussion was "very" or "somewhat useful" | | % topic was NOT discussed | |
|--------------------------------------|--|--------|---------------------------|--------|
| | Fall | Spring | Fall | Spring |
| Internships and career opportunities | 21% | 36% | 71% | 59% |
| Graduate programs in engineering | 18% | 30% | 75% | 65% |
| Strategies for academic improvement | 26% | 41% | 67% | 55% |
| Resources for academic success | 30% | 40% | 64% | 55% |
| Scholarships | 14% | 25% | 79% | 72% |
| Balancing school and work | 25% | 34% | 69% | 62% |

Table III shows the change in advising session topics between the Fall and Spring semesters. In every case, a wider diversity of topics was discussed in a useful way during Spring than in the previous Fall, many of them pertaining to improving success or long-range planning. The percentage of students reporting that they talked with advisors about strategies for improving academic success increased from 26% in the Fall to 41% in the Spring; this may be attributable to the various advising workshops attended by the DFAs where they learned

about campus resources as well as observed role models for listening to students more carefully. In addition, more advisors became familiar with the academic probation reports and thus were able to identify which students were at-risk and bring up these issues during advising.

While some of the increased discussion of "career planning" topics, such as thinking about graduate school (increased from 18% to 30%), could be the result of increased Spring semester student focus on summer internships and graduation, the faculty responses provided earlier do indicate a sense of qualitative shift in the content of their conversations. Overall student satisfaction with their advising experience increased, and the percent that were dissatisfied dropped from 15% in Fall to 5% in Spring.

In open-ended questions during the Fall survey asking students to indicate what they liked best about the advising, 37% of respondents pointed to the advice they received. "[I received advice on] how to balance the rest of my time at SJSU," one student commented. "Good advice from professors who know the best route to graduate on time," another student noted. For 32% of respondents, the best aspect of the advising was the person-to-person interaction and/or the advice. "My advisor actually advised me and cared about my class selection," one student wrote.

An open-ended question from the Fall survey about what students liked the least about their advising session identified opportunities for improvement. One student noted: "[I did not like] the rushed feeling I got due to the high volume of students trying to get in with the advisor." Some students did not like their personal interaction with the advisor. "I wasn't comfortable asking questions. I felt he was judging me because I'm behind and because of my grades," one student noted. Many students pointed out that they would like more time with advisors and opportunities to talk about internships, scholarships and graduate school; advisors learned about this need and responded with improvements during the Spring advising sessions.

V. CONCLUSIONS AND FUTURE DIRECTIONS

Four main themes were reflected in responses from both faculty and students. From Fall to Spring, there was higher satisfaction with, and efficacy of, advising sessions. Both students and faculty indicated that a broader and more useful range of topics were discussed, which moved the experience of advising from "registration hold removal" to "academic success and career planning."

There was an emergence of personal and community transformations as a result of advising sessions. More students indicated they were likely to make a change in either course selection, future career, or study and work habits after their advising session. Faculty indicated a growing sense of community and openness to bringing up topics outside of a narrow script, as well as that they became more likely to identify and pay attention to at-risk students, as a result of the DFA program.

Survey questions about online advising highlighted the importance of face-to-face meetings. Fall and Spring student data shows that a significant majority favor meeting an advisor

in person. For example, students responded that “I was able to talk to a human and not a computer,” and “[I like] personal attention and ability to ask specific questions and receive specific answers immediately.” Although many suggestions were made for online improvements, they all pertained to processes and paperwork rather than communication.

Students’ responses to “most liked” and “least liked” open-ended questions mirrored each other around the theme of caring, knowing and respect. Students liked advising the most when an advisor cared about them and knew them, for example as illustrated by having already reviewed their records. Students liked advising the least when they felt disrespected, for example for weak academic performance, or when the advisor was late, or when they had an appointment and had to wait for long times. Advisors showing caring and respect were highly valued, as indicated in these quotes, “My advisor actually advised me and cared about my class selection,” and “It gives me confidence that [the advisor says] I’m headed in the right direction.”

The human interaction and sense that somebody is interested and cares about their progress is extremely important to a large group of students. This confirms what we already know about college students: faculty have a strong influence, and a relationship with a faculty member is very important to student success [16]. Thus, faculty development resources that would improve this aspect of advising would be most beneficial.

Preliminary results from the Designated Faculty Advisor Program show that training faculty in the policies, practices, theory and mechanics of student advising is a significant task, and one that has been heretofore largely ignored. The development of a professional syllabus for engineering faculty advisors will continue over the next several years using lessons learned from the assessment of the first-year program. For example, in response to student suggestions and in concert with a broader technology push on campus, more online tools and mobile apps are being developed to make advising records easier to use and document, while freeing up time in advising sessions for more substantive interactions.

The next phase of the program will focus on enhancing faculty-student interactions through the development of a Four-Player Dialogic Conversation model [13]. This is a model for developing dialogue which emerged originally from the family therapy domain [14], but has been adapted to business settings [15]. Work is planned in which this model will be adapted to developing training methods for faculty-student interactions. One workshop was held in Fall 2011 to introduce these ideas to the DFA group, and it received very positive comments and had faculty participating actively [12]. In addition to its use as a training method in person, this model may be very adaptable to use as an interactive video training method. These ideas will be explored in the coming year.

ACKNOWLEDGMENT

The authors acknowledge funding support from the College of Engineering Dean’s Office as well as from the SJSU Office of the Provost. Kathleen Bruffett provided initial work on this program; Jared Tuberty, Cindy Kato and Katherine Casey also contributed to this work. The 2011-12 DFA Team is also gratefully acknowledged for their participation.

Abstract— In an effort to create education reform by promoting students' intrinsic motivation (IM) to learn, we are developing a program to train IM-supportive teaching assistants (TAs). We present our preliminary analysis of the first two TAs' reflective teaching journals and discuss what IM-supportive instruction looks like and how we can improve our training program.

Keywords- *motivation; intrinsic motivation, teaching assistants; training; reform*

I. INTRODUCTION

Although traditional efforts to improve engineering education focus on changing faculty's pedagogies [1], we believe that these efforts need to be complemented or even preceded by efforts that focus on improving instructors' support for students' intrinsic motivation (IM) to learn [2]. To test our beliefs, we created a pilot IM course conversion initiative to convert existing, large enrollment courses at a research-intensive university with minimal effort from the faculty instructor. The IM converted course looks like a traditional course: lecture taught by the faculty followed by discussion sections taught by teaching assistants (TAs). However, the IM TAs help the students learn how to direct their own learning rather than lead specific active-learning exercises. We have previously shown that this emphasis on IM rather than active learning can improve students' understanding of the course content and their learning experience [2].

In this work-in-progress, we discuss how we trained the first two IM TAs to be IM-supportive. We plan to continue developing this TA training program. This analysis will identify the habits of effective TAs, provide insights into the effectiveness of our training, and support recommendations for improvements in TA training. As TAs develop IM-supportive behaviors and have opportunities to transform their classrooms, they can become powerful agents of change.

II. CONTEXT AND TA TRAINING

We recruited TAs from a large-enrollment (more than 250 students), sophomore-level, computer architecture course. Two TAs volunteered to lead these IM discussion sections and attend a weekly one-hour training meeting on IM-supportive pedagogies and for peer support. IM is supported by increasing the students' sense of *autonomy, competence, relatedness*, and

purpose [3]. For example, IM-supportive teachers spend more time listening, articulate fewer directives, ask more questions about student needs, give fewer solutions to problems, make more empathetic statements, and offer greater support for students' internalization of learning goals (e.g., providing more rationale for why an assignment should be accomplished or for the value of the learning goals) [4].

In addition to training the IM TAs on these skills, we empowered the TAs to create course structures that reinforced students' senses of autonomy, competence, relatedness, and purpose [2]. For example, the TAs were given permission to let student learning teams create their own design project in place of an exam. Further, the TAs focused their attention on guiding these teams rather than presenting content or example problems during class time.

III. RESEARCH DESIGN

Each week, the two TAs wrote about 300 words in response to journaling prompts about their experiences. These prompts guided the TAs to identify challenges and successes as well as outcomes related to students' IM.

Based on a grounded theory approach, we started the analysis with by describing and conceptually organizing the TAs' journal reflections [5]. We used an open coding scheme to categorize the TAs' statements and actions to describe when and how the TAs used IM-supportive or controlling strategies in their interaction with students. A more detailed account of this analysis can be found in the I-STEM report [6].

IV. FINDINGS

Analysis of the TAs' journals revealed two contrasting behaviors: IM-supportive behaviors and controlling behaviors. Adoption of an IM-supportive mindset was challenged and revealed in two particular situations: identification of success as an instructor and responses to unwanted behaviors.

A. Identification of success as an instructor

An IM-supportive TA defines success in instruction by continual improvement. He has the mentality that all students can become intrinsically motivated to learn and aims to see that growth. This improvement orientation leads to constant reflection on himself as a teacher and how his actions impacted

the students. He explores and questions the sometimes competing demands of supporting students' learning while needing to promote specific behaviors to certify that the students have learned the required material.

"One of the hardest things to do while teaching is to find balance points. The balance comes between giving students autonomy and directing them explicitly, and between being open and friendly with them and having to chastise them if they screw up."

Similarly, IM-supportive behaviors were linked to critical reflection, a constant goal for improvement, and concrete plans of actions to create improvement. He evaluates his policies based on how those policies might affect his students (emphasis added):

*"I think it's a trait of a good teacher to have a set of relatively clear policies in place at the beginning of the semester; during the semester the teacher should not modify these policies. **This can allow students to focus their attentions on learning rather than policies.**"*

In contrast, controlling TAs define success by achievement of pre-determined goals. For example, since a controlling TA's goal is to evaluate students' IM to learn, he focuses on categorizing students as intrinsically motivated or unmotivated rather than critically reflecting on his actions.

"When I was a sophomore, I wasn't particularly concerned with grades, I was more interested in learning and understanding the material. I think the focus on grades is what separates the intrinsically-motivated students from the unmotivated/disinterested."

For example, one TA, after labeling his students, was slow to notice when students' motivations changed. When a "bad" group asked him to attend their group meeting on a Sunday, he failed to notice this auxiliary meeting or extra effort as a motivational change. Perhaps more telling, when a "bad" student approached him to get help with managing a project, his actions indicated an unwillingness to help and a lack of reflection on how to improve the situation:

"I told him that it wasn't my responsibility to make sure his group meets outside of class and distributes the project workload evenly, and that he should try to explain to his group that they should contribute more."

B. Responses to unwanted student behavior

IM-supportive TAs respond to unwanted student behavior with reflection on students' needs in addition to discipline. For example, in response to students' cheating, an IM-supportive TA identified the students' lack of a sense of competence (trust in their own ideas and freedom to fail) and relatedness (trust in the instructor) as barriers to motivation:

"...students need to learn to be creative and to trust their own ideas. This demonstrates students' current understanding, which may be slightly flawed, but as a teacher it's my job to gain students' trust and to structure

the course such that students feel comfortable making mistakes without a significant detriment to their grade."

In contrast, a controlling TA responds with quick-fixes to surface problems that do not identify students' needs.

"I'd prefer that students be relatively autonomous, but if they don't come to discussion, I can't help them. I'd prefer to never take attendance, but if the situation doesn't improve, I may start."

V. DISCUSSION AND RECOMMENDATIONS

The TA training raised the TAs' awareness of IM. Both TAs mentioned the importance of IM and sought to engender it among their students. The TAs also frequently referenced the IM-supportive goals of supporting students' four needs: senses of autonomy, competence, relatedness, and purpose. Although both TAs intellectually agreed to the importance of IM, they varied in their level of adoption of IM-supportive pedagogies.

In much the same way that intrinsically motivated students always seek to better understand a domain, IM-supportive TAs need to become relentlessly reflective to better understand their students. When students fail or appear unmotivated, TAs must reflect on how their actions meet students' four needs rather than label students as "good" or "bad." This emphasis on students' needs may be fostered by focusing the TAs reflections more explicitly on students' needs. Although we primarily intended for the TAs' reflective journals to be used as a research instrument, we discovered that reflection may be even more important as a training tool and empowering TAs to become agents of change. In response, we plan to develop tools to help TAs practice these reflective behaviors while they are in the classroom. By combining deep reflection with a solid theoretical foundation in motivation, we believe that TAs can play a major role in promoting students' intrinsic motivation to learn and creating a new learning culture.

ACKNOWLEDGMENTS

Thanks to the intrinsic motivation section TAs.

Department Climate: A Key to Recruiting and Retaining a Diverse and Successful Faculty

Rebecca Brent

Education Designs, Inc.
Cary, North Carolina, USA
rbrent@mindspring.com

Abstract—A *department climate* is the set of factors that affect whether department personnel feel appreciated, safe to express opinions, and respected by their administrators and colleagues. A 2006 study conducted by The University of Wisconsin *Women in Science and Engineering Leadership Institute* (WISELI) demonstrated that climate significantly impacts faculty members' job satisfaction and effectiveness and their decisions to stay or leave. Research also shows that climate problems have the greatest impact on members of underrepresented groups.

A project supported by the NSF ADVANCE-PAID program was carried out over a three-year period at a large public university. Heads of 25 departments (16 STEM, 9 non-STEM) participated in a series of workshops on the effects of climate on faculty recruitment and retention; faculty and staff from each department were surveyed using a variation of the WISELI Climate Survey; and the heads, faculty, and staff of each department formulated action plans to improve their climates. This paper summarizes and discusses the project implementation and outcomes, identifies the conditions that have the greatest positive and negative effects on climate, and suggests measures administrators and faculty members can take to improve their departments' climates.

Keywords: *Department climate, faculty recruitment, retention, diversity*

I. INTRODUCTION AND BACKGROUND

The *Collaboration on Academic Careers in Higher Education* (COACHE) regularly surveys 4500 tenure-track faculty members at 51 colleges and universities. In a 2006 report they reported a marked shift among junior faculty toward "caring more about department climate, culture, and collegiality than they do about workload, tenure clarity, and compensation" [1]. The data indicate that climate was as much as five times more important than compensation in predicting job satisfaction. Recruiting and retaining a diverse faculty is a continuing challenge in most STEM disciplines. In view of the dramatic finding just cited, deans, department heads, and faculty would do well to ask, "What is department climate, and how can we improve it for all our faculty, including women faculty and faculty of color who may be experiencing the climate differently from many of their colleagues?"

The *Women in Science and Engineering Leadership Institute* (WISELI) at the University of Wisconsin defines climate as "behaviors within a workplace...that can influence whether an individual feels personally safe, listened to, valued, and treated fairly and with respect." A widely disseminated WISELI study [2] indicated that department climate significantly impacts faculty members' job satisfaction, effectiveness, engagement, productivity, and decisions to stay or leave. Research also shows that members of underrepresented groups are more negatively affected than their majority colleagues by climate problems.

WISELI began offering a workshop series for department heads in 2003 as a part of their National Science Foundation ADVANCE (Increasing the Participation and Advancement of Women in Academic Science and Engineering Careers) grant. Department heads committed to attend three workshops during an academic year to learn about climate and ways they could effectively improve it in their departments. A climate survey was administered electronically to faculty and staff (and sometimes graduate students and postdoctoral fellows), and the ratings were shared with the department heads. Between 2003 and 2009, the survey was administered to 39 departments at the university with response rates varying from 27% to 76%.

Two notable findings of the WISELI project were these:

- While a majority of faculty and staff reported a positive overall climate, significant minorities ($\approx 13\%$ of faculty, $\approx 15\%$ of staff) reported a negative or very negative climate.
- Common issues emerged that contributed to negative climate ratings, including respondents' (a) feeling underappreciated for their work ($\approx 21\%$ of faculty, $\approx 22\%$ of staff) and isolated ($\approx 24\%$ of faculty, $\approx 18\%$ of staff), (b) lacking adequate resources for doing their job ($\approx 19\%$ of faculty, $\approx 11\%$ of staff), and (c) mistrusting those making decisions that affected them ($\approx 23\%$ of faculty, $\approx 20\%$ of staff).

The project described in this paper was supported by National Science Foundation ADVANCE PAID Grant Number 0820013.

II. PROJECT DESCRIPTION

In 2009, a public land-grant university with one of the largest undergraduate engineering student enrollments in the country received an ADVANCE Partnership for Adaptation, Implementation, and Dissemination (PAID) grant. The grant included (among other things) adapting the WISELI climate workshop series for department heads and the climate survey of faculty and staff [3]. This paper reports on the results of administering the adaptations to 25 departments over three academic years. Institutional Review Board approval was obtained for each component of the work to be described. The author functioned as the internal project evaluator, whose tasks included participating in all workshops, administering the survey, and compiling and analyzing the responses.

In 2009, two leaders of the grant activities went to the University of Wisconsin for training on the WISELI workshops and climate survey. In the 2009–2010 academic year the program followed the WISELI format of three workshops with the climate survey administered between the first and second ones. After the first year, the leadership team made a few minor changes to the survey in response to department head suggestions and comments from respondents and increased the number of workshops from three to four to allow more time for discussion of the survey results and their implications.

In the second and third academic years, the program organization was as follows:

- *Workshop 1: Introduction to climate and sharing of relevant COACHE data.* The value of the COACHE results is that they enable comparisons with peer institutions.
- *Workshop 2: Discussion of ways to improve climate and preview of the climate survey process.* Department heads were made aware of resources on climate improvement [4,5] and examined key ideas for improving climate and preventing biases from influencing hiring decisions. Procedures for administering and collecting the upcoming climate survey were then reviewed.
- *Administration of the survey to faculty and staff.*
- *Workshop 3: Discussion of the survey results and formulation of plans for sharing the results with the department faculty and staff.* Only the department head and project evaluator saw the results for each department's survey. The heads shared surprises and problem areas in the results and discussed possible actions to address identified problems.
- *Workshop 4: Discussion of faculty and staff responses to the reporting and of corrective actions taken in the departments and additional actions planned for the coming year.*

III. CLIMATE SURVEY

A. Survey structure and response rates

In the years 2009–2012, heads of 25 departments (16 in STEM disciplines, nine in non-STEM disciplines) participated in the workshop series, and faculty and non-teaching staff from each department were surveyed using a variation of the WISELI climate survey [3]. Respondents were given the WISELI definition of climate and were then asked to rate the overall climate in their department and their agreement or disagreement with each of 26 statements about the climate. They were also asked open-ended questions about factors affecting their department climate and the expectations they had of their department head. Surveys were sent to 1235 faculty and staff, and 913 responded for a 74% response rate, which is considered an outstanding rate of return for survey research. The breakdown of response rates by faculty and staff is shown in Table I.

TABLE I. SURVEY RESPONSE RATE

| | Surveys Sent | Responses Received | Response Rate |
|---------|--------------|--------------------|---------------|
| Overall | 1235 | 913 | 74% |
| Faculty | 829 | 625 | 75% |
| Staff | 406 | 288 | 71% |

B. Overall climate ratings

Climate ratings (5=very positive, 4=positive, 3=neutral, 2=negative, 1=very negative) were compiled for individual departments and the complete set of respondents, and the latter data were broken down into faculty and non-teaching support staff and into STEM (science, technology, engineering, and mathematics) and non-STEM disciplines. The results are shown in Table II. The heading “%neg” denotes the total percentage of “negative(2)” and “very negative(1)” responses.

TABLE II. OVERALL CLIMATE RATINGS

| | Ratings | | Dept. Range | |
|------------------------------|---------|------|-------------|----------|
| | Mean | %neg | Mean | %neg |
| Faculty (N=609) ^a | 3.90 | 11% | 2.9–4.7 | 0%–42.9% |
| Staff (N=275) ^b | 3.85 | 9% | 3.0–5.0 | 0%–32.0% |
| STEM (N=679) | 3.79 | 12% | 3.1–4.7 | 0%–32.5% |
| non-STEM (N=205) | 4.07 | 6% | 3.4–4.8 | 0%–25.8% |

^aWISELI data: Faculty mean = 3.69, %neg = 13%

^bWISELI data: Staff mean = 3.59, %neg = 15%

While roughly 70% of each group reported a very positive or positive overall climate, 11% of the faculty and 9% of the staff reported a very negative or negative climate (13% and 15% in the WISELI study). When thinking about climate, it is important to remember that underrepresented groups such as women in engineering often experience the climate differently from their majority colleagues. (Confidentiality requirements precluded separate compiling of survey results for different genders and ethnicities.) The consistency of the faculty and

staff ratings with those found in the WISELI study is quite good, suggesting that the survey data might be generalizable to comparable institutions (i.e., to large public universities).

C. Ratings of individual climate factors

Table III shows abbreviated forms of the 26 climate survey statements that respondents were asked to agree or disagree with (5=strongly agree, 4=agree, 3=neutral, 2=disagree, 1=strongly disagree), the mean responses of all faculty and staff respondents, and the responses for the departments with the highest and lowest overall climate ratings. Differences of one unit or more in the latter responses are shown in boldface.

TABLE III. AGREEMENT WITH INDIVIDUAL SURVEY STATEMENTS.

| Item | Mean | Dpt1 | Dpt2 |
|---|------|------------|------------|
| Overall climate rating | 3.9 | 4.7 | 3.1 |
| 1. Welcoming department environment | 4.0 | 4.6 | 3.3 |
| 2. Understand my role & responsibilities | 4.3 | 4.5 | 4.2 |
| 3. Have adequate resources | 3.6 | 4.5 | 3.6 |
| 4. Feel appreciated for my work | 3.7 | 4.2 | 3.0 |
| 5. Opinions & contributions respected by head | 4.0 | 4.6 | 3.7 |
| 6. Opinions & contributions respected by faculty | 3.7 | 4.1 | 3.5 |
| 7. Opinions & contributions respected by staff | 4.1 | 4.5 | 4.1 |
| 8. Trust in people who make decisions that affect me | 3.6 | 4.3 | 3.1 |
| 9. Influence decisions made in department | 3.3 | 4.0 | 2.9 |
| 10. Head appropriately consults or delegates decisions | 3.9 | 4.8 | 3.4 |
| 11. Feel safe voicing feelings in front of others | 3.7 | 4.3 | 3.2 |
| 12. Have heard faculty make biased remarks | 1.7 | 1.2 | 2.3 |
| 13. My work contributes to department mission | 4.4 | 4.6 | 4.2 |
| 14. My colleagues recognize my contributions | 3.7 | 4.1 | 3.4 |
| 15. Satisfied with professional relationships with others in department | 3.8 | 4.4 | 3.4 |
| 16. Satisfied with personal relationships with others in department | 3.8 | 4.4 | 3.4 |
| 17. Had a thorough performance review in past year | 3.7 | 4.3 | 3.2 |
| 18. Someone in department promotes my professional development | 3.4 | 3.8 | 2.9 |
| 19. Department emphasizes importance of diversity | 3.8 | 4.8 | 3.2 |
| 20. Resources are allocated fairly in department | 3.4 | 4.3 | 2.9 |
| 21. "Even though other people are around, I feel isolated." | 2.4 | 1.9 | 3.0 |
| 22. Work commensurate with my training and experience | 4.1 | 4.3 | 4.1 |
| 23. Same level of responsibility & recognition as my peers | 3.6 | 4.3 | 3.6 |
| 24. Head accommodates personal & professional conflicts | 4.0 | 4.5 | 3.5 |
| 25. Aware of places or people to go to with problems or issues | 3.9 | 4.5 | 3.7 |
| 26. Differences among people are valued | 3.6 | 4.4 | 3.0 |

On average, high ratings were given to statements regarding the respondents' sense of the importance of their work, their understanding of their roles and responsibilities, and the respect they received for their opinions and contributions, and relatively low ratings were given to their perceived influence on decisions made in the department, the existence of someone in the department promoting their professional development, and the fairness of resource allocations in the department. There were no consistent patterns of differences between responses of faculty and staff.

Some interesting results can be seen in a direct comparison of the responses to individual questions submitted by the departments with the highest (4.7) and lowest (3.0) overall climate ratings. The highlighted differences of one unit or more suggest measures that department heads and faculty wishing to improve their department climates might consider adopting. They include taking steps to make all faculty and staff members feel like valued members of a professional community; publicly acknowledging and expressing appreciation for their contributions and achievements; seeking and giving serious consideration to their opinions before making decisions that affect them; providing them with regular performance reviews; making sure that resources are fairly allocated among them; strongly discouraging any biased or demeaning language directed against any faculty member, staff member, or student for any reason, and countering it if it occurs in a public forum.

D. Preliminary analysis of open responses

Inspection of the survey respondents' open comments supports the recommendations made in the previous section. The comments suggest that both faculty and staff would welcome more opportunities for social interactions with their colleagues, greater transparency about department decisions and more opportunities to influence and inform those decisions, and less negative and bullying behavior. Staff in particular wanted more frequent communication about information and events and for others to notice and appreciate the work they do. Faculty sought more mentoring relationships and greater participation by their colleagues in seminars and social events.

IV. DEPARTMENT HEAD ACTIONS

The participating department heads received survey results for their departments and reported the results to their faculties and staffs. In some cases they transmitted all the results but more often they simply summarized response patterns, and then they discussed the results and identified actions that would be taken to improve their department climates. Actions taken included:

- establishing a task force or standing committee charged with developing plans to improve the climate;
- organizing more social events to promote interaction and reduce isolation;
- recognizing staff and faculty accomplishments in regular newsletters or in announcements in faculty meetings;
- including one or more staff representatives in faculty meetings;
- organizing brown bag lunches for the department head, faculty, and staff to discuss concerns and increase interaction.

V. FUTURE WORK

The survey responses contain a substantial body of information. Future work will include grounded theory analysis of the responses to uncover patterns and themes that may help

identify additional actions to improve department climates and reveal significant differences between faculty and staff responses and between STEM and non-STEM personnel responses. In addition, departments will be revisited to identify changes the heads made following their participation in the program and the impact of those changes on their departments' climates.

ACKNOWLEDGMENT

Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author and do not necessarily reflect the views of the National Science Foundation. This paper reports on work to which many people have made vital contributions, notably Marcia Gumpertz, Betsy Brown, Margaret Daub, and Ming Trammel.

Abstract—The use collaborative of pedagogies in undergraduate engineering courses are usually implemented by academics who place value on the student experience and their students achieving deep as opposed to surface learning. The professional development and understanding of appropriate theories needed to prepare materials and support student learning in these different teaching environments is often left to the academic to pursue independently, if at all. Whilst individual academics who revitalise courses in line with collaborative learning practices have the motivation, personality and teaching skills necessary to facilitate a class or groups of students, it may not be so for additional 'tutors' allocated to assist. Their differences in philosophy, personality and skills may have major impacts on the student learning experience. Even where tutors may be experienced academics in their own right, they may not fully understand the rationale and methods being employed and may need skill development. Professional development of academic staff is often overlooked in universities but it is vital for staff to engage in new learning and teaching practices and skill development if collaborative teaching strategies are to be sustained and make a positive contribution to the student learning journey. These factors become even more important as universities move into the online environment where meaningful engagement with the student cohort is significantly more than just making content available and having electronic submission of assignments. This paper describes the development of a strategy to train engineering tutors in online PBL facilitation, and the evaluation framework used to assess the effectiveness of this training. Results of the evaluation of training and subsequent behavioural changes of the tutors are given. The evaluation revealed a variance between the message of the training and subsequent practice. The method of evaluation, and subsequent findings were enabled, rather than constrained by the online environment.

Keywords—component; Problem Based Learning; professional development; tutor training; evaluation; online teaching

I. INTRODUCTION

The Engineering Problem Solving Strand is a core strand of four courses offered in all of the Faculty's undergraduate programs (Bachelor of Engineering, Bachelor of Technology and Associate Degree programs across all majors). The courses use a Problem/Project Based Learning paradigm and students work in teams to meet a wide range of course objectives. The team size varies in the courses from eight student per team in first year to four students per year in the

final year course. Objectives include both technical skills and knowledge as well as several key graduate attributes e.g. teamwork, communication, problem solving etc. The problems are open ended contextualized engineering problems. These courses have been recognised through several national awards for innovation in curriculum.

These types of courses have a high staff workload allocation due to the interactive and facilitative nature and often use a large number of part time (sessional) staff. Full time academic staff are also regularly rotated into the courses to balance workloads. Due to the unique nature of courses of this type and the general flexible learning environment offered at the institution, staff development is critical because each semester sees a new wave of staff who need to be quickly up-skilled in the learning and teaching philosophy, pedagogy, facilitation skills and procedural processes of a particular course. As a result of this concern, staff development resources and workshops were put in place to make sure that tutors understood the rationale of the course and how best to operate within it. However, until now they have been run on an ad hoc basis, with no formal mechanism to monitor staff requirements or evaluate either the workshop or the courses in terms of facilitator training.

PBL courses require high energy maintenance to keep delivering their promised benefits year after year. In developing staff resources it came to our attention that some of the pressure of this maintenance could be relieved by instituting ongoing monitoring and evaluation structures which would let course controllers know at any point in time how the courses were travelling and make informed decisions about change when necessary.

This paper researches and evaluates the success of the training program in changing tutors conceptual knowledge of PBL and how it operates, particularly in the online environment. We have analyzed tutor interaction with teams through postings to discussion forums to determine if this increase in knowledge changes tutors behavior from a transmission mode focusing on tasks to *facilitating* student learning and team work skills.

II. THE ROLE OF THE TUTOR IN PBL

PBL requires special skills in its teaching staff because it is a form of learning in which the learner constructs their knowledge based on prior skills, knowledge and their overall views [1]. The

prompt for the learning is an ill structured problem which is complex and does not have a single correct answer. Students have the opportunity to develop skills in problem solving, critical thinking and self directed learning [2-4].

PBL has three characteristics:-the learning is situated in a real life context or problem; students are responsible for their own learning and the direction of their own research; learning and ideas are elaborated and tested by group discussions [5]. In this student-centred discourse, students drive the discussion and the teacher serves to guide the learning process. Thus tutors or teachers of PBL do not „primarily disseminate information“ to students but guide the students to find their own answers, provide feedback, and stimulate student interest and learning [6]. Tutors scaffold student learning.

The effectiveness with which facilitators can do this is influenced by the conceptions the facilitators themselves have about effective teaching and learning [7]. Rando and Menges [8], propose that these personal theories of teaching and learning are often implicit and may be inaccurate. The theories may be broadly categorised into two main areas: „learning facilitation“ and „knowledge transmission“ [7]. Lecturers who see their role as transmitting knowledge are more focused on content than on learning. They have a didactic approach to teaching, seeing themselves as the content expert and their role is to pass on this content to the students, who passively absorb the knowledge. Many participants in our workshops have expressed concerns about how best to get the information across to students, thus revealing a transmission model. Other lecturers see their role as „facilitating“: encouraging students to learn for themselves and explore the content. These two different approaches to teaching may explain the different profiles and effectiveness of PBL tutors. [5, 7].

[6] reported on the major trends in studies investigating tutors in PBL. Not surprisingly perhaps, it concluded that the „content expert“ tutor took a more directive approach, using their content knowledge to direct the group discussions, whereas the non-content expert took a more supportive role and used „their process-facilitation expertise more to direct the tutorial group“. In addition, the research concluded that a tutor should „...know how to deal with the subject matter expertise“, although not necessarily be an expert, and know how to facilitate the learning process. Professional development for PBL tutors is therefore a matter of encouraging a truly facilitative rather than instructional pedagogic approach.

Recognition of the *skill* of facilitating and recognition that a tutors performance is not a stable characteristic but is partly situation specific are important factors to be considered by Faculty. This can be supported by opportunities that stimulate personal reflection and providing a good background in relevant educational theory and a thorough understanding of the key concepts of PBL. Our tutor training program aims to provide such opportunities by placing tutors in the role of students in a PBL session, supported by relevant resource materials and active discussion.

III. TUTOR RESOURCES AND TRAINING

Effective training programs for staff are an essential ingredient in the long terms sustainability and success of the PBL course or program [9]. It is critical that these professional development programs are ongoing, so as to support the program after the first flush of enthusiasm is over and that they can be delivered „just in time“ to meet the needs of new staff coming into the program or old hands who need to be revisit the rationale and methods of PBL.

In planning the training, several basic elements must be considered [9]:

- The educational goals and outcomes of the course or program, including the curriculum content.
- The resources which can be directed to the training program. This includes the time staff and management may be willing to devote to professional development activities.
- The evaluation of tutors/facilitators.

Our training program consists of a day-long immersive exercise, a thorough and up-to-date library of reference works to support tutors and an evaluation framework. In developing this program we have tried to tailor material for our specific implementation of PBL, our course objectives, but maintain some generic material which enables it to be used in other courses in other faculties with different goals. In time, some of the basic material will be in an online interactive format, enabling staff to undertake at least some preparation in their own time and review material as needed. All staff from the senior academic in charge of the course through to part time sessional tutors (of facilitators) were strongly encouraged to attend the course by Heads of Departments, Program Coordinators and the Associate Dean Learning and Teaching.

In line with PBL theory the training is presented as a PBL exercise using the Triple Jump Process as developed by McMaster University. The trigger for discussion and exploration of PBL is a video which shows a PBL lesson in a primary school. From the video, key concepts of PBL are explored and the participants generate a hypothesis which can be further explored in the available literature. From this exercise misconceptions and misunderstandings about PBL can be addressed and ideas for further self directed learning can be stimulated. This approach has the advantage of putting tutors in comparable situations to those faced by their students in PBL courses, which can include uncertainty about the objectives, the process and the outcome.

The second half of the training elaborates the insights of the PBL session through group discussion, typically of such topics as:

- Developing „questioning skills“; task orientated questions and monitoring questions can help students set goals, monitor progress (individually and of the group), activate prior knowledge and focus attention. These are in line with the facilitators educational goals for the student [2].

- Identifying common or recurring problems which arise in student teams and developing strategies and resources to deal effectively with these problems.
- Understanding the need for reflective practice both in

- students and for a in-depth examination of the tutor's own practice
- Understanding the implications of working in an on-line environment.

TABLE I. MATRIX FOR MONITORING ACTIVITIES

| FOCUS | PERFORMANCE INDICATORS | DATA SOURCES | DATA COLLECTION METHODS | RESPONSIBILITY FOR COLLECTION | TIME FRAME |
|--|--|-------------------------|-------------------------|-------------------------------|------------|
| <i>Objective: to encourage tutors to facilitate and scaffold learning through timely, well-placed, supportive guidance</i> | | | | | |
| Outputs Tutor participation in online discussions | Tutor responds to discussion at least once a week Tutor identifies and responds to learning process | Online discussion lists | Audit | Course controller | 2xsemester |
| Outcomes Students exchange ideas and identify learning | All students in group participate at least once a fortnight Students identify what needs to happen next | Online discussion lists | Audit | Course controller | 2xsemester |

With the clear need to redefine the tutor's role from instruction to facilitation, this day of training challenged tutors to begin their own learning journey. Although an evaluation of the day is carried out at the end of it, the true outcomes and impact can only be gauged after tutors have had some time to think over the issues presented, practice on their students and use the support materials. Since the courses build on one another from semester to semester there is also the possibility that needs and strategies will change over semesters and years. Our evaluation framework was designed to meet this reality.

IV. MONITORING AND EVALUATION

We have followed the lead of major development organisations, the World Bank and government departments in taking a program logic approach to monitoring and evaluation [10]. The approach identifies all relevant inputs, outputs, outcomes and impacts so as to decide what needs to be monitored and evaluated [11-13].

Table I shows part of the matrix we used in planning monitoring activities. For the sake of space we have dealt with only one output, tutor participation in online discussion lists and one outcome from that output. In practice several outputs and outcomes are usually associated with each goal.

The act of articulating the logic of the program in this way commonly reveals previously hidden and perhaps conflicting assumptions about what the program is designed to achieve and how it will achieve it, which immediately provides a rationale for this approach. However, once all the elements of the program have been articulated it is then possible to examine what needs to be monitored and how.

V. DATA COLLECTION

One of the goals of the project was to evaluate how well the initiative had worked and to make plans to monitor progress in order to be able to adjust training and tutor support in a timely manner if necessary. To this end a Program Logic analysis was undertaken [14]. At that time the monitoring decided on resulted in the following data collection strategy illustrated in Table II (although this may need alteration in the light of experience). The same process produced a list of evaluation questions for the first year implementation of the training and

resources which again may need to change with time. The data collection strategy was implemented using the cohort of first of the PBL courses (run in semester one of first year for all students). This is the largest course with approximately 550 students in 75 teams and 12 tutors (facilitators).

Only six of these tutors attended the training. As the course runs with the majority of students working in fully online teams the remainder of the tutors are not actually on-campus and hence could not participate. In time we plan to be able to run the training in an online format.

The tutors come from varied backgrounds including graduate students, experienced academics, a professional practicing engineer, senior school mathematics and physics teacher, a geologist and a physicist. Throughout the running of the course this team of tutors are supported to work as a team themselves with a staff discussion forum etc so as a group they can discuss student team issues, clarify „technical“ questions from the problems, moderate marking, share strategies etc. All tutors have access to all discussion forums so they can observe the work of all teams, but they generally do not post to the forum of another facilitator.

TABLE II. DATA COLLECTION STRATEGY

| Data Collection | Timing | Report |
|--|---|---|
| Exit surveys | Training day | Immediate to course controller Add to data log – annual report |
| Analysis of discussion lists – tutor behaviour | Scan Half way through semester End of semester | Feedback to tutors Add to data log – annual report |
| Analysis of discussion lists – student behaviour | Scan Half way through semester Annually | Feedback to tutors Annual report |
| Peer discussion | End of semester | Feedback to tutors Add to data log – annual report |
| Course reflection | End of semester | Feedback to tutors Add to data log – annual report |
| Library list | End of semester | Add to data log – annual report |

VI. ANALYSIS

Due to space limitations only a brief analysis from exit surveys, analysis of discussion forums and tutor course reflections will be discussed.

A. Exit surveys

The exit survey looked at both questions responses on a Likert scale and short answer responses. The survey covered the following questions. The training session:

- a) helped clarify my understandings of group learning
- b) helped clarify the role of the tutor
- c) motivated me to focus on learning processes not content
- d) gave me strategies for focussing on learning processes

A qualitative approach to the survey also asked the following questions:

- In my case the barriers to a more process-centred approach are
- Mechanisms I might use to overcome those barriers are
- The thing/s I like most about the workshop
- The thing/s I like least about the workshop

B. Discussion threads

An analysis of online teamwork and facilitation was used as a major source of data for consideration of the evaluation questions. The research team sampled the forum threads for each workgroup for one course in one semester. In order to restrict the volume of data to be analysed, a number of parameters were applied to the data collection. Only threads with greater than six posts were included for analysis, unless there was insufficient data from other threads for a given workgroup. The threads included were those in which the group facilitator contributed and responded to student discussion or interaction. Threads which were set up for the students to approach the facilitator with questions were not included, as these interactions constituted student initiated learning, rather than facilitator initiated. Likewise, posts from tutors which contained standard or generic course information or advice were not seen as significant for indicating facilitator performance, unless that information was particular to undertaking learning in PBL. Included in the data are the numbers of threads for each tutor which yielded data for analysis.

In analyzing the data, facilitator posts were coded according to seven observed nodes of interaction type. These were:

- **Confirmation**, in which the facilitator confirms a point from the discussion on the forum

- **Pointing out problems**, in which the facilitator points out a problem or potential pitfall with the team's work or procedures
- **Prompting content**, in which the facilitator prompts students to include some form of content in their report or assessment
- **Prompting learning behaviours**, in which the facilitator makes a post which encourages a certain learning behaviour or task to be performed by students
- **Providing content**, in which the facilitator gives students content to include in their report or assessment
- **Questioning**, in which the facilitator asks students a question about their learning or processes
- **Recognition**, in which the facilitator provides a positive acknowledgement that student work or processes are effective or appropriate
- **Reminders**, in which the facilitator includes a reminder regarding a task to be performed, content to be included or a procedure to be followed.

C. Course reflection

Reflections from tutors were collected in the form of responses to a structured template. Questions covered:

- **My background before joining the course** (e.g. background in Engineering, background in tutoring, new to facilitation, past experience as a student of the course, facilitated for several years, participated in training sessions, etc):
- **How I saw my role in the course**
- **My focus for facilitation during the course** (what I tried to work on and how with regards to facilitation, what I see as important in the course and how worked on this with students) :
- **My impressions of the course** (could be about course design, the role of the facilitator, the subject matter being learned, student responses, assessment, admin procedures, academic aspects, etc):
- **Conclusions/Recommendations for the future** (based on the above observations that were significant for me)
 - Problems (administrative or academic)
 - Positives (what things went well, what should we definitely keep)
 - Priorities (what should we be focusing on e.g. problem solving, technical aspects, teamwork etc) List in order
 - Processes (how can we structure the course to minimise the problems, keep the positives and hit the priorities); can be administrative, academic, resources etc

- **Comments to expand on the above (if necessary)**

VII. RESULTS

A. Exit surveys

The use of a PBL structure to teach the tutors about PBL appears to have been well received and judged appropriate as shown by the exit survey results and the comments of tutors at interview. However, some of the gap between tutors' knowledge of PBL and their practice of it may be attributable to the fact that a single workshop session may not constitute sufficient exposure to the method. One authority [15] is of the opinion that it takes five weeks for classes to adapt to the method. Nevertheless we are of the opinion that the format of the workshop was effective in changing tutors' *thinking* about what PBL means in terms of facilitation but a longer term strategy is necessary to change consistently *behaviors* and practices.

B. Discussion Threads

According to the theory of PBL, questioning and prompting learning behaviours are the most appropriate and effective facilitator behaviours. Confirmation, pointing out problems, questioning, recognition and reminders are also appropriate, as they do not contradict the tenets of PBL and they support effective learning processes, especially when used in combination with questioning and prompting learning behaviours. Prompting and providing content, on the other hand are seen as less appropriate, as they do not actively encourage student self-directed learning.

To give an idea of how each of these types of facilitation appear in practice, following are examples of each (taken from a variety of tutors).

- **Confirmation:** "You have it exactly right. For the best marks in almost every assessment criteria you should be endeavouring to demonstrate (not just theorise) this principle."
- **Pointing out problems:** "I get a lot of reports submitted where it's obvious that one person has come up with the design objectives and another has done the evaluation strategy, with barely any relationship between the two."
- **Prompting content:** One other thing that I would advise is to include your CoC within an appendix and refer to it within the TE&R."
- **Prompting learning behaviours:** "You should see your lack of knowledge (or inability to contribute further) as an opportunity to do steps 3 and 4 of the Problem Based Learning process."
- **Providing content:** "Ideas such as planting native vegetation on the W-WSW side of the shed to protect it from the hot sun in the afternoon should be part of your strategy."

- **Questioning:** "Do these evaluation questions stem from your background research and design objectives?"
- **Recognition:** "Having the two different lists is a good idea as it gives you a certain amount of flexibility for the next report."
- **Reminders:** "I would like you all to reread my opening post in this thread."

TABLE III. ANALYSIS OF DISCUSSION THREADS

| Facilitation Technique | Number of instances for each tutor | | | | | |
|-------------------------------|------------------------------------|---------|---------|---------|---------|---------|
| | Tutor A | Tutor B | Tutor C | Tutor D | Tutor E | Tutor F |
| No of threads yielding data | 10 | 8 | 8 | 2 | 2 | 1 |
| Confirmation | 4 | 3 | 4 | 3 | 1 | |
| Pointing out problems | 7 | 4 | 5 | 1 | | |
| Prompting content | 1 | 10 | 9 | 1 | | 1 |
| Prompting learning behaviours | 18 | 6 | 11 | 1 | 4 | 1 |
| Providing content | | 4 | | | | |
| Questioning | 12 | 2 | 1 | 1 | 3 | 1 |
| Recognitions | 7 | 10 | 13 | 1 | 1 | 1 |
| Reminders | 3 | 3 | | | | |

The Table III summarises the results by facilitation technique across each tutor for which data was available. However, a number of tutors' results are worth examining in closer detail.

Tutor A provided the best exemplar for PBL facilitation, by frequently displaying the desired facilitation techniques of prompting learning behaviours, questioning, pointing out problems and recognition. This tutor's discussion forums yielded a high number of instances of facilitation compared to other tutors, suggesting that this tutor was frequently, consistently and effectively involved in their groups' learning processes, without unduly directing them.

C. Tutor reflections

The tutor reflections provided a rich source of data and only a preliminary analysis can be provided in this paper. Tutors provided 'at the coal face' insight to many administrative aspects of the course from assessment criteria to the supporting technology available to the students teams e.g. wiki, synchronous and asynchronous communication mechanisms e.g. "Students found the university chat and wiki services unreliable at times" and "Students were generally unhappy with the time to receive assessment feedback."

Generally tutors believed in the aims of the course and through it provided a realistic grounding from students in many of the transferable skills which were in line with the course objectives. Given that several of the tutors were also past students who have since graduated and entered the work force their input is invaluable. However, despite the training the difficulty of „facilitation“ and understanding PBL remains a confounding issue.

However, few of the tutors made direct reference to the *training* in their reflections. The most valuable aspect of the training was in fact the „training evaluation strategy“ which they perceived as giving direct feedback to their facilitation styles and skills and directly supported student learning outcomes e.g. “Would like to get feedback on my „performance“ from other facilitators as well as students. I know we can look them up ourselves [from standard university course evaluation questionnaires] but might be a good idea to compile reports at end of semester. I liked getting feedback from [the evaluator] last semester to confirm strengths and highlight weaknesses.”

VIII. CONCLUSION

Following the training of tutors, a content analysis of online teamwork forums was undertaken to identify key appropriate and inappropriate facilitator behaviours. In comparing this data with the results from in-depth interviews with selected tutors, and broad exit data obtained following the workshops, it was found that the facilitation versus transmission message of PBL was effectively communicated, accepted and understood by participating tutors. However, key facilitation behaviours did not transfer to instances of actual practice in the online environment. It is argued that whilst the training was appropriate for promoting the required pedagogies, such training should be combined with a number of supporting strategies to be optimally effective. These strategies include specific and detailed development of questioning techniques appropriate for the PBL environment. Effective questioning needs to be continuously practiced and monitored to ensure a consistency of approach across the staff team. Further, these techniques, and facilitation in general, need to be considerate of the online environment, accommodate its constraints and capitalise on its inherent strengths.

A key component of PBL is reflection and this is true for staff as well as students. Staff need to be encouraged to maintain a program of self reflection on their facilitation practices in order to maintain and develop their skills and knowledge of PBL. It is clear that there is a requirement for on-going faculty-level development and support for academic

professional development in the area of facilitation. Without such continuous support and opportunity for skill development, PBL and other cooperative pedagogies are unsustainable, and may lead to reduced learning outcomes in collaborative learning environments.

Developing Innovative Thinking Among Engineering Undergraduates:

Examining the Role of Slate Enabled Technology

Abstract— This paper reports the planned implementation for a NSF sponsored study that is being undertaken to examine whether effective use of instructional technology, specifically slate enabled technology, has an impact on the innovative thinking skills among engineering undergraduates enrolled in large lecture classes. The methodology used in this study a quasi-experimental mixed method approach utilizing a control and treatment group. Findings from the planned study can be used to improve innovative thinking skills through effective pedagogical approaches which may include employment of various forms of slate enabled instructional technology.

Keywords—innovative thinking; pedagogy; faculty development

I. INTRODUCTION

Innovative thinking skill development among engineering undergraduates is of critical importance to the global economy. The ability to transform creative ideas into useful products and services through problem-solving that requires applying known information to unknown situations, finding new information and assessing its value or worth, and collaborating synergistically to develop ideas can be developed through pedagogical approaches that create engaging and active learning environments. Instructional technology, when used effectively, has been shown to enhance educational environments facilitating active and engaging learning strategies such as providing access to information, ideas, and collaborative exchanges focused on generating innovative solutions. Recent advancements in slate enabled laptop computers and smaller slate hand-held devices (e.g., Tablet PCs, iPads, HP Slate 500s), a form of instructional technology, and their impact on innovative thinking skills have been relatively unexamined.

II. BACKGROUND

Innovative thinking has been defined as a “complex thinking process that is used to transform creative ideas into useful products and services [1].” In the context of educating undergraduate science, technology, engineering and math (STEM) majors, included in the definition is the assumption that an innovative individual has the skills necessary to accept change, can carefully select tools employed in the thinking and design process, the ability to problem-solve by applying known information to unknown situations, the ability to find unknown information and assess its value or worth, and the ability to collaborate to synergistically develop new ideas [1,2,3,4].

Literature has attempted to highlight skills that innovative engineering undergraduates would demonstrate. Using TRIZ theory (e.g., a theoretical model for inventive problem solving), problem-solving methodologies, and a variety of corporate based literature as references, engineering educators suggest that students would be able to set goals for their own learning and identify when they need to seek new knowledge to solve problems. Innovative thinkers should be able to give and receive feedback on new ideas as well as possess the ability to represent those ideas visually and contextually. Students should also be able to think critically so that they can assess the value of their prior knowledge and elaborate, translate, and summarize known and new information [3,4,5]. Documented attempts to develop and assess these skills among engineering undergraduates have been limited to senior capstone design courses and an approach that includes additional classes or a new curriculum coupled with workshops and training for both faculty and students that introduces students to the concept of innovative thinking [2,3,4].

While these efforts show some promising results relative to the development of innovative thinking there is little literature that discusses how these skills can be developed among first and second year engineering students, many of whom are enrolled in large lecture courses where delivery of core engineering content is a priority. However, a wealth of knowledge based in cognitive psychology identifies pedagogical approaches that can be used to facilitate more collaborative, active and engaging learning environments even in large lecture-based courses. This paradigm and the body of research associated with it suggests that instructional technology, if it is employed effectively, can serve as a means to engage students and promote active learning; facilitating educational environments that are related to the development of innovative thinking among undergraduates [6,7,8]. For instance, the ability to acquire knowledge can be developed through activities that employ seamless integration of instructional technology that has students repeat concepts in new and different contexts. This can include online instructional modules that provide students with immediate feedback [9]. Scaling of ideas and information, a key skill for innovative thinking, can be facilitated by software such as OneNote that allows students to outline and organize information and then easily share it with others. Students' skills in this area as well as overall achievement increases when the ability to manipulate and add graphics is present in the educational software utilized [6, 10, 11, 12]. The ability to elaborate by paraphrasing and summarizing known information either visually or contextually through note-taking can be assisted by e-inking features that allow students to build upon instructor delivered content [6, 11, 12]. Critical thinking is also a key skill in innovative thinking and can be developed through collaborative activities and problem solving that asks students to generate new ideas and bring knowledge that is applied to new and different situations [13]. Individuals need to have the ability to identify their own comprehension and explore new solutions. Instructional technology such as instructor provided online resources or polling features that use clickers allow students to check their own comprehension and can facilitate innovative thinking skills as students build upon pre-existing knowledge [6, 14,15]. Collaborative activities that use a group of peers to generate new ideas can be further enhanced through instructional technology such as course management software that allows for discussion boards. These online forums allow students to ask questions of one another and pose new solutions; activities which are linked to the development of innovative thinking skills [6]. Finally, instructional technology can provide enhanced presentation opportunities that allow an audience to review new ideas and provide input facilitating the development of entrepreneurialism, a key component of innovative thinking [6, 7].

New and different teaching approaches that can include recent advancements in slate enabled technologies that include iPads and smaller hand held devices such as the HP Slate 500 have been identified as an attractive form of instructional technology for use among engineering undergraduates [16].

For instance, Tablet PCs have been identified as one form of slate enabled instructional technology that can facilitate learning among engineering undergraduates since this medium allows for drawing on the computer screen. This educational activity is a valuable way for students to annotate prepared lesson documents, replicate graphs and other visual content, and take and share notes that include diagrams [17]. While there is a lack of research about how slate enabled technology can be used to facilitate innovative thinking among engineering undergraduates, social constructivist learning theory provides a conceptual framework to begin to understand more clearly how this form of instructional technology can have an impact on innovative thinking skills. Constructivist learning theory posits that active learning strategies that encourage interactions between learners as well as with the instructor can aid in cognitive development [18]. Explorative research has examined how this form of instructional technology can be used among engineering undergraduates to encourage innovative thinking. For instance, critical thinking skills, interaction with peers and instructors, and active processing of engineering course content which are inherently tied to innovative thinking have been shown to be enabled by using slate enabled features such as inking features, polling, and software such as OneNote and Dyknow [19]. In addition, frequent use of slate technology and associated features such as e-inking capabilities by engineering students is correlated with an increase in learning behaviors linked to innovative thinking [20]. Other studies have shown that Tablet PCs provide opportunities for collaborative note-taking, interactive exercises, and real time assessment which can create more opportunities for active learning among students [17]. Paired with teaching strategies that encourage cooperative learning, the Tablet PC and related functionality have been shown to increase interaction between instructors and students and have encouraged more self-initiated exploration among students [21]. While primarily descriptive in nature, other studies focusing on engineering undergraduates have shown that the capabilities associated with the Tablet can serve as a means to facilitate a variety of pedagogical approaches and invite student participation and collaboration with one another [22] as well as with the instructor [23]. It is believed that the capabilities associated with the Tablet can assist engineering undergraduates who are enrolled in courses that cover material that is often mathematically and graphically intensive [24]. Surveys conducted at one university reveal that students report an increase in their confidence related to applying concepts learned in class when using the relatively easy note sharing capabilities associated with the Tablet PC [25]. Other studies examining the Tablets' role in the understanding and attitudes towards conceptual design are inconclusive [25].

The goal of our NSF sponsored TUES project is to examine whether effective use of instructional technology, specifically slate enabled technology, has an impact on the innovative thinking skills among engineering undergraduates enrolled in large lecture classes.

III. STUDY IMPLEMENTATION

An in-depth case study will examine the pedagogy in relation to how innovative thinking is taught and developed among students, including faculty use of and motivations for employing slate enabled instructional technology (e.g., Inking, DyKnow, OneNote) to develop innovative thinking skills. The methodology is a quasi-experimental mixed method approach utilizing a control and treatment group and will study how students enrolled in specific courses use slate enabled computing features and whether there is a relationship between that use and development of innovative thinking skills and student learning as measured by course GPA. Student survey data, observation of faculty teaching, observation of student engagement with course content, individual interviews with faculty, and focus groups among students enrolled in the courses being used in this study will provide these data. In addition, we will examine the technological infrastructure at the college and university including the degree to which the wireless network can actively support the use of instructional technology in large lecture courses and the amount of technological support provided to faculty and students through training sessions. Since 2006 the Virginia Tech College of Engineering has required all engineering undergraduates to have a form of slate enabled technology by requiring all entering students to purchase the Tablet PC. In order to assess the impact that these approaches have on students' innovative thinking it is necessary to have a control group of students. This control group, while exposed to slate enabled instructional technology as a result of the student Tablet PC requirement, are not in a course section where the instructor is intentionally using this form of technology to develop innovative thinking skills. The sample for the study will include among 1) entering freshmen enrolled in a first-year course and 2) upper-level students, primarily comprised of second year undergraduates, enrolled in a Statics course.

A. Data Collection

Student survey data will provide one measure of the impact of slate enabled technology on development of innovative thinking skills. Changes in students' innovating thinking skills will be measured by an online pre- and post-test administration of the Modified Strategies for Learning Questionnaire (MSLQ) (refer to Table 1). The MSLQ is a valid and reliable survey that provides a measure of the skills identified in the literature as linked to innovating thinking. This instrument has items that ask students how often they utilize the following skills including: knowledge acquisition (e.g., repetition of words or concepts), scaling (e.g., outlining, organizing information), elaboration (e.g., paraphrasing, summarizing), critical thinking (e.g., application of new knowledge to situations, generation of new ideas), self-initiated exploration (e.g., self-directed learning, setting goals, monitoring one's own comprehension), and peer collaboration (e.g., using a study group or friends to help learn and generate new ideas) [7] through the creation of scales from multiple

items. Our previous assessment efforts indicate that the scales indicate a high degree of reliability ($\alpha < .60$) based on Chronbach's alpha scores.

A more complete picture about how to effectively develop innovative thinking skills among students enrolled in a large lecture course and whether effective use of slate enabled technology facilitates that development, will be provided by direct observation of students and faculty members in class. In addition to having an observer sit in on the class, these class sessions will be videotaped for more complete analysis. Among faculty, we will examine the pedagogical approach used by the faculty member by using a rubric. The rubric will identify the frequency of use of key strategies identified in the literature that can be employed by an instructor to facilitate innovative thinking skills through active and engaging learning strategies as well as how often slate enabled technology is used in relation to those methods [6, 2,3,4].

TABLE 1. MEASUREMENT OF INNOVATIVE THINKING

| Innovative Thinking Skill | MSLQ Related Survey Questions Used to Measure Innovative Thinking Skill "How often do you do the following with your Tablet PC/Slate device?" |
|---|---|
| <i>Knowledge Acquisition</i> (Identifying new words and concepts, use of rehearsal strategies to memorize information) | -I studied by reading my notes over and over again. -I make lists of important items for this course and memorize the lists. -I memorized key words to remind me of important concepts from this class. |
| <i>Scaling</i> (Organizing information and concepts so that they can be integrated into designing of new ideas and information) | -I made simple charts, diagrams, or tables to organize course material. -To study, I reviewed my notes and made an outline of important concepts. -When I studied the readings for my courses, I outlined the material to help me organize my thoughts. |
| <i>Elaboration</i> (Summarizing known information; ability to reframe content) | -I make connections between readings and lecture notes. -I try to apply ideas from web-based sources to other class activities such as lecture and discussion. -When I studied for this course, I pull together information from lecture, readings, and discussions. |
| <i>Critical Thinking</i> (Application of previous knowledge to unknown, ill-defined and/or new situations; generation of new ideas) | -I often questioned things I heard or read in the course to see if I found them convincing. -I reread my course materials as a starting point and tried to develop my own ideas about it. -Whenever I read or heard an assertion or conclusion in class, I thought about possible alternatives. |
| <i>Self-Initiated Exploration</i> (Ability to question ideas and information being presented) | -I tried to change the way I studied in order to fit the course requirements and the instructor's teaching style. -When studying for the class I tried to determine which concepts I didn't understand well. -When I was confused taking notes |

| | |
|---|--|
| | in class, I made sure I sorted it out afterwards. |
| <i>Collaboration</i> (Ability to seek and entertain new ideas from peers and instructors; ability to utilize peers as a means to check new ideas and concepts) | -When studying for my courses, I tried to explain the material to a classmate or friend. -I tried to work with other students from this class to complete the course assignments. |
| <i>Entrepreneurialism</i> (Use of team members to determine what creative ideas can become valuable innovations; effective presentation of new ideas to others) | -I solicited input from others on new ideas. -I collaborated with peers or others outside of class to generate new ideas or concepts. |

In addition, we will conduct individual interviews with participating faculty to determine what motivated them to utilize active and engaging learning strategies, including slate enabled technology, and their perception of what impact the use of these strategies has on students' development of innovative thinking.

Student engagement in relation to strategies designed to teach innovative thinking will also be examined during classroom observations. This will also be done by using a rubric that measures how frequently students utilize strategies and learning behaviors that are linked to the development of innovative thinking as well as how often those strategies involve slate enabled technology [6,2,3,4]. Students in all course sections will be asked to participate in focus groups that will explore the degree to which students perceive different instructional strategies have helped them develop innovative thinking strategies. Focus groups with students will help identify what pedagogical approaches were most useful for helping them learn and whether slate enabled technology facilitated that learning.

Information about the infrastructure will be collected by identifying the number of wireless issues encountered during a given class. We will also document the amount of training or technology support sought by students and faculty in each participating course section. This information is provided by a card swipe feature that enacted as a sign-in feature through the Software Assistance Triage (SWAT) team that provides technology support to the College of Engineering. Given the fact this study focuses on the use of slate enabled technology and related features, several of which rely on wireless capabilities, the infrastructure is an important variable that can influence how often faculty use this form of technology as well as the success in which that technology is employed.

B. Data Analysis

In terms of the quantitative data, having students grouped by treatment and control groups will allow us to examine the impact that slate enabled technology and active learning strategies that employ this technology has on student learning and the development of innovative thinking skills. This will be done by comparing the growth in student learning (e.g., GPA) and innovative thinking skills in each skill area after creating the scales (i.e., knowledge acquisition, critical thinking, scaling, collaboration, entrepreneurialism, self-initiated exploration) as measured by the MSLQ, between and

among students enrolled in the different sections using a Factorial ANOVA. The MSLQ will be administered online to all of the students enrolled in the participating four course sections two weeks into the fall semester. Changes in students' innovative thinking skills will be measured by an online post-administration at the end of the fall semester. This will allow us to determine the differences in growth among and between students by grouping them by control and treatment groups as well as by class year (i.e., first year students, second year and upper-class students). In addition, Pearson's correlations will be used to determine whether the frequency of usage of this instructional technology by faculty and students as measured by items on the survey that gauge student perceptions about how frequently both groups use this technology and related slate enabled features in a semester has a significant relationship with student learning as measured by GPA and different innovative thinking skill areas (i.e., knowledge acquisition, critical thinking, scaling, collaboration, entrepreneurialism, self-initiated exploration) as measured by the MSLQ scales.

Observational data collected from faculty and students using the rubric will be tallied. In terms of the faculty observations, the frequency of use of different pedagogical strategies, including those using slate enabled technology, designed to develop innovative thinking will be compared using chi-square to determine if there is a difference by faculty member. Among students the frequency of use of different skills associated with innovative thinking and how often those skills are employed in conjunction with use of slate enabled technology as well as without the use of slate technology will be conducted using chi-square to determine if there is a difference in the frequency by the course students are enrolled in.

C. Model Development

Following data collection in the fall semester our analysis during the spring semester will allow us to determine the degree to which innovative thinking skills have developed over a semester, and the extent to which that was impacted by use of slate enabled technology and related features through intentional instructional strategies as well as student employment of these technologies in their classes. The mixed-method concurrent strategy being used in this study will allow for the integration of the qualitative and quantitative data. As these data are interpreted we will use the information gathered to create a model.

Following development of the model we will then use the summer to train two faculty members that did not previously receive training on how to create active and engaging learning environments through use of slate enabled technology and other methods. One faculty member will be teaching a Statics course while the other will be teaching the same entry-level engineering education course. During this phase of the implementation, the training will focus on the pedagogical approaches using slate enabled technology that impact innovative thinking skills among engineering undergraduates

enrolled in large lecture courses as determined by our first phase of data collection. The fall semester, following this training, we will use all four faculty members (both the ones that participated in the initial data collection and those that participated in the training of the model) and their four respective course sections to employ a similar research design as outlined above to validate our model. We hypothesize that after training on how to effectively use slate enabled technology and other methods to develop innovative thinking skills among students enrolled in large lecture courses that students will develop innovative thinking skills in the same manner across groups after exposure to an educational environment that maximizes use of active and engaging learning strategies that employ slate enabled instructional technology in an effective pedagogical manner. The pilot implementation during the fall semester of 2013 will allow us to determine the effectiveness of the model we developed. As the pilot model is implemented we intend to conduct similar comparisons in terms of pre- and post- assessment as well as direct observation among the new cohort that would enroll in the classes during the pilot implementation. We will also be able to track the cohort that participated in the fall 2012 collection of data. Among the first year students who have progressed to the second year of study, many of these students elect to take Statics in their second year. We will be able to group these students by who taught their first year engineering course in order to examine longitudinal differences and determine whether or not having an initial exposure to pedagogical approaches that use slate enabled technology during their first year has any residual effect on development of their innovative thinking skills as they progress through their course of study.

After the pilot implementation of the model, the data collected during the pilot phase will be examined and the information will then be used to further refine the model we have created. Following this refinement we will be able to distribute and share our results among interested stakeholders at our university as well as to a national audience through conferences and publications.

Data from the focus groups and individual interviews with faculty members will be transcribed. Following transcription, the focus group interviews will be coded using the constant comparative method to determine what themes emerge from the data in relation to students' perceptions about whether slate enabled technology and related features or other pedagogical methods assisted in encouraging innovative thinking. The faculty interviews will also be coded using the constant comparative method to evaluate what motivated faculty members to use this technology as well as how they felt different approaches they employed facilitated innovative thinking among students.

IV. CONCLUSION

Findings from this project will advance the understanding of how students learn to be innovative in the form of measurable and identifiable learning outcomes. In addition, information about how best to teach innovative thinking skills among undergraduates in an active and engaging educational environment using slate enabled instructional technology will be provided in the form of a model. The model considers faculty motivation for employing active and engaging learning strategies that utilize instructional technology in developing innovative thinking, the infrastructure (e.g., wireless capabilities, student requirements, technology support) that is necessary to facilitate such a model, and how to assess the extent to which the employment of the model has been effective. The broader impact of this project is in its ability to develop an exemplary model that can be used to develop a cadre of faculty who effectively employ instructional technology within large lecture classes in a manner shown to develop and enhance the innovative thinking skills among engineering undergraduates. We have targeted first and second year large lecture courses that are fundamental components of the engineering curriculum at our university. As this model is implemented the initial focus will be on developing innovative thinking skills among our engineering undergraduates at critical points in their course of study. As the model is refined the implementation can reach students at upper levels in their undergraduate career. We will seek to examine differences by gender and race in measurable changes in innovative thinking skills to determine whether the model is applicable across the undergraduate student population to the same degree. While certain pedagogical approaches, such as collaborative learning strategies, have been shown to have a positive impact among both male and female retention in engineering degree programs, the degree to which those approaches utilize instructional technology as a component in facilitating collaboration is largely unexplored. Our research will add to this body of literature by examining the degree to which collaborative learning strategies using instructional technology impacts attainment of innovative thinking among undergraduates by gender and racial/ethnic status.

Abstract— Recently, inquiry-based learning has been used to enable students to ask scientific questions and come to objective conclusions based on observation and experimentation. Within this context, we have been exploring the impact of mobile devices upon different modes of learning including inquiry-based instruction. While much attention has been on the acquisition of mobile devices for the classroom, mobile learning has the ability to facilitate education beyond the confines of the brick and mortar to improve information retention and student engagement. This paper describes research being performed at Miami University which explores best practices in engaging students in inquiry-based learning experiences using a suite of technological tools (including a mobile app) being developed to support citizen science and research data collection.

Keywords- *Mobile learning, inquiry-based instruction, citizen science*

I. INTRODUCTION

With more than 50% of US mobile subscribers owning a smartphone [1], it is no wonder why educators and researchers are trying to tap into the learning potential that smartphones possess. In particular, the ongoing cost of updating traditional textbooks combined with the diminution of educational funding has motivated several schools across the US to invest in tablets and other mobile technologies. Despite the hype surrounding mobile devices and their applications in education, the lack of literature and underdeveloped m-learning pedagogies has made it difficult to know the true educational effectiveness of various mobile learning solutions. At Miami University, we are investigating the effects of mobile devices on inquiry-based instruction, a particular model of learning where the fundamental focus is on “learning by doing”. Specifically, we want to know (a) how learning is affected when students are not actively engaged in the entire process of some scientific investigation and (b) whether or not there is something we can do with mobile devices that improve information retention in these types of environments. In performing this research we will be able to develop a methodology highlighting best practices of mobile devices in inquiry-based learning environments. Considering the overall lack of research on mobile learning effectiveness for specific models of learning and limitations of current apps supporting inquiry-based learning, the products of this research are a valuable contribution to both education and computer science fields.

II. BACKGROUND AND APPROACH

With mobile learning being a relatively new field, there have been several competing definitions. One of the more widely cited definitions is by Quinn who defines m-learning as simply “elearning through mobile computational devices” such as Palms and Windows CE machines [2]. Clearly, mobile devices have come a long way in terms of functionality and computing power since the advent of PDAs. As such, mobile devices are now in a better position to influence how people augment their learning experience.

Inquiry-based instruction is defined as the creation of a classroom environment where students are engaged in open-ended, student-centered, and hands-on activities [3]. With regards to science education, Banchi et al. suggest that there are four models of inquiry: confirmation inquiry, structured inquiry, guided inquiry, and open inquiry [4]. For this research, we are focusing on how well mobile devices can facilitate structured inquiry, a type of inquiry where students are given the research question and the experimental procedure, but are expected to draw their own conclusions based on the results from their experimentation.

According to an article in BioScience the term “citizen scientists” refers to volunteers who participate as field assistants in scientific studies [5]. The article goes on to say that citizen scientists (a) are not paid, (b) are often amateurs, and (c) strictly gather data and are not involved in the process of analyzing data or authoring scientific papers. On some wide-scale research projects, it may be beneficial for researchers to have assistants whose sole purpose is to perform experiments and collect data (potentially using a mobile device to gather data). In doing this, however, the assistants are potentially disengaged from core aspects of inquiry-based learning, thus affecting their ability to acquire new knowledge about the research topic.

III. APPROACH

We are studying the effects of mobile devices on inquiry-based instruction. In our study, we are randomly dividing our participants into four different groups (based on a combination of level of participation and use of a mobile device), having them gather data for a simple experiment, and then evaluating the perceived engagement, learning, and attitudes towards mobile devices through surveys administered to the

individuals in each group. The remainder of this section describes the users in each of the four groups and the expected performance of each group.

Depending on the size, a given research project could be comprised of at least two different types of people, each having a distinct participatory role. The first type would be the lead researchers; people who have specific research goals in mind and are therefore following the scientific method (or some similar model) in its entirety. If the research requires an exhaustive collection of data, lead researchers may harness the power of citizen science by having masses of volunteers (with or without formal training) collect various pieces of data and report their observations to the lead researchers. These volunteers are potentially disengaged from the scientific method (or some other inquiry-based procedure) and therefore do not fully understand the purpose of the data they are collecting or the goals of the research project. For the purpose of this research, this type of engagement will be called *limited participation*. Lead researchers, on the other hand, are cognizant of every detail of a research project and therefore have *full participation* in the scientific process that is guiding their study.

The inquiry-based model we will focus on in this research involves the scientific method, a common process researchers follow in order to properly define research problems and acquire new knowledge based on the results of experiments and observations. Specifically, the model we follow has five basic steps (define research problem, make observations, formulate the hypothesis, experiment, draw conclusion). For data collection, a mobile device would be most effective in the “Experiment” step of this particular model. This implies that users of mobile devices would not necessarily have to be engaged in any of the other steps in the scientific method. Given this implication, we would like to delve into the effects of *full participation* in the scientific method on learning with and without the use of mobile devices to gather experimentation data.

In our experiment design, we have randomly divided participants into four groups. Group one represents users who have *full participation* in the scientific method (i.e., users are following all 5 steps of the scientific method) and are using a mobile device to gather experimentation data. In group two, users still have full participation, but are NOT using a mobile device to gather experimental data. Group three represents users who have *limited participation* in the scientific method (i.e., users are strictly gathering data) and are using a mobile device to collect their data. Finally, in group four, users still have limited participation, but are gathering data without a mobile device. Data will be gathered individually (i.e., not as a group). After the experiment, participants will be asked to complete a survey gauging their perceived engagement and learning in performing the experiment.

We expect *full participation* in the scientific method with use of a mobile device would yield the most favorable outlook on perceived learning and engagement, followed by *full participation* in the scientific method without the use of a

mobile device, then *limited participation* with a mobile device and finally ending with *limited participation* without use of a mobile device yielding the least favorable outlook. However, it may be possible that the outcome from group two matches the outcome in group three. This depends on what is more important to the learner; having access to a mobile device or understanding the context of a particular research question. In addition, the outcomes may be affected by interest in the experiment and overall intellect.

In partitioning the types of participants into these groups, we will hopefully be able to gain a better understanding of the effect of mobile devices on different levels of participation in inquiry-based environments.

IV. CONCLUSIONS AND FUTURE WORK

In performing this study, we are developing a suite of technological tools (including a mobile app) designed to help instructors, students, and/or researchers collect, aggregate, and analyze different types of experimentation data for both small and large scale research projects. Specifically, these tools are dedicated to (a) establishing and assigning research tasks and objectives, (b) collecting an array of different types of experimentation data via mobile devices, and (c) extrapolating trends and verifying statistics based on the data collected. Our participants in the study described above will use these tools.

Mobile devices in inquiry-based learning environments have the potential to impact researchers from several different disciplines ranging from STEM fields such as physics and statistics to business fields such as marketing. By providing a suite of standard data documentation tools in the palm of one’s hand, mobile devices allow researchers to gather data quickly and efficiently, thus streamlining the research process. In streamlining the research process, learners are able to focus more on the research itself and less on irrelevant details often accompanying field research. The increased focus will allow users to gain more from their research and reach objective conclusions faster.

The results of our experiment may be influenced by how interested our participants are in the research question regardless of mobile device use. In addition, positive results stemming from the use of the mobile device may be due to the novelty of using the device to collect data. Also, mobile devices can be used to gather different types of experimentation data in an array of domains. Therefore, what we find to be true for one particular domain may not be true for another.

Abstract— The use of Student Response Systems (SRS) has been shown to increase student attendance, participation, and learning. Prevailing systems at universities are typically SRS that require installation of software by the university and purchasing of “clickers”. Thus, the adoption of SRS usually requires a sizable initial investment. Given the diffusion of mobile phones and wide-spread use of mobile technology by students, the possibility of using them as a cost-effective alternative to clickers is attracting more attention. The emergence of audience response systems hosted in the cloud instead of being physically connected to a computer triggered WPI faculty and staff to explore the use of mobile technology as a response tool through Poll Everywhere.

First, we present our motivations for adopting this technology (limited clicker supply, desire for open-ended response option, etc.). Second, using our experience in the classroom and findings from extant literature, we make suggestions related to course design to enable faculty to take full advantage of cloud-based SRS. We evaluate whether students concur with our perceived benefits of Poll Everywhere in terms of ease of use and facilitation of learning. We close with discussion and suggestions for future research.

Keywords—*Student response systems; mobile devices; clickers; feedback; mobile learning*

I. INTRODUCTION

Regardless of the discipline taught, instructors strive to help students learn and must make numerous pedagogical choices. One such choice has been consistently found to be effective: Providing immediate and frequent feedback to students accompanied with peer discussion has been shown to be associated with improved student performance and learning [1, 2]. A traditional way to provide this feedback to undergraduate students is to implement instant assessment of learning by means of flashcards [3] and, more recently, clickers (transmitters used to wirelessly send individual students’ answers to receiver and software) [4, 5]. We examine a new Student Response System (SRS), Poll Everywhere. This SRS is enabled by mobile technology instead of wireless transmitters and stores information in the cloud. We argue that this technology is less intrusive, but as effective as flashcards or clickers.

Academia has provided widespread evidence of the perceived benefits of clickers. They engage students, create a

more interactive environment [6], and help faculty identify and correct misconceptions, thus facilitate understanding [7]. Although the effect of clickers on learning does not appear superior to flashcards, clickers are especially helpful in large classroom [8] as they facilitate aggregation of the students’ answers and encourage attendance as well as participation [4]. Yet, clickers require an investment in technology and do not take advantage of the mobile technology students have and are comfortable with (students belong to the millennial generation; 94% of millennials own a cell phone and 87% own a laptop [9, 10]).

Taking advantage of the positive attitude students have towards technology (74% believe technology makes their life easier [9]), of technology they are familiar with, and of their preference for receiving information quickly and for active learning [11], we examine a new use of Poll Everywhere as a SRS that relies on mobile technology. Poll Everywhere not only uses technology already in the hands of students (e.g., laptops, cell phones), it also provides an easy and familiar platform for instructors to interact with students at a deeper level by using, for instance, open-ended questions, and makes student responses web-accessible to faculty as well as students. This paper builds on extant research on benefits and challenges of traditional SRS such as clickers and flashcards and shares the experience of two faculty members as well as students perceptions of Poll Everywhere. This technology was applied in different disciplines (engineering and business) and various implementation methods were tested. We find that Poll Everywhere, like clickers, not only is associated with positive perceptions of students in terms of ease of use and improved learning, but also addresses several of the challenges typically associated with clickers.

We first present a review of the SRS literature. Second, we describe Poll Everywhere and the implementation choices we made. Third, we evaluate this technology and present students’ perceptions. We close with discussion and suggestions for future research.

II. LITERATURE REVIEW

Of concern of pedagogical scholarship is not technology per se, but how technology can be used to facilitate learning [12].

Technology such as clickers enables faculty to assess and encourage different levels of learning [13].

As such, clickers have been widely used in several disciplines where they have been associated with pedagogical benefits as well as concerns. First and foremost, research finds that clickers seem to improve learning as they help instructors become aware of how well students understand the concepts they teach [7] and address misconceptions [5]. Although most articles assess the perceived effectiveness of clickers and infer that improved learning will result from improved understanding [e.g., , 14, 15, 16], Preszler and his colleagues [17] show that exam performance actually improved in the classes that used clickers. Additional benefits in the form of increased attendance and participation seem to add to the positive perception that students and faculty have of this technology and of the environment it creates [4-7, 18].

Still, it is not always clear whether those benefits are direct benefits of clickers or a byproduct (e.g., it might be the fact that students are more active in the classroom or the provision of participation incentives rendered possible by clickers that helps improve participation and attendance). Moreover, clickers seem to pose technological challenges as students forget them or they malfunction [5, 18]. They are costly (to students or the university) and instructors can incur logistical difficulties as they will likely need to distribute and account for the clickers and activate the receiver and software they rely on at the beginning of each class period [7, 18]. In addition to these challenges, most clickers are limited in the type of questions one can ask (multiple choice or true/false¹) and, accordingly, require faculty to rethink the exercises they use in the classroom [16, 18].

We argue that these challenges can be addressed by replacing clickers with technology that the student population is already comfortable with (i.e., mobile technology in the form of laptops, tablet computers, or cell phones). Although the use of mobile technology is widespread [9], mobile learning in the classroom via SRS is in its infancy. Chen et al. [1] conducted initial tests of PDAs and proprietary software as SRS and suggest that PDAs provide similar benefits as clickers. New types of SRS using mobile technology such as Poll Everywhere, iClicker and Turning Point take advantage of the accessibility and of the students' familiarity with mobile technology.² We present our application and assessment of the former, Poll Everywhere.

¹ While some clicker models allow for open-ended question, typing is cumbersome (e.g., hit 3 twice for an "e").

² After a comprehensive review of SRS and other educational learning software, we determined that there was not, at the time of selection, another viable system with synchronous response capability that does not require an internet connection. Other systems, such as Socrative (<http://www.socrative.com/>) and Learning Catalytics (<https://learningcatalytics.com>) have since appeared on the market, but do require a web-enabled device.

III. IMPLEMENTATION OF POLL EVERYWHERE

A shortage of clickers motivated us to find a technology that was easy to use for both faculty and students and that had the same benefits as clickers, but fewer drawbacks.

A. SRS Description

Our selection was guided by WPI's Academic Technology Center. Poll Everywhere is an audience response system available to higher education instructors at a low monthly cost that depends on class size.³ In order to provide participation incentives, faculty need to be able to identify the students who participate and, accordingly, need to invite student to register by email. As with clickers, the instructor initiates questions and it is necessary for the instructor to provide probing questions. These questions come in the form of polls, multiple choice (concept or skill questions), or open-ended questions. Once the faculty has generated questions, they can be incorporated in a PowerPoint presentation. These PowerPoint slides can be used in classroom without the burden of utilizing any sort of user interface. Students answer these questions in class with the mobile devices selected by the instructor (cell phones, laptops, or tablet computers) by twittering, texting, or through the Poll Everywhere website. They receive confirmation once their answer has been received by the system. Aggregated answers can be shared with the class at the discretion of the instructor by simply clicking on a built-in function button on each PowerPoint slide. Poll Everywhere also provides individual feedback that can be downloaded by faculty to assess participation or reviewed by students online.

B. Implementation Choices

We tested this technology in introductory engineering, ES 2001 Introduction to Materials Science and Engineering with 100-130 students and business, ACC 2060 Financial Statements for Decision Making with about 50 students. Before the implementation of Poll Everywhere in our classrooms, a survey was conducted to determine the students' access to mobile phones or laptops. It turned out that 100% of the students surveyed had a mobile phone or a laptop. Our application of Poll Everywhere differed on several dimensions as detailed in Table 1. Those differences were motivated by personal preferences more so than driven by our respective disciplines.

For instance, both instructors included participation incentives in the class grade. Prof. Liang chose to grade participation based on whether students answered the questions posed in randomly selected class periods because, in ES 2001, grading each question asked via Poll Everywhere would have been too time-consuming. Prof. Miller took a different approach by grading every question asked and giving full credit only to the questions answered correctly. This choice was motivated by the weight given to participation in the class grade and faculty's concern that it would be difficult to select class

³ Alternatively, students can purchase access to Poll Everywhere for an annual charge.

periods that would be representative of typical student attendance and participation.

TABLE 1. IMPLEMENTATION DECISIONS

| <i>Implementation decisions</i> | <i>Discipline</i> | <i>Choice</i> | <i>Rationale</i> |
|---|---------------------------------|---|---|
| <i>Mobile technology allowed</i> | Engineering | All Personal Devices | Increased flexibility, free answers |
| | Business | Cell phones (texting only) | Limiting distraction |
| <i>Question type</i> | Engineering | Multiple choice questions | Testing of student knowledge |
| | Business | Multiple choice & open-ended questions | Testing of student knowledge; end of class review, quiz at beginning of class, voting on team presentations |
| <i>Frequency of questions</i> | Engineering and Business | Every 10-15 minutes | Frequency seem optimal to maintain engagement |
| <i>Number of answers allowed</i> | Engineering and Business | One | Answering questions followed discussion with peers |
| <i>Display of aggregated answers</i> | Engineering and Business | Dependent on questions and proportion of correct answers | Stimulating class discussion |
| <i>Peer discussion subsequent to initial answer</i> | Engineering and Business | Dependent on questions and proportion of correct answers | Investigating challenging questions |
| <i>Participation incentives</i> | Engineering (5% of class grade) | Answers chosen at random; full credit given for any answer | Increasing attendance and participation while minimizing grading |
| | Business (10% of class grade) | All answers included; full credit for correct answer, partial credit for incorrect answer | Increasing attendance and participation |

Everywhere ahead of class and no equipment or software needs to be activated at the beginning of each class. Registration is initiated by faculty who send an email that provides a URL to invite students to register; thus, making the registration process simple for students. Furthermore, since students could use their personal mobile technology, there was no need to distribute equipment, account for it, and collect it at the end of class. Technological challenges were also rare because students did not forget their phones or laptops, did not risk bringing the wrong clicker to the wrong class, and were very familiar with how to operate their own equipment. Interestingly, students were also able to help each other when technical questions arose such as how to send answers by texting. Finally, we also noted that students' responses were transmitted quickly and reliably.⁴ In other words, using mobile technology in combination with Poll Everywhere to help students learn and encourage student participation makes preparing for and providing immediate feedback a smooth and effective process.

Despite the benefits associated with Poll Everywhere, a few new concerns arose. These concerns and the cost and benefits of their potential solutions should be evaluated before deciding how to implement Poll Everywhere. They are presented in Table 2 below.

As detailed in Table 2, requiring students to bring mobile technology to class might increase distraction as students access the internet, check their email, etc. Accordingly, faculty might want to apply the techniques they typically use when students use laptops in the classroom or limit the kind of technology they can use to answer questions. Still, we felt that the benefits associated with helping students become active learners were far greater than the challenges discussed in Table 2.

IV. EVALUATION OF POLL EVERYWHERE

First, we present our perspective and, second, describe the students' perceptions captured through surveys.

A. Faculty Perspective

Our individual experience with clickers echoes the evidence presented by the literature discussed above in terms of improved attendance, participation, engagement, and identification of misconceptions. We observed similar benefits when students used mobile technology to answer the questions we created with Poll Everywhere. Additionally, we found that Poll Everywhere helped resolve many of the challenges often associated with clickers. Logistics problems disappeared as questions are incorporated in PowerPoint slides via Poll

⁴ Because Poll Everywhere uses SMS technology, the communication occurs in one direction: from the student's device to the Poll Everywhere server. Other existing virtual clicker systems rely on two-way communication: an instructor posts a question which is sent to a student's device, at which point the student is able to answer the question. This two-way communication can slow down the speed of the responses.

TABLE 2. POLL EVERYWHERE CHALLENGES

| <i>Challenge</i> | <i>Proposed Solution</i> |
|---|--|
| <i>Student distraction: Students bring laptops to class and need to have them available to answer questions</i> | <i>Restricting participation to texting via cell phones.</i> |
| <i>Cost of texting: Some students do not have unlimited texting</i> | <ul style="list-style-type: none"> - <i>Surveying students at the beginning of the semester to evaluate the extent of this concern,</i> - <i>Allowing other medium such as laptops,</i> - <i>Asking students to work in teams and take turns to answer questions.</i> |
| <i>Texting limited to 160 characters, thus limiting the length of answers to open ended questions</i> | <ul style="list-style-type: none"> - <i>Allowing other medium such as laptops,</i> - <i>Tailoring questions accordingly.</i> |
| <i>There is currently no integration between Poll Everywhere and Learning Management Systems. Therefore, rosters and grades must be transferred manually.</i> | <ul style="list-style-type: none"> - <i>This may be a feature to look for from Poll Everywhere in the future.</i> |
| <i>Security: Students' cell phone numbers and responses are stored by Poll Everywhere.</i> | <ul style="list-style-type: none"> - <i>Students register themselves for the system, and no student identification numbers are shared. Additionally, although Poll Everywhere does offer a gradebook feature, assessment is probably best kept in a more secure environment.</i> |

B. Student Perceptions

We administered surveys (1 to 5 likert scale) anonymously to our students to gauge whether students perceived that Poll Everywhere helped them learn, was easy to use, and compared favorably with clickers. We obtained a total of 162⁵ usable responses.

- 1) *Perceived Learning Outcomes:* Students' perceptions of Poll Everywhere benefits confirmed our own evaluation. 68.2% and 70.6% of the engineering and accounting students, respectively, believed that using Poll Everywhere improved their understanding of the concept learned. 60.7% of the engineering students perceived that Poll Everywhere increased their interaction with the instructor while 82.4% of the accounting students indicated that using Poll Everywhere helped them become more engaged in the class. 80.9% of the accounting

students felt that seeing the aggregated answers was informative.

- 2) *Ease of Use:* Students had little or no difficulty registering at the beginning of the term (82% of the accounting students found this process easy) and found answering questions with this SRS easy (73.5% of the accounting students agreed or strongly agreed with this statement and 83% of engineering students reported no difficulty of registering or using the technology).
- 3) *Comparison with Clickers:* Mobile technology combined with Poll Everywhere was preferred to clickers by most students (81.3% and 84.5% of the engineering and accounting students, respectively). Finally, 84.5% of the accounting students believed they were less likely to forget their cell phone than a clicker and very few indicated that they ran into technical problems (i.e., low battery) during the term.

In sum, students perceived that Poll Everywhere learning benefits are very similar to those of clickers, but seem to prefer this technology to clickers as they run into fewer technical challenges and are more comfortable with the equipment used. Combined with our own observation of increased attendance, participation, engagement, and identification of misconceptions, the students' perceptions suggest instructors can derive the same benefits from Poll Everywhere as from clickers and confirm that this technology is less intrusive, less costly, and associated with fewer challenges than clickers.

V. CONCLUSION

In conclusion, our experience with mobile technology as an alternative SRS was very encouraging from both the faculty and students' perspective. In addition to the familiarity and widespread adoption of mobile technology by students, flexibility and the low cost of mobile technology make it particularly attractive to faculty and campus with constraints associated with cost and resources such as technical support. However, similar to other SRS systems, the actual learning outcomes largely depend on not only adoption of technology, but also on how the technology is adapted into the learning experience. For example, in our initial experiments, dialog has always been initiated by faculty using the SRS. It is expected that more benefits will result if we can close the loop and add an interactive loop with students initiating dialog/questions into the learning process [19]. Our research did not include formal assessment of learning. Future projects could test learning actually improves by comparing learning in a class using Poll Everywhere to learning in a similar class that does not use this SRS. Even though our intuition suggests that, everything else being equal, the actual learning outcomes of adopting Poll Everywhere might be similar to other SRS, a future research project is planned to assess this hypothesis.

⁵ Four different classes (two introductory material science and engineering and two introductory accounting classes) participated. Questions varied between the various classes.

ACKNOWLEDGMENT

We would like to thank Prof. Chrysanthé Demetry at WPI for her encouragement, support and insightful comments on this work.

Enhancing Curiosity Using Interactive Simulations Combined with Real-Time Formative Assessment Facilitated by Open-Format Questions on Tablet Computers

Frank V. Kowalski and Susan E. Kowalski

Department of Physics
Colorado School of Mines
Golden, CO USA
fkowalsk@mines.edu

Abstract— Students' curiosity often seems nearly nonexistent in a lecture setting; we discuss a variety of possible reasons for this, but it is the instructor who typically poses questions while only a few students, usually the better ones, respond.

As we have developed and implemented the use of InkSurvey to collect real-time formative assessment, we have discovered that it can serve in an unanticipated role: to promote curiosity in engineering physics undergraduates. Curiosity often motivates creative, innovative people. To encourage such curiosity, we solicit questions submitted real-time via InkSurvey and pen-enabled mobile devices (Tablet PCs) in response to interactive simulations (applets) run either before or in class. This provides students with practice in asking questions, increases metacognition, and serves as a rich springboard from which to introduce content and/or address misconceptions.

We describe the procedure for measuring curiosity and results from applying this method in a junior level electromagnetics engineering physics course. We conclude that students are indeed more curious than they appear in class, and students participate even without extrinsic motivation. This method of enhancing curiosity using interactive simulations coupled with real-time formative assessment in response to open-format questions could be implemented in a wide variety of engineering courses as well as elsewhere.

Keywords- *curiosity, real-time formative assessment, InkSurvey, interactive simulations, open-format questions*

I. INTRODUCTION

Most people would probably agree that good engineers and scientists are curious. An emerging operational definition of curiosity is "the threshold of desired uncertainty in the environment that leads to exploratory behavior" [1]. In spite of recent advances in cognitive science and learning theory [2], many engineering educators find themselves teaching in a lecture setting, where students' curiosity and intellectual exploration is rarely displayed. This lack of evidence of students having crossed the threshold of curiosity might have

several possible contributing factors; our experiences suggest these factors may include:

(a) Students may be embarrassed to ask questions (either in the presence of their peers or in a one-on-one setting with the instructor during office hours);

(b) Students may not want to make a genuine effort to understand the material by asking probing questions;

(c) Students' past experiences may have trained them to expect to absorb content rather than generate questions;

(d) Students may feel so lost and confused that no question comes to mind;

(e) Students may feel confident that they understand everything, and therefore have no need to ask questions; and

(f) Students may be accustomed to not asking questions, as this is not a skill generally nurtured or valued in the educational system.

However, curiosity often motivates creative, innovative scientists and engineers (and others) [3-5]. It is also seen as an important factor in student learning [6, 7]. Practical methods for encouraging curiosity have been discussed [6, 8-10]. Lowenstein [11] points out that "curiosity is influenced by cognitive variables such as the state of one's knowledge structures but may, in turn, be one of the most important motives for encouraging their formation in the first place. Positioned at the junction of motivation and cognition, the investigation of curiosity has the potential to bridge the historical gulf between the two paradigms."

This paper describes results when students in a junior-year undergraduate electromagnetics class were asked to report their questions as they explored interactive simulations related to course content. The goal was to motivate learning by enhancing student curiosity. To better understand the role curiosity plays in engineering education, a categorization scheme for questions was devised and applied as a simple measurement tool.

II. NURTURING AND MEASURING CREATIVITY

Efforts to improve student motivation have been linked with curiosity. In particular, the ARCS (Attention, Relevance, Confidence, and Satisfaction) model of motivation provides insight on how to nurture curiosity [10]. Some instruments to measure motivation have curiosity subscales [12], reflecting the contribution curiosity may make to motivation. However, curiosity is not a simple attribute to measure. Loewenstein provides a comprehensive review of instruments which use teacher evaluations, peer evaluations, and self-evaluations to measure curiosity, while he questions the validity of some of these instruments [11].

Trying to understand the underlying cause of creativity has led to theories focused around drive (curiosity results from biological/psychological drives similar to thirst, hunger, or sex), incongruity (curiosity results when an observation violates a model or heuristic rule of how the world works), competence motive (curiosity results from feelings of a lack of competence), and a gap in information (curiosity results from a discrepancy between what one perceives and what one expected to perceive) [11,13].

Rather than focus on a comprehensive study of the underlying causes of curiosity, we attempt to extract information about a student's curiosity only in terms of the questions the student asks about an observation, problem, simulation, or object presented in a STEM context.

In theories of curiosity described in the literature, the types of questions students might ask are not categorized. For example, in an incongruity-based theory, such as that developed independently by Hebb [14], Hunt [15], and Piaget [16], any question reflecting curiosity would, by construction of the theory, be defined as incongruous.

None of these theories about curiosity has emerged as the most widely accepted, but perhaps there are insights to be gained from all of them. An example, in the context of Newton's Laws, illustrates that student questions do not always conform with a single theory. A student who does not believe the rule that an object moves in uniform motion until an external force acts would ask a question such as "What object moves without slowing down?" This aligns with the incongruous theory of curiosity (above), since it indicates that uniform motion is incongruous with the student's model of how the world works. Another student question might be "How do I calculate the external force on a car coasting?" illustrating curiosity about how to apply the rule rather than about a violation of the rule. For convenience, this could be described as a question reflecting congruous curiosity.

Based on this theoretical framework, the question categories used in this study to assess curiosity are as follows. Although this list of categories may not be exhaustive for consideration of curiosity in all disciplines or even all topics within engineering disciplines, they are adequate for this study.

INCONGRUOUS: violating a model or heuristic rule of how the world functions.

Example: Doesn't this violate conservation of energy?

CONGRUOUS: understanding of or gathering information about how a model or rule is applied (typically one just presented in class).

Examples: How do I apply this in a different situation? How do I calculate the effect shown in the simulation? What examples are found in the real world?

MODIFYING: probing what happens when the assumptions, parts, application, or parameters of the model or rule are changed.

Example: What happens if the temperature is not assumed to be constant?

GENERALIZING/ANALOGY: comparing one model with another.

Example: When an earthquake occurs, do the plates slip when pressure generates melting at an interface, like a skate on ice?

CAUSAL/CREATIVE: attempt to generate a new model, improve on an existing one, or search for novel patterns.

Example: How does this simulation of classical physics change if quantum mechanics is applied?

INFORMATIONAL: finding information simply for its intrinsic interest or for diagnostic purposes.

Example: How does the platypus relate to its environment?

When the student responses are collected as students explore interactive simulations, we categorize the question responses and discuss in class these classifications with the students. Using this procedure, along with having the students become aware of questions asked by both peers and the instructor, we hope to nurture the transformation of specific state curiosity (a condition that can be manipulated) into the more general trait curiosity (a personality feature) in STEM fields, as suggested by Loewenstein [11].

III. DESCRIPTION OF TEACHING MODEL

Students used the web-based software *InkSurvey* [17] to compose and submit their responses to questions about free, interactive simulations they accessed online. There are a variety of tools that could be used for this (*DyKnow*, *Classroom/Ubiquitous Presenter*, etc.); we chose *InkSurvey* because it is free and is robust in classes exceeding sixty students. The preparation, collection, and receiving of responses was facilitated by pen-enabled mobile computing devices (in this case tablet computers) in the hands of both instructor and students. Other pen-enabled mobile computing devices (iPads, smart phones, etc.) could also be used in a similar manner. However, without facilitation by some form of technology, it is difficult for the instructor to collect and respond to meaningful formative assessments quickly.

The real-time assessment gathered with *InkSurvey* is particularly authentic since it is seamlessly integrated with the activity [18], in this case not only temporally, but physically as well, with a single tool used for both exploring simulations and using *InkSurvey*. An additional advantage of this coupling is

that students can engage in further manipulation of the simulations as they construct their responses, allowing them to explore facets they may have initially ignored. A single student is able to submit multiple responses to a question posed by the instructor. Even though student identity is concealed from their peers (see I.a), the instructor could access this, thus allowing us to track how many and which responses were submitted by a particular individual.

The student responses provide a rich springboard from which to introduce content and/or address misconceptions. Having the students document their questions and understanding in this manner facilitates both student motivation to understand and metacognition.

In this method of enhancing curiosity, comments and questions were solicited using *InkSurvey*, with open-format questions such as:

- (1) What did you learn from or observe in the simulation?
- (2) What does this simulation illustrate?
- (3) What are you curious about after running the simulation?

The students enrolled in the class were engineering physics second semester juniors having three semesters each of physics and calculus, along with courses in differential equations, linear algebra, intermediate mechanics, thermodynamics, analog and digital electronics, and a summer session in vacuum systems, optics, machine shop, computer interfacing, and electronics.

IV. RESULTS

Student responses from four interactive simulations, along with categorizations and instructor comments, are presented next. To make trends more visible, similar responses are reported together, but unique responses are also reported to show the level and breadth of curiosity within the class. However, student submissions do not represent all categories for every simulation. Every student present at the time of each simulation submitted at least one response.

A. Induced charge simulation

Students ran the simulation on electrostatic induction found here:

<http://www.cegep-ste-foy.qc.ca/freesite/fileadmin/users/29/NYB/Theorie/contactdiff.swf>.

Question 3 above (“What are you curious about after running the simulation?”) elicited 68 questions from the 40 students present. These questions fall into five of the possible six categories.

INCONGRUOUS. Two responses are in this category:

“Does this actually happen as shown?”

“Why don’t the charges move after the conductors stop moving?”

CONGRUOUS. Twenty-four student questions (35% of total) involve how the charge distributed over the conductors, as

shown in the simulation. Sixteen student responses (24% of total) involve how much charge was shared between conductors. Another eight student questions (12% of total) are related to how the charge distribution, electric fields, or forces could be calculated. Unique responses in the CONGRUOUS category are:

“How do the charges of opposite sign eliminate each other?”

“What is the charge transfer a function of?”

MODIFYING. Six of the student questions (9% of total) involve what happens if the “tear shaped” conductor is turned around or two such conductors are used. Additionally, there are three unique responses in the MODIFYING category:

“How does the shape of the conductor affect the charge distribution?”

“How would insulators effect the simulation?”

“What happens if the conductors are brought together a second time?”

CAUSAL/CREATIVE. There are no questions in this category that were submitted multiple times, but these unique questions were received:

“How much time does it really take for the charges to distribute themselves over the conductor?”

“How does this simulation differ if quantum mechanics is applied?”

“Can electrons jump between the conductors or do the conductors need to touch?”

INFORMATIONAL. Four responses (7% of total) are questions about clarification, such as “Is there charge missing on the right conductor initially?” Another student questioned, “Where do the charges come from?”

Comments: While the majority of questions focus on what happens in the simulation, some students were curious about how to calculate what happens. A major objective of the course is for students to learn how to perform such calculations. The simulation thus provided motivation for the mathematical content of the course.

The students were concurrently taking a quantum physics class. A few were curious about how the content in both classes related. The quantum and classical models of charged conductors interacting are not often discussed at the junior level. By coupling the two topics, the breadth of understanding increases, thereby enhancing capability to both construct models and understand the limitations of the models. This simulation can also be used as a springboard to discuss quantum tunneling.

Some students were also curious about how quickly the charges distributed over the conductors. While this is not a question which can be adequately addressed using the electrostatic model presented, the instructor can use this as a catalyst to question the limitations of the electrostatic model, and launch a discussion of what governs the dynamics of this process and how one would construct a more realistic model.

B. Moving charge simulation

Students ran the simulation on electric fields from a moving charge found here:

<http://www.cco.caltech.edu/~phys1/java/phys1/MovingCharge/MovingCharge.html>.

Subsequently asking the students, “What are you curious about after running the simulation?” elicited 53 questions from the 31 students present. These student questions fall into five of the possible six categories.

INCONGRUOUS. Six responses (11% of total) deal with how the magnetic field (not shown in the simulation) is generated. Four student responses (8% of total) question how it is that field lines can cross (shown when running the saw-tooth motion option). Unique responses are:

- “When the charge is moving fast why doesn’t E continue in front of the charge?”
- “Why is the charge able to outrun the E field when traveling at the speed of light?”
- “Why are there kinks in the field lines when the charge accelerates?”
- “Won’t the waves always move faster than the particle?”
- “Why does acceleration cause ripples?”
- “What makes the electric field E behave like a wave?”
- “Why does the electric field seem to get stronger towards the front as the charge goes faster?”
- “Why is there an asymmetry in the field between the front and back of the moving charge?”
- “What happens when the particle crosses a bending E field?”
- “How can the field lines cross over each other when selecting the saw-tooth motion?”
- “What is the mechanism behind the field distortions when the particle speed changes?”

CONGRUOUS. Seven responses (13% of total) deal with “compression” of the field lines when the charge moves at high constant speed. Unique questions generated by the students are:

- “How is energy shown?”
- “How can you calculate the kinks in the field?”
- “Do the distorted field lines create magnetic fields?”
- “How can we calculate the fields given the particle motion?”
- “Is the superposition principle used to calculate the effect?”
- “How does the field propagate when the charge undergoes simple harmonic motion?”
- “Is there any change in the amplitude or frequency of the electromagnetic waves produced as they propagate away from the source?”
- “How do we account for the force based on the speed of the moving wave?”

MODIFYING. Six student questions (11% of total) are concerned about what happened when the charge moved at or near the speed of light. Additional unique student questions received are:

- “How does this simulation change in a gravitational field?”
- “What happens when two particles accelerate?”
- “What are the relativistic effects?”

- “How does the magnetic field affect motion of the particle?”
- “How does the magnetic field arise?”
- “Are there kinks in the magnetic field when the charge accelerates?”
- “How does this moving particle interact with other particles during acceleration?”

GENERALIZING/ANALOGY: There are three unique questions that fall in this category:

- “When the charge moves faster than the speed of light, is this similar to a bow wave when an aircraft moves faster than sound?”
- “How does this simulation apply to light?”
- “Are there shock waves generated?”

CAUSAL/CREATIVE. A single student question is classified in this category:

- “Do multiple charges create an interference pattern?”

Comments: Some students noticed that under certain conditions the simulation generates crossing field lines. They correctly suspected that this cannot happen physically. Bringing this to the attention of the class facilitates a discussion of critical thinking skills about what methods can be used to verify models (or how the model is simplified to generate the simulation).

Questions about the interference pattern illustrate the ability to make connections between different physical phenomena. The analogy with shockwaves can be a springboard to generate more questions about what is similar or different between the two situations. The connection between acoustics and electromagnetic waves can be discussed in terms of the similarity between the partial differential equations used in each model.

C. Inductance calculator

Students ran the inductance calculator found here:

<http://emclab.mst.edu/inductance/index.html>.

The question “What did you learn in using the calculator?” elicited 35 comments from the 35 students present; 100% of the responses submitted fall into the CONGRUOUS category. Seventy-eight percent (78%) mention the relationship between geometry and inductance while seven percent (7%) relate this to the induced electromotive force changing as a function of geometry. A typical comment is “Different shapes make the calculations way harder. It is cool that we know how to calculate this.” Curiosity is apparent in the following two comments: “I didn’t realize that for the two loop configuration that the inductance would increase with the separation distance,” and “The N^2 relationship was unexpected. However when we look closer at the math I understand.”

Comments: Somewhat surprisingly, students found this calculator interesting. They demonstrated curiosity in exploring how inductance varied in different geometries. The limited number of geometries available provided an opportunity to discuss the scarcity of closed form solutions for inductance.

D. Quantum harmonic oscillator simulation

Students ran the simulation found here:

<http://web.ift.uib.no/AMOS/MOV/HO/>.

The prompt “What are you curious about after running the simulation?” elicited 32 questions from the 31 students present.

INCONGRUOUS. Ten responses (30% of total) deal with “Why are we studying this problem in a electromagnetism class?” Additional unique student questions that fall into this category include:

“Why don’t we see evidence of this non-classical behavior on a macroscopic scale?”

“Can we make such a state?”

“Why does the oscillator look more classical with a greater number of energy levels?”

CONGRUOUS. Unique student questions in this category are:

“Why are coherent states so important?”

“What gives them a stable shape?”

“What does it mean when the shape of the wavefunction splits and recombines?”

“Does this correspond to a transition to a higher energy level?”

“Can we use the superposition principle?”

“Why did the wave always move to the right?”

“How accurate is the simulation?”

“What are the limitations of the simulation?”

“What is represented by non-coherent states?”

“Why is the Glauber state important?”

“What impact do energy levels not excited have on the state?”

“How do you produce just even or odd wavefunctions?”

“Why do so many amplitudes have to exist to get a standard wavepacket?”

“Is this an example of multiple electrons or single electrons?”

MODIFYING. Two student questions belong to this category:

“What simplifications went into making the simulation?”

“How would this behave if the oscillator were damped or experienced an external force?”

GENERALIZING/ANALOGY: There are two student questions in this category:

“Is this how lasers work?”

“Are there any real world electromagnetic examples of these states?”

Comments: Students explored this simulation after having studied the separation of variables solution to Laplace's equation. The harmonic oscillator simulation is a quantum example of separation of variables applied to the Schrödinger equation. This topic was being studied by most of the members of the electromagnetics class in a concurrent quantum physics class. Some students did not see the mathematical connection between the electrostatic and quantum problems. They

therefore asked why quantum content was being covered in an electromagnetics class.

Many questions were focused on making connections between the simulation and real world applications. Answering these questions allowed the instructor to further stimulate curiosity and make connections to other physical phenomena. How a laser generates ultra short optical pulses in a manner similar to that demonstrated in the simulation is such an example.

Table I summarizes the results of categorizing the questions submitted as student responses for each of the four simulations described.

V. DISCUSSION

The use of pen-enabled mobile technology to collect student responses allows the instructor to receive student input in real-time and use it to guide students as they construct deeper understanding. This novel method of assessing and nurturing curiosity when exploring interactive simulations could be used effectively in many settings. Further explorations in contexts beyond those of using computer simulations are warranted by these results.

The results from classifying student responses, shown in Table I, are heavily predominated by curiosity associated with the students constructing an explanation of the simulation based on their understanding of the model presented in class (CONGRUOUS). The next largest contribution is associated with aspects of the simulation which do not match the student's expectations (INCONGRUOUS). Few students show curiosity about generalizing or modifying the model.

It is expected that students struggling to understand a model would have more congruous questions, focused on the details of calculating the consequences of the model, while those with a more mature understanding of the model would be curious about applications, analogies, modifying, or generating new models. Also, we suggest that the concepts and content illustrated by various simulations could influence the particular categories of curiosity they stimulate.

In this study, we have not addressed the issue of the “quality” of the questions and have considered all student responses to be equal in the level of curiosity and insight they reflect.

TABLE I. SUMMARY OF CATEGORIZATION OF STUDENT QUESTIONS SUBMITTED, FOR EACH OF 4 SIMULATIONS

| | Sim #1 | Sim #2 | Sim #3 | Sim #4 |
|-----------------------|--------|--------|--------|--------|
| INCONGRUOUS | 3% | 40% | 0% | 40% |
| CONGRUOUS | 74% | 28% | 100% | 44% |
| MODIFYING | 12% | 25% | 0% | 6% |
| GENERALIZING /ANALOGY | 0% | 5% | 0% | 6% |
| CAUSAL /CREATIVE | 4% | 2% | 0% | 0% |
| INFORMA-TIONAL | 7% | 0% | 0% | 0% |

The questions generated in these exercises are remarkable for their quantity, quality, and diversity, especially in light of the fact that students were given no external incentives for their responses. This is consistent with curiosity being an intrinsic motivational factor. Furthermore, none of the exams or homework exercises involved nurturing or assessing curiosity. From the students' questions and comments, it was apparent that they were genuinely interested in engaging with the material at a level not apparent prior to the real-time formative assessments.

The responses revealed an aspect of student thinking not often measured or even exposed in a lecture-based classroom. Many provided springboards for making connections between physical phenomena, discussing critical thinking skills, and enhancing curiosity.

Disadvantages of categorizing the types of curiosity include the non-uniqueness of the sorting categories and the potential confusion due to the redefinition of terms by which to sort.

One advantage of categorizing the questions is that students become aware of the many ways that they might be curious. This awareness can lead to a process which stimulates their curiosity. Consider a heuristic rule from a statics class that structures built in triangles are less likely to collapse. When asked what they are curious about, the students might apply the "Modifying" category to ask how the skull of a reptile exhibits this rule. A student's curiosity could expand from state to trait as they are exposed to multiple examples in class. Facilitated by technology such as *InkSurvey*, this process can be demonstrated by both the student's peers and the instructor. Hopefully, if this process is implemented often enough, students would become fluent in generating questions reflecting all categories of curiosity.

Additionally, the development of the method presented here to measure curiosity, if both valid and reliable, may lead to improved curricula. Categorization allows different levels and types of curiosity to be studied.

Other advantages of this teaching model are: (1) it reinforces the congruent category of curiosity, which aligns directly with the content STEM students are generally considered to be in class to learn about (they should be curious about how to calculate the consequences of a model they are studying, for example), (2) it encourages students to communicate what they think is incongruent so instruction can be modified to address such issues, and (3) it affords students practice in metacognition as they construct questions about which they are curious.

VI. CONCLUSIONS

When students were provided with an opportunity to submit questions they generated while exploring interactive computer

simulations, it was revealed that they are indeed more curious than they appear in a lecture-based class. They were willing to actively engage with the material they were studying, even without extrinsic motivation. Furthermore, the questions generated by individuals in the class provided relevant and worthwhile springboards for subsequent class discussions involving higher level thinking skills, as well as stimulating student curiosity to further explore the simulations. The process and classification scheme described here may prove valuable in nurturing and measuring curiosity.

Abstract—To address the need for innovative mobile security learning materials and for promoting mobile security education, this paper presents our work-in-progress effort on developing a real-world relevant security labware to provide students with mobile threat analysis and protection experience. A preliminary evaluation has been conducted on the pilot labs and positive feedback has been received.

Keywords—Labware, Mobile Security, Real World Relevant

I. INTRODUCTION

The computing landscape is shifting towards mobile devices [1]. The smartphones and tablets are permeating into nearly all aspects of our information society and many students have considered them as computers [2]. Unfortunately, security threats to mobile devices and applications are also growing explosively. Traditional security threats, e.g., malware or social engineering, are evolving in this new environment; more importantly, new components (e.g., Global Positioning System and Subscriber Identity Module) and services (e.g., call, message, and location services) in mobile devices introduce new sources of security risks. Recent security reports [3, 4] have described the rapidly growing number and sophistication of mobile threats. However, the rapid growth of mobile threats has not been accompanied by sufficient educational activities in the area of mobile security. To our best knowledge, very few courses have been initiated for teaching mobile security and there is a lack of well-prepared learning materials to provide students with the state-of-the-art mobile security knowledge and hands-on experience. This calls for innovations in educational activities and learning materials to promote the exposure of students to this emerging and important security area and to prepare them for the growing industry needs.

To address the above needs and challenges, this paper presents our work-in-progress effort on developing a real world relevant labware to provide students with mobile threat analysis and protection experience. The labware employs a novel learning approach that couples the in-depth threat analysis with the detail hands-on implementation of corresponding protection mechanisms. In addition, the labware aims at providing real world relevant learning, which means that the labware will

reflect the up-to-date mobile threats and protections, provide materials close to students' everyday lives, and instruct students implementing protection apps that are workable in practice.

II. LABWARE DESIGN

To design the labware, we collected and analyzed a number of recent mobile security reports from both academy research and security companies, e.g., Lookout, McAfee, and Symantec. Table 1 lists the ten labs that we will design in the labware. It covers important threats in multiple aspects of mobile security. Each lab focuses on one type of mobile threats and develops multiple forms of learning materials for the threat analysis and protection, including lecture, case study, demonstration, and hands-on mobile app development. Instead of implementing a comprehensive mobile security resource center, the labware is intended to create real world relevant learning materials and to provide students with hands-on mobile security experience.

III. EXAMPLE LAB

This section demonstrates the labware using *Lab 7: Mobile Messaging Threats*. Mobile messaging service, including Short Message Service (SMS) and Multimedia Messaging Service (MMS), is one of the most important functions in mobile devices; however, its convenience and popularity have also made it become a lucrative playground for various attacks and frauds such as spamming, phishing, and spoofing [5]. These threats are unique to the mobile computing systems and are seldom applicable to other information systems. The *Lab 7: Mobile Messaging Threats* aims at providing students with mobile messaging threat analysis and protection experience. In the threat analysis part, this lab first introduces the mobile messaging service and analyzes important threats to the service; then it provides a mobile app to demonstrate an SMS attack instance. Fig. 1 shows two screenshots of this demonstration app. In this demonstration, an attacker installs a malicious SMS broadcast listener on the victim's mobile phone, then he sends a malicious SMS to the victim and steal victim's contact (subfigure on the right of Fig.1), and the victim has no information about the attacker's malicious SMS activities (subfigure on the left of Fig. 1).

TABLE I. LAB LIST

| Lab | Mobile Threat Analysis & Protection | Security Aspect |
|-----|--|---|
| 1 | Threats of Lost or Stolen Mobile Devices | Mobile Device Security & Privacy |
| 2 | Unauthorized Mobile Resource Access | |
| 3 | Mobile Privacy Threat | |
| 4 | Mobile Malware | Mobile App Security |
| 5 | Mobile Spyware | |
| 6 | Secure Mobile App Development | |
| 7 | Mobile Messaging Threats | Mobile Network & Communication Security |
| 8 | Mobile Banking Threats | |
| 9 | Mobile Phishing Threats | |
| 10 | Mobile Network Threats | |

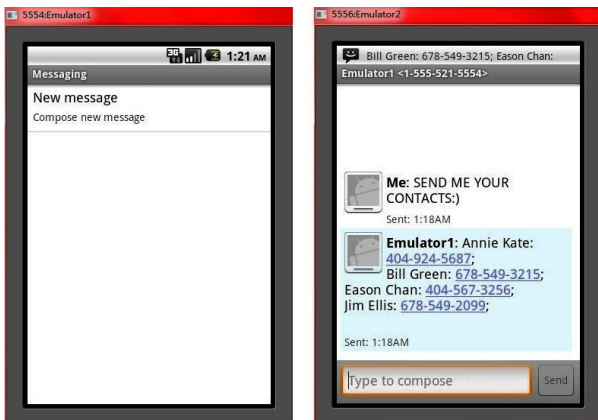

Fig. 1. Screenshots of a Mobile SMS Attack Demo.

In the protection part, the lab first gives an overview of the protection mechanisms, e.g., using white list or black list to block or filter messages. To defend the attack demonstrated in the threat analysis part, the lab instructs students implementing a protection mobile app using SMS filtering. Fig. 2 shows two screenshots of the mobile SMS protection app. In this protection app, the students implement a filter to block suspicious SMS messages (subfigure on the left of Fig. 2) from unknown users (subfigure on the right of Fig. 2). The app is workable in practice. Students can easily install their developed apps in their own devices such that they can obtain an instant gratification and confidence from the hands-on practice and they can be encouraged to create new apps.

IV. PRELIMINARY EVALUATION

Pilot labs have been presented to 28 undergraduate students in the course "Wireless Security" for preliminary evaluation. Table II shows the evaluation question and students' feedback. On average, about 90% of students gave non-negative feedback on all evaluation questions, and about 70% agreed with our design objectives of the labware. In particular, we are pleased and encouraged to see that about 65% students felt that the labs were easy to follow and practice, since none of the 28 students had previous mobile development experience.

V. CONCLUSION

This paper presents our work-in-progress effort on developing a real world relevant labware to provide students with mobile threat analysis and protection experience. A preliminary evaluation has been conducted on the pilot labs and positive feedback has been received. In the future work, we will continue to improve the design of the labware, complete the labware development, and conduct extensive evaluations.

ACKNOWLEDGMENT

The work is partially supported by the National Science Foundation under grant NSF CCLI-0942097. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

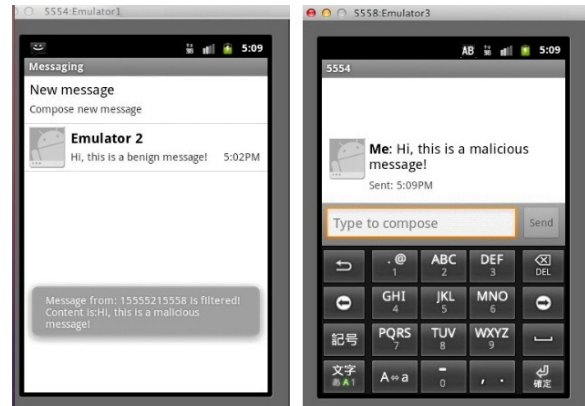

Fig. 2. Screenshot of a Mobile SMS Protection App.

TABLE II. PRELIMINARY EVALUATION

| Evaluation Question | Feedback ^a |
|--|-----------------------|
| 1) The labware helps me understand better about the mobile security concepts in the project. | 71.43 / 21.43 / 7.14 |
| 2) The labware provides me with more hands-on experience on learning mobile security. | 71.43 / 28.57 / 0 |
| 3) The labware is easy to follow and practice. | 64.29 / 7.14 / 28.57 |
| 4) The labware promotes my interest and engagement in security. | 71.43 / 21.43 / 7.14 |
| 5) The labware promotes my interest and engagement in mobile app development. | 57.14 / 28.57 / 14.29 |
| 6) I gained real world security experience from the real world relevant hands-on mobile labs | 71.43 / 21.43 / 7.14 |

a. the format of feedback data is Agree / Neutral / Disagree, e.g., the feedback to question 1 is 71.43% agree, 21.43% neutral, and 7.14% disagree

Abstract— Preliminary experience with a final year activity focusing on Entrepreneurship & Enterprise is presented. The curriculum is described and its suitability for Computing students evaluated. Persuading technical students to participate in a non-technical course is a considerable challenge. The University has recently organized an annual business competition, with prizes, to encourage students to pursue their ideas and develop commercial products and services. This has been incorporated into the assessed course with some success.

Keyword - enterprise; entrepreneurship; professional development; graduate training;

I. NEED FOR NEW ENTERPRISES

Graduates from UWE with bachelor degrees in Engineering and Computing are very likely to find employment with established firms who are currently experiencing great difficulty in finding new staff with the correct set of technical skills [1][2]. Although it is quite unusual for young UK graduates to want to launch their own enterprises and start developing services and products, it is from these new start-ups that much of our future economic growth is anticipated. To prepare technical graduates to be entrepreneurs is a great challenge for universities. Such a situation is not true for all disciplines. In Arts & Media courses, graduates are already prepared for self-employment or sole-trading because that is the more common job environment for them, and students will require business skills and a canny market awareness from their first day at work.

II. ENTREPRENEURSHIP

This course originally started in September 2009 to satisfy the requirements of a newly introduced university-wide Graduate Development Program. (GDP) [3]. Each year of the GDP program has assumed a distinct, designated mission. Year 1 GDP generally focuses on group socialization, student retention, and individual study skills. With 4 year sandwich degrees, GDP2 deals almost exclusively with preparation for the approaching third year industrial Placement/Internship. When deciding how best to exploit GDP3 sessions in year 4, we decided that a course which exposes students to skills and understanding of Entrepreneurship and Enterprise would be eminently suitable in preparing them for their future careers.

The curriculum was titled "Entrepreneurship for Computing" [4], and was only intended for senior students following the BSc Computer Systems Engineering degree (CSE). It was

broadly based on a well proven course running at University College London (UCL) given by Philip Treleaven [5]. The scheme involves groups of students working together throughout the year to bring a virtual product to market. It was primarily intended to stimulate interest in business innovation and product development amongst students on computing-based awards. So students are led progressively through the process of starting their first business, with discussions relating to technical, marketing, financial and personnel issues. Its aim is to stimulate interest, increase self-confidence and ease the pathway for emergent enterprises. Thus students are encouraged to acquire skills and knowledge for the time when they feel ready to exploit some innovative idea through a start-up business venture. Each student group must identify a new service or product which could then become the focus of the group's attention throughout the year. They must also locate and appoint a Commercial Mentor who will offer support, advice and criticism when appropriate. A Commercial Mentor may come from a Placement experience, part-time job or personal contact. The course Alumni Lists will be very useful in obtaining well qualified assistance.

On completion of this module a student will typically be able to show a detailed knowledge and understanding of the activities required at each step in launching a new product or service. This will include an understanding of the different models available for financing a new start-up and how to create a business model and a business action plan. Marketing will be an important part of this plan, requiring a high level strategy with the deployment of a website, publicity material and direct presentations. All new start-ups run an increased risk of failure, with only 50% surviving through the first four years. This stark statistic has to be factored into all real-world plans!

III. CURRICULUM DELIVERY

One important decision taken early on was to bring in a true Entrepreneur to present the course. It is unlikely that an average academic would be able to muster the experience and credibility to convince students of the wisdom of his/her words. Luckily, Jeff Graham (CEO XOR Systems) agreed not only to lead the course, but also to become closely involved in its initial development. He agreed that all teaching materials should be selected with technical students in mind, in order to gain their attention and win engagement. The module that emerged has many interesting features.

When Entrepreneurial Skills for Computing was offered as voluntary GDP3 activity it became apparent that it would be

difficult to sustain engagement beyond Christmas due to competing pressures of the final year of study. Considering this experience, it was decided to validate the activity as an academic, 10 credit module (still only contributing 8.3% of their final year), and offer it as an option on the BSc CSE degree. In addition, participation with the UWE theBizIdea start-up competition [6] was then formally incorporated into the activity and assessment schedule. This was done after discussions with the organizer, Jill Burnett, who welcomed the involvement of CSE students who previously had not been encouraged to participate.

The first year of this scheme was much more successful than had been anticipated. The benefits for CSE students are clear. TheBizIdea competition serves to introduce technically oriented students, who often have a narrow view of their work focusing on the academic challenges and merits of their work, to engage and consider the wider business aspects, such as budget planning and marketing.

Although engagement with theBizIdea has been limited in the past, it is now recognized as potentially providing a very important and beneficial role for students. This could readily be extended to other technical programs in the department.

The tasks that students have to complete for theBizIdea aid their preparation and understanding of commerce and industry. Additionally our view is that theBizIdea activities map directly onto the GDP3 targets, having an employability focus and that the external input/feedback that the students receive adds a weight and credibility over and above academic feedback – even if they do say the same thing!

Students' draft business plans are submitted to theBizIdea external assessor panels who grade the work and provide feedback. Students often found this shockingly tough and unexpectedly frank in its criticisms.

IV. COURSE CURRICULUM & ASSESSMENT

The full curriculum is obtainable on-line [4] but the significant aspects are group work, product identification, business plan development, marketing plan development, presentation of plans to external assessors and responding to the resultant critical appraisal. Assessment deals with both individual and group work by written reports and oral presentations.

V. EXPERIENCE SO FAR

A major difficulty is generating a viable business idea for each group. It's hard to develop a business concept in a short period when you've never had to do this before and it needs to be done early in the academic year, while teaching is still underway, so the students haven't fully benefited from the course. The idea needs to be sufficiently strong to sustain interest over the year and robust enough to survive competitive, even ruthless scrutiny.

This was solved in a number of ways. All the students were undertaking a final year personal project which can involve quite sophisticated concepts, potentially offering a rich source of product ideas. Staff also had a number of specific ideas and product areas prepared; smart phone apps being currently suitable for CS students. Such generic suggestions are

extremely useful in providing students with a lead towards a novel business idea.

The students then developed the idea further, to personalize it and make it their own. It is advisable to talk with students who are planning to take the module, perhaps before the summer recess, to allow them to at least explore what areas interest them before the module starts.

We had to be cautious when exploiting theBizIdea competition as part of teaching. The competition was set up separately to encourage any student who thinks they already have a viable business idea and want to pursue the idea with passion and commitment. We rather needed to co-opt the process for our own ends. Our purpose was to use it as a teaching vehicle, gaining invaluable feedback from experienced business people, and as a measurement tool to evaluate what the students had learned on the module. This is a slight distortion of theBizIdea competition. We wanted students to invent an idea and then submit it, against a time-line driven by the needs of the module.

When it came to assessment of the students' work, the intrinsic quality of their idea became an issue. Should we overlook the weaker ideas, and concentrate on the bid process and business model? In general, the ideas adopted do tend to be strong enough in their own right and it was easy to judge how well they would fare in the market place. But for the weaker ideas, the judgment was based on how well the idea was developed by the team.

It was important that the students should re-submit their work, and aim for a minimum of two attempts at theBizIdea, so that they would improve their proposal, based on the feedback they received. This encouraged a process of refinement, improved their use of business language, highlighted areas that needed further development and created some dialogue with the assessors. The marking scheme for the module therefore could reward their second attempt with an improved mark.

IP ownership has been discussed within some groups where a particularly strong idea has been proposed by a member of that group. Non-disclosure agreements could be used, involving all academic staff and external assessors as well as the students. An alternative is for those involved to acknowledge IP ownership at the outset and so avoid any later disputes.

Several new degree programs have now adopted the Entrepreneurship module for their students. The future looks bright!

Abstract — Undergraduate students are increasingly engaged in developing products and technologies that are commercially viable outside of the university through their involvement in courses and experiential programs focused on entrepreneurship and product design. It is hypothesized that this trend is increasing activity between undergraduates and university technology transfer offices, leading to questions of how best to align student interests with institutional policies and practices related to intellectual property (IP). Since most undergraduate students are not employed by their universities as are faculty and many graduate students, this raises interesting questions related to the ownership of intellectual property developed as part of a course or experiential program. This paper summarizes the preliminary results of a survey designed to examine the level and nature of undergraduate involvement in creating intellectual property as well as institutional policies and practices in response to these trends. The survey was administered to intellectual property professionals in technology transfer offices at universities in the United States with strong emphases in engineering, science, and technology and/or entrepreneurship.

Keywords — *intellectual property; undergraduate; entrepreneurship; engineering education; product design; innovation*

I. INTRODUCTION

In recent years, there has been a significant increase in the quantity and diversity of students participating in entrepreneurship education and activities focused on developing products, technologies, and services that are commercially viable. This trend has been driven by a number of factors, including: (1) a generation of students who are

aware of the financial and personal benefits of entrepreneurship; (2) a need to prepare students for a new economy where smaller companies are increasingly a source of jobs; (3) accreditation and other requirements that drive the integration of more “real world” experiences into educational programs; (4) and a general trend towards creating more entrepreneurial universities able to generate revenues by engaging with the private sector [1]. In response, institutions are developing entrepreneurship courses and experiential learning programs for students. They are also creating entrepreneurship centers, stepping up technology commercialization efforts, and expanding business incubators and technology parks.

For many years, entrepreneurship education programs existed primarily in schools of business. More recently, there is a movement to equip students in a wider range of disciplines such as engineering and the arts with entrepreneurship education so that they are able to generate value from their knowledge in more entrepreneurial ways [2]. These efforts are based on the belief that students who are involved in developing products, technologies, processes, and services will be able to generate more value from their knowledge if they understand customer needs, markets, competition, business models, and are able to advocate for their ideas. This movement is likely to continue given initiatives such as the National Science Foundation’s award of a \$10 million grant over five years to launch a national STEP Center based at Stanford University for teaching innovation and entrepreneurship in engineering [3].

The increased access to entrepreneurship education and emphasis on “real world” product design is likely to lead to more involvement by students in generating intellectual property and/or creating businesses that are viable outside of the walls of the university. Since most undergraduates are not employed by the university, unlike faculty and many graduate students, this poses interesting questions such as: Who owns

the IP developed by a student as part of a course project or experiential program? How is the contribution of a student versus that of the university defined? And, who should students turn to for assistance with intellectual property protection issues?

I. BACKGROUND

A. *Management of intellectual property at universities*

The passage of the Bayh-Dole Act is the principal factor in explaining the increase in patenting and licensing activities by academic institutions in the United States [4]. This legislation gave U.S. universities, small businesses and non-profits control of their inventions and intellectual property that resulted from federal government-funded research. Revenue generation opportunities provide considerable incentive for universities to pursue commercialization of their intellectual property, particularly in light of reductions in federal or state funding for education [5]. A summary of patent and licensing revenue data from the Association of University Technology Managers (AUTM) in 2010 revealed research-related income of \$2.4 billion generated by 155 universities and 27 hospitals and research institutes surveyed [6].

In order to manage the opportunities and challenges introduced by increased IP commercialization activity, many universities created administrative units commonly referred to as technology transfer offices (TTOs). The main function of a TTO is to act as the intermediary between the IP creators (i.e., inventors) and partners who aid in the commercialization process (e.g., entrepreneurs, industry, attorneys). As such they are responsible for putting in place policies, processes and practices which: 1) support IP creation, 2) provide clear ownership determination of IP, 3) encourage IP commercialization opportunities for the institution, and 4) align with long-term IP management strategies. Given the number of stakeholders involved in the IP management process at universities, a desired outcome is balancing the interests of all involved parties. While the alignment of the incentives are typically intended to be beneficial to all stakeholders, there are often trade-offs between participants in the process.

B. *Undergraduate students and intellectual property*

Until recently, little has been published about the topic of university intellectual property policy specifically as it relates to undergraduates. This suggests that the level of involvement by undergraduates in IP protection has not warranted much attention and/or that many entrepreneurship or product development courses were created with limited consideration of institutional IP policy. There appear to be three main contexts in which undergraduates can potentially confront issues related to the ownership of intellectual property: 1) entrepreneurship programs, 2) industry-sponsored engineering or product design courses, and 3) undergraduate research. Nordheden and Hoefflich [7] addressed the issue of ownership

of IP within the context of the increasing involvement in research by undergraduates. They pointed out that because students typically do research for credit and not money, they do not have an employment contract with the university and are not covered under what is referred to as the "workplace doctrine" and could be in a position to challenge a university for a share of the rights. They suggested the need to get students to sign away their rights before conducting research, but point out that this could conflict with university policies toward students.

An IP Policy Primer prepared by the National Collegiate Inventors and Innovators Association, an organization that works closely with student inventors, stated that a good IP policy removes gray areas, and spells out each player's stake, rights, and responsibilities [8]. Similarly, in an article describing IP issues faced by universities seeking to commercialize student innovation at all levels, Evans [5] indicated the need to create understandable IP policy and provide educational materials suited to each constituent. However, an accurate understanding of IP ownership rights and policy appears may be the exception more than the rule at many institutions. A study conducted by the University of North Dakota indicated that the perception of IP ownership related to work involving students is viewed quite differently by the students and the university faculty. Students consistently assigned more ownership to students than to faculty and attributed less ownership to faculty when industry sponsors were involved [9].

Preliminary interviews and pilot survey data collected from university technology transfer professionals prior to conducting this study suggested that there were few institutions with explicit policies directed at undergraduates [10]. Instead, most governed under the general IP policies of the institution where undergraduates operated in a gray area and where, as one interviewee stated, technology transfer offices "turn a blind eye." Cases where undergraduate IP policy appeared to be relatively straightforward were situations where students were being paid for work which resulted in the generation of IP and when students were involved in a product design or similar course that was sponsored by a company. However, this was described as leading to other complexities. One institution reported that students had to be given the opportunity to opt out of industry-sponsored engineering courses, which meant comparable curricular alternatives had to be available.

Another gray area identified in pilot survey data was the definition of "significant use of university resources" in relation to the development of IP. This referred to the use of libraries, computers, software, space, hardware, and materials owned or provided by a university. Some institutions made distinctions such as "expensive, core, specialized equipment," or "facilities not available to the public." Universities varied as to whether they included IP developed as part of classes or class assignments. Other issues included the degree to which faculty should be involved in enforcing IP policy and whether technology transfer offices have the resources to devote to student intellectual property.

The experience of the authors has been that when faculty are unable to clearly articulate intellectual property policy to students and/or when it is perceived by students to be in favor of the institution, it can inhibit innovation and prevent students from obtaining the feedback and assistance that could help advance their innovations or ventures. In some cases, students resort to working on projects that simply meet the minimal requirements of the course, while keeping their “real” projects to themselves for fear that the university will claim ownership. While these fears are unfounded in many cases, they highlight the need to communicate IP policy to students in a way that encourages them to innovate and ultimately create goodwill. This was the goal of North Carolina State University, which found that “requiring disclosure and possibly asserting university ownership of inventions created by undergraduate students as a result of their coursework was antithetical to the fundamental nature and purpose of the university, and would have a negative impact on student perceptions and alumni philanthropy.” The university has since updated their patent policy to clarify the students’ rights, allowing them to own the IP generated through their normal coursework [11].

II. PURPOSE AND RESEARCH QUESTIONS

The purpose of this study was to examine trends in the level and nature of undergraduate involvement in creating intellectual property and institutional policies and practices in relation to them. The research questions were:

- What is the extent and nature of undergraduate involvement with technology transfer offices?
- What are universities’ specific policies related to undergraduate IP?
- What are general (unofficial) attitudes and practices related to IP involving undergraduate students?

III. METHOD

A new survey instrument was developed to capture data necessary to answer the research questions. Survey items were created based on a literature review as well as pilot data collected via interviews with technology transfer professionals prior to conducting the study. It was comprised of both objective and subjective questions in order to understand trends related to and attitudes toward the management of intellectual property generated by undergraduates. The survey was reviewed by faculty, technology transfer professionals, intellectual property attorneys, and educational assessment experts.

Directors of TTOs at approximately 50 colleges and universities in the United States were asked to complete the survey. These institutions were selected because they had a strong emphasis in the STEM disciplines and/or entrepreneurship and were likely to have active involvement in technology transfer activities which may involve undergraduates. Appropriate contacts at each institution were verified by via web searchers and telephone calls prior to

administering the survey. Contacts were sent an email explaining the purpose of the study and a link to the online survey. Over the course of several weeks, email reminder messages were sent and telephone calls were made to encourage contacts to participate. This paper reports on preliminary survey data collected from 32 institutions.

IV. RESULTS

Question 1: What is the extent and nature of undergraduate involvement with technology transfer offices?

Survey respondents were asked a number of questions related to the frequency of their interactions with undergraduates within the previous year, the disciplines from which they came, and the factors driving growth in IP activity among undergraduates. There was great variation the number of undergraduate with which TTOs reported to be interacting. Of those surveyed 6% reported that they had interacted with no undergraduates; 25% less than five; 31% 5-10; 16% 11-20; and 16% 21-50 and 6% more than 50. When asked whether the number of undergraduates they see was growing, 22% responded “yes, at a faster rate than for other inventor groups (e.g. faculty and graduate students); 28% “yes, but at a rate similar to other inventor groups”; and 50% “no, staying about the same.” Fifty-three percent agreed that undergraduate involvement favored certain academic departments versus 31% who did not. Top areas were engineering, followed by science, chemistry, and computer science. Growth was attributed to a number of factors. Respondents agreed most strongly that growth was driven by entrepreneurial competitions, a general increased emphasis on entrepreneurship on their campuses, and engineering design courses and to a slightly lesser degree due to undergraduate participation in research or university success stories related to technology commercialization (Table I).

TTO professionals were also asked several questions about the frequency with which students came to their offices seeking particular types of advice. Students were reported to be most frequently seeking advice about internship opportunities, understanding their personal rights related to IP, or guidance related to a specific invention (Table II).

Question 2: What are universities’ specific policies related to undergraduate IP?

A number of questions related to the extent to which TTOs addressed undergraduates specifically in their IP policies, how these differed from those directed at faculty and graduate student inventors, and whether they anticipated any changes to their policies. In response to whether institutions had instituted any programmatic changes to accommodate undergraduates, 25% said yes, 13% said they were in progress, and 63% said no. One third of those surveyed reported to have a specific policy for intellectual property developed by undergraduates, while 66% did not. Respondents were asked whether they actively tracked undergraduate student involvement in IP generation. Of the 32 respondents 94%

reported that they did not track undergraduate student involvement in IP generation specifically. However, in a follow-up question related to how the tracking process differs from that of other inventor groups, 16% of respondents indicated that they track undergraduates as they do any other inventor. When asked whether their university's policies and practices vis-à-vis undergrads were likely to change, 3% reported it was very likely, 8% likely, 59% unlikely, and 13% very unlikely.

Seventy-five percent of respondents considered the "use of significant university resources" when assigning IP ownership to undergraduates. University resources that were taken into consideration most frequently were research labs; parts, components and supplies; and machine shop use. Taken into consideration to a lesser degree were library resources, internet access, and advice or mentoring from the TTO. The extent to which other resources were considered varied widely across institutions (Table III).

TABLE I. FACTORS DRIVING GROWTH IN IP ACTIVITY AMONG UNDERGRADUATES

| Factors | Disagree or strongly disagree | Agree | Strongly agree |
|--|-------------------------------|-------|----------------|
| Entrepreneurship or product innovation-related competitions | 9% | 38% | 53% |
| A general increased emphasis on entrepreneurship and technology commercialization on your campus | 6% | 47% | 47% |
| Engineering design/product development courses | 16% | 38% | 47% |
| Entrepreneurship courses offered on campus | 16% | 47% | 38% |
| Entrepreneurship-related clubs or student organizations | 16% | 50% | 34% |
| Seminars or workshops related to entrepreneurship and intellectual property (not semester-long) | 22% | 47% | 31% |
| More students pursuing entrepreneurial careers | 22% | 47% | 31% |
| Undergraduate participation in research | 34% | 38% | 28% |
| University intellectual-property success stories | 44% | 41% | 16% |

Question 3: What are general (unofficial) attitudes and practices related to IP involving undergraduate students?

Respondents were asked a number of more subjective questions designed to understand institutional attitudes toward undergrad IP. The first question asked respondents to characterize their degree of involvement with undergraduates. Over 50% stated they got involved with undergraduates primarily on a case-by case basis, with the remainder split between being passive and very active (Table IV).

When asked their opinions of the degree to which they should be involved with undergraduates, many agreed that they should be more involved in working with undergraduates but many also agreed that undergraduate IP yields very little return on investment of time or money (Table V).

TABLE II. FREQUENCY WITH WHICH STUDENT SEEK PARTICULAR TYPES OF ADVICE FROM TTOS

| Reasons | Rarely | Occasionally | Frequently |
|---|--------|--------------|------------|
| Opportunities for internships | 25% | 44% | 28% |
| An understanding of their personal rights in relation to university IP policies | 19% | 66% | 16% |
| Guidance related to a specific invention or technology | 13% | 72% | 16% |
| General entrepreneurship and business start-up questions | 31% | 50% | 13% |
| General knowledge about patents and the IP protection process | 34% | 53% | 13% |
| Financial benefits/obligations related to IP | 44% | 38% | 6% |

TABLE III. FREQUENCY WITH WHICH UNIVERSITY RESOURCES ARE CONSIDERED IN IP OWNERSHIP DECISIONS

| Resources | Never | Sometimes | Always |
|---|-------|-----------|--------|
| Research labs | 22% | 38% | 41% |
| Parts/components/supplies (e.g., electronic components, metal, chemicals, etc.) | 28% | 47% | 25% |
| Advice or mentoring from professors – (direct input to solve problem or generate ideas) | 47% | 28% | 25% |
| Machine/fabrication shop | 34% | 44% | 22% |
| Class assignments | 69% | 19% | 13% |
| Computer servers | 53% | 41% | 6% |
| Software provided by the university | 50% | 47% | 3% |
| Computer labs | 56% | 41% | 3% |
| Office space | 66% | 31% | 3% |
| Advice/mentoring from technology commercialization office | 78% | 19% | 3% |
| Internet access/networks provided by the university | 72% | 28% | 0% |
| Library resources/databases | 78% | 22% | 0% |

TABLE IV. STATEMENTS THAT BEST DESCRIBE INSTITUTIONS' SURVEYED PRACTICES TOWARD UNDERGRADUATE IP

| Statements | n | percent |
|---|----|---------|
| Somewhat involved – we get involved on a case-by-case basis | 18 | 56% |
| Passive – we tend to ignore it or look the other way | 7 | 22% |
| Actively involved – we play an active role in activities that can generate undergraduate IP | 7 | 22% |

TABLE V. ATTITUDES TOWARD UNDERGRADUATE IP

| Attitudes | Disagree or strongly disagree | agree | Strongly agree |
|---|-------------------------------|-------|----------------|
| We should be more involved in working with undergraduates | 41% | 59% | 0% |
| We don't have the resources to meet the needs of undergraduates | 50% | 31% | 19% |
| Undergraduate IP yields very little return on investment of time or money | 38% | 56% | 6% |
| Undergraduate students are primarily generating IP that is not within the scope of the university IP policy | 28% | 53% | 19% |

Respondents were asked whether they felt their policies were understood by students. Only 6% felt that their policies were well understood, 59% felt they were somewhat understood, and 34% felt they were not understood at all. In response to whether faculty should be more involved in handling IP topics and issues related to undergraduates; 38% indicated yes, 34% said no, and 28% were unsure. Respondents were also asked about the frequency with which they were consulted when new courses that involved entrepreneurship and innovation were developed; 28% said frequently, 47% said occasionally, and 25% said never.

V. DISCUSSION

The preliminary findings of this study indicate that undergraduate involvement in intellectual property is growing at approximately half of the institutions surveyed and remaining constant at the remainder. Growth appears to be driven by an increased emphasis on entrepreneurship and "real world" product design via coursework and experiential learning opportunities, particularly in disciplines such as engineering, chemistry, and computer science. The types of IP-related advice students are most frequently seeking from TTOs are an understanding of their personal rights in relation to policy and guidance related to a specific invention or technology.

In response to these trends, 38% of institutions indicated that they had or were in the process of instituting

programmatic changes to accommodate undergraduates and one third had specific policies for undergraduates. Interestingly, when asked whether their institution policies and practices related to undergraduates were likely to change, only 11% reported this was the case, suggesting that most institutions that intended to address undergraduates had already taken steps to do so.

The extent to which the "use of significant university resources" plays a role in assigning IP ownership appeared to vary greatly. When asked about the frequency with which specific resources were considered, there were a significant amount of "sometimes" responses as opposed to "never" and "always." This finding suggests that there is considerable gray area or subjectivity when attempting to assign ownership based on the use of these resources. Additional research is necessary to understand whether this is the case and exactly how TTOs navigate through these issues.

Only 22% of universities surveyed reported to be actively involved in activities that could generate undergraduate IP but 59% felt that they should be more involved in working with undergraduates. For half of those surveyed a barrier to doing so was not having sufficient resources to meet the needs of undergraduates and 62% felt that undergraduate IP yielded very little return on investment of time or money. This suggests for many institutions, investing more in servicing undergraduates lacks a compelling return.

These findings suggest that there may be opportunities to better address IP issues at the courses or program level. However, doing so would require a better understanding among students and faculty of institutional policies and practices. The results of the study indicated that policies were not well understood by students and respondents felt that faculty could be more involved in handling related issues. It is possible that better communication of policies and practices to students and faculty, may improve a TTOs ability to intervene on those undergraduate IP activities that have a greater likelihood of providing a return to the institution.

CONCLUSION

The emphasis on entrepreneurship and real-world product design is likely to grow as institutions seek to better prepare students to create value in this increasingly competitive, global economy. Given these trends, the results of the preliminary data collected as part of this study suggest that it may be beneficial to institutions to clarify policies as they related to undergraduate generation of intellectual property and find ways to communicate them to both students and faculty. This is likely to reduce ambiguity and provide a better return on investment to TTOs in terms of time, money, and goodwill to the institution.

Work in Progress: Integrating Entrepreneurship into Undergraduate Engineering Education

Cory Hixson, Marie Parette, and John “Jack” Lesko

Virginia Tech

hixson@vt.edu, mparette@vt.edu, jlesko@vt.edu

Abstract—As government and industry leaders place increased importance on entrepreneurship and innovation within science, technology, and engineering (STEM) in higher education, courses, programs, and centers are being developed to enhance students’ learning and development in these areas. Despite this growth in programming and the extensive entrepreneurship research in the literature, little research has been completed regarding ways in which students in STEM disciplines value, identify with, and are willing to participate in entrepreneurship activities. This paper presents work in progress to develop a survey and run focus groups to better understand STEM students’ perceptions of entrepreneurship and entrepreneurship educational opportunities. The results can be used by educators to better understand the knowledge, beliefs, and practices of students being served by entrepreneurship and innovation programming, and to identify approaches to engaging more students in this critical area.

Keywords- *entrepreneurship; STEM; undergraduate education; identification; willingness; future career, program development*

I. INTRODUCTION

A 2008 Kauffman Foundation report states, nearly 50% of U.S. startup founders hold science, technology, engineering, and mathematics (STEM) degrees. Moreover, the majority of startup founders were above the age of thirty-five when they began their ventures, not 20-somethings as might be the perception of some Americans [1]. In recent years, some M.B.A. programs have shifted their focus to emphasize entrepreneurship and schools such as Harvard Business School and MIT are developing cross-disciplinary entrepreneurial atmospheres that promote innovation, creativity, and the creation of successful technology-based startups. Additionally entrepreneurship courses and programs outside of business schools are being developed and some are calling for entrepreneurship and innovation to be addressed at an institutional level [2].

At the same time, industry and government leaders are calling for an increased emphasis on innovation and entrepreneurship in STEM education [3]. Major STEM innovation centers, including the \$10M Stanford Epicenter (Engineering Pathways to Innovation) Program (<http://epicenter.stanford.edu/>), seek to satisfy this call. Yet even as programs and research centers develop, critical questions regarding engineering students’ perceptions and beliefs about entrepreneurship remain. How do STEM students, who have been found to implement entrepreneurial concepts after graduation, identify with entrepreneurial courses and

beliefs? What is their willingness to take courses, often beyond their required course load, which promote knowledge gains in entrepreneurship, innovation, and new venture creation? Furthermore, how might these entrepreneurial-minded STEM college students view engagement in interdisciplinary training and experiences that encourage startup practices prior to and upon graduation? This paper addresses questions such as these by reporting on the development of an entrepreneurship survey and focus groups targeting science and engineering undergraduate students.

II. RESEARCH METHODS

A. Overview

To better understand STEM students’ beliefs and values associated with entrepreneurship, we draw on prior research in motivation and engineering student pathways to develop a research instrument designed to measure constructs such as expectancy-value, interest, identification, and future possible selves as they pertain to entrepreneurship. Since little data regarding STEM students in this area exists, we employ an intersection of theoretical constructs here to better identify those most salient to both students and program development. In addition to measuring core constructs, the survey will also seek to supply logistical knowledge needed by engineering educators and entrepreneurship program developers (e.g. the number of entrepreneurial courses students are willing to take). The following sections provide details on the survey population and examples of the survey items under development.

B. Population

The initial population chosen for this survey is all undergraduate students in the Colleges of Science and Engineering at a large R1 university. Including students from all levels of their undergraduate education will allow for the analysis of differences in students’ perceptions as they progress through their undergraduate education. It will also provide course and program developers the information needed to develop entrepreneurship education opportunities at the various levels of undergraduate education.

C. Survey Item Examples

The survey is currently in the pilot phase. The survey items have been developed based on existing validated survey items where possible. When applicable, we have provided the original validated survey reference.

To address willingness and logistics we seek to find the extent that students are willing to commit limited resources to

entrepreneurship activities. Questions such as the one below also provide course and program developers with important information directly from students. The following is an example of a survey item addressing willingness and logistics:

How many extra courses would you be willing to take to learn about entrepreneurship?

To address students' interest in entrepreneurship and their future career as an entrepreneur, we called on the University of Washington's Center for the Advancement of Engineering Education (CAEE) Pathway of Engineering Alumni Research Survey (PEARS) administered as part of the Engineering Pathways Study [4].

Regarding students' interest in entrepreneurship, we provide the following example:

How interested are you in doing each of the following activities? (Rated on a 5-point Likert-type scale from "Not Interested" to "Extremely Interested").

- *Reading articles or books about entrepreneurship*

Regarding students' future career as entrepreneur, we provide the following example:

Looking ahead, how likely is it that you will do each of the following? (Rated on a 5-point Likert-type scale from "Definitely Not" to "Definitely Yes" with the inclusion of a "Not Applicable" category.)

- *Start a company/organization in the near future*

To address the identification with entrepreneurship we called on survey items employed by Jones, Paretti, Hein, and Knott to measure motivational constructs among first-year engineering students [5]; the items in that survey were drawn from validated motivation instruments. The following is an example survey item adapted from the above study:

Please rate your level of agreement with the following statements: (Rated on a 7-point Likert-type scale from "Strongly disagree" to "Strongly agree").

- *Being good at entrepreneurship is an important part of who I am.*

III. RESULTS

The results of this survey will reveal insights about undergraduate science and engineering students' identification with entrepreneurship, their desire to commit already limited resources, and the potential barriers to pursuing a better understanding of entrepreneurship and innovation. Also, a focus group protocol will be developed based on the survey findings and established literature in entrepreneurship research. Findings from this research will not only assist entrepreneurship program development from within STEM disciplines, but it also serves to inform business schools as they partner to create interdisciplinary course offerings targeting STEM students.

IV. FUTURE WORK

This survey is the first step in a larger research-to-practice cycle. Future survey work includes pilot analysis, revision, and

administration of the revised survey with science and engineering undergraduates. Upon completion, we will analyze and disseminate the findings as well as develop and administer entrepreneurship-centered focus groups to obtain a more detailed view of science and engineering students' perceptions of entrepreneurship and entrepreneurship education. Survey participants will have the opportunity to sign up to participate in a focus group session providing an in-depth view of their perceptions regarding entrepreneurship and entrepreneurship education. Finally, the findings of both the survey and focus groups will be reported and used to develop and promote entrepreneurship education activities within the college of engineering and will be disseminated to key course and program developers within the university.

V. IMPLICATIONS AND CONCLUSIONS

This paper adds to the body of entrepreneurship literature, specifically addressing engineering students' entrepreneurial beliefs and desires to gain knowledge in entrepreneurship. Performing and disseminating research to understand students' values, interests, willingness, and identification with entrepreneurship is a critical step toward enhancing the nature in which we implement entrepreneurship education. Additionally, this paper reaches beyond the entrepreneurship community and into the fields of business, science, and engineering education as well as university administration, addressing the broader issue of developing curricula that meet the needs of both STEM students and our nation.

ACKNOWLEDGMENTS

We would like to thank Dr. Holly Matusovich for her continued support in the development of this survey.

Abstract—Innovation is critical to our economic and social prosperity. We rely on industry, university, and government employees to develop, modify, and implement innovative ideas while navigating ambiguous problem contexts, overcoming setbacks, and persisting in competition with courses of action. Research has shown that self-efficacy, or an individual's belief in their ability, influences the pursuit of and persistence in challenging work. This suggests that self-efficacy is critical for innovation. Despite resource-intensive efforts to foster innovation in organizations, we inadequately understand how to measure the impact of these interventions on individuals' judgment of their own innovation ability. We present the initial development and validation of the first survey measure for Innovation Self-efficacy (ISE), or the belief in one's ability to innovate.

Keywords – self-efficacy; innovation; assessment

I. INTRODUCTION

Government, academia, and industry are continuously called upon to create innovative solutions to societal challenges. To innovate is to intentionally implement novel and useful processes, products, or procedures to a new domain [1]. Contemporary examples include electric vehicles, crowd funding, and modular carpeting. The work of innovating can be unpredictable, controversial, and in competition with current courses of action despite the benefits. Innovators must develop, modify, and implement ideas while navigating ambiguous problem contexts, overcoming setbacks, and persisting through uncertainty [2].

Self-efficacy is defined as an individual's judgment of their capability to organize and execute courses of action for a given task [3]. Research has shown that being efficacious toward a task is an important factor in an individual's ability to attempt and subsequently perform the task successfully by influencing intrinsic motivation, engagement in specific behaviors, and the ability to pursue certain tasks [3]. This suggests that individuals may not

engage or persist in innovative efforts if they do not believe in their ability to do so successfully.

While resource-intensive efforts to foster innovation in organizations are plentiful, we inadequately understand how to measure the impact of these interventions on an individual's judgment of their own innovation capabilities. In this paper, we present initial steps undertaken in the development and validation of an Innovation Self-efficacy (ISE) measure.

A. Innovation Self-efficacy

Innovation self-efficacy refers to an individual's belief in his or her ability to accomplish tasks necessary for innovating [4, 5]. Researchers increasingly recognize the critical role of self-efficacy in innovation [6], which demands a high level of persistence and creativity to overcome setbacks. Positive self-efficacy beliefs lead to persistence, creative performance, learning from failure, and the tendency to expend effort [7, 8, 9].

B. Specific Abilities Necessary for Innovation

Our understanding and identification of innovation is understandably complex; however research in engineering, design, management, psychology, and education agree on a number of important components of innovative work including transferring knowledge from one domain to another [10], developing novel and useful ideas [1], experimentation with ideas [10], and learning from experimentation [11]. We synthesize these models of innovation from these different fields mimicking the past processes undertaken to develop surveys to assess self-efficacy of creativity [12], engineering design [13], modeling [14], tinkering [15], and entrepreneurship [16]. We aim to develop the first

integrated measure that relates to a collection of tasks associated specifically with innovation.

II. METHODS OF RESEARCH

Our early stage work included four components: (1) Conducting a literature review of self-efficacy and tasks associated with innovation in engineering, design, management, psychology, and education; (2) Surveying practitioners and academics in innovation-related fields; (3) Developing a preliminary model of innovation self-efficacy by clustering and mapping indicators into schemata based on existing beliefs; and (4) Piloting a preliminary set of survey items.

III. RESULTS

Our literature review and interview data suggested 38 indicators (task-related skills, behaviors or attitudes) of innovation self-efficacy that could be learned or cultivated in an innovator. To conceptualize our integrated model, we grouped the indicators into nine clusters: *communication*, *creativity*, *exploration*, *flexibility*, *resourcefulness*, *implementation*, *iteration*, *synthesis*, and *vision*.

The survey conducted with experienced practitioners and academics (N=22) afforded participants to rate each of the 38 indicators from 1 (not at all important) to 5 (extremely important). Results from this exploratory survey allowed us to see the indicators our sample of participants believed were most crucial to innovation and what indicators we want to continue to measure. A pilot survey was then created from the 25 indicators that the majority of participants found most important.

The pilot survey was subsequently administered to engineering students at a large state university (N=62). The survey asked students to rate their degree of confidence in their ability to do each of the 79 tasks (3-4 task-specific self efficacy statements mapped onto each indicator) on a 10-point Likert scale ranging from zero (cannot do this at all) to 100 (highly certain can do) [17]. A factor analysis was conducted on statements within each cluster (our sample size was not large enough to factor analyze the entire survey) and refined the groupings of statements into 13 indicators (Table 1); each with three task-specific self-efficacy items. A test of reliability using Cronbach's alpha was conducted for each 3-item scale to ensure values greater than 0.70 [18]. The alpha values ranged between 0.761-0.837.

TABLE I. INDICATORS OF INNOVATION SELF-EFFICACY

| Clusters | Indicators | Description |
|------------------------|--------------------------------------|--|
| <i>Vision</i> | Vision | Identify new opportunities |
| <i>Exploration</i> | Awareness/Empathy | Pay attention to what is around and adopt others' viewpoints |
| | Observation | Imagine and understand how things work |
| <i>Synthesis</i> | Information processing | Make connections |
| <i>Creativity</i> | Creativity | Have original and unique ideas |
| <i>Iteration</i> | Idea testing | Assess ideas for viability, feasibility and desirability |
| <i>Resourcefulness</i> | Collaboration | Work with others |
| | Knowledge building | Utilize people, tools, and other resources |
| | Persistence | Continue to approach problems despite setbacks |
| <i>Implementation</i> | Decision making | Set goals and choose how to proceed |
| | Risk-taking | Go against what is expected or safe if necessary |
| <i>Communication</i> | Oral and written communication | Craft and share information through written and oral means |
| | Visual and data driven communication | Translate ideas into visualizations |

IV. FUTURE WORK AND IMPLICATIONS

This preliminary investigation describes a pathway for studying innovation self-efficacy. Future research intends to refine and retrace these steps with larger and more diverse sample sizes to obtain more robust validity determinations. The planned extensions include: (1) administering the survey of indicator importance to an expanded network of engineering and design experts to determine focal indicators, and (2) administering a refined pilot survey of self-efficacy with a sample of 400 students and practitioners of engineering to run more powerful factor analyses on the entire measure. We also plan to examine what the resulting survey is capable of measuring by comparing results to external measures of innovation such as number of patents, project work and assessments, or employer/collaborator ratings [12]. We hope that our findings will allow us to extend our analysis of innovation self-efficacy with respect to elements like domain expertise, work experience, job design, motivation, and work place conditions that can influence self-efficacy.

Organizations spend millions of dollars on interventions to foster innovation every year. A validated instrument of innovation self-efficacy is needed to evaluate the efficacy of these interventions

and more broadly inform the design and development of such innovations and programs.

Abstract—This work will present preliminary results from a study of entrepreneurship programs serving undergraduate engineering students. The purpose of the study is to examine questions relating to students' perceptions and understanding of entrepreneurship education. In addition, the study addresses faculty members' perceptions of entrepreneurship education including the critical skills and concepts that should be taught. To address these questions, we developed a study to better understand the faculty and students who are engaged in engineering entrepreneurship teaching and learning. Entrepreneurship program directors were asked to identify program faculty who were teaching in spring 2012. Faculty completed a comprehensive questionnaire about their beliefs and practices regarding entrepreneurship education, focusing on a specific course they were teaching in the spring 2012 semester. They were also asked to invite their students in this course to complete a questionnaire that asked students about their prior entrepreneurship experiences, familiarity with technology entrepreneurship concepts, and attitudes towards entrepreneurship. In addition, students were asked to indicate entrepreneurship resources they had used on their campuses. This study will provide systematic data from a variety of institutions about faculty who teach entrepreneurship and the students they teach. We expect that this knowledge will provide an important baseline against which future improvements in the field can be identified and assessed.

Keywords— *entrepreneurship education; technology entrepreneurship; engineering education*

I. INTRODUCTION

While many case examples have been written describing specific courses and programs of study [e.g. 1], we know little about what faculty believe and how undergraduate engineers are taught entrepreneurship on an aggregate level. Likewise, we know little about the engineering students who enroll in entrepreneurship courses and programs. What are their prior experiences related to entrepreneurship and familiarity with key concepts of the technology based entrepreneurship? What

attitudes do they hold in the context of their majors and career aspirations? To address these gaps, we developed a study to better understand the faculty and students who are engaged in engineering entrepreneurship teaching and learning.

II. RESEARCH QUESTIONS

This project addresses four research questions:

- 1) What are students' reported familiarity with engineering entrepreneurship terms and concepts?
- 2) What are faculty members' perceptions of engineering entrepreneurship education?
- 3) What do instructors state are the critical skills and concepts that are taught in entrepreneurship courses?
- 4) Is there a relationship between faculty beliefs of entrepreneurship education and students' beliefs?

III. METHODS

A. Recruitment of faculty participants

In the spring of 2011, a review of course catalogs at 345 ASEE schools in the U.S. was conducted to identify entrepreneurship programs of study that were accessible to undergraduate engineering majors. Based on a cluster analysis, we identified engineering programs that focused their entrepreneurship programs around certain course attributes. The project team identified more than one hundred entrepreneurship programs that served undergraduate engineering students, 40 of which were administered solely or jointly by schools and colleges of engineering.

Program directors from these schools were contacted by NCIIA, and were asked to identify at least one faculty member who was teaching a product development or venture development in their entrepreneurship program. Interested program directors forwarded study information to the relevant faculty members. Faculty members were offered a stipend of \$500 to complete three research tasks: a) complete an online survey about their views of entrepreneurship education in engineering and about the content used in one of their entrepreneurship courses; b) administer an online survey to

students in that course about their entrepreneurship experiences and knowledge; c) provide details about entrepreneurship opportunities available to students at the institution. The faculty and student surveys are described further below. The estimated amount of time required of participants to complete the entire research study was two hours. Participating faculty members will also receive aggregated results of their student data with comparisons to peer programs, provided that the sample sizes for their particular course were high enough.

B. Student Survey

Faculty were asked to administer the Entrepreneurship Knowledge Inventory (EKI) to their students in the product development or venture development course they were teaching in spring 2012. The EKI is an inventory consisting of 103 items intended to measure students' familiarity with entrepreneurial terms in five areas: 1) Becoming and Being an Entrepreneur, 2) Finance and Accounting, 3) People and Human Resources, 4) Sales and Marketing, and 5) Product Ideation and Development. In each category, students were asked to rate their familiarity with a set of terms using a 5-point rating scale [2]. The anchors on the scale follow:

- None (Never Heard of it)
- Low (Heard of it but not sure what it means)
- Moderate (Can explain it partially)
- High (Can explain in depth but not sure how to apply it)
- Very High (Can explain in depth and can apply it)

As explained in Besterfield-Sacre, et al. (2012) [2], the instrument has been piloted with a large number of students. Significant differences in scores have been found between freshmen and senior engineering students. Participating faculty were encouraged to offer extra credit, but were not required.

C. Faculty Survey

Faculty were asked to complete an online survey consisting of two distinct parts. The first part, entitled the *Entrepreneurship Faculty Beliefs Survey*, was developed in fall of 2009. The survey was constructed based on the results of a qualitative study 26 faculty interviews at three large research universities. The results of the qualitative study are available in Hochstedt, Zappe, and Kisenwether (2010) [3] and Zappe, Hochstedt, and Kisenwether (2012) [4].

The survey is intended to address the following questions:

- How do instructors define entrepreneurial mindset, or the characteristics necessary to be an entrepreneur?
- Do instructors feel the mindset is innate? Or do they feel it can be developed with training?
- What teaching methods do instructors use to teach entrepreneurship to engineers?
- Is there a relationship between faculty beliefs and teaching methods?

The second part of the online instrument consisted of a faculty version of the EKI. The faculty survey included the

same items as the student version of the EKI but participants were asked to indicate the degree to which the terms were emphasized in their course. The rating scale was changed to the following anchors:

- None (Term is not used in the course)
- Low (Term is used in the course, but the students are not expected to understand it)
- Moderate (Term is used in the course and the students are expected to understand it partially)
- High (Term is used in the course and the students are expected to understand it in-depth)
- Very High (Term is used in the course and the students are expected to understand it in-depth and can apply it)

IV. DATA COLLECTION AND PROGRESS TO DATE

Data collection commenced in March 2012. Forty-six program directors were contacted. Of these, 17 faculty members were identified from 16 different colleges and universities; one school had more than one faculty member who participated. As of the end of April 2012, all participants had completed the faculty survey, and 16 had launched the student survey in their course. One faculty member surveyed two courses that fit the project criteria.

The survey officially closed at the end of May 2012 and was completed by 327 students. For three of the student courses, sample sizes were quite low, ranging from 2 to 8 student participants. For the remaining 11 courses, sample sizes ranged from 11 to 63.

ACKNOWLEDGMENT

The authors acknowledge the National Science Foundation grants: EEC-0835992 and DUE-0817394. The authors also would like to thank the program directors and participating faculty for their help with this study.

Work in Progress: A Pilot Project to Assess the Added Value of Engineering and Student Affairs Collaboration on Student Cognitive and Affective Development

Troy Place¹, Amanda Glick², Edmund Tsang³, Betsy Aller⁴, Laura Darrah⁵

Western Michigan University

^{1,2,4}Dept. of Industrial & Manufacturing Engineering, ³College of Engineering & Applied Sciences, ⁵Office of Residence Life

Abstract—This Work-In-Progress paper describes a pilot project at Western Michigan University to assess the added value of academic and student affairs collaboration on student cognitive and affective development. The academic performance in first-year science, technology, engineering and mathematics (STEM) courses as well as retention to STEM are used as measures of cognitive development, and the students' experience in co-curricular activities as captured in their written summaries is used as a measure of their affective development. While there is no statistically significant difference in individual course performance, first-year Engineering House (EH) students have a statistically significant higher GPA than non-EH in fall 2010, and they have a statistically significant higher fall-to-spring retention to engineering and applied sciences than non-EH students.

Keywords—cognitive and affective development, academic and student affairs collaboration

I. INTRODUCTION

At Western Michigan University (WMU), the College of Engineering and Applied Sciences (CEAS) and the Office and Residence Life (ORL) have increasingly worked together since 2006 to support student success. The collaboration between CEAS and Student Affairs (SA) has since been extended to other SA units, e.g., Career and Student Employment Services. At WMU, first-time first-year engineering and applied sciences students are placed in STEP (STEM Talent Expansion Program) cohorts during Summer Orientation where they are enrolled in the same 3-to-5 courses in the Fall semester and the same 2-to-4 courses in the Spring semester. Details on how the STEP cohorts are constructed for WMU-CEAS first-year students can be found elsewhere [1].

Many CEAS first-year students choose to live in the Engineering House (EH), a special-interest residence program created by ORL with significant CEAS input. In this Work-in-Progress paper, we will describe a pilot project to assess the added value of academic and student affairs collaboration by evaluating the cognitive and affective development of CEAS first-year students who live in the EH versus the non-EH CEAS first-year students. The research methodology and assessment measures will be described with some preliminary results.

II. THEORETICAL BASES FOR PILOT PROJECT

Writing in the journal *Change*, T.W. Banta and G. Kuh [2] argue that “improving the quality of the undergraduate experience at any institution is so complex and multifaceted that it demands cooperation by the two groups on campus that

spend the most time with students: faculty members and student affairs professionals.” Additional studies that have included the effects of involving student affairs in the affective development efforts of first-year engineering students have occurred at Arizona State University in the late 1990's and The University of Southern California in the late 2000's [3,4].

III. PILOT PROJECT DESIGN

A. Engineering House (EH) vs. Non-EH

First-year CEAS students' participation in the EH increased from 88 in Fall 2006 to 173 in Fall 2010. In Fall 2011, 163 first-year, 49 sophomore, 112 junior, and three (3) senior CEAS students lived in the EH. In addition, there were 406 CEAS students who lived in other residence halls in Fall 2011. Therefore, there are sufficient numbers of first-year students living in the EH and the non-EH to allow us to compare the cognitive and affective development of the two populations. Furthermore, average ACT math scores were used to determine that both groups had similar or equal academic preparation before choosing their living accommodations. The EH students have an average ACT math score of 25.37, while the non-EH students average a 25.21.

The distinguishing features between EH vs. non-EH include the following: (1) the Residence-hall Assistants (RA's) in the EH are CEAS students while RA's in the non-EH are not CEAS students. (2) RA programming in the EH has an engineering focus or theme, while RA programming in the non-EH does not have such focus or theme.

B. How EH and Non-EH Students are Tracked

Since 2005, all CEAS first-year students who are placed in STEP cohorts during summer orientation are tagged using their Western Identity Number (WIN). Each semester, the WMU Office of Student Academics and Institutional Research run a report that shows the academic performance of the students, their majors, as well as whether they return to CEAS or WMU. This allows the researchers to monitor the academic performance, track retention, and make comparisons between the STEP students and the non-STEP students. Beginning in 2010, as the number of students living in EH increases, the researchers made a request to Institutional Research to add a field indicating the place of residence. This allows the researchers to compare the academic performance and retention of the EH students with the non-EH students.

C. Measure of Cognitive Development

In this pilot project, performance in courses required in the CEAS curricula, as indicated in percent of students who successfully completed the course with a grade of C or better, is used as one measure of students' cognitive development. *Chi*-squared tests are performed with a significant level set at $\alpha < 0.05$. The courses monitored include mathematics (Algebra II, Pre-Calculus, Calculus I, and Calculus II, depending on the first-year students' MATH ACT score); General Chemistry I, University Physics I, Technical Communication, and Engineering Graphics. In addition, retention to the CEAS from Fall to Spring semester as well as second-year retention to CEAS are tracked and compared between the two student populations (EH vs. non EH), and between STEP students and historic baseline retention rates.

D. Measure of Affective Development

IME 1020, "Technical Communication," is a required course in the CEAS curricula. In IME 1020, students are given bonus points when they participate in out-of-class co-curricular activities and write a summary about their experience. Samples of 246 written summaries on the same 8 types of co-curricular activities are collected from the EH and the non-EH students.

A rubric based on Bloom's taxonomy in the cognitive and affective domains [5] has been previously developed by three authors of this WIP paper and later revised with the addition of three additional researchers to improve inter-rater reliability [6]. Figure 1 below illustrates the rubric used by two authors of this paper to holistically score the students' summaries to assess their cognitive and affective development.

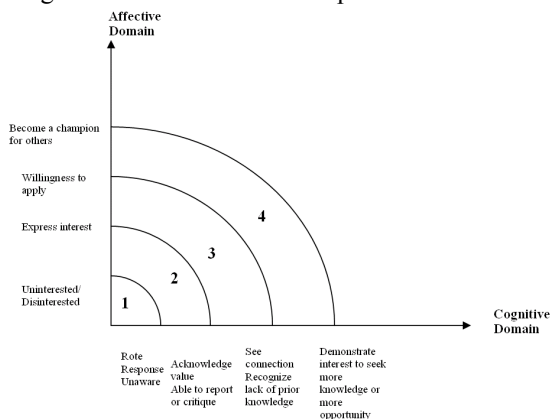

Figure 1. A 2-dimension evaluation rubric combining the Cognitive & Affective Domains

IV. SOME PRELIMINARY RESULTS

A. Cognitive Development

There is no statistically significant difference in the performance between EH students and non-EH students in individual courses in Fall 2010 and Spring 2011. However, first-year CEAS-EH students have a statistically significant mean Fall 2010 GPA (2.62) compared to first-year CEAS non-EH students (2.38). First-year EH students also have a statistically significant higher return rate to CEAS from Fall to

Spring semester than first-year non-EH students, but there is no statistically significant difference in the second year retention to CEAS. However, students in STEP cohorts have a significantly higher passing rate (course grade \geq C) than non-STEP students in Engineering Graphics, Pre-Calculus, and Calculus II.

B. Affective Development

A statistically significant difference is not apparent between EH and non-EH students in terms of where their written co-curricular responses registered on the rubric in Figure 1. The EH responses to activities categorized as cultural and hands-on averaged (by mean) a score of 2.03, whereas the non-EH students averaged a 2.41. For the activities categorized as social gatherings and student society meetings, the average scores are 2.69 (EH) and 2.41 (non-EH). EH students averaged a 2.33 on responses to activities categorized as academic lectures, and the non-EH students averaged a 2.26 on those activity types. Finally, EH responses to the Capstone Senior Design Project presentations averaged 2.11, and the non-EH responses to the same presentations averaged a score of 2.12.

V. FUTURE WORK

Statistical analysis of cognitive development indicators between EH and non-EH students will carry on at WMU, as will performance tracking of EH and non-EH students in individual courses to see if any trends arise. Differences in mean GPAs, Fall-to Spring return rates and retention will also be monitored, and any affective differences, based on Bloom's taxonomy in relation to co-curricular events, will be surveyed.

Engineering and Computer Science Community College Transfers and Native Freshmen Students:

Relationships Among Participation in Extra-Curricular and Co-Curricular Activities, Connecting to the University Campus, and Academic Success

Abstract— Research studies have shown the importance of the relationship between “a sense of belonging” and successfully adjusting to college life for undergraduate students. Few studies, however, have compared if native freshmen and transfer students connect to the campus in similar ways. The purpose of this study was to examine the relationships among participation in social and academic engagement activities, social integration, and academic success for students graduating with engineering or computer science Bachelor’s degrees at a large, public university. An additional area of interest was the role of undergraduate research experiences (UREs) in making friends on campus.

Using analysis of variance, 1,042 responses were analyzed from senior exit survey questions and cumulative GPA from student records. Students who reported higher levels of social integration on average had higher GPAs. Seven activities were found to be strongly associated with social integration for native freshmen, and three activities for transfer students. Three activities – organizations in their major, experiential learning, and intramural sports – were common to both groups. Surprisingly, given the cohort experience structure of UREs, no significant relationship was found for social integration in this study. This finding may be limited by the sample size or other factors such as self-selection bias.

Keywords- college adjustment; retention; persistence; academic success

I. BACKGROUND

This study was conducted at the University of Central Florida (UCF), a large, metropolitan university (Carnegie classification, RU/VH: Research Universities – very high research activity), and the second largest in the nation in terms of student enrollment. In 2005, the university established a higher education consortium in partnership with four of its area feeder community colleges. Through this agreement, the DirectConnect program was created which guarantees entry to the university for students who obtain an Associate of Arts (AA) or Associate of Science (AS) degree at one of these four community colleges.

Consortium transfer students at the university now represent 32% of new undergraduates in the College of Engineering & Computer Science (between 2002-2005, prior to DirectConnect, that percentage was 23%). Further analysis of
