The second group of eleven students was taking part in a third year residential school on operating systems and computer networking. The RAL activity in this example was largely software-based around Ubuntu 9.10, hosted on a virtual machine which can be accessed remotely. The activity includes a shell scripting exercise and control of a web-relay on the

local network. The main aim of this activity is to expose students to shell scripting and the control of a relay via a network connection without the need to install a Linux distribution on their own computers and to purchase the hardware.

Both activities required students to apply theory learned in academic courses to an instance of practice.

V. FINDINGS AND ANALYSIS

This section summarises the outcomes of the student focus groups. All participating students were normally studying by distance education and from different disciplines within engineering. This proved to be an advantage for this study as the students were well practised. This meant that the students were capable of discussing their perception of the QoE of both their general online studies from home and the specific experiments conducted on-campus during residential school. This included being able to report on the specific factors which had an effect on their perception of QoE and what this effect was.

A. Factors Impacting QoE for Routine Studies

The problems that students reported in relation to general online learning included:

- Inconsistent delivery of online courses,
- Disorganised learning environment,
- Learning tools not functioning properly,
- Lack of support from staff,
- Insufficient opportunities to interact with staff and students,
- Inflexible options for how students learn,
- Incomplete materials,
- Lack of pre-existing skills or knowledge.

Predominantly, these problems reflect issues with the design and delivery of courses in the online environment and, consequently, how students are able to engage with online study. This list indicates that participating students were conscious of and thoughtful about their own perceptions and experience of the learning environment, and that they understood how these problems affected the quality of their learning.

The focus groups showed that participants often understood such problems well enough that they could make practical suggestions for how they could be addressed. For example, they suggested lecturers could provide last year's recordings of lectures as a backup for when a recorded lecture was unavailable, or provide amendment pages to study guides to address gaps and errors in these materials, without the need to rewrite. Further, alongside these suggestions they could comment explicitly on how such improvements would reduce their frustration and make achieving their learning tasks easier. Significantly, these students showed remarkable awareness of the realities and difficulties of designing and delivering

teaching and learning, including the difficulties for time poor academic staff and equity issues for online versus on-campus students. These observations do not directly relate to the research question, but document the unintended outcomes of this study. This degree of awareness and concern also suggests that the picture of QoE which emerges from their accounts can be considered as thorough, thoughtful and detailed.

B. Factors Impacting QoE for the Test Experiments

In commenting on the specific RAL sessions in which QoS was intentionally varied, participating students showed equal awareness of the environment and their perceptions and experiences of the learning. In addition to the remarks above, the students made two specific comments in regards to the RAL experiments:

- Lag time in the system,
- Lack of feedback from the system.

Lag time relates to poor network performance or QoS; and resulted in increased frustration and difficulty of the task. Students "don't know if they have made an error or if the program is just not working." This sometimes prompted students to go back and check over their work. In both cases, the feedback the systems are able to provide is limited and the lack of feedback from the system makes mistakes or problems hard to identify and resolve.

This is particularly true for students that are not sure about the experiments. Students reported a reduced confidence in their knowledge of the task, and an increased level of frustration when dealing with problems. A reduced sense of achievability is associated with not being able to identify what a problem is, or how to solve it. In the RAL experiments, instances of poor QoS had a clear effect on how students experienced the task. However, despite increasing the difficulty and frustration involved, it also had the positive effect of prompting students to review their work and spend more time ensuring they had completed it correctly.

A more significant problem that students encountered in the experiment was that the design of the RAL activity gave them insufficient feedback on their progress, whether QoS was poor or not. If this was not an issue their overall frustration and difficulty may have been lower. In one instance in the water experiment, a student could not commence the activity because the system did not give him the information that the experiment was not prepared properly. He lost his scheduled session and had to simply try again another day. In a proximal experiment, the nature of the problem would be immediately evident as the student could do a visual check of the apparatus in order to identify what was wrong.

In discussing their problems with online learning and how they dealt with them, the participating students demonstrated a high degree of persistence and motivation. They discussed the enjoyment of learning in their chosen fields, despite the difficulties and frustrations they regularly encountered. Across the board, all reports were that they were time poor, with work and family obligations competing with the demands of study. It was in this light that the significance of the problems they were dealing with emerged. For every instance of frustration and

unnecessary time taken to complete a study task, it was their professional or personal life which was impacted. Ironically, participants implied that it was because of their jobs or family commitments that they had opted to study online, and that on-campus learning was not an option, despite being viewed as preferable.

In analysing the overall picture of students' comments on their experience, distinct categories of factors which make up QoE emerged. These are summarised in Table I. The factors are largely expected and supported by the literature. The interesting result is that only Frustration, Achievability, Flow and Extra Time are affected by poor performance; and only if there is an impact on the functionality of the online learning tool, the impact of QoS on Consistency and Quality of learning materials can be avoided.

TABLE I. FACTORS AFFECTING QoE FOR ONLINE LEARNING

| <i>Factors Affecting QoE for Online Learning</i> | <i>Relevance of QoS</i> |
|---|---|
| Satisfaction Level of satisfaction experienced upon completing the learning | Not relevant |
| Frustration Level of frustration experienced in completing the learning task | Relevant only if reduced functionality of tool/program due to reduced QoS disrupts the processes involved in the learning task |
| Achievability Sense of achievability of completing the learning task | Relevant only if reduced functionality of tool/program due to reduced QoS disrupts the student's ability to complete the learning task |
| Consistency Consistency of the overall learning environment (e.g. consistent provision, layout and design of tools, materials and activities) | Not relevant |
| Quality Quality of learning materials provided (e.g. clarity of recorded lectures, currency and relevance of study guides) | Not relevant |
| Flow Sense of flow when undertaking a learning task (e.g level of interruption to concentration on the task or process due to missing information, poor functionality of tools) | Relevant only if reduced functionality of tool/program due to reduced QoS significantly interrupts the sense of flow of the learning task |
| Extra Time The amount of time over and above what would required for achieving the relevant learning goal or completing the task if learning was not online (e.g. face to face/on-campus, or in print mode) | Relevant if functionality of the tool or learning environment is affected by poor QoS |

For example students reported being frustrated while undertaking activities with low QoS; however, they also reported that this did not impact on the level of satisfaction they felt once the activity was successfully completed. Students in the study also reported that the factors with a positive influence on QoE included a sense of satisfaction from completing a task and the perception that a task was going to be achievable. Detracting from QoE were a variety of problems, primarily deriving from the design or delivery of the online courses, including the quality of tools and materials used for learning. These problems include lack of consistency in how tools are designed and provided, inadequate functionality of tools for the task at hand, lack of support at the times students need it and poor quality and irregular provision of course materials or resources. Poor QoS was only reported as significant in relation to these wider problems or where wider problems were present. Students reported that experiencing any or all of these issues increased the time it took them to complete a task, the level of frustration they experienced during learning, and interrupted their preferred learning processes. Where these problems occurred concurrently, the quality of the students' learning experience was extremely low. Although QoS was sometimes mentioned in reference to these wider issues, in speaking about the factors associated with QoE, students were much more concerned with the design and delivery issues associated with their online coursework.

VI. DISCUSSIONS

These findings suggest that QoS only acts as an intermediary factor between quality of design and delivery of the course and the students' QoE. Given this and the students' overwhelming awareness and concern with the factors which impact design and delivery, pursuing a better QoS in online environments is not likely to have a significant effect on optimizing online learning. The fundamental design and delivery of a course, and students' characteristics and learning processes are much more significant in determining what goes on in the learning environment, how it is experienced, and the outcomes that result. The amount of feedback the students received from the system is also crucial as it allows students to assess their progress. The participants in this study were notably persistent and motivated in pursuing their online learning. They were all relatively competent and confident in using ICTs and operating in the online environment. They were also all studying within the field of Engineering. However, these characteristics are expected to amplify rather than detract from the findings of the project. This is because this cohort's persistence and ingenuity in pursuing solutions and the thought that they gave to understanding their experiences revealed more about the online learning environment than if they had displayed a tendency to simply give up in the face of difficulty. It is reasonable to expect that a different cohort of students, studying in different courses and disciplines would present an entirely different set of learner characteristics and learning processes. However, the problems they would be likely to encounter in the online learning environment may very well be similar or the same, deriving from the same causes. This supposition is borne out by much of the available literature on best-practice in course design, pedagogy and online learning. For example, it is known from an abundance of studies that

online learning is optimal when it is interactive, supported and collaborative. It is also well known in general learning theory that making learning more flexible is a reliable means of improving learning outcomes. The assertions made here would be testable in further studies into design and delivery and QoE for online learning.

VII. IMPLICATIONS AND FURTHER WORK

The observations in the study allow for broader conclusions about the importance of QoS to the QoE of learners. The main results of this study suggest that QoE of well designed online courses is only degraded if bad QoS means that the learning activity is no longer usable. This indicates that a QoS threshold exist which is also supported by [15]. If QoS is above the threshold, the QoE is good for well designed and supported activities, if it is below the threshold the learning activity is no longer possible and this impacts on the learning experience. For badly designed learning activities, QoE will be low, independent of QoS. As long as a learning activity is readily usable, improving QoS has little impact on the QoE. For these reasons great attention should be paid to the quality of design and delivery of online learning tools and courses. To achieve high QoE, well integrated and scaffold learning experiences are more important than high QoS, e.g. fast Internet access. Specific aspects of these assertions can be tested in future studies. The natural step to continue this work is to move from assessing the perception of students of the learning experience to assessing learning itself. This is an interesting, but difficult investigation. Assessing learning on a large scale while adjusting QoS is problematic. Another direction for future work is to research how the perception of QoE itself influences learning.

The study also led to the unintended positive insight that students can be an important source to improve course design and delivery. This opens up an interesting new research direction: Much has been written about student evaluations, but very limited work exists that has explored students as a source of pedagogic knowledge and the use of student expertise to improves learning and teaching.

VIII. CONCLUSIONS

This paper has discussed the relationship of QoS and QoE in the context of online learning and was able to address the research question of which dimensions of QoE are affected by QoS? Students reported that the factors with a positive influence on the quality of the learning experience included a sense of satisfaction from completing a task and the perception that a task was going to be achievable. Detracting from QoE were a variety of problems created by the learning environment; the online tools, materials themselves or the online course design. QoS was only reported as an issue where these problems were also present. If these problems increased the time required to complete a task, the level of frustration experienced during learning, and interruptions the students' preferred learning processes were evident. Where these problems occurred concurrently, the quality of the students' learning experience was extremely low. These findings suggest that the influence of QoS is less significant than course design and pedagogical concerns in determining QoE in online

learning. This is significant since online learning is often regarded as a means to providing more equitable opportunities for learners that do not have the option of undertaking study in face-to-face modes. Despite this, the project found a number of circumstances in which online students were specifically and significantly disadvantaged compared to on-campus students, for example in opportunities for discussion with peers and teachers, and in accessing incidental and extra materials and information from course staff.

ACKNOWLEDGEMENT

This work has been funded by a USQ Senior Learning and Teaching Fellowship. The authors would like to thank Lesley Jolly and Hannah Jolly, Strategic Partnerships, for their assistance with the evaluation of quality of student experience aspects in this study. The authors would like to thank the anonymous reviewers for their excellent constructive feedback.

Quantifying learning from web-based course materials using different pre and post tests

Paul S. Steif

Pittsburgh, PA

Anna Dollár
Miami University,
Oxford, OH, USA

Abstract - Engineering instructors seek to gauge the effectiveness of their instruction. One gauge has been to use standardized tests, such as concept inventories and to quantify learning as the change in score over the semester. Here we question whether that approach is always the best practice for gauging the effect of instruction, and we propose an alternative of administering different tests at the start and end of the semester. In particular, to gauge the influence of one aspect of instruction, the use of interactive web-based course materials that had been developed for Statics, we administered the Force Concept Inventory at the start of the course, and the Statics Concept Inventory at the end of the course. Correlations and then linear regression were applied to study how conceptual knowledge measured at the end of the course depended on conceptual knowledge measured at the start and the amount of use of the web-based courseware. Usage of the web-based courseware was found to promote conceptual knowledge at the end of the course in a statistically significant way only after accounting for initial knowledge as judged by the different conceptual test administered at the start of the course. Thus, it is not necessary to measure gain on one test; instead each test should capture well the variation in relevant ability across students at the time the test is administered.

Keywords-web-based courseware, concept inventory, interactive learning, pre-post tests, measures of knowledge, Statics

I. INTRODUCTION

Standardized tests of conceptual knowledge, such as concept inventories are of increasing interest nationally [1], and they have been used as benchmarks to gauge the effects of instruction [2, 3]. Concept inventories were inspired by the Force Concept Inventory [4], which is sometimes used in Physics courses. The most common approach to gauging effectiveness of instruction has been to administer the test at the start of a course (pre), and near its completion (post). Learning is taken to correspond to the gain, or increase in the test score (post-pre). In addition to this raw gain, Hake [5] has popularized the use of normalized gain: increase in score normalized by maximum possible increase in score. Either way, gain on the same test has been often embraced as a means of quantifying learning, with different instructional approaches being the experimental variable to be tested.

Of course, when using any test at the start of a course we are presuming that it captures meaningful variation in the initial, relevant knowledge of students. In this paper, we

consider whether using the same test as both the pretest and posttest is necessarily sensible.

II. BACKGROUND

The Force Concept Inventory (FCI) is multiple-choice test used by some instructors in physics courses to gauge the degree to which students have embraced a Newtonian viewpoint regarding forces and acceleration. While there is some dispute as to the validity of this test with respect to the meaning of scores on individual questions or groups of questions [6, 7, 8], the total score on the FCI remains a readily quantifiable measure of conceptual knowledge of Newton's laws. The FCI has been used as both the pretest and posttest for quantifying learning gain in introductory physics courses [5].

The Statics Concept Inventory (SCI), also termed CATS – Concept Assessment Test for Statics, is one of a number of concept inventories that were developed in recent years [9], following the Force Concept Inventory as a model. Psychometric studies of the SCI [9,10,11] enable one to argue in favor of its validity as a measure of conceptual knowledge of statics in students near the end of, or after, a statics course. In particular, across a wide range of institutions, it is generally found that the SCI correlates reasonably well with scores on the final examination of the local institution.

While the SCI effectively captures important aspects of students' statics conceptual knowledge at the end of a statics course, this does not imply that the SCI is the best measure of relevant incoming knowledge, especially when one's goal is to assess the effectiveness of instruction. In fact, one expects most students to have had little prior experience with statics before an introductory statics course. Indeed, it has been demonstrated [11] that SCI scores for students who have not studied statics previously, are roughly consistent with random guessing. That is, mean scores are typically on the order of 1/5 or 20% (each question has 5 answer choices). Moreover, for one class of 130 students, which was studied in detail, the actual distribution of scores on the pretest was consistent with a binomial distribution, corresponding to random selection of one of five answers on a 27-item test.

Instead, as a pretest one should use a test that better captures the variation in students' incoming abilities. Prerequisites for engineering statics courses nearly always include physics, as well as some level of mathematics. Given

the subject matter of statics, forces and equilibrium, it would appear that Newtonian mechanics is the prime scientific background to statics. Thus, the Force Concept Inventory, while it also tests aspects of motion that are not central to statics, provides a plausible measure of initial relevant knowledge for students entering a statics course. The investigation now described explores a two-test approach that is likely to be useful in many circumstances. We demonstrate the approach with a statics course for which we quantify the effect of varying usage of web-based statics exercises; the Force Concept Inventory serves as the pretest and the Statics Concept Inventory serves as the posttest.

III. METHODOLOGY

A. Participants and Data Collection

Participants included students in the mechanical engineering statics course at Carnegie Mellon University in fall 2011. The total class consisted of 150 students. As a pretest, just prior to the start of the course, students took on-line the Force Concept Inventory. As a posttest, just before the end of the course, students took on-line the Statics Concept Inventory. Students received a small amount of credit for completing each conceptual test, but, as was made clear to them, the actual scores did not count towards their course grade. In this study, the variable *FCI*, which is the fractional score on the FCI pretest, is the measure of initial knowledge. The variable *SCI*, which is the fractional score on the SCI posttest, is the measure of final knowledge. The semester-long course included 3 hours of lecture and one hour of recitation per week. Besides some written homework, students were required to use a web-based statics course [12]. The implementation of these materials utilizing an inverted classroom format was described in [13]. This instructional intervention is described next, together with the variable used in this study to quantify the amount instruction received by each student.

B. Instructional Intervention: Web-based Engineering Statics Course

The web-based OLI Engineering Statics course, described in more detail elsewhere [12, 13, 14], is freely available to individual learners and institutions, and consists of twenty modules, akin to chapters [15]. Each module is composed of several pages, each devoted to a single learning objective. Concepts are explained using not only text and graphics, which are typical of textbooks, but also through simulations. In developing the course, problem solving tasks, particular complex ones, have been carefully dissected analyzed. The resulting procedural steps are presented, first with worked-out examples and then often with "Walkthroughs", which combine voice explanation with evolving graphics. Students themselves engage in problem solving through interactive exercises in which they can practice the new skills and concepts as they receive detailed hints and feedback. Wrong answers provoke feedback that may be generic ("That's not right"), or specific feedback for each incorrect answer if a diagnosis of the mistake can be made. The hints are often provided in succession: the first hint reminds the student of the relevant underlying idea or principle, the second hint might link the problem at hand to the

general idea, and a final hint might explain how to get the answer. At the conclusion of each learning objective, students are offered brief summary and final exercises to further assess their learning and determine whether further study of the material is warranted. For students who use OLI as part of an instructor-led course, there is a quiz at the end of each module, which can be graded. Student work on hundreds of exercises are recorded and analyzed to provide overall and detailed feedback to the instructor, who can then track individual students and the class as a whole.

It is important to explain how OLI was assigned in the particular class context, how it was weighed, and hence the motivation of students to use the materials. All of students' work, aside from performance on examinations, account for only 5% of the final grade. Of that 5%, 2.5% consists of written homework, and 2.5% consists of (2/3) OLI end-of-module quiz scores and (1/3) writing a brief explanation of what they found difficult in a module. It was made clear to students that the interactive learning activities within a module before the quiz, which constitute the vast majority of activities, are there for students to learn the material to prepare for the OLI quizzes and the class exams. But, the number of the pre-quiz activities undertaken, and their performance on them, contributed nothing directly to students' grades. Thus, students regulate their usage of OLI materials, choosing which of the activities to undertake, solely with the goal of learning the material, not fulfilling an assignment.

The variable *Activities* captures the fraction of all recordable interactive activities which a student initiated. For the purpose of the present analysis, we take *Activities* to be the amount of instruction received.

C. Analysis

The analysis addressed the relationships among the three variables: *FCI* (initial knowledge), *Activities* (instruction), and *SCI* (final knowledge). In particular, we studied correlations between final knowledge and the two input variables, initial knowledge and instruction. In addition, linear regression was carried out to determine if final knowledge could be modeled as a linear function of the instruction alone, and then as a linear function of both initial knowledge and instruction.

IV. RESULTS

A. Basic Statistics

A histogram of *FCI*, the measure of initial knowledge, is shown in Figure 1 (mean = .76 and SD = .14).

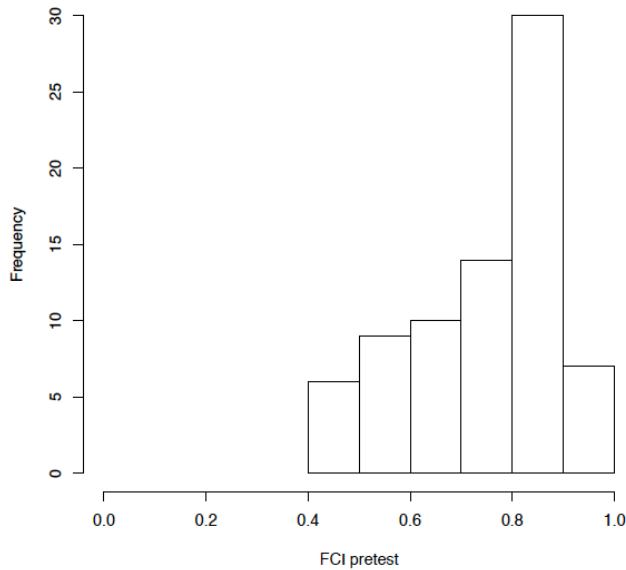

Figure 1. Histogram of Force Concept Inventory pretest scores.

The FCI consists of 30 questions, each having 5 answer choices. Hence, random guessing one of the five answers for each question would provide a mean of 0.2. Not surprisingly, these observed FCI pretest scores are significantly different from random guessing (i.e., significantly higher).

A histogram of *Activities*, the measure of instruction, is shown in Figure 2 (mean = .68 and SD = .20). Recall that students receive no direct credit for the majority of these activities, (only the indirect benefit of learning the material and then performing better on subsequent quizzes and exams). Hence, it is not surprising to see a wide variation in *Activities*.

A histogram of the *SCI*, the measure of final knowledge, is shown in Figure 3 (mean = .69 and SD = .18). Note that conceptual knowledge, as *SCI* seeks to measure, is only one component, although an important one, of all the knowledge and skills that a statics course, and the OLI web-based course in particular, seeks to impart.

Pearson correlations between *SCI* and *FCI* and between *SCI* and *Activities*, respectively, are shown in Table 3. While the correlation between *SCI* and *FCI* is significant, that between *SCI* and % *Activities* is barely significant. The significant correlation between *SCI* and *FCI* suggests that students' conceptual physics knowledge at the beginning of a statics course is predictive of their conceptual statics knowledge at the end of that course, consistent with the expectation proposed in the previous section. The relationship between *SCI* and *Activities* indicates that engagement in the online activities is predictive of their conceptual statics knowledge at the end of that course. However, this is a much weaker correlation that leaves plenty of room for improvement, as explored in the next section.

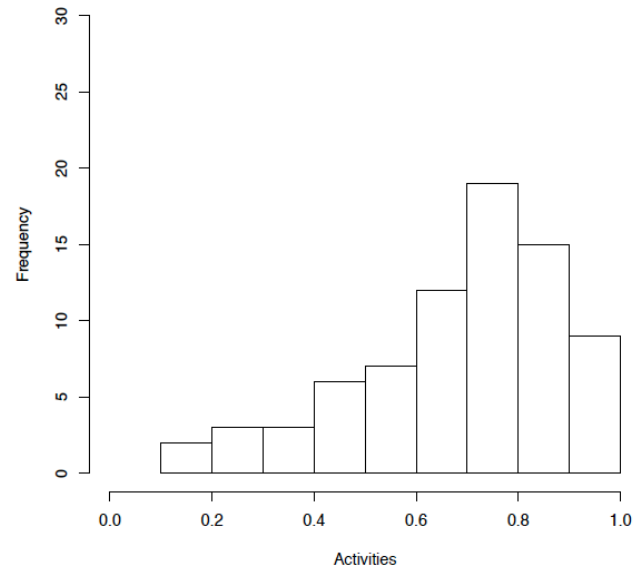

Figure 2. Histogram of fraction of activities undertaken in web-based statics course.

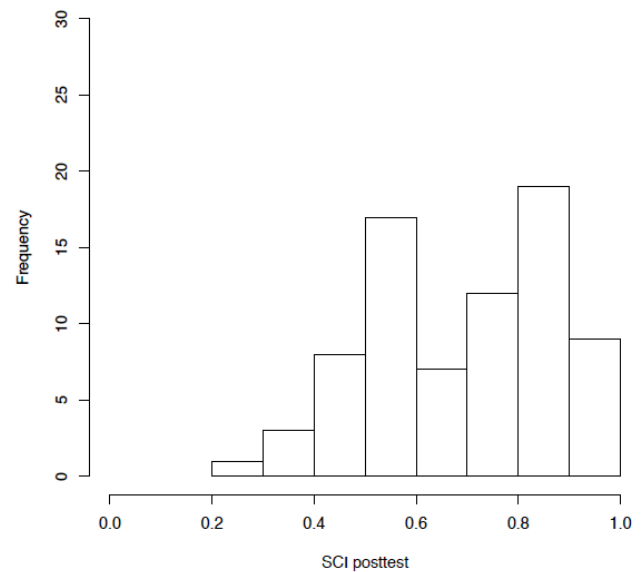

Figure 3. Histogram of Statics Concept Inventory posttest scores.

TABLE I. CORRELATIONS BETWEEN FINAL KNOWLEDGE (POSTTEST SCI) AND INITIAL KNOWLEDGE (PRETEST FCI) AND INSTRUCTION (PERCENT ACTIVITIES COMPLETED)

| <i>SCI vs. FCI</i> | | <i>SCI vs. Activities</i> | |
|------------------------|-------------------------|---------------------------|-------------------------|
| <i>Correlation (r)</i> | <i>Significance (p)</i> | <i>Correlation (r)</i> | <i>Significance (p)</i> |
| 0.38 | .0008 | 0.22 | 0.0506 |

B. Statistical Models of Dependence of Final Knowledge on Instruction

As our baseline regression model, we consider how well SCI scores are predicted if instruction, *Activities*, is the only variable; that is, if we had no useful measure of initial knowledge. The best-fit linear relation between these variables is found to be:

$$SCI = .55 + .21 \text{ Activities}$$

We find that this one-variable model captures only 5.1% of the statistical variation in SCI posttest scores, and the model is just barely statistically significant: for the coefficient of *Activities*, $t(74) = 1.99$, $p = .05$. This essentially repeats the earlier finding of a weak correlation between *SCI* and *Activities*.

Consider now a more complex model, in which *SCI* depends linearly on both *FCI* and *Activities*. In particular stepwise regression was used to include *FCI* in the model after including *Activities*. The resulting fit is of the form:

$$SCI = .07 + .29 \text{ Activities} + .56 \text{ FCI}$$

The fit of this two-variable model can be compared to that of the simpler model. First, the two-variable model captures 23.4% of the statistical variation in the data. Note the marked increase relative to the 5.1% variation captured by the one variable model. Second, the coefficients for *Activities* ($t(73) = 2.95$, $p < .01$) and for *FCI* ($t(73) = 4.17$, $p < .001$) are both much more significant statistically than with the .05 level, which found for the one-variable model based on *Activities* alone.

Thus, the two-variable model (*FCI* and *Activities* predicting *SCI*) is superior to the one-variable model in which initial knowledge is neglected (*Activities* alone predicting *SCI*). Moreover, the two-variable model also reveals a somewhat greater benefit to engaging in OLI activities than the one variable model (compare coefficients 0.29 and 0.21). While the *SCI* was not administered as a pretest, based on previous findings that it corresponds essentially to random guessing, one expects its inclusion as a variable would have provided little improvement over the one variable model, which accounted for only instruction.

V. SUMMARY AND CONCLUSIONS

Because scores on the Statics Concept Inventory at the start of statics correspond to random guessing, we argue that it is unlikely to be a useful measure of relevant knowledge at the start of statics. For the purpose of measuring the effect of instruction, we have instead used the Force Concept Inventory administered as a pretest to be the measure of initial knowledge. The posttest measure of knowledge was the Statics Concept Inventory. Based on statistical models we found that the instruction of interest, usage of a web-based statics course, had a beneficial effect, but that the effect became stronger and more significant statistically only after accounting for the initial knowledge in the form of *FCI* pretest scores. Ongoing efforts are devoted to identifying more clearly the sources of instructional benefit in using the web-based course.

The methodology applied here can be extended beyond the specific context. Many instructors seek to improve statics instruction and test the effects of aspects of the classroom context. The Force Concept Inventory, we propose, may provide a useful way of identifying the effect of initial knowledge. The particular statistical analysis of using a linear regression with two input variables is suitable when one can track a continuously varying amount of instruction, while alternative methods would be applied in other circumstances.

More broadly, with concept inventories being developed for other subjects, we need not necessarily use the same test for both the pretest and posttest. Instead, we should use tests that effectively reveal variation in students' relevant knowledge at the beginning and end of the course. As we have shown, scores on the two distinct tests can be used, with appropriate statistical methods, to weight the effectiveness of instruction.

ACKNOWLEDGMENT

The authors thank Bobbi Kostyak for her assistance in organizing some of the data. Additional support by the Department of Mechanical Engineering and by the Eberly Center at Carnegie Mellon University, and by the Mechanical and Manufacturing Engineering Department at Miami University is gratefully acknowledged.

Abstract— Nowadays, many web content editors allow teachers to create web content as learning objects; however, most of these editors do not generate accessible web content. In many cases, the generated web content is not in accordance to the Web Content Accessibility Guidelines (WCAG). As a result, teachers and students with disabilities, e.g. people with visual impairment, people with hearing impairment, among others, could not properly use the web content in their learning or teaching processes. Moreover, some automatic tools for accessibility evaluation do not evaluate the web content using all the criteria from the guidelines; the rest are usually evaluated by humans (manual evaluation). In this paper, we introduce a tool to support accessibility evaluation in the generated web content when teachers use the TinyMCE web content editor. In this manner, we help them to identify web accessibility failures that can be improved. We also introduce a new approach for the web content accessibility manual evaluation process by applying the Case Based Reasoning technique. This work has been developed in the context of the European funded ALTER-NATIVA Project.

Keywords—component; Web Content Accessibility; Manual Evaluation; Automatic Evaluation; WCAG 2.0; Case Based Reasoning;

I. INTRODUCTION

Web content accessibility has been a topic of research for organizations interested on increasing the access for all people to web environments with special attention to their personal needs and preferences. As a main contributor of guidelines in order to make the web content more accessible, the World Wide Web Consortium [1] (W3C) published the Web Content Accessibility Guidelines (WCAG) and the most recent version is the WCAG 2.0 [2]. The WCAG 2.0 are used when the accessibility in a web page or a set of web pages have to be evaluated. According to the WAI (Web Accessibility Initiative), the recommendation is to use both automatic and manual evaluation [3] considering that even in an automatic evaluation some tools can omit data or show incorrect information.

In the manual evaluation, both the experts' opinion and the obtained results from using extra aids such as web browser plug-ins, color contrast analyzers, screen magnifiers and other additional tools are considered. Current tools for supporting manual evaluations of web content accessibility are useful for

the experts, because these tools allow them to detect problems that automatic validators do not.

The widespread use of educational environments through the web requires accessible web contents and, each time, teachers use more tools to generate those contents. However, teachers are not always familiarized with web accessibility. To overcome this situation and to generate accessible web content, aid from experts can be used in the web content accessibility evaluation process.

Taking into account the above context, we applied the Case Based Reasoning (CBR), which is a technique from Artificial Intelligence, that allow us to match the experience from experts who know about accessibility in web contents (using the success criteria of WCAG 2.0) with the design of educational web content. For instance, when a teacher designs their web pages in the TinyMCE web content editor [4], he/she needs an extra aid to know about how to do each element in web pages more accessible. The CBR has been applied in a wide variety of software applications in different fields such as games [5], health [6] [7], mathematics [8], theoretical research [9], economy [10], technology [11] [12], among others. An approximation in the application of CBR in web accessibility context is T-Orienta [13], which uses an Artificial Intelligence engine "to match the needs detected for each user with a set of recommendations about software and Assistive Technology devices" [14]. After reviewing literature of CBR applications, we do not have clear evidence that the CBR had been used in the domain of web content accessibility evaluation process.

One of the most important questions we need to answer in order to provide an additional support in web accessibility content evaluations is the following: How can the CBR technique support the web content accessibility evaluation process? To answer the question, in this paper a new approach in the evaluation of web content accessibility process is introduced. The abovementioned approach is supported by a web environment that uses the AChecker [15] validator as an automatic evaluation tool, the CBR-based component developed as an extra aid to manual evaluation (using the jCOLIBRI CBR framework [16]) and the TinyMCE [4] as the web content editor.

This document is structured as follows: section II describes concepts about web content accessibility; section III shows a

general description of the CBR technique and its cycle applied to the web content accessibility evaluation process; in section IV, a detailed description of the architecture for our CBR-based component is introduced; in section V, the implementation of the CBR-based component is depicted; section VI describes the workflow of the CBR-based component; section VII shows the context of ALTER-NATIVA [17] project and the main user requirements are identified; finally, in section VIII, some conclusions and future work are presented.

II. WEB CONTENT ACCESSIBILITY

A. What is the Web Content Accessibility Evaluation?

The web content accessibility evaluation can be described as the process in which experts (with different expertise levels) verify and determine if a web site meets several standards and guidelines [2]. There are case studies that show how the web accessibility evaluation process is applied. For instance, in [18], a set of web pages are analyzed by people who are learning about WCAG 2.0, i.e. beginners. In [19], the web accessibility of a set of web pages is evaluated by experts in WCAG 2.0. In both examples there is an agreement: a web content accessibility evaluation process has two ways of evaluation, a manual evaluation and automatic evaluation. In the manual evaluation, experts or beginners use different strategies to evaluate the web content accessibility. On the other hand, the automatic evaluation is supported by software that analyzes the HTML (HyperText Markup Language) on the web pages and delivers reports according to several characteristics selected by the user.

B. Reasons to evaluate the web accessibility

According to the WAI, the Web is a space that allows people to perform different activities in different fields, e.g. education, commerce, health, among others. When the web provides elements and alternatives to people with disabilities, they can easily develop those activities. For that reason, some benefits obtained from accessible web content are highlighted, e.g. to provide equal access and equal opportunity for all people [20]. Another benefit is when “the Web offers the possibility of unprecedented access to information and interaction for many people with disabilities. That is, the accessibility barriers to print, audio, and visual media can be much more easily overcome through Web technologies” [20].

C. WCAG 2.0

Web Content Accessibility Guidelines 2.0 or WCAG 2.0 is a W3C recommendation from 2008, and “covers a wide range of recommendations for making Web content more accessible” [2]. These guidelines have four layers of guidance:

- Principles: perceivable, operable, understandable and robust.
- Guidelines: “the 12 guidelines provide the basic goals that authors should work toward in order to make content more accessible to users with different disabilities.” [2]

- Success criteria: represented by three levels of conformance A, AA, and AAA being A the lowest level.
- Sufficient and Advisory Techniques: techniques that “go beyond what is required by the individual success criteria” [2] and “address accessibility barriers that are not covered by the testable success criteria,” [2] respectively.

D. Automatic Validators of WCAG 2.0

There are a set of automatic validators for web content accessibility evaluation that works under the WCAG 2.0 recommendation. In Table I, some of them are listed and analyzed. We compare the validators by asking if they are: a) online services b) standalone applications c) free tools and d) open source tools, and also if the validators allow: e) online demonstrations and f) file uploads to test local web pages.

TABLE I. ACCESSIBILITY VALIDATORS COMPARATIVE

| Validator | Comparative attributes | | | | | |
|---------------------|------------------------|-------------|------|-------------|-------------|-------------|
| | Online | Stand-alone | Free | Open Source | Online Demo | File upload |
| AChecker | X | | X | X | | X |
| TAW | X | | X | | X | X |
| eXaminator | X | | X | | | |
| TotalValidator tool | | X | X | | | X |
| SortSite | X | X | | | X | X |

According to the previous analysis, we decided to work with the AChecker validator because this service is available online, and both free and open source; besides, the AChecker validator can be integrated within the TinyMCE web content editor.

III. CASE BASED REASONING AND WEB CONTENT ACCESSIBILITY EVALUATION

Case Based Reasoning (CBR) is an Artificial Intelligence (AI) technique to solve problems using the knowledge of previous experiences or cases [8]. In the CBR, there is a cycle known as four R or R4 [21] because the process involved on the CBR can be represented as a cycle of four stages and R is the first letter in the name of each stage: Retrieve, Reuse, Review and Retain. The CBR cycle is detailed in the next subsection.

A. Web Accessibility and the CBR Cycle

In the CBR technique new problems represent new cases to be solved by using similar problems that have been previously solved [11] [22] [23]. This process involves four stages: retrieve, reuse, review and retain, as shown in Fig. 1. In the retrieve stage, a new problem (failure with some success criteria according to WCAG 2.0) is given, and a similar case or a set of similar cases are retrieved from the library case in which all solved cases are stored. Then, in the reuse stage,

these cases are selected to reuse the relevant information and knowledge for solving the problem. In the review stage, the reused cases are analyzed to decide if an adaptation is needed

to solve the new case. Once the new solution is given, in the retain stage, the case and its solution are stored in the library case as a learned case.

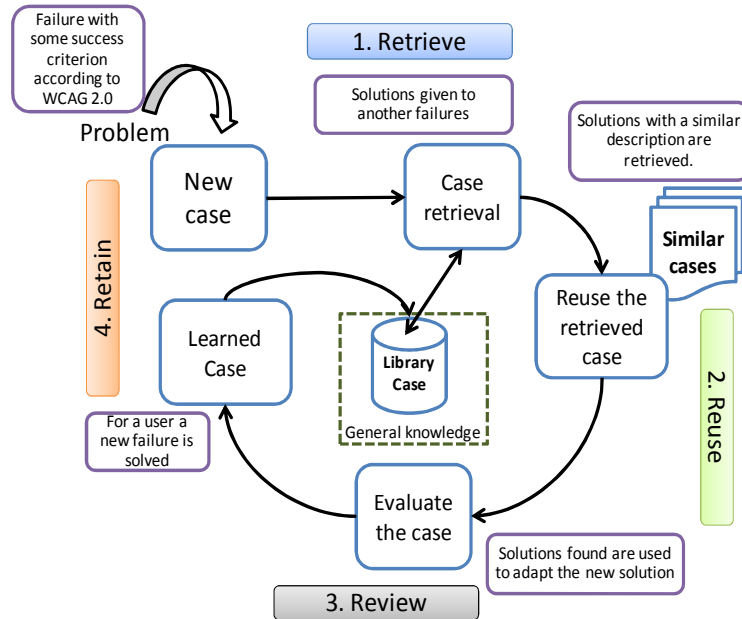

Figure 1. Process of Web content accessibility and the CBR cycle

In this work, we choose the CBR technique because it allows us to use the experiences of experts in web accessibility evaluation, which are stored as cases, for supporting the teachers in creating accessible web content. This process permits us to identify specific problems in web content accessibility, as well as the solutions given by experts for those problems.

B. Case Description

In the CBR, the cases can be described using attributes. All the cases in our work are described by a set of attributes used to find similarities between a new case and the stored cases. In this work, those attributes are defined in Table II.

TABLE II. CASE DESCRIPTION

| Attribute | Description |
|-----------------------|---|
| Case identifier | The unique identification number for each case. |
| Content type | The web content type of the web page. |
| Guideline | The guideline of the WCAG 2.0 according to the Content type. |
| Criterion | The success criterion according to the selected guideline. |
| Verification strategy | The strategy used by experts to identify failures in the web content. |
| Solution | The proposed solution for the found failure. |

One of the most important uses of the case description is the analysis of each case in the case retrieval stage in the CBR cycle. To retrieve a case, we developed a CBR-based

component (depicted in section V), which has to analyze each attribute in the stored cases in order to get the most similar cases to the new identified case.

IV. ARCHITECTURE FOR CBR-BASED COMPONENT

In this section, we describe the architecture that allows us to integrate the CBR-based component into an editing environment of accessible web content.

The architecture that supports the CBR-based component has four layers, as shown in Fig. 2. These layers are: users layer, interface layer, services layer and data access layer. In the next subsections those layers are described.

A. Users Layer

This layer is represented by two kinds of users. One type of user is the web page creator (in this work, teachers of ALTER-NATIVA project), who creates and edits web pages; the other type of user is the web content accessibility human validator (expert), who must have knowledge about web accessibility and, in particular, about the WCAG 2.0. Experts are responsible for reviewing web pages, identifying failures in web accessibility and providing comprehensible solutions for teachers.

B. Interface layer

In this layer, we consider two basic components, the user interface of the TinyMCE web content editor and the manual review of web content accessibility (manual evaluation). The last one represents the process that experts follow in order to find failures in web accessibility content and to recommend solutions to those failures.

C. Services layer

This layer represents the backend interface in which some services are used by the interface layer. Here, the CBR-based component, the AChecker validator, and the HTML structure of the web pages are represented.

D. Data access layer

The main goal of this layer is to store the HTML structure of web pages and cases generated from the CBR-based component. In our architecture, we have two storage systems. In the first one, corresponding to the repository, the web pages are stored as HTML objects; in the second one, corresponding to the database, the library cases of our CBR-based component are stored.

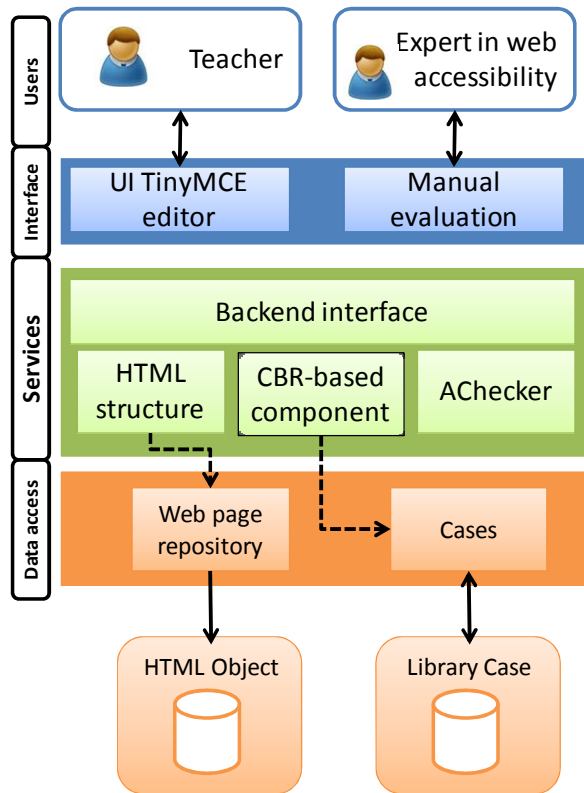

Figure 2. Architecture for CBR-based Component

V. IMPLEMENTATION OF THE CBR-BASED COMPONENT

In order to develop the CBR-based component we use the jCOLIBRI [16] framework. This framework was developed by the GAIA [24] group from the Universidad Complutense de Madrid. In Fig. 3, a screenshot of the software that supports the framework is shown. A class in the framework is implemented by using three main methods: PreCycle, Cycle and PostCycle. In the PreCycle method, the component and its connection to the library case is configured, in the Cycle method, each stage of the CBR cycle is performed and in the PostCycle method connections are closed.

Taking into account the CBR cycle, to retrieve the most similar cases in the retrieval stage, jCOLIBRI uses methods.

One of the most important retrieval methods is the Nearest Neighbour scoring (NNretrieval). This method “uses global similarity functions to compare compound attributes and local similarity functions in order to compare simple attributes” [16]. In fact, we decided to work with the NNretrieval function because, as explained in [5], each attribute is represented by a measure that allows us to sort the retrieved cases from the most similar case to the least similar case.

To integrate the CBR-based component and the TinyMCE editor, we developed two modules:

- The first module was modeled as a dynamic web application, which uses the jCOLIBRI framework. This application is connected with a library case (in a Postresql [25] database) where the expert’s experience about the failures in web content accessibility is stored. This module also supports the core services of the CBR-based component.
- The second module is a plug-in for the TinyMCE web editor developed in Javascript language, in which teachers can search for solutions about their web accessibility doubts, mainly when they need to know how to solve an accessibility problem in the web content they are editing.

Both of these modules were connected using the DWR (Direct Web Remoting) [26], a bridge to communicate the Javascript interface of the plug-in with the CBR-based component.

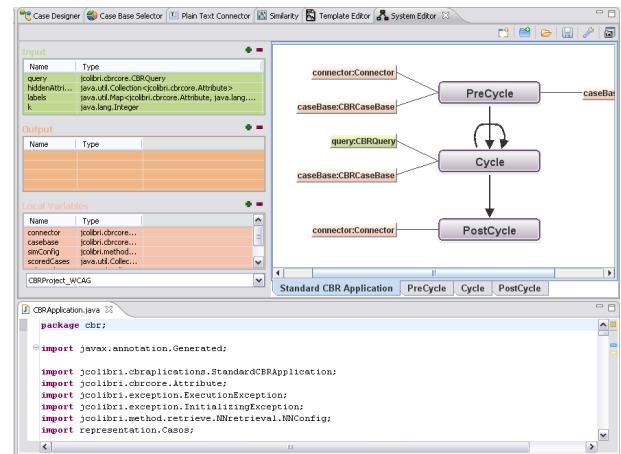

Figure 3. CBR-based component configuration at jCOLIBRI interface

VI. WORKFLOW OF THE CBR-BASED COMPONENT

This section explains each step followed by the CBR-based component. To understand how this component improves the web accessibility evaluation process, how a teacher gets information about web content accessibility is explained next.

When a teacher is interacting with the TinyMCE editor he/she adds different kinds of contents such as text, images, and videos, among others. The TinyMCE web editor includes functions that provide accessibility features for each type of

content. However, in some cases, when the content is added to the web pages, teachers can omit essential information.

Therefore, in the TinyMCE, the teacher can access to the service of the AChecker validator, but the information could not be clear for the teacher, considering that this information contains a list of results with technical definitions from an automatic evaluation. For this reason, teachers can use the CBR-based component to get extra information of the accessibility in a specific web content.

The workflow is performed as follows:

- The expert reviews the list of the available web pages in the system and then selects some pages to evaluate the web accessibility.
- Then, the expert reviews the web content of the selected page, selects the criteria that must be marked as failure (according to WCAG 2.0), and writes a solution to that failure. The solution should be written in a comprehensive way.
- Each failure and its solution are stored in the system as a new case that feeds the CBR-based component.
- When the teacher edits new web pages in the TinyMCE editor (see Fig. 4), he/she needs to know about the web accessibility of a specific content type. To search for specific doubts, the teacher uses the module integrated within the TinyMCE editor, which represents the graphical interface of our CBR-based component (see Fig. 5).
- Once the teacher sends the query, the CBR-based component runs the query searching in the library cases for one or more similarity cases. This similarity is calculated using the aforementioned attributes in each of the cases.
- A set of the most similar solutions to the current case are suggested to the teacher, who decides if he/she uses some of these suggestions to solve the case (doubt) or decides to create a new solution for the case (see Fig. 6).
- The suggestions allow teachers to improve the accessibility of the web page.

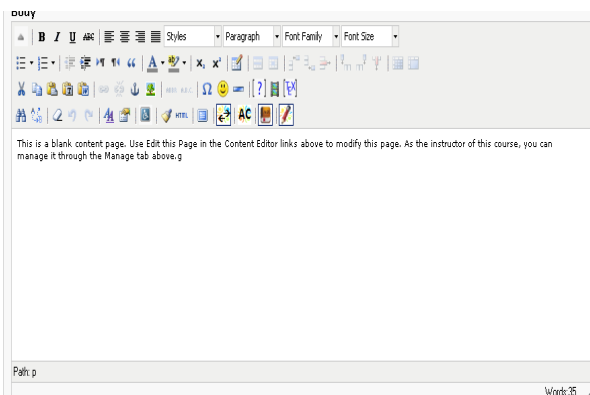

Figure 4. TinyMCE web content editor

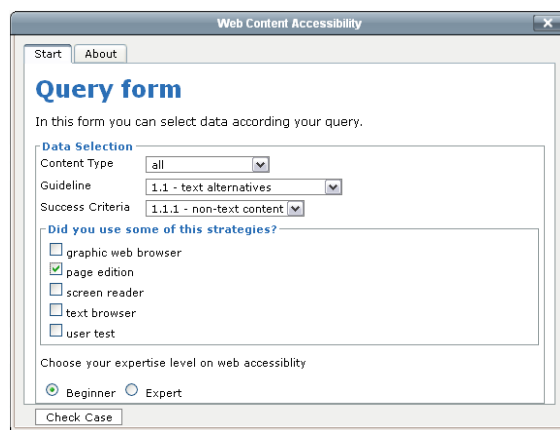

Figure 5. Web form to do the query

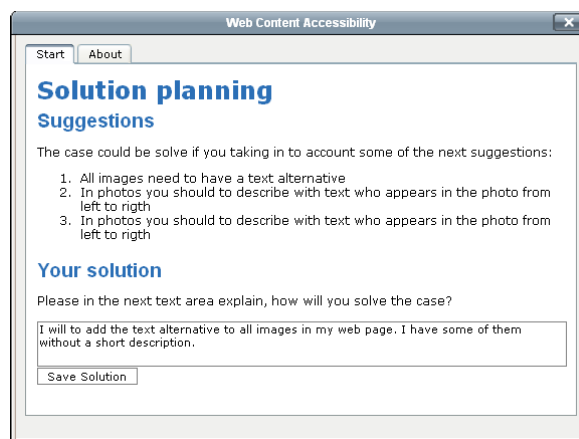

Figure 6. Suggestion from similar queries

VII. ALTER-NATIVA CHALLENGES TO SUPPORT ACCESSIBLE WEB CONTENT

ALTER-NATIVA is a European founded project whose main goal is to define curricular references with technological support for higher education in the areas of language, mathematics and science, for attending people in the context of diversity (such as people with visual impairment, people with hearing impairment and indigenous people). Taking into account the diversity covered by the project, there is a need to create accessible learning content so that all people, with different needs and preferences, can use the generated content in their learning process. In this context, we consider the following elements for a test validation scenario.

- **Actors:** There are two groups of actors in the test stage. On one hand, teachers that prepare future teachers and students that will be teachers in some of the ALTER-NATIVA project areas. On the other hand, experts in web content accessibility.
- **Technological requirements:** The introduced CBR-based component could be integrated in any instance of the TinyMCE web editor.
- **Procedure:** on one hand, the experts in web accessibility review one or more pages from a set of

web pages using the AChecker validator (or other tools), and write a solution to the identified web accessibility failures. On the other hand, the teachers create web pages with the TinyMCE editor, and use the graphic interface of the CBR-based component to use the recommendations of the experts in order to improve the web accessibility.

- Results: After using the CBR-component, teachers can learn about how to add web accessibility features to the content in their web pages.

VIII. CONCLUSION AND FUTURE WORK

The CBR-based component on this work does not intend to perform all the steps of the current manual web content accessibility evaluation. Instead, the component is defined as an aid, which is used by teachers and students to get solutions or recommendations about how to make the web content more accessible when they use the TinyMCE web editor.

This work was developed in an educational context; however, this work can be extended to other domains where users need to learn how to add web accessibility features to contents that are created using web content editors as the TinyMCE.

Using the CBR technique, we have observed that using the recommendations of the experts in the web content accessibility manual evaluation process permits us to obtain results that are easier for the teachers to understand than those obtained from the automatic validators.

As future work, we plan to integrate more algorithms to improve the case retrieval process and thus, to provide a better support to teachers in the process of editing web contents.

ACKNOWLEDGMENT

The authors would like to thank to the European Commission for its support through the funding of the ALTER-NATIVA Project (DCI-ALA/19.09.01/10/21526/245-575/ALFA III (2010)88). They would also like to thank the Spanish Government for its support through the funding of the Augmented Reality in Adaptive Learning Management Systems for All (ARrELS - TIN2011-23930) and the Catalan Government for its support through the European Social Funds (SGR-1202).

Work in Progress: Evaluation of an Online Education Portal from the User's Perspective: An Empirical Investigation of a Photovoltaics (PV) Engineering Learning Portal, pveducation.org

Refika Koseler, Susan Shapcott, Katherine G. Nelson, Jenefer Husman

Arizona State University, refika.koseler@asu.edu, susan.shapcott@asu.edu, kmuto@asu.edu, jenefer.husman@asu.edu

Abstract— In the last couple of decades, Photovoltaic (PV) solar systems have captured a lot of interest as a clean, renewable energy option. As a result, PV engineering has become an emerging field in engineering education. In order to meet increased learning requirements, new learning resources, an effective curriculum and proper assessment are needed. Pveducation.org is one of the discipline's oldest learning resources, providing PV content for photovoltaic professionals. The purpose of this paper is (1) evaluating the effectiveness of the pveducation.org learning portal from the user's perspective, and (2) find a relationship between the effectiveness of the website and user's learning gains. This study will conduct a systematic assessment of educational technology by using statistical techniques and data collected through a survey.

Keywords: *PV Engineering Education; survey development; learning portal effectiveness evaluation*

I. INTRODUCTION

With the increasing demand on new, sustainable technology in the world, the need for well-educated engineers in the solar cells sector is obvious, and ultimately escalating [1]. The green, sustainable economy is vastly dependent on highly-skilled and well-educated engineers, which in turn, requires rapid, effective, easy to use, and interdisciplinary learning portals [2]. In this context, pveducation.org fulfills a need by providing a resource to the solar cell manufacturing process with a curriculum designed to educate future PV engineers [1]. The creators of the website define pveducation.org as an online resource for educating the next generation of photovoltaic professionals [3]. It was developed in 2008 and has been serving the PV engineering community since. It is one of first comprehensive online resources in the PV engineering field. This website is designed like a textbook, where major sections are organized into chapters that are made up of individual webpages (or modules). These modules cover specific topics within each major chapter. The content of the website starts from fundamentals of PV, such as sun light, and solar energy to more complex phenomena such as the maintenance of PV (photovoltaic) systems, or design. Each topic is divided into modules and sub-chapters in a hierarchical flow which enables readers to find information easily on the website regardless of their pre-existing knowledge in PV.

II. ELEMENTS TO BE EVALUATED IN PVEDUCATION.ORG

The content of the website has been, and is currently being developed through repeated iterations by professors and experts in the PV field. During this content development period, small portions of the content are constructed at a time, allowing the developers to quality test it before it is released. Such quality testing involves criticism by other experts, or vocabulary and grammar testing. But this type of evaluation is not enough to determine the success of the delivered content. Therefore, the developers decided to evaluate it further, which involves collecting evidence from users about their perceived benefit from the content.

In addition to content development efforts, several different educational technologies have been embedded into the website to make it more user-friendly, interactive, and effective. These include simulations, animations, and metacognitive prompts - questions that allow the users to self-check their own understanding of the content covered in the modules. With the help of these technologies, pveducation.org has changed from an online textbook to an interactive website [2].

III. METHOD

This research involves administering a survey to collect data from learners who use pveducation.org. The research will assess the effectiveness of the pveducation.org website from the perspective of (1) content, and (2) the newly built educational technology tools. This study aims to examine the relationship between the quality of the website and the user's perceived value from it. Participants will be recruited from the pveducation.org website. Pveducation.org has approximately 3000 hits per day. Around one percent of users, 300, will be expected to participate in the survey. Participation is optional and the survey is delivered to participants through the website interface.

The survey used to collect data is reliable and valid for the purpose of this study. First, content validity was measured to ensure that the survey adequately measures, or represents, the constructs that the website developers wish to measure. Content validity can be defined as the extent to which the measurement reflects the specific intended domain of content [7]. For this purpose, two professors and two graduate students

in the field of engineering education were asked to assess the validity of the survey's sub-sections. The survey has been revised and developed iteratively according to the feedback gained from the content experts before it reached the stage to be used in this study.

The final version of the survey consists of two main parts. The first part is about the learner's website experience. It is divided into five sub-sections: (1) *System Quality*, (2) *Knowledge Building*, (3) *Endogenous Instrumentality*, (4) *Meta Cognitive Prompts*, and (5) *Overall Satisfaction*. The second part aims to gather demographic data about the learners.

Table 1 - Survey Scales, Number of Questions, and Pertinent Literature

| Survey Sub-Scale | Number of Questions | Pertinent Literature |
|-------------------------------------|---------------------|---------------------------|
| Learners' Website Experience | | |
| The System Quality | 12 | Ozkan et. al. , 2009 [4] |
| Knowledge Building | 9 | Shell et. al., 2008 [6] |
| Endogenous Instrumentality | 4 | Husman et. al. , 2004 [5] |
| Meta Cognitive Prompts | 3 | Conati et. al. 2008 [8] |
| Overall Satisfaction | 3 | Ozkan et. al. , 2009 [4] |
| Demographic Questions | | |

The System Quality items are related to attitudes toward technology, the usefulness of technology, and quality and reliability of the website. **The Content Quality** subscale is divided into two parts (1) knowledge building, and (2) endogenous instrumentality. *In the knowledge building subscale*, learners were asked to answer (1) whether the user set goals based on things they want to learn more about, (2) whether they will go beyond what they have learned in lectures, and (3) whether they find the topics of interest. The *endogenous instrumentality* subscale asks the user to respond to (1) do they use what they learn from pveducation.org (2) does the course content gain their attention, (3) is it easy to follow, (4) is it interactive, and (5) does the website cover an appropriate breadth of material.

The Metacognitive Prompts subscale includes three items. Participants will be asked to answer (1) whether metacognitive prompts are enhancing their academic performance (2) whether metacognitive prompts are helping them monitor their own understanding of the material, and (3) whether metacognitive prompts are improving their learning.

The last measure identifies overall satisfaction with pveducation.org. A 5 point Likert-type scale was used to collect data in all the sub-scales. The scale was anchored from 1 to 5, where 1 indicates strong disagreement and 5 indicates strong agreement. All responses are confidential and participants' IDs will be stripped from the data.

IV. EXPECTED RESULTS/FUTURE STUDIES

In addition to validating the measures used in the survey, the researchers will measure the reliability (internal

consistency) of the scale. It is expected that the subscales each have a Cronbach's alpha greater than 0.7 indicating that the items within the subscales are related.

Criterion-based predictive validity will be measured with effect size (R^2). This will be measured by regressing the survey's subscale on the learner's satisfaction value. A large R^2 value indicates a better prediction of the learner's satisfaction. The results will also inform us as to which subscales increase the user's overall satisfaction with the website and help inform future website design.

Confirmatory factor analysis will be used to determine the internal structure of the scales and ensure the dimensions have been correctly identified.

Future studies may include analyzing anonymous website transaction (log) information. Data mining, specifically clustering techniques can be used to understand the usage patterns of users. The findings will be valuable for future PV researchers who would like to create or improve online PV learning portals.

Abstract — Recent research shows that the engineering students have problems connecting the required computation to a conceptual understanding, as well as translating a graphical understanding of the process to a symbolic mathematical representation, especially when handling the multiple steps of the procedures. The students are usually able to perform sequences of the underlying calculations but cannot piece together the higher conceptual relationship that drives these procedures. This work-in-progress paper presents a viable approach and a new teaching and learning paradigm to enhance the effectiveness of teaching fast Fourier transform and significantly improve the learning outcomes. By integrating the mobile and cloud computing technologies, we are developing a handheld real-world relevance laboratory that includes an integrated learning module for Fourier transform and a shared intelligent project repository to host the module and real-world relevant data. This development is expected to overcome the intellectual inaccessibility of transform techniques and tackle the challenges in existing approaches: the prohibitive cost of project-based approach; limited access and real-world relevance data in simulation-based approach, and unreliable and unsustainable support.

Index Terms – Fast Fourier transform, mobile device, real-world relevance, interactive analysis.

I. MOTIVATION

The scientific principles and theories in electrical and computer are typically described mathematically and abstractly. One important aim in undergraduate electrical and computer engineering education is that students should understand theories and models and their relation to objects and events in the real world; they should also have the conceptual skills to apply these models and theories to formulate, develop, solve, evaluate and validate physical systems [1]. However, linking the mathematical symbols and abstract diagrams with the background concepts and their computational procedures has been proven to be not an easy task for students, especially when handling multi-step procedures. The students are usually able to perform sequences of the underlying calculations but cannot piece together the higher conceptual relationship that drives these procedures [2, 3]. In electrical or computer engineering, it has been found that the transform techniques such as

discrete Fourier transform and its efficient implementation algorithm, fast Fourier transform, dominate the list of difficult concepts although they are indispensable for follow-up courses such as communications, filter design, and digital signal processing [4]. Recent research [2, 4] (published in 2010 and 2011) showed that the intellectual inaccessibility of transform techniques is closely related to 1) the lack of connections between the concepts and real world applications, 2) the lack of reinforcement of the concepts when using them to solve problems (due to limited access to previous learning materials and labs), and 3) the lack of visualizations of each stage in the multiple-step processes.

Two approaches have been attempted to help the students better understand the concepts of transform techniques. One is to use project based exercises, where students learn through experiments [5]. The other one is to use a PC computer and/or other hardware (usually audio and video simulations) to help students to understand the concepts [6]. Unfortunately, despite existing efforts in teaching and learning transform techniques, none of them provide complete solutions to the above mentioned three problems related to the intellectual inaccessibility. Project-based approaches has been proven to be better since the students are motivated by solving real-world problems and learning-by-doing is the most effective way to learn. However, these approaches require significant investment in resources (labs and equipment) and more laboratory hours. Also, the students usually are not able to access to these experiments after learning the transform concepts in a particular course. They could not reinforce the concepts when they need to use them in the follow-up courses or when they need to solve real problems. The simulation-based approaches are cheaper, faster and can be rapidly adopted by students. However, virtually all of the simulations are performed with MATLAB [7], where the students have to work in a laboratory or purchase an expensive license. They are still constrained to a physical school building or a bulky computer. Moreover, there are few data related to the real world applications for students to simulate.

Currently, we are entering the mobile age. Today's learners have grown up with technologies and smart mobile devices have become an integral part of their daily lives [8]. They spend a considerable amount of time with these devices: talking, browsing the web, texting, social networking, and playing games. They increasingly associate computing technology with smart mobile devices rather than desktop computers. On the other hand, cloud computing has opened tremendous potential for improving cyber-based solutions to education with open and sharable; dynamic and expandable; reliable and sustainable; and affordable learning materials and environment. Integrating the mobile and cloud computing technologies enables a new model to overcome the intellectual inaccessibility of transform techniques and tackle the challenges in existing approaches: the prohibitive cost of project-based approach; limited access and real-world relevance data in simulation-based approach, and unreliable and unsustainable support.

II. HANDHELD REAL-WORLD RELEVANCE LABORATORY

To offer better learning experience and improve the understanding of the Fourier transform for electrical and computer engineering students This work-in-progress paper presents a viable approach and a new teaching and learning paradigm to enhance the effectiveness of teaching fast Fourier transform and significantly improve the learning outcomes. We are developing a handheld real-world relevance laboratory that integrates the anywhere anytime learning, authentic learning, collaborative learning, and cognitive learning. The laboratory includes an integrated learning module for Fourier transform and a shared intelligent project repository to host the module and real-world relevant data. The learning module improves learning through hands-on exercises related to real world applications and multiple facets penetration and visualization of the transform's implementation procedures. The repository supports data sharing collected from real world by geographically widespread users, collaborative learning, and intelligent counseling.

The learning module will include lecture notes for theoretical background, review questions and quizzes, assignments, and hands-on exercises with real world applications of Fourier transform technique. The hands-on exercises have multiple labs for applications in different areas and are organized at two difficulty levels: a basic level and an advanced level. The basic level hands-on labs that include image and speech signal processing and communication systems analysis do not require prior knowledge in transform technique and encourage the students to play with the mobile apps on the real world signals to learn, understand, and experience in the most interesting way. Step-by-step guideline and explanation will be provided for each lab and its implementation. These labs allow students to have instant practices on the real world signals collected by their own smart mobile device and to reinforce their knowledge Fourier transform at anywhere and anytime. The advanced level labs that include dual tone

multiple frequency detection, speech recognition, ECG signal processing and finger print identification challenge the students to learn more of the theory and develop comprehensive applications for more complicated cases. The sample results for advance level application will be demonstrated through multimedia flash so that the students could verify their results. Figure 1 shows examples of real-world image processing using fast Fourier transform.

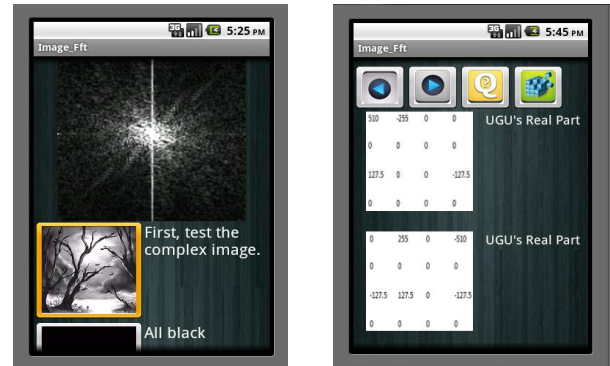

Figure 1. Fast Fourier transform for image processing. Left: Connection of the frequency and the variations in brightness across the image. Right: Visualization of the intermediate results in the fast Fourier transform

The handheld real-world relevance laboratory are designed to be cost-free, easy-to-adopt, and accessible at anywhere and anytime: they will be available online for download; the labs can be conducted real-time, anywhere and anytime without additional facility requirements; they can be used for in-classroom learning or online learning; they can also be used by the students to reinforce or review the transform technique after taking the theory class or before the application class.

Abstract—In this paper, we present a graphical-programming application to support signal processing education on the Android operating system. This application features a simulation environment and a palette of DSP functions, which will allow students to perform laboratories using Android smartphones and tablets. In order to demonstrate the application of the software in a classroom setting, a number of laboratories which incorporate the proposed functionalities have been developed. A set of assessments designed to evaluate the effectiveness of the software is also presented.

Index Terms—Android, J-DSP, graphical programming, laboratories, DSP education.

I. INTRODUCTION

Presently, classroom teaching of digital signal processing is largely restricted to algorithms and their applications. Incorporating visual representations of algorithms can foster a better understanding of signal processing concepts as well as enhance student interest. In this paper, we describe a DSP simulation application for Android devices that will enable students to visualize algorithms and perform laboratories using interactive graphical programming.

Smartphone devices have witnessed rapid growth in the past decade. A study of usage of mobile phones in various classroom scenarios across the world has been discussed in [1], showing that the usage of mobile phones in classrooms enhanced student learning. It has also been demonstrated in [2] that the learning potential is enhanced when education tools possessing a higher degree of interactivity are employed. Applications providing visual representations of complex theoretical algorithms have been found to simplify the understanding of underlying concepts [3].

Android smartphones and tablets have a large user base, powerful processors, and memory capabilities. Though applications catering to elementary education have been developed, to the best of our knowledge, this is the first comprehensive DSP simulation application for Android devices. Though MATLAB and LabVIEW provide an extensive set of functions for algorithm implementation and application development, their mobile versions are quite limited in their capabilities. For example, the mobile version of the MATLAB application [5] requires a high speed internet connection to access a remote machine running a MATLAB instance. Hence, we propose to build a standalone Android application for simulating DSP algorithms using a visual programming interface.

The proposed application is based on J-DSP, a web-based graphical DSP simulation package that was developed as a non-commercial alternative for performing laboratories in undergraduate courses [4]. The underlying architecture of Android J-DSP (A-JDSP) is based on the Model-View-Controller (MVC) Paradigm. The models are used to store data and block parameters. The controller acts as an interface between the model and the view, handling events common to both. The view comprises of the user interfaces and the workspace. This is shown in Fig 1. The rest of this work in progress paper briefly describes the set of laboratory exercises developed for the A-JDSP application and presents the planned assessments.

II. LABORATORY EXERCISES

In this section we describe a set of laboratory exercises which demonstrate the application of A-JDSP in an undergraduate DSP course. These exercises are designed to demonstrate signal processing concepts like z-domain and frequency domain representation of signals, the Fast Fourier transform, and various aspects of multi-rate signal processing. The laboratory exercises are typically performed after students are introduced to the corresponding topics in their lecture sessions.

A. Z-Transform and Frequency Response

The objective of this lab is to instil an understanding of z-domain representations of signals among the students and to study its relationship with frequency domain representations. The functionalities of Pole-Zero (PZ) Placement, the Pole-Zero Plot, and the Frequency Response are demonstrated in this exercise. The PZ placement user interface is shown in Fig. 2. The laboratory is devoted to the study of frequency response of filters. The students set up a filter design simulation and exercises pertaining to the design of cascade and parallel filters are carried out. Finally, a set of exercises to construct filters and analyse z-domain plots is provided, enabling students to understand their relationship with the corresponding frequency responses.

B. The Fast Fourier Transform

This laboratory exercise demonstrates the application of the Fast Fourier Transform and examines various related concepts such as zero padding, resolution, and spectral leakage. The simulations in this exercise are realized using the FFT, windowing, and discrete signal generator functions in A-JDSP. As

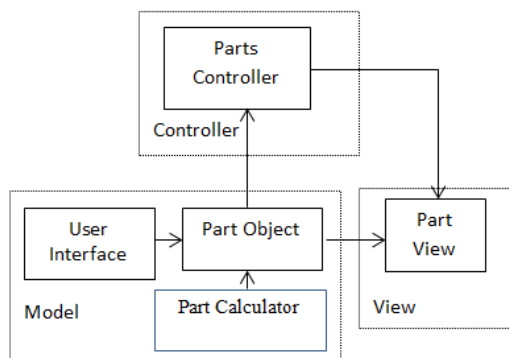

Fig. 1: Architecture of A-JDSP, based on the Model-View-Controller paradigm.

part of this exercise, the students examine the effect of signal symmetry and zero-padding on the FFT of a signal. A simple application of FFT in signal compression is also examined.

C. Multi-rate Signal Processing

The goal of this laboratory is to examine the effects and utility of sampling rate conversion. The Up-Sampler, Down-Sampler, Filter, Junction and Adder functions of A-JDSP are used here. The first exercise covers the principles of down-sampling and up-sampling of signals. The design of a 2-band Quadrature Mirror Filter (QMF), and a tree structured sub band filter are carried out. An example block diagram for designing a QMF filter is shown in Fig. 3.

III. ASSESSMENTS

In this section, we describe the planned assessment methodology to obtain evaluations for the proposed application. A-JDSP is being tested by the students of an undergraduate signal processing class at Arizona State University in Fall 2012. We will build assessments based on student evaluation at the end of the semester. The goal of this evaluation is to identify the impact of employing mobile devices to perform DSP simulations and laboratories. The evaluation will assess the interactive capabilities of the A-JDSP framework, and its ability to sustain student interest and understanding. The results of the assessments will be presented at the conference.

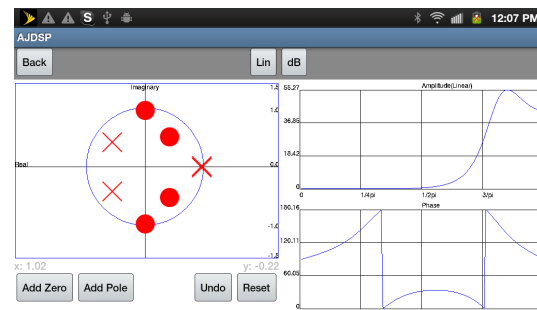

Fig. 2: Demonstration of filter design using PZ placement in A-JDSP.

The pedagogy adopted for the use of A- JDSP will include the following: (a) lecture on the pertinent signal processing concepts, (b) a pre-quiz on the concepts involved in the laboratory exercise, (c) simulation exercises and laboratories using A-JDSP, (d) a post-quiz to evaluate the effect of A-JDSP on student understanding. The results of these assessments will be used to address the issues in our software and thus enable us to provide prescriptive recommendations concerning its strengths, replication, and sustainability.

IV. CONCLUSIONS

In this paper we proposed an interactive and portable application for performing signal processing laboratories. The application is built for the mobile based Android operating system. With its architecture based on the Model View Controller Paradigm, Android-JDSP contains a comprehensive set of functions necessary to perform undergraduate signal processing laboratories on smartphone devices. Laboratories for the use of the proposed application in an undergraduate DSP course were described. Future work includes extensive testing of the application, and building functions to support interdisciplinary streams such as earth systems signal processing, sensor networks, speech, and image processing.

ACKNOWLEDGEMENTS

Abstract—Encouraging collaborative software design through the use of multi-touch interfaces has become increasingly important, because such surfaces can accommodate more than one user concurrently, which is particularly useful for collaborative software design. In this paper, the potential of using multi-touch MT-CollabUML application for collaborative software design is explored. This exploration is done by looking at how students' collaboration might be enhanced in collaborative software design using Unified Modeling Language (UML) comparing the traditional paper-based environment with the contemporary multi-touch table environment.

Keywords—Multi-touch table; Software design; UML; Collaborative work.

I. INTRODUCTION

One promising learning technology that facilitates collaborative work among students is the multi-touch table. Several projects have introduced multi-touch surfaces to enhance collaborative learning. Collaborative learning has become increasingly important for several reasons. Multi-touch interfaces can accommodate more than one user concurrently, which is particularly useful for learning through large, shared display systems like tabletops [1, 2]. Using such systems encourages students to collaborate and create an environment wherein they can discuss their findings and integrate their ideas seamlessly with no technological hindrances. In addition, such systems can enhance students' interaction skills and promote teamwork.

Multi-touch environments offer new possibilities for interaction between humans and computers. Researchers from different educational backgrounds are exploring this area and indicate that multi-touch environments can be successful because interaction through touch is both intuitive and natural [3].

Many studies have shown the benefits of using multi-touch environments to enhance collaborative work. For instance, Rick and Rogers [4] built a system called DigiTile to enhance collaborative learning, which helped students design patchwork quilt blocks. In this study, students use multi-touch surfaces to drag pieces into a quilt block and change colors to design

mathematical shapes [4]. Further, multi-touch surfaces were used for collaborative information gathering. In this study, users were provided with a tool called WebSurface, which helped them browse the Web collaboratively to gather information from different websites. Using multi-touch surfaces allowed users to search for information, browse multiple pages at the same time, and easily gather the information they found [5].

The potential of multi-touch surfaces is to enable co-located collaboration activities, which allow small groups to work together collaboratively [6]. This potential might be a result of the ability of multi-touch tables to provide equal opportunities for collaboration in group work [7]. However, there has been little research to determine the potential of using multi-touch tables to enhance co-located collaboration in software design using Unified Modeling Language (UML). However, the level of collaboration in DigiTile [4] and WebSurface [5] is limited and restricted to simple actions performed by users, such as putting words in the right context, arranging items over tables, and simple click and drag actions. However, UML design involves advanced design issues that raise new collaboration needs, such as linking nodes and annotation. To this end, in this paper we explore the potential of using multi-touch technology for software design using UML by comparing it with traditional, paper-based collaborative software design.

In Section II, we briefly describe the related research work in multi-touch tables for collaborative work and in collaborative software design using UML. In Section III, we explain a comparative study between paper-based and multi-touch based environments in software design. In Section IV, we set forth and discuss the results and findings of the comparative study and how multi-touch tables have enhanced collaboration in software design using UML. Finally, in Section V, we draw conclusions from our research and discuss future work.

II. RELATED WORK

A. Multi-touch tables for collaborative work

In the literature on multi-touch tables, there is much interesting work reflecting the role of multi-touch in enhancing

collaborative activities. However, for the purposes of this paper, the use of multi-touch tables to enhance collaborative work is considered. Morris et al [8], conducted a research study to investigate the effectiveness of utilizing multi-touch tabletops to enhance cooperation during group functions and tasks. The finding was that multi-touch tabletops were particularly useful in enhancing team member awareness. This implies that multi-touch tabletops enhance information sharing among group members. In another study, Harris et al [9] examined the variation in group task performance between single and multi-touch tabletops. Multi-touch tabletops enhance task performance, unlike single-touch tabletops. Furthermore, another research study [10] examined the efficiency of multi-touch tabletops. Comparison between multi-mouse and multi-touch tabletops was performed. Results show that multi-mice are utilized more than multi-touch tabletops because of the following factors: (1) multi-mice enable users to interact with any part of the display when compared to the multi-touch; (2) users lack of familiarity with multi-touch tabletops; (3) variability in the usage of multi-touch tables. However, the authors note that users of multi-touch tabletops had fewer grammatical errors than those of multi-mouse users. In [11], multi-touch tabletops increase the awareness and common ground of group members working collaboratively to achieve a particular outcome. Moreover, multi-touch tabletops increase the effectiveness of group tasks and obligations [12]. According to the research studies described above, it is concluded that multi-touch tabletops increase group interaction and therefore increase attainment of group goals.

B. Technologies for collaborative software design using UML

There are many research efforts to facilitate collaboration among users in software design using UML, such as COLLECT-UML [13], CoLeMo [14], CAMEL [15], and AUTO-COLLEAGUE [16]. Unlike COLLECT-UML and CoLeMo, AUTO-COLLEAGUE does not support collaborative drawing for UML diagrams, but offers a chat system as its main collaboration tool. These systems, however, are designed to support distributed collaborative work, not a face-to-face collaboration style. With the exception of the Software Design Board [17], which is a shared whiteboard application, research has produced few outcomes supporting collaborative software design.

III. COMPARATIVE STUDY

As mentioned above, software collaborative design using multi-touch has not been widely explored; to the best of our knowledge there is no multi-touch collaborative UML design tool available. So, for purposes of this study, a multi-touch enabled tool called “MT-CollabUML” was developed to encourage students to co-locate collaborative software design using UML.

A. SynergyNet lab

This study was conducted in a specialized laboratory called SynergyNet at Durham University in the United Kingdom. The SynergyNet lab has a set of multi-touch tabletops, specially

designed furniture, and software that integrate physical components into a comprehensive environment to support collaboration (see “Fig. 1”).

Figure 1. SynergyNet lab

B. Participants

Twelve MSc program students volunteered to participate in the study. Participants, at the time of conducting this study, were studying a module called “Software Engineering for the Internet.” This module was chosen specifically because students were required to design software using UML collaboratively in groups. All participants had successfully completed the UML part of the “Software Engineering for the Internet” module before conducting this study. Involved students were asked to form four groups of three; each student joined his or her preferred group.

C. Experiment design

To investigate MT-CollabUML’s strengths and limitations in supporting collaborative design for UML diagram design, a within-subject experiment was conducted to compare how the participants used paper with how they used multi-touch surfaces in terms of collaboration. Similarities and differences were examined in terms of quantitative performance and qualitative behavior in the four groups of three students, who worked on creating UML-state diagrams. The goal was to identify differences in the level of collaborative design process across experimental conditions.

To ensure the validity of our investigation, we decided to compare the MT-CollabUML system with the traditional paper-based condition currently used for collaborative UML design. In both the MT-CollabUML and traditional paper-based conditions, we ensured that participants could work collaboratively; they had the same size work space and the same display orientation, and all group members could work at the same time. To maintain comparable conditions, we provided two similar tasks with the same difficulty and complexity.

The tasks were designed with clear and measurable learning outcomes and with the aim of integrating students’ reflections and discussions. We opted to use a collaborative group condition because the students involved were required to work in groups to perform software design using UML.

We provided two experimental tasks that required the participants to create UML-state diagrams. The course tutor was consulted to ensure that both tasks were of the same level of complexity. Each task consisted of several activities, including planning, discussion, decision making, drawing diagrams, and reflection.

Repeated measures design was followed in this study to help keep the variability low and make the experiment more efficient with a manageable number of participants. In this study, the four groups of students was arranged into group pairs; for every pair of groups, we gave one group a UML design task and asked them to complete it using pen and paper “Fig. 2”. We asked the other group to complete the same task using the multi-touch table. We then switched the groups and asked them to perform the second task using paper and multi-touch conditions “Fig. 3”.

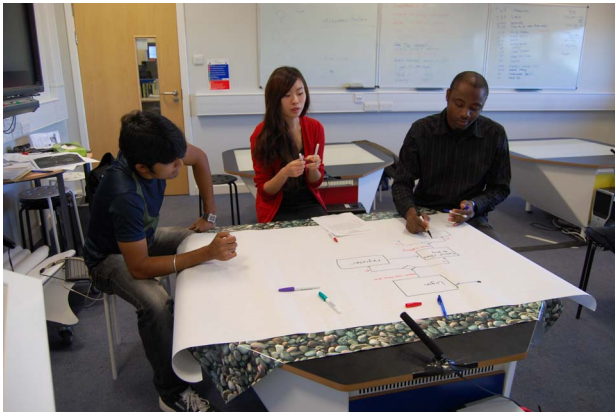

Figure 2. Paper-based collaborative software design

Figure 3. Multi-touch table based collaborative software design

D. Procedure

In the quiet SynergyNet lab, we used a within-subject study design in which we assigned all four groups both paper and multi-touch-based experiment conditions. Participants were given a 15-minute tutorial demonstration on how to use the multi-touch surface, and they were given as much time as they needed to complete the required tasks.

E. Data collection

All collaborative design activities were video recorded and transcribed for analysis. For the paper-based condition, we set up two cameras to focus on the table from two directions to ensure all group members could be seen. The multi-touch condition was conducted in the SynergyNet lab space shown in “Fig. 1”, where ceiling-mounted cameras recorded the multi-touch table from two angles and the screen capture was saved for future analysis.

F. Data analysis

Participants adopted different collaboration patterns as they designed UML diagrams in paper- and multi-touch table-based conditions. At times, they worked on the same problem, even adding nodes or annotations or using a digital keyboard; at other times, they separated work on different problems such as editing many nodes at the same time.

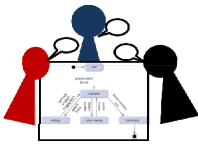

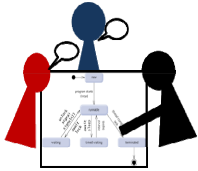

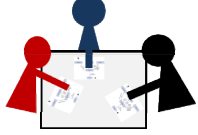

To investigate the similarities and differences between the conditions in terms of collaboration style, the collaboration style coding scheme of Isenberg [18] was adopted with modifications to fit with our study’s needs, as explained in Table I. For the purpose of this study, three collaboration styles were selected out of the proposed eight styles of collaborations by Isenberg [18]. The selected collaboration styles are: 1) Discussion (DISC), 2) View Engaged (VE), and 3) Disengaging (D).

The reason behind choosing these particular styles is that our participants performed them during the experiment. During the experiment, sometimes the participants stopped working and engaged in discussion (DISC) to explore different ways of solving the problem. At other times, some participants just engaged in watching (VE) what other participants were doing and gave them advice on how to proceed. Also, sometimes some participants were disengaged (D) during the experiment. These three collaboration styles (DISC), (VE), and (D) were common in our study and in Isenberg study [18].

Two new styles of collaboration were identified by the researcher, namely Shared Work (SW) and Working Individually (WI); these are not mentioned in Isenberg work [18]. It was observed that participants sometimes work together on the same diagram, but in different nodes or editing different areas; we call this Shared Work (SW) style. On the other hand, sometimes, especially in the paper-based condition, participants work individually (WI); each of them was creating different diagrams for the same task, so we consider WI as a style of loose collaboration. However, Isenberg mentions five other styles not relevant to our study, so we exclude them.

We calculated each collaboration style percentage for each group according to the total task time spent in both conditions. In the DISC, VE, and SW collaboration styles, participants collaborated closely by discussing and working together; some only watched, but they at least engaged in discussion. However, we considered the WI and D styles to be a loose collaboration, because one or more participants either worked separately or were completely disengaged during the task.

TABLE I. COLLABORATION STYLE CODING SCHEME (STYLES WITH DIFFERENT COLOR ADDED BY AUTHOR)

| Collab. Styles | Description | Example |
|----------------|---|---|
| DISC | Active discussion about the task. |  |
| VE | One person is actively working; the other watches and engages in conversation and comments on the observed activities but is not interacting with the table or paper. |  |
| SW | All persons share the work to solve the same specific problem. |  |
| WI | Working individually; each person is creating his/her diagram. |  |
| D | Disengaged. One person is actively working; the other is watching passively or is fully disengaged from the task. |  |

IV. STUDY FINDINGS AND DISCUSSION

This study explores the benefits of using a multi-touch table as a tool to encourage students to work collaboratively in software design using UML. In the case of multi-touch tables, students showed better and closer collaboration, and the use of multi-touch facilitated collaborative software design.

Qualitative analysis of the level of collaboration was performed as mentioned in Section III. The multi-touch finding showed that the percentages of task time that the participants spent in each collaboration style were: DISC (discussing), 26.31%; VE (view engaged), 30.82%; SW (shared work), 39.59%; WI (working individually), 0.00%; and D (disengaging time), 3.28%.

However, in the paper-based condition, the findings were: DISC, 41.86%; VE, 27.01%; SW, 5.35%; WI, 14.78%; and D, 11.00%. These findings are summarized in Table II.

There are two different levels of collaboration, namely close collaboration and loose collaboration, as explained in Section III. For example, DISC, VE, and SW are considered close collaboration, and WI and D are considered loose collaboration. In this research, we found that the total

percentages of task time spent in close collaboration styles were 96.72% in the multi-touch based condition and 74.22% in the paper-based condition. However, total percentages of task time spent in loose collaboration styles were 3.28% in the multi-touch based condition and 25.78% in the paper-based condition. Indeed, the multi-touch MT-CollabUML tool has played an important role in increasing the level of collaboration among students.

TABLE II. PERCENTAGE OF TIME SPENT IN EACH COLLABORATION STYLE IN MULTI-TOUCH AND PAPER-BASED CONDITIONS

| | Collaboration Style | Multi-touch based | Paper-based |
|---------------------|---------------------------|-------------------|-------------|
| Close Collaboration | DISC (discussing) | 26.31% | 41.86% |
| | VE (view engaged) | 30.82% | 27.01% |
| | SW (shared work) | 39.59% | 5.35% |
| Loose Collaboration | WI (working individually) | 0.00% | 14.78% |
| | D (disengaging) | 3.28% | 11.00% |

In the close collaboration styles, the participants engaged in active sharing of information and discussion regarding the task. They worked together as a team solving the same problems and pursued similar questions.

In the multi-touch based condition, the participants spent more time in close collaboration either by working actively on the same task (SW style) or by having one user actively drawing while the others contributed through discussion and comments on the ongoing design process (VE style).

In both multi-touch and paper-based tasks, participants spent a considerable amount of time in discussion prior to the actual design process (DISC style). Most of this discussion was conducted at early in the design process in order to agree on an initial design before committing to the design.

In the paper-based condition, it was difficult to revise the drawings on paper because the groups would have to redraw the whole design on a new sheet if the paper became messy. This explains why the participants in paper-based tasks spent more time in discussion before drawing. In contrast, the ability to easily revise and edit the UML design by using hand gestures in the multi-touch based condition made the participants probably feel more confident in contributing to the drawing process, because it was easy to redo and amend actions. This resulted in more active engagement by all group members in the multi-touch based condition.

In the paper-based condition, participants spent more than a quarter of the task time either working individually (WI) or disengaged (D). Participants sometimes worked individually, where each of them built different diagrams on a piece of paper and then showed their solutions to each other to decide which one was correct. As another strategy, one participant created a diagram while the others just watched, and then the active participant showed the diagram to them to discuss it. However, the results indicated that participants never worked individually in the multi-touch based condition, because the work space did not facilitate individual work. Therefore, the overall collaboration pattern results indicated that the multi-touch

based condition was better than the paper-based condition in terms of encouraging collaboration.

V. CONCLUSION

In this study, we investigated the differences in collaborative work in UML design among groups of students working in paper and multi-touch table based conditions to determine the potential of the multi-touch table. Results indicated the benefit of using the multi-touch MT-CollabUML tool in making a noticeable enhancement of the collaborative software design using UML.

The multi-touch MT-CollabUML tool allowed students to work collaboratively much more closely compared with the traditional paper-based work environment. The improvement in collaborative work between students in the multi-touch environment is a direct result of the facilities provided by the multi-touch MT-CollabUML tool in which students engage in active sharing of information and discussion of the task.

The multi-touch MT-CollabUML tool has played a role in minimizing working individually and encouraging group members to work collaboratively. On the other hand, the paper-based setting decreases the level of collaboration and encourages individual work due to the single person domination of the activity and practical difficulties in sharing the workspace and pens. Furthermore, in the paper-based condition, the correction of mistakes was to some extent difficult compared with the multi-touch table setting, and sometimes participants start the work from scratch after making mistakes. Indeed, the use of a multi-touch table helped students to better work together and enhanced and facilitated the collaborative software design of UML. More research should be done to compare between desktop-based collaborative software design and multi-touch based design to further explore the potential of multi-touch tables.

ACKNOWLEDGMENT

The authors acknowledge that the hardware for this research has been provided by the Engineering and Physics Research Council (EPSRC) under grant research number RES-139-25-0400.

Abstract—Novice programming environments (NPEs) like Scratch and Alice witnessed tremendous growth in adoption and popularity in recent years. These NPEs have successfully lowered the barrier of initial entry to programming. They have also allowed novice computing students to exercise their creative freedom more meaningfully by enabling them to work on projects which have more real life context.

Recent trends in adoption of smartphone and other mobile devices among our youth points to a time in near future when majority of them will be mobile device users. Hence, if the NPEs want to remain relevant among youth, they need to adapt to and cater to a mobile-device centric audience. Google and MIT's App Inventor for Android is one of the early NPEs that is trying to achieve this by offering a Scratch-like environment for mobile apps development. GameSalad is another free software primarily for Mac platform that can also offers a drag-n-drop rule-based environment for creating apps. In this paper we compare these two environments' suitability for computing introduction. Our comparison is based on several logistical, instructional, and operational factors and points to the fact that both these mobile NPEs have their strong points as well as weaknesses. We believe the effectiveness and success of these mobile NPEs will vary depending on particular situations, and hence our work will aid someone looking for a mobile NPE in making a more judicious choice.

Index Terms—App Inventor for Android, GameSalad, Visual “blocks” programming, Novice programming environment.

I. INTRODUCTION

Programming is a difficult skill to learn. Many novice programmers constantly struggle to understand the computational concepts and syntactic details while learning programming. Traditionally, both in universities and high schools, programming was introduced using production/enterprise level languages like C, C++, and Java. The learning-curve for students learning programming for the first time using a language like Java is very steep. Introductory programs that students often write in a language like Java also often lack any meaningful real-life applications and contexts for those students.

Designing *Novice Programming Environments* (NPEs) to address some of these challenges is one solution that computer science education researchers have looked at. NPEs are

special purpose programming languages with the main goal of lowering the barrier of initial entry to programming. Some of the main features in most NPEs are hiding of syntactic complexities of programming languages, making it easier to understand and use the basic computational concepts, and enabling the students to create more meaningful programs and projects which are more relevant to their lives. Several NPEs were designed with these goals in mind and had varying degrees of success in terms of popularity and adoption. Refer to [5], [6] for detailed surveys of NPEs developed before 2005.

Two NPEs designed within the past few years that experienced widespread adoption are Scratch [8] and Alice [4]. Both Scratch and Alice are visual “block” programming environments where students create their programs by snapping together programming blocks that behave like puzzle pieces. There are many advantages of “blocks” languages. They eliminate the need for typing complete programming statements. Incompatible blocks would not snap together. These features reduce the chances of making a syntactic error. Additionally, the blocks visually depict computational concepts like a loop. Hence, it is easier for students to use the concepts. Both Scratch and Alice are very popular. The Scratch gallery currently has more than a million members and more than three hundred thousand project creators. A huge majority of these members and project creators are teenagers¹. Many high schools, universities, and other organizations leveraged NPEs including Scratch and Alice to design and offer novel programming introduction activities. These activities range from CS0/CS1 courses in universities [11], [12], [16], to summer camp and after school activities for school students as well as teachers [1], [7], [13], [17].

App Inventor for Android (AIA) is a relatively new NPE that was initially designed at Google [18]. Since January of 2012, the newly created Center for Mobile Learning at MIT has taken over the further development and maintenance of AIA. AIA shares the same program-design philosophy with Scratch. In AIA, just like Scratch, students also drag and snap puzzle-

¹<http://stats.scratch.mit.edu>

pieces like blocks to create their programs. The key difference between AIA and other NPEs like Scratch and Alice is that students create apps using AIA which runs on any Android device. AIA has witnessed rapid adoption among colleges and schools and has established itself as a major player among the “mobile” NPEs.

Android and iOS devices currently account for a huge majority of mobile devices in use. Hence, there is room for a mobile NPE targeting iOS devices as well. GameSalad is a software created mainly as a rapid iOS game-authoring tool for non-programmers. GameSalad is a rule-based system where the programmer creates rules for various components of the app being developed. GameSalad was not explicitly designed to be an NPE. However, it shares most of the main themes of NPEs, namely easy, visual, drag-n-drop program creation, support for easy expression of the main computational concepts, and ability to create programs that resonate with the students. Hence, it can be used in a programming introduction activity.

In this paper we compare App Inventor for Android and GameSalad for their suitability for introductory computer science classes using a set of metrics that encompass (a) logistical factors, such as the cost and complexity of the initial setup, and the difficulty involved in selecting and setting up suitable mobile devices for development and testing; (b) instructional factors, such as the availability of quality lessons and tutorials, and transitioning-in and transitioning-out features; (c) usability and operational issues, such as quality of the interfaces, the existence of embedded social features like app and code sharing, students’ ability to install the apps they created on a mobile device, and platform dependence.

In order to accomplish our analysis, we installed the software and connected mobile devices to a variety of platforms. We conducted web searches for existing instructional materials and peer help groups. We also designed a set of apps for introductory programming instruction, and created publicly available tutorials of our own for both GameSalad and AIA.

Rather than establishing a clear winner, our results suggest specific conditions upon which the choice of NPE should be contingent. Our study can therefore be a useful primer for educators planning introductory programming courses and activities. It will also be useful in guiding data collection for future quantitative analyses.

In the next section we provide backgrounds and motivations for our work. Section 3 contains our detailed analysis and comparison of AIA and GameSalad and Section 4 provides concluding remarks.

II. MOTIVATIONS

Today’s youth live in a mobile world. Personal computers are not their only computing devices any more. In fact many of them use a mobile device like a smartphone more frequently than a computer. Nielsen’s recently published Mobile Youth Around the World survey points to the fact that more than one third of 15-24 year old population in USA own a smartphone with females owning a majority of them by a small margin [15]. This survey did not specify the smartphone ownership

specifically among teens. However other indicators in the survey point to teen smartphone ownership being very high as well. That survey also pointed to the facts that almost all teens owning smartphones use them for advanced data services and that data consumption has grown many fold in recent years. Pew Research Center published a similar survey called Pew Internet and American Life Project [9] that shows similar trends.

Piper Jaffray’s biannual “Taking Stock with Teens” survey released in early April 2012 shows even broader adoption of mobile devices, especially iOS devices among teens. In their latest survey [10], they found that approximately 34% of teen respondents already owned an iPhone. 86% of the teens reported that they intend to buy a smartphone while making their next mobile device purchase. 51% of the teens reported that they are likely to buy an iOS device and 40% of the teens plan to purchase an iPhone within the next six months. Similar growth trends were reported in the tablet market as well. Most of the cellphone carriers in USA require smartphone owners to subscribe to advanced data plans. So the bottom line is, very soon a vast majority of the teens in USA will perpetually have an Internet connected computing device in their pocket.

One of the main goals of NPEs is to lower the barrier of initial entry to programming. This goal is becoming increasingly important in light of the fact that in recent years colleges and universities have failed to attract computing majors, especially females and under-represented minorities [2], [3]. The fact that females and minority students are poised to grow as a percentage of the total student population [14], magnifies the problem. Research has shown NPEs play an important role in attracting and retaining new programmers in computing related disciplines. Since the smartphone is one of the (if not the) main computing devices of today’s teens, NPEs for smartphones and other similar mobile devices are quickly becoming essential.

iOS and Android are currently the two main mobile operating systems. If one considers the general population’s mobile ownership, Android powers majority of the mobile devices. But as pointed out in the Piper Jaffray surveys, iOS is still the most desirous platform among the teens. Hence, NPEs for both these operating systems are needed. AIA is quickly becoming the de-facto NPE for Android domain. There is no consensus candidate for the iOS devices. Hence we wanted to research the suitability of one contender, GameSalad by comparing it to AIA. Our analysis is qualitative in nature and presents our opinions.

The main contribution of this paper is to present various factors that determine the efficacy of mobile NPEs and present our brief opinions about AIA and GameSalad pertaining to those factors. To the best of our knowledge, no prior research contrasting mobile NPEs exist. We expect this work to help anyone who is in the process of selecting a mobile NPE by directing them to the relevant issues so that they can make a more informed choice.

III. AIA VS. GAMESALAD: OUR ANALYSIS

In this section we present our analysis and comparison of AIA and GameSalad. We made the comparisons on several logistical, instructional, usability and operational factors. The following subsections detail the process we undertook to make the comparison as well as our impressions.

A. Logistical Factors

Cost: Both AIA and GameSalad are free software available for anyone to download. So upfront, the software itself costs the same². However, GameSalad, once downloaded and installed, requires no active Internet connection to be used whereas to use AIA, an active Internet connection, preferably a high-speed connection is required.

Complexity of initial setup: The initial setup for GameSalad is very simple. Installing it is just a matter of downloading the appropriate binary file from the GameSalad website. The setup for AIA is slightly more complicated. AIA uses Java, so before going through the steps to set up AIA, one needs to verify that Java is installed on the computer. After Java has been installed, installing AIA is fairly straightforward. Both AIA and GameSalad require additional drivers in order for devices to connect to the software. AIA installer comes with drivers for some of the more popular Android devices. AIA requires a driver called Advanced Debug Bridge (ADB) to interface with any device. Since there is a plethora of Android devices that are currently available, finding the ADB driver (especially for relatively newer devices) can be difficult. In our experience the websites like AIA Repository³ maintains a list of ADB drivers for various devices with download links.

In order to test apps developed in GameSalad, a software called GameSalad Viewer must be installed in the iOS device. GameSalad's website lists YouTube tutorial⁴ about this process. But this process is quite complicated, requires a Mac, and in our opinion is more complex than the corresponding step in AIA. Additionally, the recently released Windows version of the GameSalad creator software cannot communicate with the GameSalad Viewer. Hence, GameSalad apps developed in Windows can't be directly tested on an iOS device (an app developed in Windows can be transferred to a Mac computer and then tested).

Selecting a target mobile device and associated cost:

AIA is platform dependent. Only Android devices are available for testing. Till recently, GameSalad was platform dependent as well and needed Apple products for testing. However, recently GameSalad has started incorporating Android support for testing. Their pro version has Android publishing. Even their free version has support for an Android viewer that can be installed on Android devices.

As far as available devices for GameSalad and AIA are concerned, an unlocked contract-free iPhone 4S 16GB will cost \$649.00 and the newest generation iPod touch will cost \$199.00 from the Apple store. For Apple tablets, the iPad 2 starts at \$399.00.

There are many Android products on the market. The two major categories are hand held phones and tablets. It is difficult to acquire an Android phone without signing a contract. Most tablets do not require a contract and can be found anywhere from \$55 to \$500.

Apple products certainly have more "desirability" among teens. Additionally, the popularity of a sub \$200 device, iPod touch makes device selection for GameSalad easier. The only sub \$200 Android device that has witnessed broad adoption so far is Amazon's Kindle Fire. There are numerous Android devices available with new ones introduced every day. Hence selecting a device becomes more challenging.

B. Instructional Factors

Availability of instructional resources: GameSalad and AIA both have tutorials available on their respective websites^{5,6}. Both the AIA and GameSalad tutorials are aimed towards an audience with little programming experience, however the tutorials go different ways about familiarizing the user with the environment. The GameSalad tutorial show the different features and functions of GameSalad while the AIA tutorial both demonstrate features of AIA and teach you how to use the features to interact with your device simultaneously.

The tutorials offered by GameSalad and AIA are in a text format with images interspersed throughout. For video tutorials, YouTube, the popular video sharing website, has hundreds of tutorial videos for both GameSalad and AIA. For additional support, both GameSalad and AIA have dedicated forums where users can ask questions to the online community^{7,8}.

To the best of our knowledge, there are four books on App Inventor, which are currently available. We have reviewed two of them. Both of them take a project-based approach and introduce various programming ideas through hands on projects. Recently a couple of books on GameSalad were released as well, which we have not had a chance to review yet. AIA has seen more adoption in college classes. Hence materials used in college courses are more readily available for AIA⁹.

Ease of creation of instructional resources: We created and made publicly available several elementary tutorials to guide novice students through the creation of a few simple games in both GameSalad¹⁰ and AIA¹¹. These included a pong like game, and a baby catch game. The creation of such simple applications is not particularly more difficult in one

²GameSalad has recently launched a pro version which costs \$299/year. This comes with advanced features like Android publishing, Twitter integration, ability for in-app purchase etc. The basic version used for all our analysis is still free.

¹¹<http://www.youtube.com/playlist?list=PL2D27126F35E50A1B&>

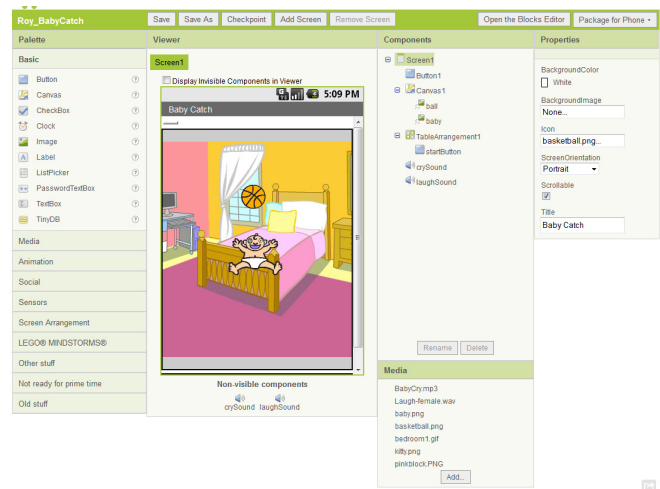

environment than the other. However, construction of lessons on loops, variables, functions, is more straightforward in AIA, which provides ready-made blocks to represent such constructs, than it is for GameSalad, which obscures these things to a great degree. While it is certainly possible to demonstrate the relevance of these concepts to GameSalad projects, doing so requires care and finesse. What is more, GameSalad's abstraction away from such basic computing concepts might present an impediment to student understanding.

Transitioning-in and transitioning-out: AIA shares its look and feel with Scratch, which has a substantial pool of current users. Hence, a student transitioning-in to AIA from an environment like Scratch will find it very seamless. Even then, the barriers to entry are lower for GameSalad. GameSalad users are able to create simple but slick looking games without having to learn anything about lists, loops, event listeners and the like. On the other hand, from early on AIA has been envisioned, at least in part, as teaching software. Consequently some thought and energy has been invested in facilitating the graduation of its users to more complete programming environments. Not only is the block syntax somewhat reminiscent of the Java programming language upon which it is built, with its “Java Bridge”, AIA provides a platform that allows users to incorporate AIA components into Java and Android SDK applications. GameSalad was designed without pedagogical motivations. Rather than providing a gentler introduction to programming, its aim is to obviate programming altogether, to allow professional app development without the use of a programming language. While experience with GameSalad will no doubt benefit students going on to learn computer science, students for whom experience in app development has been limited to GameSalad will be starting over when learning a first professional programming language to a much greater extent than will students with commensurate experience with AIA.

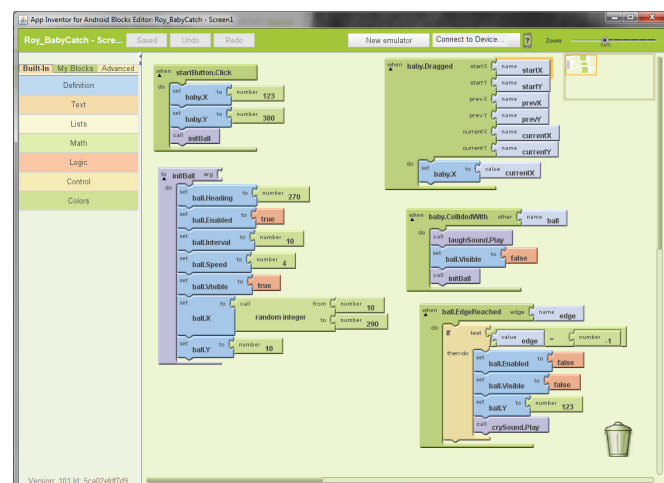

Suitableness for introducing basic computing concepts: Several factors make AIA more attractive as a platform for teaching elementary computing concepts. AIA is more general than GameSalad, which as the name implies, was designed specifically to facilitate game development. While GameSalad can be used to create non game applications, doing so can be pretty awkward. AIA provides ready-made blocks that allow students to use loops, incorporate simple data-structures (such as lists), and define variables and procedures without learning complicated syntax. While introducing OO concepts, objects and classes, is fairly straightforward, GameSalad does not provide support for data structures or loops, and is less extensible than AIA.

C. Usability and Operational Factors

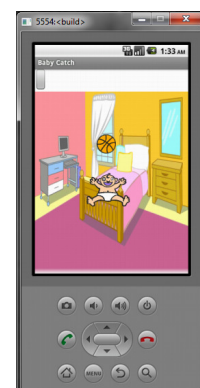

Quality of the software interface: Figure 1 shows the various components of AIA interface while Figure 2 depicts that of GameSalad for the same app. The AIA software interface has three main components, the browser based designer where the layout of the app is created (Figure 1(a)), the blocks editor which creates the programs for all the objects of the app

(a) AIA app designer

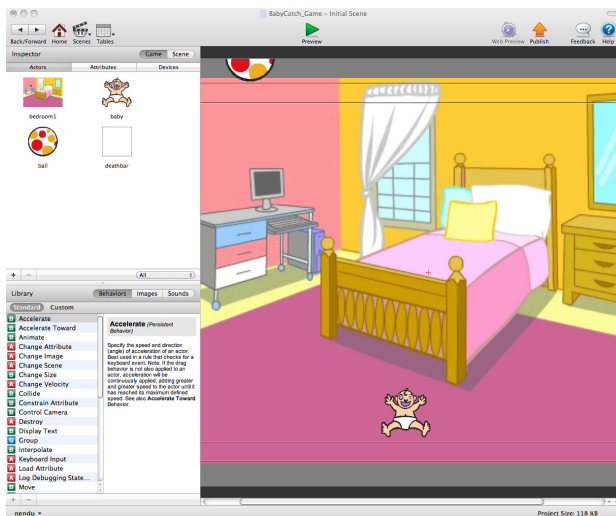

(b) Blocks editor

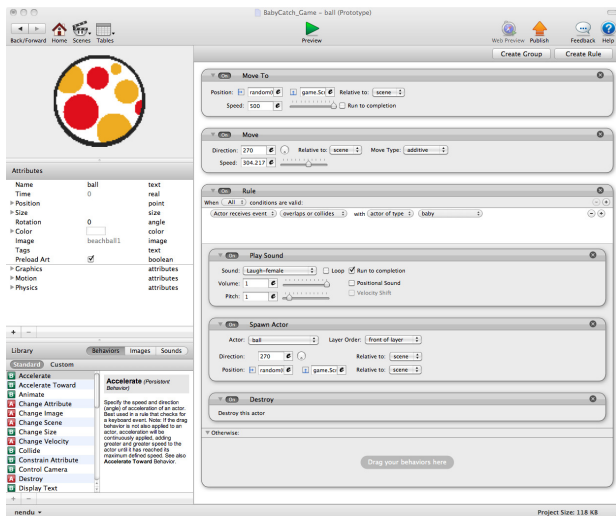

(c) Emulator

Fig. 1. The AIA interface

(a) GameSalad layout window

(b) Rules window

(c) Emulator

Fig. 2. The GameSalad interface

(Figure 1(b)), and the emulator (Figure 1(c)). When a student is creating an app, they have to move between these three components.

GameSalad also has three similar components, however they are integrated in a single window. Figure 2(a) shows the GameSalad layout window, Figure 2(b) the “rules” window with all the rules controlling the ball in this game and Figure 2(c) shows the working app running in the emulator.

In our opinion, GameSalad has a sleeker and more refined interface. Additionally, in GameSalad, rules for each object are separate unlike AIA where the single blocks editor window shows all the blocks for all the objects. This effects the readability of the code. In GameSalad it is very trivial to figure out what code corresponds to what object. Code object mapping is not as obvious in AIA.

Embedded social features: One of Scratch’s main strengths is its popular project gallery where thousands of users share their projects and codes. Neither the AIA website, nor the software has any support for an app gallery. However, researchers at University of Massachusetts at Lowell are currently creating such a gallery for AIA app and code sharing (it is under beta testing). GameSalad has better code and project sharing feature. GameSalad has a gallery on their website called Arcade and any user can publish their projects from within the GameSalad software to the Arcade.

App installation: It is easy to install apps created in AIA to a device. As long as the device is capable of installing apps from unknown sources, the AIA software itself can install the app to the connected device.

It is much harder to install an app created using GameSalad on an iOS device. This is not a limitation of GameSalad however. This has more to do with the fact that iOS does not allow the installation of any app unless it is through the app store. We feel students creating basic apps would not be able to navigate the app-store app submission and review process which will enable them to install their apps on their devices.

Platform dependence: AIA works both on PCs and Macs. Until recently, GameSalad was Mac specific software. GameSalad launched a windows version of their creator software in May of 2012. However, apps created using the Windows version of GameSalad cannot be directly tested or installed on an iOS device. A Mac is still needed to achieve this step. We believe this will be a major impediment in broader adoption of GameSalad as not many schools have a lab with Mac computers.

IV. CONCLUSION

To summarize, in this paper we compared AIA and GameSalad, two mobile NPEs based on various logistical, instructional, and operational factors. Mobile novice programming environments are relatively new, but they hold tremendous potential in attracting students to computing as they can appeal to the mobile-computing-centric mindset of today’s youth. Hence, our work and results will serve as a starting point for any educator who is making a decision about selecting a mobile NPE.

In our view, there is no one clear winner among AIA and GameSalad. Both the NPEs have their strengths and weaknesses. GameSalad might be more suitable in schools that have labs with Mac computers and in programs where there are no expectations for students to work on their own computers outside of class and for programs in which the primary goal is to get students excited about development rather than more serious introductions to computer science. AIA on the other hand might be more suited for a more formal CS setting where the ultimate goal is programming proficiency. In this paper we detailed various factors that will affect the decision of selecting one NPE over the other. In the future we plan to broaden this work to cover more mobile NPEs and more relevant factors based on which a comparison can be made. We also plan to conduct a quantitative study on the effectiveness of different features of the mobile NPEs in teaching computational concepts to novice programmers.

ACKNOWLEDGMENTS

We thank Dr. Larry D. Hilgert, Associate Professor, Department of Psychology and Counseling, and the iDocs group at Valdosta State University for loaning us an iPad used in this research.

Abstract—Audience Response Systems can benefit the normal course of the classes. Dedicated Audience Response Systems can be quite expensive to purchase and maintain. Additionally, the question types supported are somewhat limited, usually only choice questions are available. In our previous works we have developed a set of OpenSocial gadgets that can be included in a personal iGoogle page. Our future work is centred in providing a electronic voting system based on gadgets with iGoogle using mobile devices as smartphones and laptops for voting.

Keywords: Audience Response System; iGoogle; OpenSocial; gadget;

I. INTRODUCTION

An Audience Response System (ARS) allows teachers to ask questions to an entire class that can answer electronically [1]. The teacher displays a question on a screen and the students send their responses to a receiver using their remote devices. The results are collected, summarized and presented to the class. The participation can be made anonymously or identifying the participants by increasing the teachers' efforts and the complexity of the devices. The system is usually composed by a receiver, responsible of storing the answers and dispatching the result statistics, and a set of remote devices used by the students. Many devices support simple choice questions and some of them numeric text entry, so teachers cannot make complex questions to the class.

New technologies are involved in our everyday life; this concerns both teachers and students. It is not uncommon for students to bring smartphones or laptop to class. We must consider that mobile devices have more computing and communication capabilities. Current smartphones can use a Wi-Fi connection or a data plan from any cell operator to get access to Internet. For these reasons, an ARS using these technologies can be developed and maintained at lower cost than normal systems.

In previous experiences we have developed a set of OpenSocial gadgets to provide e-learning specific features over iGoogle. As part of the testing we realize that although iGoogle

offers a complex presentation in a normal Web browser, it has a simpler layout for small devices. Our works are centred in modifying the students' gadget Edu-GAL (Educational – Gadget Activity List) [2] and create a new gadget called Edu-GAR (Educational – Gadget Audience Response) in charge of displaying in-class questions and let students to answer them.

II. RELATED AND PREVIOUS WORK

Existing ARSs are composed by remote control devices that are specifically developed for this purpose. In this way, they must be purchased and maintained in good conditions. Other problems with the use of these devices in the class are that students can damage or loss them. Some remote devices use infrared (IR) to communicate remote devices with the receiver. This type of communication needs to have direct vision between transmitter and receiver, which can be difficult to obtain in a crowded class.

On the other hand, the current trend in mobile phones is to create more advance devices. Our last survey to our students revealed that the 40% of them have a smartphone with Internet access or Wi-Fi connection and the 87% have a laptop. These devices are used by the students in their everyday life, so students will take more care about them than other casual devices.

There are cheaper approaches in the development of an ARS using Web-based solutions (compatible with mobile devices); but they usually provide support only for a restricted amount of participants and as the teacher needs more features (i.e. multiple users, identify participants, etc.) the price increases significantly.

In previous works, we make a set of OpenSocial gadgets focused on providing e-learning functionalities to iGoogle: learning paths, activity creation/completion/monitoring and resources manipulation [3]. These gadgets provide a Graphic User Interface (GUI) to a sub-set of the Web service functionalities. Gadgets are not linked to a particular Web service and support different types of activities. One of the

activity types supported is centred in the answer of a questionnaire composed by IMS QTI [4] based questions (currently only simple and text-based) to evaluate the students' knowledge. We created one gadget for each of the following learning roles: authors, teachers and students.

Our gadgets can make use of existing Web service to create and display information to the users. The communication can be made anonymously or identifying the user to provide personal information. Users can do some actions according with the Web service limitations. This approach allows users to take advantage of existing gadgets to compose their personal learning environment and help themselves:

- creating activities as authors using Edu-GAAT (Educational - Gadget Activity Authoring Tool),
- managing activities and checking students' results as teachers using Edu-GAM (Educational - Gadget Activity Manager)
- attempting activities and completing learning paths as students using Edu-GAL (Educational - Gadget Activity List)

III. PROPOSAL

The developed gadgets are small applications that ask for information to the Web service when needed (e.g. when a user selects one resource the gadget asks the Web service for its content). There isn't any synchronization method. We are planning to modify Edu-GAL to create a new gadget called Edu-GAR (Educational - Gadget Audience Response) that will periodically poll the Web service searching for new questionnaires. This new gadget will display one questionnaire composed by one or several questions at a time, if there is any published. Users will be able to select between two operation modes: automatic polling or manual polling. The former polls the Web service periodically and the latter let users decide when to poll for information. Manual polling reduces the amount of traffic generated during the class.

To provide a complete ARS, teachers should use Edu-GAAT to create activities before the class starts setting it as unavailable. When the class begins the students can prepare themselves accessing their iGoogle page with Edu-GAR selected. During the class, the teacher will enable an activity using Edu-GAM. Edu-GAR will display the questionnaire with a small delay, depending on the gadget's configuration (if there are more than one activity at a time, it is the Web service duty to decide which activity is shown). At this point students can answer the questions and submit the results. Once the time is over, the teacher can stop the poll by setting the activity as completed and check the result statistics using Edu-GAM.

IV. CONCLUSIONS

The gadgets can be used by any smartphone with a Web browser regardless of the operating system (i.e. iOS, Android,

Windows Mobile or BlackBerry OS). The creation and the maintenance of a specific application for each operating system may be time consuming and overtake the developers' workload.

This approach can decrease the price of the creation of a new ARS, and its maintenance is simple. The only need is to create/find a Web service to store and process the information. There is not necessary to purchase any remote device for voting; the cost of an ARS using this approach is independent of the number of participants.

The iGoogle page is related to the personal account of each student and gadgets can use OAuth protocol to make signed requests to the Web service. This fact eases the participant identification because every student will be logged with her/him personal account; students don't need to log an additional account in order to participate. For this reason, a student can use different devices along the course without being tied to a single remote device; moreover, devices can be also shared to give support to different students.

Our proposal is not suitable of making first-to-answer questions because students won't be using the same cell operator neither a device of identically specifications. Another drawback can appear when a student outside the class has her/his iGoogle page open during the poll. In this case, s/he may be able to answer to the questions. At this point the teacher should check the amount of responses and the identity of the participants if only in-class answers are allowed.

Using this gadget the teacher may be able to create more complex questions than choice interactions and make questionnaires of more than one question.

Special Session: What do student-generated diagrams say about their understanding?: Developmental trajectories of model-based reasoning in engineering students

Joseph M. Le Doux, Wendy Newstetter, and Alisha A. Waller, *Member, ASEE*

Abstract—The main goal of this special session is to foster a continuing conversation within the FIE community about model-based reasoning in general and the essential role of diagrams in engineering education in particular. During this session, small groups of participants will develop categorization schemes using a collection of student diagrams. Groups will share their categorization schemes and ideas through a gallery walk.

Index Terms— Diagrams, Expert – Novice, Model-based reasoning, Think aloud protocols

THE main goal of this session is to foster a continuing conversation within the FIE community about model-based reasoning generally and the essential role of diagrams in engineering education specifically.

It is our hypothesis that experts solve problems in CSTEM disciplines by using a complex series of cognitive moves in a non-linear and iterative fashion, in contrast to the linear problem solving described in textbooks and often modeled in classrooms. More specifically, the expert must navigate three semiotic systems as she transforms a textual/linguistic account of a problem to a diagrammatic representation and finally to a symbolic mathematical representation. At each stage, salient elements are extracted and re-presented in a new semiotic form. Such cognitive transformations are grounded in model-based reasoning, or the ability to represent a system with its interactive parts or dependencies, which is a form of reasoning fundamental to engineering problem-solving.

Motivated by the importance experts place on diagramming, cognitive scientists have conducted numerous studies to understand the role of diagrams in problem-solving. These studies have shown that it is a complex phenomenon with multiple facets and that not all diagrams are helpful for

solving problems. Despite the complexities, it is clear that drawing diagrams can facilitate multiple aspects of the problem solving process.

This session turns the lens around and asks what we can learn about student understanding from the diagrams they produce. How do a student's choices about which features to include from the text and which to ignore indicate their conceptual understanding? How does their decision to abstract a particular part into a black box with inputs and outputs reveal the knowledge they bring to the solution process? If a student draws a more realistic depiction of a process, does it indicate a lack of abstraction of thought?

During the session, participants will solve a problem which requires a diagram and then work in small groups to categorize the types of diagrams produced by students. The goal is to discover what a diagram might say about the students' model-based reasoning and conceptual understanding. The small groups will produce bulletin boards for a gallery walk, followed by a period of reflection and integration of ideas.

The session agenda includes:

- Introductions of people and session
- Example problem
- Mini-lecture on Representational transformation
- Small group work: Creating a categorization scheme for the diagrams. Goal of scheme is to identify how well students understand diagrammatic reasoning
- Gallery walk
- Small groups reflection and wrap-up

Since diagrammatic reasoning is important in all STEM disciplines, we expect this session to appeal to a wide variety of FIE participants. Faculty who teach courses requiring diagrammatic reasoning should find the session very useful. Since there has been very little rigorous research on the text to diagram translation, education researchers interested in cognition, representation, problem solving, and design will find the session thought-provoking. In addition, attendees who are interested in community and identity formation will find the session relevant as different disciplines have different community-sanctioned diagrams and diagramming standards.

J. M. Le Doux, Ph.D. is with the Wallace H. Coulter Department of Biomedical Engineering, Georgia Tech and Emory University, Atlanta, GA 30332 USA (404-385-0632; e-mail: joe.ledoux@bme.gatech.edu).

W. Newstetter, Ph.D. is with the Wallace H. Coulter Department of Biomedical Engineering, Georgia Tech and Emory University, Atlanta, GA 30332 USA (e-mail: wendy@bme.gatech.edu).

A. A. Waller, Ph.D. is with the Wallace H. Coulter Department of Biomedical Engineering, Georgia Tech and Emory University, Atlanta, GA 30332 USA (e-mail: Alisha.Waller@gatech.edu).

This research is supported by NSF REESE #1109309.

Finally, since the topic is truly at the frontiers of current research, graduate students who participate will be introduced to an area ripe for research.

This session will introduce the FIE community to a frontier area of research which is rich with questions and opportunities. We expect that it will start new lines of conversation and collaboration across STEM disciplines, resulting in new research projects. Participants will benefit from the opportunity to think deeply about diagrams and what they reveal about students' understanding.

Finally, this session is the beginning of a planned series of Special Sessions and research papers by the facilitators to be presented at FIE conferences over the next several years.

Challenges and Issues in the Development of a Software Engineering Simulation Game

Daniela C. C. Peixoto, Rodrigo M. Possa, Rodolfo F. Resende, and Clarindo Isaías P. S. Pádua

Federal University of Minas Gerais, cascini@dcc.ufmg.br, rmposa@dcc.ufmg.br, rodolfo@dcc.ufmg.br, clarindo@dcc.ufmg.br

Abstract— In Software Engineering courses, students are introduced to important theories and concepts. However, these courses lack a practical opportunity for students to experience them more effectively. Even with the team-based project approach it is not possible to train students in all the real situations of a software development organization, due to the very nature of software applications and the large variety of organizational cultures. Simulation games are an appropriate complementary approach to the traditional educational techniques. Students' preparation can be improved by allowing them to practice, through a simulator, activities that are infeasible to practice during a Software Engineering course, due to restrictions of time and resources. Unfortunately, the creation of a simulation game is not a straightforward activity; it involves many different skills and addresses different viewpoints. In this work, we discuss the issues and challenges associated with the creation process of a Software Engineering simulation game. We adopted an incremental and iterative approach, where each step involves different knowledge, allowing us to point out a set of important aspects that should be taken into account during the development. These aspects can guide new developers and instructors in the design and selection of educational simulation games.

Keywords- *software engineering; simulation game; software process improvement*

I. INTRODUCTION

Simulation in education can be an effective tool for enhancing complex subjects learning and understanding. By using a simulator, several aspects of difficulties can be planned and experienced without great risk, with low cost and without logistics restrictions [1]. A Software Engineering simulation game provides an environment where development processes are practiced by “playing” them [2]. In this environment, a common situation is for the players to receive a task that should be completed during the simulation game.

The development of simulation games with the aim to improve students' learning experience is gaining increasing attention [3]. A number of simulation games have been developed [2], [3], [4], [5], [6], [7], [8], and [9]. Most of these simulation games make use of a software development project that drives the game play [10]. Typically, they have a graphical user interface which simulates a software development organization, creating a game-like environment. The main goal is to create an enjoyable atmosphere that will make the learning process more effective.

The design process is at the heart of the simulation games development [11]. Despite the design process importance for attaining students' learning, we have noticed that it is not

receiving much attention in the literature. The steps that should be taken into account during the simulation game design are (i) Software Engineering concepts addressed by the game; (ii) the game-like elements used to enhance motivation and the effectiveness of learning; and (iii) the modeled real world phenomena.

In this article, we address the design decisions took during the development of SPIAL, a graphical and interactive Software Engineering simulation game, highlighting the faced challenges and issues. The aim of SPIAL is to improve Software Engineering education in dealing with the complexity of what happens in a real software development organization. Using SPIAL, we evaluated how a Software Process Improvement (SPI) simulation game can teach to students the best practices of Software Engineering. The results of this research can guide new developers and instructors during the design and selection of educational simulation games. Our study confirms the high level complexity of this subject and the missing process support for Software Engineering simulation games development.

The remainder of this paper is structured as follows. Section 2 outlines the related work on Software Engineering simulation games and a brief description of SPIAL. Section 3 presents an overview of the steps carried out during the simulation game design and development. Section 4 discusses the issues and challenges of our development approach and Section 5 presents the final considerations and future work.

II. BACKGROUND

Most of the simulation games have as their goal to develop a software project within a certain set of constraints, and their rules are based on Software Engineering lessons (e.g. SimSE [2], SESAM [5], SimJavaSP [6], and MO-SEProcess [7]). Typically, they present a metaphor of a software development office, where the player assumes a project manager role. The experimental evaluations of using these tools have shown a restricted number of new concepts that students have learned after playing them [2], [12]. This can be a result of a not straightforward performance feedback that is presented to the students, or the way that the virtual world was designed. In order to address these aspects, we changed the context from Project Management to SPI and we integrated feedback during the whole simulation game playing.

SPIAL (*Software Process Improvement Animated Learning Environment*) is a graphical, interactive, simulation game, which emphasizes SPI concepts. Despite its focus on SPI, it is a teaching tool that reinforces Software Engineering concepts to students.

SPIAL is a single-player game in which players take on the role of a manager of an SPI group in a software development organization. The player is given a process improvement task and he/she can interact with other stakeholders (high level management, project manager, team member, consultant, or customer) represented as non-player characters, i.e. a character controlled by the computer (see Figure 1). In order to complete the task, the player can make investments for improving specific process areas of a software development project (which can be considered a pilot project). A good investment strategy will result in improvement of process areas and a bigger budget for further investments. SPIAL incorporates some of the concepts defined in CMMI-DEV version 1.3 [13] (*Capability Maturity Model Integration for Development*). In the first SPIAL version, we considered an organization with maturity levels 1, 2 and 3, with capability levels of process areas varying between 0 and 3.

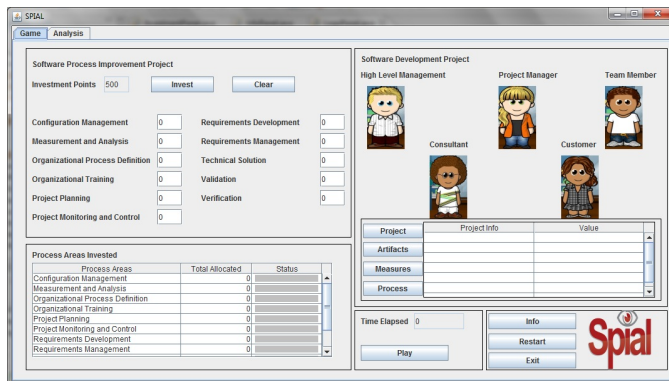

Figure 1. SPIAL Graphical User Interface.

The player can visualize project estimations, indications of process areas capability level and decide in which process area to invest. During project execution, the player can visualize the effects of his/her selections on the outcomes (productivity, defect, cost, and time-to-market measures) and if needed, change his/her investments. The occurrence of events follows some probability distribution, for example, the software development team can have resistance to adopt the changes, and the player can overcome it with specific actions, such as promoting training. The final outcome is a score that represents how close the results are to the initial proposed target. During the game, the non-player characters communicate the effects of the player's actions through bubbles over their heads, for example, "Since there is dependency among process areas some of your investments may not be effective", or "Poor investment decisions result in a reduction of business value, and a reduction in the number of investment points."

The analysis tab sheet (see Figure 2) was designed with the aim to give players a better insight of the correctness of their decisions, specifically providing graphical information about the measures, the description of the rules used in the game, information about the achievement or not of their improvement targets and the final score. All events occurring during the game are recorded in the events log table.

For illustrative purpose, we elaborate the following initial scenario, which is a narrative description [14] of what the user

(in our case, the player) will perform and experience as he/she makes use of the application:

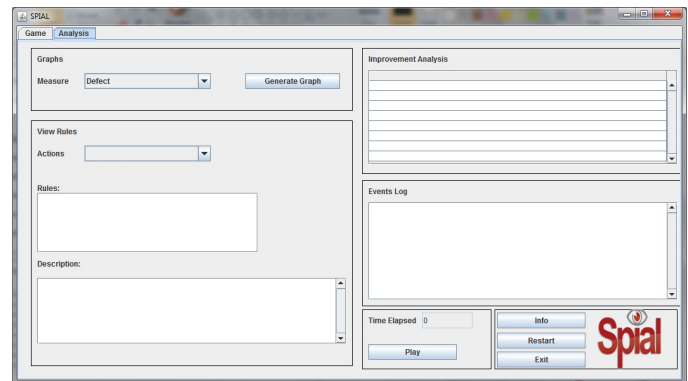

Figure 2. SPIAL analysis tab sheet.

"You are a student of a Software Engineering course and you already know some concepts of Software Engineering. Now, you want to learn more about Software Engineering, with emphasis in software process improvement, using a simulation game. You need an intuitive game to help you learn how software process improvement works in the industry, the software process improvement techniques and the best practices of Software Engineering [motivation]. In this game, you will play as a manager of an SPI group [player role] and your responsibility is the coordination of a process improvement in a specific project. You need to analyze the current situation of the project and select in which process areas to invest. The type of improvement that is required [improvement task] will be stated at the beginning of the game and it can include, for example, reduce defects, improve the productivity and/or reduce costs [goals]. After making investments, you can verify their effects on the process areas capability level (status column) and on the defect, productivity, cost or time-to-market measures. Right investments will increase the budget of investment points and wrong investment will decrease it. Other possible functionalities are: you can stop your game, you can see the Software Engineering rules applied in the game and you can receive information from the team. During the whole game you can see your performance and some tips about the available functionalities. At the end you receive a final score."

III. AN OVERVIEW OF THE SPIAL DESIGN AND DEVELOPMENT STEPS

In the course of SPIAL development we adopted an incremental and iterative process, comprising the following steps:

A. Identification of students' mistakes

We investigated the common problems incurred by students in a Software Engineering course [15]. The most striking observations are the difficulty that students have to bridge the gap between the theoretical lectures and the team project, the limited range of skills that they apply during the project development, and, usually, they do not follow the prescribed software development process during the team project development. They first elaborate the technical artifacts and then they complete the baseline with the managerial artifacts.

In SPIAL, students can reinforce and learn concepts related to the best practices of Software Engineering and SPI. Specifically, students can practice concepts related to technical and managerial aspects of software development (CMMI Levels 2 and 3); follow the stages of a development process in an organization; learn the events that can occur during an SPI project (e.g. resistance to change and high-level management commitment); and observe the results of improvement actions changing an immature software development process to a more mature process (e.g. the reduction of defects).

B. Analysis of other simulation games

We identified and compared the main Software Engineering simulation games [10]. Based on this analysis, we defined the essential design aspects for the development of our simulator. The assessment of the simulation games revealed that, although they are, in some cases, developed with different aims, they have a considerable number of common aspects, for example, "trial and error" strategy, goals, rules and some game features. They also have different features mainly regarding the feedback instant and type, and the adaptability characteristics. Five important design characteristics that we took into account during the SPIAL design are: clear goal/rules, feedback, realistic virtual world, adaptability and game features. Regarding the feedback, it is important to have informative and performance feedback during the whole game. This provides challenge for the players and motivates them [16].

C. Investigation of the SPI and Software Engineering domains

We investigated the domain of our simulation game. Since a simulation game should reflect what happens in the real world, we analyzed the main results reported by organizations in research papers regarding their SPI initiatives. Through a systematic literature review [17], we gained an up-to-date view of the SPI area, allowing us to identify and characterize the actual results of SPI initiatives. In the SPIAL context, the results of this study provided the bases for the simulation model and requirements definition. We observed that SPI initiatives do not bring "dramatic" changes (the improvements in measure values are between 5 and 35%); the main common reason for launching SPI efforts is the reduction of the defect rates detected during development and after delivery; and the companies did not describe the context where the initiatives happened, preventing us a better assessment.

In addition, we collected 123 Software Engineering rules from text books and other Software Engineering simulation games. These rules are used to teach the best practices of Software Engineering to students, rewarding or penalizing their actions. This set includes rules that are imprecise (do not specify values) and rules beyond the Software Engineering area, including a wider range of business processes. From this set, we selected the ones related to the SPIAL process areas, resulting in 57 Software Engineering rules. For example: "Requirements deficiencies are the prime source of project failures." [18], and "A combination of different V & V methods outperforms any single method alone." [19]

D. Development of SPIAL

Based on the steps carried out previously we identified

important requirements for our simulation game, which were used in the definition of the SPIAL behavior.

We evaluated the available components for simulation games development. Since we did not find components that were generic enough to be reused, we decided to develop our own framework, FASENG [20]. FASENG has three main components: simulation model, simulator, and simulation engine. The simulation model is used to represent the structure and behavior of the simulated process. Instructors can tailor a simulation model according to their course. The simulator takes the simulation model as input and interprets it, calculating the behavior of each element. The simulation engine is a component which the player interacts with, receiving visual feedback of the simulation results and being able to change the model parameters.

FASENG was developed based on a set of selected requirements related to the application of learning theories. Specifically, requirements specifying (i) main focus on students and their learning process; (ii) learning acquisition by students; (iii) interactivity; (iv) complexity of real world problems; (v) reflection about the learning subject; (vi) teamwork skills; and (vii) different learning styles. Since there is a clear structural and conceptual separation among these components, they can be reused in new developments. Nevertheless, FASENG and SPIAL requirements had some interplay not discussed here.

E. Evaluation of SPIAL

Finally, we evaluated SPIAL from two viewpoints: specialist and player.

An inspection using the Semiotic Inspection Method [21] was conducted by a specialist and communicability breakdowns were identified¹. According to the specialist, despite feedbacks given during the whole game, such as measurement charts and improvement analyses, important aspects to understand the core behavior were missing, such as the reason why sometimes investments do not produce any improvement.

We evaluated the game carrying out a pilot experiment with undergraduate students of a Computer Science Software Engineering course as players. We selected (i) questions to evaluate whether students enjoyed the game; (ii) questions that evaluate the students' perceptions about the appropriateness of the game; these were organized in eight dimensions [12]: duration, difficulty, content relevancy, correctness, sufficiency, sequence, teaching method, and adoption in a Software Engineering course; and (iii) questions about the learning perspective. The first two categories of question are related indirectly with the learning, showing how effective is the educational environment. The students' answers were mapped to a value range $R = [0,1]$, where a "strong negative" is encoded as "0", a "weak negative" as "0.25", undecided as "0.5", "positive" as "0.75", and a "strong positive" as "1". We recruited 12 undergraduate computer science students to participate in this pilot experiment (one student gave up, leaving us with 11 students). Table I presents the average results for each question (some questions depend on material not presented here). On average, students found the game quite enjoyable and they had fun during the game play. They also felt

¹ We have used this information in order to enhance SPIAL.

that the game duration is appropriate and it is relatively easy to play. They agreed about adopting this game in a Software Engineering course as a complementary approach. They moderately learned new concepts; however, they felt this game more successful in reinforcing concepts taught in Software Engineering course than teaching new concepts.

TABLE I. ANSWERS FOR PILOT EXPERIMENT.

| Question | Avg |
|---|------|
| Did you enjoy playing this game? | 0,84 |
| Did you have fun during the game play? | 0,75 |
| Is the game duration adequate? | 0,70 |
| Is the game difficult to play? | 0,59 |
| Are the Software Engineering concepts covered by the game adequate considering the classes? | 0,68 |
| Did you feel that the game reflects a real SPI initiative? | 0,64 |
| Is the game sufficient for its purpose? | 0,70 |
| Is the play sequence satisfactory? | 0,73 |
| Is the game an adequate complementary teaching method? | 0,91 |
| Do you agree with this game adoption in a Software Engineering class? | 0,91 |
| Did you learn a lot about new Software Engineering concepts playing this game? | 0,40 |
| Did you learn a lot about practical application of an SPI program in an organization? | 0,47 |
| Is the game useful to reinforce Software Engineering concepts that were presented in class? | 0,62 |

IV. DISCUSSION

The primary purpose of educational simulation games development is to match the learning objectives tightly with a suitable solution. The design and development is an iterative process, involving a number of different skills and activities. During this process, designers select the conceptual content to be addressed, model the real world processes, and employ suitable game-like elements to represent these processes and concepts. The final goal is to create an environment that can motivate and engage students. These steps are illustrated in Figure 3 and described in the following subsections.

A. Conceptual content

The conceptual content of SPIAL was designed around the Software Process Improvement, Software Engineering rules, and Software Engineering process concepts. Our first challenge was to define the reference model that would work as the subjacent theoretical background. In the analyzed SPI initiatives, the most widely adopted models are the ones from SEI, CMM and CMMI. Therefore, we decided to use the latest version of the CMMI model (CMMI-DEV version 1.3 [13]), which guided the definition and validation of the mathematical framework represented in our simulation model. Typically, other simulation games employed some abstraction of a software development process, rewarding or penalizing students according to a selection of Software Engineering rules (e.g. SimSE [2], SimJavaSP [6], and MO-SEProcess [7]). They lack a basic reference which can guide designers in the simulation model definition and validation.

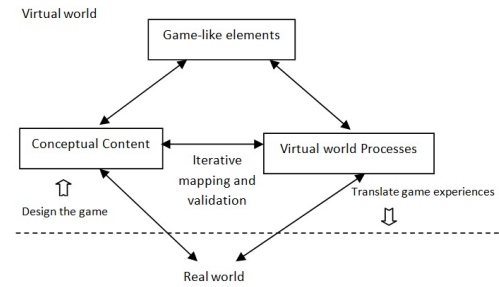

Figure 3. Educational simulation games design. (adapted from Martin [11])

SPIAL was designed to be used as a complementary tool in an introductory Software Engineering course. As a research work, it was not our purpose to cover all the SPI body of knowledge. In this way, we restricted the process improvement concepts to the basic ones of CMMI Level 2 and 3, not covering tools or specific methodologies (e.g. adoption of a requirement tool or execution of a perspective-based reading review), only process issues. Since our simulation system can be extended for more advanced classes, this restriction can be overcome by including into the simulation model high-maturity levels concepts.

The selection of the rules was a task that took us a considerable effort. The reason is that we were interested in rules that can be applied in a simple waterfall development project, covering some concepts of CMMI. In most of the cases, either these rules are too generic or they are from other domains (e.g. agile software development). We restricted the set of the rules to be applied in this simulation game (57 of 123 rules). We mapped each rule to a specific process area of the model (e.g. Requirements development) and the corresponding measurements that they can impact (e.g. defects and productivity). This helped us in the calibration activity of the simulation model.

The set of concepts to be covered by the game should be defined according to the students' needs and the instructors' teaching objectives. It is not possible to address all the content of an introductory Software Engineering course, so designers and instructors have a non-trivial task to select which concepts would be covered by the simulation game. In our case, we conducted a case study to identify the recurrent problems detected in the artifacts produced by students. The lack of students' preparation for dealing with real world Software Engineering projects has also been recognized by the industry [22], [23]. This was an assurance with respect to the main problems that we have identified [15]. Example of these problems are students not following a prescribed process, not being able to make the connections between theoretical lectures and their practical applications, and lacking of skills, mainly managerial ones. With SPIAL we tried to overcome the students' deficiencies, focusing on basic concepts of Software Engineering such as: process, project, product, artifact, stakeholders, Waterfall development process, requirements, design, implementation, test, and software measures (defects, cost, productivity and time-to-market). In addition, we focused on the following software process improvement concepts: pilot project, process areas, improvement investments, motivators and de-motivators factors, and capability levels.

B. Virtual world processes

The simulation game is anchored in a particular reality where players play roles of characters in a particular situation following a set of rules and interacting with other characters. The settings, players' role, and players' activities are important design aspects related to the virtual world where the game occurs [10]. In respect of the virtual world processes, we can, for instance, think of flows of information or resources, and interactions between actors [24]. Since the simulation model is a simplified representation of the reference system, it is not feasible to depict all elements and relations on it.

In SPIAL, we identify the core virtual world processes from the analysis of SPI initiatives reported by organizations in research papers. In most of the research studies, the context where the improvement happens was not defined. This brought some difficulties during the reuse of information and restricted the number of phenomena represented into the simulation game. We observed this problem when we conducted the validations. Five students (45%) were undecided regarding the real aspects of an SPI initiative presented in SPIAL, five students (45%) felt that they learned only basic new concepts (i.e. not advanced concepts) of SPI, and also six students (55%) reported that they only learned the basics about the real world of SPI initiatives in organizations. Examples of the represented phenomena in SPIAL are:

- When the organization is immature, players have no access to the measurements that can help them to monitor the development project improvement and progress. In the real world, this corresponds to an organization where the measurement processes are not defined.
- When players have doubt about which process areas to invest, they can meet the (virtual) team members responsible for each area (e.g. the non-player characters requirements manager or test manager) in order to collect more information about the main process problems. In addition, they have to make the connection between the problem description and the corresponding process area, for instance, the problem: "Baselines of identified work products aren't established" is related to the Configuration Management process area and the problem: "The inspections are not carried out for every artifact", is related to the Verification process area.
- The team can be resistant to some improvements. In order to avoid the impact on the investments, the game has features allowing players to pay for team training/mentoring, or improvement feedback.

Another important issue in the simulation development is the simulation model calibration. One first barrier for the calibration of our model was the lack of specific values of the Software Engineering rules. Since most of these rules are quite imprecise, it is not possible to map them directly into the simulation model. In addition, most of the SPI studies reported only qualitative evaluations. When the quantitative evaluations were available, the information was limited, or it had validation problems, preventing their application in our model. We incorporated rules and SPI results by experimenting them with different values and we selected the values that were most suitable for an educational environment. We made sure that the

real system is approximate sufficiently well by the simulation model and students can check the effects of their actions.

C. Game-like elements

Educational games incorporate some features that do not exist in the real world, for example score or fantasy, mainly to enhance challenge, motivation, and in consequence, improve the learning process. The game features can be used to represent the concepts and processes of the simulation game. The designer should evaluate the trade-offs of representing these concepts and processes in a graphical or in a textual way.

In SPIAL, we considered essential the following game features which can also be found in other Software Engineering simulation games: not too easy nor too difficult life-like challenges (e.g. constraints on the investment budget, and the target of defects and cost reduction); interaction (player can stop the simulation at any moment to make investments or to access measurements information); feedback from other stakeholders represented as non-player characters (we use bubbles over the stakeholders' head and also a table that informs players whether they have achieved the measurements targets); random events (during the improvement some team motivators and de-motivators factors can occur, e.g. the senior management is committed with the improvement or the team is resistant to improvement changes); graphical representation (players can check the measurement charts evolution during the whole project); and performance indication (at the end players receive a score).

V. CONCLUSION

This work presented an analysis of the steps carried out during a Software Engineering simulation game development, named SPIAL. The development process comprised five steps: (1) Identification of students' mistakes; (2) Analysis of other simulation games; (3) Investigation of the SPI and Software Engineering domains; (4) Development of SPIAL; and (5) Evaluation of SPIAL.

Our experience with SPIAL has highlighted some important aspects that can be used to enhance the field of Software Engineering education and simulation game development. The most concrete result is the simulation game itself, along with its SPI simulation model. SPIAL was developed using a reusable framework, which allows its adjustment to distinct learning environments. This can assist students with different learning styles, different levels of initial knowledge and instructors with different expectations and objectives.

Another important result corresponds to a set of issues that emerged during the simulation game design and development. These issues can guide new developers and instructors in the design and selection of educational simulation games. It was identified:

- The importance of having a core theoretical reference model, in order to assist the simulation model definition and validation. During the preparation of experiments, this model can assist in the questions definition.
- The considerable effort needed to filter the Software Engineering rules. They should be selected for each specific simulation game domain.

- The importance of concepts definition scope to be covered by the simulation game. This should be done according to the students' needs and the instructors' teaching objectives.
- The influence of the virtual world processes addressed by the simulation game on the students' learning. It is interesting to include activities that trace back concepts, processes and game-like elements during the design step.
- The considerable effort needed to calibrate the simulation. In the Software Engineering area, it is difficult to find enough data in the literature (or with appropriate quality level). Beyond the instructor, as discussed in Section III.D, we can appeal, for example, to specialists to help in the model calibration. However, we need to verify whether the results approximate the real world and whether they are suitable for an educational environment.
- The game-like elements assist the students' learning process, enhancing challenge and motivation. The designer needs to select which concepts and processes will be represented as game-like elements.

As a future work, we plan to address important issues detected during the first evaluations, mainly incorporating other phenomena that happen in the real world. This will make the simulation closer to the real software development organizations. We will also carry out additional experiments in order to assess other aspects of SPIAL, as for example its relationship with the instructor.

Abstract— Simulation games can help teaching and learning in several areas of Software Engineering. One important research issue is providing support for simulation games development, making the results of their adoption successful in Software Engineering courses. In this work, we identify a set of requirements focusing on some of the Constructivist learning theories. These requirements were used to evaluate Software Engineering simulation games. Based on these requirements, we created FASENG, a framework for development of Software Engineering simulation games. FASENG has three main components: simulation model, simulator, and simulation engine. Since there is a clear structural and conceptual separation among them, they can be reused in other development environments. In order to check the framework flexibility, we developed two distinct Software Engineering simulation games. The two main results of this research are a better understanding of Software Engineering simulation games requirements and the development of FASENG.

Keywords— software engineering; simulation games; requirements; framework; software engineering education

I. INTRODUCTION

In the Software Engineering field, one of the greatest challenges is to provide practical experience to students in order to handle a number of situations intrinsic to the software development [1]. Students should be able to identify practices and techniques that can be applied in a real software development project. This is a complex issue due to the very nature of software applications and the large variety of organizational cultures [2].

Besides the traditional teaching methods, alternative approaches have been created to attempt to be more close to what happens in real organizations. This includes executing programs that resemble the medical residency programs [3], requiring students to apply software quality engineering concepts in an industrial representative real-world project [4], and using simulation games [5].

Simulation games¹ seem to be an appropriate complementary approach to traditional lectures [6], [7]. One reason is that they are quite natural for students who grew up using computers, cell phones and other gadgets, i.e. “Digital Natives” [8]. Unfortunately, there is no agreement regarding the main simulation game aspects that support learning, the process for engaging students and the type of learning results [9]. This is essentially related to the difficulty of designing an effective educational simulation game.

In this work, our main motivation is to support simulation game designers and instructors during the creation and selection of simulation games for educational purposes. In this

context, one important research issue is to identify which requirements make the results of the simulation games adoption successful in Software Engineering courses. We present a study of requirements in terms of Constructivist learning theories. These requirements were used to evaluate eight Software Engineering simulation games. The results of the study show that some learning theories, even having potential to be applied, are rarely addressed by the analyzed simulation games. In order to have some support during the development of simulation games, we created FASENG, a framework of reusable components that addresses the identified requirements. In order to check the framework flexibility, we developed two distinct Software Engineering simulation games.

The remainder of this paper is structured as follows. Section 2 outlines the background of our work. Section 3 presents the requirements considered for FASENG development. Section 4 describes the framework architecture. Section 5 depicts FASENG initial applications. Section 6 discusses some of the research limitations and Section 7 presents the final considerations and future work.

II. BACKGROUND

In contemporary history of pedagogy, we can find several approaches for learning processes, such as [10]: Behaviorism, Cognitivism, and Constructivism. Considering software development characteristics and these approaches, one suitable complementary paradigm for Software Engineering courses is the constructivism [1]. Constructivism focuses on learning instead of teaching, encourages the information construction and discovery-oriented approaches [10].

When discussing educational approaches, it is essential to connect this discussion to the theories that describe how people learn, i.e. learning theories. In our work, we evaluated the following learning theories related to constructivism²: **Learning by Doing** (individuals learn actually doing a task, not only hearing about it), **Discovery Learning** (individuals learn by discovering the knowledge on their own), **Situated Learning** (individuals learning are situated, being in large part a product of the activity, context and culture in which the knowledge is developed and used), **Anchored Instruction** (individuals learn in a context similar to the real world), **Constructionism** (individuals learn by constructing or doing something), **Learning through Reflection** (individuals learn when they reflect on their learning experience), **Cooperative and Collaborative Learning** (individuals learn when they help each other to achieve a goal or learning about something), **Elaboration Theory** (individuals learning is facilitated when the information is organized in order of complexity, from least

¹ In this work, simulation games are defined as simulation tools with some game features (e.g. fantasy, mystery, or challenge).

² <http://www.instructionaldesign.org/theories/index.html> presents some theories of learning and instruction, retrieved March 22, 2012.

complex to most complex), and **Aptitude Treatment Interaction** (individuals learn when the learning environment is tailored to their aptitude).

III. REQUIREMENTS

The creation of the simulation framework started with the identification of common requirements found in the Software Engineering simulation games. In order to obtain these requirements, we conducted a Systematic Literature Review (SLR) [11] with the aim to evaluate the following aspects of existing Software Engineering simulation games:

- Characteristics that promote the application of the learning theories associated with Constructivism.
- Design decisions adopted to deploy each identified characteristic.

Our SLR research procedures are the same carried out in Peixoto et al. [2]. The identified simulation games are: SESAM [12], SimSE [13], The Incredible Manager [14], SimJavaSP [15], MO-SEProcess [16], SimVBSE [17], qGame [18], TREG [19]. When we conducted our evaluation, we not only read the related articles, but whenever possible we also played the simulation games.

The identified characteristics were organized as a catalog of requirements, similar to the one used by Hoffmann et al. [20]. They are important for the following roles:

- **Instructors** who adopt a simulation game as a complementary approach to the traditional educational methods. These requirements can assist them during the simulation game selection process.
- **Designers** who need to know which requirements are more effective for the learning process and the way they are implemented.
- **Players** who play the game to complement their knowledge in specific Software Engineering subjects.

Table I shows the requirements traced back to learning theories and Table II shows whether the simulation games implemented them.

The requirements are presented next.

REQ1 - A simulation game should give support to the transfer of learning: It is important for players to understand the lessons of a simulation game and develop their own mental model [10]. In consequence, they will be able to transfer this knowledge to a real situation. Transfer of learning happens when the knowledge, skills, or information is transferred from one situation to another [10]. A good transfer of learning occurs when the performance in real situation is improved [10].

Two common characteristics were found in the evaluated simulation games that can enhance the transfer of learning. The first one is the players' active role during the whole game, e.g. as a project manager, they can hire or fire employees. The second one is to allocate players to a hypothetical work or to a problematic situation, where they need to develop solutions. The most common scenario in the evaluated simulation games is students acting as project managers in a project with time, quality and budget constraints.

REQ2 - A simulation game should be interactive: One of the most beneficial aspects of simulation games is their ability to engage learners in meaningful activities through various forms of interactivity [10]. These include actions such as: making choices and decisions, manipulating objects, reacting to events, and collecting information [10]. Interactivity gives the player a sense of control over the game, improving motivation during the learning process.

The interactivity characteristic is presented in all the analyzed games with different levels of implementation. For example, SimSE implements all the actions listed above, in contrast, in qGame, players can only make choices.

REQ3 - A simulation game should reflect the complexity of the problems found in the real world: Besides simplifying the environment, it is important to support learners working in complex situations [10]. Fast and flexible simulations allow repeated experiences and different situations can be introduced and practiced [10]. The goal is that players act in specific roles, solve the problems, and observe the effects of their decisions. Simulation games can take different paths depending on the players' actions and reactions. Therefore, a simulation is a case study involving a specific reality where players play roles with responsibilities and restrictions.

All the simulation games implementation fully satisfied this requirement. For instance, the task allocation follows some of the complex aspects of the real world such as the allocated person should have the abilities required for the corresponding task.

REQ4 - A simulation game should facilitate the reflection about the learning subject: Some studies have shown that students who are encouraged to reflect on what they are doing, learn better both the declarative and procedural types of tasks [21]. Therefore, active reflection on experiences during activities carried out in a Software Engineering course (e.g. team project) promotes the acquisition of more meaningful and persistent learning [21].

In a simulation game, one example of an element with great potential for reflection support is the revisiting session, which is generally referred to as the debriefing sessions [22]. In this session, it is possible to analyze the decisions taken during the game, draw conclusions and make the connection with the real-life situation. Unfortunately, none of the assessed simulation games provided any guidance for carrying out the debriefing sessions. Another element that can promote partial reflection is the explanatory tool or a feedback mechanism, allowing individual performance assessment.

REQ5 - A simulation game should support teamwork skills development: It is well-known that computer science students need to learn communication and collaboration skills [23]. Although many programs today make team projects fundamental elements of their curricula, students receive almost no orientation about how to work effectively in a team [23]. One way to meet this requirement is to build multiplayer simulation games. In these games, players can collaborate among themselves, allowing students to develop teamwork

TABLE I. LEARNING THEORIES AND REQUIREMENTS.

| Theories vs. Requirements | REQ1 | REQ2 | REQ3 | REQ4 | REQ5 | REQ6 |
|--|------|------|------|------|------|----------------|
| Learning by Doing | √ | √ | - | - | - | - |
| Discovery Learning | - | √ | √ | - | - | - |
| Situated Learning | √ | - | - | - | - | - |
| Anchored Instruction | √ | - | - | - | - | - |
| Constructionism | C | - | - | - | - | - |
| Learning through Reflection | - | - | - | √ | - | - |
| Cooperative and Collaborative Learning | - | - | - | - | √ | - |
| Elaboration Theory | - | - | - | - | - | C ^b |
| Aptitude Treatment Interaction | - | - | - | - | - | √ |

a. “√” indicates that this requirement facilitates the application of the specific theory. “C” indicates that theory application is conditioned by the way that the requirement was implemented. “-” indicates that we did not identified a relationship.

b. This requirement tracks to the theory where the difficulty level increases gradually.

TABLE II. SIMULATION GAMES AND REQUIREMENTS IMPLEMENTATION.

| Simulation Games vs. Requirements | REQ1 | REQ2 | REQ3 | REQ4 | REQ5 | REQ6 |
|-----------------------------------|------|------|------|------|------|------|
| MO-SEProcess | √ | √ | √ | P | √ | - |
| qGame | P | P | √ | P | P | P |
| SESAM | √ | √ | √ | P | P | P |
| SimJavaSP | √ | √ | √ | P | P | - |
| SimSE | √ | √ | √ | P | P | P |
| The Incredible Manager | √ | √ | √ | P | P | P |
| TREG | P | P | √ | P | P | - |
| SimVBSE | √ | √ | √ | P | P | - |

a. A simulation game can address the requirement completely “√”, partially “P”, or not “-”.

skills (e.g. MO-SEProcess). In contrast, single-player simulation games, where players can interact with other Non-Player Characters (NPC), i.e. a character controlled by the computer, can address partially the teamwork skill (e.g. qGame, SESAM, SimJavaSP, SimSE, The Incredible Manager, TREG, and SimVBSE). These games have some restrictions in representing real work situations, as communication breakdowns and conflicts between team members.

REQ6 - A simulation game should support different learning environments: The learning process may vary among students. Some students may learn better by watching and listening, others by reading, and others by doing and moving or using a hands-on environment [24]. Adaptation of the learning environments can assist students with different learning styles, different levels of initial knowledge and different expectations and objectives [25]. Adaptation can be static, for example, increasing the complexity in the course of the game, allowing students to choose different simulation models, or instructors to change the simulation model. Adaptation can be dynamic, for example, if players have some difficulties during the simulation game, a hint can be presented to them or the difficulty level of a task can be decreased gradually [26].

Among all simulation games that we found, no one presented dynamic adaptation features. Three of them support different simulation models: SESAM, SimSE and The Incredible Manager; and only qGame has different levels of difficulty.

IV. FRAMEWORK

The knowledge of Software Engineering simulation games and their common requirements, and the lack of support to simulation games development led us to the decision to create our own framework, FASENG (*Framework for Software Engineering Simulation Games*). FASENG is composed of three components (simulation model, simulator, and simulation engine) that can be reused in new simulation games creation (see Fig. 1). These components can also be found in other Software Engineering simulation games [12], [14], however, in our case, they can be reused in new developments. In the first version of this framework, we developed components that support requirements REQ1, REQ2, and REQ3, and partially requirements REQ4, REQ5, and REQ6.

A. Simulation model

The simulation model represents aspects of the world to be simulated (REQ3) and it is defined externally in a XML file. The applicability of a simulation model depends on the model builder’s ability to capture these aspects [14]. In essence, the Software Engineering processes are difficult to model, mainly because of their intrinsic characteristics, mostly involving human behavior, such as, non-linear relation of cause and effect, feedback cycles, dynamic behavior and socio-cultural issues that can affect them.

In the XML file, instructors can tailor a simulation model according to their course (REQ6). This model allows the

representation of an active role to players (REQ1), reaction to events (REQ2), feedback (REQ4) and different participants to actions (REQ 5). We used some modeling constructs similar to those defined by SimSE [13]. These elements are shown below followed by a corresponding XML excerpt.

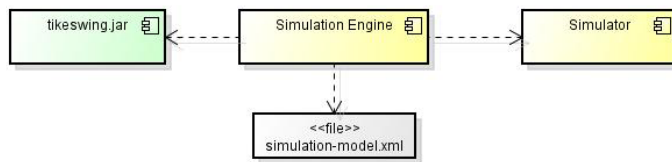

Figure 1. FASENG architecture.

Object types: The object types define the templates for all the objects. The object type consists of a name, a boolean value indicating whether a log will be generated for each object and a set of attributes. For each attribute, its name, type, and two boolean values can be defined. The boolean values indicate the visibility of the object (i) during the game and (ii) at the end of the game. Unlike SimSE, there is no object type creation restriction.

```
<type name="ImprovementProject" log="false">
  <attribute name="InvestmentPoints" type="integer" visible="true"
    visible-end="true"/>
</type>
```

Initial state: The initial state contains a set of objects that are active at the beginning of the simulation. Each object is an instantiation of a given object type, containing initial values for their attributes.

```
<object name="IProject" type="ImprovementProject">
  <attribute-value name="InvestmentPoints">500</attribute-value>
</object>
```

Analysis: The analysis represents types of rules that are created specifically to provide some performance feedback to the players. It contains the name of the analysis and a reference to their implementation.

```
<analysis-result>
  <analysis-result name="Improvement_Analysis" class="br.ufmg.dcc.
    engsoft.spial.analysisrule.RuleImprovementAnalysis"/>
</analysis-result>
```

Actions: The actions represent a set of activities presented in the simulated process, for example, give training to the team or invest in some process area. Each action has a name, description, one or more rules, one or more participants, a trigger and one or more destroyers. Triggers, rules, and destroyers behavior is implemented in Java language. The advantage of this approach is a greater power of expression.

```
<action name="investment" description="Investing in Process Areas" >
```

Participant(s): The participant restricts the types of objects that can participate in the action, as well as their minimum and maximum amount.

```
<participant name="ProcArea" type="ProcessArea" minimum-occurrence="1"
  maximum-occurrence="2"/>
```

Trigger: The trigger represents a condition to start the execution of an action. There are three distinct types [13]: autonomous, player, or random. Autonomous triggers cause the action to begin automatically, without player interaction. Player

triggers start actions when players carry out some operation, for example, selection of a menu item. Random triggers specify the likelihood of the action to be executed. Triggers can cause the end of the game and the calculation of a score; this is represented by the “game-ending” parameter.

```
<trigger name="investmentTrigger" type="player" user-operation="Invest"
  description="Investment in Process Area" class="br.ufmg.dcc.engsoft.
  spial.trigger.TriggerPlayerInvestment" game-ending="false"/>
```

Rule(s): Rules specify the effects of the execution of an action. They modify the objects attributes that participated in the action. Each rule identifies the time of its execution, which can be: trigger, destroyer, or continuous. Trigger rules will be executed at the time the action is triggered. Destroyer rules will be executed when the action is destroyed. Continuous rules, on the other hand, will be fired every clock tick, representing continuous behaviors of the model. Rules also specify the order they will be executed through the “priority” parameter.

```
<rule name="investmentRule" description="Investment made in some
  process area" timing="trigger" priority="3" class="br.ufmg.dcc.engsoft.
  spial.rule.RuleDiscretInvest"/>
```

Destroyer(s): Opposite to the triggers, destroyers represent a condition to ending the execution of an action. It has four types: three like the triggers (autonomous, random, or player), and an additional one: timed. The timed destroyer specifies the duration of an action (time-to-live).

```
<destroyer name="investmentDestroyer" type="timed" time-to-live="3"
  class="br.ufmg.dcc.engsoft.spial.destroyer.DestroyerTimedStandard"
  game-ending="false"/>
```

B. Simulator

A great number of simulators are either continuous or discrete. Since in software projects both mechanisms are presented, we decided for a hybrid approach in which [27]:

- At a higher level of abstraction, the structure of the software process, activities, interactions and artifacts are best modeled by a discrete event approach;
- At a lower level of abstraction, the behavior of the activities and the factors that influence the simulated project are best modeled by a continuous approach.

In the simulator component, aspects of discrete events are used to represent individual objects (e.g. process areas, and artifacts), actions (“give training or mentoring”, “make an investment”), conditions of triggers and destroyers, and the rules executed at the start or at the end of an action. The continuous characteristics are represented through continuous rules, which are performed at each step of the simulation, whether the actions that define them are currently active.

The simulator runs in a loop. For each time step, it looks whether the conditions of triggers and destroyers were satisfied, executes continuous rules, generates log, and gives feedback to the players. If triggers or destroyers conditions are satisfied, the rules associated to the actions are checked. Continuous rules are fired every clock tick, whether their respective action is active. The log is generated for the object types defined in the XML file. The calculations of performance feedback are defined by the instructor. The detailed communication between the simulation engine and the simulator is shown in Fig. 2, using a simplified UML diagram.

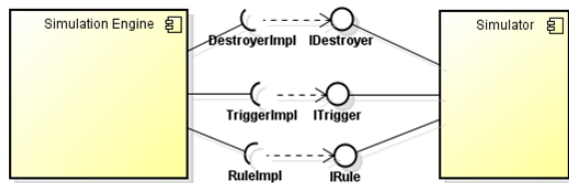

Figure 2. Communication details between simulation engine and simulator.

The simulator has several component interfaces, representing the start (triggers) and end (destroyers) conditions for each action, as well as rules to be executed. Since there are several types of triggers, rules, and destroyers, a hierarchy of interfaces was created in the simulator component. For each condition or rule to be created in the simulator engine, an interface of the simulator should be implemented in a Java class. Then the rule class must be referenced in the XML file of the simulation model. When the simulator encounters this class name in the simulation model, it learns which class should be instantiated. The simulator was designed to handle the simulation model, defined externally in an XML file, and to generate the internal representation of it.

C. Simulation engine

The simulation engine is a component with which the player interacts, receiving visual feedback from the simulation results and through which the player changes the model parameters. This component uses the MVC (Model-View-Control) design pattern, which allows the separation of domain logic from the user interface. TikeSwing³ was used in the implementation of this design pattern. During the tailoring phase, instructors can change the interface according to their needs, without worrying about other aspects of the application (model and control). Since the Software Engineering simulation games can have different scopes, we did not restrict the interface design to fixed graphical elements.

V. SIMULATION GAMES DEVELOPMENT

We created two simulation games using this framework in order to make initial validations of its flexibility. In both of these games, it is required basic Software Engineering knowledge. The first one was a simplified version of the waterfall SimSE model⁴. This simulation model consists of employees, artifacts, tools, project, and customer object types. A participant plays the role of a project manager of a team of developers. The player's goal is to develop a software project within a certain set of constraints.

The second simulation game is called SPIAL [28] (see Fig. 3). SPIAL simulation model contains initial game description, process areas, improvement project, development project, motivators and de-motivators SPI factors, development process, artifacts, stakeholders, control measurements, and analysis. A participant plays the role of an SPI group manager in a software development organization. The player is given a process improvement task, and he/she can interact with other stakeholders. The goal is to achieve the established improvement targets of defect, cost, time-to-market and productivity. This simulation game has 16 rules and 12 actions. The validations demonstrated that SPIAL can be

beneficial to reinforce and teach new Software Engineering concepts. Students mentioned having fun during the game play.

Using this framework it was possible to represent distinct simulation models. The instructor's work was restricted to the definition of the simulation model, rules implementation, and GUI design.

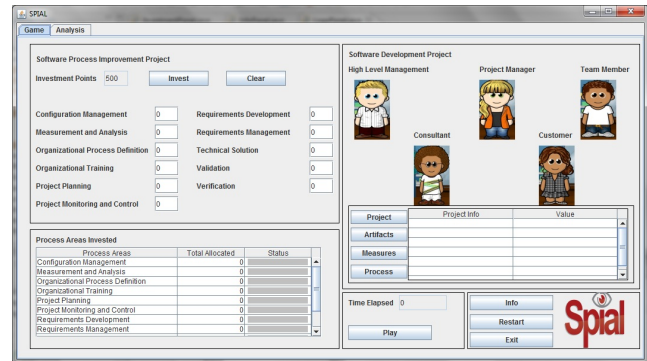

Figure 3. SPIAL Graphical User Interface.

VI. LIMITATIONS

Regarding the limitations of this study, one could argue that we did not identify all requirements that can be traced back to the described learning theories. Although this is a valid criticism, we believe that for the evaluated Software Engineering simulation games they are appropriate, mainly considering an initial development of a reusable framework.

As one of the aims of this research was to develop a reusable framework, a broad validation mechanism should be carried out. We did not create validation mechanisms to verify requirements from different stakeholders' viewpoints (instructors and other developers). We only carried out a systematic literature review and an experiment with students using SPIAL. We obtained more positive than negative results. We expect that these initial results will help the investigation of further research questions.

We cannot *a priori* assume that the results of this study generalize beyond the specific environment of Software Engineering simulation games. We identified requirements exclusively from simulation games of the Software Engineering field. However, we believe that many considerations can be applied to the whole educational simulation game field.

VII. CONCLUSION

This paper described a study of simulation games requirements that can help instructors and designers during selection and creation of Software Engineering simulation games. The research took into account the best practices of simulation games development, their main characteristics and the learning theories related to Constructivism. Based on these requirements, we analyzed eight simulation games and we defined a framework, with three main components, that can be reused in new developments.

We observed that some learning theories, such as Learning through reflection, Elaboration Theory and Aptitude Treatment Interaction, were not completely addressed by the analyzed

³ TikeSwing is a framework for Java Swing development providing high-level MVC architecture.

⁴ <http://www.ics.uci.edu/~emilyo/SimSE/downloads.html>

simulation games. The identified requirements and the corresponding framework can support designers of new simulation games to address important learning theories during the initial development phases.

As a future work, we plan to enhance the framework evaluation considering, for example, other learning theories, and the interplay between requirements, implementation and validation. During FASENG development, we identified three roles: simulation game developer (who adapts the interface and creates the Java classes), simulation model designer (who specifies the behavior), and developer (who creates the XML file). We are planning to create guidelines for each of these roles and supporting tools, for instance, a tool to help simulation model tailoring and XML file creation.

Abstract— Students usually love games. They captivate their attention and hold it for lengthy periods of time. Educational systems have taken advantage of this fact and have used games in education for many years. However, teachers cannot create their own games as easily as they create other learning objects. A tool to assist this labor would be very useful for them. In this paper, we present NICE-Game, an innovative game-like educational content creation tool. It is divided into two modules, the builder to create the games and the viewer to play them. With NICE-Game, different kinds of educational contents (i.e. images, videos, texts) can be easily integrated into a game. Using personal handheld devices is a growing trend among students, hence multi-platform and multi-device issues have been also considered in this implementation. Details about the design, development and the tool itself are explained in this paper as well as an example of an educational game available online.

Keywords; *Games in education, NICE-Game, games and mobile—learning.*

I. INTRODUCTION

Teachers always try to increase students' motivation and the quality of the learning experience. With this same purpose, learning tools and methodologies are improved every day. They can benefit from the increasing popularity of video games and the spreading of personal devices such as smartphones and tablets, introducing video games in learning in order to motivate students and train specific competences.

Educational video games can be really improved with the introduction of new technologies. But the development costs are very high (even higher if we consider the opportunity costs of developing another kind of video game) and teachers or learning centers usually cannot afford it. Therefore, teachers usually have to resort to existing games. However, most of them are focused on specific topics that cannot be reused to explain in other academic subjects. The type of educational content used in the game (e.g. video, images or audios) or the content's language are important parts of the game that need to be adequate for students bearing in mind their context (e.g. age, gender, etc.).

This is the main problem that we found when started to create an educational game for the GLOBAL excursion

(Extended Curriculum for Science Infrastructure Online) European project (<http://www.globalexursion-project.eu/>).

GLOBAL excursion [1] is a supporting action funded by the European Commission under the Research and Innovation Infrastructures programme of FP7. The project will develop a common understanding, teaching use cases, as well as pedagogical and technical artifacts. The aim of this project is to provide young citizens and their educators (teachers, parents, etc.) across Europe with a range of e-Infrastructures and access to expert knowledge on its usage for a joyful exploration of e-Science through e-Infrastructure.

The main purpose of the GLOBAL excursion project is to enable students and teachers access to the experimental laboratories and resources of selected e-Infrastructures in order to improve science curricula by enriching school's existing teaching and learning materials.

In this paper we explain how this problem was tackled in GLOBAL excursion. With details about the design, architecture and development issues of the solution proposed. The rest of the paper is organized as follows. The next section reviews the state of the art in educational games. Section 3 explains our solution. Section 4 presents the results showing some captures of a game. In section 5 we discuss the issues that arose and section 6 finishes with some conclusions and future work.

II. RELATED WORK

The usage of games in education is a growing trend in recent years. Educational games have potential to improve students' motivation [2] [3], promote self-directed learning [4] and develop social and cognitive skills [5] [6].

The potential for educators to become involved in the development of educational games is substantial [6]. Interesting initiatives are providing frameworks to develop adaptive educational games, where teachers can create and evaluate their own games and simulations from scratch. Like those provided by e-ucm (www.e-ucm.es), a research group from Complutense University of Madrid, with several related projects and research lines like Game-Tel [7] and e-Training DS [8].

There are other commercial software packages available that make it easier to create computer games, replacing part of the programming by mechanism in which games are constructed from simple building blocks. Examples are StageCast (www.stagecast.com) that is particularly aimed at young kids or the products by ClickTeam (www.clickteam.com) or Game Maker [9].

On the other hand, mobile learning or m-learning is another interesting approach in Technology-Enhanced Learning (TEL). M-learning is defined as the provision of education and training on mobile devices [10]. The combination of m-learning and game-based learning can improve the attractiveness of the educational activities, promoting collaboration and competition between students or improving the immersion in games. As a result that combination offers new opportunities and scenarios for learning [11].

As smartphones and tablets come into play, m-learning and game-based learning have a great opportunity to reach a wider audience. Smartphones penetration rates are already very high in some countries and they are a growing trend in some others [12], [13]. Tablets penetrations are lower, but growth is promising [14].

With all these issues in mind, we have designed a web tool to introduce educational contents into games. Our main goal is to allow educators to choose the design of the game, introduce the educational content and customize the game story. The created game will have also to run on multiple devices such as smartphones or tablets.

III. NICE-GAME: NATURAL INTEGRATION OF CONTENT AND EDUCATION IN A GAME

A. Scenario and Architecture

NICE-Game is a web tool to integrate educational content into simple games. It can be divided into two sub-tools: one to create the game (i.e. Game Builder) and one to visualize the generated games (i.e. Game Viewer).

The content types that can be integrated in the game are texts, images and videos. Considering the combination of these types of contents, like with classroom presentations, the teacher (or game creator) will be able to generate very interesting and amusing lessons. Different games can be created for different targets depending on the pupils' age, the topic to be addressed or the time that the teacher wants to dedicate to create the game.

Teachers will be able to choose the content from a pool of educational contents available in the NICE-Game platform. They will also be able to upload their own content or indicate the content URL in case it is hosted in another site. So with the combination of the three kinds of content, they can create enhanced educational games.

In the initial phase of our scenario related to the GLOBAL excursion European project, the available content will be provided by the scientific infrastructures participating in the project. But as more teachers join the platform, this content will be increased.

Once the game has been created it can be accessed from any kind of modern device, either tablet, smartphone or laptop/desktop computer. Even televisions when they have web browsers will be able to execute these games (although maybe we will have to change the interaction mode to adapt it to the television interface). In addition, the game viewer can be easily integrated in any kind of learning management system (LMS) such as Moodle or Blackboard, as it is visualized in a browser.

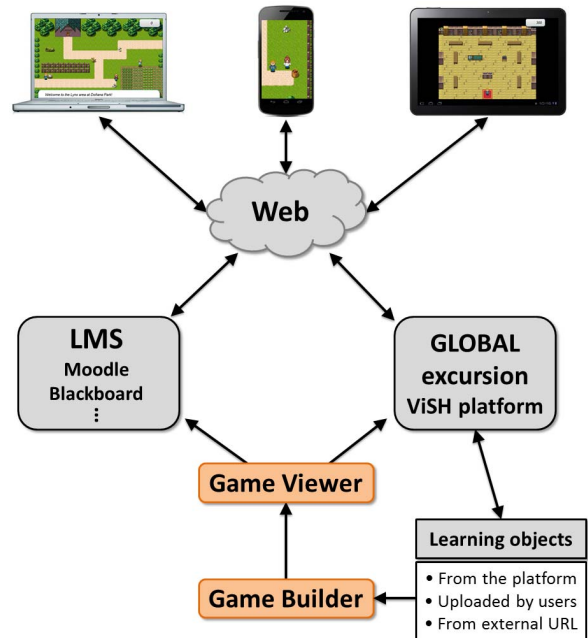

Figure 1. NICE-Game architecture

Figure 1 illustrates the NICE-Game architecture composed by several modules that are going to be described in detail in the next sections.

B. Game Builder

Once a user (usually a teacher) registers and logs into the platform, she/he will be able to create a game. The process of game creation is divided into three phases. In the first phase the user have to select the game levels and in the second and third phase she/he can customize the points of interest (POIs) and non-playing characters (NPCs) of each level.

1) Selection of the game levels

The first phase consists of selecting the game levels. The builder currently offers several screenshots to choose, each of them with a different design (e.g. library, laboratory, nature, etc.). The selected levels have to be dragged to the final positions. In every level the player starts in the left side and enters the next level in the right side (see figure 2).

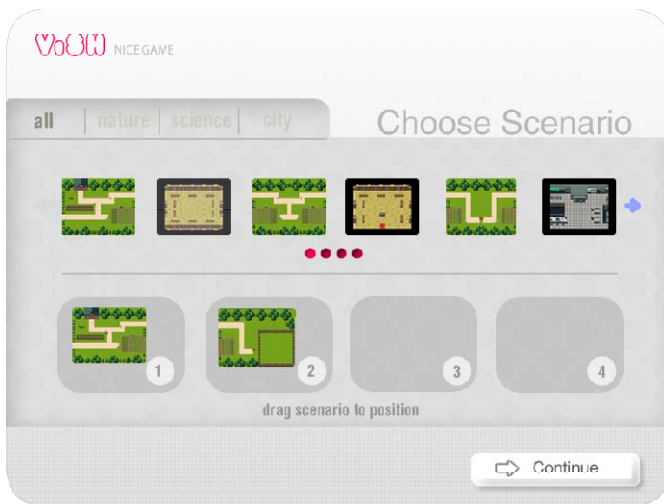

Figure 1. Level selection

The way we achieve this phase is one of the main differences between our solution and another solutions presented in the related work section. In some frameworks, teachers have to upload the background images and the characters with all the movements. The resulting game is usually very poor or requires a lot of work and design knowledge from the teacher side.

Game design is a very complex task [15], [16] and with this phase we try to avoid teachers to worry about it. They only have to select a scenario among a growing number of them.

2) Adding POIs and NPCs

In the second phase the user will be able to add interactive objects (POIs or NPCs) to the game and place them where desired. Some scenarios have more default decorations and more free space than others (see figure 3).

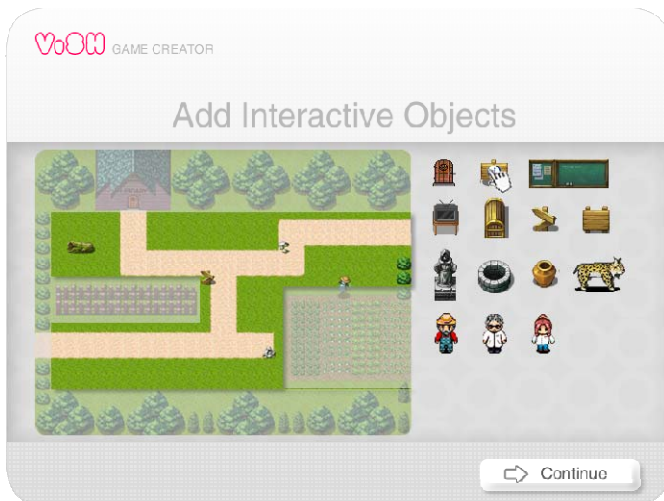

Figure 2. Add interactive Object

3) *Add educational content*

The final phase is focused on adding the educational content and write dialogues and multiple choice questions.

Three possibilities exist to add content:

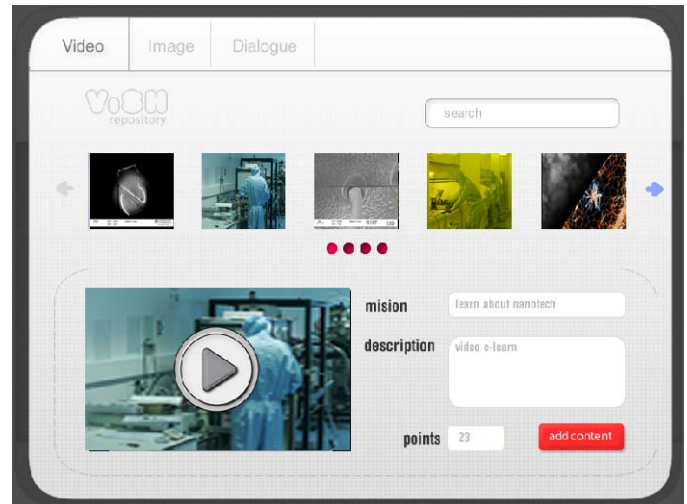

Figure 3. Add educational content

For the NPCs the user can add any dialogue and/or multiple choice questions. The limitation (at least in this first version) is the lack of interactivity. There is no workflow definition and no conditions, the NPC tells the player all the dialogue with the only possibility of answering a multiple choice question if any.

Together with the educational content a mission can be defined as an educational objective that has to be consumed by the student (e.g. study the presentation at the blackboard to learn things about the biology of the lynx). These missions will give points to the student and unlock new scenarios (if they exist) so as to motivate her/him to complete the whole game. As a result, the teacher has to define not only the mission itself, but also the score related to every mission in this phase (see figure 4).

C. Game Viewer

The game viewer is a component that allows the integration of the educational game in any modern device browser. It works offline, as there is no interaction with the server during game playing time.

The main difference here is about the player controls. In the laptop or desktop computer, the character is controlled with the keyboard, whereas in touch screens there is a virtual pad.

As the game viewer works in the device browser and there is no need to install anything on the user's device, it can be integrated in any LMS or web page as any other external web resource.

After loading the game, the user gets some welcome screens that explain how it works, how to move the character (depending on the device used) and how to interact with other objects (POIs) and characters (NPCs).

Then, while playing the game, the user gets points when progressing with the educational contents related to the missions defined. By using this scoring method, we try to increase the user motivation and amusement. There is also available a missions' panel that indicates what the user has done/viewed, and what remains undone to guide her/him through the game.

D. Implementation: Technological Decisions

The technology that we have used to develop this solution is HTML5 (HyperText Markup Language, version 5 [17]). HTML5 is the standard for the web. This new version allows many new possibilities like game developing based on the canvas, geolocation or device multimedia access between many others.

The main advantage of HTML5 is that it is standard and any modern browser runs it. So what is developed in HTML5 can be executed in any device with a browser in it (even new televisions and car entertainment systems are starting to include a browser in them). Any server technology is compatible with HTML5. In our case we have used Ruby on Rails. The server hosts the game builder, the generated games and the game viewer.

For the game builder, the server has a pool of educational resources stored in the GLOBAL excursion platform. It also allows the user to upload new objects (that will be automatically stored in the platform) or reference them via their URL. Once the game is created, the server stores the game generated, which definition is now based on JSON (JavaScript Object Notation). This JSON object contains all the information about the game levels, the POIs and NPCs and has references to the educational objects as absolute URLs.

For the viewer, the server will only have to send the files related to the game to the user to be shown in the user's device browser. As we have commented above, the game viewer can be integrated in any educational platform as web content in order to allow reusability in different contexts.

IV. RESULTS

NICE-Game has been developed in relation with the GLOBAL excursion European project. GLOBAL excursion has developed a platform called Virtual Science Hub (ViSH) to host all the activities carried out by the teachers and researchers in the project and to foster collaboration between them.

The initial fields covered in the project are nanoscience, biology, biotechnology, volunteer computing and grid computing. To enhance the students' interests and make this topics enjoyable and amusing for them, a new kind of complex

learning objects called virtual excursions have been defined. These virtual excursions are created by the teachers and consumed by their students, and NICE-Game is one of the possible types.

As a result, the architecture depicted in Figure 1 has been implemented and deployed inside the GLOBAL excursion project. Therefore, to create a virtual excursion the teachers have to follow the steps described in section 3 and select among educational contents hosted in ViSH.

An example (available at [18]) of a generated game can be seen in the figures 5 and 6. The scenario is related to a biology use case in which the students will learn about the Iberian lynx that lives in the Spanish Doñana Park. Doñana Biological Station [19] is one of the selected e-Infrasstructures that collaborates in the GLOBAL project providing information about the activities, fauna and flora related to the park.

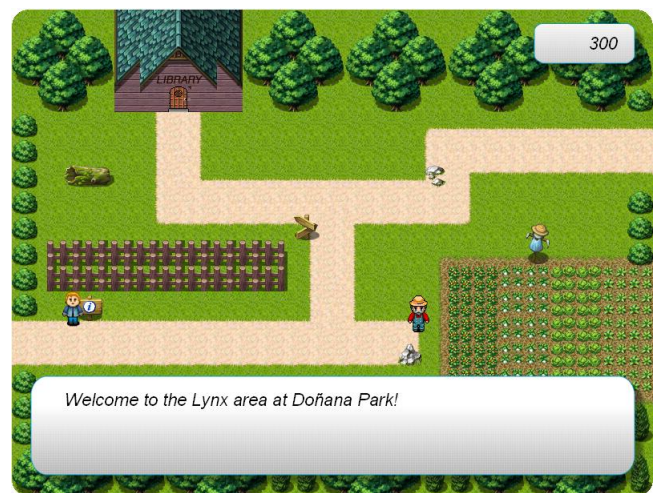

Figure 5. Player starting game

In Figure 5, we can see the nature scenario of a very simple generated game in which the player is interacting with a POI (i.e. an information point). There is also one NPC (a farmer in the middle) and a path to a next phase in the right.

Figure 6. Multiple choice question

In figure 6 there is another NPC that is making a question to the player related to the knowledge acquired in the previous phase.

Furthermore, as we can see in all the figures, there is a scoreboard in the upper right corner informing about the points that the student has won by completing the game missions.

V. DISCUSSION

Designing a new model to create educational games in a proper and easy way considering aforementioned issues was our first priority. It has been based on taking important decisions related to the design and the technologies used.

The first one was about letting users upload images to be used as scenario maps or providing pre-designed scenarios. We decided to keep it simple by providing these pre-designed scenarios, allowing the teachers to concentrate their efforts on choosing the most suitable educational contents. This way, we eliminated a usability barrier and the resulting games look more professional as we avoid teachers from designing their own characters, elements and scenarios.

On the other hand, the way to add dialogues was also very controversial. Some existing tools allow the user to create a workflow with the possible dialogues. This way they create interactive dialogues with conditions where the player can choose options. From these complex workflows we only took the possibility of making multiple choice questions, as we consider them enough to assess what the students have learned in the majority of cases.

Finally, the technology chosen (i.e. HTML5) has numerous advantages as we have summarized above, but it also has some objections. The most important related to our use case is that we cannot integrate any flash object (e.g. videos) with it. Hopefully the number of HTML5 videos and educational objects are growing day by day in the Internet, and it is becoming a less important issue.

VI. CONCLUSION AND FUTURE WORK

In this paper we have presented NICE-Game, an innovative model to generate educational games based on integrating learning objects inside a game scenario that is built in an easy way by teachers. We have shown an innovative way of doing it using current web technologies like HTML5 or JSON, so as to make possible running both, the game builder and the viewer, in different platforms (e.g. Windows, Linux, etc.) and devices (e.g. desktop computers, smartphones, tablets, etc.).

This tool is being used now in the GLOBAL excursion project by its integration in the ViSH web platform. It is being evaluated now by teachers involved in the project and after that it will be released as open source tool and opened to the teaching community.

We have presented in this paper the first version of NICE-Game so there any many future works that we have considered.

The first functionality that we would like to add is about allowing teachers to get the students' results of the questions in the game. This way they can use the game as an assessment

method to check if the pupils have read the contents and viewed the videos and images.

Another interesting functionality to consider would be letting students to customize their characters (clothes, hair and skin colors, etc.) or involve them even more in the story in order to increase their motivation.

Exporting the game to educational standard formats such as SCORM and LOM will also be considered to facilitate the teachers the integration with their LMS corresponding to their specific institution.

An additional open issue to study is related to the number of resources hosted in the platform since it can be very high, and become higher with time (because when new researchers and teachers join ViSH, they will upload new resources from their institution). Recommendation of suitable learning objects to build the virtual excursions will be very important here to increase personalization and accuracy. This will make easier for teachers to select the most suitable learning objects depending on the context and subject they want to teach. The final aim of this task would be to recommend directly a finished game to the teacher to use it with his/her students if it is related, for example, to the teacher's subjects.

ACKNOWLEDGEMENTS

We wish to acknowledge our gratitude and appreciation to all the GLOBAL excursion project partners, and each one of the project team members, for their contribution during the development of various ideas and concepts presented in this paper. This work is financially supported by the European Union under FP7, Infrastructures.

Work in Progress: Integrating Game Design and Development into Undergraduate Biology Education

Yunkai Liu, Mary Vagula and Stephen Frezza

Gannon University, Erie PA, United States

liu006@gannon.edu, vagula001@gannon.edu, frezza001@gannon.edu

Abstract— While research has investigated the application of computational methodologies in undergraduate biology education, those approaches require students certain backgrounds from multiple disciplines. Recently, game design and development for education has moved into different fields of science, including biology. Several multi-media interactive products have been developed to simulate biological mechanisms and can be used by undergraduate students. However these approaches focus on students as game users and, not as game developers. Here, we propose an innovative approach to involve game design and development into undergraduate biology classroom. The approach assumes no additional background, and aims to increase engagement in the complexities of the course material through the process of game design and development. We initialized a case study that systematically combines a game application-driven project into genetics teaching. In the pedagogical experiment, undergraduate biology and computer science students designed educational games to enhance the speed and depth of comprehension of both biological and software engineering concepts. The result of this study shows that the reinforcement effects of biological education games apply differently on students with or without biology backgrounds.

Index Terms - Game Design, Game Development, Biology Undergraduate Education, Genetics, Software Engineering

INTRODUCTION

The computational components of undergraduate biology education have hardly changed in the last several decades, even though advances in computing have forever changed the practice of biological research. Some recent studies [1, 2] advocate the idea of applying computational methodologies into biology education. However, the strategy requires students to have significant prerequisite knowledge of algorithms, mathematical and statistical concepts, which could lead to a large amount of extensions and revisions of current biology curriculums. Moreover, principles and practices of software engineering and quality assurance are rarely introduced and adopted by biology major students. Recently, game design and development has become a fast growing major in computer science education [3, 4]. A few practices [3, 5-6] have been established to improve the learning curve of undergraduate biology major students. However, biology major student involvement in the phases of application design and development is not sufficient in most of those approaches because students are usually only considered as users.

Our innovative approach is to directly involve biology major students into game design and development. Students from biology, computer science, even bioinformatics, work

together on game application-driven projects, which are derived from college-level biology concepts. During the pedagogical experiments, we focused on research around three main questions: (a) Does the approach help biology major students reinforce their learning in biology? (b) Does the approach help biology major students better understanding the principles in software engineering? (c) Does the biological education games help general college students understand biology better?

OUR CASE STUDY

A. Game Design and Development

Gene expression, the Central Dogma of genetics, is proposed to serve as the biology context of the hybrid approach. During the game design and development, students are expected to answer the following questions. A) How to design a game story that fits the educational context? B) How to make it more intriguing and easier to use? C) What application architecture style or model is appropriate to demonstrate the biology concept? D) How to decompose and manage the system?

Three students majoring in biology and two students majoring in computer science volunteered to work on the project. The biology major students designed the games and prepared the project requirements. The computer science students develop two prototype applications. All five students met monthly over one semester. Google Project Hosting (<http://code.google.com/hosting/>) was used for project management. Monymoon, a social productivity platform, was used for team communications and collaborations.

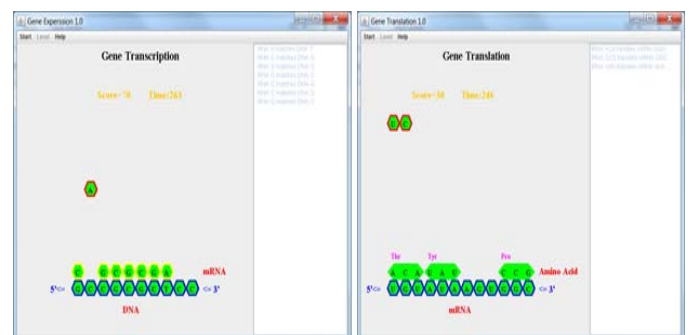

Figure 1. Tetris games for gene transcription and gene translation

The team developed two Tetris-like games (see Figure 1) to describe two phases of gene expression: *gene transcription* and *gene translation*. The applications were developed using Java.

The biology major students served as the content experts, and referred back to their textbook for the details of the genetic concepts. Moreover, creative biological questions, such as “what is the color of DNA nucleotides”, were derived during the game design. Due to the systematical collaboration, both biology major and computer science major students had better understanding of the principles and practices of software engineering, such as objected-oriented, standards and reusability. These prototype games, as developed by students for students, were then used for educational and usability testing.

B. Educational and Usability Testing

We obtained IRB approval to conduct a pre- and post-game study comprising of three focus group sessions. A total of 74 junior students from either biology major or computer science major participated in the focus groups. 25 of students are NOT or only A LITTLE familiar with the content before playing the games, 28 students are SOMEWHAT familiar with the content, and 21 students are familiar with the content.

We self-designed two quizzes to evaluate content performance of students before and after playing the two games. Both quizzes contain the same content-evaluation questions related to gene expression. In the pre-quiz, we inquired the background of each student and their familiarity with the content. In the post-quiz, we also inquired a) their completion status of games, b) entertainment worthiness, and c) educational achievement. Extra questionnaire are provided for students on improving the games. Most items used a 5-point Likert scale with response options from “1 = Strongly Disagree” to “5 = Strongly Agree”. Students have 30 minutes to complete the pre-quiz, two games and the post-quiz.

In our initial results, majority of students finished the games (91% for gene-transcription game and 76% for gene-translation game) on time. The average grade of pre-quiz is 62; and the average grade of post-quiz is 79. 89% of students think the games are worth their time (entertaining); and 81% of students think the games could enhance biology learning in college-level (educational).

We are analyzing the focus group sessions to determine how biological education games affect populations with different science backgrounds. The comparisons of feedback on different groups are showed in Figure 2. Those who are not familiar with genetics (group 1) improved 26 point after playing the games; while those who are already familiar with the topic (group 3) only improved 7 points. The t-test of the average improvement also shows the difference between group 1 and group 3 is statistically significant (p-value is 0.0016).

Preliminary observations from the focus groups suggest that: a) games have better effect on those who are not familiar with the content than those who already knew them, and b) that students who are more familiar with the content think the games are more entertaining and less educational.

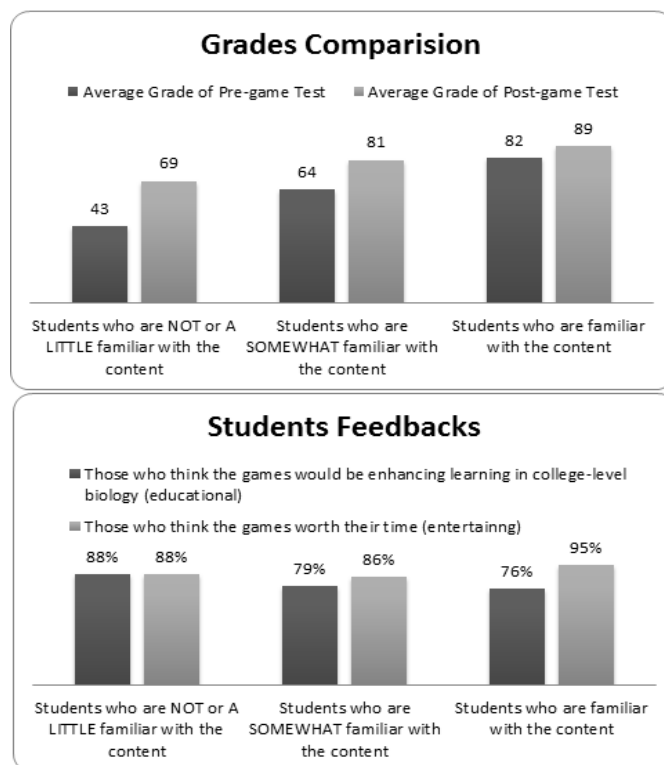

Figure 2. The average grade and feedback comparisons among three groups.

FUTURE WORK

We will complete the analysis of the focus group sessions. We also intend to repeat the process in a wider group of students or broader topics in the coming semester. In addition, we will conduct further statistical analysis by using mixed measurement item response theory (MM-IRT) to model the actual response patterns, rather than relying on the observed variable of backgrounds [7].

Work in Progress : Learning flow-of-control with FlipLogic:A game-based approach

Elham Beheshti and Michael S. Horn
Computer Science and the Learning Sciences
Northwestern University, Evanston, IL, USA
beheshti@u.northwestern.edu

Abstract— We present FlipLogic, a puzzle game that we developed to help children (ages 10-12) become familiar with conditional logic statements in programming. We designed the game to be embedded in an existing after-school curriculum on computer programming fundamentals. Our broader goal is to create a series of games to help students learn a variety of programming concepts including control statements, conditional branches, logic expressions, loops, and variables. We plan to study the effectiveness and motivational appeal of our design in after-school settings, comparing this game-based approach with a more traditional instructional approach.

Keywords - Children, programming languages, learning games

I. INTRODUCTION

Computer programming has long been a focus of study in the field of educational technology. Many researchers have argued that programming is an empowering tool that provides a creative and fertile medium for children's activities and learning [1–3]. However, learning to program isn't easy, and novices of all ages face a number of conceptual barriers. One area of difficulty relates to how language is used to express problems [4], [5]. Pane et al. [5] examined the language and that novices use to solve programming problems before being exposed to programming. They found that participants rarely used explicit looping and always used one-sided conditionals (*if* with no *else* statement). Their results also show that participants tended not to use complex Boolean conditionals, and instead write a series of mutually exclusive simple rules. Here, we present a puzzle game that we designed to help children better understand the meaning of conditional terms.

II. BACKGROUND AND RELATED WORK

A. Computer Programming for Novices

Since the 1970s a large number of programming languages have been built to make programming more accessible to novice learners and children (see [6]). However, despite the fact that computers have become pervasive in many children's lives, few learn to program. Previous research suggests two main reasons for children's discouragement and low engagement in programming [3], [6]. First, for beginners, programming can be very difficult because of the challenges with learning a rigid syntax. And, second, the programming activities are often not exciting and not aligned with children's experiences in the world [3].

Figure 1. A screen shot of the FlipLogic game.

In recent years, many new languages have been developed to make programming easier for younger learners by offering alternatives to text-based programming. Some examples of these systems are Scratch [3], where children construct programs using graphical object, and Tern [7], which uses a tangible programming interface. Following these examples, we are attempting to familiarize children with fundamentals of programming without the emphasis on learning syntax. FlipLogic has a blocks-based programming environment, where children can create conditional rules to control the game, using a set of visual blocks (Fig. 1).

B. Game-based Learning

Today, computer games occupy a central role in the lives of many children. Recently, there has been increasing interest in the role of computer games as a powerful new resource to support children's learning [8–10]. Researchers argue that computer games can be effective educational tools by motivating children to learn and by supporting them through direct experience. Further, with highly interactive games players can become involved in complex reasoning tasks and can develop the understandings that are difficult to achieve otherwise [11]. However, despite these promises and the recent effort in developing game-based learning, there has been little success in designing effective educational games [9], [10]. Many factors determine the effectiveness of an educational game. For example, among other things, Gee [8] argues that good games introduce well-ordered problems; are challenging, yet doable; and provide links between skills and strategies for playing the game. Other researchers have argued that to achieve both motivation and learning outcomes, good educational games should *intrinsically integrate* target learning objectives with the mechanics of game play [9]. In

other words, the best (most fun) parts of the game should be where the learning happens. In designing FlipLogic, we were careful to apply these principles by closely aligning our learning objectives with the mechanisms of the gameplay. Additionally, despite its simple rules, we attempted to make the game challenging enough to encourage children develop computational strategies while solving the puzzle.

III. GAME DESIGN

FlipLogic is a rule-based puzzle game with a short play-time of 15 to 20 minutes. Our design was inspired by a number of computational puzzle games, where the players “program the behavior of game”, such as Escape Machine [12]. We implemented the game using HTML5 and JavaScript to ease its access in classroom settings as the game could simply run in a web browser on a computer.

In FlipLogic, the player has to complete the puzzle by creating a set of rules (or codes) for flipping puzzle pieces to control the game. These rules take the form of conditional statements. The puzzle pieces (tiles) are arranged in a 5 x 4 grid, which have to be flipped one at each turn. The goal is to create a successful board arrangement that meets a number of predefined criteria, like to connect the two houses with a stone road. In order to achieve these goals, the player controls the pieces, before flipping them, by making certain rules: *if the tile is a stone then keep it, else replace it with a stone* (Fig. 1). When the created rules are evaluated, the actions are performed according to the *true* rule.

The player can switch between different modes of conditional statements: *If-Then* mode (for mutually exclusive conditionals), *If-Then-Else* mode, and *If-Anything-Then* mode (for making general rules). By playing the game, children will ideally become familiar with various conditional logic terms and concepts such as mutually exclusive conditionals (represented as *if-then* structures), and conditional statements with *else* branching (represented as *if-then-else* structures).

One important feature of the game is a *code window* that shows the equivalent code of the rules in the language that is used in the curriculum (Fig. 2). By incorporating this feature in the game we hope to make it easier for children to adapt their intuitive sense of how conditionals work to the particular syntax used in their programming codes.

IV. STUDY DESIGN

We will investigate the learning outcomes of our games by integrating them into an existing curriculum designed to help middle-school students learn fundamental concepts of computation. In this 9-week after-school program, students create their own videogames using DrRacket language in a web browser. We will compare three different scenarios on introducing the programming concept: (1) the existing approach, which will be an instruction lacking the gaming aspect, (2) a game-based approach, and (3) a hybrid approach, which will be an instruction followed by a computational game. We will assess the effectiveness of each approach, by evaluating the students’ performances and their abilities in implementing the new concepts in their videogame programs.

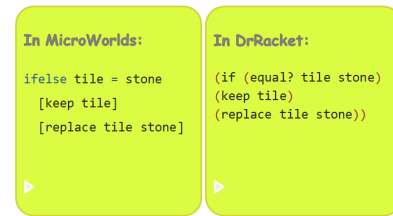

Figure 2. code windows showing the equivalent code of the rule created in Fig. 1 in two Microworlds EX (left) and DrRacket (right).

V. CONCLUSIONS AND FUTURE WORK

This paper reports our design of an educational game with the goal of introducing the concept of conditional statements in programming, to children ages 10-12. Our broader goal is to design a series of games focusing on different aspects of programming fundamentals including logic expression, control statements, and variables. We will then assess the effectiveness of game-based instructions in promoting students’ understanding of computation, comparing it to a non-gaming approach. We believe that incorporating the game-based approach in existing curricula will help children succeed in their first experiences with programming.

ACKNOWLEDGEMENTS

We thank Uri Wilensky for providing us his valuable help in our design study.

Intensive International Summer Schools in Global Distributed Software Development

Art Farley, Stuart Faulk, Virginia Lo, Andrzej Proskurowski, Michal Young
Dept. of Computer and Information Science, University of Oregon, Eugene, OR 97403
Email: lo@cs.uoregon.edu

Abstract—Computer science graduates face unprecedented opportunities and unforeseen challenges in today's highly global economy. These students will have to work and to think with international perspectives and cultural awareness.

In this paper, we report on our experiences organizing and teaching the *Pacific Rim Summer Schools in Global Distributed Software Development*. We describe the motivation for our focus, our summer school curricula and programs, provide information on the costs of organizing and running the summer schools, and examine the sustainability of our program. We conclude with a discussion of the role of such experiences in computer science curricula and in the education of American and international computer science professionals.

I. INTRODUCTION

Computer science students face unprecedented opportunities and unforeseen challenges in today's global economy after graduation. These students will pursue careers as software developers, managers, scientists, and policy makers. As the software industry increasingly deploys globally distributed teams for software development, there is commensurate demand for computer science graduates with the software engineering skills needed to manage the technical problems of Distributed Software Development (DSD), as well as the human skills required to address the issues of managing or working in project teams that span languages, cultures, and time zones. All of these positions will require our graduates to work and to think with international perspectives and cultural awareness. Why not introduce them to this challenge while they are still students? How can this be done effectively?

With the support of two NSF CPATH grants, the authors have engaged in a five-year effort to internationalize computer science education through the creation of an international community of computer science departments, development of relevant curricula, and the realization of effective, international experiences for undergraduate majors. The two NSF grants are: *CPATHi18n*,¹ *Internationalization of Computer Science Education: the Pacific Rim Community Model* (NSF-CISE-0722341) and *Globally Distributed Software Development: an Instructional Community Model* (NSF-CISE-0939198).

As the names of these projects indicate, the geographic focus of the projects has been the Pacific Rim, while the professional concentration has been on issues in distributed software development. These efforts have been previously

reported at SIGCSE [3] and [12], at ICSE [5] and in [4]. More information can be found at www.cpathi18n.org.

During the summers 2010 and 2011, we organized two-week summer schools, first at Peking University in Beijing and then at the University of Oregon in Eugene. The events brought together students from computer science programs around the Pacific Northwest and East Asia for an immersive experience in which students were organized into small cross-cultural software teams to learn techniques and tools for global software development, and to acquire skills and knowledge in cross-cultural communication, team dynamics, and international computer ethics issues. Students also attended classes on cutting-edge industry-led topics and special topics symposia, and participated in team-building and social activities.

The motivation for our two-week summer program is to expose our students to the multicultural and ethical issues that can arise in an international setting while placing them in the software engineering context of distributed software development. The main technical thread was software engineering methods and tools and how these must be adapted to a distributed development situation. In separate short courses we discussed the multicultural and ethical issues.

Both the content and the format for the summer schools were based on lengthy deliberations among computer science faculty from our Pacific Rim partner institutions and industry partners from Google, Intel, IBM, Microsoft, and Avaya Research. In this paper, we describe our curriculum and compare it with regular academic-year courses that we currently teach on these topics. We also present the positive student, faculty, and industry reactions to their summer school experience, and discuss impacts on the participants. We provide information on the costs of organizing and running the summer schools and consider the sustainability of our program. We conclude with a discussion of the role of such experiences in computer science curricula and in the education of American and international computer science professionals.

II. BACKGROUND

This project set out to build a Pacific Rim Community of universities and industry in the Pacific Northwest and Asia focused on internationalization of computer science education. Our goal was to identify curricula and activities which would help to infuse with international aspects the education of computer science majors which to date remains largely parochial in both course content and student experiences.

¹The term i18n is a well-known industry abbreviation for the word *internationalization*, which starts with i, ends with n, and has 18 letters in between.

We built this community “from scratch” through personal contacts, an Asian Friendship Tour, and a series of international workshops and ancillary activities that took place during 2007-2011. During the four community-wide workshops we conducted during 2007-2009 we identified the following items of priority to our Pacific Rim academic and industrial partners:

(i) Need for *international experiences* for North American and Asian computer science students. Computer science majors on both sides of the Pacific Rim rarely participate in Study Abroad programs and software engineering project courses are limited to face-to-face interactions with classmates. In Asia, students have few opportunities for team-based projects.

(ii) Need for *new curricula* in global distributed software development that introduce geographic, temporal, and cultural differences as these give rise to software engineering coordination and control problems that differ both qualitatively and quantitatively from those of co-located developments.

(iii) Need for *soft skills* in the areas of cross-cultural communication and teamwork, with sensitivity to East-West differences in management and teamwork styles as well as social cues and conventions.

(iv) Need for an *efficient way* to provide international experiences and education in global distributed software development. Given the high credit hours and sequential nature of the computer science major, a year or semester abroad is difficult to coordinate with programs at one’s home institution; a full summer program competes with summer employment.

After much discussion, the CPATHi18n community decided to focus on curriculum development in three related areas: global distributed software development, cross-cultural communication, and international computer ethics; and delivery of this curriculum in a two-week international summer school.

III. GLOBAL DISTRIBUTED SOFTWARE DEVELOPMENT

The core course in our Pacific Rim Summer Schools is the 32 hour course on Global Distributed Software Development. This course is an abbreviated version of our greater efforts to develop term or semester-based courses on DSD. We first describe the general principles and challenges of DSD and then describe the course taught in our summer schools.

A. Principles and Challenges of DSD

Most students are introduced to software development, project management, and teamwork in software engineering project courses where the teams are formed from their classmates and development proceeds by face-to-face interactions among peers. In contrast, industrial experience shows that “distance matters” in the sense that geographic, temporal, and cultural differences result in software engineering coordination and control problems that differ both qualitatively and quantitatively from those of co-located developments. When students work in co-located teams, many of these problems simply do not arise. Moreover, informal communication tends to fill the gaps left by problems like unclear requirements, ambiguous specification, or poor planning. As a result, few students have the opportunity to encounter the kinds of problems that arise

in DSD or apply their skills to development issues beyond programming.

A pedagogical model that can provide a more globally relevant experience is one in which student teams are actually geographically distributed. Under this model, development teams are formed of students from different schools who must collaborate to complete a common software project. However, this pedagogical model requires significant pedagogical resources and collaboration infrastructure. Institutionalizing such courses also requires compatible and reliable teaching partners.

Our work under the NSF CPATH grant seeks to address these problems by using an “open source community” approach. This includes: developing a core set of reusable instructional material and establishing a common web-based infrastructure supporting distributed collaboration. Community members then partner with one another to teach instances of a DSD course tailored from community resources. The materials are available on our community web site [6].

The skill-sets identified under the NSF’s CPATH initiative, the substantial body of literature on the software engineering of distributed development, and our own experience developing software engineering courses for industrial practitioners [7] helped identify topics critical to addressing the problems of distributed development:

Project. A good project must be motivating for students, scoped appropriately to require teamwork for success, but not so ambitious that failure is common. International collaborations make selection and preparation of an appropriate project even more challenging. Local resources including the types of available computing platforms, compilers, etc. will vary as does access to the Internet or particular web sites. The students’ background in programming languages and tools likewise vary. Issues can also arise where projects that may be current and interesting to students in one locale are either unfamiliar or old hat to those in another. Finding a project that is interesting and equally challenging to all participants requires active collaboration among sites.

Tools. Distributed development requires common (typically web-based) tools. These include a version control system, project management tools, task tracking, synchronous and asynchronous communication tools, and programming tools. Tools that are widely and freely available, with minimum dependence on a particular environment are more appropriate than tools that require a substantial investment in time or money or that require a uniform computing environment across participating sites. Finally, the infrastructure should provide appropriate support for teaching (e.g., maintaining developer logs and tracking contributions of individual team members) as well as instrumentation for evaluation of the course.

Distributed Team via Community. We have been developing a community of computer science educators around the Pacific Rim (CPATHi18n) over the past several years. We followed this with a workshop at ICSE 2011 focused on understanding the issues around DSD course delivery and initiating the effort to teach a pilot course. One result has been the creation of a small web-based community of educators interested in

| Topic | Learning Objectives |
|--|--|
| Difficulties in DSD and the role of SE | Understand the kinds of project coordination and control problems that arise in distributed development and the kinds of Software Engineering methods used to address them. Coordinating the work of distributed teams by developing a common project plan (roles, schedule, milestones, deliverables, etc.) |
| Software Requirements | Understand the issues in negotiating and converging on a common set of requirements when stakeholders are distributed. Understand how to check understanding, write, and validate common requirements. |
| Principles of Software Architecture | Understand how required system qualities are achieved in the software architecture. How architectural decomposition (into components) can be used to manage the goals and constraints of distributed development. |
| Architectural Design | Understand principles and methods for achieving specific design goals that support distributed development. These include decomposition into modules for concurrent development and design for incremental delivery. Understand how to specify module interfaces as contracts. |
| Verification and Validation | Understand how to conduct effective reviews of development artifacts. Understand how to plan and implement effective test suites to check assumptions. |
| Lessons Learned | Conduct project postmortem to understand the whole development picture, issues that occurred, how and where Software Engineering principles and methods have facilitated distributed development. |

TABLE I
DSD CURRICULUM TOPICS AND LEARNING OBJECTIVES

DSD courses. Our class materials and project specifications materials have been validated through several collaborative teaching experiences between the University of Oregon and Peking University (2010-2012) as well as between Iowa State University, Jilin University, and the Federal University of Bahia in Brazil.

B. DSD in the Two-week Intensive Summer School Format

We have tailored the DSD curriculum to support a two-week summer session. While students in the summer session come from universities all around the Pacific Rim, the pedagogical experience differs in that the students are co-located. Thus, while student teams continue to have issues with language and culture, the effects of geographic distribution must be simulated. This is accomplished by using two computer labs to physically separate student teams for all project activities. This has proven effective if less challenging than separation by both distance and time zones. In other respects, the course content is the same if a somewhat abbreviated version of our core DSD content. Table I summarizes the curriculum content.

IV. SUMMER SCHOOL STRUCTURE

A. Pacific Rim Partners and Management Team

The institutional participants in the Summer Schools are listed in Table II. This group evolved naturally from the partners most committed to realizing the project goals. The management team from the University of Oregon (the authors), took the leadership role in all aspects of curriculum development and summer school organization. They were supported by an administrative assistant and a web design student employee. Faculty and industry partners provided teaching faculty, guest lecturers, and faculty advisors at their home institutions. Dean Zhong Chen from Peking University hosted and helped to organize the 2010 Summer School as well as the second CPATHi18n workshop in 2008.

The faculty advisor from each participating computer science department was responsible for recruiting and screening students, deciding whether or not to award academic credit. The Summer School Advisory Committee includes both academic and industry members. The Advisory Committee was

| Institution | Country | Students | Faculty Advisor |
|--------------------|---------|----------|---|
| Beihang | China | 5 + 4 | Prof. Zhang Xiong |
| Peking | China | 10 + 4 | Dean Zhong Chen Prof. Ming Zhang |
| Tsinghua | China | 6 + 2 | Prof. Bin Xu |
| Tohoku | Japan | 2 + 3 | Prof. Takeshi Tokuyama |
| KAIST | Korea | 2 + 1 | Prof. Key-Sun Choi Prof. Doo-Hwan Bae |
| Yonsei | Korea | 1 + 1 | Prof. Bernd Burgstaller |
| British Columbia | Canada | 3 + 4 | Dr. Ed Knorr |
| Simon Fraser | Canada | 2 + 0 | Prof. Ted Kirkpatrick |
| Victoria | Canada | 2 + 0 | Dr. Mike Zastre |
| Oregon State | USA | 1 + 0 | Dr. Molly Shor |
| Portland State | USA | 2 + 0 | Prof. Cindy Brown |
| Oregon | USA | 9 + 4 | Prof. Andrzej Proskurowski Prof. Virginia Lo |
| Seattle University | USA | 1 + 1 | Prof. Rich LeBlanc |
| Washington | USA | 2 + 0 | Prof. Steve Tanimoto |

TABLE II
PARTICIPANTS IN THE PACIFIC RIM SUMMER SCHOOLS 2010 AND 2011

instrumental in setting curriculum goals and topics, coordinating the summer term schedules of multiple international universities, and deciding on locations for the summer schools.

B. Curriculum and Schedule

The centerpiece of the Summer School consisted of the lab-based course on Global Distributed Software Development and the lecture classes on Cross Cultural Communication and International Computer Ethics. The following are brief descriptions of the course modules delivered in our 2010 and 2011 Pacific Rim Summer Schools. Course syllabi, assignments, and reading lists are available on the web at [1].

Global Distributed Software Development: Increasingly, industrial software is being developed using teams that are distributed around the world. While offering the potential of increased productivity, distributed software development (DSD) also introduces new risks. Coordinating distributed teams requires overcoming a range of software engineering issues that arise where sites are separated by time zones, languages, and cultures. In this course students develop an understanding of the problems inherent in distributed development and are introduced to software engineering methods and

| Day/Time | Activity |
|---------------------|--|
| Day 0 | Arrival and Check-in |
| Day 1 All Day | Orientation and Campus Tour Welcome Banquet |
| Days 2-5 Morning | Global Distributed Software Development |
| Days 2-5, Afternoon | Cross Cultural Communication International Computer Ethics |
| Days 2-5 Evening | Team Project or Special Events |
| Day 7, All day | Cross-cultural Team-based Activity |
| Day 8, All day | Field Trips, Shopping, etc. |
| Days 9-12 Morning | Global Distributed Software Development |
| Days 9-12 Afternoon | Writing Computer Science Research Industry Courses and Hack-a-thons |
| Days 9-12 Evening | Team Project or Special Events |
| Day 12 Evening | Farewell Banquet |
| Day 13 Morning | Departure |

TABLE III
SUMMER SCHOOL SCHEDULE

principles that help address these issues. Students apply these methods and principles to small problems simulating some of the characteristics of distributed development.

Cross-cultural Communication for Software Teams: The course looks at definitions of “culture” and articulates “cross-cultural communication”. In particular, the course concentrates on the role of culture in distributed teams, as related to the dichotomy of individualistic vs. social societies, tendencies in the workplace, and handling conflict. Other concepts discussed are: sending and receiving “messages”, perceptions, redundancy and convention, and the role of language (written and conversational) and non-verbal communication. The course presents several case studies. Students get involved in cross-cultural interaction exercises.

International Computer Ethics: This course addresses a wide range of ethical issues that have arisen from the creation of the global Internet and related information technology. In particular, we discuss issues that are due to differences in cultural perspectives. We review the history of information technology, including a look into the future, and discuss differing ethical reasoning systems. Ethical topics discussed are privacy, intellectual property, freedom of speech and information access, and issues that arise in the creation and application of software globally. Finally, we review a code of professional ethics for software engineers and discuss international dimensions to the code.

Writing Computer Science Research: This mini-course in writing computer science research papers (in English) provides students with important guidelines for writing publication quality scientific research papers. The course is targeted to native and non-native speakers of English. We developed this course module in response to requests from our Asian partners.

Industry Courses: Our industry partners offered a variety of hands-on courses for our summer school audience. They included Kinect Hack-a-thon (Microsoft), Mobile Apps (Intel), and Web Apps (Google), Cloud Computing (Microsoft), and Parallel Programming (Intel).

Table III shows the general format of the Summer School.

C. Academics

The two-week schedule involved team-based project work and classroom lectures during the day, with evenings dedicated to team-work or special events. Students were given a pre-arrival Reading List that included papers on DSD [9], Cross Cultural Communication [8], [10], and International Computer Ethics [2]. After the summer school, all students completed a final exam and graduate students wrote a research paper on a DSD topic. Grades and course credit were administered in consultation with the students’ home institutions.

Below we describe the details of the 2010 and 2011 Pacific Rim Summer Schools in Global Distributed Software Development. In 2009 a pilot Summer School was offered in partnership with UO’s Network Resource Startup Center that included students from Africa, South Asia, China, and the University of Oregon.

D. 2010 Peking University, Beijing China

In July 2010 we organized the Pacific Rim Summer School in Beijing. The CPATH grant-supported activities included: curriculum development, soliciting and supporting instructors, defining the audience and recruiting students, soliciting local support (Peking and Tsinghua Universities), managing and supporting logistics: stipends for the participants, academic credits, classrooms and labs, lodging and meals. The UO Office of International Affairs provided logistic support to students.

The Summer School brought together 52 students from 14 universities from the U.S./Canadian Pacific Northwest and from Asia (China, Japan, and Korea). To qualify for the Summer School, computer science students had to be at the level of junior through second year graduate, and have completed an upper level software engineering course. Students had the option of earning 6 credits in computer science. The Summer School faculty team were from the University of Oregon, Peking University, Beihang University, Tsinghua University and industry partners Microsoft, Intel, and Avaya Research. Students lived together with cross-cultural roommates and faculty on the campus of Peking University, and participated in team-building and cultural activities around Beijing.

The core curriculum was augmented by lectures on topics in software engineering, industry lectures on software measurement (Avaya Research) cloud computing (Microsoft) and parallel computing (Intel), as well as on-the-street cross-cultural and team building exercises. Dean Zhong Chen gave a distinguished lecture entitled “A Dragon Awakes: How China Handles Data Security.” Team-building activities included a bridge-building exercise involving newspaper and masking tape. On the weekend, teams of students were also sent around Beijing with the assignment to develop requirements analysis for a mobile application to aid western tourists visiting China. Social activities included excursions to the Great Wall, Forbidden City, and free time for shopping, eating out, and exploring Beijing nightlife.

E. 2011 University of Oregon, Eugene, Oregon

In August 2011, we organized the Pacific Rim Summer School back at the University of Oregon, in keeping with our plan to alternate locations between North America and Asia. In addition, we organized a campus-wide symposium on International Computer Ethics, securing additional funding from the UO Center for Asian and Pacific Studies.

The Summer School brought together 22 students from 9 universities from the U.S./Canadian Pacific Northwest and from Asia (China, Japan, and Korea). Eligibility criteria and grading arrangements were the same as in the previous year. The Summer School faculty team were from the UO, Peking U., Beihang U., and industry partners Microsoft, Intel, and Google. Students lived on the UO campus, and participated in team-building and cultural activities around Eugene with the assistance of faculty from the UO School of Business and the UO Center for Asian and Pacific Studies. The smaller group size of 22 students (versus 50 in 2010) was due to inadvertent scheduling that made it inconvenient for more Oregon students to attend. The ratio of Asians to North Americans was 2:1. However, the smaller group size and intense curriculum resulted in the formation of strong friendships and excellent classroom and lab experiences.

That year, we introduced a course in Writing Computer Science Research Papers in response to requests from our Asian partners. Stanford Law Professor Mei Gechlik taught a one-day seminar in computer ethics on a case study of Google's Presence in China. The campus-wide symposium on *China's Revolution in Information Technology: Ethical Issues* had as guest speakers Mei Gechlik, Eric Priest, UO School of Law, and Denis Simon, UO International Affairs. Industry courses included Web Apps (Google), Kinect Hack-a-thon (Microsoft), and Mobile Apps (Intel). Intel donated a HP tablet PC to each participant. Academic activities were complemented by a trip to the Oregon coast, and movies, music, sports, and shopping.

V. EVALUATION

A. Faculty and Student Feedback

Feedback on the Summer Schools was solicited through student exit surveys and a survey of the faculty advisors from the partner institutions. Overall, the student exit survey shows the Summer School to be very successful in raising students interest and awareness of the value of global distributed software development and cross-cultural experiences. The students value the opportunity to learn and work together with students from another culture as much or more than the actual course content. The full survey results, including answers broken down by country, can be obtained by contacting the authors. Some typical student quotes:

Student from UBC: "This workshop was one of the most amazing experiences in my university career. Not only did it help change my outlook on cross cultural communication in regards to computer science, it helped me appreciate and understand other cultures in more ways than one can list."

Student from USA: "Impressive (curriculum). This workshop is a great introduction to issues we will face working for the big companies."

Student from KAIST: "It was a really good chance to realize how difficult a software development in a globally distributed environment is. The most impressive thing was a variety of teaching methods I've never experienced in South Korea."

Student from PKU: "In this summer workshop, I learned a lot, both professional and personal."

Feedback from our faculty survey indicated that the partners value the new ties among the Pacific Rim Partner institutions and are committed and enthusiastic about future summer schools. The Asian partners were very eager for engagement with colleagues in North America, sending their Deans and department heads to the workshops and offering to host. The North American partners were interested and supportive, but tended to delegate duties to instructional faculty, rather than research faculty. All partners used a rigorous process to screen and select the student participants. Departments on both sides of the Pacific Rim committed financial support to their students to defray high costs of travel.

The summer school was deemed an invaluable experience for most if not all of the student participants. The majority of students had never traveled abroad nor lived and worked closely with students from another country. The small group size and intense team-based curriculum resulted in the formation of friendships that have continued beyond the short two weeks. The synergy and collaborative spirit by all (students and faculty) exceeded expectations.

B. Logistics, Costs, Personnel

The summer schools were funded by grants from the NSF CPATH program. In-kind donations of labs, lecture halls, and technical support were provided by Peking University and University of Oregon, while industry partners Intel, Microsoft, and Google provided travel support for their instructors. Out of town faculty received a full stipend for travel, housing, and meals, and out of town students received a partial stipend for travel, housing, and meals. In 2010 the total cost was close to \$50,000. A major commitment of time and energy was expended by the management group from the University of Oregon and Peking University to prepare and run the event. Our administrative assistant who lived for seven years in Beijing provided invaluable assistance with the local arrangements and clear communication with our colleagues at Peking University. The 2011 the summer school was funded by grants from the NSF CPATH program and from the University of Oregon College of Arts and Sciences. Instructional faculty were compensated through the UO Summer School tuition receipts. The total cost was close to \$60,000.

C. Challenges, Sustainability and the Future

The key challenge in sustaining the Pacific Rim Summer Schools is funding. While hosting universities are often able to provide in-kind support, a revenue source is needed for student financial aid, staff for logistics and publicity, and at a minimum

faculty travel support. We believe that a research theme is essential to the sustainability of the Pacific Rim Summer School. To this end, we are investigating the development of a focus that combines the goals of the i18n project with the research interests of the i18n leadership team. One area under discussion lies in the intersection of distributed data mining and software engineering, while another is computer security. Both areas are accompanied by issues related to cross-cultural and international ethical considerations. The Summer School Advisory Board is looking to return to Asia for Summer 2013. A switch to a research emphasis will involve establishing new ties with Pacific Rim faculty interested in a target research area as well as development of new projects and curricula.

Our activities during 2007-2011 were focused on building a community of computer science educators and industry partners interested in internationalization of computer science education. During this period, we developed cutting-edge curricula, strengthened our Pacific Rim community ties, and held two successful summer schools. What is needed now is a well-designed research study to evaluate the effectiveness of our curricula and of the two-week summer school in preparing students for their future professional endeavors.

VI. IMPACTS ON UNDERGRADUATE CS EDUCATION

Computer science education needs enhancement in several key areas in order to better prepare graduates to work in the de-facto global distributed software team environment.

Global distributed software development: students need to be exposed to the formal methods, logistical, and cultural issues of working in a software team distributed across geographic, cultural, and timezone barriers. Our industry partners especially emphasized the value of student exposure to these topics before entering the job market.

Cross-cultural communication for software teams: productivity, motivation, and overall success are greatly improved when team members are sensitive to communication across cultures.

International computer ethics and societal impacts: students must graduate with a global understanding of these topics rather than the western-centric view of current computer science courses in the U.S.

Cross-cultural HCI: courses need to be enriched with cross-cultural content towards the broader view of universal HCI. The current draft of ACM Curriculum 2013 echoes our belief in the need for i18n in the sections on social/professional responsibility (tier 1) and HCI (tier 2).

Our findings show that international experiences must fit conveniently into the heavy requirements and constraints of a computer science major. Furthermore, majors need to be educated to value international experiences such as study abroad, foreign language and international studies courses. We found it important to offer financial support for students to attend the school.

Faculty and students at Asian computer science departments are very eager for more engagement with their western counterparts at the undergraduate level. While research collaborations and exchange programs for international faculty and

graduate students are fairly common, there are fewer formal opportunities for exchanges among undergraduates.

We plan to continue to develop and disseminate our course modules in DSD, cross-cultural communication, and international computer ethics for the computer science education community to use in required courses for CS majors in software engineering and computer ethics, as well as for topics in introductory courses for majors and non-majors. A by-product of our curriculum innovation in soft skill areas such as cross-cultural communication and international computer ethics has led us to new cross-disciplinary interactions with faculty in several non-science departments. Our CPATHi18n management team worked with faculty in the School of Law (intellectual property law in China); School of Business (cross-cultural communication, team-building and leadership); Asian Languages, The Oregon Confucius Institute, and the Oregon K-20 China Flagship Language Program. We participated in a grant from the Dept. of Education to the Oregon Center for Asian and Pacific Studies and received a small grant from the Oregon International Studies and Global Scholars Program to support curriculum development in the above areas. These new ties enriched all participating disciplines.

VII. ACKNOWLEDGMENTS

The authors would like to thank NSF, University of Oregon, College of Arts and Sciences, UO Center for Asian and Pacific Studies, Peking University, Bing Li, David Elliot, Jim Allen.

Work in Progress: Preliminary Survey Results on the First Year of the Bologna Process in Engineering Education in Spain

Martín Llamas, Manuel Caeiro, Manuel Castro, Inmaculada Plaza, and Edmundo Tovar
IEEE Education Society Spanish Chapter
martin@uvigo.es, mcaeiro@det.uvigo.es, mcastro@ieec.uned.es, iplaza@unizar.es, etovar@fi.upm.es

Abstract— This paper shows the preliminary results of a study carried out by the IEEE-Education Society Spanish Chapter on the state of implementation of the Bologna process in engineering degrees along Spain and the opinion of teachers about the main aspects of this implementation. These include the implementation of new learning methodologies (problem-based learning, collaborative learning, project-based learning, etc.), resources, assessment criteria, workload of students and teachers, the support of each university for the EHEA implementation, and the general satisfaction (or not) about the EHEA. The aim of this paper to contribute to a reflexive debate, not only in Spain but also in the international community, about the advantages and drawbacks of the EHEA implementation in engineering education.

Keywords-component: EEES, Engineering Education, Bologna Process

I. INTRODUCTION

The objectives of the EHEA (European Higher Education Area) or colloquially known as Bologna Process are to provide instruments to understand and compare the different education systems more easily, to facilitate the recognition of professional qualifications for both national and international mobility, and to progressively increase the collaboration across European universities towards the convergence of educational structures. Independently of these objectives, in Spain the Bologna Process or EHEA has been the opportunity to change deeply the university degrees. One of the main ideas of EHEA is to focus on a learner-centred approach as opposed to the traditional teacher-oriented approach. From the year 2010, the EHEA has been implemented in all engineering degrees in Spain. Therefore, there exists at least one year of experience applying the Bologna Process. The IEEE-Education Society Spanish Chapter has carried out a study on the state of implementation of the EHEA in engineering degrees along Spain and the opinion of teachers about the main aspects of this implementation. These include the implementation of new learning methodologies (problem-based learning, collaborative learning, project-based learning, etc.), resources, assessment criteria, workload of students and teachers, the support of each university for the EHEA implementation, and the general satisfaction (or not) about the EHEA. The aim of this paper is to show the main results

of this study, and therefore to contribute to a reflexive debate not only in Spain but also in the international community about the advantages and disadvantages in engineering education that the EHEA implementation may provide.

In Section II the survey method is explained. The preliminary results of the study are given in Section III. The paper ends with some conclusions and implications for the future

II. METHODOLOGY

As long as we know this is one of the first studies about the implementation of the EHEA in Spain. Therefore, we didn't want to produce a very large survey form, but to focus on the more general aspects of the application of the Bologna Process, such as the workload, the learning methodologies, the continuous assessment and the general satisfaction degree. The survey involves questions about these issues, some professional information (e.g., years of experience, academic degree) and the degree of participation in the process.

The dissemination of the survey form was performed with the help of members and supporters of the IEEE Education Society Spanish Chapter through the CESEI network [1]. This network is promoted by the IEEE-ES Spanish Chapter [2] and currently is composed of more than a hundred teachers in 40 universities throughout Spain, all of them strongly related to Engineering Education.

Teachers from engineering degrees have filled in the survey since the last week of March 2012. Around 500 teachers from 45 Spanish universities have already answered it (a previous survey carried out by the CESEI was answered by just 126 teachers [3]). In addition, notice we are currently in the second year of implementation of the EHEA. In this way most teachers in engineering education have not any experience in the adoption of the Bologna system and therefore, they couldn't answer the survey.

III. FIRST RESULTS

A. Participation in EHEA

While practically all ages are represented, the majority of teachers are in the age group of 40-49. Around 75% of the teachers have more than 10 years of teaching experience, and

almost half of the teachers have among 10 and 20 years of teaching experience. Most of the teachers have lectured 1 or 2 subjects.

More than half of the teachers acknowledge that they have changed his teaching style with respect to the former one in a high degree. Nevertheless, they feel their colleagues have not changed their styles in a so high degree. Therefore, we can say that the EHEA has promoted a change in the teaching style in the majority of the teachers.

B. Preliminary results

- **Workload:** A main concern for teachers about the EHEA implementation was that it might require a higher workload. Around half of the teachers estimate that their own workload is much higher than the former one and a large number of the remainder ones consider that the workload is just slightly higher. In any way, almost all the teachers feel their workload has increased. This feeling comes to confirm the lack of practical support from the institutions. As a result, teachers consider that their work has increased considerably. The perception in the academic staff about the students' workload is that it has also been increased. In summary we conclude that EHEA has produced an increase in the teachers and students' workload.
- **Continuous Assessment:** A key aspect in the EHEA is the adoption of a continuous assessment model. Previously, the most popular assessment model was the final exam. From the first results of our study, we can see that a large majority of teachers have in a better consideration the continuous assessment than a final exam. Nevertheless, this option is not unanimous. In other way, despite continuous assessment is the recommended method in EHEA, such an assessment method is not mandatory in all the higher institutions, as teachers' perception reflects.
- **Pedagogical Methodologies:** Another main aspect in EHEA is the adoption of new learning methodologies. Around half of teachers admit the adoption of new learning methodologies, while the other half continues using their former methodologies. It is really exciting to consider that around half of teachers have adopted new learning methodologies with EHEA. In addition, the fact that the other half of the teachers has not changed anything doesn't mean that such methodologies were not appropriate.
- **Resources:** This part of the survey was oriented to capture the use of new learning resources. In this way, the survey included directly as possible answers items such as: video, reusable learning objects, games, remote and virtual laboratories, and simulators. We have not paid attention to other more classical resources such as slides, real laboratories, etc.
- **General Opinion:** Teachers were also surveyed about if they feel that students learn more or less in the EHEA model or in the former one. Related with this, teachers' opinions are also divided: around a third of teachers consider that EHEA is better for students'

learning, a quarter is neutral and the remainder ones consider that EHEA is worse. Around half of the teachers find the number of students who fail is fewer than the former model, but they also associate this result with a higher pressure for teachers to get more succeed students. Directly enquired about which model is better, EHEA or the former one, there is not a clear opinion. These results are complemented with the opinion about their preference for the EHEA or the former model. In a high degree, just a few amount of the teachers prefer EHEA, while some are neutral and more than half of the teachers do not prefer EHEA model.

We think that these results should promote a general reflection about the EHEA implementation in all the stakeholders, mainly in politicians and academic authorities. It seems quite challenging to implement a new system when the people that has to use it don't have any faith.

IV. CONCLUSIONS

The EHEA in Spain was implemented from academic year 2010-11. Some years remain to have a complete implementation of the new model in all the academic years of the engineering degrees. Nevertheless, at the time of this study, the results captured are very worrying. On the one hand, teachers and students' workload has increased, but this has not been followed by an increase in the student success. On the other hand, all the teachers and institutions are not adopting the continuous assessment model, that is a key aspect in the EHEA [4]. In addition, universities are not supporting the EHEA implementation appropriately. Moreover, the general feeling about EHEA implementation in Spain is unsatisfactory. At the present time, it seems that the unique positive result from EHEA implementation is the adoption of new teaching methodologies.

ACKNOWLEDGMENT

We want to thank to all the anonymous teachers that filled in the survey making possible this study. We would like to thank Madrid Regional Government for its support through the EMadrid Network of Excellence S2009 TIC-1650

Abstract— The arising of European Higher Education Area (EHEA) brought up the implementation of new degrees throughout most of European Universities. In the realm of this upcoming environment, during 2009-2010 the School of Design Engineering (ETSID) at Universitat Politècnica de València in Spain, developed a pioneer experience in the first year of the Bachelor Engineering (BEng) degree in Mechanical Engineering, the guidelines of this innovative experience being defined in accordance with the EHEA approaches. Thus, this pioneer experience co-existed with non-Bologna teaching-learning methodology followed in the rest of groups of this BEng degree.

Positive academic outcomes found in this first pioneer group encouraged to extend this experience to the second year of this degree during 2010-2011, in order to ease the upcoming full Bologna implementation. In this line, classroom activities were established so that collaborative work was promoted, autonomous tasks were developed and an assessment that took into account both classroom and autonomous activities was implemented.

In this paper, we present a statistical analysis of the achieved academic outcomes of the pioneer group in the second year of the BEng degree in Mechanical Engineering, relating them to the rest of non-pioneer groups of the same year and degree.

Keywords: *classroom activities; autonomous activities; formative assessment; EHEA adaptation*

I. INTRODUCTION

Over the last years, European Universities have undertaken several reforms within the framework of the Bologna process with the aim of creating a European Higher Education Area (EHEA) and with degree programs based on profile, learning outcomes, competences and student workload [1,2].

The implementation of a competences approach for the design of educational programs has involved the review of teaching, learning and assessment strategies to be used in order to guarantee the development of the required competences [3].

This shifting has meant a change of paradigm: from teacher-centered to student-centered teaching, learning and assessment, in which teachers act as facilitators and guides whereas students play an active role and take the responsibility for their learning [4,5]. It has subsequently been necessary to adopt teaching and assessment approaches that highlight active and dynamic learning and that allow students to acquire the desired competences.

Along this adaptation process, new EHEA structured Bachelor degrees have been finally implemented in most of European Universities. Before this occurred the School of Design Engineering (ETSID) at Universitat Politècnica de València (Spain), developed a pioneer experience during 2009/2010 in one of the groups of the first year of its Bachelor Engineering (BEng) degree in Mechanical Engineering [6] as prelude towards the establishment of the EHEA adapted degrees. Let us mention that as a further step the EUROpean ACcredited Engineer (EUR-ACE) project (2004/06) formulated a framework for the European Accreditation of Higher Education Programs in Engineering to which some national agencies have already adhered (France, Germany, Ireland, Portugal, Russia, and UK), [7]. This is becoming the European counterpart to the well-known ABET, [8].

Logically this experience was designed according to the EHEA approaches by implementing a new teaching-learning system based on active methodologies and formative assessment [9-11], so that the acquisition of knowledge, abilities and competences of students would be promoted. This innovative experience co-existed with non-Bologna teaching-learning methodology followed in the rest of groups of this BEng degree. Academic performance of the students taking part in this innovative experience was later assessed by means of different rates. This analysis showed that active participation of students in their learning process, along a formative evaluation of their progress, improved their academic success [12]. These positive academic outcomes encouraged the extension of this experience to one group of the second year of the BEng degree in Mechanical Engineering during 2010/2011.

“Vicerrectorado de Estudios y Convergencia Europea” and “Instituto de Ciencias de la Educación” of the Universitat Politècnica de València (Spain)

In addition to the above mentioned guidelines, in this second pioneer experience, interest was focused on the further improvement of student success and learning. Thus, for every subject, collaborative classroom activities [12-14] together with autonomous tasks were designed, so that the acquisition of generic and specific competences associated to this BEng degree might be assured. Furthermore, different formative assessment strategies [11] taking into account both classroom and autonomous activities, were implemented.

This paper provides a detailed analysis of the academic performance of this second-year pioneer group on the basis of various rates that have been defined for every subject, degree and student, and a further comparison with those corresponding to the other groups of students, of the same year and degree, which followed non-Bologna teaching-learning methodology.

II. DESCRIPTION

One of the main objectives of this second-year innovative experience in the BEng degree in Mechanical Engineering at ETSID has been the use of collaborative learning methods for classroom activities. As it has been shown in similar experiences of its implementation in engineering higher education, collaborative learning improves the academic performance, promotes the acquisition of generic competences and enhances life-long learning [9, 10, 15-18]. The main collaborative learning methods introduced in this second-year pioneer group were problem-based, cooperative work and project-based learning. Figure 1 displays the instructional methods that have been applied in this pioneer group compared with those used in the other groups following traditional educational approaches, mainly based on lectures and with a very limited use of collaborative methodologies.

During these collaborative activities, students were divided into small groups (3-4 students) in which they solved cases, problems, projects, etc. in the classroom under their instructors supervision, these activities being collected for their evaluation and subsequent feedback. On the other hand, autonomous activities to be performed after class hours were also designed in every core subject of this pioneer group.

Both classroom and autonomous activities were evaluated by using a formative evaluation approach. The implementation of such evaluation involved the use of a variety of assessment strategies (one minute paper, portfolio, report, data recording...) including written exams, in contrast to the exam-based traditional evaluation used in the other groups, Fig. 2.

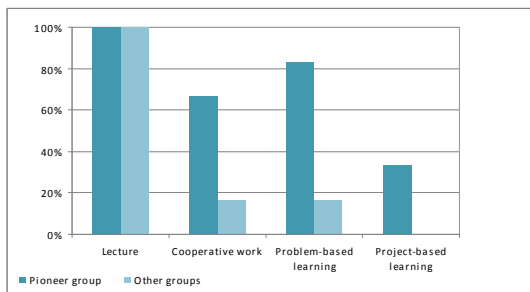

Figure 1. Teaching methodologies in the second year of the BEng degree in Mechanical Engineering during 2010/2011.

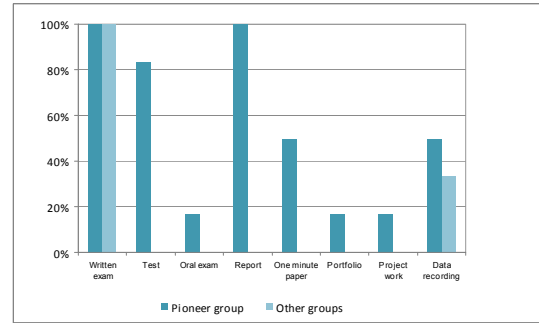

Figure 2. Assessment strategies in the second year of the BEng degree in Mechanical Engineering during 2010/2011.

Assessment of this pioneer experience has been first performed according to the following rates that have been determined for every core subject:

$$\text{Exam attendance rate} = \frac{\text{n}^\circ \text{ students who take an exam}}{\text{n}^\circ \text{ enrolled students}} \times 100 \quad (1)$$

$$\text{Success rate} = \frac{\text{n}^\circ \text{ pass students}}{\text{n}^\circ \text{ students who take the exam}} \times 100 \quad (2)$$

$$\text{Performance rate} = \frac{\text{n}^\circ \text{ pass students}}{\text{n}^\circ \text{ enrolled students}} \times 100 \quad (3)$$

Furthermore, the following overall rates have also been calculated for this degree in terms of both the number of European Credit Transfer System (ECTS) and students:

$$\text{Total success rate} = \frac{\text{n}^\circ \text{ pass ECTS}}{\text{n}^\circ \text{ enrolled ECTS}} \times 100 \quad (4)$$

$$\text{Relative course rate} = \frac{\text{n}^\circ \text{ students who pass all the subjects}}{\text{n}^\circ \text{ students who take all the exams}} \times 100 \quad (5)$$

$$\text{Course rate} = \frac{\text{n}^\circ \text{ students who pass all the subjects}}{\text{n}^\circ \text{ enrolled students}} \times 100 \quad (6)$$

Finally, student success in terms of the number of enrolled ECTS has been determined as well for every student in this BEng degree:

$$\text{Student success rate} = \frac{\text{n}^\circ \text{ pass ECTS}}{\text{n}^\circ \text{ enrolled ECTS}} \times 100 \quad (7)$$

All these rates have been obtained both for the students of the pioneer group and those enrolled in the rest of the groups of the second year of the BEng degree in Mechanical Engineering, in order to perform a further comparative analysis of these results.

In particular, these rates have been determined for 55 students enrolled in the second-year pioneer group of the BEng degree in Mechanical Engineering, and on an average of 315 students enrolled in the other groups of the same year and degree.

III. RESULTS

A. Subject results

First, academic performance of the students taking part in this innovative experience has been analyzed for every subject. Exam attendance rate, success rate and performance rate have been determined for every core subject for the pioneer group and the rest of the groups of the second year of the BEng degree in Mechanical Engineering (Tables I, II and III).

In general, the exam attendance rate has increased for most of the subjects in this pioneer group, when compared to that corresponding to the rest of the groups. However, the success rate is improved for all the subjects in the pioneer group. This group displays an average success rate of 96.6%, whereas in the other groups, success rate is on average 87.1%.

TABLE I. EXAM ATTENDANCE RATES IN THE SECOND YEAR OF THE BENG DEGREE IN MECHANICAL ENGINEERING DURING 2010/2011.

| Subject | Exam attendance rate | |
|--------------------------------------|----------------------|---------------------|
| | <i>Pioneer group</i> | <i>Other groups</i> |
| Mechanics and Theory of Mechanisms | 71.4% | 55.1% |
| Mechanical Technology | 66.7% | 66.9% |
| Fluid Mechanics Engineering | 69.0% | 68.4% |
| Elasticity and Strength of Materials | 71.4% | 71.1% |
| Thermal Engineering | 85.7% | 60.9% |
| Statistical Methods | 88.1% | 75.6% |

TABLE II. SUCCESS RATES IN THE SECOND YEAR OF THE BENG DEGREE IN MECHANICAL ENGINEERING DURING 2010/2011.

| Subject | Success rate | |
|--------------------------------------|----------------------|---------------------|
| | <i>Pioneer group</i> | <i>Other groups</i> |
| Mechanics and Theory of Mechanisms | 93.4% | 93.3% |
| Mechanical Technology | 100.0% | 75.8% |
| Fluid Mechanics Engineering | 100.0% | 83.9% |
| Elasticity and Strength of Materials | 96.9% | 96.7% |
| Thermal Engineering | 94.4% | 82.7% |
| Statistical Methods | 94.6% | 90.2% |
| | | |

TABLE III. PERFORMANCE RATES IN THE SECOND YEAR OF THE BENG DEGREE IN MECHANICAL ENGINEERING DURING 2010/2011.

| Subject | Performance rate | |
|--------------------------------------|----------------------|---------------------|
| | <i>Pioneer group</i> | <i>Other groups</i> |
| Mechanics and Theory of Mechanisms | 66.7% | 51.5% |
| Mechanical Technology | 66.7% | 50.7% |
| Fluid Mechanics Engineering | 69.0% | 57.4% |
| Elasticity and Strength of Materials | 69.0% | 68.9% |
| Thermal Engineering | 81.0% | 50.4% |
| Statistical Methods | 83.3% | 68.1% |

These results confirm a higher performance rate in the pioneer group with regard to the other groups of the same year. On average, this rate is increased in about 15% in the pioneer group. In some subjects (Thermal Engineering), this improvement approaches 30% with regard to the performance rate of the students of the rest of the groups of the same year and degree.

B. Degree results

Academic performance of the students taking part in this pioneer group has later been analyzed for this degree. Total success rate, relative course rate and course rate have been calculated for the second year of the BEng degree in Mechanical Engineering (Table IV).

Active learning and formative assessment implemented in the pioneer group have led to a better total success rate (76%) than traditional teaching and evaluation methods employed in the rest of the groups. This means an increase of this rate of approximately 18%.

On the other hand, in the pioneer group 86% of the students who attempt to pass all the subjects, finally accomplish it, compared with 70% of the students of the rest of the groups.

Results also show a substantial improvement of the course rate in the pioneer group. While approximately 45% of the enrolled students in the pioneer group finally pass all the subjects, only 24% of the enrolled students pass all the subjects in the rest of the groups. Such low values of the course rate imply that next academic year the number of non-continuing students will be significant in these other groups.

TABLE IV. TOTAL SUCCESS RATES, RELATIVE COURSE RATES AND COURSE RATES IN THE SECOND YEAR OF THE BENG DEGREE IN MECHANICAL ENGINEERING DURING 2010/2011.

| Degree rates | Success rate | |
|----------------------|----------------------|---------------------|
| | <i>Pioneer group</i> | <i>Other groups</i> |
| Total success rate | 75.8% | 58.0% |
| Relative course rate | 86.4% | 70.2% |
| Course rate | 45.2% | 24.3% |

These results confirm the better performance of this teaching-learning methodology based on a student-centered model, compared with the traditional one based on a teacher-centered model.

C. Student results

In order to complete the analysis of the academic performance of this innovative experience, the percentage of students as a function of their success in terms of ECTS has been determined as well for the pioneer group, Fig. 3, and the rest of the groups of the second year of the BEng degree in Mechanical Engineering, respectively, Fig. 4.

Results reveal an improvement in the student success of the pioneer group with regard to that of the other groups. In particular, 69% of the students of the pioneer group passed more than 75% of their enrolled ECTS, compared with 43% of the students of the other groups. Furthermore, while 41% of the students of these groups passed less than 50% of their enrolled ECTS, only 26% of the students of the pioneer group failed to pass these ECTS. This significant improvement of the student success in the pioneer group confirms the suitability of the teaching and evaluation approaches that have been implemented in this innovative group.

On the other hand, 0% success corresponds to the dropout percentage. Results reveal that dropout has decreased 5% with regard to that of the other groups. This seems to indicate that collaborative work activities implemented in this group have actually eliminated the dropout rate. Similar results have also been found in other innovative experiences involving group-based methodologies in BEng degrees [19].

With regard to students, these results suggest that this innovative experience has contributed to improve their academic performance.

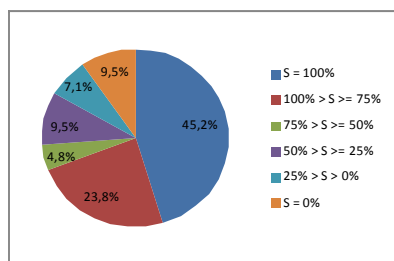

Figure 3. Student success rates (S) in the second-year pioneer group of the BEng degree in Mechanical Engineering during 2010/2011.

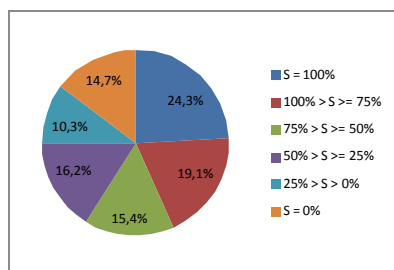

Figure 4. Student success rates (S) of the second year of the BEng degree in Mechanical Engineering at non-Bologna groups of during 2010/2011.

III. CONCLUSION

As a first stage towards the implementation of its new EHEA adapted degrees, during 2009/2010, the School of Design Engineering ETSID of the Universitat Politècnica de València (Spain) developed student-centered teaching and assessment approaches in a pioneer group of the first year of its BEng degree in Mechanical Engineering. Positive academic outcomes of this pioneer group have encouraged the extension of this innovative experience to one group of the second year of the BEng degree in Mechanical Engineering during academic year 2010/2011. For every core subject, collaborative activities have been organised during classroom sessions together with autonomous tasks to be performed after class hours. Both classroom and autonomous activities have been evaluated using a combination of formative assessment strategies.

Academic performance of the students taking part in this innovative experience has been assessed by means of different rates that have been defined for every subject, degree and student. Results have revealed that active participation of the students in their learning process together with a formative evaluation of their progress have led to a considerable improvement of all these rates.

Implementation of teaching methodologies that enhance active and autonomous learning of students together with formative assessment, such as those followed in this pioneer group, promotes their greater engagement. As it has been shown, the performance rate increases as a consequence of the rise of both the exam attendance rate and the success rate in every core subject.

The significant improvement of the overall degree rates under consideration in this study, confirms that the use of a teaching-learning methodology based on a student-centered model, is better than traditional teacher-centered approaches.

Furthermore, the analysis of the student success rate has revealed that personal success has been improved as well in this pioneer group compared with that of the other groups of the same year, following non-Bologna teaching-learning methodologies.

Finally, it has also been found that collaborative work activities together with formative evaluation strategies, such as those implemented in this group, seem to reduce the dropout rate.

Abstract— European Universities have been exposed to major changes in order to implement the so called Bologna process. Many facets have had to be addressed in the teaching-learning system, moving from a teacher-centered model to a student-centered one, where a competence-based structure had to be facilitated, and so that the basic competences related to the integral formation of engineers should be accomplished along specific competences, making possible a professional profile and enabling the graduates to get integrated into the job market. Hence, this change has provided the opportunity to create a more active and dynamic teaching-learning model, with more personalized methods and the integration of new technologies.

In the midst of this situation, a case study has been undertaken to analyze the consequences of such change in the academic results of the BEng Industrial Design Engineering degree of the School of Design Engineering ETSID (Polytechnic University of Valencia, Spain) along the first course of the European Higher Education Area (EHEA) adapted program and those obtained by the corresponding pre-EHEA course at ETSID.

This paper aims to become an instrument to monitor the development and effectiveness of the teaching-learning policies adopted, thus contributing to the continuous process of educational improvement at ETSID by comparing various performance and success rates.

Keywords: *classroom activities; autonomous activities; formative assessment; EHEA adaptation*

I. INTRODUCTION

Design arises in general as a response to functional and symbolic needs of people in order to get some, social or personal, public or private, well-being goal. Hence Product Design quintessence relies on a crystallizer dimension by means of which some given ideas must become real objects. Industrial Design Engineers must have this in mind since they are involved in the design of products in addition to the resources management and its costs. Most of the standard goods that people buy and use have previously been designed and manufactured., thus it is not strange to find a BEng Engineer in Industrial Design behind the conception or materialization of many of the products that we are continuously using.

From the above it follows that Bachelor Engineering (BEng) in Industrial Design Engineering degree should train professionals with technical and scientific skills to manage the whole production process of products, with a special focus on innovation in a global context. This a consequence of the fact that design brings together technological, economic, functional and stylistic dimensions which enable to carry out the creation and development of a wide variety of products in terms of scale, type and nature. This confluence of different fields in design activities requires a multidisciplinary professional profile coping with humanistic sensitivity as well as scientific and technical knowledge [1].

The need of acquiring these multidisciplinary competences, including a technological and socio-cultural compound, makes that BEng Industrial Design Engineering students must take from the very beginning courses which encourage the development of creativity, pragmatism and drawing skills together with scientific and technical knowledge, as well as the ability of dealing with abstract comprehension which enable them to analyze and synthesize a variety of situations.

The School of Design Engineering (ETSID) of the Universitat Politècnica de València (UPV), Spain, has reviewed its BEng Industrial Design Engineering degree in order to fit the requirements of the European Higher Education Area (EHEA) [2,3]. This adaptation process has given birth to a new study plan based on profile, learning outcomes, competences and student workload, which on the other hand has implied a change of paradigm in the teaching-learning process moving from teacher-centered to student-centered teaching where instructors are viewed as facilitators and guides whereas students play an active role and take the responsibility for their learning [4, 5]. This has brought out the incorporation of teaching [6-9] and assessment [10-12] approaches that highlight active and dynamic learning enabling students to acquire the desired competences.

This paper analyzes some consequences of these changes in BEng Industrial Design Engineering at ETSID. The study aims to compare academic performance between first grade students of the EHEA adapted study plan with the one obtained by the first grade students of the pre-EHEA study plan at ETSID. This study is intended to monitor the effectiveness of different teaching-learning strategies, thus contributing to the continuous educational improvement process at ETSID.

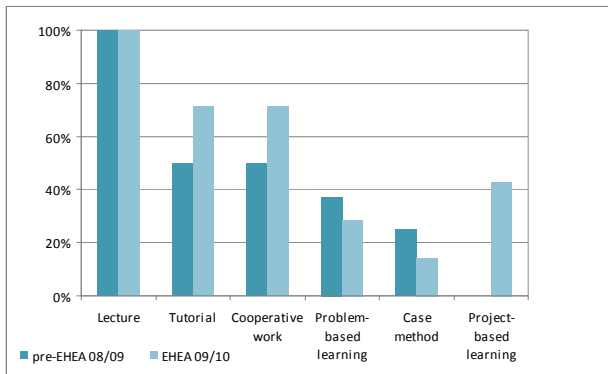

FIGURE 1. Teaching methodologies in Year 1 of the pre-EHEA and EHEA structured BEng Industrial Design Engineering degree at ETSID

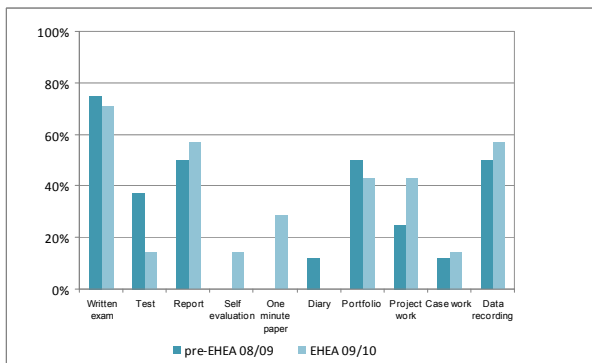

FIGURE 2. Assessment strategies in Year 1 of the pre-EHEA and EHEA structured BEng Industrial Design Engineering degree at ETSID

II. DESCRIPTION

In 2009/2010, the School of Design Engineering (ETSID) of UPV implemented the first year of its EHEA structured BEng Industrial Design Engineering degree.

According to the EHEA requirements, active learning methodologies [6-9] were incorporated and a more significant use of tutorial, cooperative and project-based learning was developed as shown in Fig. 1.

On the other hand, the use of written examinations and tests was reduced and other evaluation strategies [10-12] were applied as shown in Fig. 2 (report, one minute paper, self evaluation, project work, case work and data recording).

The aim of this study is comparing the academic performance of first year students of the EHEA adapted study plan during 2009/2010 with those obtained by pre-EHEA students during the previous academic year 2008/2009. This detailed analysis has been performed on the basis of various rates that have been defined for each core subject:

$$\text{Exam attendance rate} = \frac{n^{\circ} \text{ students who take the exam}}{n^{\circ} \text{ enrolled students}} \times 100 \quad (1)$$

$$\text{Performance rate} = \frac{n^{\circ} \text{ pass students}}{n^{\circ} \text{ enrolled students}} \times 100 \quad (2)$$

$$\text{Success rate} = \frac{n^{\circ} \text{ pass students}}{n^{\circ} \text{ students who take the exam}} \times 100 \quad (3)$$

Furthermore, student success in terms of the number of enrolled credits according to the European Credit Transfer and Accumulation System (ECTS) [13] has been determined as well for every student in both degrees:

$$\text{Student success rate} = \frac{n^{\circ} \text{ pass ECTS}}{n^{\circ} \text{ enrolled ECTS}} \times 100 \quad (4)$$

These rates have been calculated for the students enrolled in Year 1 of the EHEA and the pre-EHEA study plans, 138 and 181 students, respectively.

III. RESULTS

A. Subject results

Initially, the academic performance of all the students of BEng Industrial Design Engineering has been analyzed for every subject.

With the above aim, we have determined for every core subject in the first year of both degrees:

- The exam attendance rate.
- The performance rate.
- The success rate.

Table 1 contains the data of the pre-EHEA case during 2008/2009 while Table 2 contains the data of the EHEA case during 2009/2010.

TABLE 1. Exam attendance rates, performance rates and success rates in Year 1 of the pre-EHEA structured degree during 2008/2009

| Subject | Exam attendance rate | Performance rate | Success rate |
|-----------------------|----------------------|------------------|--------------|
| Physics | 65% | 56% | 86% |
| Mathematics | 74% | 59% | 81% |
| Material Science | 57% | 46% | 81% |
| Engineering Design I | 83% | 69% | 83% |
| Engineering Design II | 85% | 77% | 92% |
| Drawing | 90% | 74% | 82% |
| Fundamental Design | 88% | 88% | 100% |
| Computer Science | 87% | 73% | 84% |

TABLE 2. Exam attendance rates, performance rates and success rates in the first year of the EHEA structured degree during 2009/2010

| Subject | Exam attendance rate | Performance rate | Success rate |
|---------------------------------|----------------------|------------------|--------------|
| Physics | 84% | 69% | 82% |
| Mathematics I | 78% | 71% | 91% |
| Engineering Design I | 77% | 75% | 98% |
| Engineering Design II | 82% | 79% | 97% |
| Drawing | 84% | 73% | 87% |
| Fundamental Design & Creativity | 88% | 88% | 100% |
| Computer Science | 69% | 69% | 100% |

In the EHEA adapted degree, the implementation of a student-centered approach together with compulsory attendance to classroom/laboratories activities has led to an increase of both the exam attendance rate and the performance rate of scientific subjects, i.e. Physics and Mathematics.

However design related subjects display similar rates in both degrees.

These results indicate that changes in the teaching-learning system mainly influence the academic performance of scientific subjects rather than that of humanistic subjects, with traditionally better academic results in this BEng degree.

On the other hand, the success rate of most of Year 1 subjects has improved in the EHEA structured degree with regard to the corresponding pre-EHEA degree.

A closer inspection shows that students who passed the courses got even better grades, as shown by the increasing number of A and B grades in the EHEA degree compared with the corresponding pre-EHEA degree (Figs. 3 and 4).

This result suggests that the combination of a detailed monitoring of students progress by means of formative assessment strategies and their active participation during courses promotes the quality of the teaching-learning process.

B. Student results

In order to complete the analysis of the academic performance of the pre-EHEA and EHEA degrees in Industrial Design Engineering at ETSID, the percentage of students as a function of their success in terms of ECTS has also been determined for both first years.

Fig. 5 displays the pre-EHEA case and Fig. 6 displays the EHEA structured degree.

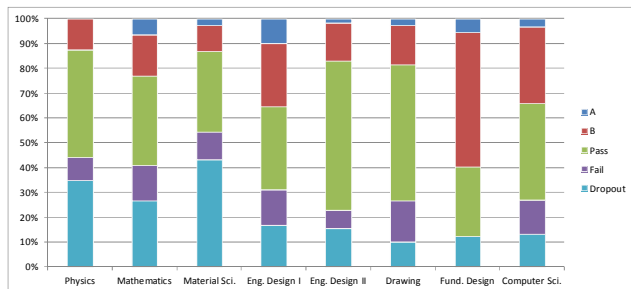

FIGURE 3. Grades in the first year courses of the pre-EHEA structured BEng degree in Industrial Design Engineering at ETSID during 2008/2009

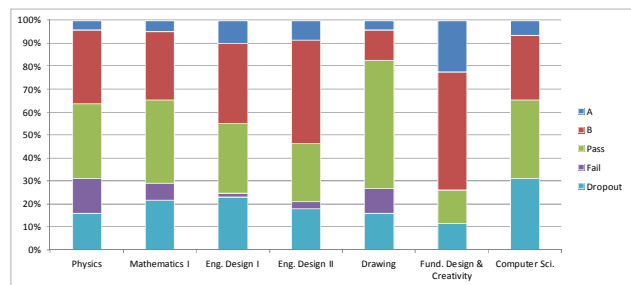

FIGURE 4. Grades in the first year courses of the EHEA structured BEng degree in Industrial Design Engineering at ETSID during 2009/2010

The incorporation of active methodologies together with formative assessment strategies has increased the average success rate from 86% in the pre-EHEA degree to 94% in the EHEA degree. A fast look of the grades obtained by the first year students of both degrees reveals the number of students who failed or dropped out has, in general, diminished.

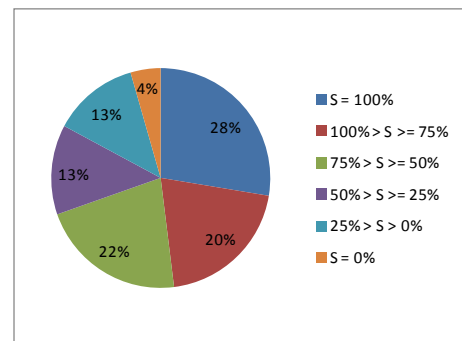

FIGURE 5. Student success (S) in the first year of the pre-EHEA structured BEng degrees in Industrial Design Engineering at ETSID

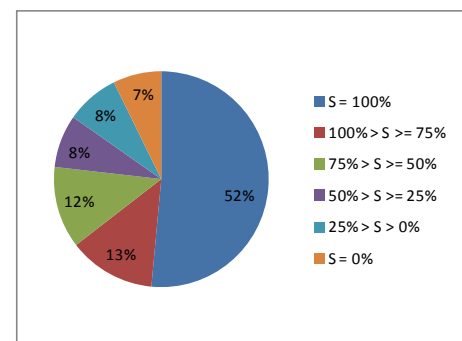

FIGURE 6. Student success (S) in the first year of the EHEA structured BEng degrees in Industrial Design Engineering at ETSID

A 100% success for a given student means that this student has passed all the subjects of which this student has taken the exams.

Results display that while 52% of the first year students of the EHEA structured degree exhibited 100% success, just 28% of the students of the corresponding pre-EHEA degree passed all the subjects they intended to. Furthermore, whereas 30% of the students of the pre-EHEA structured degree passed less than half of their enrolled ECTS, only 23% of the students of the EHEA structured degree failed to pass these ECTS.

This significant improvement of the student success in the first year of the EHEA structured degree confirms the suitability of the teaching and evaluation strategies that have been implemented in this new degree.

On the other hand, 0% success corresponds to the dropout percentage. Results reveal that for both the pre-EHEA and the EHEA structured degrees, the dropout percentage is similar and equal to 4% and 7%, respectively. This indicates that in the first year of the degrees under study, dropout seems to be independent of the teaching-learning methodologies that have been employed.

Similar results have been obtained in previous EHEA adaptation experiences in other BEng degrees at ETSID [14]. It will be therefore convenient to analyze thoroughly these results in order to propose some alternative strategies that might mean a diminishing in this rate in new EHEA structured degrees.

III. CONCLUSION

The keys to the EHEA adaptation lie in the qualitative changes that should be introduced in the teaching-learning process. This has moved from a teacher-centered model to a student-centered model which highlights student participation and commitment. For this reason, it is convenient to assess the impact of these methodological changes in the academic performance in order to identify and promote the best possible educational practices.

This paper has provided a case analysis of the consequences of such changes in the academic results of the first grade students of the EHEA adapted BEng Industrial Design Engineering degree at ETSID and those obtained by the first grade students of the corresponding pre-EHEA degree. This comparative analysis has been performed on the basis of different rates that have been defined for every subject and student.

In general, results have proved that active participation of students in their learning process together with their formative evaluation lead to an improvement of the success rates of most of the subjects. Furthermore, the implementation of teaching methodologies that promote active and dynamic learning of students, such as those followed in the EHEA structured

degree, contributes to their greater engagement. As it has been shown, this has resulted in an increase of the academic performance in scientific subjects rather than in humanistic ones, with traditionally better academic results in this degree.

Moreover, it has also been found that the implementation of a student-centered approach enhances the quality of the teaching-learning process, as proved by the better grades of the first year students of the EHEA adapted degree.

On the other hand, the analysis of the student success rate has revealed that personal success in this new degree has been considerably improved as a consequence of the incorporation of active methodologies and formative assessment strategies. Furthermore, it seems that the dropout percentage is not directly related to the teaching and assessment strategies. In consequence, it has been suggested to further analyze this result, in order to propose some improvement strategies.

Learning Artificial Intelligence Clip by Clip

Post Class Reflections on the First Online Norvig-Thrun-Stanford-Know Labs Artificial Intelligence Course

Alexandra Branzan Albu

Electrical and Computer Engineering
cross-listed with Computer Science
University of Victoria
Victoria (BC) Canada
aalbu@uvic.ca

Abstract—The free on-line Artificial Intelligence (AI) course taught by Norvig and Thrun in Fall 2011 is likely to be a game changer in postsecondary education. The huge course enrollment demonstrates that there is a keen interest in this new type of open education, and that no campus-based alternative can be suitable for educating such large numbers of students. The AI course was offered as a sequence of granular, interactive video clips grouped into topics. Homework and exams were video-based as well. This paper provides a critical evaluation of the author's experience as a student enrolled in the advanced track of the AI course. The author is a tenured associate professor at a Canadian medium-sized, research-intensive university. Her expertise lies in Computer Vision, a topic that is closely related to Artificial Intelligence. The paper is based on participatory action research methods.

Keywords: *on-line learning, video-based learning; open education; participatory research methods.*

I. INTRODUCTION

In Fall 2011, Stanford premiered the experimental free online offering of three Computer Science courses: Artificial Intelligence, Databases, and Machine Learning. Our focus is on the Artificial Intelligence course.

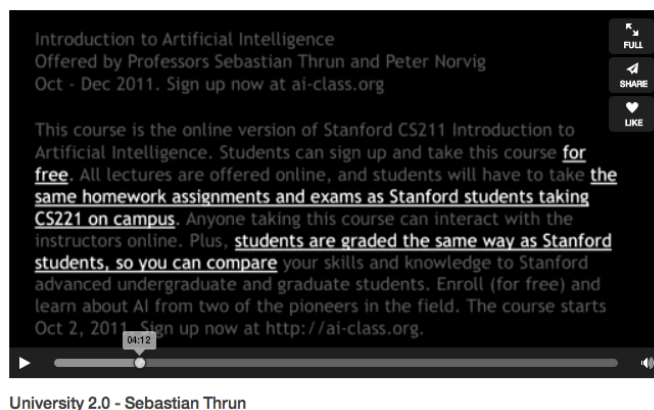

The Artificial Intelligence experiment is likely to be a game-changer in postsecondary education. Three main features differentiate it from previous initiatives in open education:

- The course was free and open to registration for anyone with an Internet connection and an interest in the topic. To account for differences in prerequisite knowledge, the course offered a basic track (no homework, no exams, only completion of quizzes required as a proof of on-line attendance), and an advanced track. Registrants were free to choose any of these tracks.
- For the advanced track, students had to study the same topics, do the same homework assignments and take identical on-line midterm and final exams as the Stanford on-campus equivalent class [1] The grading scheme for Stanford students and on-line student was the same (see Figure 1).

- a statement of accomplishment was emailed to all students passing the AI course. The statement of accomplishment was digitally signed by the course instructors and included a disclaimer that prevents the recipient to claim the course for Stanford credit, or to claim that he/she was registered in a Stanford course.

The Artificial Intelligence (AI) online class [2] was taught during October-December 2011 by two world class AI experts: Sebastian Thrun and Peter Norvig. This experimental offering was made technologically possible by a partnership between KnowLabs and Stanford.

Knowlabs, a start-up company in Silicon Valley, provided new technological solutions for the course delivery. This is how they introduced themselves: *"We're a Silicon Valley-based startup looking to change the future of education by making it more accessible and less expensive. We provide a high-quality online learning experience using interactive videos, intelligent software, mobile apps, and the social web. Our initial launch is online this fall: Introduction to Artificial Intelligence, taught by Sebastian Thrun and Peter Norvig in partnership with the Stanford University School of Engineering. The class is open to everyone at ai-class.com and is run by the technology we are developing for a larger site: **know it**."* (quote retrieved from Schmoller's site [3]. Note: knowlabs.com has now evolved into udacity.com).

University 2.0 - Sebastian Thrun

Figure 1. Snapshot from Thrun's presentation at Digital Life Design (DLD) Conference, Munich 2012 [4]

To summarize, the on-line Artificial Intelligence course offered by Norvig and Thrun in Fall 2011 took on-line education at a new level. This was made possible by new technology for course delivery and grading provided by KnowLabs. The course enrollment was huge: 160,000 students initially enrolled and 23,000 finishing the course on the advanced track according to course announcements [2] and Thrun's DLD presentation [2]). This demonstrates that there is a keen interest in this new type of open education, and that no campus-based education can be suitable for educating such large numbers of students.

This paper provides a critical evaluation of the author's experience as a student enrolled in the advanced track of the AI course. The author is a tenured associate professor at a Canadian medium-sized, research-intensive university. Her expertise lies in Computer Vision, a topic that is closely related to Artificial Intelligence. The paper is therefore based on participatory action research methods. The process of course delivery and the learning experience are analyzed from multiple perspectives (student enrolled in the course, teacher having taught similar courses) with great care for objectivity and non-bias. The main questions guiding this study are as follows:

- What are the pros and cons of video-based on-line learning with respect to traditional in-class learning for computer science courses?
- Can on-line and traditional learning models co-exist?
- Will on-line courses gradually replace traditional courses?

The remainder of the paper is structured as follows. Section II provides an overview of previous initiatives on open education. Section III is dedicated to the analysis of the course content, delivery, and assessment from a teacher's perspective. Section IV provides details about the author's learning experience as a student enrolled in the AI course. The paper ends with a brief overview of recently announced free on-line initiatives and concluding remarks.

II. OPEN EDUCATION

Several major open education initiatives are discussed in this section, namely the MIT OpenCourseWare [5], iTunesU [6], and Khan Academy [10, 11]. The discussion provides some brief historical details for background, then focuses on the distinct educational contributions of each initiative.

A. MIT OpenCourseWare

The MIT OpenCourseware (OCW) project was initiated in 2001, and represented MIT's strategic response to the reverberations of the dot-com phenomenon in higher education [5]. The academic world in the early years of the 21st century was finding itself at crossroads, unable to fully understand the future impact of Internet on the higher education landscape. MIT professor Abelson depicts this state in [5]:

"December 1999 was still full-fledged dot-com euphoria time, and the possibilities for a world-leading university like MIT seemed limitless – and daunting. Three years earlier, the eminent management consultant Peter Drucker had famously

predicted that "thirty years from now the big university campuses will be relics ... The college won't survive as a residential institution,"¹ and murmurs about the displacement of the traditional university rustled throughout the halls of academe."²

The MIT OCW concept was about the free sharing of complete course packages, consisting of lecture materials (slides and sometimes video lectures), assignments, and past exams with their solutions. The OCW framework project was initially established at MIT, but it rapidly grew to include other universities at a global level. According to Carson [5], the OCW consortium was established in 2005 with the mission "to advance education and empower people worldwide through OpenCourseWare". More than 40 Universities worldwide were funding members of the OCW consortium, which estimated to have more than 1700 course packages made available at that time.

The OCW project marked a critical moment in the development of open online education. It defined open education as one of MIT priorities, and in doing so, it steered away from commercial models of on-line education. As Carson states:

"In proposing OCW at a time when the prevailing trends in higher education were toward commercialization and competition, MIT also staked out a new model for the role of universities in the digital environment, one that reflected longstanding commitments in academia to dissemination of knowledge and shared scholarship – a model that would ultimately resonate worldwide."

However, the OCW model does have clear limitations. The shared course materials were developed for traditional class-based courses, therefore their relevance for a global audience was limited. Most of the published course materials had no interactive content. One may argue that the OCW initiative was more relevant for instructors in traditional learning contexts (allowing for the enrichment of their own campus-based courses), rather than for students trying to learn a subject on their own.

B. iTunes University

iTunes University is a free web-based tool provided by Apple [6]. Its latest app-based version, released on January 2012 enables educators to upload audio and video podcasts of their lectures, as well as link these podcasts with other course documents such as handouts, assigned readings, digital textbooks and make their course available worldwide.

iTunes University was first released in 2007, with an initial focus that was similar to OCW. The main effect of iTunesU on higher education was the introduction of podcasting as an educational tool. While audio and video educational materials have existed on the web before iTunesU, podcasting is a distinct phenomenon, characterized by the ease of uploading, downloading, subscription, and sharing of audiovisual content. Most importantly, podcasts are easy-to-consume digital media,

¹ Drucker's quote is from Lenzer and Johnson [7]

² Abelson's quote is also used by Carson [5]

as they can be listened to or watched while commuting, exercising etc.

There are at least two distinct trends in using podcasts in higher education. First, Campbell [7] argues that short podcasts (less than 10 minutes each) can be used in a similar way to movie trailers; they are intended “*not to give away intellectual property but to plant seeds of interest.*” So, podcasts can be used to support and enhance traditional classroom-based education by providing short insights in what the next class will be about, by engaging students in podcasting competitions etc. The podcast is therefore viewed here as an educational pill used for stimulating the student’s interest, motivation, and engagement with traditional classroom-based courses.

Alternatively, a podcast can include the content of an entire class lecture, and therefore it might become a perfect substitute for the lecture. McKinney et al. [8] show via a controlled experiment that using podcasts instead of lectures is a viable alternative. Their study involved undergraduate psychology students who participated either in a podcast condition or in an in-class lecture condition. The lecture condition involved participants listening to a 25 min lecture given by a professor using Powerpoint slides. The podcast condition involved students listening to the exact audio recording of the lecture. Students in both conditions received handouts of powerpoint slides for the purpose of note taking. Their learning was assessed via an exam on the lecture content. McKinney et al [8] found that the students in the podcast condition scored significantly better than their peers in the lecture condition. However, this applied only to students who were taking notes while listening to the podcasts. Their main conclusion is that podcasting is a very viable alternative to class lecture, as long as students maintain the same learning process (note taking while listening). They argue that the main advantage of podcasting over traditional lectures is the ability of students to listen to the podcast on their own time. This argument is also made by Read [9] who points out that podcasts allow for replaying important passages from lectures.

To summarize, the podcasts are still considered most relevant when supporting traditional lecture-based education. It has been shown [8, 9] that when podcasts provide a perfect replica of in-class lectures, the student’s class attendance does not seem to be affected. Podcasting is therefore mostly viewed as an innovative review tool, rather than a replacement for traditional lectures. Moreover, podcasting and open education seem to evolve in parallel tracks. A professor recording her own lectures might or might not post them on an open platform. There is little evidence, as in the case of OCW, of the potential benefits of openly sharing such educational media. Questions have arisen with respect to IP issues on podcast authoring.

However, duplicating lecture content via podcasts or using podcasts as ‘educational pills’ has just scratched the surface of potential educational uses of this new tool. The next section introduces a new way of using audiovisual materials for supporting more active learning strategies in an open education world.

C. Khan Academy

Although Khan Academy [10] is primarily oriented towards K-12 education, we discuss it here because its model is the closest to the AI course. Thrun mentions Khan [4] and its wide-reaching educational videos as an inspiration for changing his own teaching style. Khan Academy offers a free online library of over 3000 short videos covering a diversity of topics (math, physics, chemistry, history, finance etc) as well as over 300 practice exercises.

What is conceptually new about Khan Academy? It does not use videos for motivating students to attend longer lectures; it does not replace traditional lectures with their filmed podcast. Khan Academy rethinks the video podcast as an elemental teaching unit. Each video is about one concept, and it explains it as concisely as possible, so that students can use the new knowledge immediately in practice exercises. The granular videos are organized in a knowledge map, and students get to gradually advance in the map as they master more complicated concepts.

Mastery is key in Khan’s approach to the design of the Academy. He points out that one major flaw in the current educational system is the fact that “*it penalizes you [i.e. the student] for experiment and failure, but it does not expect mastery*”. He further explains this with the analogy of learning how to ride a bicycle:

“I give you a bicycle for two weeks, and a lecture ahead of time. I come back after two weeks. Let’s see, you are having trouble taking turns, you can’t quite stop. You are an 80% bicyclist. And then I say, here is a unicycle...” (transcript from Khan’s TED talk [11], min 8:31 onwards).

In Khan’s view, the traditional K-12 educational system leaves students with many knowledge gaps due to improper teaching and assessment techniques; therefore, it fails to provide students with a solid foundation of basic skills in STEM topics.

With respect to assessment of student’s knowledge and skills, Khan’s academy provides teachers with tools that can very precisely track the student’s progress over time. When students are logged in, the system collects historical data on all exercises that they have attempted, time spent on every exercise, errors made, gradual self-corrections of these errors etc. While this type of data collection is standard practice in financial and marketing fields, it has never been used for educational purposes before. The system can build a very accurate description of the current status of the student’s knowledge without any traditional test being necessary, therefore eliminating the time spent by K-12 teachers on marking.

Perhaps the most significant innovation provided by Khan Academy is related to the new role of video podcasts in the teaching and learning process. Podcasts become the primary source of knowledge rather than a complement to traditional in-class teaching of new concepts. This enables the “class flipping” phenomenon [10], where students are required to watch theoretical videos at home and work on practice problems in class. The teacher becomes a facilitator of the learning process, and steps down from the more central,

traditional role of conveyor of knowledge. The teacher is also aware of all difficulties that students may encounter in their learning (due to the very precise, real-time, on-line ‘portrays’ made available by Khan Academy) and thus can provide highly customized help to every student in need.

To summarize, Khan Academy has elevated podcasts to a new level of educational relevance via three key innovations:

- podcasts are granular and organized in a highly structured manner that enables students achieve mastery; theoretical and practice podcasts are closely interlinked.
- the progress of students engaged in learning with podcasts can be very accurately tracked with monitoring software that is already mainstream in finances and marketing.
- podcasts enable teachers to focus less on delivery of content (lectures) and more on personalized interventions via class flipping.

Are the main principles of Khan Academy applicable or adjustable to higher education? Is it possible or even desirable to foresee a higher education meta-system that functions according to these principles? These are complex questions that might become a hot topic for discussion in the academic world as free online undergraduate courses offered by reputable US Universities multiply.

III. ANALYSIS OF COURSE CONTENT, ASSESSMENT, AND DELIVERY METHODS

The AI course [2] was structured in twenty-two units that closely replicate the typical structure of a traditional lecture-based course. The content of each topic is freely available for viewing by visitors. Homework, exams, and forums are closed for visitors and available only for course registrants; however, homework and exam solutions exist on YouTube, therefore they are in theory accessible to non-registrants as well. Registration to this course was free, however it had to be completed prior to the start of the course (October 2011).

This section provides an analysis of the course content, assessment and delivery methods from an instructor’s point of view. The educational value of the materials and the pedagogical methods are the primary points of discussion. The course content, homework, and exams are discussed in separate subsections.

A. Course content and delivery

Table 1 summarizes data about the topics taught in the AI courses on a weekly basis. Information about who taught each topic, the number of videos that each topic consisted of, and the number of videos ending with a quiz are shown in Table 1.

The videos composing every topic vary in length from 30 seconds to 5 minutes. Short videos typically contain quizzes only. Longer videos introduce usually a new concept. The visual appearance of videos is very informal and lo-tech. According to Thrun [4], all that was needed to record the videos was ‘a camera, a pen, and a napkin’. For answering quizzes/homework/exam questions the student simply has to enter the answer (either a multiple choice or a numerical result)

into a case that is initially specified by the instructor on paper, then activated on screen by software using computer vision technology. An example of student interaction with quizzes is given in Figure 2.

TABLE I. OVERVIEW OF TOPICS TAUGHT IN THE AI COURSE

| Week | Topic | Instructor | Total no. of videos | No. of videos with a quiz |
|------|--------------------------------|------------|---------------------|---------------------------|
| 1 | Welcome to AI | Thrun | 13 | 8 |
| 1 | Problem Solving | Norvig | 38 | 20 |
| 2 | Probability in AI | Thrun | 37 | 29 |
| 2 | Probabilistic Inference | Norvig | 21 | 12 |
| 3 | Machine Learning | Thrun | 37 | 22 |
| 3 | Unsupervised Learning | Thrun | 30 | 16 |
| 4 | Representation with Logic | Norvig | 13 | 6 |
| 4 | Planning | Norvig | 22 | 3 |
| 5 | Planning under uncertainty | Norvig | 27 | 10 |
| 5 | Reinforcement Learning | Norvig | 22 | 3 |
| 6 | HMMs and Filters | Thrun | 22 | 6 |
| 6 | MDP Review | Thrun | 4 | 4 |
| 7 | Midterm | | | |
| 8 | Games | Norvig | 23 | 13 |
| 8 | Game Theory | Norvig | 19 | 10 |
| 8 | Advanced planning | Norvig | 11 | 5 |
| 9 | Computer Vision I | Thrun | 33 | 14 |
| 9 | Computer Vision II | Thrun | 20 | 12 |
| 9 | Computer Vision III | Thrun | 6 | 3 |
| 10 | Robotics I | Thrun | 13 | 8 |
| 10 | Robotics II | Thrun | 11 | 4 |
| 11 | Natural Language Processing I | Norvig | 30 | 10 |
| 11 | Natural Language Processing II | Norvig | 12 | 3 |
| 11 | Optional programming NLP | Norvig | 1 | 1 |
| 12 | Final exam | | | |

From a content-based perspective, the AI course is more broad than deep, as it provides an overview of the many fields related to AI (machine learning, computer vision, games, robotics, natural language processing), as well as a brief introduction to the primary mathematical tools used in AI (theory of probabilities, hidden Markov models, game theory, particle filters etc.). This ratio of breadth over depth is typical for an introductory course. One may wonder though whether linear sequences of granular videos would be effective tools for teaching more specialized, higher-level courses, where interconnections between various topics are more frequent.

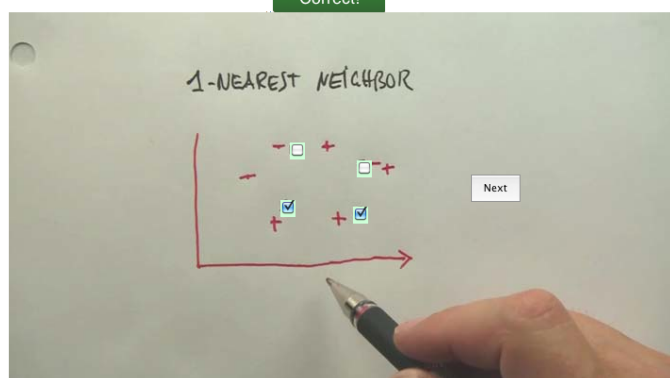

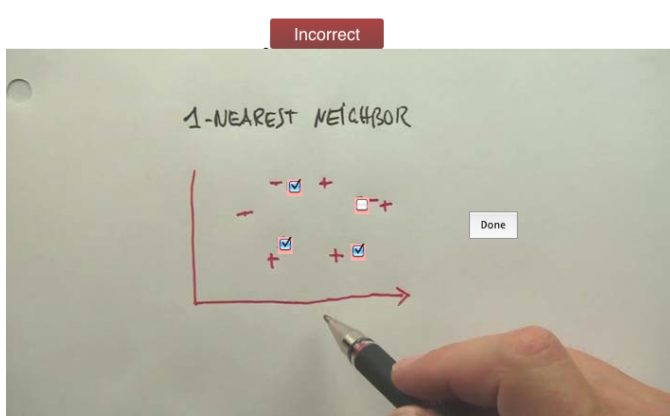

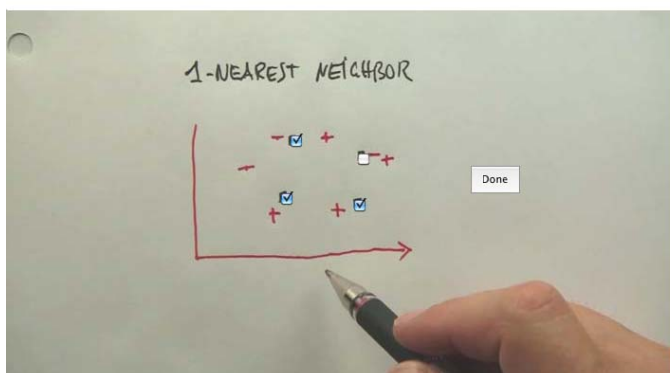

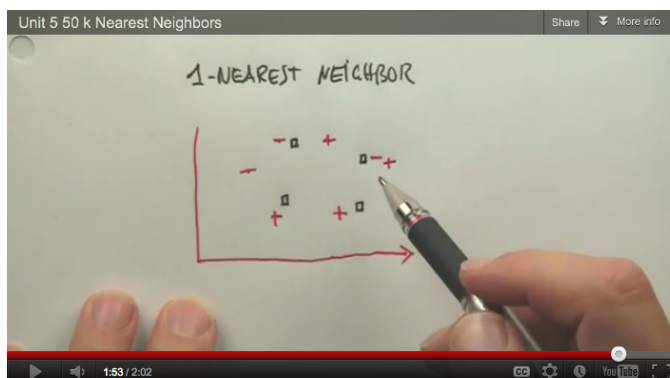

Figure 2. Top to bottom: instructor states the question and draws cases for the student to click on; software creates ‘hotspots’ for each of these cases; student answers by clicking on selected cases; software interprets answer and offers immediate binary feedback. When the answer is correct, the student may proceed to the next video. All snapshots are from [12]

The usage of video clips in the AI course brings elements of novelty with respect to the Khan Academy style. The quizzes are integrated throughout the course (note the large ratio of quiz to non-quiz videos in Table 1). Some quizzes introduce a concept in an intuitive way; an example is the quiz on the nearest neighbor classifier, whose snapshots are shown in Figure 2. Other quizzes are designed as direct applications to concepts already introduced, and they are usually grouped in series with an increasing level of difficulty. Answers to quizzes with explanations are immediately accessible via links provided after the student response has been entered.

The large number of topics covered in the course (see Table 1) reveals that breadth is favored over depth, and this is to be expected in an introductory course. However, there is no clear relation between the topics, no logical ordering. Thrun and Norvig seem to teach on parallel tracks, with virtually no common points. These comments could be of course applicable to traditional in-class courses; however, it is believed that the clip-based nature of the course has a significant impact on the lack of connectivity amongst course topics. The information is encapsulated in video clips in the parallel-serial structure shown in Figure 3, which makes random connections between concepts situated in different topics virtually impossible.

| Topic A | Topic B | Topic C |
|-----------|-----------|-----------|
| Video A.1 | Video B.1 | Video C.1 |
| Video A.2 | Video B.2 | Video C.2 |
| Video A.3 | Video B.3 | Video C.3 |
| Video A.4 | Video B.4 | Video C.4 |
| ... | ... | ... |

Figure 3. Parallel-serial structure of concepts taught in the AI class using video clips.

B. Assessment (homework and exams)

The course was assessed via six homework sets, one midterm, and one final exam. All homework and exams were presented using quiz-like video clips, in a consistent manner to the course delivery.

Homework sets contained questions that were very similar to the quizzes contained in the respective topic. A relatively small number of questions were included in each homework, which provided limited opportunities for practice, as well as a rather incomplete assessment of the student’s knowledge on a particular topic.

The levels of difficulty for midterm and homework were comparable. The final exam contained some non-trivial questions that demanded the ability to generalize concepts learned in class (for instance, counting parameters for a non-binary Bayes network), and to make connections between various concepts (for instance, particle filters and basic probability). This is current practice in the design of final exams; however, the students’ ability to make connections/extensions between/of various parts of the course was not facilitated by the video-based course delivery style.

An interesting collaboration with two German Universities was announced before the midterm. Students enrolled in the on-line AI class were given the opportunity to write the exams in class at either University of Freiburg or Technische Universität München (TUM). For those students passing these exams, certificates of completion of the AI course would serve as certificates of equivalence with the traditional AI class at the University of Freiburg. The announcement can be consulted at <https://www.ai-class.com/home/?page=10>. This type of course equivalence is a “premiere” in the academic world, since it blurs the boundaries between traditional residential education and on-line education.

The overall average student performance in the AI class scored at slightly less than 90%. Compared to traditional class averages, this is extremely high. Thrun talked in [4] about going away from ‘weeder’ course models, which typically fail 20% or more of students initially enrolled. A very high class average is consistent therefore with Thrun’s beliefs. It is difficult to say though whether this high average reflects true mastery of the topics taught. See also next section for some related ideas.

IV. THE AI COURSE FROM A STUDENT’S VIEWPOINT

As a student, the author has definitely appreciated the hands-on teaching approach, and found that immediate experimentation with concepts via quizzes is very engaging, to the point of developing a quasi-addiction to quizzes. The informal, lo-tech aspect of the videos adds an interesting social dimension to the course, which provides the experience of being tutored on an individual basis. This is a very different dynamic from an in-class environment (especially in large classes) where students relate to the teacher as a group. Thrun [4] mentioned the same effect, noting that in-class attendance for the traditional AI course at Stanford had dropped significantly due to the availability of on-line materials.

However, learning on a clip-by-clip basis poses some important challenges with respect to revision of materials. Typical tools that help students engage with teaching materials such as annotating class notes and handouts do not transfer well on video materials. To date, there is no annotating tool for videos. There is no possibility of making explicit interconnections between topics taught in different videos. There is no simple solution for querying the video database with concepts, or for reorganizing it according to new criteria.

The granularity and high consumability of the videos is a mixed blessing. Studying those videos can be squeezed in short spare time periods, which is very convenient for adult learners juggling many responsibilities. However, the author feels that students should not be encouraged towards this type of learning. For a deeper understanding of the course materials, it is preferable to dedicate longer times for study; this might be one of the few arguments in favor of keeping lecture-based teaching (or longer podcasts) alive. The same conclusions apply for exams. While one might be tempted to work on separate small time chunks on a three-hour exam delivered over a three-day period, it is unlikely that the proper level of focus will be reached in this manner. Without proper focus, more difficult questions requiring abstraction and generalization skills will not be handled correctly.

V. LOOKING INTO THE FUTURE

This paper has provided a critical analysis of the first free on-line AI class taught by Norvig and Thrun in Fall 2011. Participatory research methods were used for this study. The paper highlights some strengths and limits of teaching by granular video clips.

The ripple effect of the Stanford experiment in Fall 2011 is currently propagating through elite North-American schools. Thrun has launched his own company www.udacity.com dedicated to free on-line courses in computer science and robotics. A collection of nineteen on-line courses from various universities (Stanford, Berkeley, Michigan) is advertised on www.coursera.com. MIT has launched its own on-line learning initiative MITx (mitx.mit.edu) with one prototype course (Circuits and Electronics) running from March 5 to June 8 2012.

It is difficult to estimate the consequences of this ripple effect on traditional on-campus education. However, it is clear that on-campus education will have to reinvent itself in order to survive in the era of mature on-line teaching technologies and massive on-line learning communities. It is hoped that this paper provides a platform of discussions within the STEM academic community on redefining the roles of on-campus and on-line education, as well as finding their right balance.

Work in Progress: Redesigned First-Year Seminar Course in Engineering - Delivery, Learning Outcomes Assessment, and Lessons Learned

Ramakrishnan Sundaram
Gannon University, sundaram@gannon.edu

Abstract - This paper discusses the delivery of content and rubrics for assessment of learning outcomes in the redesigned version of the critical entry-level course, *First-Year Seminar in Engineering*, for undergraduate engineering students. The *First-Year Seminar in Engineering* at our institution is offered once each year during the fall term. The course comprises 45 to 50 first-year students who will graduate with engineering degrees from four-year programs. The redesign of this course was necessitated by the (1) disparate nature of the content from session to session (2) lack of continuity across sessions, and (3) absence of a common thread to bind the content of the course. For the incoming engineering student to receive both the holistic University experience and develop the ability to learn and retain fundamental engineering principles and practices, the course has been redesigned to incorporate *community-based engineering projects* as the *core theme* of the course. The students formed teams, and maintained *team-based blogs* to document their progress on the engineering project. In addition to the traditional learning outcomes assessment methods (e.g. in-class testing, homework assignments, individual and group reports), rubrics were developed to assess the performance of the students in the engineering projects.

Keywords - Service learning, Course modules, Team blog, Engineering projects

INTRODUCTION

The critical entry-level course at our University, titled *First-Year Seminar in Engineering*, is designed to orient the new student to the University and to introduce engineering as a professional field. In addition, the course seeks to (a) establish the connection with the Liberal Studies Core (b) assist in the transition from high school to university life, and (c) encourage the development of academic, personal, and spiritual aspects of the student's life. The *First-Year Seminar in Engineering* intends to stimulate and enhance the student's interest in and their understanding of engineering.

Unfortunately, the previous offerings of this course failed to deliver the desired learning experiences due to (1) disparate nature of the content and delivery from session to

session (2) lack of continuity across sessions (3) absence of a common thread to bind the content of the course.

The primary aspect of the redesign was to deliver the content in modules which focused on a *central engineering project* comprising *service learning components* and *project-based team-managed blogs*. Service learning is of vital importance in the engineering profession [1], [2] and must be integrated into the engineering curriculum at an early stage of career development. Engineering projects with aspects of service learning are both challenging and motivating to students entering the engineering profession. In addition to teaching the students engineering design and practice in the context of society and values, and instilling the recognition of engineering issues and concerns, engineering project activity with service learning incorporates reflection and collaboration as the critically required facets of engineering education.

In this paper, the approach and implementation of the course redesign based on linking the classroom to the community is discussed and represents the implementation of a work in progress [3] paper presented at the last FIE conference. Section 2 provides details of the approach to course redesign. Section 3 identifies the rubrics adopted for learning outcomes assessment. Section 4 summarizes the delivery of the redesigned course and the process of learning outcomes assessment. The lessons learned are documented in Section 5.

SECTION 2: APPROACH TO COURSE REDESIGN

First, the sessions of the course are reorganized to integrate them around a core theme. The core theme provides the link between the classroom activities in the course and the community through *engineering projects* with clearly identified *service learning components*. Examples of the engineering projects chosen are (a) Solar-panel installation (b) University Community garden fence (c) Roofing materials for energy-efficient buildings, and (d) Vermicomposting bin.

These projects are determined prior to the start of the term in discussions with the Office for Service Learning and the Center for Social Concerns at our University. Funding was provided to each team for their bill of materials. Student

teams were organized and project selections made within the first week (after two sessions) of the term. Figure 1 represents the conceptual bridge between course modules and these projects through *team blogs* for reflection and collaboration.

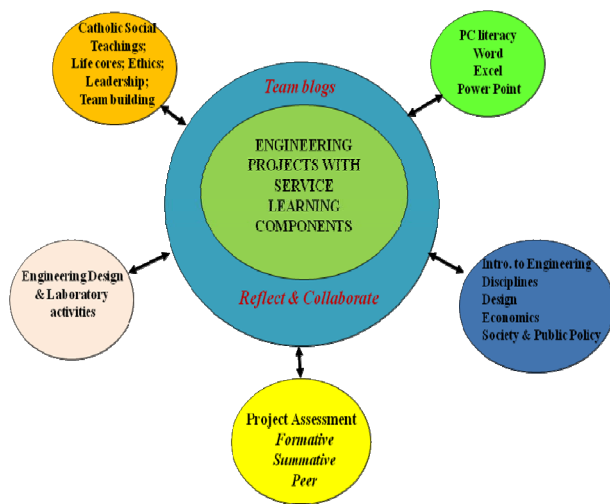

Figure 1. Core theme, course modules, and bridge.

SECTION 3: RUBRICS FOR OUTCOMES ASSESSMENT

The assessment of student performance in the course outcome specific to the service learning experience is based on the following rubrics.

- (a) *Team-based blog*
- (b) *Formative* (in-class presentation – update)
- (c) *Summative* (final report on the core project)
- (d) *Peer or internal* (intra-team performance)

(a) *Team-based blog*

The four categories of assessment of the *team-based blog* are as follows:

1. Overall use of blogs
2. Intellectual engagement with key concepts
3. Personal response to key concepts
4. Engaged writing

(b) *Formative assessment*

The rubric to assess the in-class presentation by each team (progress report) has four categories.

1. Presentation style
2. Team involvement
3. Overall progress
4. Schedule/Timeline provided

(c) *Summative assessment*

The final report submitted by each team at the end of the term is assessed in four categories.

1. Project overview and goals
2. Project description and task plan
3. Discussion of the project tasks completed
4. Conclusions and overall organization of the report

(d) *Peer or internal assessment*

The rubric for each team to assess individual contributions to the team project is based on a scale from 0 (not involved) to 5 (actively involved) for their level of involvement.

SECTION 4: DELIVERY AND RESULTS

The redesigned First-Year Seminar course in Engineering was delivered in the Fall 2011 semester (August 2011 to December 2011) at our University. The following highlights of the delivery are noted.

- Fifty one students were enrolled in the class
- Thirteen teams worked on six service learning projects
- Team leaders received training on the creation and maintenance of team blogs
- Teams completed and submitted *peer assessments* each week
- Teams documented their progress on the project using their team blogs
- Teams provided progress reports as part of the *formative assessment* during the term
- Teams submitted the final report and updated the entries on their team blog page
- *Team blog assessment* and *summative assessment* were completed at the end of the term

SECTION 5: LESSONS LEARNED

The redesigned *First-Year Seminar course in Engineering* successfully met and exceeded the following expectations.

- Relate classroom content to engineering problems in the community
- Understand engineering project constraints and requirements in practice
- Develop leadership and communication skills through team work
- Use the experience to strengthen their preparation for future careers in engineering

The inclusion of innovative instructional and learning tools such as *team blogs* to instill reflection and collaboration has a profound impact on undergraduate engineering education.

Work in Progress: En route to lifelong learning?

Academic Motivations, Goal Orientations, and Learning Conceptions of Entering First-Year Engineering Students

Abstract— Although lifelong learning is among the most critical skills required of today's engineering graduates, the complex processes through which individuals develop the attitudes, beliefs, and skills of lifelong learners remains unclear. Instructors have only begun to understand the impacts of academic background, institutional climate, and pedagogy on students' development of the motivations and learning strategies characteristic of lifelong learners. In this ongoing mixed-methods investigation, we draw on existing motivation and self-regulated learning theories to examine how undergraduate students at a small private college and a large public university become more self-directed as they progress through the first two years of their engineering programs. Preliminary findings indicate that first-year students at the two institutions report significant differences in their motivations and goal orientations. Students at the small private college express higher intrinsic motivation and learning orientation, and lower external regulation and grade orientation, compared to students at the large public university. The two groups also show differences in their beliefs about individual versus social learning. We briefly discuss how differences in motivations, goals, and beliefs may impact student responses to early program experiences, and require instructors to tailor their approaches to support the needs of emerging lifelong learners.

Keywords— *motivation, lifelong learning, self-directed learning, self-regulated learning, goal orientation, epistemic beliefs*

I. INTRODUCTION

A capacity for self-directed learning (SDL) and lifelong learning is widely recognized as a critical outcome for today's engineering graduates [1-5], and prior educational research has elucidated what it means for individuals to be self-motivated, self-regulating, and self-determined [e.g., 6,7]. The processes by which teacher-controlled learners *become* self-directed learners, and the roles that pedagogy and learning climate play in these processes, however, remain unclear. Instructors need to gain more insight into the transformation from teacher-controlled to self-directed learners in order to effectively design curricula that support students' emergence as empowered, adaptive learners. To better understand students' growth as self-directed (and eventually lifelong) learners, we initiated a two-year longitudinal study of undergraduate engineering students' development of SDL attributes. We draw upon self-determination and achievement goal theories of motivation [8-15] and social-cognitive frameworks and empirical research in self-regulated learning (SRL) [16-23]. We posit that self-directed learner development is a complex and multifaceted

process shaped by the interaction of specific learning environments with students' learning beliefs, motivations, goal orientations, and metacognitive knowledge and skills. We pose four questions: How are entering students characterized with respect to SDL-relevant attitudes and skills, and how do these attitudes and skills change over a two-year period? What are the gender and institutional differences in entering students' SDL attributes and SDL growth over a two-year period? (4) How do students evaluate learning experiences with respect to their own SDL development?

II. METHODS

The present investigation is a mixed-methods longitudinal study that tracks student SDL development over the first two years of their engineering programs. This paper presents quantitative results from the start of the study, when first-year students were beginning their engineering programs.

A. Participants

Participants in this study are first-year undergraduate students enrolled in engineering programs at two different institutions: a small private college and a large public university. Selection of these schools enables examination of incoming student attributes and SDL development in settings with gender, geographic, learning culture, and academic background diversity. Students in this study experience a variety of pedagogical approaches as they progress through their typical coursework, ranging from open-ended projects to traditional lecture and lecture/lab.

B. Measures and Analyses

This study makes use of several existing instruments to periodically gauge students' SDL-relevant attitudes and skills. **Academic motivations** are measured using the Academic Motivation Scale (AMS) [24]. Based on Deci and Ryan's self-determination continuum [8], the AMS measures *contextual level* motivations, i.e., students' general attitudes toward school and learning, on a 7-point Likert scale (1=corresponds not at all, 7=corresponds exactly) [25-27]. **Goal orientations** are evaluated using the Learning Orientation Grade Orientation (LOGO-II) survey [28-29], which measures college students' predominant attitudes and behaviors with regard to learning, testing, and grading. LOGO-II uses a 5-point Likert scale (1=strongly disagree, 5=strongly agree) and provides learning orientation (LO) and grade orientation (GO) scores

in two parts: (1) academic attitudes and (2) observable behaviors. **Conceptions of learning** are characterized using an adapted version of the Learning Inventory, an instrument that uses a 4-point scale (1=first item agreement, 4=second item agreement) designed to measure conceptions of learning in five areas: (1) external versus internal regulation, (2) reproductive versus constructive knowledge, (3) individual versus social learning, (4) fixed versus dynamic ability, and (5) tolerance of uncertainty [30]. Descriptive statistics were compiled for all survey data, and across-institutional differences were analyzed via independent samples t-tests.

III. PRELIMINARY RESULTS AND DISCUSSION

A. Academic Motivations

As shown in Table I, both of the first-year student groups report generally positive academic motivational orientations, with high intrinsic motivation (IM) and identified regulation (IR) scores, and low amotivation (A) scores. Despite the generally positive AMS findings, the two groups do show statistically significant differences in their motivational orientations. Students at the large public university indicate lower intrinsic motivation and higher external regulation (ER) compared to students at the small private college. Since external regulation is a type of extrinsic motivation associated with attaining rewards or avoiding punishments, the high ER at the large public university suggests that these students could benefit from assistance in transforming extrinsic inputs into personally endorsed, or “internalized,” values and self-regulations [8]. For example, instructors in this setting may help students shift to more autonomous motivations by avoiding excessive external pressures, emphasizing mastery learning, encouraging peer collaboration, and supporting the pursuit of student-endorsed interests or values [31].

TABLE I. ACADEMIC MOTIVATIONS OF ENTERING FIRST-YEAR ENGINEERING STUDENTS.

| AMS Subscale | Small Private College (N=33) | | Large Public University (N=22) | | P-value |
|------------------------|------------------------------|------|--------------------------------|------|-----------------|
| | Mean | SD | Mean | SD | |
| Intrinsic Motivation | 5.95 | 0.83 | 5.38 | 1.31 | .05 |
| Identified Regulation | 5.69 | 0.91 | 5.55 | 0.95 | ns ^a |
| Introjected Regulation | 3.66 | 1.63 | 3.84 | 1.68 | ns |
| External Regulation | 4.25 | 1.56 | 5.34 | 1.10 | .007 |
| Amotivation | 1.24 | 0.54 | 1.48 | 1.20 | ns |

a. ns = not significant

B. Goal Orientations

The LOGO-II results (Table II) indicate that both student groups are more learning oriented than grade oriented, in both their academic attitudes and observable behaviors. The two participant groups do, however, show significant differences in their goal orientations. Students at the small private college report extremely high LO attitudes, and high LO behaviors, indicating that these students generally find learning fun; they have a positive regard for instructors and a negative regard

for easy, but irrelevant, material; and they have positive feelings for formative feedback over evaluative grading. Relative to the small private college group, students at the large public university report lower LO and higher GO attitudes and behaviors, which may indicate that these students have a reduced valuation of ungraded assignments; a stronger tendency to resent material and testing of topics not covered in class; and a stronger tendency to view grades as the basic reason for learning [29].

TABLE II. GOAL ORIENTATIONS OF ENTERING FIRST-YEAR ENGINEERING STUDENTS.

| LOGO-II Subscale | Small Private College (N=33) | | Large Public University (N=22) | | P-value |
|--------------------------|------------------------------|------|--------------------------------|------|---------|
| | Mean | SD | Mean | SD | |
| LO: academic attitudes | 4.00 | 0.58 | 3.60 | 0.51 | .011 |
| GO: academic attitudes | 2.69 | 0.39 | 3.36 | 0.55 | <.001 |
| LO: observable behaviors | 3.17 | 0.57 | 2.34 | 0.47 | <.001 |
| GO: observable behaviors | 1.50 | 0.33 | 1.91 | 0.57 | .001 |

C. Conceptions of Learning

Entering first-year engineering students at the two institutions showed similar beliefs about learning (Table III), with no statistically significant differences in their endorsement of external vs. internal regulation, reproductive vs. constructive knowledge, fixed vs. dynamic learner ability, and certainty vs. uncertainty in learning. The only across-institutional difference was found in the individual vs. social learning subscale, with students at the small private college more strongly endorsing peer learning. This finding may have important implications in the classroom, as first-year students at the large public school may initially show a preference for direct instructor guidance over collaborative exploration of problems with their peers.

TABLE III. LEARNING CONCEPTIONS OF ENTERING FIRST-YEAR ENGINEERING STUDENTS.

| Learning Inventory Subscale | Small Private College (N=33) | | Large Public University (N=19) | | P-value |
|--|------------------------------|------|--------------------------------|------|---------|
| | Mean | SD | Mean | SD | |
| External vs. internal regulation | 2.66 | 0.58 | 2.39 | 0.52 | ns |
| Reproductive vs. constructive knowledge | 3.02 | 0.50 | 2.97 | 0.55 | ns |
| Individual vs. social learning | 3.39 | 0.36 | 3.12 | 0.38 | .014 |
| Fixed vs. dynamic ability | 3.57 | 0.31 | 3.43 | 0.32 | ns |
| Intolerance vs. tolerance of uncertainty | 2.91 | 0.29 | 2.77 | 0.47 | ns |

a. ns = not significant

Work in Progress: Early Prediction of Students' Academic Performance in an Introductory Engineering Course Through Different Mathematical Modeling Techniques

Shaobo Huang and Ning Fang
Department of Engineering Education
Utah State University
Logan, Utah, USA
ning.fang@usu.edu

Abstract—This paper presents our ongoing efforts in developing mathematical models to make early predictions, even before the semester starts, of what score a student will earn in the final comprehensive exam of the engineering dynamics course. A total of 1,938 data records were collected from 323 undergraduates in four semesters. Employed were four different mathematical modeling techniques: multivariate linear regression, multilayer perceptron neural networks, radial basis function neural networks, and support vector machines. The results show that within the five predictor variables investigated in this study, there is no significant difference in the prediction accuracy of these four mathematical models.

Keywords: *Early prediction; engineering dynamics; students' academic performance; mathematical modeling*

I. INTRODUCTION

Early prediction of how well (or how poorly) students will perform academically in engineering courses helps the instructor design and implement early interventions of appropriate instructional strategies to achieve maximum student learning outcomes [1, 2]. The results of early prediction can also stimulate students, especially those academically-at-risk students, to think about and explore effective ways to improve their learning strategies.

Engineering Dynamics is a high-enrollment, high-impact, introductory engineering course that nearly all students in mechanical, aerospace, and civil engineering majors are required to take. The course covers numerous foundational engineering concepts and principles, and encompasses many fundamental building blocks essential for advanced studies in subsequent engineering courses, such as Machine Design, Advanced Structural Design, and Advanced Dynamics [3].

This work-in-progress paper presents our ongoing efforts in developing a set of mathematical models to predict students' academic performance in an engineering dynamics course. The models can make early predictions, at the beginning of a semester or even before the semester starts, of what score a student will earn in the final comprehensive exam of the engineering dynamics course. The predictive models were

developed by using four different mathematical modeling techniques: multivariate linear regression (MLR), multilayer perceptron (MLP) neural networks, radial basis function (RBF) neural networks, and support vector machines (SVM). The inputs of the mathematical models include five predictor variables: a student's cumulative grade point average (GPA), and grades earned in four closely-related pre-requisite courses, i.e., Engineering Statics, Calculus I, Calculus II, and Physics. GPA is a comprehensive measurement of a student's problem-solving skills. The statics grade was included because numerous concepts of statics (such as free-body diagram, force equilibrium, and moment equilibrium) are employed in dynamics. Calculus I and II grades represent a student's mathematical skills needed to solve calculus-based dynamics problems. The physics grade represents a student's basic understanding of physical concepts and principles behind various dynamics phenomena. The above-described five predictor variables are known before students take the dynamics course. The output of the model is a student's final dynamics exam score.

Extensive literature review showed that no prior literature, except for the authors' own work, exists that compares these four mathematical techniques to model students' academic performance in engineering dynamics. The central *research question* of the present study is: Within the five predictor variables investigated in this study, is there a significant difference in the prediction accuracy of MLR, MLP, RBF, and SVM models? The answer to this research question will help the instructor choose the most appropriate mathematical modeling technique.

II. DATA COLLECTION

A total of 1,938 data records were collected from 323 undergraduates who took dynamics in four semesters: Semesters #1 ($n = 128$), #2 ($n = 58$), #3 ($n = 53$), and #4 ($n = 84$). The majority of the students were either from the mechanical and aerospace engineering major (174 students, or 53.9%) or from the civil and environmental engineering major (93 students, or 28.8%). Each student was associated with six

data: the final dynamics exam score and the scores/grades of the above-stated five predictor variables. For 323 students, there are $6 \times 323 = 1,938$ data records. No significant instructional changes were made across the four semesters that influenced the students' final dynamics exam score.

Before entering into a model, all letter grades were converted into numerical values based on the following scales: A = 4.00; A- = 3.67; B+ = 3.33; B = 3.00; B- = 2.67; C+ = 2.33; C = 2.00; C- = 1.67; D+ = 1.33; D = 1.00; F = 0.00. The numerical values of all data were then normalized through dividing the initial value of the data by its maximum possible value in its same category. The purpose was to avoid the cases in which one variable received a high or low weight due to its initial low or large scale of measurements.

III. MATHEMATICAL MODELS

The full dataset collected in Semester #1 was used to develop mathematical models. Multivariate linear regression (MLR) generated an explicit prediction formula:

$$\text{Final dynamics exam score} = 0.022 + 0.715 \times \text{GPA} + 0.034 \times \text{Statics score} - 0.063 \times \text{Calculus I score} - 0.077 \times \text{Calculus II score} + 0.204 \times \text{Physics score} \quad (1)$$

As seen from Eq. 1, the five predictor variables have different effects on the final dynamics exam score. The commercial software package SPSS and MATLAB codes were employed to develop MLP, RBF, and SVM models. The default value of relevant parameters in SPSS, such as the minimum relative change in training error, the minimum relative change in training error ratio, and the maximum training epochs, were adopted to optimize MLP/RBF models. Because the algorithms were complex [4], no simple mathematical equation can be provided in this paper to show what the MLP, RBF, and SVM models look like.

IV. COMPARISON OF PREDICTION ACCURACY

The models developed based on the dataset collected from Semester #1 were validated using the datasets collected from the other three semesters. Two criteria were used to compare prediction accuracy: (1) The average prediction accuracy (APA): It indicates on average, how well a model predicts final exam scores of all students as a whole in the class. (2) The percentage of accurate predictions (PAP) among all predictions: It is calculated as the number of accurate predictions divided by the total number of predictions. An accurate prediction is defined as the prediction in which the predicted value is within 90~110% of the actual value.

Tables I and II show the comparison of the four mathematical models in terms of APA and PAP, respectively. As seen clearly from Tables I and II, within the five predictor variables investigated in this study, there is no significant difference in the prediction accuracy of the four mathematical models. The four-semester average of APA varies slightly within 2.1% (between 86.6% and 88.7%). The four-semester average of PAP also varies slightly within 2.0% (between 52.9% and 54.9%).

TABLE I. COMPARISON OF THE AVERAGE PREDICTION ACCURACY

| Model type | Sem. #1 | Sem. #2 | Sem. #3 | Sem. #4 | Four-sem. average |
|------------|---------|---------|---------|---------|-------------------|
| MLR | 88.6 | 90.1 | 87.8 | 88.1 | 88.7 |
| MLP | 88.6 | 90.1 | 87.6 | 88.0 | 88.6 |
| RBF | 88.1 | 90.0 | 87.4 | 86.7 | 88.1 |
| SVM | 80.4 | 90.6 | 87.3 | 87.9 | 86.6 |

TABLE II. COMPARISON OF THE PERCENTAGE OF ACCURATE PREDICTIONS

| Model type | Sem. #1 | Sem. #2 | Sem. #3 | Sem. #4 | Four-sem. average |
|------------|---------|---------|---------|---------|-------------------|
| MLR | 54.7 | 62.1 | 49.1 | 53.6 | 54.9 |
| MLP | 54.7 | 60.3 | 45.3 | 51.2 | 52.9 |
| RBF | 50.8 | 62.1 | 49.1 | 51.2 | 53.3 |
| SVM | 56.3 | 65.5 | 47.2 | 47.6 | 54.2 |

V. IMPLICATIONS AND DISCUSSIONS

The above results imply that if one intends to make early prediction of students' final dynamics exam scores, s/he can use any mathematical model, e.g. the simplest model (i.e., the MLR model shown as Eq. 1). That model has a good average prediction accuracy of more than 80%. However, the percentage of accurate predictions is still low (around 50%). This means that other important factors must also be considered in the model to increase the PAP. The other important factors would include 1) students' non-cognitive factors (such as learning style, motivation and interest, time devoted to learning, and family background), 2) the instructor's teaching effectiveness (such as teaching style, course management, and preparation for courses), and 3) learning progression in dynamics [1].

VI. CONCLUSIONS

Four mathematical models were developed based on 1,938 data records collected from 323 students in four semesters. The results show that within the five predictor variables investigated in this study, there is no significant difference in the prediction accuracy of the four mathematical models. The results imply that it is possible to predict, with accuracy of more than 80%, the *average* performance of all students based on rather simple models and using easily available data.

Work in Progress: How do first-year engineering students develop as self-directed learners?

Abstract— Although self-direction is among the most critical skills required of today's engineering graduates, the complex processes through which individuals develop the attitudes, beliefs, and skills of lifelong, self-directed learners remains unclear. In this ongoing mixed-methods investigation, we draw on existing motivation and self-regulated learning theories to examine how undergraduate students at two institutions develop as self-directed learners during their first two years of their engineering programs. Preliminary findings indicate that both groups of first-year students make progress as self-directed learners, even after their first semester of college. However, the data indicate marked differences in specific areas of self-directed learner growth at the two institutions. Compared to those at the large public university, students at the small private college report stronger learning goal orientations, help-seeking behaviors, and metacognitive strategy use. We discuss how the learning opportunities and environments may contribute to these differences in learner development.

Keywords: *lifelong learning, self-directed learning, self-regulated learning, goal-orientation, help-seeking, metacognition*

I. INTRODUCTION

A capacity for self-directed learning (SDL) and lifelong learning is widely recognized as a critical outcome for today's engineering graduates [1-5]. Prior research characterizes self-directed learners as those who possess the motivation, or *will*, to engage in learning, as well as an array of behavioral, cognitive, and contextual *skills* that they may readily deploy in the learning environment [6-12]. The processes by which students *become* self-directed learners, and the roles that pedagogy, learning climate, and classroom environment play in these processes, however, remain unclear. This study poses several questions related to SDL development: How do the SDL skills and attitudes of engineering students change during their first two years at college? What causes these changes to occur? What experiences and classroom conditions best promote self-directed learner development? By examining *how* and *why* students progress from teacher-controlled learners to autonomous learners, we hope to inform the design of curricula that better facilitate SDL growth.

II. METHODS

As part of a larger mixed-methods longitudinal investigation that tracks students' SDL development over two years, this study uses qualitative methods to explore shifts in

SDL attitudes and skills in the first year of engineering programs, and to gain insight into *why* the shifts occur.

A. Participants and Environments

Participants in this study are first-year undergraduate students enrolled in engineering programs at two institutions: a small private college and a large public university. The *small private college* emphasizes project-based learning and peer collaboration. In their first term, students at the small private college complete a common set of technical courses and one humanities course, all of which are graded as "pass-no credit." First-year students at the large public university complete a one-credit hands-on engineering project along with a range of more traditional introductory courses offered outside of the engineering school. Students at the large public university receive letter grades in all courses.

B. Data Collection and Analysis

At the start and end of their first term of college, participants in this study responded to open-ended survey questions related to their SDL experiences in high school and college, learning goals, and development as learners. An open-coding method was used to select emergent themes and a framework was created to evaluate individuals' developmental level for SDL-relevant behaviors (effort regulation, time management, help-seeking), cognitions (metacognitive skills and awareness), motivations (extrinsic to intrinsic), and goal orientations. The emergent themes and SDL evaluation framework draw heavily on self-determination, achievement goal, and self-regulated learning theories [8-25].

III. PRELIMINARY RESULTS & DISCUSSION

After only one academic term, engineering undergraduates at both institutions showed signs of SDL skill and attitude development. The qualitative data indicates shifts in students' behavioral self-regulatory strategies at both schools, as well as increased learning goal orientation, metacognitive strategy use, and help-seeking strategy use at the small private school.

A. Similarities Across Institutions

The start of college prompted significant behavioral strategy development at both schools. As one male student from the small private college describes, "*With so much on my plate being on three extra-curricular teams and taking a full course load, I have so little time that I have gotten much better*

at time management... The primary driving force behind this change has been the sheer decrease in the amount of free time I have during the semester. With so much going on all the time and fun activities always going on that I could participate in, I need to really manage my time in order to learn through all of my classes and teams." Similarly, many students from the large public university spoke about improving their time management skills, and they contrasted the college environment with that of high school. As a male student comments, "I have learned that procrastination is the enemy. In high school it's docile and easy to flirt with, without any repercussions. With the speed of the quarter system, it is a luxury that we can no longer afford. This has taught me to, in general, manage my time in a more sane fashion and procrastinate less." Students attribute their behavioral shifts to the increased challenge of the schoolwork and the availability of interesting new opportunities. Time and effort management, two important behavioral self-regulatory strategies [26-29], emerge at both schools and appear to be prompted by an increase in learning activities and workload, combined with feelings of being overwhelmed.

B. Differences Between Institutions

Student responses reflected an emergence of different goal orientations, help-seeking skills, and metacognitive awareness at the two schools.

1) Goal Orientation

Prior education research shows that goal orientations can have a significant impact on self-regulated learning outcomes [e.g.,13,20,30,31]. Students at the large public university reported primarily performance-oriented goals. For example, one male student from the large public university expressed a goal of "getting an A" in his math class. Another male student reported, "The main goal that I set for myself last quarter in calc 4 was to complete all the homework." In contrast, students at the small private college tended to report learning-oriented goals that ranged from course-specific learning to broader, long-term competency development. One female student set a course-level learning goal as follows: "For a particular project in a design class, I set goals to get better at coding and to have a better understanding of motors." Another female student focused on larger competency goals to develop design and creativity skills, and to explore unfamiliar topics: "In [design class], my learning goals were primarily design based. I wanted to improve my ability to solve design issues creatively, effectively, and practically." The more learning-oriented goals set by the small private college students appear to be linked to the classroom environments at that institution. Non-graded, heavily project-based first-semester experiences at the small private college encourage (and sometimes require) students to set their own goals, pursue their own interests, and focus on learning, collaboration, and exploration of personal interests over performance, competition, and instructor constraints.

2) Help Seeking

Help-seeking is a resource management strategy that is important to self-direction [12,23,28,32]. At the large public university, students rarely mention going to others for help; while at the small private college, help seeking seems to be a regular practice. One female student describes the situation in

this manner, "Prior to that semester, I was pretty confident that I could learn a lot by studying by myself. However, through this semester, I learned that I will have to find as much help as I can, rather than struggle and waste time while trying to figure something out. I learned to rely on others more to learn better." Students at the small private college seem to have internalized the importance of help seeking and collaboration as useful strategies that can enhance their learning. They report that both in-class environments (e.g., project-based courses) and out-of-class academic culture influence the development of their help-seeking behaviors. Although the impetus to seek help is typically a desire to reduce stresses on their time, the learning-oriented environment at the college may help students gain comfort in engaging others in finding solutions to problems.

3) Metacognition

Metacognition, a key component of SDL that interacts with motivations and behaviors [26,28,33], appears to develop differently at the two schools. Students at the small private college show a marked improvement in their metacognitive skills after the first semester. One male student described discovering new insights about his own learning process in his first semester, "I've discovered that I am certainly not an auditory learner, preferring instead to learn by doing or experiencing. I would much rather carry out an experiment or simulation than listen to lectures or write out problems." In contrast, students at the large public university engaged in less reflection overall - and those who did, focused their reflection more on their behaviors than their learning. A male student's response illustrates this: "A moment of self-realization really was a large turning point in my outlook towards each class. I thought of myself in the future, and didn't want to look back and regret any decisions I had made regarding my education. Also, my GPA the first quarter was not something to brag about, and that really made me change the way I was approaching my college curriculum." Although this student is taking responsibility for his learning and linking actions to outcomes - signs of SDL development - he remains focused on extrinsic goals such as achieving good grades and avoiding feelings of guilt.

IV. CONCLUDING REMARKS

As early as the first academic term, engineering students at the two institutions appear to develop a range of SDL-relevant goals, behaviors, and cognitive strategies. Students link their SDL attitudes and skills directly to their *learning experiences* and *learning environments* - a promising finding for instructors who seek to design SDL-supportive courses and programs. In the words of students, key factors include the level of *exposure* to self-directed activities (e.g., open-ended projects), the amount of *choice* to set one's own goals and pursue one's interests, the available *resources* and *support* (professors, peer mentors, course assistants, course scaffolding), and the *academic culture* of the school.

First-Year Engineering Students' Peer Feedback on Open-Ended Mathematical Modeling Problems

Kelsey Rodgers, Heidi A. Diefes-Dux, Monica E. Cardella, Amanda Fry

School of Engineering Education
Purdue University
West Lafayette, IN, U.S.A.

Abstract—Peer feedback is a key component of STEM education, but there is not an accepted pedagogy for teaching students effective critical feedback skills. The quality and nature of current peer reviews must be understood to establish what students need to learn to give effective feedback. This research begins to identify the nature and quality of peer feedback on mathematical models through a mixed-methods approach. The quantitative analysis shows that students typically score models higher than an expert, and the qualitative analysis shows that most students do not address the mathematics used in solutions but rather focus on the presentation of solutions. This research indicates that students need better guidance on how to engage in a more critical feedback process on solutions to open-ended problems. This research also raises some new research questions.

Keywords – *peer feedback; mathematical modeling; first-year engineering; model-eliciting activities*

I. INTRODUCTION

Giving feedback is a process of identifying a gap between current and optimal solutions; then determining methods to advance the current work [1]. Feedback involves analyzing solutions, critiquing current shortcoming, and brainstorming potential improvements. Feedback is necessary to improve the quality of solutions to complex problems and professionals' work. Feedback can be a formal or informal process of critically evaluating one's work by peers or superiors. Formal feedback is a deadline-driven, often criteria-driven, review of a work in progress. This may more commonly be feedback from a supervisor or instructor, but is not limited to feedback from an authoritative figure. Informal feedback is any other feedback that occurs throughout the progression of work, such as team discussions.

The ability to provide formal and informal feedback is an especially crucial skill for science, technology, engineering, and mathematics (STEM) professionals because participation in feedback is so embedded in practice. Giving ethical and professional peer feedback on technical work, acknowledging criticism, utilizing peers' feedback to advance one's work, and helping colleagues professionally advance are recognized by the Institute of Electrical and Electronics Engineering (IEEE) to be important components of professional engineering practice in industry that require effective peer feedback skills [2]. Peer review is a vital step in the dissemination of rigorous research within the STEM research communities through journals and conferences [3]. Without this sharing of research, the STEM communities could not advance. Due to the need for informal and formal feedback in STEM careers, it is vital to

teach future STEM professionals how to give and utilize effective feedback during their undergraduate education. Teaching peer feedback to students not only enables them to give effective feedback, but it also enhances their communication, teaming, and critical thinking skills. All of these skills are nationally and globally recognized to be key for engineering students to develop [4,5] and are important for all STEM students.

Although an ability to provide peer feedback is a vital skill for STEM students to develop, there is a lack of research on how to foster effective learning of this skill. Nelson and Schunn recognize the lack of direction on how to facilitate students' learning of peer feedback skills and state this need cannot be addressed without understanding student performance [6]. They state it is important to research and understand the quality, nature, and impact of current peer feedback. Through an understanding of the gap between current and ideal peer feedback performance, further research can be conducted to determine effective teaching methods to close the established gap. The goal of this paper is to begin to characterize this gap, specifically in the context of mathematical model development.

Much research has already been conducted on the implementation of Model-Eliciting Activities (MEAs) [7]. MEAs are open-ended, authentic, mathematical modeling problems used in the First-Year Engineering (FYE) program at Purdue University [8]. MEAs are utilized in other undergraduate engineering courses at several other universities, including California Polytechnic State University and the University of Pittsburgh [9,10]. Successful MEA implementation requires steps that prompt students to iteratively and critically evaluate their own team's solution (informal feedback) and assess another team's solution (formal feedback). Through previous quantitative research on students' perceptions of their ability to give formal peer feedback on solutions to MEAs, students thought they gave good critiques of peers' work and gave the best advice on the Mathematical Model (MM) component of feedback on the *Just-In-Time Manufacturing (JITM)* MEA [11]. However, analysis of student work on the *JITM* MEA revealed that there were major changes in the mathematical models of only 11 out of 50 teams' solutions (22%) after formal peer feedback [12]. Since students think they are capable of giving good feedback on others' models, but there is a lack of impact on the quality of the solutions following peer feedback, the research team will specifically focus here on peers' ability to give feedback on the MM component of the *JITM* MEA.

The research questions are: (1) What is the accuracy of peer versus expert scoring of the Mathematical Model dimension?, (2) What is the nature of peer feedback on the mathematical aspects of solutions?, and (3) What are the students' perceptions of the quality and nature of the peer feedback received as it pertains to the mathematical aspects of solutions?

II. SIGNIFICANCE OF WORK

Students' learning of how to give effective peer feedback is a key component of their education [1,4,5,6]. Since it is the responsibility of educators to ensure this learning, it is important to begin to determine peer feedback pedagogies to facilitate this education. Once the current quality and nature of peer feedback and students' perceptions of their work is better understood, an effective pedagogy for enhancing students' feedback skills can be determined [6]. Peer feedback pedagogies are becoming even more crucial for STEM learning, not only for teaching students how to develop this vital skill, but also for ensuring an effective learning environment. Today's STEM courses are transitioning from traditional lectures to collaborative and team-based pedagogies, which increases the amount of unmonitored peer interaction. To encourage the most positive team interactions in emerging STEM pedagogies, there needs to be strategies for teaching how to give constructive feedback to mitigate neutral and negative effects that can occur with ineffective feedback [6].

III. THEORETICAL FRAMEWORK

Lesh and his mathematics education colleagues spearheaded the development of the Models and Modeling Perspective (M&MP) [13] and the six design principles that guide the development and implementation of MEAs [14,15]. These principles ensure problems are set in realistic contexts that elicit mathematical model development and require a natural documentation trail. These activities expose students' internal thought processes and conceptual understandings via their approach to solving a given problem [13]. These principles, when paired with engineering practices, are the foundation for the design, implementation, and assessment of MEAs in the FYE program [16]. This work is also informed by the theory of conceptual change [17], which expresses the importance of characterizing students' initial/current behavior in contrast to behaviors we would like them to eventually display.

To understand the complexity of the MEA learning experience, as well as to continue to improve teaching practices, a design research approach is adopted [18,19]. This approach allows researchers to "trace the evolution of learning in complex, messy classrooms and schools, test and build theories of teaching and learning, and produce instructional tools that survive the challenges of everyday practice" [20].

IV. METHODS

A. Settings and Participants

All FYE engineering students (1200-1700 per year) solve authentic engineering problems in teams of 3 to 4 students through MEAs. In Fall 2008, approximately 1200 students completed three MEAs. This study is concerned with the second of these: the *JITM* MEA. For this MEA, teams develop

a mathematical model to rank prospective shipping companies in order of most to least able to meet the client's timing needs based on historical late delivery time data for each shipping company (this MEA is described in greater detail in [21]). All MEAs are solved using the same implementation sequence and assessed using the same *MEA Feedback and Assessment Rubric (MEA Rubric)*. The implementation sequence in this particular semester was: 1) individual problem formulation to understand the problem context, 2) team generation of Draft 1 of their MEA solution, 3) feedback from Graduate Teaching Assistants (GTAs), 4) team revision of Draft 1 to create Draft 2, 5) individual peer calibration, 6) individual double-blind peer review of teams' Draft 2 solutions, 7) team revision of Draft 2 to produce a Final Response, and 8) final grading by GTAs. Peer calibration is training for peer review. Each student individually critiques one prototypical student solution. Then, each student is shown an expert's review of the same solution and is prompted to compare their feedback to that of an expert with the intent to improve their feedback abilities [11].

All of the GTA and peer feedback of team solutions are completed using the *MEA Rubric* which focuses on three dimensions: Mathematical Model (MM), Re-Usability & Modifiability (R&M), and Share-Ability (Audience) [22]. The MM dimension ensures the mathematics utilized address the complexity of the problem. The R&M dimension evaluates a solution's ability to be used by the client for new but similar situations and modified easily by the client for slightly different situations. The Share-Ability dimension considers how easy it is for the client to apply the solution.

B. Data Collection

The implementation of the MEA was supported by a web-based interface connected to a database system. This system was utilized to collect student and GTA work throughout the MEA sequence. To address the research questions, the focus here is on the student peer feedback for the *JITM* MEA. Peer feedback consisted of numeric scores and written feedback for each of the three *MEA Rubric* dimensions. Peer feedback associated with only the MM dimension was analyzed for this study. Within the MM dimension of the *MEA Rubric*, there are three scored items. One item addresses MM Complexity - the evaluation of the utilized mathematics to address the complexities embedded in the problem. To clarify, the evaluator is not looking for a complex solution but rather a simple and elegant solution that addresses what makes the problem difficult to solve. This study focuses on students' ability to apply this one item. The item requires peers to select a level to which the solution addresses the complexity in the problem (Table I) and respond in writing to three prompts. The three prompts ask peers to 1) "summarize in your own words the mathematics used in the procedure", 2) "state the results found by applying the procedure as written to the historical data for the *eight* shipping companies, providing some quantitative results", and 3) "provide constructive recommendations on how to better address the complexity of the problem or eliminate errors".

The peers' scores and responses to the three prompts are the primary source of data analyzed in this paper, and will be

supported by the students' perspectives on the overall peer review process. These perspectives emerged from semi-structured interviews with 24 student participants who shared their experiences with the *JITM* MEA sequence after completing the MEA.

TABLE I. *MEA RUBRIC* MM COMPLEXITY PEER SCORING RUBRIC

| Score | Score Description |
|-------|---|
| 4 | The procedure fully addresses the complexity of the problem. |
| 3 | A procedure moderately addresses the complexity of the problem or contains embedded errors. |
| 2 | A procedure somewhat addresses the complexity of the problem or contains embedded errors. |
| 1 | Does not achieve the above level. |

C. Data Analysis

The peer feedback data collected were analyzed using a mixed-methods approach. The evaluation includes a quantitative assessment of the peer application of the scoring rubric (Table I) and a qualitative assessment of the written peer feedback. The student interviews were qualitatively analyzed. Out of ~1200 students enrolled in the course (~350 teams), students from 11 teams (42 students) participated in the individual student interviews. These 11 teams' Draft 2 solutions were analyzed and scored by an expert grader, who has a high level of understanding of MEA solution assessment and scoring. The expert scored the *JITM* MEA using the MM Complexity criteria as shown in Table II (information only seen by GTAs and professors). These scores were then quantitatively compared to the peers' (28 student reviewers) scores to understand the accuracy of peer scoring using the MM Complexity item of the *MEA Rubric*.

TABLE II. EXPLANATION OF MEA SCORING FOR MM COMPLEXITY

| Score | Description of MM | Mathematics Used in MM |
|-------|-----------------------------------|--|
| 1 | no variability or distribution | central tendency (mean or median) |
| 2 | variability without distribution | variability (e.g. standard deviation) |
| 3 | distribution without a tiebreaker | distribution (e.g. histogram or frequency of one or more values) |
| 4 | distribution with a tiebreaker | same math as score 3 with tiebreaker |

The 11 teams received feedback from 28 students (ranging from 1 to 4 peer review/s per team). The 28 student reviews on the MM Complexity item were qualitatively analyzed to understand the nature of the peer feedback. Coding of the feedback was done to determine which of the three *MEA Rubric* dimensions the students' actually provided feedback on when assessing the MM dimension.

The 24 students' interviews were qualitatively analyzed using an emergent coding scheme [23] to determine the students' perceptions of the peer feedback received and process in general, as well as their perspective of the quality and nature of the feedback that they gave to other teams. When relevant, some of the teams' *JITM* MEA solutions were also analyzed for change to understand the interview responses. It is assumed that this sample group of students interviewed is representative of the population of their fellow classmates.

V. FINDINGS

The quantitative comparison of the peers' and expert's MM scores on the 11 teams' Draft 2 solutions is shown broken down by team in Fig. 1. It shows a range of scores amongst the peers and an overall differing average peer score compared to the expert (Fig. 1). Only 3 out of the 11 teams (Teams 7, 8, & 11) received the same score from each of their two peer reviewers. Out of the 11 teams, no team received the same average peer score and expert score.

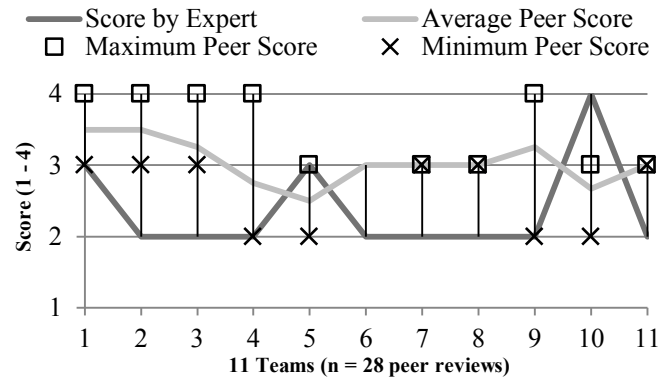

Figure 1. PEER VS. EXPERT SCORES ON MM COMPLEXITY

Table III is a tabular comparison of peer scores to expert scores that shows the distribution of each set and break down of each peer score. The expert scores consist of lower scores (mode = 2; $\mu = 2.4$) and the peer scores consist of higher scores (mode = 3; $\mu = 3.0$). It was found that 19 out of 28 peers rated the MM Complexity of the teams' solutions higher than the expert (Table III). The majority of the peers (82%) scored the teams' solutions a 3 or higher, when the majority of expert scores (8 of 11 teams) were a 2. Also it can be seen in Table III that only 5 out of the 28 peers (18%) scored the MMC the same as the expert.

TABLE III. PEER VS. EXPERT SCORES ON MM COMPLEXITY

| Peer → | | Scores (1 - 4) | | | | # of Teams Expert Scored |
|----------------------------|----------|----------------|---|----|---|--------------------------|
| Scores (1 - 4) | Expert ↓ | 1 | 2 | 3 | 4 | |
| | 1 | | | | | 0 |
| | 2 | | 3 | 13 | 5 | 8 |
| | 3 | | 1 | 2 | 1 | 2 |
| # of Peers that Gave Score | 4 | | 1 | 2 | | 1 |
| | | 0 | 5 | 17 | 6 | |

Results of the qualitative analysis of the peer feedback on the MM parallel the quantitative findings; students struggle to make mathematical model recommendations (Table IV). Even though the math model is the component of the MEA solutions that needs the greatest work (average expert scoring—all on a scale of 1-4—for the 11 teams on Mathematical Model: 2.4, Re-Usability & Modifiability: 3.1, and Share-Ability: 3.3), the students commonly gave praise or commented on the Share-Ability aspect within the MM dimension. In fact, 18 out of 28 peers gave recommendations that related to the Share-Ability

dimension and only 4 out of 28 peers (Peers: 6, 7, 23, & 25) gave a recommendation that related to the MM dimension (Table IV). Only 2 peers gave R&M recommendations related to irrelevant scenarios, so it will not be discussed further.

TABLE IV. PEERS' WRITTEN FEEDBACK AND SCORES ON THE MM

| Team# | Peer# | Peer Review on the MM | | | | Scores | |
|--------------------------------------|-------|-----------------------|-----|---------------|--------|----------|-----------|
| | | MM | R&M | Share-Ability | Praise | by Peers | by Expert |
| 1 | 1 | | | x | x | 4 | 3 |
| | 2 | | x | | | 3 | |
| 2 | 3 | | | x | x | 4 | 2 |
| | 4 | | | x | | 3 | |
| 3 | 5 | | | x | x | 3 | 2 |
| | 6 | x | | | x | 3 | |
| | 7 | x | | | x | 3 | |
| | 8 | | | | x | 4 | |

| | 28 | | | x | | 3 | |
| # of coded written feedback segments | | 4 | 2 | 18 | 13 | | |

Out of 28 peers, 13 gave positive feedback that consisted of direct statements that confirmed the team had addressed the problem complexity, praised the team for a really good model, and/or indicated that the peer was not capable of critiquing the work because the mathematical model was so well developed (Table IV). One example of peer feedback that consisted of only praise is the review from Peer 8: *"I currently have no recommendations because your team seemed to address all aspects of the problem. You explained your mathematical reasoning also."* This review was given to Team 3, who received a 2 on their MM Complexity from the expert.

The peers' MM recommendations that related to the Share-Ability dimension consisted of requests for grammatical fixes, explanations of how to use the mathematics or computer tool, and/or sample calculations. For example, Peer 3 gave Team 2 the following advice related to verbal communication: *"... The information is a little hard to decipher, and I had to read it a couple of times before understanding the process. Perhaps rewrite it to be a little more easily understood. Otherwise it's a good procedure and can be followed."* Although not related to the mathematics used, suggestions similar to these were seen to

be helpful by teams during solution revision. One student interviewee from Team 2 stated: *"I think a lot of what we responded to was the share-ability and how adaptable it was to other people that didn't really know exactly what we were trying to say."* During revision, Team 2 responded to their peers' reviews and focused on Share-Ability, even though they scored a 2 on the MM. Team 2 was not the only team that was given advice to improve their share-ability, while the expert scored the MM at a level 2. Out of the 8 teams that the expert scored at a level 2, only 2 teams (25%) received MM feedback.

Advice on MM Complexity was given by only four peers. These peers took different approaches: Peer 6 identified errors through the use of a specific example, Peer 7 addressed a specific portion of data (outliers), Peer 23 specifically pointed out a missing step (tiebreaker missing), and Peer 25 questioned the current math used in Team 10's solution. Peer 6 wrote to Team 3, *"I think they have taken into account most of the complexities. They're mathematical model is good. I just want to recommend to them that if the standard deviation for a team is 0 and their average time is 300. This means that this team is the winner according to your procedure. But the team mentioned above is consistently late. So do think over it."* Peer 7 wrote to Team 3, *"...However, your model doesn't talk about outliers or what to do with them..."* Peer 23 wrote to Team 9, *"...Also include what to do in the case of a tie breaker..."* Peer 25 wrote to Team 10, *"Does the average really provide a good estimate? What if the range was very big? Is there a way of combining both? Why is percentage on time the deciding factor for ties? Why not the other calculations like standard deviation?"* These are examples of MM recommendations that should encourage teams to re-evaluate their current models. However, Team 10 already had an expert score of 4, so they could not receive a higher score on their MM Complexity. Team 3 and Team 9 still had a lot of room for improvement due to an expert score of 2 on their MM Complexity. It is important to note that the students did not see these expert scores since this analysis was completed later for research purposes only, so this is just an indication of each team's standing at the time they received the feedback.

Even though Team 3 had 2 peer reviews (Peer 6 & 7) that addressed the MM Complexity, their final MM still only consisted of mean and standard deviation, and thus a final score of 2 (Table II). A member of Team 3 reported making significant changes after peer feedback. When asked how Team 3 handled their peer feedback, he reported using two peers' reviews, *"...But the two that were good offered pretty excellent suggestions for our mathematical model and we -- can't remember what this one guy said, but he was a huge part in picking what we wrote."* A review of Team 3's Draft 2 and Final Response revealed that the only change made was the addition of this sentence, *"This allows for the standard deviation to never become zero."* The only change in their model addressed why they did not need to consider the scenario given in feedback from Peer 6.

Team 9, who was given specific advice to add a tiebreaker from Peer 23, did not make any changes to their model and remained at an expert score of 2 on their Final Response. In their solution, the team did address the peer's advice by writing, *"In all calculations in this procedure, carry out all numerical*

answers and calculated data to three decimal places. This is to decrease the chances of having to use a tie-breaker procedure.”

While there was opportunity for both Team 3 and 9 to make significant MM changes, they did not. As a reminder, Team 3 and 9 did receive an average peer score of 3.25, Team 3 received praise in all 4 peer reviews, and Team 9 received praise in half of their peer reviews.

Although there was minimal MM constructive feedback in the reviews, the peers’ summary and results from applying the teams’ mathematical models show adequate effort on the part of the reviewers. The majority of the peers (79%) were successful in accurately summarizing the mathematics found in the models. Also, the majority of the peers (75%) were able to apply the mathematical models and generate the same or similar results as the teams. The interviews confirm this finding - students widely reported generating results using the teams’ mathematical models. Out of the 24 interviewed students (from the 11 teams), 10 students said they focused on the MM dimension in their peer feedback.

Of the 10 students who said they focused on the MM, one student (Peer 21) stated, *“A lot of mathematical stuff was mostly what I liked to focus on, because I’m not too good with the Share-Ability or the Re-Usability stuff. I like math, so I think the majority of my feedback consisted of how they could change around their mathematical model.”* Peer 21 gave Team 9 a score of 4 and the following feedback for the MM Complexity dimension: *“You guys pretty much nailed it on the head as it was very detailed math”*. Team 9 only received a score of 2 from the expert. Peer 21 was one of three peers who was able to generate results, but gave a high score to the team and praised them on their ability to address the complexity of the problem without giving any recommendations. This is one particular peer that stated their feedback focused on the mathematics, but showed an inability to give critical or constructive feedback on that MM dimension.

VI. CONCLUSIONS AND IMPLICATIONS

This mixed-methods analysis provides evidence that students need more guidance on how to give and receive critical feedback on the mathematics used in models. This was thought to be an issue by Carnes, Cardella, and Diefes-Dux (2010) when it was found that students’ solutions do not improve significantly following peer review [12]. The qualitative analysis shows that the students typically understand how to summarize and apply the models, but they lack the ability to give constructive feedback. Even though 42% of interviewed peers explicitly said they focused on the MM, only 14% of peers gave MM recommendations within their feedback. The students may spend the majority of their time summarizing and generating results, but this is not sufficient to prompt change in students’ models. The element of feedback that could lead to improvement is missing from the peer feedback.

There are three potential reasons for the lack of constructive feedback regarding MM Complexity that have been identified. The students may not be able to critique other teams’ models because (1) they do not understand the foundational mathematics of the problem, (2) they do not understand the

concept of constructive feedback, and/or (3) they have a lack of understanding of the established dimensions of the rubric.

Although the students are capable of summarizing and applying the mathematical models, they still may not have a strong enough understanding of descriptive statistics to critique other teams’ models. If the students do not have the appropriate understanding of the domain knowledge, or have not thought through the full complexity of the problem, they could perceive the other teams’ models as having a sufficient process for addressing the complexities inherent to the problem. In this case, the students may have not understood the statistics well enough to advise their peers to progress from looking at the central tendency to the distribution of the data. To address this potential problem, there should be instruction in the classroom on the relevant domain knowledge prior to students participating in the peer feedback process.

One way to determine if students’ lack of statistical understanding is a factor in the effectiveness of students’ reviews is to investigate whether the students’ quality of their own models is related to the quality of their feedback. A study could analyze whether peers who come from teams with high quality mathematical models are better able to give constructive feedback than peers who come from teams with poor quality solutions. For example, a comparison could be made between the mathematical model solutions of Peers 6, 7, 23, & 25, since they were the only peers to give constructive feedback along the MM dimension, and Peers 8, 9, & 21, since they only praised teams on their current models, even though the expert gave the teams a score of 2. This could reveal whether or not having a high quality solution, in terms of math, gives a student a better ability to critically evaluate a solution and give constructive feedback along the MM dimension.

It is also important to understand what peers view as constructive feedback. For example, 10 out of 24 interviewed students specifically stated they focused on giving feedback on the mathematics in the models, but only 4 out of 28 students that gave feedback gave recommendations along the MM dimension. One specific example of this confusion was shown with Peer 21, who discussed a concentration on the mathematics of the solution, but did not give any recommendations to improve the team’s model in the feedback. Clarification in class on the difference between various types of feedback, including summarizing current work, applying mathematics, and constructive feedback to improve work may be needed. Constructive feedback can consist of comments identifying errors or shortcomings and advice on how to improve the current solution. Helping students understand the different levels of feedback may enable them to give more constructive feedback.

A second issue was that peers did not address the appropriate dimension, MM Complexity, within their feedback. To ensure students address all relevant issues within the feedback, there should be clarification in the classroom regarding rubric dimensions prior to the peer feedback process. This could be completed by supplying the class with examples of feedback for the various dimensions and then challenging the students to identify the dimensions that various feedback examples are related to.

It is also important to recognize that effective peer feedback requires two parties: 1) someone to give constructive feedback and 2) someone to utilize the received feedback. It appeared that teams not only had difficulty giving feedback, but also receiving feedback. For example, Team 3 received two peer reviews and Team 9 received one peer review that addressed shortcomings in their model, but both teams only made very minor changes. This could have been caused by the high peer feedback scores (Fig. 1 and Table III) which may have left the teams satisfied with their current solutions. This lack of response could have also been caused by the mismatch between the feedback peers wrote and the scores they gave. For instance, Peers 6, 7, 23, and 25 all gave constructive feedback on the MM Complexity dimension but also gave the respective teams scores of 3 or higher. In contrast, all five peers that gave teams a score of 2 on the MM dimension only gave constructive feedback on the Share-Ability dimension and over half of them included some praise within that portion of their feedback.

Both the highly positive peer scores and mismatch to written feedback could have caused the lack of response to peer reviews. To mitigate this potential problem, peer scoring as part of the feedback process could be removed. If peer scores are a part of the peer feedback process, they should at least be removed from the feedback that the students receive. After the removal of peer scores, analysis of written feedback should be completed to determine the change in peer solutions to determine any positive or negative effects. Furthermore, research will be needed on the interaction between peer reviews and team revisions to understand the lack of change in solutions even when constructive reviews are given.

Special Session: An Interactive Exploration of Gender and Engineering: Unpacking the Experience

Debbie Chachra, Lynn Andrea Stein, Alisha Sarang-Sieminski, Caitrin Lynch, Yevgeniya V. Zastavker

Franklin W. Olin College of Engineering

Needham, MA, USA

corresponding author: debbie.chachra@olin.edu

Abstract—The engineering student experience is understood to differ for male and female students; gendered interactions affect the development of academic and professional role confidence, as well as engineering identity. The purpose of this session is twofold. First, we aim to introduce participants to concepts of gender schemas, privilege, and identity using a range of interactive activities, including brainstorming and structured discussion. Second, we intend to share information about and obtain feedback on a Gender Discussion Exploration Kit, which the participants will be encouraged to review, use, and share at their home institutions.

Keywords- gender; engineering; technology; STEM

I. CONTEXT

The engineering student experience is understood to be different for male and female students, in many ways. For example, fewer women than men are enrolled in engineering programs. Female engineering students who successfully complete their programs have lower self-confidence in their engineering skills than their male counterparts [1]. Women also have lower retention rates in both engineering programs [2] and in professional practice [3]. This lower retention rate is linked to both the lower self-confidence and also to a pervasive sense of not belonging [4]. This is not an exhaustive list; it merely serves to illustrate some of the ways in which gender affects the experience of being in an engineering program and in the profession at large.

While considerable effort has been centered on studying the student experience, the focus of this special session is to provide faculty and other members of the educational community with a model for understanding gendered interactions in academic environments. The session will further attempt to support participants in building an understanding of how these interactions affect the student experience.

This special session has several goals. The first is to engage participants in a discussion-centered learning experience about gendered experiences in engineering education. The second is to provide participants with the tools and confidence to lead such a discussion at their home institutions. To this end, we are developing a Gender Discussion Exploration Kit, which provides the materials and information necessary to facilitate this conversation. The third goal of the session is to introduce

participants to the kit, and to solicit their feedback on its design and content.

II. AN INTERACTIVE DISCUSSION

To facilitate small-group discussion, the participants in this special session will be divided into groups of 4-6. The session will focus on self-reflection, discussion, and sharing among the participants. The content and format of the discussion will be guided by the Gender Experience Discussion Kit, discussed in the next section.

During the session, participants will be asked to explore their own understandings of and relationship to gender by engaging in a range of activities, including the following:

Implicit Awareness Test: A series of images will be shown, and participants will be asked to immediately respond by noting and recording images they associate with women and men. As the goal of implicit awareness tests is to reveal unconscious biases, this part of the session will aim to allow participants to reflect on their own implicit biases [5].

“Unpacking the Invisible Knapsack”: Participants will be introduced to the concept of ‘privilege,’ based on the essay by Peggy McIntosh [6]. They will be asked to “experience privilege” through a set of exercises, to write a list of examples of privilege based on their gender and other dimensions of identity, and to share and discuss these lists.

Gender Schemas: The workshop facilitators will discuss gender schemas, our mental models of the behavior of others, and how these schemas affect social and other interactions [7]. Participants will be asked to provide examples of gender schemas in action and to discuss them in their group.

Identity Threat: The concept of identity threat will be discussed, and participants will be asked to provide examples of identity threat and to discuss them with their group.

After the interactive activities above, participants will be provided with copies of the draft Gender Discussion Exploration Kit materials (which will have been used to structure the session). They will be asked to review the materials and provide feedback on design and content. More details on the Kit follow.

III. THE GENDER DISCUSSION EXPLORATION KIT

For a number of years, we (the facilitators of this special session) have been leading a co-curricular discussion group on gender and engineering education at Olin College, an undergraduate engineering school that is unusual in that it has an institutional commitment to gender parity. (Approximately equal numbers of male and female students are admitted each year.) Several of us have research programs that focus on the engineering student experience at the intersection with the issues of gender, and one of us (DC) regularly speaks to student and industry groups about gender and science/technology. Our dissemination efforts frequently result in participants and audience members reporting that exposure to these ideas—gender schemas, privilege, identity and self-confidence—is transformative: that it changes the way they view interactions they have had within the context of their own educational or professional experience.

We are in the process of distilling our experiences and insights into a downloadable Gender Discussion Exploration Kit that students, faculty, and other community members in education can use to facilitate discussions around gender and technology, as described in the previous section. The fundamental premise behind this Kit is to provide a scaffold that anyone with an interest in the area can use to facilitate these valuable discussions. A goal of this session is to bring our working version of the Kit to participants from a range of institutions, in order to test it and gather feedback.

The downloadable Kit is still in the prototyping stage, but we anticipate that it will consist of a number of components:

- a slide deck that the lead facilitator can use to walk participants through the material;
- printable discussion and activity prompts;
- additional notes and background material;
- handouts for participants;
- feedback forms.

The Kit utilizes structured discussions as a medium to convey and assimilate these ideas (rather than, for example, readings) for two primary reasons. The first is that a discussion format leverages the participants' own experiences; a discussion allows participants to reflect on their interactions in the context of schemas and privilege, thereby reinterpreting their own discourse and that of others. By sharing these interactions, facilitators and participants demonstrate that a) there are a wide range of gendered interactions, b) these interactions are a part of our daily communications, and c) these types of interactions have affected all of us. The second reason is that sharing their experiences in an interactive session allows participants to begin developing a common understanding and awareness of these issues within their community.

The Kit itself will be available online (the proposed URL is <http://gender.olin.edu>) in a range of appropriate formats (e.g., PDF, Keynote, PowerPoint; both US and international paper sizes). We intend to release it under a Creative Commons Attribution-NonCommercial-ShareAlike (CC BY-NC-SA) [8]

license. This would allow users to freely share the materials (with attribution), to use it for non-commercial purposes, and to edit the material as desired, with the caveat that any modified form of the Kit must be made available under the same license. We will encourage people who modify the Kit to share their changes with us; the intent is that the Kit will continue to evolve to meet the needs of its users.

In order to evaluate the impact of the Kit, we will track downloads and encourage users to provide feedback on their experiences. We will also create an online survey in order to gather more detailed information from facilitators. Finally, we will provide a link to an online survey as well as a printable feedback form for participants, so that feedback can be provided to both the facilitator and to us as the Kit creators. Two kinds of feedback will be sought: usability feedback (was everything comprehensible? was it easy to use? did you feel confident using it?) and feedback on the participants' experiences (did the session change your understanding of your experiences in engineering school? if so, how? how do you think this session will affect you in the future?).

IV. CONCLUDING REMARKS

In addition to a demonstrated need for research on gender and the student experience within engineering education environment, there is a great need for providing students, faculty, and other educational and professional community members with the tools to understand how this experience is affected by gender. From research on students, we know that interactions are colored by gender schemas and privilege, which affects the development of academic and professional role confidence, as well as engineering identity and belonging. We hypothesize that providing students (and faculty) with the tools to develop and explore this area will have a positive impact on their persistence and happiness within the engineering environment, both in the university setting and the post-graduate engineering practice.

Special Session: Raising P-20 Engineers – Nurturing Creativity and Curiosity by Getting STEAMd

Susan K. Donohue, Whitney G.S. Hunter, and Larry G. Richards
University of Virginia, susand, wgh3p, lgr@virginia.edu

Abstract – The primary goal of this special session is to engage participants in a dialogue regarding two skills critical to the personal and professional development of engineers, creativity and curiosity, and discuss and practice pedagogies for nurturing them in students through STEAM (STEM + art) activities. The emerging STEAM approach emphasizes a hands-on, project-based, interdisciplinary approach to the study of science, technology, engineering, and math (STEM). To emphasize the importance of using engineering design principles to integrate learning in science and math and gain technological literacy, we also refer to this approach as STEAMd. By the end of the workshop, participants will be introduced to key concepts in the engineering design process, the STEAMd initiative, and Dweck's groundbreaking work on "mindsets"; be able to identify methods for integrating engineering design and art activities into STEM studies; and gain experience in using STEAMd activities to promote the development of creativity and curiosity while strengthening critical thinking and problem-solving skills. This special session will be of interest to those involved in P-20 engineering education and in developing a philosophy of engineering education that stresses the development and maintenance of non-traditional skills that are nonetheless critical to the processes of innovation and invention.

Index Terms – Creativity, curiosity, Engineering Teaching Kits, mindset, P-20 engineering education, STEAMd.

INTRODUCTION

Creativity and curiosity are vital to the processes of innovation and invention, and innovation and invention are vital to meaningful and significant outcomes in science, technology, engineering, and mathematics (STEM) and, eventually, to the ability of a society to be competitive locally, nationally, and globally. However, the way in which people perceive "creativity" and "curiosity" – as either innate talents or skills that can be learned – may affect the degree to which they develop and implement truly effective solutions. The implications of these "mindsets," to use Carol Dweck's terminology, are very important not just for the nurturing and support of creativity and curiosity, but to all knowledge, skills, and abilities important to success in engineering.

The primary goal of this special session is to engage participants in a dialogue regarding two skills critical to the personal and professional development of engineers, creativity and curiosity, and discuss and practice pedagogies for nurturing them in students through STEAM (STEM + art) activities. The emerging STEAM approach emphasizes a hands-on, project-based, interdisciplinary approach to STEM studies. To emphasize the importance of using engineering design principles to integrate learning in science and math and gain technological literacy, we also refer to this approach as STEAMd. Engineering design activities will be supported by Engineering Teaching Kits (ETKs). ETKs are self-contained STEM education standards-based units grounded in the constructivist philosophy of education [1], [2] and the principles of guided inquiry and active learning [3] which engage students in a series of age-appropriate engineering design challenges to reinforce selected concepts in math, science, and technological literacy. They were initially developed in conjunction with the Virginia Middle School Engineering Education Initiative (VMSEEI) for students in grades 6 – 8 [e.g., 4 and 5], but have been proven scalable for use by students throughout P – 12.

By the end of the workshop, participants will be introduced to key concepts in the engineering design process, the STEAMd initiative, and Dweck's groundbreaking work on how perceptions of the malleability of intelligence and talent affect achievement; be able to identify methods for integrating engineering design and art activities into STEM studies; and gain experience in using STEAMd activities to promote the development of creativity, curiosity, and a growth mindset while strengthening critical thinking and problem-solving skills.

CONCEPT OVERVIEW

Dweck proposes a social-cognitive approach to the analysis of motivation, (Achievement) Goal Orientation Theory in [6]. According to this theory, a person's motivation to achieve is driven initially by his/her perception of intelligence as either fixed or malleable; this perception in turn affects goal orientation, which is either learning/mastery (goal is to increase competence) or performance (goal is to gain/avoid judgment of competence) in earlier models; and expanded to learning, performance, work-avoidance (goal is to minimize effort), or a combination thereof in later ones. The combined effects of goal orientation and level of

confidence in present abilities affect one's ability to achieve goals. [7] Following research and the maturation and generalization of these findings has culminated in the concept of "mindsets." A mindset is a belief about your skills and abilities. If you believe that a certain skill or ability is an innate talent and no amount of work will alter what you've been given, then you have a "fixed" mindset. If you believe that you can develop a skill or ability through practice and dedication, then you have a "growth" mindset. A growth mindset supports resilience and perseverance, qualities necessary for long-term success. [8]

The following definitions will be used: creativity – the primary components of scientific creativity are convergent, divergent, and logical thinking [9]; curiosity – "an appetitive state involving the recognition, pursuit, and intense desire to investigate novel information and experiences that demand one's attention" [10, p. 159]; innovation – the adaptation or modification of an existing principle, product, or process; and invention – the development of a heretofore unrealized principle, product, and/or process.

ETK BACKGROUND

Since 2002, teams of students and faculty at the University of Virginia (UVA) have developed, tested, and distributed ETKs for use in middle school science and math classes. [4], [5] An ETK is a set of five 50 minute lesson plans designed to teach math and science concepts within the context of engineering design. Lessons are structured to develop understanding of key concepts at both abstract and concrete levels. ETKs promote awareness of and excitement about the nature of engineering. Students develop an appreciation for the tradeoffs involved in the practice of engineering, and how engineering decisions have an impact on society and the environment. Each ETK emphasizes the engineering design approach to problem solving through a series of design challenges, and includes real-world constraints such as budget, cost, time, risk, reliability, safety, and customer needs and demands. ETKs are also designed to integrate other subjects in the curriculum with the exploration of math, science, and engineering concepts.

WORKSHOP AGENDA

The workshop is structured as follows:

- **Welcome, Introductions, and Agenda Review** (10 minutes)
- **Initial Exercises** (20 minutes)
Participants will work through a set of multimedia STEAMd activities designed to pique interest in exercising one's curiosity and creativity through the practice of the engineering design process. ETKs used include *Catapults in Action* (energy and simple machines), *HoverHoos* (hovercrafts: flight, propulsion, and Newton's Laws), *Save the Penguins* (heat transfer and shelter design and construction), and *Under Pressure* (submersibles: buoyancy, drag, and propulsion).

- **Overview of Important Concepts** (15 minutes)
We will review research on creativity and curiosity from the psychology and education literature, and on the STEAMd movement and its demonstrated abilities to encourage the development of creativity and curiosity. Additionally, Carol Dweck's Achievement Goal Orientation Theory, which has matured into the concept of "mindsets," will be reviewed. [2] – [4] A group discussion of experiences and concerns will follow.
- **Follow-on Activities** (40 minutes)
Participants will work in groups with the facilitators to work through additional design activities. We will also discuss scaling the activities to various grade levels. This discussion will include a review of expectations as to cognitive development and skill levels for students in those grades.
- **Concluding Activities and Discussions** (5 minutes)

ACKNOWLEDGMENT

We are grateful to the Payne Family Foundation and the National Science Foundation for their prior financial support of the development and implementation of ETKs and to the reviewers for their feedback and recommendations.

Improving Students Understanding of Engineering Concepts Through Project Based Learning

Hudson Jackson, Kassim Tarhini, Brian Maggi, Nathan Rumsey

Department of Engineering
United States Coast Guard Academy
New London, Connecticut

Abstract—Traditional methods of teaching are falling short in engaging students at higher levels of learning. To adequately prepare students for engineering practice, innovative methods of teaching, learning and assessment are required. Particular emphasis should be placed on enabling students to make the connection between theory and practice. The authors discuss how the approach of “theory to practice” was implemented using project based learning and case studies in two courses at the United States Coast Guard Academy. Students’ feedback and other assessment tools indicated that students were engaged in a higher level of learning and understanding of engineering principles.

Keywords—case study; design, geotechnical engineering; project based learning; reinforced concrete

I. INTRODUCTION

With the current trend in globalization, engineering educators continue to be challenged in preparing graduates who understand global and societal issues, have the ability to solve complex problems and adapt to technological changes, and meet the needs of the engineering profession. To address this challenge, innovative methods of teaching and learning are required with particular emphasis on making the connection between theory and practical application. The traditional teaching method used at most engineering institutions has been lecturing or “teaching by telling” where students are passive spectators. The traditional teaching approach is based on precise, well defined problems and formal definitions presented to students in a one-way, lecture format. Concepts are presented as well-structured subtopics with the connections between them and real world applications left for the professor to develop. In general, the traditional teaching approach is a three-step system of lecturing, assigning of reading and homework, and testing. This teaching approach has been demonstrated to engage a low level of learning as students gather information from lectures and memorize facts and procedures in order to pass exams. Students complete the courses with only a limited understanding of concepts and have limited opportunities to integrate concepts. There is a growing need to modify the traditional style of lecturing and transition to a more balanced format of teaching that involves using practical projects in the classroom.

A vast amount of published literature emphasizes that learning and retention are enhanced by performing real project activities which simulate the actual work environment. This

reinforces the ancient Chinese philosopher Confucius who said: “I see and I forget, I hear and I remember, I do and I understand” [1]. Various learning paradigms have emerged in the past few decades to enhance student engagement and improve learning. Common terms used to describe these paradigms are: *case studies, project-based learning, interactive learning, active learning, role playing, and computer simulations*. These learning paradigms are used by engineering educators to achieve a higher level of learning based on the six levels of cognitive domain in Bloom’s Taxonomy [2]. These levels (lowest to highest) include: (1) the fact-based knowledge, (2) comprehension, (3) application, (4) analysis, (5) synthesis, and (6) evaluation. Educators have considered Bloom’s Taxonomy of learning to be a valid benchmark that measures a student’s level of understanding in the learning process.

In order to enhance student learning at the higher levels of Bloom’s Taxonomy, engineering faculty throughout the nation are engaged in innovative methods of teaching. Dewoolkar reported hands-on inquiry educational modules used in two undergraduate geotechnical engineering courses at the University of Vermont [3]. The four modules initiated in two courses were designed to achieve three objectives: (1) meet the goals of the civil engineering curricular reform (e.g. inquiry-based experiential learning and civic engagement through service learning); (2) reach higher levels of Bloom’s Taxonomy in specific topical areas addressed by the modules; and (3) help meet ABET student outcomes and civil engineering program specific criteria. The modules were conducted within team settings and required students to write formal technical papers and reports followed by presentations. The student self-assessment results and direct assessments of student work indicated that many curricular reform objectives, ABET student outcomes were achieved, and higher levels of Bloom’s Taxonomy were reached through those modules. Chinowsky introduced an alternative approach to construction and management education at the University of Colorado by changing from lecture to project-based format [4]. In project-based learning (PBL), students are challenged with open-ended problems requiring greater application of multiple engineering concepts as well as requiring interaction with outside experts from the construction industry and related professions. PBL teaches concepts through real life problems, creating an association between theory and practice. This association enables students to better retrieve the pertinent theoretical

knowledge when faced with real world engineering problems. Chinowsky proposed a cognitive concept model called the “Knowledge Landscape Approach” that construction engineering educators are encouraged to adopt. In this approach, students are required to evaluate project scenarios with a diverse range of external and internal project variables that require both technical and non-technical skills to be applied during the solution process. This concept supports the PBL perspective that engineering is a knowledge transformation process where solutions are generated by transforming and integrating existing and context-dependent knowledge. Powers and Dewaters reported that the development of project-based units as outreach activities for middle school students in science and technology classes increase student’s awareness and aptitude for math, science, and engineering [5]. These project-based units replicated Clarkson University’s successful efforts in utilizing PBL in educating multidisciplinary undergraduate teams. This approach has been shown to improve the understanding of basic concepts, to encourage deep and creative learning, and to develop teamwork and communication skills.

Akili presented the process of developing a case study and case history course in geotechnical engineering at Iowa State University [6]. The case studies were designed to engage students in a learning process through analysis, open discussion, and ending with evaluations and recommendations. The course focused on engineering design and practice, teamwork and leadership development, organizational management, and communication skills. Case studies were used to extend the learning experience beyond the traditional classroom activities and expose students to the analysis and decisions encountered by practicing engineers. Delatte reported on the integration of failure case studies in the undergraduate civil engineering and engineering mechanics curricula [7]. Delatte compiled details of failure cases and related them to the principles and concepts in various undergraduate engineering courses. He developed resources for faculty that include a book, several publications, and a companion website. It was demonstrated that the study of failure cases enhanced student learning of basic concepts and enabled them to understand the role prevention of failure plays in engineering design. Case studies can tie together technical aspects, ethical issues, procedural issues, and help students engage in a higher level of thinking to synthesize and evaluate the relevant concepts.

Project-based learning and case studies were implemented in two courses (*Geotechnical Engineering Design* and *Reinforced Concrete Design*) at the United States Coast Guard Academy (USCGA) to encourage a high level of intellectual stimulation by challenging students to become effective learners thus improving their competency to solve real world engineering problems. The authors discuss the development and delivery of the projects used in the two courses as well as assessment results of both students’ performance and course evaluations. The integration of case histories and field trips to enhance student learning are also presented.

II. DESIGN PROJECTS AND CASE STUDIES

In the *Geotechnical Engineering Design* course at USCGA, students are required to complete a series of open-ended design projects that are structured to balance the need for fundamental engineering instruction with an infusion of skills required for engineering practice. The course is purely project-based and the projects are intentionally open-ended, requiring students to make decisions and develop alternatives, similar to what is expected in actual engineering practice. Case studies and case histories involving design, construction and legislative disputes were also used to simulate real life engineering practice. This course plays a vital role in the assessment of ABET student outcomes within the Civil Engineering curriculum and is used as a source of assessment data on performance indicators (PI) listed in Table I. The PIs represent the skills, knowledge and competencies students should develop in meeting the corresponding student outcomes. The student outcomes listed in Table I have multiple performance indicators; only the PI assessed in the Geotechnical Engineering course are listed.

TABLE I. PERFORMANCE INDICATOR ASSESSED IN GEOTECHNICAL ENGINEERING DESIGN

| Student Outcome | Performance Indicator (PI) |
|--|--|
| CE01 – Can apply knowledge in the areas of structural, construction, environmental, and geotechnical engineering. | Apply fundamental principles needed to solve a civil engineering problem in the geotechnical engineering subfield. |
| CE03 - Can design a system, component in the context of structural, environmental and geotechnical engineering. | Apply engineering principles and design concepts (including design codes and specifications) to solve a civil engineering problem. |
| ED03 - An ability to design a system component or process to meet desired needs within realistic constraints such as economic, environmental, social, political, ethical, health and safety, manufacturability, and sustainability. | Apply engineering principles and design concepts (including design codes and specifications) to solve a civil engineering problem. |
| ED05 - An ability to identify, formulate and solve engineering problems. | Apply theories, assumptions and principles to the problem by demonstrating the use of relevant formulae and relationships, verify results. |
| ED08 - Understand the impact of engineering solutions in a global, economic, environmental, and societal context. | Clearly articulate and defend choice of an engineering solution. |
| ED11 -An ability to use techniques, skills, and modern engineering tools necessary for engineering practice. | Use computer programs in analysis and design. |

A. Design Projects

The main focus of the *Geotechnical Engineering Design* course is to provide students with a well-rounded exposure to the geotechnical engineering design process. Students are required to complete six projects that build on each other in several modules. The course is structured such that part of the lessons are used to cover basic concepts and design principles, but most of the time is spent discussing and working on the projects either individually or in small groups. Details of the projects and the learning outcomes are presented in Table II.

The projects are designed to lead students through several levels of Bloom's Taxonomy within the cognitive domain. In project 1, students are required to remember previous material learned in the prerequisite course and make the connection with the design process--this is mostly related to the knowledge level of Bloom's Taxonomy. By the completion of project six, students' cognitive learning is expected to have occurred at all six (knowledge, comprehension, application, analysis, synthesis and evaluation) levels of Bloom's Taxonomy. The transition is also summarized in Table II.

TABLE II. PROJECT DESCRIPTION AND LEARNING OUTCOMES

| Project Title | Description | Learning Outcomes |
|--|--|--|
| Project 1: Subsurface Investigation | Students are provided data from a geotechnical investigation including laboratory and in-situ tests results. They were required to prepare a geotechnical report and recommend suitable soil parameters for the design of a foundation system as well as evaluate the adequacy or completeness of the investigation program. If found inadequate, they are to propose a new investigation program to collect the additional data required. Must justify proposal of new investigation including economic implications. Prepare detailed report in acceptable engineering format. | <ul style="list-style-type: none"> • Critique on the quality and completeness of a geotechnical investigation. • Identify and/or determine suitable soil parameters required for design. • Familiarization with minimum standards for tests and boring (amount & depth requirements) • Recommend possible foundation options based on soil properties (no foundation design required at this stage). <p><i>Remembering previously learned materials in Soil Mechanics and making the connection to their relevance in the design process. Low level of critical thinking in evaluating adequacy and suitability of the geotechnical investigation for the proposed construction.</i></p> |
| Project 2: Construction Dewatering | For a proposed construction site, ground water was encountered at shallow depths and a dewatering program recommended lowering the water table in order to construct the foundation. Students are required to design the dewatering system using well-points to ensure the foundation is constructed above the water table. Students are required to select the relevant size of the pipes, soil parameter and determine the capacity of the required pump. They are also required to sketch a layout showing the location of the well-points. | <ul style="list-style-type: none"> • Identify purpose of dewatering • Familiarization with construction dewatering methods. • Exposure to hydrogeology and ground water engineering. • Design of a dewatering system. <p><i>Grasping the importance of dewatering and its role in construction safety. Apply knowledge to complete design process.</i></p> |
| Project 3: Bulkhead Design | Students are required to apply the theory of lateral pressures to design a retaining bulkhead structure for a water front facility for mooring Coast Guard cutters and small boats. Due to tidal fluctuations, reasonable assumptions must be made on the height of the water level to be used in the design. Furthermore, the navigational draft of the largest cutter to be moored must be considered and a dredging depth recommended if required. Some constraints are placed on the soil and environmental conditions. Design must meet stability and other requirements. | <ul style="list-style-type: none"> • Apply the theory of lateral stresses • Identify effect of soil profile and surface on lateral stresses. • Determine net loading on bulkhead due to active and passive lateral forces. • Design a steel sheet-pile bulk head including selection of suitable sheet-pile section to meet allowable stress requirements. • Design an anchor or tie back to meet stability requirements. • Familiarization with design codes. <p><i>Higher level of critical thinking and application of knowledge to complete design process. Evaluation through making judgment based on constraints.</i></p> |
| Project 4: Retaining wall Design | A retaining wall at a Coast Guard facility needs to be rehabilitated or replaced. Students are required to design a new retaining wall and are required to determine suitable dimensions for the wall, evaluate stability of wall by checking factors of safety against overturning, sliding, and bearing capacity failure. Determine the ultimate bearing capacity. Determine the amount of reinforcement for the stem, | <ul style="list-style-type: none"> • Apply the theory of lateral stresses • Identify effect of soil profile and surface on lateral stresses. • Determine loading on wall due to active and passive lateral forces. • Design a reinforced concrete retaining wall to all stability requirements. • Determine the amount and size of reinforcement required. • Determine construction cost. |

| | | |
|---|---|--|
| | heel and toe (as per ACI 318), prepare detailed drawing showing reinforcement. They must also make recommendation to ensure that the problems of the existing wall are avoided as well as recommendation to minimize impact on mission readiness of the station during construction. | <ul style="list-style-type: none"> • Apply ACI 318 reinforced concrete design code. <p><i>Application, analysis and evaluation through making judgment on cause deterioration, choosing correct parameters to complete design, breaking down design problem into components.</i></p> |
| Project 5: Pile Foundation Design/Drilled Shaft Design | Information of the structural load and soil profile is provided and students are required to design a pile foundation system. Design must include the determination of the bearing capacity of pile group system, settlement calculations and a comparison between piles and drilled shafts. Students are also required to evaluate and select the "best" option based on several constraints. Students must compare the results from their hand calculations with those from a pile design software. | <ul style="list-style-type: none"> • Identify soil design parameters. • Apply different static formulas to determine pile capacity. • Identify effect of soil profile & properties on capacity. • Understand the importance of load tests. • Design single pile & pile groups to meet vertical loading requirements. • Determine settlement of single pile & pile group. • Familiarization with methods of constructing drilled shafts. • Design a drilled shaft. <p><i>Application, analysis and evaluation through choosing correct parameters to complete design, breaking down design problem into components. Synthesis by comparing design options and writing a comprehensive report.</i></p> |
| Project 6: Design of Shallow Foundations | The foundation for a new facility requires the use of a mat foundation system for the main building, and isolated footing for a walkway. Students must design the mat foundation for the structural loading using the rigid closed form solutions and one isolated footing ensuring that ACI standards are met. Information on the soil properties are provided; student are also required to determine whether settlement is within acceptable limits as well as check other relevant factors of safety. | <ul style="list-style-type: none"> • Select design parameter based on soil properties • Understand the practical importance of flexural principles and apply them. • Understand the interaction between soil and foundation. • Design a mat foundation. • Design an isolated footing. • Use design codes. <p><i>All six levels of Bloom's Taxonomy in cognitive domain. High level of critical thinking, making the connection with practical applications of knowledge gained in other civil engineering courses. Development of some professional judgment.</i></p> |

In the *Reinforced Concrete Design* course, a multistory building design project was recently created and various teams (3-4 students per team) were assigned the task of designing one of the floor systems. Design components for this project include a one-way slab, various beams and girders, interior and exterior columns along with foundation elements. This project lends itself well to continued development and integration with other courses where students can draw upon their knowledge of foundation design (through the *Geotechnical Engineering Design* course), as well as their knowledge of constructability issues, construction cost estimating, and life-cycle cost analysis (through the *Construction Project Management* course). Detailed assessment of this design project is ongoing, but early indications show that it is providing students with the opportunity to reach the higher levels of the cognitive domain.

B. Case Studies and Oral Presentation

Within geotechnical engineering, understanding the interaction between the soil and the constructed structure is very important. Given the fact that it is difficult to accurately predict the soil behavior and that the soil profile of a proposed construction site is determined by nature, there are usually high risks involved in geotechnical engineering design. Advancement in technology and observation of soil behavior through instrumentation and research has helped geotechnical engineers better understand the interaction between soil and

structure to reduce the associated risks. Some of this knowledge was acquired through the study of situations where something went wrong in the design or construction leading to a failure or safety concerns. In order to engage students in this process of forensic investigation and evaluation, case studies were used. Suitable case studies were extracted from the archives of the *Association of Engineering Firms Practicing in the Geosciences* (ASFE) [8] and from Delatte's book "*Beyond Failure*" [9]. ASFE has an extensive archive of practical case histories, several of which were used to engage students in open discussions on the lessons that can be learned from unsuccessful projects. The cases are not limited to design, but include project and construction management, as well as consultant-client relation issues. "*Beyond Failure*" is an excellent resource in which the case studies are grouped by courses and subfields. Detailed background information and analysis of the failure cases are provided and supplementary material is also available on a companion website.

In addition, there is a field trip component to the *Geotechnical Engineering Design* course to provide an opportunity for students to visit a construction site and witness firsthand construction and constructability issues of a design. The objective of these trips is to reinforce concepts and principles discussed in class through exposure to practical applications. Field trips provide familiarization with equipment, operation, production management and problem solving in real life conditions. Instructors also use the opportunity to emphasize important concepts and applications during the visits.

III. INFORMATION LITERACY

In engineering practice, there are occasions in which the engineer must seek out information in order to successfully complete a project or in some cases to be awarded one. To simulate this and encourage some aspect of information literacy, students in the *Geotechnical Engineering Design* course are required to research a geotechnical topic (new to students) and give a 10 minute presentation to the class. The main objective of this component was to encourage students to research a project involving a soil improvement or ground modification technique and present it as part of the case study discussions. A list of topics was generated by the instructor, but students had the option of presenting on their proposed topic with prior approval from the instructor. The topics must be from a geotechnical journal or magazine article involving a case study and/or practical application of any ground improvement technique. During the presentation, students were expected to address: the site description, problem statement (why was ground improvement used), type of technique, problems encountered, cost (if available), and other design alternatives considered. In the *Reinforced Concrete Design* course, students make presentations early in the course, with the goal of increasing awareness of industry issues and strengthening the tie of theoretical concepts and principles to engineering practice. Each student is assigned a section or a topic covered in the American Concrete Institute (ACI) Building Code to present to the class. Sample topics considered for presentations are: loading, design strength, spacing limits of reinforcement, max/min reinforcement, bearing strength, shear strength, flexural reinforcement,

development length, slenderness effects on compression members, and shear in footings. Students are expected to investigate the underlying purpose of the topic, not just summarize or paraphrase the code, explain the meaning of the topic, its importance to the course objectives, and how it relates to the design process. In addition to the presentation, students are required to provide a handout to supplement their explanations. Through this assignment, students are exposed to the ACI Building Code and topics to be presented in the course.

IV. DESIGN-BUILD-TEST PROJECT

Typical undergraduate civil engineering programs require students to take a course in reinforced concrete design with no laboratory component. Such a course may incorporate the analysis and design of a multistory building or investigate case studies when new topics are introduced. The *Reinforced Concrete Design* course at USCGA incorporated a course requirement that have students design, construct, and test full-scale, reinforced concrete beams with five unique failure modes. This component of the course is performed by teams of students throughout the semester as a term project. Teams of four to five students select one mode to predict the typical failure mechanisms: shear, compression (brittle), transition between compression and tension (brittle and ductile), and one of two modes of ductile failure related to the magnitude of the tensile strain in the reinforcing steel.

Each reinforced concrete beam is assumed to have constant material properties, constant span length of 16 ft, cross-sectional area of 160 in², similar loading conditions, and an overall weight of approximately 2700 lb. Each team designs the reinforcement necessary to demonstrate the assigned failure mode and submit design calculations in a technical report. The design process is iterative with continuous faculty feedback provided after each submittal. Design submittals are required after coverage of singly reinforced beam design, shear design, and doubly reinforced beam design. Three weeks before actual construction of the beams, teams submit material requests to the faculty for the construction of the beams. To ensure adequate lead times for the purchase of reinforcing steel and to provide students with the greatest exposure to different sizes of rebar, a list of preselected reinforcing steel rebar is provided to assist the students in selecting the bar sizes for their selected failure mode. Once reinforcing steel bars become available, the four or five student teams meet to build the reinforcement cages. In the meantime, formwork is built by laboratory technicians for all the beams. On the day of placing the concrete, all the teams come together to place the reinforcement cages in the proper formwork location and help construct all of the beams at the same time. Ready-mixed concrete of a specified strength is delivered by truck and students work together to properly place the concrete in the formwork, finish the surface, prepare standard concrete cylinders for compression testing as well as perform the slump test. Teams take turns to maintain the proper curing schedule of the reinforced concrete beams until testing. Students enjoy working together and seeing their designs come to life.

Throughout the curing process, each team is assigned additional responsibilities to conduct compression tests on three concrete cylinders on the specified date to determine the concrete strength at 1, 2, 4, 7, 14, and 28 days. Prior to beam-testing day (28 days after casting), teams are asked to analyze their constructed beams and calculate the expected failure load. As part of the final technical report, teams are expected to help each other when loading each beam to failure using the full-scale testing apparatus. The testing apparatus is used to apply concentrated point loads at the 1/3 points along its length. Typical failure loads range between 50,000 and 120,000 pounds per beam. During testing, students are able to see first-hand how constructability issues can impact the performance and failure modes of the beams. They also gain a better understanding of the various failure modes for reinforced concrete beams and appreciate the factors of safety built into the ACI concrete building code. Each team submits a final technical report that includes iterations of flexural and shear design, analysis of the constructed beam with expected failure load, test results, conclusions, and recommendations.

In designing the beams each team was required to develop several Microsoft Excel spreadsheets to analyze basic reinforced concrete beams for flexure (singly or doubly reinforced), shear design, and the analysis of a typical reinforced concrete beam-column. Developing these spreadsheets requires a good understanding of reinforced concrete design principles and concepts, ACI code requirements and other factors that influence the design of reinforced concrete members. The spreadsheet allows students to focus on the fundamental logic necessary to complete the assignment.

V. ASSESSMENT AND STUDENT FEEDBACK

In addition to the graded assignments, student feedback was collected using in-class surveys. The focus of the survey was to have students self-assess their understanding of the principles and provide feedback on the effectiveness of the instructional method in meeting the course objectives. Data from the in-class end of semester survey for both courses indicated that approximately 90% of the students felt that they acquired a good to excellent understanding of the concepts and principles. Students felt the project design format enhanced their learning in both courses. Results indicating the level of understanding of the concepts and perception of the classroom instruction are presented in Figures 1 and 2. Additional details of the student feedback and self-assessment are summarized in Tables III and IV. Most of the results from the in-class survey are in agreement with students' performance on the direct measure assessment tools (graded projects and other assignments). The *Geotechnical Engineering* course is fairly new; it was first offered as an elective in 2008 and became a required course in 2009. Since then, other instructors have observed that students performed better on their senior capstone design projects. The PBL components of the *Reinforced Concrete Design* and *Geotechnical Engineering Design* courses have helped students understand the overall design process, improve their comprehension of basic design principles—knowledge and experience required for successful completion of capstone projects.

The structure of the Civil Engineering Program and class sizes at USCGA make it challenging to concurrently use different types of instructional methods (traditional and PBL) in courses offered. Therefore, it has not been possible to use control groups to fully quantify the impact of PBL on intellectual development. However, future plans include developing assessment tools that will be used concurrently in both courses to track the level of students' improvement and understanding of engineering principles and design concepts throughout the semester. One of the common assessment tools will be a grading rubric that will be used to evaluate students' ability to perform the following:

- Define the problem statement, identify constraint and scope of the project.
- Identify objectives and gather information from relevant sources such as codes and specifications.
- Identify and select appropriate analysis, design method(s) and design parameters.
- Consider practical constraints and constructability issues.
- Apply analyze and design methods.
- Prepare professional design drawings and sketches.
- Present details of analysis and design in a professional engineering report.

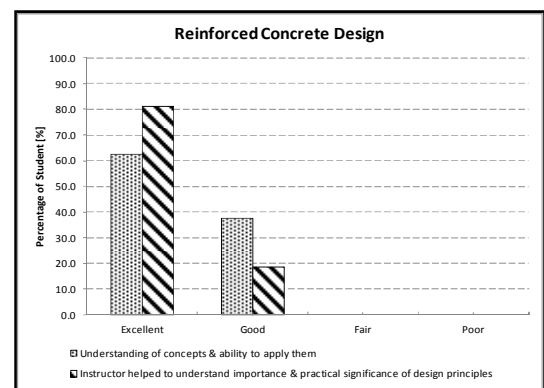

Figure 1. Students' Self Assessment in Reinforced Concrete Design

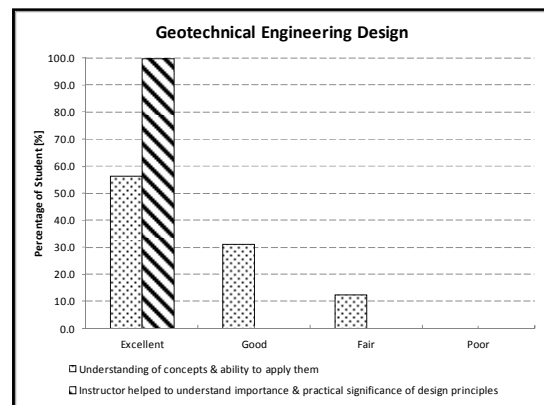

Figure 2. Students' Self Assessment in Geotechnical Engineering

TABLE III. SUMMARY OF STUDENT FEEDBACK IN REINFORCED CONCRETE DESIGN

| Survey Question | Excellent [%] | Good [%] | Fair [%] | Poor [%] |
|--|---------------|----------|----------|----------|
| Understanding & ability to apply concepts and design principles. | 62.5 | 37.5 | 0.0 | 0.0 |
| Instructor helped you understand importance & practical significance of concepts & design principles. | 81.2 | 18.8 | 0.0 | 0.0 |
| Ability to analyze & design reinforced concrete beams. | 56.2 | 37.5 | 6.2 | 0.0 |
| Ability to analyze & design columns. | 62.5 | 37.5 | 0.0 | 0.0 |
| Ability to analyze & design footings. | 18.8 | 56.2 | 18.8 | 6.2 |
| Ability to develop a spreadsheet application to analyze & design reinforced concrete structural members. | 25 | 12.5 | 31.3 | 31.3 |
| Use of engineering codes and design charts. | 47.8 | 37.5 | 12.5 | 6.2 |

TABLE IV. SUMMARY OF STUDENT FEEDBACK IN GEOTECHNICAL ENGINEERING

| Survey Question | Excellent [%] | Good [%] | Fair [%] | Poor [%] |
|---|---------------|----------|----------|----------|
| Understanding & ability to apply concepts and design principles. | 56.3 | 31.3 | 12.5 | 0.0 |
| Instructor helped you understand importance & practical significance of concepts & design principles. | 100.0 | 0.0 | 0.0 | 0.0 |
| Ability to describe relevance of site investigation & determine geotechnical parameters from tests. | 43.8 | 37.5 | 18.8 | 0.0 |
| Ability to select suitable design parameters based on soil profile, construction & other constraints. | 56.3 | 31.3 | 12.5 | 0.0 |
| Ability to analyze interaction between soil & geotechnical structure in a design problem. | 25.0 | 56.3 | 18.8 | 0.0 |
| Ability to apply soil-structure interaction to design. | 25.0 | 56.3 | 12.5 | 6.3 |
| Use of engineering codes & design charts. | 50.0 | 37.5 | 6.3 | 6.3 |

Students were also asked in the end of semester survey to provide additional information on how they felt about the format of the two courses affected their learning. Typical comments for both courses are summarized as follows:

- The projects helped reinforce the concepts presented in class.
- Enjoyed building and testing reinforced concrete beams to failure.
- It helped make the course easier to understand.
- Worked hard and learned a lot of new material.
- I understand more of the concepts when we had example projects.
- The flexible format enhanced the learning experience; using class time on projects helped a lot.
- I enjoyed the projects and the design aspects of this class.
- I thought the open-ended projects were extremely valuable in learning, thinking and applying the concepts.
- The projects were helpful and hands on.

In addition to course feedback, students were asked to complete a survey subsequent to the field trip. This provided students with an opportunity to comment on the effectiveness

of the trip in making the connection between the principles and concepts presented in class and the real world applications. The students' feedback on the field trip survey has been overwhelmingly positive.

VI. CONCLUSIONS

The students' feedback and in-class performance affirmed the effectiveness of the project-based learning and case study review implemented in the *Geotechnical Engineering Design* and *Reinforced Concrete Design* courses at the United States Coast Guard Academy. Through multiple iterations of these courses, students demonstrated a high level of understanding of the engineering principles and design concepts addressed in both courses. The two courses will continue to focus on improving students' abilities to think critically and apply their knowledge of fundamental engineering principles to solve real-world problems. It continues to be a challenge to consistently maintain very high levels of learning due to the diversity and varied educational backgrounds of the student population. Nonetheless, project-based learning and case studies can be adapted to address these generational challenges in students' learning abilities, personality types, and educational experience. This flexibility helps to ensure a larger percentage of the students are actively engaged in their intellectual development and gain practical design experience to better meet the needs of the engineering profession.

Constructive scaffolding for accessible PBL

Situated meta-critique in the classroom

Abstract—We reflect on the success of embedding legal, social, ethical and professional issues (LSEPI) into computing courses while at the same time encouraging a "growth mindset" in our students. We review the only compulsory course for our first year computing undergraduates, with a broad range of technical ability, impairment and educational background. We chose problem-based learning (PBL) as a natural fit with contextual demands but also paid special attention to the scaffolding required to make PBL effective with novice learners. Our main PBL element is a final "capstone" activity, in which small multidisciplinary teams of students who have not worked together before, design and deliver a Web-based game inside a week, using techniques and technologies seen during the preceding 12 weeks. This paper describes the approaches taken to practical and tutorial learning events and evaluates the results of the PBL phase. The main contributions of this paper are a) the identification of PBL as a vehicle for delivering generic graduate attributes (GGA), b) the use of PBL with novice learners, and c) the use of situated meta-critique as a constructivist trigger for developing self-reflection.

Keywords Problem-based learning, HCI, growth mindset, first year computing undergraduates, situated meta-critique

I. INTRODUCTION

Building on previous work [1] we reflect on the success of embedding legal, social, ethical and professional issues (LSEPI) into technical courses within our School of Computing, while at the same time encouraging a "growth mindset" [2] in our students. In the UK, state funding of universities is contingent on meeting such needs and this is currently referred to as the "Graduate Attributes" agenda [3] and is one of a number of external drivers for curriculum design. Some of these are **mandated** by the UK government through its Quality Assurance Agency and described as Enhancement Themes¹. These are essentially what a university must conform to. Others are **promoted** by professional bodies such as BCS, The Chartered Institute for IT, who accredit degrees towards achieved Chartered Professional status, or trade bodies such as ScotlandIS, IntellectUK or TIGA, who represent the views of employers, and to whom we must react effectively. Lastly there are areas where individual academics, based on their reflective practice and pedagogical research

interests, can operate ahead of the previous two sets of stakeholders, and the encouragement of a "growth mindset" among students is an example of this proactive approach.

We reflect here on the first three deliveries of a first semester, first year undergraduate course (one sixth of a full year's academic credits). We argue in favor of using PBL to deliver on contextual and discipline-specific demands. We then explore our success in achieving the desired growth mindset, and the extent to which this learning is achieved and retained, reflecting on the notion of "deep learning". First, however, we present some contextual information about the students and the course, before reviewing the literature on problem-based learning, scaffolding to support PBL, and the notion of mindset. We follow this with a description of how we ran the module before reviewing the outcomes and identifying priorities for further development.

II. CONTEXT

A. Learners

"Introduction to Human Computer Interaction", is the only compulsory course for all (typically 200) first year students in the school. These students are diverse - a broad age-range, multiple first languages and nationalities, 10-15% with impairments such as dyslexia or Asperger's syndrome. While most students in a School of Computing anticipate and desire to learn technical subjects, far fewer approach the human aspects of technology with as much enthusiasm. In this module, however, we lay the basis for later work in effective requirements gathering, design, and legal, social, ethical and professional issues (LSEPI). Three years ago, in designing this course, our challenges were to encourage a stronger sense of self-efficacy, to embed basic understanding of LSEPI and to lay the groundwork for achieving the required graduate attributes. At the same time we had to ensure the achievement of the required subject matter learning outcomes. Additionally we had to reverse what was then an unacceptable failure and drop-out rate amongst first year students which stemmed at least partially from a predictable drift in attendance starting around mid-trimester. Our institutional policy of avoiding end-of-trimester examinations for first year undergraduates presented an opportunity to engage in some innovative activities in the final two weeks of the trimester. At that time, the students would be free of any other academic obligations,

¹ www.enhancementthemes.ac.uk contains many publications on this topic

and access to dedicated resources would be much easier with all formal classes having come to an end.

III. LITERATURE REVIEW

A. Delivering “graduateness”

In 1964, Justice Potter Stewart ruling in a pornography case in the United States Supreme Court concluded that “I know it when I see it, and the motion picture involved in this case is not [pornography]” ([12]). Since then the phrase has been debated in legal circles and appropriated in many other contexts. It could equally well be applied to the problem of defining what it means to be a university graduate, a debate that has grown increasing more intense over the last few decades.

Australian academics, in particular, have been influential, and Simon Barrie’s considered approach [13] provides an excellent snapshot of academic opinion at the time. Barrie demonstrated a diversity of opinion among Higher Education (HE) teachers as to what constituted generic graduate attributes (GGA). His framework, summarized in Table 1, divided that opinion into four categories, two of which were further labeled “additive” and the other two “transformative”. The additive view of GGA is that they are transferable soft skills which are essentially distinct from any discipline-specific skills that the student might learn during a course of study at university. The transformative view, in contrast, holds that GGA are integrally connected to discipline-specific skills and allow the student to apply those skills more effectively in context.

Table 1: Generic Graduate Attributes [4]

| Group | Category | Conception of GGA |
|-----------------------|------------|--|
| Additive | Precursor | Generic skills acquired prior to university entry and therefore in advance of discipline-related skills |
| | Complement | Distinct and can be acquired independently of discipline-related skills |
| Transformative | Translate | Facilitate the application of discipline-related skills in the world and acquired in parallel with discipline-related skills |
| | Enable | Are inextricably linked with discipline-related skills and are acquired at the same time |

The diversity of opinion exposed by Barrie, and the challenge in reconciling discipline-specific needs, puts into stark relief the difficulties of attempting to pin down a single list of GGA that all academics would be willing to endorse. Indeed, since the articulation of a classification of perspectives, opinion appears to have diverged rather than converged [14]. Building a consensus around the definition of candidate skills, such as “critical thinking” throws up challenges when cross-disciplinary requirements come into play. Nevertheless, Green et al. [14] provide a strong argument for preferring the transformative view of GGA, which they develop as **specifist** (integrally related to discipline-specific knowledge and skills) and **relativist** (necessarily different from one discipline to another).

Despite the seemingly intractable problem of achieving academic consensus over the definition of GGA, universities are nevertheless under pressure to articulate their approach to

delivering employable graduates. Nowhere is this more clearly exemplified than in Scotland where the Quality Assurance Agency for Higher Education, Scotland (QAAS) maintains a rolling program of work whose aim is the enhancement of the student learning experience in Scotland. Through a series of “enhancement themes” Scottish universities contribute to reflective and developmental projects, the most recent of which, entitled “Graduates for the 21st Century” (G21C) ran between 2008 and 2011. A concluding summary of the G21C theme makes specific reference to need to allow HE institutions and subject disciplines to fine-tune the outputs and approaches [3], and the set of GGA identified during the theme – shown in Figure 1 – is therefore necessarily couched in general terms. The final framework based as it is on current existing practice demonstrates a balance between the managerial need for articulation of goals and the complex nature of the area.

Figure 1: Scottish GGAs [3]

B. Psychological mobility

Several of the attributes identified in [3] are concerned with the graduate’s responsibility for on-going personal development, typified by “lifelong learning”. This growth-oriented perspective, however, is not one that can be assumed to exist in all students and often needs to be actively cultivated during a higher education program.

Indeed, encouraging students to take a “deep” approach to learning rather than a “surface” approach has been a recognized problem for higher education for around 30 years [15]. According to a study at an Australian university [16] school leavers demonstrated a tendency towards a surface approach compared to mature students, and the authors suggest that school leavers may be more syllabus-bound and rely more on rote learning because of their recent secondary school experience. This observation accords well with Perry’s (1970, cited by [17]) finding regarding the development of a student’s conception of knowledge over time. According to Perry, the conception of knowledge shifts through a series of recognizable stages from the dualistic right-or-wrong perspective at one extreme to a commitment within relativism at the other.

In this context, the role of the tutor is to manage the student's transition from a simplistic understanding of the subject through to the more sophisticated understanding expected of the university graduate. However, attempts to modify the learning environment to promote the deep approach have met with mixed results [18]. One explanation for this may lie in the development of the deep/surface distinction articulated by Dweck [19]- that a psychological disposition towards an entity or incremental self-theory can be identified in children as young as 10, and this disposition can be reinforced according to the learning goals they are set during their school years, and the feedback they receive. Those with an entity self-theory, or "fixed mindset", hold the belief that intelligence is fixed, and that learning consists of the accumulation of essentially independent facts, while those espousing the incremental self-theory, or "growth mindset", believe that intelligence is malleable and that learning consists of mastering the subject. Mindset can thus be interpreted as a precursor to a particular approach to learning, and the university tutor may have considerable work to do to instill a growth mindset before a deep approach can be expected to emerge.

Dweck's view is that learners' beliefs about learning, knowledge and their own abilities directly impact their selection of approach to learning, and by extension on the quality of that learning. A similar relationship between beliefs and behavior was articulated by Bandura, in his work on self-efficacy [20]. He hypothesized that a strong sense of self-efficacy – a belief in one's own capabilities to carry out the behavior required to deliver a particular outcome – predicts a greater expenditure of effort to achieve an outcome and the sustaining of that effort over a longer period. Both of these behaviors could be used to characterize a deep approach to learning in a student making sense of subject material. A low sense of self-efficacy in contrast would predict a greater tendency to give up on a difficult task. Dweck [19] calls this the "helpless response" exhibited by students with a fixed mindset compared to the perseverance or "mastery-oriented response" of those with a growth mindset. In his original work, Bandura suggested that self-efficacy could be enhanced by persisting in activities which appeared initially threatening, but which eventually proved to be safe. Studies of self-efficacy among university students have borne out this prediction, indicating that it is not only possible to influence self-efficacy through intervention, but also that the most effective way to do so was through "enactive mastery experiences" [21]. These are experiences in which the student is exposed to apparently difficult tasks in which they can test their own capabilities and experience authentic success.

C. Solution opportunities

Originally pioneered with highly motivated medical students in the 1960s [4], PBL has been adopted more recently by teachers in a range of university-level courses [5] as well as in some high school settings (eg. [6]). As an inherently constructivist approach it promises to encourage high levels of self-efficacy among learners [7]. Although proponents (eg. [8]) claim PBL provides a more engaging alternative to traditional university instruction, the poorly-structured nature of realistic problems leads some (eg. [9] [10]) to suggest that PBL may be less appropriate for learners who have not yet developed a high

degree of self-direction. On the other hand, various forms of scaffolding have been suggested to compensate for the lack of structure (eg. [11]; [6]), and adequate attention to appropriate scaffolding was clearly essential in our application of PBL to novice learners. We saw PBL as a natural fit with disciplinary demands on the one hand and contextual demands on the other. Computing professionals are continually presented with novel, poorly-structured problems in a constantly changing technical environment while externally the generic graduate attributes agenda requires students to develop a reflective, self-directed approach to their own skills development. Other authors have drawn similar conclusions in other disciplines such as engineering for example [22].

The constructivist position casts the tutor's role as that of facilitator while the learner constructs personal knowledge of a subject through experience [22]. Despite debates about the nature of constructivism (e.g. [23]) and a persistent mismatch between teachers' beliefs about constructivism and their actions in the classroom (e.g. [24]), it remains a leading model of academic learning. Much of the debate surrounding constructivism arises from the fact that a theory of learning is not the same thing as a theory of instruction [25]. Unguided discovery learning in which the learner sets the learning goals, pace, process, etc. might be considered the most extreme form of constructivist learning. In this model, a learner typically selects a problem on which to work which then subsequently determines the content of the learning programme. However, this form of problem based learning (PBL) has been shown to be less effective than those which are structured by a tutor (See [25] for references). Proponents of PBL on the other hand argue that scaffolding provided by a tutor is required for successful PBL [26] and that effective pedagogical design centers on the choice and application of appropriate scaffolding for the subject domain. This disagreement suggests the need for a more nuanced approach to PBL such as that offered by Barrows (1986 cited by [27]) which is shown in Fig. 2. For models other than "Pure PBL" which corresponds to Kirschner's undirected learning, scaffolding is provided by the tutor. It should be pointed out that the model in Fig. 2 in which PBL is the broad category which is then subdivided is not the only way of conceptualizing the field. Prince and Felder [28] for example prefer the term *inductive teaching and learning*, in which PBL, as a technique, is contrasted with project-based learning and a number of other approaches. Their arguments correspond closely with those presented here, and in addition they review a number of empirical studies which demonstrate the medium- to long-term benefits of problem- and project-based learning, compared to more traditional ones in the field of engineering.

The term "scaffolding" was originally introduced [28] to describe support activities for children between 3 and 5 trying to solve a puzzle with wooden blocks. The concept is equally applicable to older students working in the zone of proximal development [22] to describe the support provided to enable them to perform tasks they would be unable to do independently. The term is specifically chosen to emphasize the temporary nature of such support so that when the learner has achieved competence, the scaffolding can be removed. Hmelo-Silver et al. [26] discuss a wide range of support that

could be considered scaffolding for PBL which includes traditional lectures as well as other more subjective interactions between learner and tutor.

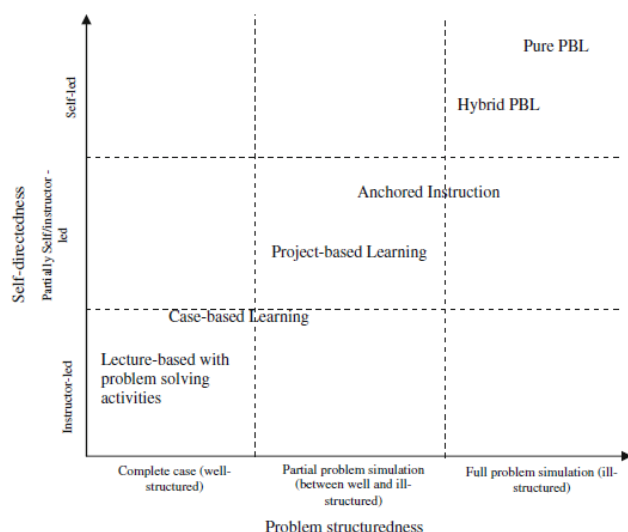

Figure 2. Six representative PBL models in Barrows' PBL taxonomy [27].

In seeking to make sense of the array of scaffolding available, others [29] distinguish between hard scaffolds which are prepared in advance, and soft scaffolds which are situational and ad-hoc. In this classification, lectures are clearly hard scaffolds, and question-and-answer techniques to guide the learner's thinking are soft. However, the distinction does not capture the possibility that some scaffolds may be both planned and situational, such as a problem-specific critique session. A further useful distinction not found in the literature therefore is between preparatory scaffolds and others which are concurrent with the problem-based activity. This leads to a 2x2 matrix shown in Table 2.

Table 2: Scaffolding approaches

| | Hard | Soft |
|--------------------|--|--|
| Preparatory | Traditional lectures, tutorials, etc | Feedback during tutorials, modelling during practical exercise, etc. |
| Concurrent | Scheduled group events during the PBL exercise | General ad-hoc support |

It should be noted that a particular scaffolding activity (eg. expert modeling of a technical strategy) may feature in more than one quadrant. Thus the model represents a tool for planning PBL activity rather than a static taxonomy of activities.

IV. IMPLEMENTATION

A. Module Design

The approach we took best corresponds to Barrows' *Project Based Learning* in that the main problem-based element was an independent group project which followed a relatively traditional series of learning events. The final project requires

that students work in small multidisciplinary teams of to design and deliver a Web-based game using techniques and technologies seen during the preceding 12 weeks. The problem is of realistic complexity and only loosely structured, thus fulfilling the requirements for a PBL subject. To further add to the realism it is time-limited, and concurrent scaffolding measures are provided as the work progresses.

The first four weeks involve the students learning and applying Benyon's [30] PACT techniques (People carry out Activities in a Context, using Technology), gradually learning about the people-technology system. The middle four weeks involve learning how to give and take criticism of requirements and designs, and to formulate and apply criteria for evaluation. The last four weeks combine learning the formalities of group-work, with some case studies and research technology designed to develop imagination. In parallel students' technical skills are leveled up.

B. Preparatory elements

Of the three main components of the module, only lectures were delivered in an entirely traditional way while a more inductive approach was used in practical sessions and tutorials. The practicals were focused on establishing a minimum skill level with basic Web technologies which could then be relied upon during the project itself. Self-study materials were provided at the beginning of the module, and later a series of staged practical problems and reference material was introduced. Students were instructed to make use of the scheduled practical session to consult with the module tutor, but also to continue working on the practical tasks during private study time. The intention was to instill in students a sense of responsibility for their own skill development, and to encourage the development of personal strategies for information discovery when faced with a novel problem. As expected, some students took this in their stride, while others expressed their frustration in the final module evaluation at the lack of direct step-by-step instruction in the practical stream. This divergence can easily be interpreted as a difference in mindset and self-efficacy.

A hands-on workshop approach was adopted for the tutorials associated with the module. The tutorial classes were large - typically 40-50 - split up into tables of 5-7. Each table tended to have the same groups as the students were in for weekly meetings with their Personal Development Tutor (PDT), and thus were usually all classmates from the same degree course, and with identical timetables. These students tended to know each other well after the first few weeks – a specific goal of our PDT system. In the tutorials, students were asked to put techniques into practice, such as storyboarding, design critique and system specification. The usual format was an introductory stage, which included expert modeling of the technique in question, followed by a staged exercise in which students worked in groups to apply the technique. Each tutorial concluded with a sharing of final results in which each group could see the work of others and could raise issues. Stationery items such as flip chart pads, marker pens and post-it notes were provided to encourage active participation, discussion and the development of final artefacts.

An underlying theme from lectures was the need to be conscious about ways in which documentation communicates ideas and choices to other stakeholders. This is exemplified by a particular tutorial exercise in which groups created and reviewed a system specification. To demonstrate the importance of accuracy and attention to detail, one group prepared the specification for a simple computer-based game using a simple template and a second group provided feedback on the content from the perspective of a development team who would have to implement the application. Finally, the first group had the opportunity to correct and complete their initial specification by responding to the feedback from the second group, before presenting their specification to the rest of the class. In other classes we used a third group to critique both quality of the second group's critique, and the adequacy of the first group's response. Because the exercise allows for several layers of evaluation of one group's input by another in the context of a goal-oriented activity, we refer to this process as "situated meta-critique". As preparation for the final project, the purpose of this type of activity was to emphasize the need for accurate and complete communications when working in a team. The group presentations at the end of the module demonstrated that the majority of project teams had taken this on board and had put considerable effort into their design documentation.

For the final project, teams of five students were constructed according to their specialist subject areas. A typical team would therefore include at least one software engineer, digital media designer and business computing specialist, and some also had computer networking students. Coming from different courses, team members were unlikely to know each other well, and therefore have only the common experience of the HCI module on which to build their working relationship. The approach to team construction actively encourages students to adopt roles within their teams that are appropriate to their own specialisms and therefore imposes a certain degree of reflection on the type of skills that they are supposed to be developing. The project task is to design and implement one of four simple Web-based games for one of four specific target audiences with rich contextual issues to consider (such as off duty soldiers in a war zone, rally car drivers between races, people with limited memory capacity, children in a kindergarten), and is designed to occupy the students on a full-time basis for an entire week (35 hours) in a week when the students have no other classes or assessments due.

The week begins with a workshop session on teamwork during which the students discover with whom they will have to work. The kick-off session and the final presentation of results, at the beginning of the following week, are the only compulsory events related to the project. However, several opt-in sessions are offered to the teams to guide their work. At the start of the project week, a software design workshop specific to each of the games is held during which the software developers from different teams can contribute to the development of a viable application design. These are lively affairs in which there is a good level of active participation from the students. Often though, the first workshop takes the students by surprise and has to be repeated. However, this helps to underline the need to be aware of what is going on.

In the middle of the project week, a series of design critique sessions are run, this time organized around the intended target audience rather than the game itself. This allows the team designers to discuss different ways in which the interface can be adapted to suit a particular group of users. As with the code design sessions, participation is lively.

In addition to these hard concurrent activities, soft concurrent scaffolding is provided in the form of student demonstrators and ad-hoc access to tutors. Teams draw on these resources heavily during the week, and there are always interesting problems to deal with. The ratio of students to tutors during the project is very high (approximately 100:1), and the effect is that teams are forced to focus their questions very specifically. This leads to a demand-led model of support in which students are obliged to take responsibility for identifying, describing and resolving problems.

V. RESULTS

The student attendance stayed reasonably strong throughout the term with at least 75% attending at least one class each week, an improvement on previous years. The pass rates were comparable with other modules as can be seen in Table 3, demonstrating that the PBL approach had no adverse effect on student attainment despite the inexperience of the cohort.

Table 3: Module pass rates

| Module | Numbers and pass rate | | | |
|--|-----------------------|------|------|-----------|
| | all | pass | fail | pass rate |
| Introduction to Human Computer Interaction | 197 | 174 | 21 | 88% |
| Being Digital | 47 | 40 | 7 | 85% |
| Digital Imaging | 70 | 59 | 11 | 84% |
| Information Systems in Organisations | 150 | 143 | 7 | 95% |
| Software Development I | 142 | 133 | 7 | 94% |

Given the aim of improving student engagement with the material, and the development of self-directed learning skills, comments provided by the students themselves in the end-of-module questionnaire gives a better measure of the success of the module as a whole. Feedback was collected using a standard pro-forma which asks students to rate the module on a five point scale from very poor to very good. In addition, free text comments are invited on the least and most rewarding aspects of the module. Out of a total of 102 questionnaires received, 34 chose to mention the final project in their comments, and of those 29 were positive and only 5 were negative. These results, shown in Table 4, indicate that the approach taken was successful in providing an engaging experience for the majority of students. The following exemplify positive comments about the project:

"Having a physical item (...) to show at the end of the course. It felt like I had something to show for my effort."
"The intensity of the [project] process felt meaningful and productive. Good professional atmosphere during this time. Not taken on a task like that before."

The negative comments tended to be less detailed, but two of the more informative focused on the fact that the students already had experience of group work, and therefore learned

nothing new during the project. This perspective could be interpreted as indicating a fixed mindset showing that some work still needs to be done on communicating the rationale to the students. We also plan further support in web-authoring for the practical classes.

Table 4: Student ratings and feedback

| | Very good | Good | Neutral | Poor | Very poor |
|------------|-----------|------|---------|------|-----------|
| Rating | 22 | 56 | 22 | 2 | 0 |
| Project | | 29 | | 5 | |
| Practicals | | 13 | | 26 | |

VI. CONCLUSION

The available evidence suggests that the course design is generally successful; however, there are specific issues that remain to be dealt with, the students who did not understand the purpose of the final project being one example. Another is the dissatisfaction with the practical element of the module as shown in Table 4. Informed by reflection on the experience so far, the priorities for further development are:

- More scaffolding for practical skill development
- Preparation for tutorial session in the form of expert modeling during lectures
- Further refinement of the general format for tutorial sessions including wider use of situated meta-critique

Work in Progress: A Quantitative Study of Effectiveness in Group Learning

Saket Srivastava and Richa Singh
Indraprastha Institute of Information Technology, Delhi

Email: saket@iiitd.ac.in, rsingh@iiitd.ac.in

Abstract—It is generally assumed that group studies are more effective for students than individual studies. The objective of this work in progress is to quantitatively evaluate and analyze the effect of collaborative studies on individual students performance. This effort would help the student stimulate interest in group learning and collaboration along with exposing them towards multiple problem solving approaches while working individually or in groups. This way the students are challenged to use their existing knowledge and approach, and augment it further with the knowledge and approach provided by group partners. While there are several efforts that focus on developing new group learning techniques, we intend to study the efficacy of previously proposed techniques under various test settings for EE and CS courses without significantly diverting from the course framework.

I. INTRODUCTION

Group learning in students has always been advocated as the best form of knowledge dissemination [1], [2]. The idea seems logical and intuitive as it paves way for collaborative learning environment in which multiple users with different skills and intellect assist each other in learning and understanding a topic. There have been studies in the past that have shown the effectiveness of group learning in certain topics [3], [4]. However, the biggest challenge in evaluating the efficiency of this approach is to establish a testing mechanism that is neither biased nor flawed. It is difficult to quantify the learning progress made by an individual student unless there is an exam that can test a student's ability on a given topic while working individually or in a group. The biggest problem in this evaluation is that you give the same set of questions twice, there is a high probability that the second exam using same questions was already compromised since students discussed the answers. At the same time, if they are not tested on the same set of questions, there is always a chance that the students may have known one set of questions better than the other. Moreover, if the students already know that they will be evaluated in groups, it may affect their performance as is a possibility that not everyone may contribute to the best of their ability in the group assignment.

Hence, the first task towards quantitative evaluation of group learning outcome is to design a testing mechanism that has the least bias and is still technically equivalent in all test cases. Further, the test should also ascertain the effect of student performance under various marking schemes, multiple choice or single answers with and without negative marking. The

rationale behind this approach is that students tend to be more conservative in answering questions when there is a scope of negative marking as compared to no negative marking. So the testing mechanism we have proposed also takes into account the effect of group learning under such a scheme. We can state that group based performance is better than individual performance only if it holds true under all different types of marking schemes.

In the next section, we discuss the testing methods employed and some background on the students as well as the subject. Further sections discuss the results and analysis of these testing methods to achieve a quantitative assessment of effectiveness in group learning over individual learning.

II. BACKGROUND OF TESTING TECHNIQUES

We conducted this study in March 2011 and March 2012 with the students of Digital Communication course. This course is offered to second year (fourth semester) students of IIIT Delhi. The students were oblivious to the fact that there will be a surprise quiz as the instructor had only given announced quizzes in the entire semester. Further, the second quiz in the very next class was also unannounced to minimize the effect of other factors such as the level of preparation. The students were given a surprise quiz based on the topics already covered in previous classes of the course. The topics covered in this quiz dealt with modulation techniques and bandpass communication techniques.

In the 2011 batch, there were 42 students (out of a class size of 57) who took all the quizzes individually and in groups while in the 2012 batch, there were 19 such students (out of a class size of 36) who took all the tests individually as well as in groups. In the first part of this study, we intentionally kept the group size limited to two students. All other students for whom the data was incomplete, were not included in the analysis. No special effort was made to increase class participation in order to maintain the surprise factor.

The first quiz was a mix of 15 multiple choice and fill in the blank type questions and there was no negative marking (+1 for correct and 0 for incorrect). There were multiple sets of question papers all having the same questions but different ordering of questions. Once the students completed this quiz, they were asked to repeat the quiz and this time they worked in a group of two students. In the next class, students were given another surprise quiz containing a different set of 20

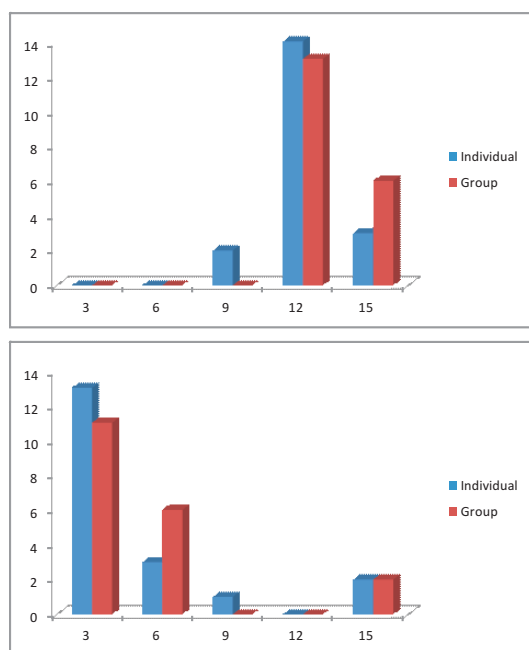

Fig. 1. Histogram demonstrating the performance of 2009 batch students in quiz 1 (top) and quiz 2 (bottom). X-axis represents the marks obtained and Y-axis represents the number of students.

questions on the same topics covered in quiz 1. However, this time the quiz had negative marking (+1 for correct and -1 for incorrect). Once they finished this quiz, they were again asked to repeat the quiz while working in a group of two students.

III. ANALYSIS AND RESULTS

Since the questions were from similar topics and almost similar in complexity for both quizzes, it was expected that the performance of students, both individually as well as in a group, will be better even if the quiz was negatively marked. The mean and variance for the first quiz, while working alone, was 10.36 and 5.08 respectively and while working in group it was 12.68 and 5.82 respectively. For the second quiz (with negative marking), the mean and variance while working alone was 2.55 and 10.07 respectively and while working in group it was 4.57 and 10.92 respectively.

The histograms in Figures 1 and 2 show that in group quiz, there are more students in the higher bins thus indicating better performance of the students in group quiz than individual quizzes. Analyzing the marks obtained and correlation between group and individual observations shows interesting results. The correlation between the first group and individual study was 0.27 whereas the correlation in the second group and individual quizzes increased to 0.53. Our results based on the rank order test [5] shows that group performance is statistically different and better than individual performance in both the cases.

IV. CONCLUSION AND FUTURE WORK

We believe that this work will serve as a good resource for faculties to benchmark the performance of students working

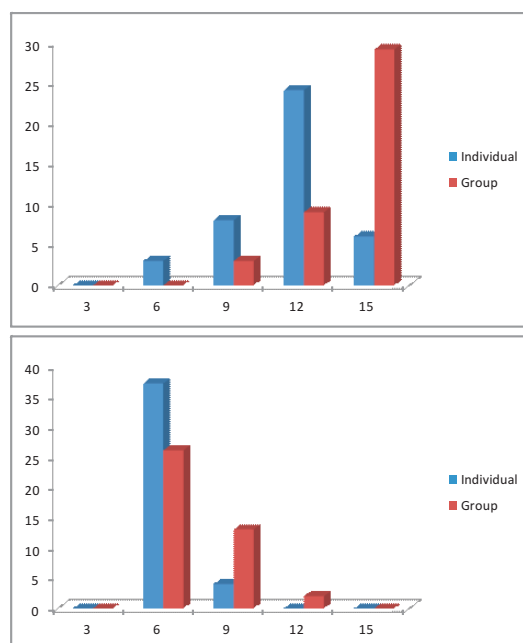

Fig. 2. Histogram demonstrating the performance of 2010 batch students in both quiz 1 (top) and quiz 2 (bottom). X-axis represents the marks obtained and Y-axis represents the number of students.

TABLE I
PEARSON CORRELATION BETWEEN INDIVIDUAL AND GROUP QUIZZES.

| | 2009 | 2010 |
|---------------------------------------|------|------|
| Quiz 1 Individual - Quiz 1 Group | 0.27 | 0.56 |
| Quiz 2 Individual - Quiz 2 Group | 0.54 | 0.88 |
| Quiz 1 Individual - Quiz 2 Individual | 0.51 | 0.50 |
| Quiz 1 Group - Quiz 2 Group | 0.46 | 0.54 |

in groups. The deliverables of this work simple quantitative methods that can be used under various grading schemes. In future semesters we also intend to incorporate other kinds of testing schemes and also study the effect of surprise factor on group performance. Another interesting study could be to identify the optimal group size that facilitates maximum learning.

ACKNOWLEDGMENT

The authors would like to thank the students from 2009 and 2010 batches of IIIT Delhi for participating in this study.

Abstract—One of the most debated areas of computer science education is how to arrange programming courses. One of the debates is concerned with the amount of guidance a learning environment should grant to the learner. This research study reports on development and testing of a model where students work on their homework under guidance, facilitated by active student-teacher collaboration, continuous feedback, and student support. While qualitative results, observations, and student feedback about the intervention were exclusively positive, controlled experiment showed no significant advantage over the control group. This paper reports the results of the experiment described above, and suggests ten hypotheses for further research.

I. INTRODUCTION

Over the course of development of programming education at Tumaini University in Tanzania, several visiting professionals from developed and developing countries have attempted their own approaches to teaching programming. In general, the learning outcomes have remained unsatisfactory. In order to explore the reasons behind the challenges of programming education, in 2009 we started to systematically collect and combine the teachers' experiences, ideas, and best practices together.

In the course of curriculum development at Tumaini University, it has become clear that curricula and pedagogy can not be imported from western institutions, but must be based on contextual understanding [1]. Standard curricula, such as the ACM/IEEE Computing Curriculum [2], does not fit a Tanzanian institution as-is. The pattern of factors which affect learning in different contexts, countries, cultures, and continents, vary a lot. In our case, many of the contextual factors that affect learning are still unknown. In order to better understand the contextualizable elements of education, we decided to include action-research based development and research activities as a part of teaching.

By utilizing the action research approach, this research study extended our previous research by focusing on students' problem solving processes during homework practice and exercise work. Hands-on practice is essential for acquiring programming skills. Most of that practice is typically conducted on students' own time, in an environment that educational psychologists consider to be "minimally guided", and hence not suitable for novice learners [3]. By utilizing ideas from successful pedagogical approaches, such as the eXtreme Apprenticeship (XA)-method [4], we developed and

tested a model where students work on their homework under guidance with active student-teacher collaboration, continuous feedback, and student support constantly available.

The aim of this study was twofold: Firstly, to test the impact of this pedagogical vehicle on learning outcomes, and secondly, to gain a better understanding of the students' problem solving processes during hands-on practice. This study used a randomized controlled research setup, triangulated by a survey study and by qualitative data collection through participant observation.

II. BACKGROUND STUDIES

Since 2007, Tumaini University's IT program has seen several attempts to teach programming, by teachers from Spain, Uganda, USA, and Finland (e.g., [5]). These approaches have mostly utilized a traditional lectures-exercises-homework-pattern, with several pedagogical extensions. The extensions include the use of a program visualization tool Jeliot [6], the *coding-while-lecturing*-technique [7], and various approaches for generating contextual learning materials, course content, and e-learning support tools.

In 2009 we started to collect and combine teachers' views of factors that affect the learning environment and their ideas for improving the learning environment [5]. The teachers' views revealed challenges related to students' educational background, lack of equipment (hardware and software), lack of study materials, lack of efficient learning strategies, great variation in students previous skills within a class, erroneous assumptions about and feelings of insecurity towards programming, time management issues, counterproductive group work dynamics, and language problems. Concerning what worked well, the teachers named easy interaction in classroom and positive experiences with e-learning materials. The teachers suggested several improvements, such as increasing individualized and of open-ended exercises and need for affective support.

As a starting point, we came up with a five-factor model of challenges in learning programming (Table I), and proposed several practical ideas on how to address them [5].

For addressing the factors identified in Table I, we designed a contextual set of pedagogical practices based on educational theory: this included further utilization of the *coding-while-lecturing* technique, using contextualized affective support

TABLE I
FIVE-FACTOR MODEL OF CHALLENGES IN PROGRAMMING COURSES [5]

| Component | Explanation |
|---|--|
| Educational Background | Due to the multidimensional nature of the Tanzanian education system, the background skills in science topics, language, and problem solving vary a lot. |
| Learning Strategies (Deep/Surface Learning) | The mainstream learning strategy is rote memorizing and surface learning, aimed at solving well-defined, closed problems. |
| Motivational Orientations | Students risk generating extrinsic motivations when their learning strategies fail. |
| Groupwork Tendencies | Communal groupwork tradition, inherent in many African cultures, has both positive and negative effects for learning. |
| Study Environment and Habits | Language problems, copying, and plagiarizing of coursework is a common challenge. Internet, availability of computers for training, and other teaching facilities are often lacking. |

based on the self-determination theory (SDT) [8], introducing an adaptive set of multi-level exercises, and switching to constructivist student-centered classroom interaction. While the introduction of these approaches provided some promising results [7], [5], the performance results still remained too low.

In order to investigate the students' viewpoints to learning programming, we conducted a mixed-method study on the new pedagogical arrangements [5]. Through action-research based teaching, we formed a set of hypotheses and open questions regarding, for instance, programming language choice, affective support, students' backgrounds, academic performance, and learning outcomes. As the lack of deep-level learning skills and suitable problem-solving skills was confirmed to be one major challenge [5], it was selected as a priority for further research.

Those students, who lack the deep-level learning and problem solving skills that are essential for understanding computer programming, will easily resort to unproductive learning strategies, such as rote memorizing. When that method inevitably fails in programming classes, extrinsic motivation grows, which, in turn, results in attempts to pass the course through whatever means available.

If one looks at time usage by learners in programming courses, a major part of that time is spent on homework and other tasks that students are required to perform outside the instructed learning sessions. In our earlier experiences, even though we had put great effort into designing the classroom learning environment and exercises, something was still missing. We did not know how learning happened outside the school walls, and we had no means of changing any habits that students might have had.

A. Investigative Learning Environment Design

In this research study we utilized an *investigative learning environment* design, which extends traditional teaching environment by adding several research-oriented activities to the teaching. Our approach includes, in a cyclical process, a background study; a literature study; a detailed plan for teaching, designing, and conducting research; teaching and

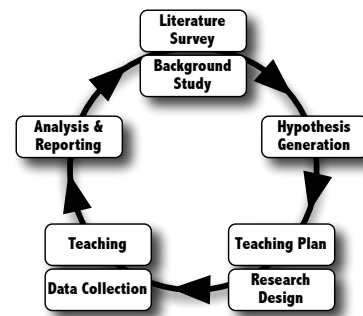

Fig. 1. Cycle of Activities in Investigative Learning Environment Design [9]

researching in collaboration with students and other staff (by observing, interviewing, and surveying); combining the results systematically; and iterating the cycle [9].

We taught the class and conducted the research in a small collaborative team of three teachers-researchers. Each of us worked in different roles—as teachers, researchers, observers, and interviewers—discussing the learning environment, combining our viewpoints, and making further plans. In this context, our research-oriented approach was superior compared to the traditional modes of teaching and researching, because it allowed us to make well-informed, flexible choices over the learning environment. The cycle of work is described in the figure below.

III. THEORETICAL FRAMEWORK

A. Programming Pedagogy: XA–Method

A strong movement in the pedagogy of programming describes programming as an application of problem solving, while another movement considers the learning of syntax and structure to be the most important issue [10]. According to the problem-solving approach [11], the ideal chain for cognitive accomplishment in programming instruction starts with novices learning language constructs, progresses to novices being able to combine programming structures together, and finally progresses to novices acquiring the generic problem-solving principles behind the processes. The student at the highest level will learn to transfer the learned skill to other programming problems, and to other problem-solving domains also, even if they are not related to programming [11]. It has been argued that in a typical programming course too little time is spent on practice in order to support the necessary cognitive chain for learning [11]. Additionally, little is known about the factors that affect the learning process in different cultures.

A promising modern approach to instruction is the XA–(eXtreme Apprenticeship) *method* [4]. The XA–method emphasizes practical work, questions the utility of instructivist lectures, and advocates strong teacher-student collaboration through one-on-one advising with continuous feedback. The core ideas of the XA–method are, firstly, that the craft of programming can only be mastered through practice, which must be done as long as necessary, and, secondly, that the

problem solving process must be promoted with continuous feedback, which in XA is seen as a necessity to make the learning process meaningful and effective [4]. One study showed that introduction of the XA-method resulted in significant decrease in dropout rates and in significant increase in pass rates and grade distributions in CS1 courses [4]. The main requirements for the XA-method are substantial increase in lab hours, considerable increase in the number of teachers or teaching assistants, and extended exercise sets for practice.

B. Minimally Guided Environments

The environment where students work with their homework in computer programming courses, outside the instructed learning sessions, is a prime example of a minimally guided environment (MGE) [3]. Educational psychologists argue that a minimally guided environment offers weak prospects for novice learners, who require direct instructions and guidance on procedures and concepts related to the topic [3]. Minimally guided environments interfere with the natural processes of human cognitive architecture, and unguided learning may have many negative results such as acquisition of misconceptions and disorganized knowledge, which may need to be later unlearned. For novice learners who are learning a cognitively challenging task, guided learning practices provide greater potential for efficient learning [3].

IV. RESEARCH QUESTIONS AND DATA ANALYSIS

There were two main objectives for this research: firstly, to test how a guided learning environment in exercise work affects the learning outcomes, and, secondly, to gain deeper understanding of the students' problem solving processes when they work on their homework. Main research questions of this study were:

- *RQ1*: What are the main factors that influence a student's problem-solving process when working with practical exercises?
- *RQ2*: What is the impact of guided exercise sessions to the learning outcomes?

The first research question (*RQ1*) was approached from two directions. Firstly, researchers observed and wrote detailed observation notes during the guided practice sessions. Secondly, a survey study was conducted among the learners.

The second research question (*RQ2*), was answered by using a controlled pretest-posttest research setting. A class of students was randomly split to half. The first group conducted their homework exercises under guidance, while the second group worked on their own. The experimental and control groups were switched half-way the study, so that everyone received equal amount of guidance during the course. The learning outcomes were frequently measured by giving both groups quizzes after the completion of each set of exercises. The grading of the exercises was conducted by, and co-validated between two teacher-researchers.

V. RESULTS: A GUIDED ENVIRONMENT

This research was conducted in the course *Programming II – Introduction to Object Oriented Programming*, which is a second year course in Tumaini University's IT program. We decided to continue with the previously developed pedagogical approaches (see Section II), and in addition extract ideas from the XA-method [4] to add into the learning environment guided practice sessions with continuous, collaborative student-teacher feedback loop. The first exercise set of the course, which was primarily for rehearsing content from *Programming I*, was used as the pretest condition for the research. For the second and third exercise sets we arranged two full day (from 9am to 5pm) *code-camp practice sessions* at a computer hall on the main campus. In these code-camp sessions, students were provided with a set of exercise tasks, a computer, guidance, and a peaceful and less formal (as compared to the lectures) environment for working.

We had three teacher-researchers working in different roles during the course, as instructors, observers, researchers, interviewers. We also had one additional teacher who joined in to instruct at the code camp sessions. For those of us working in the role of instructors, we designed several guidelines.

- 1) Only individual work is allowed. Thus, students are not allowed to discuss with each other during practice.
- 2) Exercises are continued as long as necessary to gain the required skills—no exceptions.
- 3) The learner should not be left without help at any time, but the learner should continuously receive small signals to tell if he or she is progressing in the right direction. The instructor must constantly be aware of the activities of each student.
- 4) The instructor must never give correct solutions, but must direct each student's thinking to the direction of the solution.
- 5) Syntax mistakes are corrected and explained by the instructors whenever those mistakes keep the student from focusing on the high-level problem solving.

In the sessions each student picked up an exercise task from the instructors, and then individually started to work on that. When facing any trouble, the student was able to call an instructor for help. Instructors also went around the class to observe the progress of students and to give guidance when necessary (even if not asked for). When the student completed the task, he or she presented it to the instructors and if the student's solution was correct, he or she was allowed to proceed to the next task.

The instructor-researchers continuously asked students questions, trying to get a clear picture of the students' thinking and problem-solving process. Students were encouraged to draw or verbalize what they would need in order to build the required program in full. The researchers wrote down extensive field-notes of their observations. We aimed to provide a continuous feedback loop and to recognize the stages of problem solving with each student as they appeared during the visualizations and verbalizations of building the program.

A. Observation Notes and Survey Study (RQ1)

The first broad theme that arose from the observation notes was concerned with the multiple problem types that students faced during their work on the exercises. Examples of common problems that students brought up were difficulties with understanding the task description, challenges in formulating a plan for solving the problem, and syntax problems, such as missing commas. The continuous feedback loop was effective and necessary for all the above-mentioned problems that the students faced.

The second theme that was brought up was concerned with the enthusiasm, interest, motivation, and determination of the students to work and to complete the exercises. The code-camp sessions were designed to be relaxed with a sense of freedom from restrictions. The students could go outside to enjoy soda and snacks anytime they wanted to, and they were also free to leave should they wish to do so. Still, most of the students worked intensively with only very short breaks, for almost the full time of the sessions. The students seemed to appreciate and enjoy the personal contact and the continuous feedback loop, and all students seemed to be well concentrated.

The students' comments during the guided learning sessions were typically very positive. One student mentioned it to be "*the first time I started to understand programming.*" Several students who reported struggling with their home exercises gave similar feedback. Students showed remarkable motivation and effort throughout these long sessions: For example, in all sessions most students continued to work although they were asked to have a break outside. Another comment from a group of students revealed that they had "*never programmed so much before*"—this may refer to the challenges that occur with group work methods in programming courses.

1) *Student Viewpoint*: To gain deeper insights to the students' views of the course activities, we conducted a survey study. That survey asked 12 questions measuring the perceived utility of the different parts of the learning environment (course materials, classroom interaction, unguided practice, guided practice). The survey also collected some demographic data.

For the survey, we got a response rate of 25 ($n = 25$). The survey results revealed that the students considered programming to be a moderately difficult topic: the question *Programming is a very difficult topic* resulted in a mean of 4.3 on a scale from 1 (not at all true) to 7 (completely true). Programming was also considered to be an interesting topic (*Compared to other topics, I find programming to be a highly interesting topic* resulted in mean 5.16). In an earlier study students ranked programming to be by far the most difficult topic in the IT program [12].

Overall, students considered that all the course activities support learning quite well. The question *In general, the course activities supported my learning* resulted in a mean of 5.64. Also the means for the questions which measured the opinion on learning materials (mean 6.08), classroom interaction (mean 4.92), unguided homework exercises (6.12) and guided learning sessions (5.96) were all high. It is interesting that while the observers as well as students considered the

guided learning sessions to be very valuable, in the survey students perceived unguided exercises to be slightly more useful for learning than guided exercises were. There clearly is a role for both activities.

The positive role of guided learning came also clear in the free comment section of the survey study. A representative example of a typical student's comment towards guided learning was: "*The guided exercise lesson was very interesting and helpfull [...] it provide a direct support to individual students when he/she faces challenge on entire exercise. Due to this model being helpfull, I suggest to be used not all programing class but also with other topics, because it increases understanding and concept acquisition.*" (Student, IT 2). The exact roles of guided and unguided environments call for further research.

Another constantly recurring theme in the free comments section was time management issues. Many students reported that they have too many concurrent courses, all with high workload. Without careful time management and prioritizing, there is not enough time for deep-level learning in every study topic.

The *code-camp* sessions were an eye-opening experience to observe the issues that affect students' learning when they are working on their exercises. This study revealed many obstacles and barriers that restrict the learning of programming. Time management, group work dynamics, and language problems exist worldwide, but their extent may vary a lot between different institutions.

According to our observations, the guided environment directly addresses some of the learning barriers related to time management issues, group work dynamics, and language problems by restricting the environment to promote only individual work, and by directing the study activities towards programming tasks only. The environment also provides necessary affective support which gives the ever needed motivation for students. By guiding the environment, we were able to gain understanding on the actual problem solving process in a situation where learning is not restricted by external barriers.

In the guided environment we found out that the students' learning processes were very sensitive to many kinds of errors or interruptions. Often, when a student was stuck with problem formulation or syntactical error for too long a time, that student easily lost motivation. The guided learning environment with continuous feedback helped to address also these issues.

The *code-camp* sessions provided students an environment that eased each student's workload on organizing his or her study work. When students work simultaneously with multiple courses, they have to actively prioritize and make choices on which homework they will work at each moment. In a situation where a student is frustrated with a missing comma for 30 minutes, that student might easily choose to switch to study another topic. According to several studies the self contains limited resources related to self-control, which is depleted by every act of volition [13], [14]. Thus, it is more exhausting to be responsible for one's own active choices than to be in a situation where someone else is responsible for making

the choices [13]. Sensitivity of the learning process to minor yet frustrating problems also suggests that the simpler the programming language syntax, the better.

In our guided environment students were freed from the psychological burden of making active choices, but they were able to better concentrate on deep-level learning than they can in the work that they conduct on their own time. The guided environment also partly solved the earlier issues with group work. When the environment set the rules for group dynamics, it inhibited some aspects of groupwork that previously hindered learning, such as unbalanced workload and weaker group members not getting enough practice. However, externally given rules also inhibited the positive aspects of students' freely formed group and work dynamics, so the outcomes might not be solely positive.

From the teacher's side, organizing the guided learning practices consumed a lot of resources. In the future, we will recommend the invitation or hiring of older students from each class to work as course assistants. As we got promising results both from student feedback as well as the observed results in development of programming skills during the sessions, in the future we propose the preparation of the student assistants to follow the principles described earlier in this paper. We will also recommend the changing of the regular course structure of two lectures per week into one full guided day of programming per week for the whole semester.

B. Controlled Research Setup (RQ2)

To our surprise, the results of the controlled research setup contradicted our positive observations during the code camp sessions. In the pretest condition, a one-way ANOVA was conducted to make sure there is no difference between the performance of the randomly assigned groups. The guided (G_G) and unguided (G_{UG}) groups performed equally well, with almost equal mean performance ($G_G = 2.23$, $G_{UG} = 2.18$), and with no statistically significant difference [$F(1, 40) = 0.116$, $p = 0.736$]. In both posttest conditions we had three programming tasks with an increasing difficulty level.

In the first task of the first posttest condition, the performance of the guided group and the unguided group were almost equal (means: $G_G = 1.33$, $G_{UG} = 1.35$), with no statistical significance shown in one-way ANOVA analysis [$F(1, 42) = 0.005$, $p = 0.995$]. In the second task, the means for the groups were also nearly equal (means: $G_G = 1.44$, $G_{UG} = 1.5$), with no statistical significance in one-way ANOVA analysis [$F(1, 41) = 0.042$, $p = 0.839$]. In the third task, the guided group performed slightly better (means: $G_G = 2.3$, $G_{UG} = 2.06$), but with no statistical significance shown in one-way ANOVA [$F(1, 42) = 0.880$, $p = 0.353$].

The total performance between the unguided and guided groups in the first posttest condition was: (means: $G_G = 1.72$, $G_{UG} = 1.63$), with no statistical significance between the condition means in one-way ANOVA test [$F(1, 41) = 0.242$, $p = 0.626$], and thus, there was no difference in the learning outcomes between the group that received guidance and the group which did not receive guidance.

In the second posttest condition, the groups were switched and the following scores for the three learning tasks were achieved. In the first task the guided group performed better (means: $G_G = 1.32$, $G_{UG} = 1.24$). In the second task the unguided group performed slightly better ($G_G = 1.34$, $G_{UG} = 1.4$). In the third task the guided group performed better ($G_G = 2.22$, $G_{UG} = 1.90$). Total performance for the second posttest condition was $G_G = 1.62$, $G_{UG} = 1.51$. There were no statistically significant differences between group performances in either of the learning tasks or in the total performance in the second posttest condition. The results of the one-way ANOVA analysis for the first task was [$F(1, 45) = 0.118$, $p = 0.773$], for the second task [$F(1, 45) = 0.059$, $p = 0.809$], for the third task [$F(1, 45) = 2.061$, $p = 0.158$], and for total performance [$F(1, 45) = 0.499$, $p = 0.483$].

With our positive experiences from the code-camp sessions, the performance results struck us with a surprise. We were left to hypothesize between various explanations for the reasons why the groups performed equally well. The most plausible explanation is that students indeed do learn equally effectively under guidance and outside of guided environments, and that our qualitative results from participant observation and student feedback were misleading. Further research is, however, needed for resolving the dissonance between the qualitative results and the quantitatively measured learning outcomes.

While exploring why our qualitative results suggested better learning outcomes that did not materialize, we also propose research on alternative hypotheses. Firstly, due to resource limitations, the tests had to be conducted on a pen-and-paper format, which is different from hands-on computer-based work with the exercises. Perhaps we tested the wrong thing: If we learn-by-doing, perhaps we should test-by-doing also. Secondly, while in our observations the students succeeded well, and they clearly started to capture effective problem-solving process for solving programming tasks, perhaps our intervention was not deep enough to change students' learning and test-taking habits. Similar phenomena have been observed in other contexts also: In another study researchers found out that it took years for change in learning styles to show up in test scores [15].

In the workshop situation it seemed clear to all the researcher/teachers that many students started to understand certain learning tasks and perform well in them, such as in understanding how a for-loop works. Despite their apparent mastery of the concept and skill, in the exam, the same students failed to solve similar tasks that they had successfully completed in the workshop sessions. This might result from an imbalance in *constructive alignment* between the learning environment and the assessment tasks [16, pp. 95]. In the future, we will consider the possibility to develop test-while-doing practices instead of pen-and-paper exams.

VI. DISCUSSION

Over the course of development of programming education at Tumaini University in Tanzania, we have begun to utilize an action-research approach to systematically test

the impact of educational interventions. We have designed several pedagogical approaches, and studied their outcomes using the mixed-method approach. By utilizing ideas from successful pedagogical approaches, such as the XA-method, we developed and tested a model where students work on their homework in a guided, safe, and relaxed environment, and where teachers are available for active student-teacher collaboration, continuous feedback, and student support.

The results of this study were contradictory: while there was no significant difference in the learning outcomes between guided and unguided groups, the observation notes, as well as the opinions of researchers, teachers, and students all spoke highly in the favor of guided learning. There are many open issues in this particular learning environment which pose opportunities for further research. In the following we propose a list of open hypotheses for further studies of learning programming in this particular context of education.

- 1) Students have too little practice:
 - a) Students do too few independently done (home) exercises.
 - b) There are too few guided exercises.
- 2) We fail to teach students effective learning strategies (e.g., students do not trust in their own ability to create code but they try to memorize code snippets).
- 3) The styles of programming education that we have introduced are not well aligned with students' epistemological positions.
- 4) We test the students' learning wrong. (If we want them to learn-by-doing we should test-by-doing)
- 5) Students try to adapt to each individual teacher's characteristics (in terms of questions posed, proper answers, cues for support etc.) and they would benefit from more variety in teaching/practice styles.
- 6) We fail to shift the students' focus from the syntactic level to the semantic level.
- 7) Students' English language skills are lacking (the university's official teaching language is English, though).
- 8) Some other programming language (currently Java) would produce better results.
- 9) Students rely on group work in a subject that is essentially an independent "craft" type of subject.
- 10) Due to nationally acknowledged deficiencies in basic education [17], teaching of abstract thinking in primary and secondary school level is inadequate.

Based on the positive experiences gained from guided learning, our recommendations for future activities include extending the guided learning activities by training top performing students from previous class to work as assistants. As guided learning did not produce worse results than unguided learning, the guided approach could be deepened to cover the whole course. In future, more focus should be put on the possibility of switching to test-while-doing instead of paper-and-pen exams. Programming is a challenging topic to teach worldwide. Thus, many of the open issues and challenges identified by this research may be relevant in other educational

contexts also.

ACKNOWLEDGMENT

Tedre's research was funded by the Academy of Finland grant #132572. The authors would like to thank Dr. Dan McIntyre of Tumaini University for his insights and his work as a member of the classroom teacher/researcher team. The authors would also like to thank Tumaini University's staff and students.

Work in Progress: Supporting Latino and English Language Learners' Written Communication Skills

A Research-Based Pedagogical Intervention

Alberto Esquinca, Elsa Q. Villa, and Gabby Gandara

The University of Texas at El Paso, aesquinca@utep.edu, evilla@utep.edu, gabby@utep.edu

Abstract—This paper reports preliminary findings from a qualitative study of a research-based pedagogical intervention in a freshman-level course for engineering majors. In this intervention, engineering instructors collaborated with an applied linguist in education to design activities to improve writing skills, an important professional skill in engineering. Development of effective writing skills is challenging for students, and particularly for Latinos and English Language Learners (ELLs). This challenge can be effectively addressed with meaningful writing tasks and appropriate pedagogy. Preliminary findings show improved communication and interpersonal skills among students.

Index Terms—Latinos in engineering, English Language Learners (ELLs), project-based learning, effective writing.

I. INTRODUCTION

It is widely accepted that engineers must be able to communicate effectively. Simultaneously, research on academic writing and second language writers has focused on the unique challenges that academic writing in a second language entails [1]. This paper reports preliminary findings from a qualitative study of an intervention in a required freshman-level course for engineering majors in an institution where the vast majority of engineering undergraduates are Latinos. Instructors in engineering collaborated with an applied linguist in education to integrate research-based pedagogical approaches as the instructional framework for the intervention. The intervention supported student teams in writing how mathematics topics connect to engineering applications.

II. SETTING

The University of Texas at El Paso (UTEP) is a minority four-year institution with an undergraduate enrollment of 1,711 in the College of Engineering. UTEP is located on the U.S./Mexico border and its demographics reflect that of the community it serves (76 percent are Latino). In El Paso, 76% of households speak a language other than English at home, with the vast majority speaking Spanish. Many UTEP students, even those not classified as ELLs, are Spanish speakers.

III. THEORETICAL FRAMEWORK

Appropriate pedagogical support is essential for developing engineering communication skills, and includes feedback and purposeful reflection integrated with an interactive instructional approach [3,4,5,6]. Enhancing

writing in a university course is important for a number of reasons, such as its ability to assess and promote students' understanding [7]. Moreover, authentic writing assignments, such as writing applications for internships, can serve to situate learning [8] and construct new understanding [4,5].

Research with ELLs points to the importance of meaningful participation as crucial to developing engineering communication skills. For example, Vickers [9] draws on language socialization and a situated learning framework to show how participating in a community of practice can be essential for ELLs where more proficient peers and the instructor can scaffold ELLs' learning while designing engineering projects.

Our intervention was informed by this prior research and our aim was to guide Latino and ELL students in developing a disciplinary discourse of engineering in a second language.

A. Inquiry-Based Teaching and Learning

In our design of this pedagogical intervention, we also integrated inquiry-based approaches for creating a dialogic environment and opportunities for constructing new understanding. Thus, we needed to engage learners in meaningful tasks to situate their learning [10,11] where novices have more opportunities to learn discipline-specific practice through social interaction with those more expert [11]. Thus, in our design, we infused situations where our students could interact with engineering research professors and graduate students in engineering research laboratories.

We employed project-based learning (PBL), a particular form of inquiry-based instruction, since PBL has more sustainable outcomes than other approaches to learning in terms of retention and skill development [12]. More important, it creates an environment for stimulating improvement of written communication skills. In PBL, learners drive the learning goals and construct their understanding through investigation and development of a project in answering a driving question [12]. In our intervention, teams of students were each given a mathematical concept, such as transformative functions or least squares, with the driving question: How is this applied in engineering?

B. Description of Intervention

The project was titled Mathematics Connections Project (MCP) and was framed as an opportunity to write a paper for high school students to explain how a mathematical concept is applied to engineering. The instructors engaged student

teams in researching, writing, and editing the assignment using an iterative process to improve their writing. Their investigation entailed interviewing faculty in engineering research labs and conducting library searches of relevant papers. Then they synthesized into one sentence what they had learned and brainstormed supporting ideas, generally three to four. These ideas were assigned to each group member who wrote an explanatory paragraph related to the synthesized statement. After peer edits of individual paragraphs, the team merged all paragraphs into one paper, which was individually edited and merged into a single paper for further group editing. This incorporated individual accountability, a key element for effective teams [13].

IV. ABOUT THE RESEARCH DESIGN

The questions guiding our research were: (1) In a PBL course, how do freshman pre-engineering students develop 21st century engineering skills and dispositions? (2) What are the benefits to student written communication skills in a PBL course with explicit focus on writing and the writing cycle? We collected data from field notes of participant-observation, written assignments, focus groups, and written learning reflections. These data were analyzed to identify patterns of writing development across the semester.

V. PRELIMINARY FINDINGS

Preliminary findings emerging from the data analysis were that Latinos and ELLs benefited from (a) participating cooperatively in meaningful tasks and (b) focusing on communication explicitly.

A. Participating Cooperatively in Meaningful Tasks

Students' cooperation in writing the MCP allowed them to understand the value of clearly communicating engineering applications of math concepts, and group communication with a team of peers. Cooperative groupings allow peers opportunities to socialize each other [10] into engineering discourse through immediate feedback or peer critique on performance. Thus, a written task, such as writing an email to a professor to seek an interview or writing drafts of a formal research paper, can permit ELLs to receive feedback from the professor and/ or from their peers.

To exemplify and illuminate how the cooperation unfolded in the whole class, we present the case of one student team consisting of two Latina females, Daniella and Clara, who gave consent to participate in this project and are identified with pseudonyms. Daniella is English monolingual, and Clara is Spanish dominant student who is proficient in English. The math topic assigned to these two students for their MCP was matrices.

Daniella and Clara's initial joint draft drew strongly from math content sources and began with "*A matrix is a rectangular system of numbers organized into rows and columns.*" It goes on to list 13 kinds of matrices without any analysis and a brief mention of engineering applications. Finally, a basic matrix is copied and pasted on the draft.

In the next cycle, they were asked to conduct further research on engineering applications. They contacted and interviewed an engineer on the engineering application of matrices. To prepare for writing the second draft, students read and peer reviewed each other's drafts. They received feedback on the following sentence written by Clara: "*There are many different types of matrices and there are many different ways of solving them.*" Peer reviewers asked that the sentence be changed to remove the repetitive noun phrase. Their second draft included the actual applications their interviewee mentioned, with appropriate citations. Whereas the first draft drew strongly on published sources, their second draft drew strongly on the interview and focused more on applications.

Research suggests that feedback from a more proficient peer is essential to develop second language proficiency [3]. Thus, the example shows that, while the feedback that Clara received was not substantial (it does not change the central meaning of the sentence), it could still be beneficial for her as she masters the English language. Importantly, the writing task is embedded in a meaningful context directly related to engineering content [3], rather than in a de-contextualized grammar review.

B. Focusing on Communication Explicitly

We found that freshmen engineering students indicated valuing communication as central to the work of engineers. For instance, students had to contact a researcher through email to seek an interview. Their emails often had to undergo several drafts because students were accustomed to writing only informal emails to their peers. In their reflections, students noted that it was important to write clearly and professionally to professors. For some students, like Daniella, contacting a professor was a new experience and in her reflection, she wrote the following:

Writing emails that are professional and will receive a response along with doing a research project that requires one to take the given topic and relate it to the real world is not so simple. During the process of writing, rewriting, completely starting over and then writing emails, I learned that an email . . . must be to the point, no ranting on about things that may not be important to the reader.

Daniella's reflection demonstrates her realization of the importance of writing a well-crafted text to achieve its purpose. Moreover, she contextualizes writing an email as part of the work of researching her topic on matrices and achieving her end purpose—becoming an engineer. She continues her reflection with the following excerpt:

During the process of developing the math connections project, I did not just learn about my math topic, matrices and how they are used throughout the engineering field, but also about the do's and don'ts of emails and interviews.

In sum, she began to see that the work of engineering includes learning math and its applications to engineering. In addition, she makes the connection to researching through a

variety of published and original sources, such as personal interviews.

In addition, students experienced the way in which team building can become a valuable resource to solve problems, in this case writing the MCP paper. Clara added in her reflection the following:

I learned how to work in teams too. We always tried to do the things together, that way the contribution of us three could be fair . . . I not only learned things from the research we did but I also learned many things from my teammates.

VI. DISCUSSION AND CONCLUSION

An important professional skill in engineering, effective written communication is even more challenging for Latinos and ELLs. However, meaningful writing tasks related to engineering and cooperative grouping [4,7] are part of providing appropriate pedagogical support for peer review, peer socialization, and scaffolding [9]. Academic literacy experts have argued for several years that becoming proficient in a specialized disciplinary discourse not only involves control of language but also an acceptance of the values and beliefs implicit in disciplinary discourses. Students might see the value of using language in a new way “if they recognize and understand the sorts of socially situated identities and activities that recruit the social language, if they value them or, at least understand why they are valued” [14, p. 23].

As Daniella’s reflection suggests, students began to see the importance of writing in the context of a whole host of experiences related to engineering. She situated writing in the context of interacting with research engineering professors, conducting investigations, and interacting with her group. For Latino students and in particular ELLs, explicit attention to how a text is composed focuses their attention to the language resources they need for conveying the intended meaning and gaining control of the second language [3,15].

ACKNOWLEDGMENT

Funding for this research project was supported in part by a U.S. Department of Education grant under the Minority Science and Engineering Improvement Program (MSEIP), Award #P120A110086.

Abstract— Improving spatial ability in the academic curriculum is crucial for engineering degrees. Prior research has shown that spatial abilities can be trained; that's why in this work we propose several kinds of short duration trainings aimed to improve those abilities. We have established a ranking based on the improvement rate that the student may reach knowing his starting level before undertaking training. These trainings take place before starting the academic course so students don't receive theoretical or practical contents of Graphic Engineering during the week. Before training and after its completion, the level of spatial ability is measured through validated tools for this aim. We perform a statistical analysis obtaining the gains from higher to lower levels of spatial skills acquired through each training (videogame/ augmented reality/ sketching/ descriptive geometry). With data from all training, the curves have been set up by least squares (linear, exponential, algorithm, potential and polynomial). The most suitable predictive model for all cases is the linear one.

Keywords— engineering education; spatial skills; training courses; best practices; introductory courses.

I. INTRODUCTION

La Laguna University as a pioneer and innovating center offers several training programs for improving the spatial ability of students belonging to all degrees in every engineering field of higher education [1,2,3]. These trainings aim to improve those spatial abilities in a short time (always less than 10 hours) and until now they have been based in tools supported by several technologies or devices (smartphones, iPads, augmented reality, videogames, notebooks, etc...). During training, orthographic normalized views from elements and pieces are used. We are not only looking for improvement of the student's spatial ability but for his motivation and satisfaction prompted by the job done as well. During the last few years, several experimental tests have been carried out for validating each one of these trainings [1,2,3], and actually they have been broadly implemented in the curriculum of the Graphic Design subjects at the start of the semester [4].

Development of spatial skills by engineering students is directly linked to future success in their professional work [5,6,7], and is critical for understanding the contents of engineering graphics subjects [8]. This capability can be described as the ability to picture three-dimensional shapes in

the mind's eye. Acquiring this ability can be done through an indirect process by means of Engineering Graphics subjects where students perform sketching tasks, create and read orthographic and axonometric projections [9].

Some studies demonstrate that spatial abilities can improve by means of specific training. These abilities, in engineering area, can improve with multimedia exercises, 3D software and other technologies used in graphic engineering [7,10,11].

In this paper, we present the results obtained by several groups of engineering students so each one of them have undertaken a different kind of training. All groups enjoyed significant difference in their spatial abilities and from this point onwards, we may establish a ranking of trainings and a prediction model for each one of them, so every students' level can be found according to the kind of training performed.

II. THEORETICAL FRAMEWORK

There can be no doubt that spatial ability is one of the components of human intelligence as this is backed by countless lines of research [12, 13]. There is not, however, any clear agreement on the sub-skills that this component is made up of. McGee [14] distinguishes five components of spatial skills: Spatial Perception, Spatial Visualisation, Mental Rotation, Mental Relation and Spatial Orientation. Some of the most widely accepted theories are the paper by Lohman [13] and the Meta-analysis conducted by Linn and Petersen [15], which identifies three kinds of spatial skills: *Spatial Perception* that requires participants to locate the horizontal or the vertical in a stationary display while ignoring distracting information. *Mental Rotation* involves the ability to imagine how objects will appear when they are rotated in two or three-dimensional space. *Spatial Visualisation* refers to the ability to manipulate complex spatial information when several stages are needed to produce the correct solution. Researchers from the fields of psychology [16] and geometry [17] simplify this classification into two components:

- Spatial Relation “The ability to imagine rotations of 2D and 3D objects as a whole body”
- Spatial Visualization “The ability to imagine rotations of objects or their parts in 3 spatial dimensions by folding and unfolding”.

A. Measurement of Spatial Skills

There are a large number of tools available for measuring spatial abilities but using this latter classification, in this work we chose two tests, one for each of the main categories outlined above, to enable us to quantify the values of the spatial ability:

- Mental Rotation Test (MRT) for spatial relations [18].
- Differential Aptitude Test - Spatial Relations Subset (DAT: SR) for spatial visualisation [19].

B. Spatial skills: an overview

Differences in spatial skills between men and women have been studied in many studies, which suggest that men have the edge over women in mental rotation tasks [15, 20, 21]. On the other hand, some authors have suggested that these differences may be influenced by the different social status of the people concerned [22], or by environmental and socio-cultural aspects [23]. Knowledge of the relation between the regular tasks that men and women carry out and spatial abilities would therefore be a good indicator. Some studies done along these lines [24] conclude that videogames may be a tool to improve these abilities.

Spatial skills can improve with specific training. The methodologies used may differ, depending on the area of application (pen and paper sketches, Isometric sketching, multi-media platforms, on-line platforms, video games, virtual reality, augmented reality, specific software, physical materials, etc.). Contents such as descriptive geometry, orthographic views, three-dimensional modelling, etc., have been used in engineering in order to improve the spatial abilities of students. Sorby [25] and Alias, Black and Gray [9] used a traditional graphics course on sketching activities, orthographic projection, isometric drawing. S.E. Wiley [26] concluded that 3D solid models and animation may help in developing visual perception abilities. Martin-Dorta, Saorín & Contero [3], compare the effect of several different methodologies for improving spatial abilities. Dünser et al [27] conclude that augmented reality is a highly useful tool for training spatial abilities. Rafi, Samsudin & Said [28] demonstrate the effect of virtual reality based training on improving the spatial abilities of men and women.

III. TRAININGS FOR IMPROVING SPATIAL ABILITY

In this work, we analyze six different trainings. Didactic material and proper tools have been developed for planning and designing a training series of short courses where the spatial abilities needed by engineering students may be improved. The course's contents introduce the students into the basic knowledge for sketching systems (except those based on videogames).

A. General description and trainings' programming.

The training has one week duration and starts on Monday. The first action before undertaking training is providing the students belonging to each training group with the MRT and

DAT-5:SR tests for measuring their levels of spatial ability. Later, each group performs the training proposed during five days. Every day, the series of exercises planned will be resolved in two hours, except the last day which is dedicated to an evaluation of one hour. All training end on Friday and have nine hours duration. The students rest on weekend so the following Monday they are provided with the MRT and DAT-5:SR tests once again for measuring their new levels of spatial ability and finding out the gain acquired.

For training the spatial ability, the activities proposed require performing spatial tasks mentally which are measured in the spatial tests (Puzzles, Figures' rotation, Block, Intersection, Blocks' rotation, Assemblies).

B. Trainings based on videogames.

Two trainings were designed for developing spatial abilities through videogame's use. One of them was configured for being completed on a PC (21 students) meanwhile the other was set for performing it on a Nintendo DS games console (14 students). The training consists on playing according to plan the different modes of the 'Tetris' videogame available for both PC and Nintendo DS versions (Figure 1). The training duration is nine hours. The choice of the videogame Tetris was conditioned for accomplishing the following requirements:

- It's a game that requires geometric figures and shapes.
- It allows performing operations of rotation and movement of figures.
- The spatial tasks that should be performed in the game will be related to both spatial ability components: spatial relations or spatial visualization
- The same videogame should have its own version on both platforms: PC and Nintendo DS.
- Possibility of using the tactile pen on Nintendo DS platform.

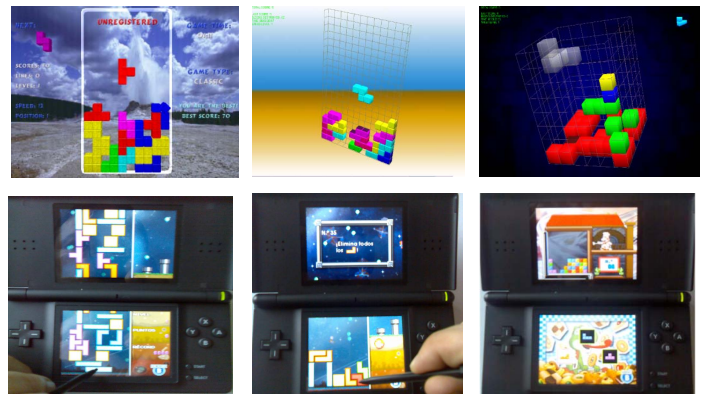

Figure 1. Tetris videogame modes on PC y NDs platforms.

C. Training based on descriptive geometry.

The problem that the student usually finds while studying descriptive geometry's contents is facing static graphic sketches on paper or any web platform which don't offer the possibility of following the solution sequence in a 3D dynamic way.

The aim of descriptive geometry is transforming the 3D objects into 2D projections. For training based on descriptive geometry, we have developed a viewer which allows performing the exercises' sequence in 3D being controlled and manipulated by the student. The 3D space may be rotated to any point of view with a simple movement from the mouse.

The viewer shows descriptive geometry (points, straights, planes, polyhedral figures...) and the solution sequence through the dihedral system's method. Besides, the projections of elements belonging to the projection planes are available for consultation.

This fast course or training has been taught in two versions according to the methodology used. One version is based on master classes through blackboard explanations where 21 students attended (group DG) and another through master classes and computer viewer support which provides the student with greater learning autonomy (group DG-3D). On both cases, the theoretical content is the same as a 65 pages book format.

The book fulfills a double condition: it's a manual for the students so they may be able to understand the basics of the dihedral system besides being a manual for those who have spatial vision difficulties but can develop it through spatial reasoning. The contents of the course are shown on table I.

TABLE I. CONTENTS OF DESCRIPTIVE GEOMETRY TRAINING

| | |

| 7 | Polyhedrons - Hexahedron projections. Study of three characteristics positions of a tetrahedron respecting the HP. - Tetrahedron projections. Study of three characteristics positions of a tetrahedron respecting the HP. |

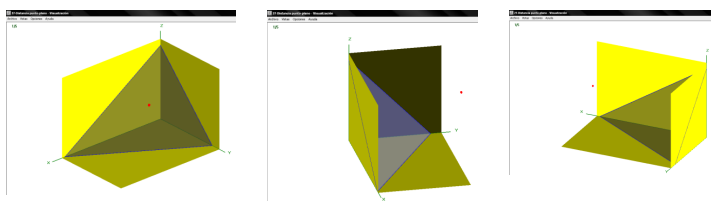

Figure 2. Dihedral system 3D viewer.

D. Training based on hand sketch based orthographic views.

Several authors have designed courses for developing spatial abilities of students through classic activities of Graphic Design (objects' sketching by normalized views/ isometric perspectives) and sketching techniques [7, 25]. This strategy

allows teacher to develop the student's spatial ability while introducing them to Graphic Design contents.

Following the same strategies that in previous courses, a printed exercise manual is designed containing a compilation of exercises about pieces in different categories according to difficulty levels for working over the sketching systems by orthographic views and perspectives. This course (Traditional Exercises –ET) or training has been performed by 29 students and its structure has five levels of growing difficulty where each level has several kinds of exercises for working on the sketching of objects through orthogonal views.

E. Training based on augmented reality

The new generations of students pay more attention and are more interested in contents when teachers use CAD tools for performing exercises, multimedia material for explanations, web resources, virtual tutorships, forum's communication... (everything related to Web 2.0) and show lesser motivation or even boredom at exercises performed with pen and paper through traditional graphic design tools [29].

The augmented reality application developed for this kind of training needs a book containing fiducially marks which encode the 3D virtual models that the application contains. Over each page there are a couple of marks that encode the proposed exercise in that page. When the camera captures that marks, the AR system may sketch over a main mark the 3D model matching the exercise on that page.

The student can turn the mark with his hands and see the model from any point of view. In this training, a new variable is added consisting on mind and hands coordination for visualizing the desired point of view. The training/course have been performed by 24 students with a five levels structure and a duration of two hours for each one, except level 5 (evaluation) where six exercises must be completed in just one hour without any kind of help about the models (*knowledge, comprehension, application, analysis-synthesis, and evaluation*).

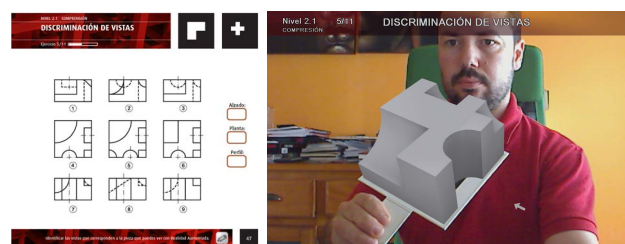

Figure 3. Exercise Sample with Augmented Reality

F. Control group and overall student's population

Each sample group is composed by freshmen students belonging to La Laguna University degrees. At the moment of performing this study, a control group has been taken into account, composed by 25 students from the overall population that have not undertaken any training.

IV. RESULTS AND RANKING

In first place, we made sure that spatial abilities belonging to every group are analogue. Having that in mind, the ANOVA is carried out and the results obtained show that all groups have analogue MRT and DAT starting levels. Each training achieves an improvement of spatial ability although values vary accordingly. However, we consider certain limitations in this study due to huge standard deviations among groups as shown on results due to the lack of detection of significant differences between groups. Possibly groups may be different but our sample used is too small for causing that difference to become significant.

TABLE II. DESCRIPTIVE GEOMETRY TRAINING CONTENTS

| *(SD) des. Std. | Pre- test | | Post- Test | | Gain MRT | Gain DAT5:SR |
|-------------------------|-----------------|------------------|-----------------|------------------|-----------------|-----------------|
| | MRT | DAT5:SR | MRT | DAT5:SR | | |
| VideoGame PC n=21 | 20.76 (8.01) | 37.76 (9.33) | 27.48 (9.03) | 45.46 (5.85) | 6.72 (4.54) | 7.70 (5.09) |
| VideoGame NDS n=14 | 12.43 (5.73) | 40.78 (6.37) | 22.79 (9.19) | 46.07 (5.34) | 10.36 (4.76) | 5.29 (3.76) |
| DG n=21 | 20.81 (7.40) | 31.29 (10.41) | 27.76 (8.81) | 39.43 (9.36) | 6.96 (6.68) | 8.14 (5.32) |
| DG-3D n=19 | 17.32 (9.56) | 29.53 (8.44) | 26.42 (8.33) | 38.53 (5.55) | 9.11 (7.83) | 9.00 (4.37) |
| AR n=24 | 19.67 (7.91) | 29.17 (7.29) | 27.71 (7.83) | 38.46 (7.05) | 8.04 (5.31) | 9.29 (4.08) |
| ET n=29 | 19.79 (7.62) | 28.48 (9.48) | 28.76 (8.79) | 37.10 (9.00) | 8.97 (5.41) | 8.62 (6.25) |
| Control Gr. n=25 | 17.44 (9.82) | 28.40 (10.17) | 22.08 (9.94) | 33.52 (11.77) | 4.64 (4.36) | 5.12 (7.13) |
| Tot.Population N=445 | 18.65 (8.35) | 29.41 (9.18) | | | | |

For checking out if the improvement of training is significant, we use t-Student considering as null hypotheses H_0 the fact that average values of spatial ability don't vary when the course ends meaning that 'students who undertake the course don't develop their spatial abilities'. In every case, the result of comparing the average pre and post test values through t-Student series in paired tests point out that the difference is significant, so it can be stated that courses have provided an improvement from the statistic point of view. For assessing the improvement values, a covariance analysis is performed (2-way ANCOVA). The ANCOVA method allows us to eliminate the difference of pre-test scores between groups and the adjusted post test scores, revealing the real effects of the experimental treatment. So, it eliminates the possible memory effect. As a reference, the control group is taken with a pre/post test difference of zero points and it's adjusted to a new post test value. This way, we may be able to compare the groups knowing the post-test adjusted value. This statistical procedure tested the interaction between training conditions (all groups). The dependent variables, co-variants and independent variables were post-test measurements, pre-test measurements and training condition respectively. The suitability this analysis' usage was tested by assessing the analysis through a statistical model containing interaction terms between the co-variants (pre-test mean scores of MRT and DAT-5:SR) and the independent variables for assessing the assumption of homogeneity between gradients.

A. ANCOVA results for MRT and DAT-5:SR.

The ANCOVA table breaks down the variability of post-test into contributions due to various factors. Since Type III sums of squares have been chosen, the contribution of each factor is measured after removing the effects of all other factors. According to the results of the Co-variance Analysis for Post-MRT, there is a statistical difference between the training courses and the control group, all p-value ≤ 0.05 , thus there are differences in the levels of spatial abilities depending on the kind of training undertaken. Similar results were obtained for the Post-DAT-5:SR as there is statistical significance between the different kinds of training (all p-value ≤ 0.05).

| PC | 41.525(a) | 1.011 | 39.529 | 43.521 |
| NDS | 40.366(a) | 1.254 | 37.891 | 42.841 |
| CONTROL | 36.757(a) | .927 | 34.927 | 38.586 |

V. RANKING AND PREDICTION MODELS

The real gain values of each training, obtained from tables VII and VIII are arranged in table IX so all trainings are arranged in table IX so their ranking can be observed according to the gains obtained in the development of spatial ability.

TABLE IX. COURSES' RANKING FOR IMPROVEMENT OF SPATIAL ABILITY.

| RANK | Gain MRT | RANK | Gain DAT-5:SR |
|-----------|-------------|-----------|---------------|
| 1° | NDS 5.060 | 1° | PC 4.768 |
| 2° | ET 4.634 | 2° | AR 4.385 |
| 3° | DG-3D 4.449 | 3° | DG-3D 4.193 |
| 4° | AR 3.694 | 4° | DG 3.825 |
| 5° | DG 2.754 | 5° | NDS 3.609 |
| 6° | PC 2.510 | 6° | ET 3.524 |
| CONTROL 0 | | CONTROL 0 | |

We propose a mathematic model for predicting the result of post-test measurements for all trainings according to the student's pre-test spatial ability level. So, according to the MRT and DAT each student have, it's possible to find out which level may be reached later if he performs a certain course.

With the paired data of pre/post test scores belonging to each course, the adjustment of different curves by least-squares and is chosen the most suitable expression to the data known (linear, exponential, logarithmic, potential or polynomial). The coefficient of determination R2 identifies the curve's adjustment goodness of fit.

These adjustment models of the different curves for each course. The following adjustment models for each course's different curves (y=post-test ; x=pre-test) are exposed with the most suitable choice shaded having in mind the correlation coefficient's value and the model's simplicity.

TABLE X. PREDICTIVE MODELS FOR TRAINING AUGMENTED REALITY

| MRT_RA | | R2 |
|-------------|--|------|
| Linear | $y = 0.7644x + 12.676$ | 0.60 |
| Exponential | $y = 14.574e^{0.305x}$ | 0.59 |
| Logarithmic | $y = 10.854\ln(x) - 3.4218$ | 0.55 |
| Potential | $y = 7.2746x^{0.4512}$ | 0.59 |
| Polynomial | $y = 0.0233x^3 - 0.6623x^2 + 8.0668x - 11.707$ | 0.63 |

| DAT-5_AR | | R2 |
|-------------|-------------------------------|------|
| Linear | $y = 0.8107x + 14.812$ | 0.70 |
| Exponential | $y = 19.587e^{0.0225x}$ | 0.70 |
| Logarithmic | $y = 19.28\ln(x) - 25.868$ | 0.65 |
| Potential | $y = 6.1273x^{0.5453}$ | 0.67 |
| Polynomial | $y = 0.15x^2 - 3.13x + 44.59$ | 0.73 |

From the prediction's point of view, the coefficient of determination shows the variability percent between the y variable (after test) that may be explained by the x variable (prior to test). A linear prediction model is proposed in every case because of the model's simplicity and similar magnitude to every other model according to the R2 adjustment.

TABLE XI. OPTIMUM SPATIAL ABILITY PREDICTION MODELS FOR DIFFERENT KINDS OF TRAINING.

| Course | | Regression models |
|----------------------|-------|---|
| AR based | MRT | Post-MRT = $0.7644 \cdot \text{Pre-MRT} + 12.676$ |
| | DAT-5 | Post-DAT = $0.8107 \cdot \text{Pre-DAT} + 14.812$ |
| Traditional Exercise | MRT | Post-MRT = $0.9132 \cdot \text{Pre-MRT} + 10.684$ |
| | DAT-5 | Post-DAT = $0.7333 \cdot \text{Pre-DAT} + 16.216$ |
| DG-3D | MRT | Post-MRT = $0.805 \cdot \text{Pre-MRT} + 11.593$ |
| | DAT | Post-DAT = $0.5835 \cdot \text{Pre-DAT} + 21.144$ |
| DG | MRT | Post-MRT = $0.8626 \cdot \text{Pre-MRT} + 10.581$ |
| | DAT | Post-DAT = $0.7736 \cdot \text{Pre-DAT} + 15.225$ |
| NDS | MRT | Post-MRT = $1.4395 \cdot \text{Pre-MRT} + 4.8947$ |
| | DAT | Post-DAT = $0.7348 \cdot \text{Pre-DAT} + 16.104$ |
| PC | MRT | Post-MRT = $0.9755 \cdot \text{Pre-MRT} + 7.2233$ |
| | DAT | Post-DAT = $0.5628 \cdot \text{Pre-DAT} + 23.796$ |

VI. CONCLUSION

While starting the academic year, students are proposed several short courses for developing spatial abilities. In courses

based on performance of sketching exercises with pen and paper format there is a risk of students quitting because of boredom, lack of motivation and unattractive tasks, that's why all contents and developing task should be supported by an attractive platform which may attract their attention while keeping them interested while following training.

Aiming that tasks do not become a routine so students lose interest on both training and the technology used, the training should be of short duration, with different kinds of exercises and many ways to use the tool so the students will not repeat the same kinds of exercises and consider that tool as repetitive. Dealing with it this way, the tool used for this training may favor the student's commitment to the course.

- The linear model is the most suitable choice for predicting the improvement of spatial abilities one individual may have, regardless of the training performed.
- The training with videogames is the strategy which most improves the spatial abilities, but doesn't contribute knowledge about Graphic Design content so they don't provide any learning to students.
- The training with augmented reality can be performed autonomously as material designed allows this possibility.
- The use of 3D tools improves attention and motivates student for working on Graphic Design contents.
- A short duration course of roughly 10 hours, aimed to develop the spatial ability on engineering students provides a huge improvement on spatial vision's levels.

As a pending future work, the validation of these predictive models will take place. So, the spatial ability levels will be measured predicting the level achieved through a certain training. Afterwards, that value will be compared to the one obtained once training is complete.

Debra.Jusak@wwu.edu

INTRODUCTION

Abstract—The overall objectives of the research performed in the iCollaborate Materials Science and Engineering [MSE] project are to measure if improvements in student learning outcomes, student engagement, and successful course completion rates are possible if the structure in a basic materials engineering course is transformed from primarily deductive practice to an Information Communication Technology (ICT) enabled inductive teaching and learning environment. There are two overarching components of our project. The first component required the transformation of the course structure from deductive practice to inductive practice. This element is supported by research results in STEM education and educational theory based on cognitive and social constructivism. The second component is the ICT support as there is an additional research base that supports connections between ICT enhanced collaborative learning, distributed cognition, and enhanced student outcomes. We propose that ICT support combined with immersion in an inductive teaching and learning environment will improve student outcomes more than either singular component case.

The capabilities of the iPod Touch allowed us to build applications (apps) that utilize different multi-media formats. Eight different MSE apps have been built so far. The apps facilitate and support daily collaborative learning opportunities that target specific student learning objectives that are known to be challenging. Bi-weekly in-class, low-stakes quizzes help the students evaluate how well they are building their own knowledge base. Three kinds of data sets will be used to evaluate our research. Data set one is from deductive practice. Data set two is with inductive practice. The third data set, which we are now collecting, is similar to data set two, but with ICT support.

This work-in-progress paper will describe the project, its theoretical base, the apps, experiences with the deployment of the devices, and focus group findings. The National Science Foundation is supporting the project (NSF CCLI #0941012).

Keywords—Collaborative learning; ICT enabled inductive teaching; iPod Touch applications; Materials science and engineering; Low-stakes quizzing; MSE apps.

The objectives of the iCollaborate MSE project are to understand whether student learning outcomes, commitment, and success are enhanced if the course structure is transformed to an ICT enabled student-centered, inductive teaching environment. Because of its personalizable, multi-touch user interface, we chose the 4th generation iPod Touch as our ICT device. There are two overarching components of our project. The first component required the transformation of the course structure from deductive practice to inductive practice. This element is supported by research results in STEM education and educational theory based on cognitive and social constructivism; and, there is a substantial body of evidence that favors the inductive teaching approach [1]-[8] and a summary of this evidence has been reported elsewhere [9]-[10]. This component of the project has been successfully implemented. The second component is the ICT support as there is an additional research base that supports connections between ICT enhanced collaborative learning, distributed cognition, and enhanced student outcomes [11]-[14], which also has been reported [9]-[10]. We proposed that ICT support combined with immersion in an inductive teaching and learning environment will improve student outcomes more than either singular component case.

The multi-media format of the iPod Touch allowed us to build applications (apps) that present information in a variety of formats: lists, graphs, visuals, and audio. The following apps have been built: Vocabulary, Concept Questions, Tune-Up, Basic Knowledge, Material Properties, MSE Convert, Composites Calculator, and we are building the content for the completed MSE Knowledge Tools application. These apps are designed to facilitate and support daily collaborative learning opportunities that target specific student learning objectives that are known to be challenging, (also reported elsewhere [9]-[10]). The materials within the applications are conceptually contained so that while exploration and higher order connections are encouraged, the students are not overwhelmed with too much data or have no contextual basis for judgments.

Bi-weekly in-class, low-stakes quizzing help the students evaluate how well they are building/reconstructing their own knowledge base. The results from the low-stakes quizzes are used to identify the problems and concepts that the students

are still struggling with after the mini-lectures and collaborative work, and are subsequently covered once more in the lecture portion of the class. The students see this as a highly effective way to facilitate their own learning, as well as way to compare their own outcomes to the outcomes of their peers. From the faculty perspective, the remaining outstanding learning objectives are clearly identified in this process and succinctly move the course toward a very robust continuous improvement loop.

Focus groups were used as formative assessment tools to help us evaluate and understand the perceived effectiveness of the targeted collaborative work, the low-stakes quizzes, and the iPod apps from the student perspective. While student teams were engaged in their ICT enabled collaborative exercises, most students wanted an additional, personal device to continue their studies beyond group work. We found that students consider iPods as personable devices.

STUDENT PERCEPTIONS - FOCUS GROUP RESULTS

Two groups of students (alpha and beta) have provided focus group feedback, thus far, for the project. A third focus group was recently recruited to further the development and effectiveness of the apps deployment cycles. In the alpha deployment, the apps were not all that well integrated into the course activities, and we had just made the shift to all collaborative learning, peer learning, and low-stakes quizzing. We felt this deployment was for more us to understand how the students would react to the devices and for us to understand how to deploy them, rather than for data collection purposes. In the beta deployment, the apps were much more integrated into the course, but most importantly, the collaborative learning and the low-stakes quizzing were well integrated into the course. Interestingly, the student feedback (perceptions) from the two cycles of deployment was consistent. While the students often complained about the in-class, low-stakes quizzes during the class sessions, they rated them as the most effective of all the pedagogical strategies employed in the course. More than 90% of the students find the low-stakes quizzes of value, and can understand the alignment among the various course components [10]. The students also feel the quizzes encourage them to complete the collaborative work on time and keep up in their course work. The students are indeed correct in that completing the collaborative work is necessary to do well on the quizzes, but the quizzes are designed to provide individual accountability and mastery. While the students may not understand these complexities, they almost universally agree (perceive) that the low-stakes quizzes help them master course outcomes.

The students rated the collaborative work as the second most effective pedagogical strategy in the course [10]. While the ratings for the collaborative work was slightly less (2%-5%) on average [10], the differences are perhaps more about perception as the low-stakes quizzes provide more immediate feedback and count for more in their overall course grade. And, there is no chance to redo the work in the quizzes. Here student feedback is consistent with other work on low-stakes retrieval effectiveness [15].

Based upon an initial assessment of our learning outcomes data (exams and projects) we believe that the combination of the targeted collaborative work and low-stakes quizzing does improve student outcomes. Previously, we did not see learning gains with low-stakes on-line quizzes in a deductively taught course with traditional homework assignments.

Initially, we were disappointed that the students were rating the new iPod apps of lower use than the other course strategies [10]. Do the students really prefer taking an in-class quiz, rather than using new MSE specific iPod apps to facilitate their learning? In order to find out, we recently convened our third focus group. The results from that focus group provided much insight as to why the student perception was that the apps are less effective tools than the other pedagogical approaches in the class. First, even though the iPod apps provide immediate feedback on their own outcomes, the apps do not provide any comparison data regarding the performance of their peers. Students want to know how many of their peers are struggling with similar concepts. In retrospect, this is obvious. The students want the apps to be “operationalized” in the same way as the low-stakes quizzes and collaborative work are. In class, we discuss the problematic student learning outcomes one more time in lecture after we review the results of the quizzes or collaborative work. We need to do the same when we are reviewing the results from the apps! We also found that many students will not generally complete all the app work unless they receive some reward for it (also not surprising). The reward should match all the other course work, and the students must also perceive the completion of the apps as essential to their success. Third, the students have an overabundance of course resources and, many students choose to optimize their time with the reward. The highest achieving students complete the apps regardless, as do the students who are struggling the most in the course. It is the students in the middle who are choosing to use the apps less. We have found successful course completion rates and retention rates have gone up after the iCollaborate approach has been implemented, which is accompanied by an overall rise in course GPA and scores on exams (which will be outlined in a future paper). The number of high achieving students remains the same. But, as expected the iCollaborate pedagogical has a much more meaningful change in outcomes for the students who traditionally struggle with the course.

CONCLUSION

The iCollaborate MSE project has successfully created an innovative approach to inductive practice where most of the known STEM education best practices are present (plus ICT support). The project has created 8 MSE apps for the iPod Touch. The next phase of the project will be to modify the apps to provide peer comparison data/difficulty level along with the individual group outcomes. We must add a sufficient reward structure within the course to stimulate iPod app use.

Work in Progress: Engaging New PIs Using an Electronic Mentoring System

Elizabeth T. Cady and Simil Raghavan

National Academy of Engineering
Washington, DC U.S.A.
ecady@nae.edu

Abstract— Success as a Principal Investigator (PI) of a National Science Foundation (NSF)-funded project requires both project management and change leadership skills, disciplinary knowledge, and familiarity with the project itself. Because gaining the skills of management and leadership involves either first-hand or vicarious experience, new PIs might struggle to find the best course of action when facing a difficult situation. While individual mentoring could enable new and prospective PIs to acquire these skills, arranging a mentor for all new PIs is not feasible. In addition, prior work has indicated a preference in faculty for gaining knowledge informally (e.g., using case studies) from mentors who have experienced similar situations rather than in more formally assigned partnerships. Thus, we seek to understand whether a many-to-many electronic mentoring website is an effective method to aid new and prospective PIs in a range of NSF programs in developing project and change management skills.

Keywords—component; electronic mentoring; community of practice; principal investigators

I. INTRODUCTION (HEADING 1)

Successful Principal Investigators (PIs) utilize skills in both project management and change leadership in addition to their disciplinary and project-based background. However, developing these skills takes time and experience, so new PIs may find it difficult to decide on the best course of action in a complex situation. While individual mentoring would be a way of gaining these skills, arranging a mentor for all new PIs is not feasible. In addition, prior work [1] indicated a preference in faculty for gaining knowledge informally (e.g., using case studies) from mentors who have experienced similar situations rather than in more formally assigned partnerships. Thus, we seek to understand whether a many-to-many electronic mentoring website is an effective method to aid new and prospective PIs in a range of National Science Foundation (NSF) programs in developing project and change management skills.

The National Academy of Engineering (NAE) has developed a website that will provide many-to-many electronic mentoring for new and prospective PIs. The Principal Investigators Garnering Useful Information on Developing

This work was supported by the National Science Foundation via grants DUE-1036255, DUE-1102114, DUE-0814328, and HRD-0533520. Opinions expressed by the authors are their own and do not necessarily reflect the policies of the National Science Foundation.

[Project] Effectiveness site (<http://govpiguide.org/>) includes information valuable to new and prospective PIs from the Advanced Technological Education (ATE), Transforming Undergraduate Education in STEM (TUES), Robert J. Noyce Scholarship (Noyce), and Research on Gender in Science and Engineering (GSE) NSF programs. Although the final development process is ongoing, several features are active.

II. WEBSITE FEATURES

The 28 Video Scenarios show the experienced PIs from discussing fictionalized situations that new PIs might encounter. The scenarios were written based on interviews with 49 veteran PIs so they include some aspects but no details of those the PIs themselves experienced, allowing for frank discussions without identifying individuals or institutions. The Video Scenarios fall into one of five broad topic categories: Staffing, Partners, Finance, Communications, or Donors. For each scenario, the interviewee answered three guiding questions, with each answer broken out into a separate video to allow website visitors to choose what information on which to focus. The three guiding questions were:

- What additional information do you wish you had and what assumptions are you making?
- Given the information provided, what advice do you have for the principal investigator? Please be explicit about the assumptions you are making and how they are influencing your guidance.
- How would you advise a new prospective principal investigator to avoid the indicated situation?

Each Video Scenario page includes 2-4 PIs responding to each of the three questions, and users can sort by question, respondent, NSF program, or topic categories as they search for information related to their own situation and tailor their electronic mentoring to their own needs.

In addition to the Video Scenarios, the site contains Leadership Perspective videos, in which experienced researchers, faculty members, and NSF program officers who discuss topics of potential interest to users. Sample topics include avoiding common problems among new PIs, overcoming resistance, diversity, and assessment and evaluation. Like the Video Scenarios, the Leadership Perspective videos are approximately one minute long, which

presents new information in a short, easily-processed form that provides the viewer with the awareness needed as a basis for further research on that topic [2]. The videos also have associated transcripts.

Several other tools support the development of on-line communities. The website supports RSS feeds and users can create their own resource library (e.g., documents to share, external web sites, recommendations on consultants, etc.), personalize their home page, chat live with other users (both new and experienced PIs), and share links and bookmarks. Other features include the ability to establish a new community, invite others to join, keep a common calendar within a community, discuss proposal ideas or other topics of interest, and share documents. Finally, users can post photos (for example, of activities at PI meetings) and contribute to a blog.

Although users will be required to log-in, membership is free and all aspects of the site will be available to all users. Users will join one of the networks (ATE, TUES, Noyce, or GSE) as their primary association, but will be able to join the other networks as well.

III. EVALUATION

An evaluation form has been posted on the site and users will be encouraged to provide feedback about their experience. The survey asks general questions (e.g., overall impression of

the site) as well as more specific questions on the utility of various PI GUIDE aspects (e.g., usefulness of the social networking capabilities; quality and helpfulness of the videos). We also ask whether the site has increased their knowledge of project management and change management and how they plan to use that knowledge in the future. In an effort to maintain continuous improvement, we also ask respondents to list any additional resources, information, links, or features that would be useful additions to the PI GUIDE website.

ACKNOWLEDGMENT

The authors thank Norman L. Fortenberry, Executive Director of the American Society for Engineering Education and former Director of the Center for the Advancement of Scholarship on Engineering Education at the National Academy of Engineering, who developed the idea for PI GUIDE and performed the majority of the foundational work.

Abstract— For 20 years, nine institutions in the University of Texas System and five partnering community colleges have collaborated to promote STEM undergraduate research through the Louis Stokes Alliance for Minority Participation (LSAMP). The primary programmatic activity of the Alliance is its Summer Research Academy (SRA) which has engaged a total of 1,565 undergraduates. Of these, 242 have been supported within the last five years. The Alliance has also partnered with the US Department of Energy to support a number of faculty and student teams (FaST) to engage in research at several national laboratories. Since 2003, 37 students and four faculty members have participated in this effort. This paper will describe both the SRA and FaST. Data on program participation and success will be discussed. The Alliance is now posed to expand its effort to include research abroad. The general direction of the Alliance for the next five years will be discussed.

Keywords—undergraduate research; STEM; National Science Foundation

PROJECT HISTORY AND ACTIVITIES

The University of Texas (UT) System Louis Stokes Alliance for Minority Participation (LSAMP) became a coordinated effort in 1992 with leadership that consisted of presidents and provosts from the entire UT System. The objective of the first phase was to increase the number of STEM undergraduate degrees that were awarded to underrepresented minority (URM) students. Phase II focused on increasing the number of community college students transferring to four-year universities in the STEM disciplines; the initiative to increase BS production continued. Phase III saw a shift in objectives when the primary goal became an increase in the number of students entering into STEM MS or Ph.D. programs following receipt of their undergraduate degree. Phase IV was inceptioned in 2007 and the focus continued to be graduate degree promotion but was expanded to include international travel/research experiences.

The primary activity of the UT System LSAMP is the annual Summer Research Academy (SRA). The SRA is an

eight-week program in which undergraduate STEM majors work on an intensive research project with a tenured or tenure-track faculty member at one of the nine UT System campuses. The SRA is intended to be an exchange program in which the students have the opportunity to engage in research outside of their home institution to preview another UT System campus's programs and environment. The participating students work as part of a research team under their faculty mentor's supervision on a cutting-edge STEM project. Students at each of the campuses also participate in a series of developmental workshops, videoconferences, laboratory trainings, and other meetings to enhance their research experience. They learn how to create conference-style research posters and present their work locally at the end of each SRA. The annual UT System LSAMP Student Research Conference, held in the fall semester gives the SRA students the opportunity to gain more presentation experience and to share their research findings with a national audience.

Since undergraduate research is the proven method of the UT System LSAMP to increase minority student graduation, we have partnered with the Department of Energy to offer faculty and students from our partner campuses the opportunity to participate in the Visiting Faculty Program (VFP), formerly the Faculty and Student Teams (FaST) initiative, at one of the US National Laboratories. As part of VFP, each faculty member will lead a team of 2-4 undergraduate and/or graduate students at a national laboratory. The team will work on-site at the national laboratory as part of a larger research group on an established project. The team will be hosted and mentored by a research scientist housed at the lab and will perform their specific research for 10 weeks. In the past, the UT LSAMP has sent teams to Argonne National Laboratory, Lawrence Berkeley National Laboratory, Pacific Northwest National Laboratory, and most recently, Oak Ridge National Laboratory. The teams may originate from any campus in the UT System and the lead institution (UT El Paso) submits a NSF proposal on their behalf to secure the funding and manage the grant.

National Science Foundation (HRD-0703584)

PROGRAM SUCCESS

For almost 20 years, the UT LSAMP has been one of the premiere research programs for undergraduate students in the UT System. Over 1,500 STEM students have conducted meaningful research as participants in the SRA and have developed professional skills through the various activities offered as part of the SRA experience. Project goals have been met and exceeded during the duration of the grant.

Since its inception, the UT System LSAMP has tracked enrollment of and degrees awarded to URMs in STEM disciplines by partner institutions. The results achieved to date are extremely encouraging. Enrollment has grown steadily from 8,367 in Fall 1991 to 17,593 in Fall 2009. This is an increase of 110% with respect to 1991 LSAMP baseline data. Similarly, the number of baccalaureate degrees awarded annually to underrepresented minorities in STEM disciplines has increased from 575 in AY 1992-1993 to 2,004 in AY 2009-2010. The rise is an unprecedented increase of 351%. This increase in degree production has consistently placed four institutions in the Alliance among the Top 10 in the nation for awarding undergraduate degrees to Hispanics in Engineering, Education, Nursing, and Business to name a few. In 2009, STEM fields accounted for 22.1% of UT System degrees awarded as compared to the national public university average of 18.4%.

A large range of STEM majors is represented by SRA alumni with the most common being Biology (21%), Electrical Engineering (10%), Computer Science (9%), Mechanical Engineering (9%), Chemistry (8%), and Mathematics (8%). The majority of students in the VFP have been from various engineering fields and chemistry.

LSAMP'S FUTURE

In October 2011, the UT LSAMP submitted a fifth proposal to the NSF for funding as a Model Senior Alliance to conclude the work it has done for 20 years. This proposal will continue best practices and will address three primary objectives: 1) enhancing the UT System SRA to ensure that a significant number of students, including veteran students, participate in a sequence of research experiences, starting with on-campus training and culminating with a UT System summer undergraduate research exchange, a national laboratory opportunity, or a research abroad capstone experience; 2) ensuring that URM students who are co-enrolled in partnering community colleges and universities complete their STEM associate degrees and advance towards their baccalaureate degrees; and 3) creating synergy among closely related NSF-funded projects-e.g. S-STEM, STEP, REU, and AGEP- at each one of the Alliance's partnering institutions to create pathways to success for URM STEM students. The proposal also included the addition of two community colleges to the Alliance: Tarrant County Community College District and Tyler Junior College.

The Alliance's plan for the next five years, which is derived from an analysis that looks at internal strengths and weaknesses and external opportunities and threats, is to provide STEM students continued opportunities to perform research at UT System universities, the US Department of Energy's national laboratories, and various international research sites.

CONCLUSION

Based on NSF's goal to diversify the STEM workforce and include more URMs in academia, the UT LSAMP's mission is more important than ever before. The global research community continues to grow and the demand for competent undergraduate and graduate students will continue to increase in the United States. The UT LSAMP is in the unique position to make a positive change for URM involvement at the undergraduate and graduate research level. The UT LSAMP's work to improve the number of URMs graduating with STEM degrees and continuing on to graduate school is also directly in line with the Texas Higher Education Coordination Board's "Closing the Gaps" initiative. This plan includes four focus areas: 1) student participation in higher education, 2) student success in college, 3) excellence in teaching, and 4) high quality research and scholarship. Because of this, the UT System LSAMP will help insure that talented students from diverse backgrounds will have the support necessary to earn bachelor's and, ultimately, doctoral degrees in a timely fashion and become future leaders in STEM disciplines both in Texas and across the nation.

Abstract— For many scholars conference papers are a stepping stone to submitting a journal article. However with increasing time pressures for presentation at conferences, peer review may in practice be the only developmental opportunity from conference attendance. Hence it could be argued that the most important opportunity to acquire the standards and norms of the discipline and develop researchers' judgement is the peer review process - but this depends on the quality of the reviews. In this paper we report the findings of an ongoing study into the peer review process of the Australasian Association for Engineering Education (AAEE) annual conference. We began by examining the effectiveness of reviews of papers submitted to the 2010 conference in helping authors to improve and/or address issues in their research. Authors were also given the chance to rate their reviews and we subsequently analysed both the nature of the reviews and authors' responses. Findings suggest that the opportunity to use the peer review process to induct people into the field and improve research methods and practice was being missed with almost half of the reviews being rated as 'ineffectual'. Authors at the 2011 AAEE conference confirmed the findings from the 2010 data. The results demonstrate the lack of a shared understanding in our community of what constitutes quality research. In this paper in addition to the results of the above-mentioned studies we report the framework being adopted by the AAEE community to develop criteria to be applied at future conferences and describe the reviewer activity aimed at increasing understanding of standards and developing judgement to improve research quality within our engineering education community.

Keywords—peer review, research quality, engineering education research.

I. INTRODUCTION

For many new scholars, a conference paper is the first way to try out an idea on those who should be able to offer informed opinion. A common practice is to turn conference papers into journal articles in the light of feedback received on the initial presentation. However, with ever decreasing time to present and have discussion at most conferences, the comments

of anonymous reviewers of the submitted paper may be the only developmental help many authors get from conference attendance. We argue that with this in mind reviews of conference papers need to be taken seriously and not treated as a mere formality to meet government and/or institutional requirements to be regarded as a research publication. It is therefore worth asking just how well conference reviews are performing this developmental role.

II. BACKGROUND AND MOTIVATION

Arguably, the most important opportunity to acquire the standards and norms of the discipline and develop researchers' judgement is the peer review process [1] – but this depends on the quality of the reviews. 'Good' feedback has been identified as being timely, specific and relevant [2], yet often reviews lack these basic qualities. Reasons for poor feedback include the quality of feedback is generally not assessed, lack of time or the reviewers available do not have the required expertise. This may also be because reviewers see their role as a gatekeeper rather than for quality improvement or development. For example, in 2011 the authors received a review for a research paper investigating peer reviews that stated:

I personally do not think that it is the reviewer's role to be friendly, or provide training to naïve researchers. Most important seems to assist the editor in deciding whether a paper is acceptable or not for publication (i.e. screening).

With the advent of various forms of online publishing the peer review process has recently come under scrutiny [1], particularly as the process functions as a kind of censorship, deciding what personnel and whose views are deemed acceptable in any scholarly society. Needless to say, we are not interested here in this gatekeeping function. Rather we want to focus on the way that peer review can and ought to be a *conversation* among people with similar intellectual interests for the purposes of improving understanding and expressing (and where necessary altering) community standards and opinions.

It has been well demonstrated that there are many ways in which peer review fails its developmental function [3] including through restricting the dissemination of new ideas, excessive in-group gatekeeping and inconsistency [1, 4]. Origgi [5] has argued that an important function of the review process is a “*conversation in slow motion*” amongst scholars in order to improve, disseminate and develop their ideas and we argue that such a conversation is much needed in the emerging field of engineering education research. Academics engaging in this field frequently have to argue for the rigour and significance of their work [6]. While some of the necessity for this argument is a result of institutional resistance to the pursuit of educational research by engineers, some of it arises from a perception (sometimes accurate) that conference presentations and published work in this still emerging field are not of the highest quality. There are only a small number of graduate students undertaking engineering education research dissertations at Australasian universities. Hence, most researchers in this field were trained in quite different paradigms than those that underpin educational research. Bridging the epistemological divide between technical training and the more social science of education continues to be problematic for some [7]. Improvement requires not only developing knowledge of the relevant research theories and methods, but for novices to develop their judgement about what is acceptable practice in the field [8]. Conferences are important times and places to share strategies and to encourage more systematic and well grounded research.

The current review process does not encourage conversation to change ideas on both sides, but is more often a hurdle to be overcome for publication. We believe that work in our field can be improved by conversations, debate and publication, but we want to know what role peer review currently fulfils and we want to consider what kinds of mechanisms are likely to maintain and improve standards while allowing the conversation to go on. Finally we want to consider how such mechanisms might be instituted in this community of engineering education research.

The Australasian Association for Engineering Education (AAEE) has been actively pursuing improvement in engineering education research quality, including examination of the quality of the peer review process. In this study we were investigating whether peer review as practiced in the AAEE annual conference has a developmental function for authors. Papers submitted to this conference are double-blind peer reviewed, however the review criteria are currently subject to change at the discretion of the local organising committee. We were interested in authors’ assessment of the impact of reviews of their paper, and the quality of the reviews themselves. Preliminary studies were conducted using the 2010 data [9]. These studies were repeated in 2011 to confirm the findings of the previous year. We were also looking for evidence of shared understanding between authors and reviewers of the standards required for research. In 2011 we decided to specifically investigate the authors’ judgement of the quality of their own paper and whether academic rank is a reliable indicator of expertise in engineering education research. The intention of these studies was to inform the design of a developmental process for reviewers. This paper reports the

2010 data with the new 2011 data, describes the adopted strategy for improving the peer review process, and outlines the future work proposed to continue this line of research.

III. METHODS

Authors who submitted a paper to the 2010 and 2011 AAEE conferences were invited to assess the usefulness of the reviews they received. The online tool SPARK^{PLUS} [10] was used to collect and store authors’ responses. In line with ethical practice, when authors initially logged on they were asked to indicate their agreement to their responses being used in this research.

In the analysis that follows for the 2010 AAEE conference we considered only the reviews of papers that were accepted into the ‘Research’ category (n= 66 reviews: two each for 33 papers), since clearly expressed criteria were provided for these papers and were available for authors and reviewers from the beginning of the review process. These criteria are listed in [9]. The 2011 conference did not have an explicit research category so responses from authors of all papers were considered, including authors whose papers were rejected (n = 74 reviews: two each for 37 papers).

Three types of data are included in this paper:

- authors’ assessment of their reviews (2010 & 2011)
- the research team’s analysis of the reviews (2010 & 2011)
- authors’ self assessment of their reviewed paper (2011)

A. Authors’ assessment of their reviews

In 2010 23 authors (70%) from the research category responded to the invitation to assess and comment on their reviews and we have considered all of these here. The online tool used to collect these assessments comprised a set of open-ended questions about the impact of the review.

Author responses were entered into NVivo [11] and coded for recurring themes using the constant comparative method [12] to build up a codebook for analysis. The coder was a graduate student who had not been involved in the original review process although he had been a co-author on one of the papers submitted. He did not submit an author response and thus represents someone with experience of the community but no prior involvement in the review process which might have biased his reading of the texts. He was trained in content analysis methods [13] and results were discussed with the other researchers on the project to establish a shared understanding of the content of the categories. The categories established through this process to describe the reviews are:

- Counterproductive (CP)
- Ineffectual (I)
- Cruel to be kind (CK)
- Positive impact (PI)
- Future impact (FI).

The content of these categories is described in more detail in [9].

In 2011 authors were invited to rate their reviews against these categories using the question and rating scale shown in Figure 1. All authors received information about the categories in the rating instructions.

Figure 1. Authors' ratings screen for 2011 reviews

B. Analysis of the reviews

We were surprised by some of the favourable ratings authors awarded their reviews in 2010. To benchmark these ratings, we developed a content analysis of the reviews, using the same method as for the author's responses, to gain a more objective description of them.

The reviews of the 23 authors who participated in this research in 2010 were analysed by the graduate student using the method outlined in Section A above. In coding the reviews the explicit advice within each review was examined to determine whether it fell into any of the following five major categories:

- Gaps in logic
- Typographical/grammar errors
- Inadequate data handling
- Identifying relevant literature
- Quoted from paper under review

In 2011 another member of the research team used the same categories to code the reviews of those authors who responded in that year to the invitation to assess their reviews.

C. Authors' self-assessment of their reviewed paper

In 2011 authors were invited to rate their own paper according to the same scale used by reviewers for the 2011 AEE conference:

- 3 Unsuitable for this Conference
- 2 Strongly Reject Paper
- 1 Weakly Reject Paper
- 0 Borderline Paper
- +1 Weakly Accept Paper
- +2 Strongly Accept Paper
- +3 Strongly Accept + Worthy of Best Paper Nomination

The statement and rating scale is shown in Figure 2. As well as rating their paper, 2011 AEE conference authors were asked to identify their paper's strengths and weaknesses.

Figure 2 Authors' self-assessment rating screen

IV. RESULTS AND DISCUSSION

A. Authors' assessment of their reviews

Not all authors took the opportunity to comment in writing on their reviews, but the comments from those who did in 2010 were analysed into the categories in Table I. Note each author response was allocated to only one (the most dominant) category.

TABLE I. CATEGORIES OF AUTHOR RESPONSES TO OPEN-ENDED QUESTIONS

| | 2010 Reviews % (n = 30) | 2011 Reviews (authors) % (n = 37) |
|-------------------|-------------------------------|---|
| counterproductive | 10 | 9.5 |
| ineffectual | 47 | 26 |
| Cruel to be kind | 3 | 9.5 |
| Positive impact | 33 | 43 |
| Future impact | 7 | 12 |

Counterproductive reviews were those which authors felt were actual impediments to improving their paper, either because the tone of the review was too carping or the reviewer had misunderstood the work. The high number of ineffectual reviews is of particular concern in the light of the present discussion calling for reviews to have positive impact and improve future work. In the eyes of the authors at least, the unhelpful reviews outnumbered the helpful ones.

While the 2010 data was categorised by researchers from author comments, in 2011 authors were asked to directly rate their reviews as best fitting into one of these categories. Each author was asked to rate each of their two reviews and 28% of authors (37 of 132) responded. While there is a pleasing reduction in the number of reviews assessed as ineffectual by the 2011 authors, this reduction is not statistically significant ($p = 0.07$). There is a corresponding increase in the number of reviews assessed as having some impact whether that impact is likely to be immediate (i.e. improving the paper being reviewed) or for future research projects. The results listed in Table I suggest that in the view of authors, the reviews in 2011 were more useful than those in 2010.

B. Analysis of the reviews

As described in the methods section, explicit comments in the reviews were coded into five categories listed in Table II. Table II also shows the number of reviews that contained explicit advice in each category for both of these conferences.

Although the provision of criteria in 2010 was meant to make it clear to reviewers what the expectations of the conference organizing committee were, only 4 reviewers made explicit reference to them. Instead reviewers seemed to respond to the papers on the basis of what they decided was important (Table II), such as grammatical errors.

Gaps in logic were identified with advice such as “*lack of alignment between the research question, the literature cited, the data and the analysis*”(2010) or the fact that “*conclusion is not related with the results of this study*”(2011). While this is potentially helpful advice, a lack of specificity was often apparent. New scholars may need to be told what alignment looks like for instance, or at least what the reviewer means by alignment. There is very little difference in the number of comments in this category from the 2011 reviews compared to the 2010 reviews.

TABLE II. CATEGORIES OF EXPLICIT ADVICE GIVEN BY REVIEWERS

| | 2010 Reviews % (129 comments from 46 reviews) | 2011 Reviews % (135 comments from 74 reviews) |
|---------------------------------|---|---|
| Gaps in logic | 30 | 28 |
| Typographical/grammar errors | 26 | 18 |
| Inadequate data handling | 21 | 21 |
| Identifying relevant literature | 13 | 10 |
| Quoted from paper under review | 9 | 10 |
| Other | | 13 |

The attention to typographical errors in 2010 was a surprise but is in line with journal review practice. While there are fewer comments in this category from the 2011 reviews than the 2010 reviews, the difference is not statistically significant ($p = 0.116$).

Reviewers' comments on data handling tended to be more specific, drawing attention to ways to improve tables or what extra information could be added to clarify or support the author's argument, for instance. For both the 2010 and 2011 reviews, 21% of comments related to inadequate data handling.

Similarly, where reviewers drew attention to specific sources in the literature we expected that this would help improve not only the paper under discussion but future work as well. There were examples such as “*Make a direct connection to the Bradley Review and the government response, so all readers can understand the importance of this study and how it could relate to their institution*” (2010) and others giving actual citations. Relatively few (13% in 2010 & 10% in 2011) pointed out where authors might go in the literature to improve their argument.

Quotation from the paper under review was in our opinion another form of specificity in advice but only 9% (2010) and 10% (2011) of the reviews identified the actual words in the paper that were of concern. If the aim of review is partly to improve practice, then reviewers need to be specific about how to do so and make clear what was wrong and how it could be corrected.

In 2011 review statements that did not align with any of the existing categories were aggregated into an ‘other’ category. The ‘other’ category consists of 1 comment that the paper concerned does not fit any of the conference themes, 8 comments regarding the 6 page limit being exceeded (6% of all

comments) and 8 comments (6% of all comments) saying that the paper is/is not a ‘research’ paper or is a ‘show & tell’ paper and some include why the reviewer has that opinion e.g. “*The paper is lacking robust research methodology, and objective measures and evaluation of the outcomes*”(2011). In 2010 only the reviews of papers in the ‘research’ category were analysed while for 2011 reviews of all papers were analysed as there was no specific research category. The similarity in the proportion of all comments across the five categories between the 2010 and 2011 conferences confirms the initial 2010 findings that, in general, reviews did not provide useful information to authors and did not demonstrate good feedback practice by being specific. Yet Table I shows that authors perceived the 2011 reviews as more helpful than the 2010 reviews.

This perception is difficult to understand as apart from the slight reduction in focus on typographical and grammar errors, there is no significant difference in the distribution of comments between the two conferences. We did observe that there were some one line reviews for 2010 papers such as: “*Overall a good paper presenting an interesting evaluation of collaborative learning*” whereas the 2011 reviews were generally longer and there were no one line reviews. De-identified information from the 2010 reviews was discussed with delegates in an open forum at the 2010 conference and we could speculate that this attention to the review process may have encouraged the non-trivial reviews in 2011. However, as noted above our analysis of the reviews found them no more helpful for influencing quality research than in 2010.

C. Authors' self-assessment of their reviewed paper

Sixty authors of papers submitted to the 2011 AAEE conference responded to the invitation to self-assess their paper and rate it on the same scale used by the reviewers. The range of ratings used by authors varied from -1 (weakly reject paper) to +3, while reviewers' ratings were in the range from -2 (strongly reject paper) to +3. Figure 3 shows the difference between the authors' self rating of their paper (S) and the average of the reviewers' ratings of the paper (R). As shown in Figure 3, 18% of authors rated their paper at exactly the same level as the average of their reviewers ($S = R$). For 45% of authors there was a difference of 1 or less between their rating and the average of their reviewers, while for 37% of authors this difference was greater than 1. Overall 75% of authors rated their paper higher than the average of the reviewers' ratings for their paper.

Examining the academic rank of authors who rated their paper the same as the average of their reviewers and those with a self rating more than 1 category higher or lower than the average of their reviewers showed that there is no discernible link between academic rank (Lecturer/Senior Lecturer/Associate Professor/Professor) and whether the author could accurately predict the average of their ratings from reviewers. These results confirm the findings reported in [14] that for their medical journal “*characteristics such as higher academic rank...failed to predict higher-quality reviews*”. This is not surprising as many members of the engineering education community in Australasia earn their PhD in engineering before they develop an interest in engineering

education or indeed in engineering education research. In contrast some of the more junior members of our community may earn their PhD in engineering education research. This has the consequence that their academic rank may not reflect their expertise in this area.

Not all authors that rated their paper also identified the paper's strengths and weaknesses – in fact there were 33 responses from the 60 authors that rated their paper. These strengths and weaknesses nominated by authors were compared to the strengths and weaknesses identified by their reviewers to investigate if authors and reviewers agreed. In our estimation some high-quality reviews were unappreciated by the authors as they did not understand comments referring to frameworks, research methods and qualitative analysis.

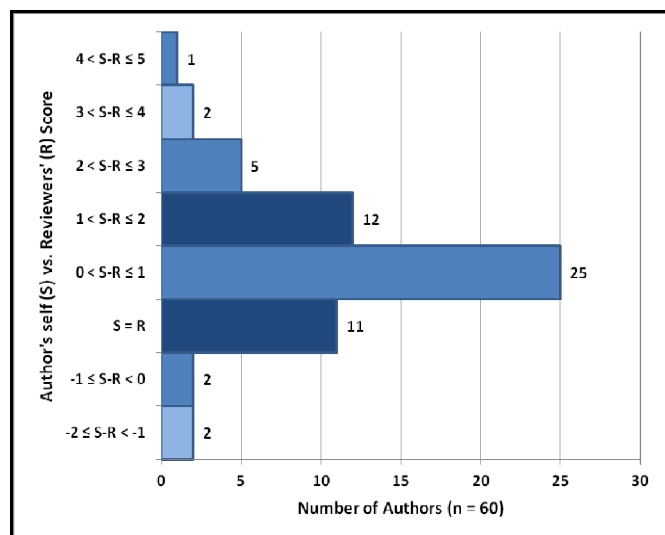

Figure 3. Authors' self-rating of paper (S) compared to the average of the reviewers' ratings of the paper (R)

Most reviews (58%) commented on the issue that the author had identified as a strength, and most of these reviewers (63%) agreed with the author that this was a strength, the remainder thought the paper was weak in the identified aspect. The authors' nominated weaknesses were identified by 36% of reviewers, with 52% of reviewers commenting on weaknesses other than those identified by the author.

This variability between authors and reviewers in terms of both rating papers and identifying strengths and weaknesses of the papers may not necessarily be a reflection of the authors' expertise and judgement, since some recognised experts differed significantly from their reviewers. It could also be an indication of the reviewers' (lack of) expertise. These results indicate that the academic rank of authors and reviewers is not a reliable indicator of the quality of conference papers submitted or reviews written about these papers.

The results reported in this paper (author ratings and comments from their reviews and their self-rating of their papers compared to the reviewers ratings) demonstrate that there is not a shared understanding in the AAEE community of what constitutes quality research in engineering education. Establishing such a shared understanding is important if engineering education is to continue to develop as a credible

research domain. Dialogue on research is as important for establishing a shared understanding of the required standards as it is in establishing the standards for assessing student learning outcomes. The UK-developed Assessment Manifesto [15] urges a move to the establishment of appropriate forums for the development of a shared understanding of standards across multiple communities:

Assessment is largely dependent upon professional judgement and confidence in such judgement requires the establishment of appropriate forums for the development and sharing of standards within and between disciplinary and professional communities.

Consequently any developmental process for reviewers should be designed with an opportunity for discussion between the participants about research standards.

The three inter-relating aspects of the peer review process: review criteria, reviewers, and authors need to be addressed if we are to have any confidence in peer review contributing to ongoing research quality. With this in mind the AAEE Executive tasked the authors of this paper to develop reviewing criteria that can be applied for all future AAEE conferences, and to devise a reviewer developmental process for AAEE members.

V. ADOPTED STRATEGY TO IMPROVE PEER REVIEW

The process of developing reviewing criteria for future AAEE conferences was focused around the use of a Delphi panel [16]. This panel was convened to establish reviewing criteria for future AAEE conferences. The authors and the Chair of the 2012 AAEE conference reworked the Journal of Engineering Education (JEE) criteria to better fit the Australasian community and then sought comments from twelve researchers of varied experience (nine Australian and three international) on these reworked criteria. The first round of Delphi panel responses has been incorporated into restated review criteria. These restated criteria were then distributed to the Delphi panel for further comment. At the time of writing we are waiting for responses to these criteria

Reviews using these criteria will then be written for several example conference papers so that members of the AAEE community will have exemplars to indicate not just the criteria to use, but also the expected standards of writing about research and practice that meet those criteria. These exemplar reviews will be available via an electronic site (discussion forum, blog or wiki) where AAEE community members can familiarise themselves with the criteria and standards and participate in discussion of engineering education research. This site will augment but not replace standard peer review which will still be necessary for institutional reasons.

All members of the AAEE community (both authors and reviewers) will then be invited to participate in a collaborative peer review activity that will be designed according to the framework outlined in [17], as follows:

- Individual: Participants review and provide feedback on an exemplar paper using the chosen criteria

(entering their reviews into the online tool SPARK^{PLUS})

- Collaborative: Participants are able to anonymously compare the reviews to each other and explore the reasons given for different ratings by other participants. An open review discussion forum will be made available to seek clarification and/or debate differences etc.
- Confirmation: Participants confirm their understanding by rating and providing feedback on another exemplar paper using the chosen criteria (entering their reviews into SPARK^{PLUS})

At least one round of these activities is planned to be completed before the review process commences for the 2012 conference.

VI. FUTURE RESEARCH

These results suggest that the academic rank of authors and reviewers does not correlate with the quality of conference papers submitted or reviews written about these papers. The authors of this paper suggest that whether an author is likely to develop expertise in this domain will depend on whether and how strongly they identify themselves as an engineering education researcher.

Identity theory [18, 19] will be used as the lens to analyse the interactions between authors/reviewers on the discussion forum, and authors' responses to reviews of their paper/s. Identity models are ways of thinking about educational research which appear to either enable or constrain the acquisition of research expertise [20]. Interviews with individuals who display attributes of various identity models within the Australasian engineering education community will also be used to investigate any link between professional identity and development of research expertise.

VII. CONCLUSIONS

This study provided contradictory results between authors' perceptions of their submitted papers, their reviews and analysis of the usefulness of the same reviews. This indicates that there is little shared understanding in the Australasian engineering education community of what we mean by quality research in engineering education.

The study confirmed the results of Callaham and Tercier [14] that academic rank is not a reliable indicator of the quality of a paper or a review written on it. This is not surprising in our community since most members were not trained in educational research methods [7]. However this is no reason not to work towards improving the expertise of the community and the Australasian Association for Engineering Education is committed to improving the knowledge and expertise of its members with a collaborative peer review development activity. A critical component of the proposed process is the opportunity for discussion which is necessary to establish a shared understanding of standards.

ACKNOWLEDGMENT

We thank all the authors and reviewers from the 2010 and 2011 AAEE conferences who generously shared their views with us, the 2010, 2011 and 2012 Conference Committees, and the AAEE Executive for their support of this project.

We also thank the reviewers of this paper who offered helpful suggestions for data presentation.

Work in Progress: A Model for Facilitating Problem Based Learning

Deirdre A. N. Hunter, Holly M. Matusovich, and Marie C. Paretti

Abstract— This work in progress reports preliminary findings from a study of six teams in a well-established Problem Based Learning (PBL) curriculum. As PBL gains popularity in engineering curricula, it is increasingly important to understand faculty roles in order to best prepare faculty for this type of teaching and to effectively design meaningful learning environments. Because PBL facilitation requires skills and techniques that differ markedly from traditional content-delivery modes, engineering faculty need a clear model to describe their roles and practices in such an environment. To develop such a model, we employ the theory of cognitive apprenticeship to analyze audio-video recorded sessions of PBL in engineering.

Keywords—problem-based learning; facilitation;

I. INTRODUCTION

Problem-based learning (PBL) is growing in popularity in engineering classrooms. Some of this growth may be attributed to the changes in ABET accreditation in 2000. In particular, the change to outcomes-based criteria for accreditation has put more focus on the ways students learn to apply knowledge, design, and problem solve, as well as on professional skills such as team work, communication and life-long learning. In response, many engineering departments have engaged in strategic curriculum reform, and PBL is often seen as an effective strategy to achieve these desired outcomes. Additionally, recent conferences and journals dedicated to PBL, as well as increased publications on PBL indicate that interest in PBL is on the rise, particularly in engineering [1].

PBL fosters student agency to promote development of content knowledge, cognitive skills and professional skills. The pedagogy is student-centered such that students engage in self-directed small-group learning guided by a facilitator [2-3]. Much PBL research has examined student outcomes, and a meta-analysis of such studies shows that students achieve the expected outcomes as well or better than students in traditional classrooms [4]. Additional research shows that students in PBL classes have a deeper understanding of content, retain this knowledge longer, and are better able to transfer their knowledge to other situations [2, 4]. Research has also begun to focus on the ways that PBL might promote student motivation and increase student retention in engineering programs [5]. However, despite the many demonstrated benefits, PBL is still not a widely used pedagogy in engineering.

Barriers to implementing PBL in engineering may be associated with faculty training and support, student transition from lecture based to self-directed learning, designing effective problem statements, and concerns over content coverage. An instructional model for PBL in engineering would be useful to guide faculty in effectively implementing PBL in their classrooms [2, 6]. Such a model is the long-term goal of the research presented here. As a first step, we identify and describe facilitator roles in an engineering PBL classroom. While there are suggested practices for facilitators, little research has examined how facilitators enact their roles [7]. One such study has examined faculty-reported practices in project-based capstone design courses, which share many features with more traditional PBL approaches [8, 9]. Yet much work remains to be done to better understand these practices in engineer PBL environments. We begin closing this gap through a longitudinal examination *in situ* of facilitators working with students over a seven week period, utilizing cognitive apprenticeship theory to address the research question [10], *How do faculty foster the transformation from student to apprentice engineer in PBL engineering course?*

II. THEORETICAL FRAMEWORK

Cognitive apprenticeship is a framework, developed by [10], as a tool to design learning environments. It includes four main elements – *content, method, sequencing and sociology*. Since our goal focuses on understanding how facilitation happens, we focus on the *method* element, which refers to the ways in which the instructor promotes the development of students' learning. *Method* has six components - modeling, coaching, scaffolding, articulation, reflection and exploration. General definitions for these components are:

- Modeling – teacher performs a task so that students can observe
- Coaching – teacher observes and facilitates while students perform a task
- Scaffolding – teacher provides supports to help the students perform a task
- Articulation – teacher encourages students to verbalize their knowledge and thinking

- Reflection – teacher enables students to compare their performance with others
- Exploration – teacher invites students to pose and solve their own problems

The first three methods are used to help students develop cognitive understanding and the next two support meta-cognition. Instructors use the last method to guide students to independently explore using their knowledge in other contexts. Importantly, these components occur independently, but not in a rigidly specified sequence.

III. METHODS

To describe facilitator roles, we studied a well-established PBL program in a first year engineering course. We observed six PBL groups multiple times over a seven-week period; the six groups were facilitated by five different instructors. Observing students over time as they worked through assigned problems enabled us to analyze facilitator roles and how these roles changed as students progressed in self-directed learning skills. The observations were recorded (audio and video), transcribed, then analyzed using qualitative coding with codes developed from the cognitive apprenticeship framework. The six components of cognitive apprenticeship served as *a priori* codes, but we allowed the data to inform the operationalized definitions for the codes and the appropriate sub-codes.

As an example, we started with the general definition of *coaching*, in which instructors observe and facilitate while students perform a task. Initially, we examined the transcripts for instances where the instructor provided input to the students while they were working. Then we collected these coded segments and looked for commonalities and differences that could be used to define the code and sub-codes. For coaching, the emerging definition focuses on instructors prompting students to make decisions to follow or not to follow a particular path in the problem solving process.

IV. PRELIMINARY FINDINGS

Preliminary results suggest that modeling, coaching, and scaffolding are of primary importance in the PBL process, though coaching was the strategy used most often by the facilitators who were observed. This technique is very student-centered, such that the students are working on a problem and determining the path to a solution; the instructor is in the background. The instructor observes the students as they progress; when she sees that they have come to a decision point and are unsure about how to move forward or have chosen to proceed down a path that is not productive, she poses a question to help them continue to progress. For example, students designing an experiment to test a body fat analyzer had to select an analyzer for their experiment. A few students suggest buying the cheapest one, while others had different ideas. The instructor questioned the students: *“What’s the advantage to buying a cheaper one over a better one?”* The students had come to a decision point and had trouble moving forward, so the instructor provided a question that led the students to evaluate their choices.

Importantly, to support continued student development, the prominence of each strategy changes with time. Final results from this project will enable us to provide distinct examples on what each of these activities look like in a real and tangible way that is specific to an engineering context yet transferable to different engineering content or subjects.

V. CONCLUSIONS AND FUTURE WORK

Preliminary, findings from this work provide a strong foundation for the longer-term goal of developing a model for implementing PBL in engineering classrooms. This is the first of three critical components of a workable model:

1. Identify and describe the roles of the facilitator in fostering student learning,
2. Describe the intersections of facilitation and the students’ roles in their learning processes, and
3. Determine barriers faced by faculty in implementing PBL.

Once the first item is complete, we will turn our attention to items two and three. Our data set is sufficiently rich to complete this task. In addition to the observations currently being analyzed, we have longitudinal interviews with student participants and observations and interviews from another first-year program where PBL was implemented experimentally. This full data set provides an opportunity to analyze students’ roles in their learning process. The implementation of PBL at the second site provides us with great insight into the barriers faced by faculty when implementing PBL.

Abstract—An educational remote laboratory is a software and hardware tool that allows students to remotely access real equipment located in the university as if they were in a hands-on-lab session. Federations of remote laboratories have existed for years: they are based on enabling two universities to exchange remote laboratories directly, without registering students of the latter on the former university. Integration of remote laboratories on Learning Management Systems (LMS) or Content Management Systems (CMS) have also been addressed in the past, enabling institutions to delegate the authentication or authorization of the experiments to the LMS/CMS. However, these integrations are usually achieved in an ad hoc way, integrating each particular laboratory to a LMS/CMS. This contribution studies the use of federation models to integrate remote laboratory management systems in LMS/CMSs, since both approaches (integrating a laboratory on an external electronic learning tool, and integrating a laboratory on other laboratory) are essentially equivalent. The contribution defines two case studies to evaluate this approach, showing how this integration is achieved on a LMS (Moodle) and on a CMS (Joomla).

I. INTRODUCTION

An educational remote laboratory is a software and hardware tool that allows students to remotely access real equipment located in the university, as if they were in a hands-on-lab session. Federations of these remote laboratories have existed for years, as well as integrations of remote laboratories in Learning Management Systems (LMS), developed to integrate the remote laboratories on institutional platforms. However, these integrations were mostly done in an ad hoc way, binding a particular laboratory to an LMS and focusing on the integration itself.

The contribution of this paper is to model and evaluate how a general federation model for remote laboratories can be used to support third party consumer systems such as LMSs, CMSs or e-learning tools. Since the discussed federation model is focused on simple rules (priorities, access) for third-party

agents consuming laboratories -regardless they are remote laboratories or other kind of software- it becomes reusable for the integration of other e-learning tools. With this approach, the remote laboratory will still establish particular rules for each system and for each external institution. Furthermore, the provider university can establish high level rules (e.g. University A grants 10,000 accesses on Laboratory 1 to University B) and the consumer university can decide to let their users consume it through different technologies (e.g. different LMSs or remote laboratories) without notifying the provider.

In order to evaluate this contribution, a federation model is defined and implemented on an existing open source remote laboratory called WebLab-Deusto¹, enabling two universities to share laboratories through this remote laboratory. The federation protocol has been implemented in an LMS (Moodle), so users can consume the laboratories and educators can select which users can access which laboratories. Finally, the federation protocol has been incorporated to a CMS (Joomla) through an extension. The feasibility of this approach to support heterogeneous web environments is described detailing the differences over existing e-learning integration approaches.

This paper is structured as follows: section II explains the federation model, section III describes the existing integration of remote laboratories in LMS/CMS, section IV discusses the approach proposed, and section V describes case studies, focusing on Joomla (CMS) and Moodle (LMS). Finally, section VI sums up the conclusions and draw the future work.

II. FEDERATION OF REMOTE LABORATORIES

This section details what is a federation of remote laboratories and its relevance.

¹<http://www.weblab.deusto.es/>

Fig. 1. Remote laboratory

A. Remote laboratories

A remote laboratory is a software and hardware tool that allows students to remotely access real equipment located in the university. Figure 1 represents the essentials of a remote laboratory: a student connects -normally through a web browser- to a physical, real laboratory deployed in the university. There are a wide range of remote laboratories in the literature for different engineering and sciences fields: robotics, electronics, chemistry...

Every remote laboratory manages at least a subset of the following features: authentication, authorization, scheduling users to ensure exclusive accesses -typically through a queue or calendar-based booking-, user tracking and administration tools. However, most remote laboratories are developed aiming a particular setting (a laboratory for robots based on PIC18, an electronics). So the focus is usually achieving that the particular setting is available through the internet.

B. Remote Laboratory Management Systems

As many features of remote laboratories are common among them, Remote Laboratory Management Systems (RLMS) arised. RLMSs were focused on providing the required common tools for remote laboratories, and managing the common features. Examples of these systems are: MIT iLabs² [1], Labshare Sahara³ [2], VLCAP [3] and WebLab-Deusto [4]. Each RLMS can manage different concurrent experiments. They provide tools for establishing which users can access which experiments, tools for reporting teachers which students did what and when, and other administrative tools. For instance, if a RLMS supports a new feature, such as LDAP (a directory protocol used to authenticate and authorize users), automatically all the experiments developed with that RLMS will support it.

In order to do so, RLMSs usually provide some guidelines or even APIs that allow experiment developers to create new experiments. For instance, WebLab-Deusto provides an web service interface for experiment developers and working libraries for a wide range of software technologies, both for server (Python, Java, .NET, LabVIEW, C++, C) and client side (JavaScript, Flash, Java).

The advantage of using these RLMSs is that they speed up the development process of remote laboratories. Teachers aiming to create a remote laboratory do not need to work on scheduling, authentication, authorization, etc. but focus on making the experiment available through the Internet. If a new version of one of these RLMSs is released and comes with

more features, the developed experiment will automatically include them.

C. Federating remote laboratories

A unique characteristic of remote laboratories when compared to traditional laboratories is that the distance of the student to the real equipment is not an issue, so remote laboratories can be shared with other institutions. This sharing can be managed in a direct, simple way: the *provider university* (the one where a remote laboratory is located) creates accounts of users of the *consumer university* (the one interested in using the provider university's equipment for their students). Students of the consumer university directly access in the provider university and the provider university does all the work: it authenticates the user, authorizes him to use the laboratory and provides the laboratory.

There are multiple problems with this solution. First, the provider university must create and manage the user accounts of all the interested consumer universities. In a complex scenario, where a wide variety of consumers exist -such as foreign universities and even secondary schools that simply do not speak the provider university's language-, this approach does not scale. Second, the management of this approach is cumbersome: consumer universities would need to notify providers every change, and local databases or protocols such as LDAP would not be available. Third, the consumer university cannot carry a proper accounting of the uses performed: it must trust the provider university. If both institutions come to an agreement where users of the consumer university can access up to 10,000 times, there will be no way for the consumer university to audit this if the provider university at some point says "you have already the limit".

In order to handle these and other problems, a two-side model is required (see figure 2), where both universities have the same RLMS that manages this sharing. The consumer university can authenticate and authorize local students, and once authorized, the local RLMS will contact the provider university and request a slot. This way, the provider university does not need to manage students and courses of the consumer university, and the consumer university can track all the requests performed to the provider university, being able to track students and audit the overall use.

In this sense, MIT iLabs have been effectively sharing remote laboratories around the world for years [1][5]. Different universities can use the MIT iLabs RLMS to develop, maintain and share their remote laboratories with other universities. In the federation model defined by the iLabs Shared Architecture (ISA), two types of remote laboratories can be shared: batch laboratories (using queues) and interactive laboratories (using a calendar-based booking system).

However, this mature architecture lacks a feature relevant to this contribution, which is *transitive federation*. Transitive federation refers to the capability of re-sharing a remote laboratory to a third university. For instance, one university could share 10,000 accesses to other university, and this other university could split these 10,000 accesses on two: the

²<http://ilab.mit.edu/wiki/>

³<http://www.labshare.edu.au>

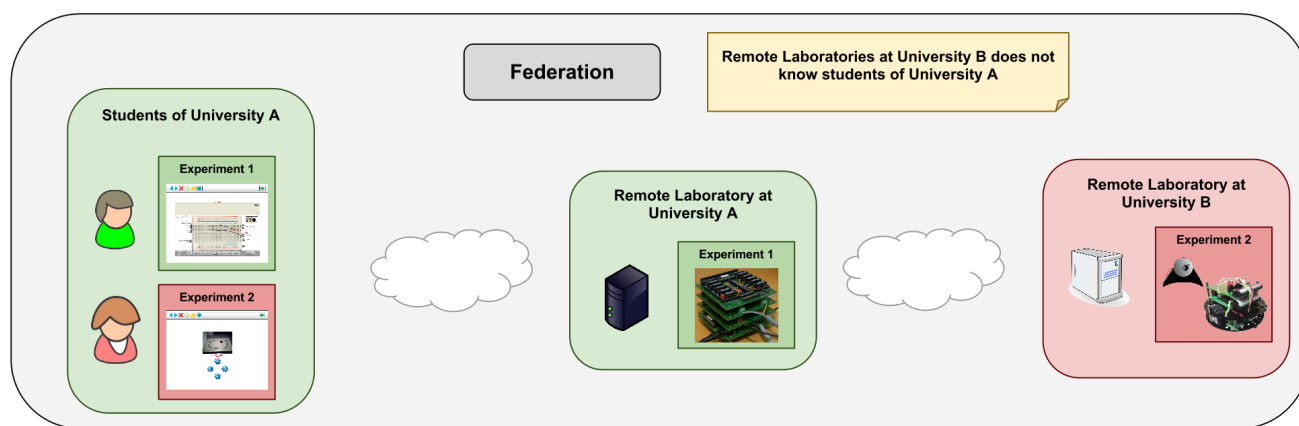

Fig. 2. Federation of remote labs. Students registered in the federation

first 7,000 being exclusive for their students and the other 3,000 might be re-shared to a third university interested in consuming that laboratory. This would work in the same way a real market works, where prices adapt to the offer, demand and required quality of service. The RLMS used in this contribution (WebLab-Deusto) defines a federation model which supports transitive federation, as well as load balance among different copies of the same experiment distributed through the federated universities.

D. Relevance

The federation of remote laboratories has a major role on engineering and sciences education. It makes possible for students of one university to access hands-on-lab sessions of other universities through an institutional RLMS and through agreements among the institutions involved. Furthermore, secondary schools connected to local universities can transitively access laboratories of federated institutions.

Indeed, the interest on federation of remote laboratories is growing. The Labshare project survey [6], made on all 34 Australian universities offering undergraduate engineering programs, reflects that interviewed executives were more interested in getting involved for the pedagogic merits of the remote laboratories, and were more inclined on initially being laboratory consumers than providers. Indeed, the European Union Commission will invest 60 million euro in research actions, projects and network of excellences in Technology-Enhanced Learning (TEL), under the objective ICT-2011.8.1 of the call FP7-ICT-2011-8. One of the target outcomes is precisely supporting a European-wide federation and use of remote laboratories and virtual experimentations for learning and teaching purposes.

III. EXISTING INTEGRATION OF REMOTE LABORATORIES IN LEARNING / CONTENT MANAGEMENT SYSTEMS

Proper integration of remote laboratories on LMSs is an active field of research. The relevance of this field is that, as detailed in [7], there are several services duplicated between remote laboratories and learning management systems. The

administration and user experience would increase if they were merged. Both systems usually support user authentication, authorization, group management, administrative tools, user tracking, and even scheduling. Some integration approaches suggest to delegate all these services to the LMS, but some of these services will still be at least shared, such as scheduling (especially when federation systems arise) or user tracking (since some interactions with the remote laboratory might occur outside the scope of the web browser).

In order to integrate remote laboratories and LMSs, [8] discusses the usage of SCORM and [9] implements an architecture around it. This technology is designed to be supported by different LMSs and indeed multiple LMSs have implemented different versions. However, since it is a client-side technology and therefore it cannot contain any server code, it does not support a secure way to exchange credentials, ensure reservations or return results to the LMS.

Other approach is to develop an ad-hoc plug-in to include a particular remote laboratory on a LMS[10]. This approach is common in the literature, and sometimes it is implemented by just copying or exchanging the users among both systems. Within the field of integrating remote laboratories on electronic tools appears the integration of remote laboratories on CMSs. In [11], the remote laboratory relies on Joomla to perform all the administrative tasks. This approach is interesting since it does not duplicates all the tasks referred in [7]. However, it is an example of an ad-hoc integration which does not support the integration of other remote laboratories neither the integration on other CMSs.

IV. DISCUSSION

Most integrations among remote laboratories and LMSs or CMSs are ad hoc integrations of one particular LMS/CMS to a particular remote laboratory. The target of these integrations is to delegate the tasks for authentication, authorization, user tracking and scheduling to the LMS/CMS. This delegation is the same delegation described in section II as the target of federation models: the consumer remote laboratory will manage the authentication, authorization and user tracking,

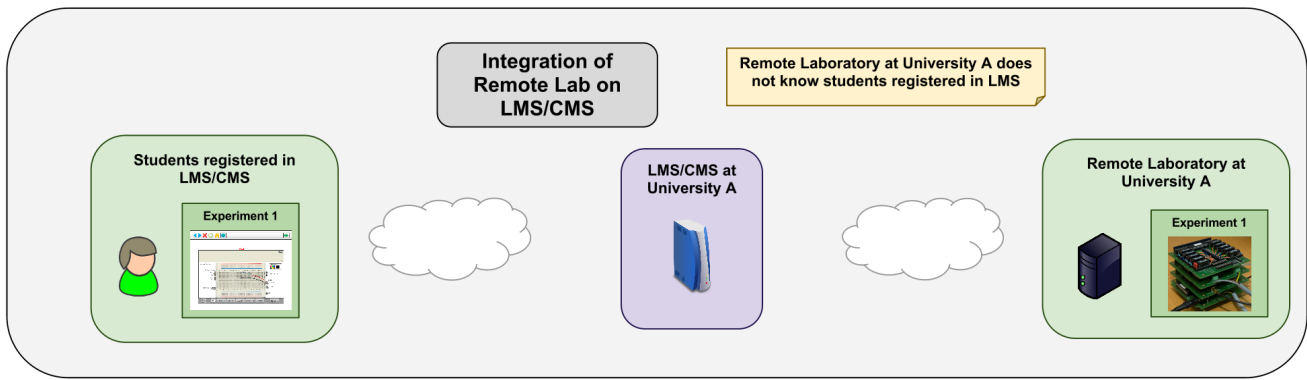

Fig. 3. A LMS/CMS can act as a federated node consuming the federation protocol

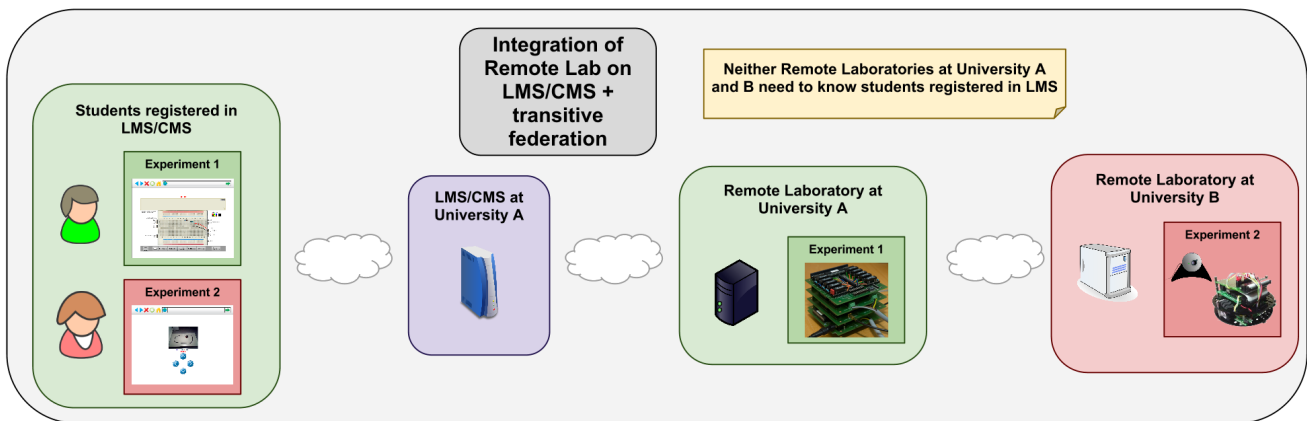

Fig. 4. If the federation is transitive, the LMS/CMS will still be able to consume remote laboratories in other universities

while the provider remove laboratory will be in charge of enabling the interaction of the user with the experiment.

The key concept introduced in this contribution is that the remote laboratory integration on LMS/CMSs is essentially equivalent to the integration of two federated remote laboratories. Thus, a LMS/CMS could be considered an external consumer of the federation protocol of a RLMS. As described in figure 3 and compared to figure 2, the LMS/CMS acts as a federated node, even if it is in the same university as the remote laboratory. This way, the student in the figure will access through the LMS/CMS to the remote laboratory.

The relevance of this concept is that it simplifies notably the integration of both systems. Under this approach, the LMS would not need to exchange user information, or use standards such as OAuth or Single Sign On protocols to effectively perform reservations in the remote system. If the protocol is simple enough, different systems can adopt it, since the interface only needs to provide three actions:

- Listing of possible experiments (so administrators of the LMS/CMS can choose who has access to what)
- Reserving the remote experiment
- Usage retrieval (to be stored in the LMS/CMS database)

It is worth mentioning that if the federation model does not

support transitivity, the LMS will not be able to consume remote laboratories on other universities through the institutional remote laboratory. This means that in the example of figure 3, students registered in the LMS will be able to use experiments located in University A. But, if no transitivity is supported, and if the remote laboratory of University A was federated with one of University B, students registered in the LMS would not be able to use them. The only way to achieve this would be registering also the LMS in University B. However, given the transitivity property of the federation model supported in WebLab-Deusto, figure 4 becomes possible without expliciting all the contracts and subcontracts.

V. CASE STUDIES

For the sake of clarity and evaluation, two case studies are presented. They describe sample integrations in a LMS (Moodle) and a CMS (Joomla) of the remote laboratory WebLab-Deusto. WebLab-Deusto is a remote laboratory used for the latest 8 years by over 1,000 students in 12 different courses in the University of Deusto. WebLab-Deusto supports federation with other instances of WebLab-Deusto in a transitive way, and this federation protocol is indeed being used with local

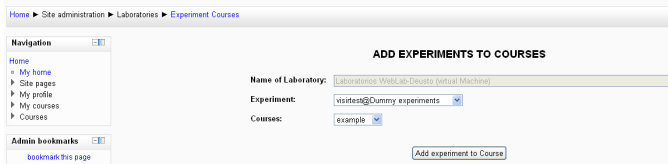

Fig. 5. Admin granting permissions of an experiment on a course

secondary schools ⁴.

While both Moodle and Joomla use the same technology (PHP) and therefore some code is reused (the federation protocol client), the same code has been implemented in other kinds of systems. WebLab-Deusto experiments can be consumed from iLab systems through the federation protocol of WebLab-Deusto: iLab acts as a federated node that interacts with WebLab-Deusto. As part of the european *e-pragmatic* project, a commercial LMS is also integrating WebLab-Deusto using .NET and it will be used in the context of the project.

The federation protocol of WebLab-Deusto requires a web service with the following methods:

- System authentication → The consumer system will call the *login* method to authenticate the institution, providing the institution ID and password.
- Available experiments retrieval → The consumer system will call the *list_experiments* method to retrieve the list of experiments available for the consumer system. The provider university can choose through a permissions system to what experiments the consumer system will be able to access.
- Reserve an experiment → The consumer system will call the *reserve_method* to request a reservation and start on a queue.
- Check the state of a reservation → The consumer system will call the *get_reservation_status* to know the current state of the reservation requested, such as the position in the queue or if it has already been assigned. The consumer system is free to cancel the reservation at any point if a similar resource was found during this process in other university. Finally, it will provide a URL that the user will be able to use to consume the laboratory.
- Usage retrieval → The consumer system will call the *get_experiment_uses* to get what messages were exchanged among the user and the final remote laboratory. The system may respond that the final user cancelled the request or that it is still running so the consumer must request again some minutes later.

A. Moodle

A Moodle plug-in using the federation protocol has been developed. In the Moodle system, different RLMSs can be registered. The connection data will include the URL of the remote system, and a single username and password, identifying the university. Three roles are defined:

⁴<http://weblab.colegiourdaneta.com/>

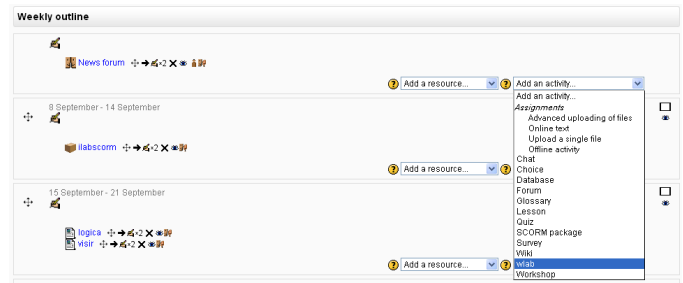

Fig. 6. Teacher adding a remote lab as an activity for a course

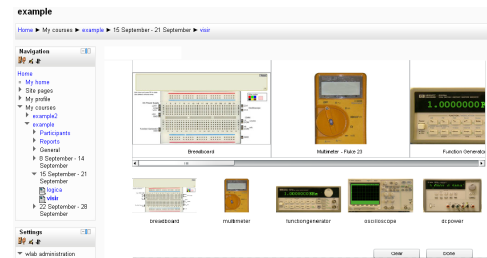

Fig. 7. Student running an experiment

- **Administrators:** Administrators can associate courses to experiments. As shown in figure 5, they can define that the course “Electronics IV, Electronics Engineering can access the VISIR experiment in University A”. In order to do this, the plug-in use the *list_experiments* method detailed above.
- **Teachers:** Teachers of courses with associated experiments are automatically allowed to add accesses to laboratories as Moodle activities to the course. In the menu shown in figure 6, in the second step they will choose among the associated laboratories. They can add, remove or hide the activity as any other Moodle activity.
- **Students:** Students of courses with associated experiments can automatically use the experiments (see figure 7), once teachers have created the activities. Whenever a student requests an access, the plug-in will perform the request in the name of the student, using the university credentials.

Only moodle administrators can define which courses have access to each external remote lab. The management becomes simple: every teacher added to a course through the Moodle administrative tools can automatically manage the associated laboratories. Every student enrolled in a course can use the laboratory. Remote laboratories do not need to exchange any user information (credentials, full name, etc.) with the LMS.

B. Joomla

A plug-in for Joomla using the federation protocol has been developed (live demo ⁵). The schema used for this integration was simpler, with only two roles involved:

- **Administrators:** they will manage which groups have access to what remote experiments. This is done through

⁵http://www.weblab.deusto.es/weblab_joomla/

| User Menu | | Group | Experiment Name | Category Name | Launch |
|--------------------------------|--|-------|-----------------|-------------------|--------|
| » Your Profile | | 14 | ud-logic | PIC experiments | Run |
| » Experiments of WebLab-Deusto | | 14 | visir | Visir experiments | Run |
| » Site administrator | | | | | |

Fig. 8. List of experiments available for current user

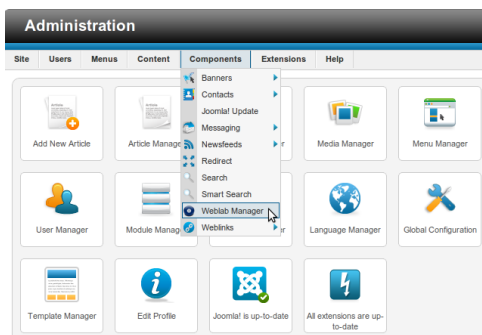

Fig. 9. WebLab-Deusto manager in the Joomla Administration panel

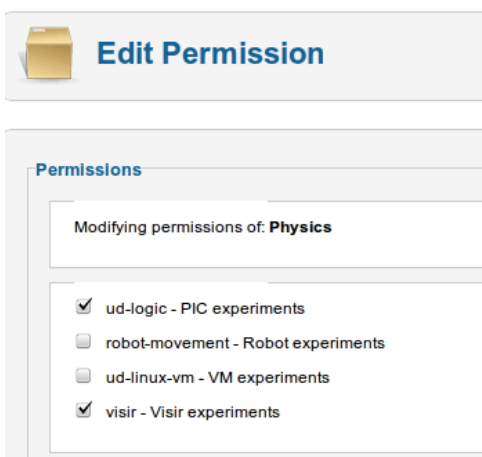

Fig. 10. Permissions editor for each group

the standard Joomla's administration site (see figures 9 and 10).

- **Users:** there is a link where every user can see what experiments can be run. This way, users who are members of groups with associated experiments will see those experiments and they will be able to start using any of them (see figure 8).

As in the Moodle case, users and administrators of Joomla use the standard tools provided by the framework. In this case, authentication and group membership is managed with the standard tools. The plug-in only needs to define which groups can access which laboratories, as well as provide a small component to start the reservations. The remote laboratory does not need to exchange credentials or register students.

VI. CONCLUSIONS AND FUTURE WORK

This contribution shows a novel approach for integrating remote laboratories on LMS/CMS, using the federation model of remote laboratories. The impact of this contribution is not restricted to the users of those remote laboratories that support federation -especially to those that support a transitive federation model-, but to every remote laboratory which aims to be integrated into a LMS/CMS. This is so since this feature will automatically be available for laboratories integrated in a Remote Laboratory Management System (RLMS) that supports this federation model. For instance, the integration of VISIR on WebLab-Deusto [4] makes VISIR benefit from this integration, as seen on figure 7. Furthermore, the integration model proposed does not need to exchange information related to particular students, neither it requires to constantly synchronize this information, becoming a simple approach to be implemented. Indeed, the contribution details the integration of a LMS (Moodle) and a CMS (Joomla), showing how the integration of other LMS/CMS could be done.

Regarding future work, the Moodle plug-in is expected to be used with students of the University of Deusto during the next course, and support for other LMS -in particular, the "LRN" LMS, used in UNED- is under development. At the time of this writing, it still misses the retrieval of usage data. It would be desirable that other RLMSs provided new or supported existing federation interfaces to evaluate the proposed integration approach with more remote laboratory systems.

Abstract— Based on research, constructing a program to increase accessibility for students with financial need, and diversity of students graduating with engineering baccalaureate degrees requires multiple components and partnerships to recruit, retain and graduate students. This paper describes how a program at Texas A&M University was initially constructed, how it has evolved, and what influences on student success have been observed.

Keywords—engineering students, diversity, recruitment, retention

I. INTRODUCTION

Earning an engineering degree is a route from high school graduation to many fascinating, financially attractive career paths; however, for many academically talented students with substantial financial needs and diverse backgrounds, access to undergraduate engineering programs is becoming increasingly difficult, in part due to rapidly increasing costs of undergraduate education, both in the United States [1, 2] and worldwide [3]. Designing programs to address this challenge involves multiple elements. Specifically, plans should address twin challenges of recruiting and retaining engineering students who have the academic qualifications to complete an undergraduate engineering degree, but have hurdles in addition to the cost of higher education that deter them from considering or choosing to enroll and complete this degree. Thus, recruiting and retaining academically talented students with substantial financial needs and from diverse backgrounds requires a comprehensive program. The intent of this paper is to offer the programmatic response that one engineering college has developed for these challenges and indicators of the extent to which these responses have addressed these challenges. For the purposes of the paper, results will be presented only for students that the university and the college have supported financially using funds from the S-STEM program of the National Science Foundation (NSF), who will henceforth be referred to as S-STEM scholars. The S-STEM grant intends to increase the quantity, quality, and diversity of the engineering workforce in the state, the US, and globally through enabling academically talented and financially needy students to obtain a baccalaureate STEM degree. It should be noted however that the programmatic elements discussed herein are available to a wider range of students than those receiving funding from the NSF S-STEM program.

II. LITERATURE BACKGROUND

Considerable research has been done on challenges faced by entering students from populations who historically have not sought degrees in science, technology, engineering, and mathematics (STEM) disciplines, or engineering more

specifically, in numbers consistent with their representation in the general population [4-6]. Research indicates that increasing the number and diversity of engineering majors will call for financial assistance for academically talented African American and Hispanic high school students whose families do not have the financial resources to fund the rising cost of a college education. Research and internal findings at Texas A&M University indicate that students with high financial need often will enroll if tuition and fees, and room and board, are covered by scholarships and grants. This finding is particularly applicable to the targeted groups of first-generation and traditionally underrepresented potential students. This includes studies on retention in STEM disciplines [e.g., 4] and in engineering alone [e.g., 7, 8]. Further, based on this research, many programs have been developed to recruit and retain one or more segments of these STEM students [9-12]. However, each institution that launches or redesigns programs to improve recruitment and retention of one or more segments of these engineering students must do so within a set of constraints that includes the history of the institution, profiles of students who traditionally have attended the institution and successfully completed their engineering degrees, the mission and characteristics of the institution, and characteristics and needs of populations from which the institution primarily recruits.

III. COLLEGE OF ENGINEERING PROGRAM BACKGROUND

The college of engineering has been refining and improving a two-pronged recruitment-retention plan to recruit, retain, and graduate diverse students. This section overviews these efforts, while details are provided in the following two sections.

To recruit diverse engineering students, the college has many different programmatic elements, but the focus for this paper is the set of components that directly involve collaborations with 12 strategically selected high schools. Program recruitment components include summer camps and visits to campus, focused on these selected high schools. The program also involves support during the application process, receptions hosted by industry partners for admitted students and their families, and scholarship awards. When considerable resources (human and financial) have been used to recruit these targeted students, it is important to also invest in their retention; therefore, Texas A&M University has also developed a retention program with an overall goal of creating a community of scholars. These components focus on student support strategies such as living learning communities, course clustering, industry interaction, student professional society involvement, and student career placement. It also includes elements to address difficulties in transitioning to the university environment and help students develop study and time management skills. More detail will be provided below on the

recruitment and retention efforts to provide information that may be useful to other institutions.

In terms of how recruitment and retention efforts have influenced student success, this paper focuses on students supported with funding from the NSF S-STEM program. Since 2001, Texas A&M University has received a series of three grants (totaling \$1,270,000) from NSF to support scholarships for financially deserving, academically talented, and first-generation engineering students. Criteria used for the most recent S-STEM scholarship awards include a family income level below \$60k, a combined SAT of 1300, US citizenship or permanent resident status, and a minimum score of 65 in the university Freshman Scholarship Awarding Scoring Model (FSASM) that considers academics, adversity, and curricular and extra-curricular activities. These grants have provided up to two years of partial funding for students majoring in various engineering disciplines and computer science.

The first NSF-supported project resulted in first-year retention of 87.2% (compared to college-wide retention of 70%) and an average first-year GPA that was 0.3 points higher than the college average. The second project served 53 first-generation and low-income students (29 Hispanic, 1 African American, 11 women). Retention of these students was very encouraging, with 95% of S-STEM Scholars continuing their studies in engineering for their first two years of the project, compared to a 71% retention rate for all entering engineering students in the College. The third project is serving 57 low-income and first-generation students (35% of recipients were first generation and the numbers include 12 Hispanic, 3 African American, and 14 women students). To date, first-year retention for the third project has been 85.7% (compared with a college average of 74%), with a first-year GPA above 3.0.

What were elements that have contributed to the success of these students, and how were decisions made to arrive at these elements? The following two sections on recruitment and retention will address multiple components in this question.

IV. RECRUITMENT

Need for programs to attract underrepresented students to STEM fields became more acute following a series of Supreme Court decisions which limit the ability of higher education entities to use race in university admissions (*Regents of the University of California v. Bakke*, *Grutter v. Bollinger*, *Adarand v. Peña*, *Hopwood v. Texas*). In response to these factors, the engineering college decided early in program development that it would need partners to address manifold challenges associated with recruiting and admission. Texas A&M University reached out to high schools and partnered to provoke and sustain student interest in studying engineering.

Description of the recruitment component at Texas A&M University will be framed in terms of the following questions to be addressed by a university interested in forming and sustaining collaborations with high schools for the purpose of improving the recruitment of diverse students: (A) What are criteria by which a university can identify collaborators? (B) How will collaborators who satisfy these criteria be identified? (C) How will unproductive partners be identified and handled? (D) How

will potential students be recruited? and (E) What factors contribute to successful collaborations? Addressing these questions is the focus of the following subsections.

A. What are criteria for identifying collaborators?

Over the years, the engineering college had worked with a number of high schools through many programs. From these programs, the college constructed a list of high schools that were potential collaborators. To reduce the list to a manageable number, the college first used ratings by the state educational agency. The agency had rated some high schools across the state as academically unacceptable (due to results of state mandated testing), and the college removed these high schools from consideration. Next, the college, with its interest in increasing enrollment of African American and Hispanic students in engineering, focused on high schools with large minority populations. Also, high schools chosen had high percentages of students with significant financial need. Third, because engineering students need to be academically prepared, the college focused on high schools that offered advanced (honors or AP) courses in mathematics and science. Finally, the college did not include geography as one of its criteria. Although this decision increased travel demands on college personnel, the college thought it was important not to limit potential participation based on the ease with which an institution could be reached. Eventually, interest in collaborating with Texas A&M University would be a critical factor in determining partners, but interest would be ascertained in the next step, described in the following section. In summary, state educational agency ratings, student enrollment demographics, mathematics and science course offerings, and interest were the four criteria utilized to identify potential partner high schools.

B. How will collaborators be identified?

Starting with the above criteria, the college identified an initial list of school partners across the state, from which it intended to select 12 high schools. From this list, the college ordered the list in terms of which high school would be contacted first. Ordering was done by the average SAT score of graduating seniors, highest first. With the ordered list, college personnel visited the first school on the list, described the program, asked about interest, and attempted to evaluate the level of interest. After the visit, both potential partners would gauge likely interest in collaboration. Some high schools were interested and willing to commit, others were not. If the school was interested in participating and willing to put forth effort to partner, they remained on the list. If not, they were removed and number 13 on the list was moved up, and so on. Eventually, the college selected 12 high schools.

The list of potential partners is not fixed. Each year, Texas A&M and the 12 partner high schools evaluate the program. The University is interested in the level of engagement by each high school. For example, did a high school select the expected number of interested students? How qualified to study engineering at Texas A&M were the identified students? Did the juniors participate in the summer program? How many of the identified students applied to Texas A&M? Also, each high school evaluated its participation. Based on this evaluation,

Texas A&M has replaced some high schools due to low level of engagement, and added other high schools to the list.

High schools are interested in whether participation provides an additional, viable pathway for its students to attend college, particularly in engineering. Each wants a sufficient number of its students to express interest in applying to Texas A&M, apply to the university, and see them accepted. The “sufficient number” varies across the high schools, but each high school monitors the results to decide, in part, whether it will continue to participate in the program.

C. How will potentially qualified students be identified?

When the high school partnership program was started in 2008, each partner school was asked to identify a total of 12 junior and senior students using the following criteria: (i) academic performance, (ii) interest in engineering, and (iii) enrollment in advanced math and science courses. As the program evolved through evaluation and experience, some changes have been made. Since 2011, a partner high school is asked to identify its 12 seniors and 12 juniors who are US Citizens and have: (i) expressed interest in engineering, (ii) demonstrated a strong work ethic, (iii) shown academic excellence in advanced math and science courses, and (iv) have a minimum Math SAT of 550 (or equivalent). The minimum MATH SAT score was added, in part, because the college started requiring a 550 MATH SAT score for admission into engineering. The high school would then work with the identified students to encourage their interest in engineering and application to Texas A&M University.

D. How will potential students be recruited?

Each high school encourages its selected students to participate in the full range of Texas A&M recruitment activities. High school juniors attend a four-day residential summer program on the university campus to learn more about the institution and engineering. It is offered to students for minimal cost (\$100/student) and provides prospective engineering students with opportunities to experience engineering team design projects first hand under the direction of engineering faculty members. Also, students are invited to visit and tour the campus (including the living learning community discussed below). They meet with college representatives and current engineering students to discuss career prospects in engineering and why high school students might want to consider studying engineering. Sessions provide information about what would be necessary to succeed in engineering. Finally, the college invites seniors, together with their families, at each partner school who are admitted to a reception hosted by engineering industry (usually at their place of business) where the students can interact with working engineers, as well as college and university recruitment personnel.

Since its inception, both partners worked to improve the program based on input from both partners and observed outcomes. Since 2011, the engineering college has added an ambassadors program for these high schools that involves sending current engineering students from these high schools to visit their schools at least once a year and share their college experience. In fall 2012, the high school partners requested,

and the college has provided, Skype sessions with information on different engineering majors for their junior students.

E. What factors contribute to successful collaborations?

At least two major factors contributing to successful collaborations are: (1) Program support at the K-12 institution and (2) Institutional (university) support for the program through staff support and scholarship funds.

Each partner institution identified a teacher/counselor who led the support of the program. The lead teacher or counselor is expected to collaborate closely with Texas A&M staff and to have a good understanding of the program goals and components. The lead teacher or counselor is familiar with the college’s admission requirements, works closely with other teachers to recruit qualified students for the program, and encourages targeted students to actively participate in the program. The engineering college has several opportunities to meet with teachers who support this program and get their feedback on the value of this program for their school and how this collaboration supports their goals.

Commitment and impact of the program has varied across the 12 partner high schools. In one school, the teachers drove for several hours to bring the students to the summer camp. At another school, the teacher brought the students to the engineering open house while he was on crutches. For these two high schools, we have observed a significant improvement in recruitment (200% and 900% higher than before program was established). In several other schools, moderate increases in recruiting their students have been observed, while there are a few schools with almost zero change on recruitment. However even at these schools, administrators and teachers report they value this collaboration and that it benefits their students.

Institutional (university) support, in the form of staff support and scholarship funds, is also essential for the success of the program. At the college level, staff support organizes campus visits for high school seniors designed specifically for each partner school. These visits include presentations, lab tours and interactions with current engineering students from their high school. In addition, college staff members coordinate local receptions for seniors (who have been admitted into the engineering college) and their families. These receptions are hosted by industry partners at a location close to the high school, and students are eligible to win scholarships provided by the industry sponsor and university financial aid office. Finally, college staff members maintain regular communications with all targeted students and provide support during the application and admission process. Recruiting is staff-intensive, thus requiring institutional support to maintain.

V. RETENTION

Although there has been considerable research on retention in engineering and there are many engineering retention programs, the authors have not uncovered foundations or methodologies that guide development of a new retention program. For its design, the engineering college now uses the fourteen (14) components of the Meyerhoff Program [13] as a starting point for constructing a framework for a retention program: (1) Financial aid, (2) Recruitment, (3) Summer bridge

program, (4) Peer study groups, (5) Tutoring, (6) Summer research internships, (7) Mentors, (8) Program community, e.g., Meyerhoff scholars live in the same residence hall, living-learning community, (9) Minority Access to Research Careers (MARC) program, (10) Personal advising and counseling, (11) Program values, (12) Faculty involvement and commitment, (13) Family involvement, and (14) Administrative involvement and public support.

Of these fourteen components, components 1-9 may be categorized as programmatic components; i.e., they are concrete initiatives that a retention program can implement. When the Meyerhoff Program began in 1988 [10], program designers included these elements. Components 10-16 may be categorized as cultural components; i.e., they are components that have developed around the program during its history. For example, when the Meyerhoff program was initiated, program designers could not have prescribed faculty involvement and commitment; they have taken steps to cultivate this component, but the degree to which it would occur had to wait until the program was sustained for several years.

Using this framework and considering its resources to invest in retention of engineering students, the engineering college has designed a retention program with the following components: (i) Scholarships, the college has raised funds for scholarships from many sources, (ii) Summer bridge program, (iii) Engineering living learning community, (iv) Course clusters, i.e., engineering students take multiple first-year courses together, (v) Assessment of incoming proficiency in mathematics and placement in first mathematics course, (vi) Assessment and development of knowledge and skills for self-regulation of learning, (vii) Mid-semester advising, (viii) Monthly seminars, and (ix) Community-building activities.

Description of the retention component will address the following questions: (A) How will the students be supported financially? (B) How will the students be academically supported to achieve success in engineering when many of these students have traditionally lacked strengths in important factors such as strong mathematical backgrounds, study skills, self-directed learning, etc.? (C) How will the students be socially and culturally supported to achieve success in the university environment?

A. How will the students be supported financially?

"The availability of financial aid at both the undergraduate and graduate levels impacts students' decisions to enroll in post-secondary education, choose a specific major, and complete a degree" [14]. In addition to financial aid as a factor in recruitment, financial need also plays a role in retention. The higher the financial need of a student that is not met by scholarships or family resources, the greater the likelihood that the student will not be retained in engineering. Therefore, the first component of the college retention program is to reduce unmet financial need of its students. At Texas A&M University, the Office of Scholarships and Financial Aid identified top candidates for the scholarships associated with the program from the pool of all freshman engineering students with a valid scholarship application and a completed FAFSA. To select students, both with financial need and likely to succeed in engineering, university financial aid utilizes a

detailed scoring model (Freshman Scholarship Awarding Scoring Model) that captures academics, activities, and adversity.

For the S-STEM program, over the past three years, the college awarded sixty (57) scholarships with award levels ranging from \$1,500 to \$10,000 per year. Students were eligible to receive a renewal award for their sophomore year if they remained in engineering and were in good academic standing (Grade Point Average of 2.75 or higher). Eight awardees came from the high schools selected in the recruitment program described above, two in 2009, two in 2010 and four in 2011. The college would like the numbers of awardees from the targeted high schools to be greater and continues to work with the high schools to achieve that goal.

B. How will the students be academically supported?

Several components of the retention program that emphasize academic support are described below.

1) Summer Bridge Program: Based on a survey of engineering department chairs, summer bridge programs are being implemented at 45% of engineering programs [15]. Often, they support students during the transition from high school to college, and frequently they are intended to strengthen their academic backgrounds. At Texas A&M University, the summer engineering program focuses on mathematics, physics and engineering study skills. Participants take 3 credit-bearing courses for a total of 6 hours and "engage in community-building activities with their peers, upper class students, and university faculty and staff" [16].

All S-STEM scholars receive a letter encouraging them to apply for the summer bridge program designed for at-risk engineering students. Priority admission is given to S-STEM scholars and students who attend partnering high schools. S-STEM Scholars usually have high Math SAT scores, because of the intent of the program and the selection criteria. Nevertheless, the engineering college thinks they would benefit from components of the summer bridge program for physics and study skills as well as transition to university life.

2) Assessment of Incoming Proficiency in Mathematics and Placement in First Mathematics Course: Success in first mathematics course in engineering programs at Texas A&M has been established as a crucial predictor of retention in engineering [17]. However, high school grades and SAT scores have limited use in predicting success in calculus. Preparatory courses taken in college have some ability to predict success in calculus. For example, students who entered calculus with lower grades in prerequisite courses were not generally successful [18]. Furthermore, while commercially available placement tests have been very effective for placement in lower level mathematics courses, many universities have found them less effective in placing engineering students into the calculus sequence [19, 20]. More colleges are using locally developed placement exams along with high school performance and standardized test scores [21, 22]. Placement exams are used not only to predict success, but to place students in courses where they are most likely to be successful [21, 23]. At one college, approximately 80% of students who took the recommended course or an easier one were successful over a period of five

years. Researchers concluded that a “well-designed in-house placement test geared towards [their] curriculum is a simple and powerful tool for placing incoming students in an appropriate mathematics course” [21, p. 32].

Students entering Texas A&M as engineering majors take a Mathematics Placement Exam (MPE) to determine whether they should take Calculus I or a preparatory pre-calculus course. According to available student data, many students do poorly on the MPE even though they had several advanced mathematics courses in high school, including AP Calculus. Analysis of data over a period of years shows that students who attain a raw score of 22 (out of 33 questions) or above have at least a 70% probability of success in the first engineering calculus course (course grade of A, B, or C).

3) *Course Clusters so Students Take Multiple First-year Courses Together in the Same Sections*: Since 1992, Texas A&M has offered first-year engineering courses in clusters, and participation in these engineering course clusters has been correlated with improved retention in engineering, including women engineering students [24]. Course clusters are another form of learning community, one in which efforts to promote belonging, are organized around students seeing each other multiple times during the week in common course sections [25, 26]. At Texas A&M, the most common form of engineering cluster courses consists of linked sections of Introduction to Engineering I and II, Calculus I and II, and University Physics I and II, in the first and second semesters, respectively. Another form of engineering course clusters groups a study skills course with one or more of the trio of courses: calculus, engineering, and physics. S-STEM Scholars and students from the partner high schools who were calculus-ready were invited to participate in course clusters. Unfortunately, the 2011-2012 cohort was not enrolled in course clusters, partly due to reduction in college funding.

4) *Monthly Seminars*: S-STEM Scholars participate in a non-credit, monthly, one-hour seminar. The seminar is designed to develop good study and time management skills. Also, they showcase successful former student engineers, faculty and staff from diverse backgrounds as guest speakers. Seminar topics include: transitioning to college, engineering study skills, goal setting and time management, effective communication, career choices, leadership, and team building.

5) *Assessment and Development of Knowledge and Skills for Self-regulation of Learning*: In addition to developing knowledge and skills in mathematics, physics, engineering, and other subjects, engineering students must often also improve the tactics needed to learn new content. Self-regulated learning is thought to play a role in success of engineering students [27]. Further, two studies, one at Penn State and another at Texas A&M, failed to discern any improvements in knowledge and behaviors associated with self-directed learning [28, 29]. Therefore, one component in the retention program intends to improve knowledge and skills for self-regulated learning.

To help students understand their current knowledge and behaviors with respect to learning, S-STEM Scholars take the Learning and Study Strategies Inventory (LASSI) [29] in their first monthly seminar of the year. The assessment is administered and interpreted by the student counseling

services. Students are advised during subsequent workshops to address areas of improvement needed in regards to learning and study skills via a one-on-one counseling session. Informal observations of and conversations with S-STEM Scholars suggest the learning and study skills component does not yet have an observable improvement in how students address their learning, e.g., they do not begin studying for an exam until the night before.

6) *Mid-Semester Advising*: S-STEM Scholars meet with their departmental advisors during the fourth week of classes as an early intervention tactic to discuss their academic progress. At midterms, students whose GPA is below 2.0 are required to meet with their academic advisor again to develop an action plan to improve their grades.

C. How will students be socially/culturally supported?

Social and cultural support is provided at Texas A&M University primarily through a living-learning community. Also note that this is a program providing significant academic support, which is woven into the design of the community (hence living AND learning). “Participation in some form of learning community is positively related to student success, broadly defined to include enhanced academic performance, integration of academic and social experiences, positive perceptions of the college environment, and self-reported gains since starting college. The effects are somewhat stronger for first-year students” [30]. Encouraged by positive influences on student success by learning communities, in particular living-learning communities, the engineering college formed a living-learning community for women engineering students as early as 1992 [31]. In 2006, the college established a living-learning community for 400 first-year engineering students (about one-third of the entering engineering students). Based on positive feedback from participants, the college has sustained the community and continues to explore ways to improve the experience and results and has grown the living-learning community to 600 students [31].

The engineering college provides several programs to support student academic success and connection with engineering. Students participating in the living-learning community have access to free on-site peer tutoring sessions in mathematics, physics, freshman engineering courses and chemistry (Sunday thru Thursday, 6 – 10 PM) as well as supplemental instruction [32] sessions in mathematics. Tutoring and supplemental instruction are offered within the residence hall used for the living-learning community. In addition, living-learning community students have opportunities to engage in the freshman team projects with NASA or the city utilities group. Finally, there are about fifty upperclassman engineering students with a GPA of 2.75 or higher who are housed in the dorm and they either work as resident assistants or support social events with engineering faculty. In 2010-11, we logged more than 2,691 help tutoring sessions in the dorm. The first-year retention of the fall 2010 living-learning cohort was 83% compared to 76.9% of the college. In 2010-2011 and 2011-2012, 9% and 41% of the S-STEM Scholars participated in the living-learning community, respectively.

All S-STEM Scholars are invited to apply for and participate in the engineering living-learning community for engineering students via an official award offer letter.

CONCLUSIONS

A multi-pronged approach has improved recruitment, retention, and graduation of a greater diversity of engineering students. Collaborating with high schools to attract diverse students to engineering has been critical. Further, implementing a multi-component retention program is necessary to help retain these students. Recruitment and retention programs require resources by both the college and high school, and it is important that all involved have a clear understanding of how this partnership supports their goals. The NSF S-STEM program has been an important component in developing a program for students who may not have considered Texas A&M University or an engineering degree within their reach.

Abstract - Projections indicate that video will be responsible for 90% of network traffic until the end of the decade. Considering the high cost of media production and, mainly, the high consumption of network resources for applications that explore it, it will be extremely important to monitor such use, preventing against wrong or distorted views of this consumption. Within this scenario, it is necessary to develop mechanisms and tools that provide a clear vision of video effectiveness consumption, as well as the measuring of "viewer engagement". What tools can be developed to evaluate such consumption? What should be measured, i.e., which are the parameters and metrics necessary, and how can we obtain them, in order to measure the effectiveness of video applications use, for example in engineering courses and distance learning environments? These are some of the questions considered in this paper, especially evaluated within a scenario of video usage for teaching/learning purpose.

Keywords - video delivery, viewer engagement, distance learning.

I. INTRODUCTION

Many systems are designed to provide educational materials in video format for distance learning environments, as well as support material and learning material. The production of these videos requires a sophisticated infrastructure and a team to manage the entire process: the recording of videos, their edition, and the delivery process. Given the fact that this process requires time and an expensive production, it is important for educational institutions to assess the real benefits of using video in teaching and learning environments.

Statistical surveys show the increase in use of Web videos for multiple purposes, whether for entertainment, information dissemination, education or training. In addition, prospective studies indicate that such use will continue to grow, reaching much higher numbers than the bandwidth occupied by the transmission of data at the end of this decade. [1].

In this context of strong growth in video consumption it is necessary to develop mechanisms and tools that can measure the real use of video streams. For this purpose, the monitoring of the following is considered:

- **Video transmission:** In order to understand precisely which requests are met and for how long they are met. Often, when a video is requested, one session is established, but for a momentary network problem, the video stream may not be received by the requester, who will then place his or her request once again. **If the transmission** system uses the number of sessions to account for its cargo of use, there will be a misjudgment. In other situations, the video may have been only reproduced partially, because the user has closed the connection. Also, being aware of the quality of service (QoS) transmission [16], such as delay, delay variation (jitter), and bandwidth consumed, is relevant to the operation and maintenance of the transmission network. All these situations need to be planned in order to get a closer view of the video quality users are receiving.
- **Video Reproduction:** In this area it is important to evaluate video stream reproduction, which can be influenced by different factors, as it may have different users' QoE (Quality of Experience) [16], and consequently the levels of engagement with the content ("viewer engagement") [15] [12] may vary. To estimate such subjective parameters, we can evaluate for example, the quality of the playback video (using the comparison of signal to noise ratio, NSR, the original video with the video received), the degree of user satisfaction, or user behavior during reproduction.
- **Absorption of the video content:** We wish to evaluate the degree of absorption of knowledge through this media consumption, as well as engagement with the subject. The concept of "viewer engagement" can be used in many ways, considering aspects such as usage scenario, age, or user's cognitive characteristics, or by verifying the degree

of involvement, using interactive tools and social networks to disseminate information or feelings about watching the video. In our case, we are more focused on education scenarios, with engineering and computer students. Considering this, one possibility is to compare students' opinion about a video explanation, for instance, and their results in formal evaluation.

Different scenarios may require distinct techniques to assess the quality of video streams and extent of absorption of video contents. Educational scenarios demand different assessment techniques from those used in commercial environments. Likewise, the metrics for evaluating the level of information comprehension may also be different. For example: in producing a marketing video, an advertising campaign of a particular company often makes use of techniques to increase the viewer's attention, where one possibility is to increase the frequency of changing scenes, [13] and this strategy may not be effective in educational environments. In marketing field the effectiveness of a visual element used can be measured by the growth of sales. For a movie, the producer can measure its acceptance by verifying ticket sales.

In the learning process, the effect of audiovisual content should be measured considering the degree of absorption and the ability to address issues related to the object of study. Distinctions can be considered when the public belongs to different age or social groups, because the cognitive perception and interpretation of information may vary depending on age and environment [11].

Some research shows that video use in teaching can be as effective as a live class, reaching satisfactory educational goals when the involvement and motivation are maintained [9] [10]. In this sense, it is extremely important for an educator to have reliable information regarding student's involvement, in a way that it will be possible for him/her to trace a connection between said involvement and student's performance.

This shows that necessary definitions must be established in order to provide actions that can develop content more aligned to student's expectations and cognitive profiles, thus improving knowledge absorption and making learning activities more attractive and thus more efficient. Furthermore the results of such evaluation will allow educational institutions to plan the financial and technological infrastructure necessary for the delivery of educational materials. Therefore, in order to obtain these parameters it is necessary to define appropriate metrics with which to measure them [14] [15].

II. RELATED WORK

Projections indicate that by 2012, video use will represent half the consumption of network in the world, already surpassing the P2P traffic, currently the most responsible for network traffic. By the end of the decade, projections indicate that this percentage will fit about 90% of the network bandwidth [1].

Currently, connected TV content providers invest many resources in mechanisms that capture information from viewers, developing applications that encourage them to provide more information about their characteristics, preferences and opinions. From there, databases are built in order to carry out various analyses, which should give the advertisers the necessary feedback in order to direct programming to the user's interest. [6].

Another important concern of advertising professionals is the use of new rich media, to ensure awareness among new generations. However, there is some concern about the lack of consistent metrics to gauge the ROI (return on investment) for investment in the development, production and dissemination of media [7].

On the other hand, based on usage statistics mentioned above, this idea of measuring the impact and ROI of media can be extended to other scenarios where it is also important to check user's interest and engagement in the content offered. We can, for example, use the same for educational environments, or distribution systems or even web video IPTVs. This concept can also assist in the operation and maintenance of network infrastructures, to verify the effectiveness of video consumption, and consequently the consumption of network resources.

So far, few academic papers in monitoring and evaluating video consumption field have been published. Studies found, which will be discussed below, can be classified into: studies on cognitive engagement in TV ratings, user engagement with the consumption of Web videos, and videos using the method of teaching / learning.

In television, Smith [12] makes a study of viewer's involvement and interest with respect to the dynamism of a scene, showing that the increased frequency of changing scenes and semantic association with humorous or unexpected elements, activate cognitive engagement. This study considers the influence of alpha waves and their role in the brain region which processes visual functions. Liebes [13] categorized spectator's involvement with soap operas, and concluded that relating to a character of the plot leads to a greater interest in the show. Sawahate [16] developed another study focused on evaluating TV cameras, used to detect eye-gaze in order to measure viewer's engagement with the content offered and correlate it with the absorption of knowledge. Milliken [14] studies the potential of UGOV (User-Generated Online Video) tool, which allows video generation. These videos are posted on YouTube to check the contribution of regional identity in their consumption, level of involvement and engagement of Internet users. Engagement, in this case, is measured using a questionnaire that includes, for example, questions about frequency of application use, how much a user learned, how a particular video changed user's opinion on a particular subject, and how many comments posted on social networks were related to the concerned video.

In another study, conducted by Bardzell [15], physiological measures, such as heart rate and respiration per minute, were used to measure the emotions caused by the most

popular videos. They also used strategies such as emotional **tag** (user indicates their emotional state by choosing emoticons), space for adding a text review and logging the user actions with respect to the video (pause, stop, browse the timeline of video (seek), etc.). The work uses triangulation to analyze results obtained, crossing information, relating them to perception and emotional experience, preferably video, as well as contextual factors.

Another work that deserves attention, as it deals with an educational context, is the article written by a group at Microsoft Research. The article's aim is to test the effectiveness of a video annotation tool, which provides video and synchronized slides, and space to include participation textual support [9]. The tool was tested for learning purposes in group work, and also with individuals, showing that there was excellent absorption of educational content with its use. Another study presents a tool that defines the best place to put ads in a video [3]. The evaluation was done subjectively, using as parameters the relevance of the site, comfortability and user satisfaction.

III. REQUIREMENTS

The functional requirements which direct all activities considered within the scope of the project are:

- Data collection: providing mechanisms that enable the collection of information from different data sources (such as data servers, transmitters, applications, video players);
- Reception and data persistence: receiving the information collected and persisting it properly so it can be analyzed;
- Analysis: providing mechanisms that enable the analysis of collected data, extracting information that can be used to improve video distribution service, the application that makes use of this service, or even the production of content.

A. Technical Requirements

Among the technical requirements we can enumerate:

- Technological Independence: The goal is to enable the collection of information from video distribution systems. The service must be as independent as possible from the technologies used in the elements to be monitored;
- Weak coupling: The service must be easily integrated into applications to be monitored, in order to facilitate their use;
- Scalable: The service must be scalable to meet growing demands for monitoring;
- Flexibility: It should support the monitoring of any parameter, enabling different scenarios and meeting different interests.
- This will allow the service to be used in contexts and scenarios not originally provided,

enabling high reuse;

- Modular architecture: it must be based on layers with well-defined roles, thus facilitating the service operation and maintenance. That is, a module can be improved or changed without affecting the other modules.
- Insurance: Mechanisms that ensure protection from improper actions against the service should be provided.

B. Premises

The following assumptions are being considered in the project:

- Designing a comprehensive model: In the design process, create a solution that addresses the requirements presented in the best way possible. The goal is to specify a complete monitoring and analysis, that goes beyond not only the prototype to be designed, but also the original purpose of the project. Several other usage scenarios could be explored. For example, adding data mining tools, which will allow the verification of trends or usage pattern behavior in a given video application. Another example is: from the tools implemented we may identify, for instance, that a certain group of people tends to be more interested in a topic-specific knowledge. Another possibility of use would be to incorporate geolocation tools to extract regional behaviors, such as concentration of users of a particular video service in a specific region.
- Prototype Development: the prototype will be developed to meet as many requirements as possible. Initially, the focus will be on features that make up the core of the service, then the service will be extended gradually, through improvements and developments of each of the modules in the system.

These requirements and premises are based on the high video exposure, which brings forth the effectiveness of this consumption. The idea is that the greater the possibility of interaction with the video element, as well as with other tools (social community and evaluation, for example), the better we can monitor these actions, based on the video application, service and software components, allowing the measurement of the engagement, ie, the consumption effectiveness. This idea is illustrated in figure 1.

IV. PARAMETERS AND METRICS

In order to allow the video engagement assess, it is necessary to monitor user interaction with the video application. We

consider four groups of parameters, indicated with the following metrics:

Transmission Parameters - Monitored based on the video transmitter usage:

- Delay;
- Jitter;
- Bandwidth consumed;
- Number of open sessions;
- Percentage of CPU used.

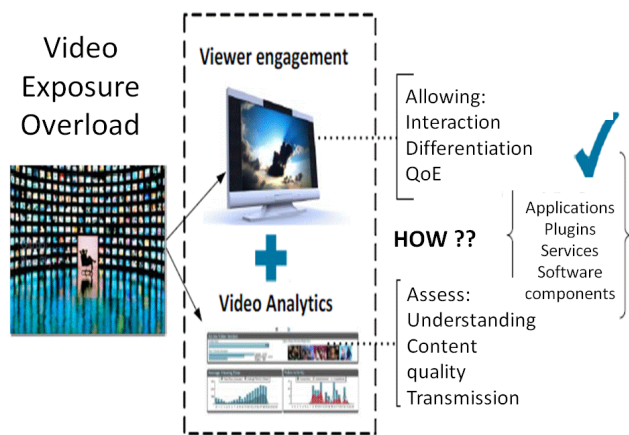

Figure 1: Framework for video applications

Video Player Parameters – monitored based on user interaction with video player:

- Mouse actions;
- Windows focus;
- Pause, fast forward, rewind
- Use of Comments tool;
- Interaction with social network tools (facebook, twitter).

QoE – check the level of user satisfaction proposing a poll;

- Related to video content quality;
- Related to video quality;
- Related to transmission quality.

Content Absorption – check how much user has learned watching video content:

- Evaluation based on test learning validation;
- Other activities to check content absorption (debates, work groups, etc).

V. SYSTEM DESING

With these parameters and metrics in mind, it was possible to design a monitoring system, which is composed by 4 modules, as showed in figure 2.

- Server module: monitors the metrics related to server;
- Application Module: responsible for metrics related to user interaction with application;

- QoE and Content Absorption Module: records the QoE and content absorption's assessment score;
- Report Module: responsible for the use of the data obtained, crossing it to allow proper result analysis.

As the purpose of this system is to monitor the learning actions and check the student's engagement to consume a video element, we chose to integrate the monitoring module to a system of teaching/learning, as LMS (Learning Manager System). Thus, we can join quickly and easily the video element to a course material, and monitor the student interactions.

Although monitoring modules are independent from any system, we choose Tidia-Ae LMS [17] to integrate QoE and Content Absorption Module, in order to build a learning context.

The video server used is VIUSP, a software for video distribution, developed in University of Sao Paulo, where monitoring server module was coupled. To implement the application module, we used a video player based on jwplayer [18], through which monitoring functionality was developed. PostgreSQL v.9, was used as database, and the framework Pentaho (Open Source Business Intelligence), which allows data manipulation and plotting graphics (like Cartesian, pie and bars), as well as data tabulation, was used to implement the Report Module.

The diagram in figure 2 show the system overview and its modules, focusing on the communication flow, where solid lines indicate the request between user desktop/LMS and LMS/Video Server; the dashed line indicates the video streaming from video server to user desktop or device and the dotted line represents monitoring of data persistence in database.

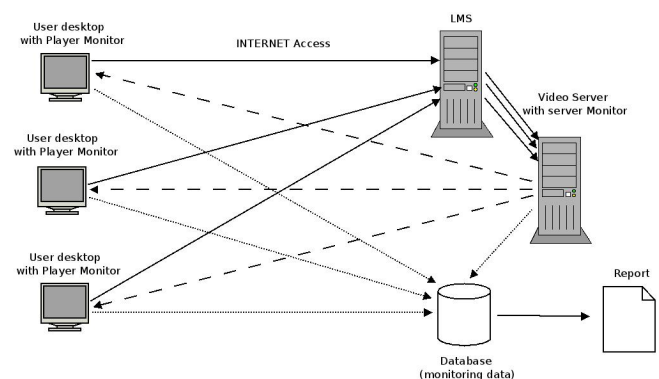

Figure 2: System overview with communication between modules indicated.

Figure 3 shows the interface of the LMS integrated with the monitoring modules. In this screen it is possible to see the video player, the text box for comments, the facebook and twitter icons, the stars that allow classification of video quality

(and consequently transmission quality), and finally, next to the video player, the tests to assess content absorption.

Figure 3: Shot screen of LMS integrated to monitoring modules

VI. USAGE SCENARIO

When a user accesses a video he/she can interact with it in different ways: evaluating it using tools provided in the application interface (chat, forum), commenting on it (by blogging, writing in a wiki or publishing comments in a public site), as well as sharing it in social networks. In addition, the user can be asked to answer several types of polls and tests about the watched video.

The use of video application to support the learning process is being considered as a baseline to guide the project development. We understand the potential of using video in this type of scenario and see that the goal is to design a monitoring service to assess the benefits of using video in this context.

Besides trying to measure how much the videos help in the learning process, we aim to enable the service to extract various other important informations, such as quality of content, level of effectiveness of a particular video on learning a specific concept, and the level of student interest in the subject.

In order to evaluate the service being developed, first we must create the following test scenario:

- Use of two groups of students. For the first group, class material will be available on video as supporting content. For the second group, this video material is not available, thus serving as a control group for testing.
- For the team using the video material, the assessment of student awareness and engagement with regard to the material will be made through a set of subjective questions, for example:
 - Evaluating the perception:
 - Overall: excellent, good, indifferent, bad, very

- bad;
 - Understanding of content: it helped a lot, helped, indifferent / did not help, made me confused.
- Evaluating the engagement:
 - Through comments made about the video;
 - Through the sharing / recommendation of the video.

Figure 4 illustrates the usage scenario.

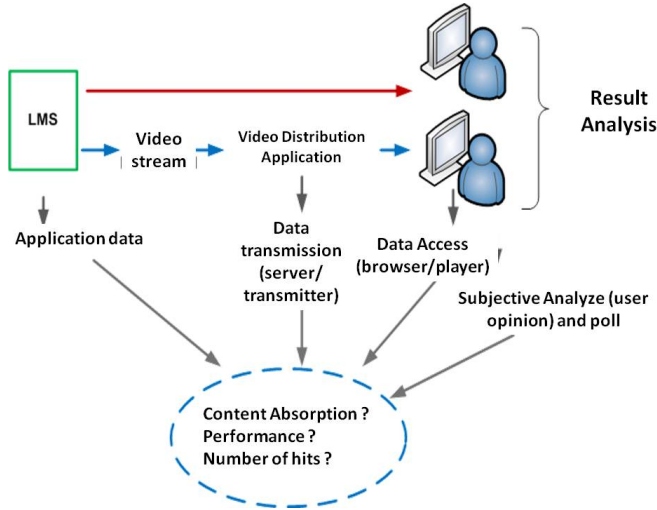

Figure 4: Learning scenario of system use

After the tests, based on the average score of each team and within the group that received the video as learning support , the variation of the grades will depend on the level of subjective evaluation, combined with evaluation of technical parameters collected (If the student had trouble watching the video due to a long buffering time or transmitter overload, for example, if he or she has watched all the content or not, interacted with the content by making a comment or engaging in video sharing/recommending)

Then, the final score of each group will be compared and analyzed, and within the group which received the video material, specific parameters will be created for the evaluations, such as the variation of grades depending on the subjective evaluation questionnaire that each student has answered. Adding to this, the technical data collected (directly related to the reception quality of the user), will also be considered. For example: difficulty in watching the video due to problems arising from the user's network infrastructure, the video application, network video transmitters, as well as analysing whether the user has watched the video in its entirety or only partially, written comments or recommended the content in any way. Thus we have a complete analysis of the user experience quality and how these factors affect student performance.

From this scenario it will be possible not only to assess the potential of the service, but also to allow extraction of information that may be useful to improve the attractiveness of the videos and content, or make it possible to adapt the content (for example, videos should not last longer than a certain time, or the absorption level drops) These are just some examples of analysis that could be made from the data collected.

VII. PRELIMINARY RESULTS

With the first tests using the monitoring system, we were able to verify its potential and observe that:

- Different generations have different interaction profiles with video application;
- Low quality video and network transmission problems discourage the student to use this material;
- Long videos discourage the students in watching them thoroughly.

Of course these observations are only preliminary, and not conclusive. During the next months, we will be working in the continuity of the tests, applying the usage scenario described above.

VIII. CONCLUSIONS AND FUTURE WORK

As presented in this paper, video consumption tends to grow in coming years and it will be increasingly important for institutions that produce and use videos in their core activities, to have metrics and parameters with which to scale the physical infrastructure and human resources needed for such use. At the same time, it becomes increasingly imperative to know the validity and effectiveness of using this type of media. Especially in teaching and learning activities, it is very important to be able to assess how much knowledge a particular material in video format was effective in building, considering a student or group of students. In engineering courses and computer courses, besides being able to offer a didactic content of a concept in a video format, it is possible to offer recorded experiments. This, of course, does not present the same didactic purpose as that achieved if a student got to perform this experiment him or herself, but can in some cases (in which this possibility does not exist), help them better visualize concepts and practices. Given these facts, it is very important to have metrics to evaluate the effectiveness of this material. We have made some preliminary tests which showed that use of video among younger students is effective. However, this kind of material requires a proper use, in order to maintain student's interest and attention. We continue

making our experiments to observe what is the best way to use video content in our engineering and computer courses.

ACKNOWLEDGMENT

This project and research has been supported by the RNP - Rede Nacional de Ensino e Pesquisa (Brazil) in the context of the work group GT-IMAV, which we would like to thank. We would also like to thank the research team: Lucas Chigami, Helcio Pimentel, Waleska da Silva e Adriano Adoryan.

Abstract— Knowledge Management (KM) is a new, evolving computing paradigm based on a collection of processes that govern the creation, dissemination, and utilization of knowledge. We present and discuss a novel method, Systematic Knowledge Pattern (SKP), based on utilizing innovative computing tools for teaching KM. The SKP builds on powerful computing tools employing generic logic-based problem-solving methods that provide an insight into and an understanding of common problems and knowledge processes in any area of KM. The method combines disciplinary principles, a pedagogical approach based on utilizing pedagogical patterns, and intelligent use of technology. We discuss pedagogical aspects of utilizing the method and how it can be specifically adapted to teach KM to high-school students.

Keywords- Knowledge Management, high school curriculum, knowledge pattern, pedagogical pattern, innovative computing tools

I. INTRODUCTION

Knowledge Management (KM) is a new, evolving computing paradigm based on the collection of methods and processes that govern the creation, dissemination, and utilization of knowledge [3]; it is an assortment of techniques for representing and managing codified knowledge. The field has emerged from a number of areas in computer science, notably, artificial intelligence, databases, software engineering, and information systems [11]. Researchers and practitioners in the field usually have extensive formal education in computer science/information sciences. They are involved in constructing information management systems, intelligent systems, reengineering, groupware, etc. To them, knowledge means objects that can be identified, handled, and used in knowledge systems. The objects are created and presented in terms of knowledge patterns, and processed using innovative computing tools.

Teaching KM, especially since it is a young discipline, is challenging to computing educators. Teaching and related learning strategies involve solving typical KM problems, designing systems, and understanding human behavior. Teaching should be planned to develop students' abstraction abilities and their computational thinking [17]. Since KM deals with the creation, dissemination, and utilization of knowledge, which is a complex ongoing task usually performed by a group of people, it is important to emphasize

to students the collaborative aspect of distributed and shared knowledge, using a collaborative learning approach.

The next sections of this paper relate to a novel method, based on utilizing innovative computing tools for teaching collaborative knowledge in the KM area. The first section presents the essence of KM and presents the concept of Knowledge Pattern. In the second section we discuss challenges in teaching KM and refer to the Information and Knowledge Systems (IKS) course. Thereafter we present the Systematic Knowledge Pattern (SKP), and discuss pedagogical aspects of employing it for teaching KM.

II. WHAT IS KNOWLEDGE MANAGEMENT?

Knowledge Management consists of a range of strategies and practices used in an organization to identify, create, represent, distribute, and enable adoption of insights and experiences. Such insights and experiences comprise knowledge, either embodied in individuals or embedded in organizations as processes or practices [10][11]. Knowledge management efforts typically focus on organizational objectives such as improved performance, competitive advantage, innovation, the sharing of lessons learned, integration, and continuous improvement of the organization. Business organizations are continually developing and implementing a variety of techniques and information technologies to enhance knowledge management. Knowledge management efforts overlap with organizational learning. They may be distinguished from the latter by their greater focus on the management of knowledge as a strategic asset and an emphasis on encouraging the sharing of knowledge. Knowledge management addresses the lack of sharing knowledge among members of organizations by encouraging individuals to make their knowledge explicit by creating knowledge elements, which can be stored in knowledge bases for later reuse or for participating in communities of practice [11]. Knowledge in organizations has the following components:

1. *Knowledge about customers*- the most vital knowledge in most organizations.
2. *Knowledge about Processes*- applying the best know-how while performing core tasks.

3. *Knowledge about Products and Services*- smarter solutions, customized to users' needs.
4. *Individual Knowledge*- experience and creativity of individuals in the origination.
5. *Collaborative knowledge*- collaborative information shared by several departments in the organization.
6. *Organizational insight*- insight databases that include implicit and deduced knowledge about the organization.

A. Knowledge patterns

Knowledge is one of the most important assets for any organization, and for all areas of science [9]. Whereas experience describes events in one specific context that can only be reused carefully, knowledge is usually applicable in previously unknown contexts with a fair amount of certainty [13]. The concept of knowledge patterns can be used to support practitioners and researchers in their knowledge management activities. Knowledge patterns share one way to formalize and describe lessons learned and best practices (i.e. proven experiences) about structuring knowledge, the design of KM systems, or the development of underlying ontologies. Such patterns capture aspects that positively or negatively influence the KM activities. A knowledge pattern is a general, proven, and beneficial solution to a common, recurring problem in knowledge design, i.e. the structuring and composition of the knowledge, defining metadata (information about information) and potential relationships between knowledge components [13]. The basic structure of a knowledge pattern is as follows:

Name: What is the pattern called?
Issue: What is the issue (e.g., problem) addressed by this pattern?
Q-Effect: What "knowledge quality aspects" are mostly affected by this pattern? This section clearly states whether there is a positive, negative, or neutral effect.
Solution: What suitable solutions underlie this pattern? Multiple alternative solutions may be suggested.
Causes: What are the basic causes of this pattern?

Patterns may include additional information entities such as context, examples, anecdotal evidence, or exceptions. Knowledge patterns may refer to knowledge components of an organization, as well as to semantic relations between knowledge components. The following are examples of knowledge patterns that deal with problems related to the main process in different departments: (a) the annual budget in a financial department, and (b) customer complaints in a customer service department.

Example 1:

Name: Exception in the annual budget

Issue: Exception in the annual budget issue, exception in the wages of workers in the year 2010.

Q-Effect: Wastefulness of resources.

Solution: Increasing efficiency in the work shifts, building worker profiles, incompatible workers, specialization and combining the workers in courses, and outsourcing.

Causes: Increasing earnings and employing professionals.

Example2:

Name: Faults in the customer service based on the customers' complaints.

Issue: Customers' complaints are not closed and untreated in time.

Q-Effect: Loss of existing and potential customers.

Solution: Constructing a warning system that will alert one about untreated complaints in time, and will set a time limit for making complaints.

Causes: Tunneling processes in organizations, ignorance toward an existing complaint.

III. TEACHING KNOWLEDGE MANAGEMENT

A. The Information and Knowledge Systems curriculum

The curriculum Information and Knowledge Systems (IKS) [8] was developed in Israel (2003) for high school students with average skills and achievements who might not be able to succeed in an academic study track, yet can manage to graduate in a low-level technological study track. Regarding computing studies, although above average students would usually prefer to major in computer science in the academic track [5] or in software engineering in the high-technological study track [6], average achievers may benefit more from learning how to use fluently and reflectively innovative computing tools to create and process knowledge.

The IKS curriculum integrates the area of Knowledge Management in business organizations. It deals with methods of production, collection, organization and processing storage and focuses on processes and assembling insights that derive from real problems. The curriculum deals with collaborative information and knowledge processes that investigate the nature of information and information processes [8]. The IKS curriculum derives its origins from the scientific paradigm of the future, which was suggested by Dyson [4]. Dyson distinguished between a paradigm of concepts and a paradigm of tools and asserted that tools may manufacture conceptions and not only vice versa. As an example of this trend, he described the personal computer as a technological tool that shaped the most important theories of the beginning of the 21st century [4]. A few years later, the authors of the *Science 2020 Report* [16] stated a similar vision regarding the ongoing influence of the development of computing technology regarding the way scientists perform science: "*Conceptual and technological tools developed within computer science are...starting to have wide-ranging applications outside the subject in which they originated, especially in sciences investigating complex systems*" [16, p. 8]. In particular, "*Scientific computing platforms and infrastructure are making possible new kinds of experiments that would have been impossible to conduct only 10 years ago, changing the way scientist do science.*" [16, p. 14]. In the context of knowledge management, innovative computing tools enable one to define

new methodologies for dealing with explicit, implicit, and distributed knowledge embedded in complex organizations. Based on the aforementioned ideas, the IKS curriculum enables the students to learn the essence of knowledge and knowledge management through the use of innovative computing tools. The curriculum intends to promote real-life insights by means of information, technological tools, as well as information and communication technology using the internet, sites and portals. Teaching IKS requires guiding the students in performing a continuous knowledge management process (KMP) aimed at collecting and processing knowledge about a chosen organization [9].

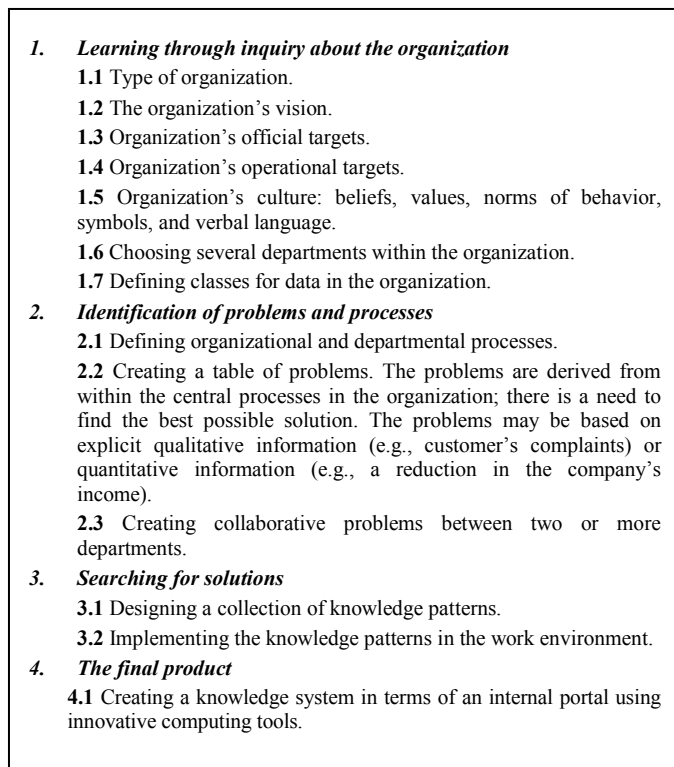

Figure. Stages of the Knowledge Management Process (KMP)

The final product of the course is an internal information business portal used as a major gateway to all enterprise resources. The portal provides information needs that are common to all the employees in the organization, such as information about the organizational structure, human resources, professional units, service units, phonebook, products, payroll, attendance, professional information, social services, bulletin board for employees, as well as integration of advanced services such as computer forms, queries, and access to personal information. Knowledge components tools assist to create the portal such as database management, SQL queries, blogs, wiki, surveys, document management, protocol of meetings, and subject trees.

B. Challenges in Teaching KM

Problem-solving processes in the KM area require abstract thinking and integrating: understanding the problem, acquiring relevant information and using tools effectively and wisely.

Combining these levels might be difficult for average students. Specifically, learning fundamentals of KM require students to develop and use skills related to various aspects of knowledge:

- (a) *Explicit knowledge*: Emerging assumptions; codifying known knowledge (information);
- (b) *Systematic and reflective processing*: Finding implicit knowledge by repetition;
- (c) *Differentiating vital knowledge*: Abstracting and focusing on the main issues;
- (d) *Sharing knowledge*: Sharing distributed knowledge and integrating it into a deduced (implicit) knowledge base to obtain insights about the organization; and
- (e) *Smart use*: Using innovative tools in an intelligent way.

These skills are required for understanding the essence of KM and for internalizing knowledge patterns discussed in class. Average students might have difficulties in comprehending the complexity of knowledge and the compound structure of an abstract problem.

These considerations motivated the first author, who is a leading teacher, to develop a suitable pedagogical approach for teaching the IKS course to students with average achievements and to establish a culture of building collaborative knowledge in class. Long-term teaching experience with average students motivated her to find ways to trigger changes in the students' approach to KM problems while gradually developing their aforementioned required skills and enhancing their problem-solving methods. This was basically obtained through reflection and investigation of different teaching methods. The outcome of this informal action research process was an innovative approach to teach KM, which builds on the power of innovative computing tools, and combines disciplinary principles, pedagogical tools, and intelligent use of technology.

IV. THE PEDAGOGICAL APPROACH

We suggest a pedagogical tool that combines three main components: (a) disciplinary (KM) knowledge, (b) innovative computing tools, and (c) pedagogical approach based on utilizing pedagogical patterns [1][2][15]. The tool, called Systematic Knowledge Pattern (SKP), features a new style of teaching and learning; it enables students to systematically organize and process explicit and implicit knowledge, and eventually to create collaborative collections of knowledge patterns for a variety of organization-related problems [13].

A. The Systematic Knowledge Pattern (SKP) model

The SKP model leads to a variety of expected solutions, and the inference of insights related to organizations. SKP attempts to provide an easy way to answer questions such as the following: What is knowledge? How to produce knowledge? How can knowledge be presented and shared in organizations? How can implicit information be retrieved from an organization? And how can the explicit information be organized in an organization?

The SKP model is organized basically as a linear process composed of components marked A-H executed in alphabetic order (Figure 2), but pragmatically, it supports an iterative

back-and-forth process owing to the possible discovery or emergence of new problems, or as a result of refining already identified problems (components E, E1 in Figure 1).

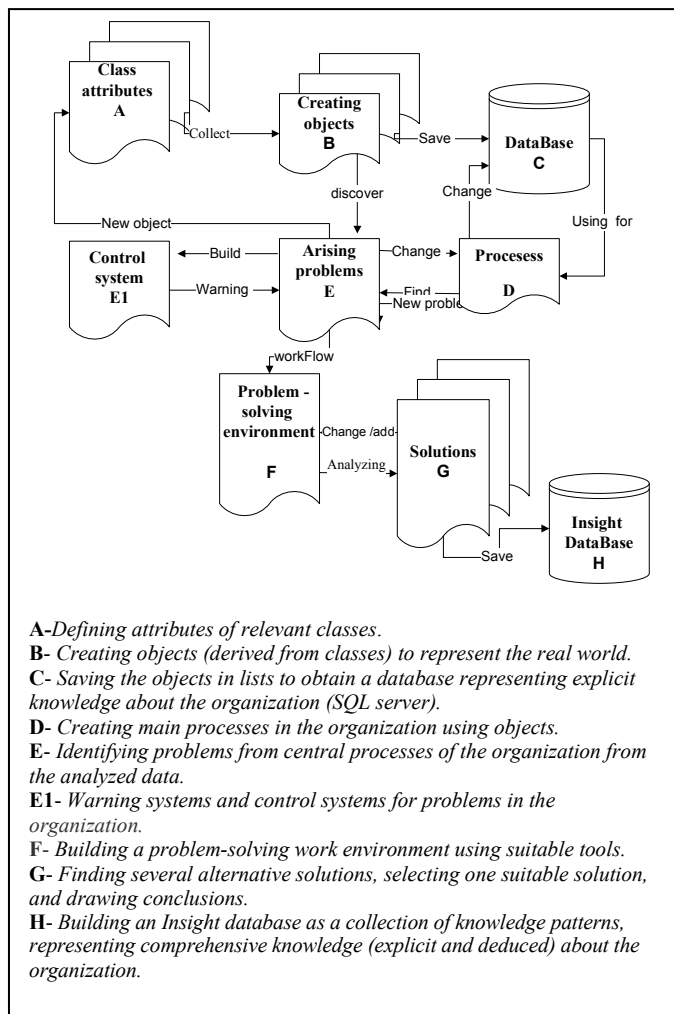

Figure 2. The Systematic Knowledge Pattern (SKP)

The SKP builds on powerful computing tools employing generic logic-based problem-solving methods that provide an insight into and an understanding of common problems and knowledge processes in any area of KM. The tools enable one to create: (a) knowledge patterns (suitable solutions for identified problems) and (b) deduced insight knowledge bases related to specific organizations. The tools support collaborative work of the students. Using tools that include components such as survey, blogs, wiki, discussions, meetings, queries, lists, and web parts, and workflows (an environment for describing knowledge patterns) enable the students to capture relevant information and to organize it in the form of knowledge patterns, thus showing suitable solutions for the identified problems. Without using such tools the student could not possibly present knowledge patterns and preserve the deduced personal knowledge.

Using SKP help the student to build a collection of insights and then translate the possible solution to a work environment. For example, a final product can be a working environment (workflow) for finding solutions. The workflow is a collection of information and knowledge tools including discussions, documents, lists, queries, surveys, and documents of conclusions, and a list of knowledge patterns.

Microsoft SharePoint 2010 [14] is a collection of tools that enable one to create sites, insights, contents, and communities. It also includes a built-in search engine. It is an example of an innovative tool for implementing computerized knowledge management processing. The tool supports collaborative working, and thus could be used for collaborative learning. Students can set up web sites to share information with others, manage documents from start to finish, and publish reports to help everyone make better decisions. The above-mentioned characteristics of Microsoft SharePoint 2010 led us to choose it as a suitable environment for teaching the IKS course. Actually, the computerized tool shaped The SKP model. Each component of the SKP is implemented using corresponding components of the computerized tool.

The SKP method suggests collaborative learning in a situation in which two or more students attempt to learn something together via a knowledge system (e.g. a portal). We believe that collaborative learning that combines pedagogic strategies with advanced technological tools can promote students' learning and their problem-solving performance. Specifically, knowledge can be attained within the class where members actively interact by sharing experiences, solving problems and better understanding processes in any area of Knowledge Management.

B. Utilizing SKP to teach KM processes

Table I describes how the components of the SKP (Figure 2) relate to corresponding stages in the knowledge management process (KMP) (Figure1).

An example of utilizing SKP in class: OSEM is one of the largest food manufacturers and distributors in Israel. We demonstrate in Table II the knowledge management process (KMP) that students should perform related to the company.

TABLE I. SKP COMPONENTS-KMP STAGES

| SKP Components | Stages of KM process |
|--------------------|--|
| A, B, C | 1.7 - Defining classes for data in the organization. |
| D, E, E1(optional) | 2.1 Defining organizational and departmental processes. 2.2 Creating a table of problems. 2.3 Creating collaborative problem between two or more departments. |
| F, G, H | 3.1 Designing a collection of knowledge patterns. 3.2 Implementing the knowledge patterns into the work environment. 4.1 Creating a knowledge system in terms of an internal portal. |

TABLE II. THE ACTUAL KMP RELATED TO OSEM

| KMP stages | SKP comp. | The actual KMP related to OSEM |
|------------|-----------|--|
| 1.1-1.5 | | Collecting information about the organization. |
| 1.6 | | Choosing departments: Financial department and client service department. |
| 1.7 | A,B,C | Classes: Client, Budget |
| 2.1 | D | Central processes - Annual budget, client complaints. |
| 2.2-2.3 | E | <p>Problem: Increase in the anomalies of the annual budget in the year 2010.</p> <p>Presenting the problem as a knowledge pattern:</p> <p>Name: Anomalies in the annual budget</p> <p>Issue: Finding the reason for the anomalies in the 2010 budget.</p> <p>Q-Effect: Waste of resources, the creation of inefficient processing in the system.</p> <p>Solution: Building a list of objects of the annual budget for 2010. Querying, excel pivots, looking for exceptional factors, building a presentation for the solution. Meeting for decisions regarding managers, departments, documents.</p> <p>Causes: Increased earnings and employing professionals.</p> |
| 3.1 | F | Construction of an environment that solves the problem. |
| 3.2 | G | Creating solutions with technological tools in the above environment, for example: querying for making management decisions, pivots in Excel, graphs, web parts. |
| 3.3 | H | Preserving solutions in the insight database. |

C. Integrating Pedagogical Patterns into the SKP model

Pedagogical patterns are intended to capture the expert knowledge of the practice of teaching and transfer that knowledge to others [www.pedagogicalpatterns.org]. They do not, however, express new pedagogical ideas, but rather, the tried and proven solutions for pedagogical problems. Communities such as the Pedagogical Patterns Project [15] have been collecting many types of patterns that can help teachers teach and students learn. Educators consider pedagogical patterns as suitable tools to document the successes of pedagogical frameworks in order to enable their reuse [7].

We decided to utilize several pedagogical patterns, some of them were originally were designed to teach computer science, and to integrate their principles into the SKP disciplinary model in order to teach knowledge management processes as follows:

Pedagogical pattern - Explore for Yourself

A person's success is based mainly on her ability to learn new concepts efficiently and to act as a team player by sharing knowledge and insights [1].

Using for SKP- Innovative KM tools are very user-friendly for the students; they give immediate feedback and thus support learning. Feedback increases the students' confidence, and encourages them to take responsibility for the learning process. Use of SKP enables the students to explore their abilities, inspires them to search for new solutions, and supports internalization of knowledge.

Pedagogical pattern – Role Play

The complexity of some concepts makes them hard to understand with only abstract explanations. Furthermore, difficulties in understanding complex concepts may frustrate the students [1].

Using for SKP - The SKP model has several components and is suitable for collaborative learning. A group of students who are working on a project divide the missions and take responsibility for each mission; this may reduce the complexity. Innovative KM tools make abstract problems and solutions more concrete. From the collaborative point of view, competition from different teams can be performed, where the team playing will be observed by the other teams.

Pedagogical pattern - Different Approaches

Every person obtains information differently, using different approaches to the same topic [1].

Using for SKP - The SKP model enables students to find solutions in different ways. The SKP is a non-linear model. Each student can use a variety of tools to capture knowledge and build some possible solutions such as an alert system, workspaces for decisions, workspaces for documents, workspaces for social events, blog, a publishing site with workflow, and more.

Pedagogical pattern - Test tube

Students are often naive about what resources are available to them. They often ask questions they could answer by themselves. While this is not bad in itself, they would be happy to know they can find their own answers quickly. Students need to learn to be effective in answering their own questions [2]. When students encounter holes in their knowledge, we would like for them to seek out an answer. Unfortunately, students often resort immediately to the "easy fix" of asking an authority for the answer [2].

Using for SKP - Students are often afraid of taking responsibility for their own learning. Searching for solutions by using KM tools (e.g., search engines) may reinforce students' independence and motivate them to find the answer on their own. The tools provide independent research for self-control. Self-control navigates the student to higher level of independent thinking for finding alternative solutions for a problem.

Pedagogical pattern - Toolbox

Let students build a tool kit in early courses for use in later courses. If well-thought out and implemented, it can be a wonderful guide to reusable software... Having a personal tool kit of reusable software components can be a wonderful help in a difficult project [2].

Using for SKP - The KM tools enable students to develop a collection of methods for solving a problem, and to accomplish a complex project effectively.

V. IMPLEMENTATION

The curriculum Information and Knowledge Systems (IKS) was developed in 2003 and has been gradually implemented since then at Israeli high schools. For the last 4 years the number of schools which choose to teach the IKS course has significantly increased. During the last academic year the IKS course was taught in 50 schools, 1-2 classes in a school, and 20-30 students in a class. The students developed final projects (an internal information business portal related to some organization) which were evaluated by external examiners, especially nominated for this task by the Ministry of Education.

During the last academic year, the SKP model was utilized to teach the IKS course to a class of twenty high school students. We conducted a pilot study aimed to check the effect of utilizing SKP on students' perception of the concept of knowledge. The students were asked to answer an open questionnaire (same, Pre and Post) that related to the essence of knowledge and basic information (data). The findings indicated that before studying the course most students could not distinguish between knowledge and data, and could not explain the difference between acquiring and using knowledge. After the course the situation was significantly different. Students grasped *knowledge* as a complex collection of inferred insights and could distinguish implicit *knowledge* from explicit *information*. Interestingly, even though students used computerized tools to deduce knowledge, they related *knowledge* to human inference processes, acquired by people (stored and processed in their brains), whereas *information* was perceived as "external" and tangible presentation of data, usually expressed in terms of computerized tools. From empirical evidence, we got the impression that after students have gained experience in building knowledge systems utilizing the SKP approach, they could more easily grasp the essence of collaborative knowledge. We further plan to conduct a comprehensive study aimed at classifying students' knowledge management processes, as well as their perception of KM concepts. Specifically, it would be interesting to investigate if and how students use computerized tools in an intelligent way to deduce new knowledge from already gained knowledge, and the way they collaborate to obtain distributed and shared knowledge.

VI. CONCLUDING REMARKS

Knowledge Management is an evolving computing paradigm based on a collection of methods and processes that govern the creation, dissemination, and utilization of knowledge. We presented here the Systematic Knowledge Pattern (SKP) based on utilizing innovative technology tools for teaching collaborative knowledge organization and processing. The tool was adapted to teach the *Information and Knowledge Systems* course to high school students with average achievements. Combining tools that create knowledge and build knowledge systematically by listing all the appropriate template broad issues in knowledge management allows students who have difficulty in organizing information and generating knowledge to understand how knowledge is created and what is known in the broad sense. Students have

to deal with abstract thinking when finding solutions to compound problems and are required to integrate distinct abstraction levels: (a) understanding the problem, (b) acquisition of relevant information; and (c) effective and wise use of tools. Students who have difficulties in abstracting information should receive guidance from an expert who has mastered KM methods, KM technological tools, and related pedagogy. The SKP, in integrating pedagogical patterns, serves as a powerful tool for the teacher in supporting students. Teaching with the tool should be based on concrete associated examples while continuously analyzing students' knowledge management processes.

Work in Progress: Putting Control Engineering in Middle School Girls' Futures

Sarah Lyden, William Colvin and Bernardo A. León de la Barra

School of Engineering
University of Tasmania
Hobart, Australia

Bernardo.LeondelaBarra@utas.edu.au

Abstract—The purpose of the project described in this paper is to increase the number of female students in middle school who have a basic understanding of control engineering principles and how these apply to modern engineering and technological devices. Project work is being implemented within a local girls' school in Hobart, the capital city of the state of Tasmania, Australia. Project activity has included running a series of hands-on workshops for two separate middle school classes. These workshops have introduced control engineering principles and the engineering design process. Project experiences so far are discussed and recommendations for future project work are outlined.

Keywords— *K-12 initiatives; control engineering; gender; communal goals.*

I. INTRODUCTION

It is commonly observed that there is an underrepresentation of women in STEM professions, particularly in Engineering [1-2]. This underrepresentation can be partly due to the limited understanding of the work done by engineers and the role of engineers in helping society. The literature indicates that women often gravitate towards careers that they perceive will enable them to contribute to society and help people, such as careers in the health services [2-3]. Unawareness of the communal goals that are integral to engineering, such as helping people, working with people and benefiting society as a whole, can also contribute to girls showing less interest in the profession [2]. More accurate or holistic perceptions of the engineering profession need to be encouraged in the middle school years [3]. The middle school seems to be a suitable educational setting to target as students have not yet begun selecting subjects [4]. Importantly, research indicates that students often exclude engineering as a viable career option by the age of 14 (grade 8 in Tasmania) [1, 5].

Control Engineering is usually introduced to middle and high school students through the use of robotics programs that focus on the control of actuators based on sensor inputs [5]. Additional programs involving sensor science can be used to introduce some control engineering ideas [4]. These approaches show control in a more traditional light to the methods proposed in this paper. The purpose of the work

undertaken in this project is to introduce control engineering to middle school students through a series of hands-on activities in a variety of fields. These fields include civil engineering, sound, optics, vehicles, biomedical engineering, planes, rockets and rollercoasters, among others. The remainder of this paper will outline the preliminary approach taken and our experiences so far. Recommendations to improve the program throughout the remaining project duration are also described.

II. EXPERIENCES SO FAR

Two classes, one grade 5 and the other grade 6, from St Michael's Collegiate School attended one workshop a week for four weeks. Each workshop was run by undergraduate engineering students who are part of the University of Tasmania's STEM Education and Outreach team (<http://www.utas.edu.au/stem>). Program content included two civil, one optics, and one sound engineering workshop. All activities were linked to the new Australian standards in Science. Most activities involved students working in small teams to emphasize the role of teamwork in engineering practice. The Draw an Engineer Test (DAET) [6] was used as a pre- and post-survey to gauge student understanding and perception of engineers.

The number of participants in each workshop was 21 and 24 for grades 5 and 6, respectively. In the pre-survey, half of the DAETs of each grade depicted an engineer similar to a car mechanic. Typically, these drawings showed an adult male, wearing dirty overalls using basic tools to repair an engine or motor. In the post-survey this was not drawn by any student in grades 5 or 6. Post-surveys most commonly showed civil or electrical engineers. Aspects of design, planning, teamwork, problem solving and the engineering design process were also evident in many drawings. These were all topics that were discussed across the various workshops, implying that the students did retain these important engineering concepts beyond the end of the program.

The role of communal goals in engineering was emphasized in this series of workshops. While the topic of women in engineering was never directly addressed, the number of female engineers drawn in the post-surveys increased from 2 to 10 for grade 5 students, and from 4 to 8 for grade 6. Each workshop conducted had at least one female facilitator, and

this may have demonstrated to students that engineering is not a male-only profession. The increase in female engineers drawn in the post-surveys could also be due to the revelation that engineers are not necessarily car mechanics. The students appeared to relate to engineering more once some of the basic aspects of the profession were introduced.

The DAET was accompanied by a worksheet asking students about the engineer they drew. Communal goals were not referred to at all by either grade in the pre-survey. In the post-survey, only one grade 5 student discussed communal goals such as safety and environmental considerations and societal impact. However, 10 grade 6 students made reference to these ideas. This may be related to a higher level of maturity in the grade 6 class. In general terms, the grade 5 class was also less attentive and more eager to complete only hands-on activities, so perhaps did not engage with as much content as the grade 6 students.

The civil workshops included discussions and hands-on activities that focused on water and structures. In general, these workshops were less technical than the optics or sound workshops. Control ideas were integrated into a water purification activity. After designing and constructing a filtration system, the basic control loop of input, output and feedback was introduced. It was then linked to the purification activity by discussing how the performance of a purification system determines the changes that are later made to it. Students were responsive in this section and seemed to gain a basic understanding of control concepts. Towards the end of the water engineering workshop, an industrial application was presented. Facilitators introduced a local paper mill that uses fresh river water in its processes. With the help of the facilitators, students then worked together to describe a basic system to control the temperature and quality of the water being returned to the river.

Control was integrated into the optics workshop through use of a fibre optics activity which involved students using a microcontroller-based fibre optics board. Students could control the light sequence being sent down the fibre optic cable by interacting with the microcontroller.

Students explored the basics of how sound travels through air and constructed a speaker from low cost materials as part of the sound workshop. Inputs and outputs were discussed relating to the operation of the speaker and the notion of feedback was also introduced. It was observed that student understanding of control engineering principles could have been improved by directly reinforcing these ideas in other activities throughout the workshop.

Students participating in the program were provided with a feedback form to fill out at the conclusion of each workshop. The general sentiment expressed by the students was that they did not enjoy engaging in discussion as much as participating in hands-on activities. This suggests that the standalone workshops run at the university need to be more closely linked into classroom work so that students take responsibility for their own learning, rather than just viewing the excursions as a fun activity where they are not expected to learn.

Preliminary evidence suggests that students have enhanced their understanding of what engineers do. Students have also made connections with women in engineering and the potential to help people and society through engineering work. The integration of control activities has had more limited success leading to the following recommendations for future project work.

III. FUTURE PROJECT WORK

Integrating a control engineering activity into a broadly themed engineering workshop has been seen to have some limitations. Those ideas related to communal goals and the overall theme for a workshop were generally better understood by students due to their continuity throughout the workshop. Post-surveys indicated that students generally grasped and retained the overarching concept introduced throughout the workshop, but often lost the "smaller details" such as the specialist language of control engineering and the direct connections with control systems that were embedded in the activities. Feedback from the classroom teachers who attended the workshops indicated that the language used could be more age-appropriate to enhance student understanding.

Due to these limitations, a revised approach to teaching control engineering to middle school students will be tested for the remaining duration of the project. This approach will involve creating a control themed collection of activities which rely on other fields such as the civil engineering, sound and optics control activities already described. By utilizing this approach, control principles will be explored with groups of students in a number of different applications areas. This will create greater opportunities for students to learn about control engineering and make connections to many engineering disciplines.

ACKNOWLEDGMENT

The project is funded by an IEEE Control Systems Society Outreach Grant.

Abstract— as part of a national strategic plan recently established by the Ministry of Education in Israel to strengthen science and technology education, an innovative Computer Science (CS) curriculum for middle school was developed. One main goal of the new curriculum is to expose students at an early stage of education to the fundamentals of CS and computational thinking, and to encourage students to study CS in the future. We present the curriculum and its initial implementation, focusing on issues of teachers' professional development.

Keywords- *algorithmic thinking, computational thinking, computer science, curriculum, middle school, education, teachers' professional development*

I. INTRODUCTION

Aiming to increase the number of high-school students who choose to major in science and technology, the Israeli Ministry of Education launched the *Science and Technology Excellence program* (STEP) in 2011 to increase the number of high-school students who choose to major in science and technology. This unique program is part of the overall strategic plan to strengthen science and technology K-12

education in Israel¹. Currently, less than ten percent of Israeli high-school graduates major in both science and technology. Raising this low percentage may improve the readiness and preparation of potential candidates for academic studies in science and engineering, and eventually influence their becoming part of the high-tech industry.

The main goals of the STEP are therefore to expose middle-school students to the fundamentals of science and technology in order to encourage them to choose a major in these areas in high school, and to develop a sense of leadership in science and technology during their high-school studies. The new middle school STEP curriculum, which precedes the existing high-school curriculum in science and technology, creates a continual and comprehensive six-year science and technology curriculum for highly capable students. It includes extra hours of Mathematics, Natural Sciences (Chemistry, Biology, and Physics) and Computer Science (CS) combined with Robotics.

The Israeli CS curriculum for high school is well known internationally [7]; however, until recently, in typical Israeli middle schools the students studied computer literacy, except for a few short-term educational initiatives practiced on a local

¹<http://cms.education.gov.il/EducationCMS/Units/MadaTech/>

basis for learning CS. The need to rethink computing education on a national level complies with the current national effort to adapt the education system to the twenty-first century.

The education authority's decision to include CS in the middle-school's new STEP was based on the premise that learning CS in middle school would promote early acquisition of computational thinking, which in turn, would enhance students' scientific thinking and technological literacy. The guiding principle for the new CS curriculum has therefore been to focus on developing thinking skills rather than programming skills, and to expose students to various development environments using an inquiry-based approach, and utilizing learning-through-enjoyment pedagogical methods that can increase young students' motivation.

The curriculum consists of both mandatory and elective modules: *a. Introduction to CS*, which provides the basis for the entire program, and emphasizes the fundamentals of algorithmic thinking; *b. the spreadsheet*, with an emphasis on its usage for scientific inquiry; its inclusion in the CS curriculum bridges the gap between the CS middle school curriculum and other parts of the six-year STEP; *c. Selection between Introduction to Robotics*, which exposes students to engineering concepts and problems, and *Basic Internet Programming*; *d. The last module is devoted to developing a small programming project from scratch.*

The above modular program has been designed by a professional committee established by the Israeli Ministry of Education. The authors of this paper are all members of that committee. From 2011 to the present, the first two modules have been implemented in 183 pilot schools, concomitantly with the initiation of professional development activities under the supervision of the first author.

The next sections of this paper elaborate on the principles and constraints that guided the committee in designing the curriculum. The first section presents the rationale for teaching computing at the K-12 level, and lists the programs currently taught in Israel. Thereafter, the new CS curriculum for middle school is described, and finally, implementation issues are discussed, focusing on teachers' professional development.

II. K-12 COMPUTING PROGRAM IN ISRAEL

A. Rational and Motivation

Computer science provides the knowledge and skills foundation for contemporary technological advances: "Maintaining our ability to meet present and future challenges requires us to acknowledge CS as a core element of all STEM (science, technology, engineering, and mathematics) initiatives" ([11], pp. 15). Learning CS enhances computational thinking and may contribute to a better understanding of other subjects as well [12]. Strengthening the status of CS as a full-fledged and self-contained subject in the educational system is most important [11]. However, the increasing complexity of the field led to an unfavorable external image [3] and posed new challenges in motivating students to pursue CS as a career choice or a course of study in

which to major [11]. "Despite many years of our trying to broaden our image, computing is still widely perceived as a programmer's field... Many outsiders wonder whether CS departments will eventually disappear as the technology evolves and other fields take over as the main contributors of new computing technology" [3, pp. 336].

To address this problem on a national as well as a global level, Cohen and Haberman (2007) suggested that CS be presented as a **language of technology**, which describes structures, processes, relationships, and communications. Computer science serves as a platform for problem solving, knowledge representation, and formalization of processes, as well as for understanding technology and for performing technology-related processes [1]. CS should be taught to youngsters as one of five basic languages: a mother-tongue, an elective international foreign language, a language of science (mathematics), a language of art and body, and a language of technology (computer science), each of which is used to express themes and ideas or feelings associated with specific domains and contexts. "Long-term study of these five languages, along with intelligent practice while elaborating on utilizing communication skills, is highly useful for successful functioning on personal, national, and global levels" [2, pp. 54].

B. K-12 Computing Curricula in Israel

During the last few decades, various computing curricula have been taught in Israeli schools as an elective subject, ranging from computer literacy, up to computing fluency, usually learned at elementary and middle school as part of other subjects. This includes CS for high school in the academic track [7] and software engineering for high school in the high-technological track [9]. The curricula evolved over the years according to changes and development of the field. Pre-service and in-service teacher training courses were created to provide teachers with technical and pedagogical knowledge [7,10]. Many research papers were published regarding the implementation of these curricula using various pedagogical approaches and students' conceptualization of CS concepts and their problem-solving performance (for example, see a review in [11], pp. 29-51).

The CS curriculum for high school introduces CS concepts and problem-solving methods independently of specific computers and programming languages, along with their practical implementation in actual programming languages [7]. The program consists of five modules (90 hours each): (a) *Fundamentals of CS 1 and 2*, which introduce algorithmic problem-solving (two modules, 180 hours in total); (b) *Software Design*, which focuses on abstract data types and object-oriented programming; (c) *A Second Paradigm* - alternatives to this module are logic programming, functional programming, computer organization and assembly language, computer graphics, information systems, and stateless programming; and (d) *CS Theory*: Computational models.

The programming languages chosen for teaching fundamentals and software design have changed over the years and currently are Object Oriented (JAVA or C#).

The Software Engineering program: During the last two decades, a Software Engineering (SE) program especially designed for high-school level has been in operation in Israel [8]. The program consists of (a) an elective topic in natural sciences/introduction to technology sciences, (b) Computer Science, and (c) an elective and advanced topic in CS.

The program has scientific foundations and can be viewed as an extension of the CS program. The main goals of the program are (1) to introduce students to knowledge representation, system-level perspective and formalization of processes, and (2) to promote students' creativity, and enable them to construct an integrative knowledge of CS topics. The specialized topics that schools can choose from are as follows: Operating Systems, XML Web Services, Computer Graphics, Expert Systems, and Design & Programming of Information Management Systems. The students' final assignment is to develop a comprehensive software project related to the elected specialized topic.

III. THE NEW CS CURRICULUM FOR MIDDLE SCHOOL

The new CS program for middle school is part of the STEP, based on an overall strategic plan to strengthen science and technology K-12 education in Israel [13]. The program (180 hours: 60 hours a year, two hours a week) is intended for students from the seventh to the ninth grades. With regard to the high-school curriculum, a six-year sequence of the curriculum is created. The main goal is to impart knowledge and skills required for a person in the twenty-first century. It is not aimed at training students to be programmers or computer scientists, but rather to introduce students to logical and algorithmic thinking and to expose them to different development environments at an early stage. A somewhat similar approach has been recently suggested by the American Computer Science Teacher Association (CSTA) in their Level I model curriculum for K-12 Computer Science, in the parts that discuss K5-K8 [5].

Lowering CS contents from high school to middle school will enable excellent students from the academic track to complete the high-school curriculum a year earlier, during the eleventh grade. That will allow such a student to be exposed (if interested) during the twelfth grade to one of the specialized areas in the SE program taught in the technological track, and to develop a software project.

The first module constitutes the core of the whole program. Its main goal is to expose the students to the fundamentals of computational thinking and programming. The subjects include serial execution, variables, conditions, loops, counters, accumulators, messaging, and event handling. Since this is the first year the students study CS at school, it was important to choose a suitable programming environment that will:

- Expose the students to algorithmic problems and their solutions and enhance algorithmic thinking.
- Enable students to implement various control structures.
- Make programming enjoyable, interactive, easy to use, and graphically appealing.

- Be translated to different natural languages.
- Be free of charge (if possible).

Scratch (<http://scratch.mit.edu>) was the chosen environment. Other alternatives that exist worldwide include Logo-based environments, Alice (<http://www.alice.org/>), Greenfoot (<http://www.greenfoot.org/book/>), and more recently Bootstrap, "a standards-based curriculum for middle and high-school students, which teaches them to program their own videogames using purely algebraic and geometric concepts" (<http://www.bootstrapworld.org>).

The second year begins with introducing the students to using a spreadsheet for scientific research (**second module**). Teaching a spreadsheet is required for the mathematics and physics curricula. Hence, its inclusion in the CS curriculum helps to create a bridge between the curriculum in middle school and the general six-year STEP. The tools to be taught include representation of graphs, using mathematical and statistical functions, and wise use of conditionals.

The third module is elective and its guidelines are as follows:

- It is based on the knowledge taught during the first year.
- No new control structures are introduced
- Students are exposed to new kinds of algorithmic problems and new technologies.

It was decided that in the second year the main subject will be *Introduction to Robotics*, focusing on algorithmic problem solving and not (just) on the mechanical and electrical aspects. Students receive a ready-to-program robot and can add to it various sensors and download their software. The goals of adding robotics to CS curricula are to (1) combine logical thinking with engineering thinking, (2) expose students to other technological areas, and (3) stimulate the students to be independent learners. The module contains the following topics: controllers, actuators, sensors, electrical energy and mechanical energy, energy transformations, motors, an open-loop control, and a closed-loop control. Students in the program can compete in FLL competitions (<http://www.firstlegoleague.org/>).

Since the *Introduction to Robotics* module is budget dependent (which might be a problem) and because those teachers without an engineering or electrical engineering background were reluctant to teach this program, the authors decided to suggest an alternative module that is less engineering oriented and free of charge. In order to create more continuity between the middle-school and the high-school curricula, it was decided to suggest teaching *Basic Internet Programming* by focusing on client-side programming as an introduction to stateless programming (taught in an elective module in high school). The module focuses on HTML5 and JavaScript; the students practice conditionals and loops.

The fourth module, which is taught during the third year of study, is devoted to developing a programming project including writing a project proposal, modeling a problem,

designing a solution, and implementing it. The teachers can choose the development environment for their students. The programming project helps students internalize the use of algorithms for solving problems and prepares them for further studies in high school.

IV. IMPLEMENTING THE NEW PROGRAM

The program has been implemented in stages for the past two years. At the first stage 30 schools were selected to participate in a pilot program, most of which are located in the periphery of the country in order to promote a segment of the population that is less accessible to educational resources. Twenty-seven of them (709 students) continued to the next stage the following year.

At the second stage 183 middle-schools (5696 students) participated in the program. In each school, the students that were chosen for the program excelled in their age group. At the third stage about 100 additional schools are planned to join the program the following year (2013). The total number of teachers who teach the CS program this year is 172.

Teachers constitute the cornerstone of any curriculum [4,8,11]. Successful implementation of a new curriculum greatly depends on the pedagogical and content knowledge of the teachers as well as their satisfaction from the ongoing training and the support offered by the curriculum's initiators. Prior to the development of the curriculum presented here, no formal CS program was available for middle schools in Israel. Accordingly, recruiting and retraining teachers for the new program has been challenging but rewarding.

A. Preliminary criteria for approving teachers to teach the CS program

Initially, the Ministry of Education in Israel decided that the new STE curricula will only be taught by experienced and professional teachers. The rationale behind this decision is that qualified teachers should exhibit the following general qualities: (a) possess at least a Bachelor's degree in CS or engineering and a teaching certificate, and (b) have experience (of at least 3 years) in teaching the CS program at the highest level and in successfully preparing students for the high-school matriculation exam.

Since the criteria plan was restrictive, its implementation produced a shortage of qualified teachers. Academic retraining courses for prospective teachers with professional hi-tech experience were established to alleviate teacher shortages. Teachers having a background as high-tech professionals were assumed to have an additional advantage of encouraging students to study sciences, especially computer science.

B. Difficulties in assigning teachers

Shortly before the school year began, it became clear that assigning qualified teachers is problematic for the following reasons: (a) Qualified CS teachers who previously taught high-school students felt uncomfortable and even refused to teach middle-school students since:

- The emotional needs of the younger students were unclear to them;

- Teaching skills at the middle-school level seemed foreign to these teachers;
- Different physical locations of the middle-school and the high school complicated their work day logistically;
- Middle-school computer labs have a limited number of computers compared with high-school labs.
- The teachers needed to prepare lesson plans and teaching materials for the new program.

(b) The Ministry of Education had to assign tenured teachers to the program, even though they were not qualified for it.

(c) In schools that had not established a computer-related program and thus had no qualified CS teachers, it was difficult to find qualified teachers in the surrounding area, or to find a suitable teacher who would agree to come on-site and teach only two hours a week.

These kinds of difficulties were also encountered with Math teachers, but mostly in CS and Physics, since it was the first time those subjects were taught at middle school.

C. Reducing the criteria for qualified teachers

Owing to the difficulties in finding qualified teachers who could teach the program, it was decided to relax the criteria for accepting teachers, and to develop training courses for them. Teachers who did not meet the original requirements were permitted to teach the program provided that they agreed to participate in a suitable course. Relaxing the professional criteria resulted in accepting to the program less qualified teachers, for example, CS teachers who had previously taught only the lower levels in high school, qualified and experienced science/electronics teachers who had some CS education but who had not taught CS so far, students who were in their last year of academic CSED studies, and Computer Literacy teachers.

In implementing the program, several difficulties were encountered:

- Experienced high-school teachers were able to cope with the challenge of teaching excellent students but were not accustomed to teaching younger students.
- New teachers faced typical difficulties of entering the education system.
- New teachers and teachers with no CS background often taught at the technical-applicative level and did not focus on the program's algorithmic requirements.

D. Training Courses

Teachers are obligated to participate in a training program that was designed to provide them with pedagogical tools for enhancing their students' algorithmic thinking. The training consists of several courses, each of which is related to a specific module of the program. Additional course in Java and C# extends teachers' knowledge in order to give them an idea of what direction the students are heading to in high school. Each course lasts approximately 3 months. The courses are taught both in a computer lab and in an online environment to

ease the teachers' burden. There are three or four lectures per course and coursework is assigned weekly via a website.

E. Teachers' Support System

Reducing criteria implied that teachers constitute a heterogeneous group, with different backgrounds and knowledge. In addition, the fact that the teachers are physically scattered throughout the country made it difficult to support teachers and to arrange face-to-face (F2F) meetings. Therefore, there was an urgent need to create a supporting system that could overcome these constraints. In the beginning, the Ministry of Education program coordinators communicated with the teachers mainly through emails and phone conversations; therefore, a forum designed for the teachers in the program was established. The forum is mostly used for interacting with the program's coordinators. In addition, a blog was established in order to manage the distribution of instructional materials, either those developed by professionals or materials developed by teachers in the training courses that were found appropriate for distribution to other teachers.

F. Preliminary Evaluation

The program will be evaluated at two levels. One is by administering a nationwide exam aimed at assessing the students' understanding of the material taught. The first exam was administered at the end of the first year of the program and a preliminary evaluation of it is described in [13]. The second evaluation is planned to take place at the end of this year. The other level concerns the teachers.

Teachers completed a Likert-type questionnaire assessing their perception of the program (1 (strongly disagree) - 5 (strongly agree)). The questions evaluated the extent of students' internalization of programming structures and algorithmic thinking in their teachers' eyes (Table 1), and teachers' sources of support, and their general satisfaction with the program (Table 2). Sixty teachers completed the questionnaire; fifty of them taught the program to 7th grade classes for the first time, whereas the other ten teachers taught the program for the second year, in both the 7th and 8th grades. In addition to the questionnaire, personal conversations with teachers were conducted.

TABLE I. TEACHERS' ATTITUDES REGARDING STUDENTS' LEARNING

| <i>The Statements:</i> | <i>1st year teachers (N=50)</i> | <i>2nd year teachers (N=10)</i> |
|---|--|--|
| <i>The program is interesting</i> | 4.5 | 4.6 |
| <i>The program promotes students' algorithmic thinking</i> | 4.2 | 4.1 |
| <i>Students master conditional statements</i> | 4.2 | 4.5 |
| <i>Students master loop statements</i> | 4.1 | 4.3 |
| <i>The Algorithmic module contributed to students' algorithmic thinking</i> | 4.3 | 4.2 |
| <i>The Robotics module contributed to students' algorithmic thinking</i> | | 3.8 |

TABLE II. TEACHERS' ATTITUDES REGARDING THE PROGRAM'S SUPPORTING TOOLS AND THE TRAINING COURSE

| <i>I was assisted by:</i> | <i>1st year teachers (N=50)</i> | <i>2nd year teachers (N=10)</i> |
|---|--|--|
| <i>Colleagues who teach the program</i> | 3.2 | 3.0 |
| <i>Other teachers</i> | 2.5 | 3.3 |
| <i>The program's blog</i> | 4.1 | 4.0 |
| <i>The teachers' forum</i> | 3.0 | 3.6 |
| <i>The program's supervisors</i> | 3.1 | 3.6 |
| <i>The materials developed for the program</i> | 4.1 | 4.2 |
| <i>Comments regarding the training:</i> | | |
| <i>F2F meetings may be given up</i> | 1.9 | 2.9 |
| <i>I've developed additional materials based on examples I've seen in the course.</i> | 3.7 | 3.1 |
| <i>I would recommend my colleagues to join the training course.</i> | 4.3 | 4.1 |

According to Table 1, the teachers were highly satisfied with their students' learning outcomes. According to Table 2, the blog and the program materials are the teachers' most appreciated support tools. Despite the differences between the original program design and the actual situation, providing virtual support tools in addition to F2F meetings, established during the pilot stages, show that teachers were satisfied with the course plan and that their ability to use remote supporting tools is increasing. Teachers need fewer F2F meetings, and are able to study through consulting and by using virtual support tools. Apparently collaboration tools contributed mainly to retrieving more instructional materials and less to maintaining ongoing communication among the teachers themselves.

Additional information gathered from personal conversations and documentation of the difficulties encountered indicated that there was a great diversity of teachers' content knowledge and pedagogical knowledge. In addition, teachers' perceptions of the goals of the program and its feasibility in teaching middle-school students differed. For example, teachers expressed significantly different perceptions regarding the need for an informal, game-like learning approach, compared with the desire to move CS contents from high school to middle school.

V. DISCUSSION AND CONCLUDING REMARKS

The *Science and Technology Excellence* program for middle school, which includes the new CS program described here, is an educational initiative that aims at motivating and encouraging highly capable young students to choose science and technology studies in high school and academia. It is based on the assumption that early exposure to science and technology is a critical factor in attracting youngsters to these fields and in adequately preparing them as well as sowing the seeds for the development of the next generation of scientists and engineers.

The program is based on expanding the scope of math and science studies, beyond what most middle and high-school students learn today, and to new areas of science and technology that young students are not usually exposed to in the traditional and existing curricula. Computer Science

integrated with Robotics was chosen as one of the main scientific-technological areas to be included in the program. Until recently, no official CS curriculum by the Israeli Ministry of Education has been tailored to the needs and capabilities of seventh to ninth graders, which also takes into consideration the background and expertise of most middle-school teachers.

Lowering CS content levels from high school to middle school will enable excellent students from the academic track to complete the high-school curriculum a year earlier and during the last year of study to get a taste of the SE curriculum in the technological track, and to develop a software project. The aspiration to recreate for outstanding students a sequence of six-year high-level studying of computer science necessitated the construction and operation of a formal curriculum for the lower grades. The new program emphasizes the gradually building of basic concepts and principles in computer science, the development of logical reasoning and computational-algorithmic thinking, coping with the cognitive challenges of problem solving, exposure to the processes of software project development and the development of students' creativity skills. Achieving these goals is fostered by familiarizing the young students with several learning environments where these concepts and principles can be identified and elaborated.

The cornerstone of implementing a new educational idea or a program lies in the teachers; therefore, at this stage of implementing the program, we focused on in-service training and on evaluating the process that the teachers underwent and their feelings and attitudes at the end of one or two years of experience.

It was realized that the original plan of setting high criteria standards for approving teachers to teach the program was unrealistic; this resulted in reducing the professional criteria of acceptance to the program and the training courses; still, the formation of an array of courses and support tools during the first two years of implementation evidently helped those teachers with different backgrounds.

The information gathered in the preliminary assessment indicated that teachers' content knowledge and pedagogical knowledge were very diverse, as were their perceptions of the goals of the program and its feasibility in teaching middle-school students. They reflected on their satisfaction with their students' achievements and the available supporting tools. Noteworthy are the improved attitudes of those teachers who taught the program the second time regarding the program's potential to teach problem solving and to develop algorithmic thinking among young students.

A main conclusion to be deduced from this preliminary study is that building a properly tailored training courses for a heterogeneous group of teachers, as well as diverse supporting tools and suitable guidance, mostly on the web, contributes to the professional development of teachers and enables bridging the pedagogical and content gap between the desired and the actual availability of qualified teachers.

Future work will further examine the relationship between teachers' backgrounds and how they deal with the program's instruction, and the effect of teaching the entire 3-year middle-school program on teachers' perceptions of the program and its implementation. In addition, students' achievements will be evaluated as well as the percentage of students who choose to study computer science in high school.

Abstract: This session reports on the experiences of seven NSF GK-12 fellows, A PI and Co-PI and external evaluator who participated in a one month trip to India in December, 2011-January, 2012. The seven fellows are a part of a GK-12 STEM capacity building program sponsored by the National Science Foundation that pairs graduate fellows with K-12 teachers to bring hands on, cutting edge, inquiry based science to the classrooms in the Northern Virginia area.

1. INTRODUCTION

This session reports on the experiences of seven National Science Foundation GK-12 Fellows who are graduate students in bioinformatics and computational biology, environmental science, physics, and computational sciences at George Mason University, the PI and Co-PI and external evaluator who participated in a one month trip to India in December, 2011-January, 2012. The seven fellows are a part of a GK-12 STEM capacity building program at George Mason and sponsored by the National Science Foundation that pairs graduate fellows with K-12 teachers to bring hands on, cutting edge, inquiry based science to the classrooms in the Northern Virginia area. Fellows are paired with elementary and middle school teachers over a two year period. The fellows are required to spend ten hours a week in classrooms in elementary and middle schools in Northern Virginia and spend an additional 5 plus hours a week in creating hands on activities based on their research. The fellows also design and deliver annual summer science camp, and provide “just in time” professional science content development for teachers. The fellows serve as mentors and models for the school students providing a concrete demonstration of the value and excitement of a career in science and the promise of careers

in science for woman and minorities. The fellows have also strengthened communication and presentation skills, and have gained new understanding of the challenges and opportunities of STEM teaching in US K-12 schools.

The National Science Foundation GK-12 program encourages projects to include an international component to their activities and provides supplemental funding for approved projects. The GMU GK-12 project PI, Rajesh Ganesan, wrote a supplementary proposal to NSF for funding for a one month trip to India which was subsequently funded for December 2011- January 2012. The objectives of the trip to India for the seven Fellows were threefold: 1.) Fellows were to gain knowledge of the ways in which research is carried out in Indian Universities and to make face to face networking contacts with researchers working on similar research topics. 2.) Fellows were to gain an understanding of STEM teaching in K-12 schools in rural and urban areas. 3.) Fellows were to gain an increased cultural knowledge of India and the Indian people.

4. Evaluation Procedures

The evaluation of the trip activities was carried out by the project external evaluator who was also one of the participants in the trip. Both quantitative and qualitative methods were used to perform the evaluation. Pre-trip and post-trip interviews and surveys have been done with the Fellows. Copious evaluator notes were taken during pre-trip meetings and during the entire course of the trip as well. The participant-observation method is often used in social science research and is a particularly valuable tool for anthropological research. This method is less used in evaluation studies, particularly ones that have as their focus STEM outreach activities.. The considerable amount of data

that has been collected is now being analyzed. Preliminary data analysis indicates that the trip has had a significant impact on Fellows views of research in India and future collaborations as well as on their views of Indian K-12 STEM education. The data also indicates that Fellow views on Indian culture and the Indian people have changed significantly. Add to paper:

2. RESULTS

Results from the post-trip survey indicate that 100% of the seven participating fellows were either satisfied or very satisfied with the trip overall. The participants confirm this finding by reporting in all of their open-ended post trip interviews that the trip was very fulfilling and met or exceeded their expectations. The pre-trip planning sessions were viewed as very valuable by 29% and valuable by 71%. As reported in the post trip interviews, the pre-trip details may have been too specific for those with previous international travel experience. One of the goals of the trip was to gain a better understanding of Indian K-12 STEM education. In response to seminars held at Miranda House, at the University of Delhi, 29% of the participants said their knowledge of Indian K-12 education increased significantly and 29% gained a new and deeper understanding of Indian K-12 education as a result of the talks at the university. In contrast, as a result of visiting a number rural and urban schools, 79% of the participants said they experienced a new and deeper understanding with the rest saying their knowledge had increases significantly. The impact of site visits had a much stronger effect on the fellows than did the lectures at Miranda House on K-12 education. When asked to rate the research meetings at the University of Delhi, 43% said the meetings were valuable or very valuable, the remaining fellows saying the meetings were either not very valuable or not valuable. The difficulty of arranging these meetings from a distance with a country such as India is reflected in the variety of experiences that the fellows had at their research meetings as reported in the post-trip interviews and open-ended questions on the surveys.

3. IMPLICATIONS

The implications of the data from the pre-and post trip interviews and surveys will be covered in more detail in our WIP presentation. Evidence for trip outcomes will be drawn from the surveys and from narrative material from the interviews.

A somewhat similar trip to China was organized during the same time frame by another NSF funded GK-12 program by a group at the University of Colorado at Denver (1). A significant difference between the two trips was that the trip to China had a narrow focus at only two institutions whereas our Indian trip involved about ten institutions. The advantages of a breadth versus depth approach for planning international STEM outreach trips will also be discussed.

Some of the questions that are to be answered by a close examination of the quantitative and qualitative data are:

- What are the specific indicators of change in Fellow attitudes as result of the trip? -
- What has been learned concerning trip planning and implementation?
- What are some of the unanticipated findings that arose as a result of the trip?
- What are kinds of things have been learned by our hosts in India as a result of the trip?
- How did our hosts and their students perceive our group and our activities?
- What is the evidence for long term impact of the trip six months after the end of the trip?
- What are some of the benefits and limitations of using participant-observation as one tool to evaluate intercultural experiences for graduate STEM students?
- What are the overall benefits for STEM capacity building here and in India as a result of this trip?

This work in progress session will present answers to these questions and will provide an interactive forum for the discussion of international STEM capacity building trips as a means to foster international STEM collaboration and cultural understanding.

Abstract - National calls have been made for the identification of preconceptions and misconceptions in science and engineering. Identifying misconceptions can provide a basis for improved research-based curriculum development and implementation. The recognition of false beliefs and flawed mental models of these concepts can also contribute to theories of conceptual change. The purpose of this research was to identify misconceptions related to open channel flow. During spring and fall of 2011, out of 91 students from two sections of 'Water Resources Engineering' course, 50 students were interviewed, and 41 students were given a pre/post test. The goal of these open-ended interviews and pre/post-tests was to obtain detailed data on students understanding of open channel flow concepts. Results suggest students have misconceptions relating to the hydraulic and energy grade line (HGL/EGL), flow transitions, and flow profiles. Many students have the correct terms of the HGL and EGL but lack understanding of where the terms re on an open channel flow profile. A large percentage of tested students revealed false beliefs relating to transitions. For example, more than 50 percent of tested students drew a decrease in water depth for a subcritical drop, rather than an increase in depth. Students also had difficult in labeling subcritical, critical, and supercritical places along flow profiles and how water flows over or under different weir structures. Repairing these fundamental misconceptions is essential for students to be able to apply these concepts in diverse situations and learn more advanced topics.

Keywords – *Misconceptions, Open Channel Flow, Conceptual Change*

I. INTRODUCTION

Every engineering student has some sort of life experience with moving water. Therefore, every student in a course involving open channel flow concepts has some sort of constructed understanding of water and how it flows. Research has shown that some of these understandings are incorrect, and cannot be easily corrected [1]. Research on conceptual change can inform why some of these notions are harder to change than others by providing a theoretical framework for understanding the integration of existing knowledge with things that are learned in class. The purpose of this study is to

provide insights on students' misconceptions related to open channel flow within the context of the idea of synthetic frameworks developed by conceptual change theorist Stella Vosniadou [2].

II. BACKGROUND

Although all students have some form of preconceived beliefs about how water could flow from one point to another, their individual beliefs are different from student to student [3]. The difficulty of changing these beliefs is related to how embedded they are in students views of the world. Arguably, the most difficult misconceptions to change are those tied to ontological beliefs [4, 5]. Ontological beliefs are fundamental categories made of the types of things that exist. In engineering education, students have been found to miscategorize heat and diffusion in the incorrect ontological categories, and these misconceptions addressed through ontology training [4, 6]. As a simple example, it would sound odd to discuss how strong red is, because the "red" is not a type of thing that can be strong or weak: we share an ontological belief that "red" is categorized as a "color," and that "strength" is not a regular property of colors. It would be very difficult for students to learn about the relative strengths of different colors until they had undergone an "ontological shift" [7] to recategorize "colors" as types of things that can be strong.

When students attempt to learn around incorrect ontological beliefs, they can develop what Vosniadou calls "synthetic models." For example, in her work investigating students' conceptions of the shape of the earth, students would say the shape of the earth is round, but then indicate that if they walked a long way in a certain direction they would reach the edge [8]. She suggests in this work that students rely on what they have seen and develop ontological commitments based on these observations. For example, students believe that "things are as they appear to be" [9]. In other words, students have developed models of a flat earth through observation but have heard that the earth is round, and integrate both pieces into a 'synthetic model'. The idea of a flat earth is particularly robust, though, because it is tied to their commitment that

things are as they appear to be; in order to truly learn about a round earth, they need to shift their ontological commitment to things (i.e. the Earth) being as they appear to be (i.e. flat).

This study identified common misconceptions in open channel flow concepts in a junior level water resources engineering class at a public university, and interpreted these misconceptions within the context of ontological categories and synthetic models. The broader study included hydraulic and energy grade lines (HGL/EGL); flow transitions; flow profiles; identification of supercritical/critical/subcritical flow along an open channel; and hydraulic jumps. However, this article focuses on the results from the broad crested weir questions.

III. METHODOLOGY

A. Course Structure

The course of interest focused on water resources at a public university and is composed of three different main sections in the following order: pressurized pipe flow, open channel flow, and hydrology. However, participants were only interviewed about open channel flow concepts. Also, to be enrolled in the course, all students had to have completed the fundamental prerequisite course, fluid mechanics. The prerequisite course briefly covers the fundamentals of open channel flow such as laminar and turbulent flow, but does not detail anything related to the tested concepts. Lastly, the course was based on a popular textbook that details the fundamentals of the three topics that compose the course.

B. Participants and Interviews

Students that participated in this study were selected in order to include students from the top, middle and bottom quartiles in terms of academic performance, and were interviewed in a random order. The class is primarily composed of junior level students with the exception of few senior standing students. Only civil engineering students were enrolled in the course and participated in the interviews. We asked each participant to not discuss or reveal any of the interview questions to other classmates so internal validity would remain strong. Finally, the participants were told that a key containing the correct answers and detailed responses to each question asked would be provided at the end of all the interviews.

During spring 2011, 50 undergraduate students were interviewed using an open-ended interview method over a period of two weeks. Interviews followed a typical protocol that was semi-structured and allowed for probing questions related to difficult topics of open channel flow. The instructors identified the difficult concepts that compose the interview questions before this study began and the concepts were based from their previous knowledge, experience, and course notes. Interview packets were composed of a six-page handout that contained five questions related to open channel flow and one question related to pressurized pipe flow, shown in figure 1.

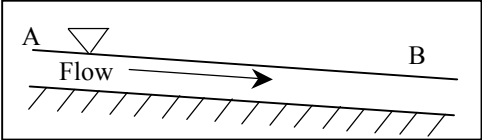

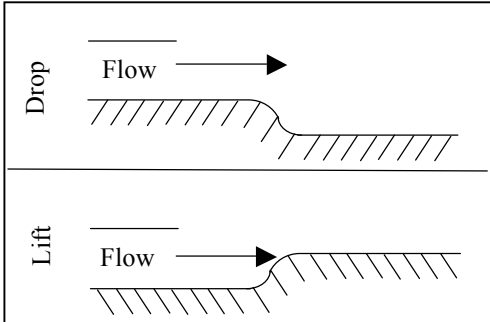

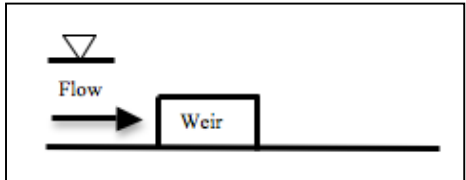

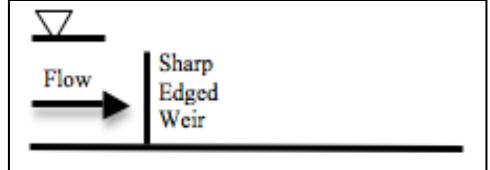

| Concept | Questions Asked |
|---|--|
| 1 Pressurized Pipe Flow | A) Draw the HGL and EGL between two points B) Write the energy equation between two points C) How would you figure out how much water flows between two points |
| 2 Open Channel Flow – HGL/EGL | A) Draw the HGL and EGL from points A to B. B) How would you figure out how much water flows from A to B? C) Write the Energy Equation between A and B.  |
| 3 Most Efficient Section | A) What is the most efficient section, A - D? B) How would you define the most efficient section? C) How many variables control most efficient section for figures A – D? (Choices were between a triangle, trapezoid, rectangle, and square channel geometry) |
| 4 Specific Energy | A) How does water flow downstream? B) How does the specific energy change between points one and two? (supercritical and subcritical drop and lift)  |
| 5 Flow Profiles | A) Draw the flow profiles for A – D. B) Label places of super/sub/critical flow  |
| 6 Hydraulic Jumps | A) Draw the flow profiles for A – D. B) Label places where a hydraulic jump occurs. C) What do you think a hydraulic jump is?  |

Figure 1. Interview protocol standard questions and order.

The pressurized pipe flow was question number one and held the purpose of an introductory question to allow students to become familiar and comfortable with the interviewing process. The remaining five questions covered the fundamental concepts of open channel flow in the following order: hydraulic and energy grade line; the most efficient section; transitions; flow profiles (broad crested weir results); and hydraulic jumps (sharp edged weir results).

C. Analysis Techniques

One graduate student coded all 50 interviews in a qualitative coding software program to prevent any inconsistencies within the data. The same graduate student transcribed three of the 50 open-ended interviews; a professional company transcribed the remaining 47 interviews.

Coding software was used to separate the collected data into common groups. A code is a piece of data that holds information of interest. In this specific case, when participants indicated preconceptions through using words such as 'built up' or 'previous experience', those statements were given a code. Once the data was coded for preconception evidence, data that held similar codes were grouped together to create a node. The process that was used is outlined below:

The first step in the analysis was simply to identify correct and incorrect responses to each interview question. The interviews were structured so that most questions had a clearly correct answer, such as the specific shape of the flow profile over a weir. Participant responses that were fundamentally correct, but lacked pertinent details (for example a flow profile in which the differences in water elevations were slightly too exaggerated, or where the area of critical flow was incorrectly identified) were still marked as "correct" for the purposes of this study.

The second step included differentiating the incorrect answers provided by the participants from step one. Although many students provided slightly different answers to a single question, the stated answers only differed by a small amount. Therefore, if similar answers were globally the same, they were grouped together.

Once the incorrect answers were grouped, specific words related to preconceptions were identified and coded. Many participants used common fundamental language such as 'subcritical flow' and 'uniform conditions'. When a participant stated they gave their answer based from previous experience or if they used words that were very primitive such as 'lift' or 'build up', the answer was coded, as those words were not taught during lecture.

Finally, once specific words and/or phrases were identified, more nodes were made to group common words together. For example, students that indicated their answer was based from previous experience were grouped together in relation to a specific answer. From the nodes, individual answers are analyzed in detail and specific quotes are pulled out to represent a common misconception and used in the results/discussion section.

The results detailed in the next section were a product from this process, and serve as an introduction to identifying what is difficult for students to understand.

IV. RESULTS

A. Content Review

A broad crested weir is essentially a three-dimensional rectangular block that crosses the full width of a channel and can vary in length. Participants were given the upstream water surface elevation and details shown in question 5 in Figure 1 above, and asked to draw and explain the flow profile. Figure 2 below shows the correct flow profile.

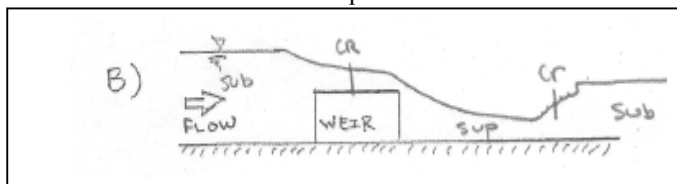

Figure 2. The correct flow profile for a broad weir.

The various changes in flow depth and velocity shown in Figure 2 can only be explained in terms of changes in the specific energy, and the complex interrelationships between specific energy, inertial forces and gravitational forces. Upstream water was in a subcritical condition, which would result in a transition to supercritical flow after the weir and critical flow at some point over the weir. Subcritical flow is located in the upper curve (1) of the specific energy curve as shown in Figure 3 below. As the fluid travels over the weir, it transitions energy from static (depth) to inertial (velocity) and transitions to point 2 on the specific energy curve (supercritical flow). Eventually, inertial forces would decrease due to friction on the channel bottom and sides, causing a shift from curve 2 to curve 1 in Figure 3. This appears as the hydraulic jump shown downstream of the weir in Figure 2.

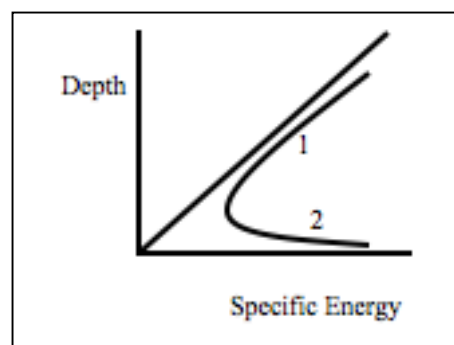

Figure 3. The specific energy curve. 1 is subcritical, 2 is supercritical flow.

B. Results and Discussion

Forty percent (20/50) of students drew the correct flow profile. Among the incorrect answers, the most common misconception was that the depth increases over the weir, then decreases after the weir. Figure 4 shown on the next page is a common misconception identified through the open-ended interviews. As you can see, the water level rises over the weir, and then decreases after the weir despite the fact that this

participant labeled subcritical flow before the weir. This participant indicated that critical flow would occur at the middle point of the weir, which is incorrect as the water level increased and did not transition to supercritical flow over the weir.

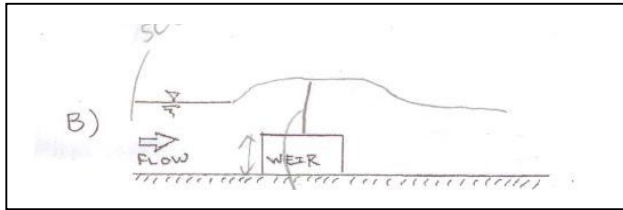

Figure 4. Common student drawing for this flow profile.

The following excerpt is typical of many students' explanations of this incorrect flow profile:

Student 1: *Oh, boy. So we're going to go over this weir. I think it kind of might hump up a little here. We have some, I don't remember what it's called, it's backflow...*

Interviewer: *Why do you think it humps up like that?*

Student 1: *Well, sometimes, there's that- I'm not remembering the term, it's basically gets- it can't go over this fast enough and so it kind of gets that buildup, it's that kind of- I can't remember the term but it kind of builds up on the back side there a little bit, builds up some energy. So then, anyway, over a weir, we'd probably kind of get the same, just depends on the speed and stuff.*

In terms of ontological categories and synthetic models, there are three significant components to this common incorrect answer: (1) the use of sequential language, (2) the emphasis on two linked variables, and (3) the image of a process with initiation.

1) Sequential Language

Some participants justified their flow profile as a logical chain of events in time with the latter events being caused by the former, or as a sequential process unfolding along the profile, with downstream events being caused by upstream conditions. For example, consider the following student quotes explaining their incorrect fluid profiles:

Quote 1: *"Okay. I know that it [the fluid] would hit the weir, and it would flow choke at least a little bit until it increased, and then as it goes over the weir, it would actually start going down."*

Quote 2: *"We have flow-choking occurring right here. Water is going to kick up against the weir, push back up from the subcritical and then force down to supercritical."*

Quote 3: *"So it's fallen in, it hits the weir; it wants to go over the weir."*

Quote 1 appears to explain the process as a temporal sequence: first the water hits the weir, then the "flow chokes," then it goes over the weir and finally "it would actually start going down." Quote 2 appears to be more spatially oriented and indicates locations along the profile where the water "kicks up" or is "forced down."

Characterizing flow over a weir as a sequential process is an ontological commitment: this phenomenon is the kind of thing that can best be explained by a list of events in which the order has causal significance. This misconception leads the students to create synthetic models to justify incorrect answers with concepts learned in class. Quote 2, in particular, correctly emphasizes the importance of subcritical and supercritical flow, but the ontological commitment to a sequential process leads to misidentifying then with different steps in the process, rather than fundamentally different physical processes.

2) A Two Variable System

Many students strove to find relationships between two (and only two) variables to explain their flow profiles. This misconception often, although not always, co-occurred with the two other misconceptions described here: for example quote 1 attempts to describe the flow profile as a relationship between the weir and flow depth. As exemplified in the following quotes, this relationship was the most common one, although velocity and energy were sometimes also invoked:

Quote 4: *"I'm not remembering the term, it's basically gets- it can't go over this fast enough and so it kind of gets that buildup."*

Quote 5: *"There'd be a jump initially at the weir, because it's going to push it up and afterwards it's going to go lower because the velocity will increase it, putting it lower."*

Quote 6: *"This weir slows down the energy right here so the pressure decreases and it drops in level."*

As a result of some students holding this framework knowledge, the system is composed of two things rather than a multitude of forces that contribute to how a fluid flows over a broad crested weir. These quotes also provide evidence that some students may not view an open channel system as a constrained system. Due to their ontological beliefs about the nature of open channel flow, these students are satisfied with their two-variable explanations – and indeed may be intentionally simplifying their answers in recognition of the value of parsimony. Ideally, the students' explanations would lead them to realize a flaw in their logic – quotes 4 through 6 do not explain the drop in water level predicted, for example. This is strong evidence for, and a product of, the students' synthetic models because there is a fundamental mismatch between the concepts applied, and the framework in which they are applied. Quote 6, for example, is technically correct in attempting to explain the profile in terms of energy, and is confounded by the synthetic model where energy can "slow down" at one location.

3) Process with initiation

Finally, many participants explained their profiles in terms of a process that had been initiated; some students indicated their answer was as a result of the fluid starting to flow after the weir was placed in the channel.

Quote 7: *"Okay. For this one you have flow coming into the channel, and into the weir. It's going to hit this and it will force super critical here. It will come down."*

Quote 8: *"I guess I would only put a weir into a system that's already in subcritical flow. I don't know why I think that,*

but that's just what I think, and so it would force the flow to go down to critical at some point."

Quote 9: "Because it needs to cross over the obstruction and the amount of flow decreases. It's all of a sudden obstructed."

Rather than looking at the instantaneous point in time, which would be ideal to draw the flow profile, these participants indicated that they are working with a dynamic model that began after placing the weir into the system. Quotes 7 and 9 show this clearly by indicating the system has flow "coming into the channel" which is "all of a sudden obstructed." Again, this approach often co-occurred with the ontological belief that flow over a weir is a sequential process: this is logical as a sequential process needs some kind of special initiation to being the causal chain. Students' preference for this type of reasoning is particularly interesting in light of the fact that all students were specifically instructed to consider the system in steady state. This mismatch between fundamental characteristics of the system (steady state, complex, conservative of mass and energy) and approaches to explanation is, again, evidence of the students' synthetic models.

C. Evidence of Misconceptions with Sharp-Crested Weirs

These misconceptions were reiterated in many cases in the context of sharp edged weirs. A sharp edged weir is essentially a thin broad crested weir. The correct profile of a sharp edged weir can be seen in Figure 5 below. As the water flows over the weir, it immediately drops (unless flood conditions are present) and transitions from subcritical to supercritical flow.

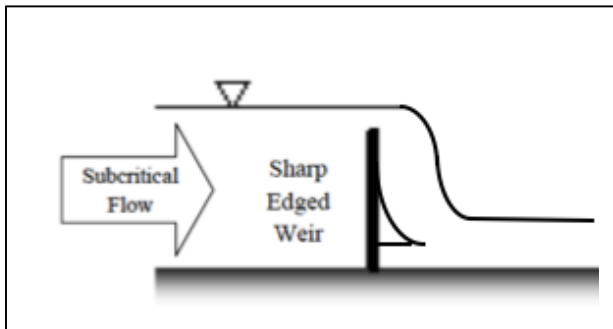

Figure 5. The correct profile for a sharp edged weir. Student two made very similar statements in relation to a sharp edged weir.

Student 2: For B there'd be a jump initially at the weir, because it's going to push it up and afterwards it's going to go lower because the velocity will increase it, putting it lower.

Interviewer: Why do you think the weir wants to push the water up?

Student 2: Because it has a constant flow initially. Has a constant flow and then it's you know hitting basically an object right there so it's got to go somewhere so it's going to go up first.

This exchange shows Student 2's characterization of the flow as a sequential process ("afterwards it's going to" and "then it's, you know, hitting basically an object") featuring two

primary variables (the weir and flow depth) to describe a process that has been initiated when the weir was introduced to the flow channel.

Student 2: For B [the sharp edged weir], because the weir's right there, the water underneath is going to have to jump up once it hits it, and so that's why there's a jump right there, and then after the initial jump, since there's nothing else the rest of the way, it's going to kind of even out.

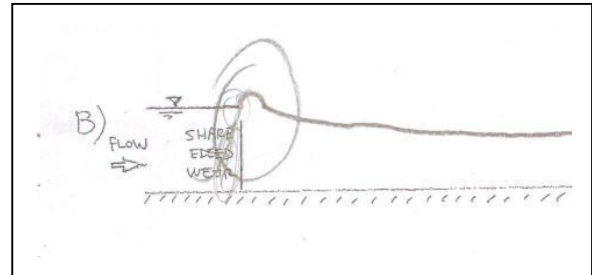

Figure 6. The incorrect flow profile drawn by student 2.

Again, this explanation relies heavily on working through the process sequentially with reference to two key variables (this time the weir and the "jump") and the initiation of the process ("have to jump up once it hits it").

V. DISCUSSION

There are interesting and potentially fruitful parallels between the misconceptions and synthetic models identified here and Chi's theory of direct versus emergent causal narratives [3]. Chi argues that one particular type of ontological belief is responsible for many misconceptions: the incorrect categorization of "emergent processes" as "direct processes." In her terminology, a direct process is one that is intentionally initiated by a causal agent and follows a logical pattern directed at achieving an end state. Research has shown that students incorrectly categorize diffusion as a direct process, where it is in fact an emergent process, and the result of random movement of molecules [4]. An everyday example of a direct process would be when a teacher instructs a group of students to line up, and then they do so. In contrast, an emergent process is one in which an observable phenomenon is actually caused by ongoing, non-directional and unobservable interactions that do not directly affect nor are they directly affected by the observable phenomena. An example of an emergent process would be if, in a roomful of students, every student wants to maximize the distance between him-or-herself and the whiteboard along one wall. After a while, the students would end up lined up along the opposite wall – not because they wished to form a line, but because each individual student would continue moving until they felt they could get no further from the whiteboard. Note that the students' desire to be away from the whiteboard does not have a necessary beginning, and does not change or end when the students form a line – it is simply a property or characteristic behavior of the students that, in some circumstances (a whiteboard along one wall of a room) results in students lining up.

In our findings, the flow profiles are equivalent to the students' line. The students' interviewed seem inclined to identify special causal agents (the weir, or the installation of

the weir) and sequences of events, which suggests they tend toward a direct causal explanation. The correct explanation of the flow profiles is more emergent, however, in that the fundamental processes do not have beginnings, or sequences, and are not intentionally causing the observable phenomena of interest.

VI. CONCLUSIONS

The identification of common misconceptions of open channel flow concepts is important and provides a way to qualitatively understand what the majority of students are having difficulty learning, and potentially why they are having these difficulties. Determination of these misconceptions is particularly compelling in light of the fact that these students' misconceptions have very likely been directly contradicted in their classrooms, homework and exams. Identifying other preconceptions can help further the validation of the argument presented here that students are operating incorrectly within a 'direct' process ontological category.

Some of the language that students' used to describe this process indicate that they may draw off of analogies with solid objects. For example, some students say the water 'steps up' the weir, as if it was a 'chunk' of water and not a viscous fluid. This is further evidence of direct and linear process thinking. Future research in other areas of fluid mechanics could investigate how and when students' use these analogies.

Additional research is needed to help build upon the current popular approach of addressing long lists of misconceptions, with varying results. Research utilizing theories of conceptual change and ontological categories could lead to approaches to instruction, such as ontological training, that address several misconceptions with one instructional approach. For example, students may not explicitly realize that they are utilizing direct process rules, where emergent ways of thinking could be more valuable. Future research could involve interview protocols that explicitly examine student's thinking about direct and emergent processes as they relate to open channel flow. This approach could be especially fruitful for examination of open channel flow because the use of emergent and direct rules depends on the scale of analysis (e.g. flow in a channel from one city to another vs. the development of eddies in open channels).

The identification of common misconceptions of open channel flow concepts is important and provides a way to qualitatively understand what the majority of students are having difficulty learning. Further, identifying any preconceptions can help professors teach more efficiently and effectively.

The results provide clear evidence that students are having difficulty understanding the fundamentals of open channel flow concepts. Whether this is due to lack of proper instruction, preconceptions and misconceptions are hindering the ability for these students to remotely understand open channel flow concepts. Although some concepts are easier and more intuitive than others, the global impact of the results is that students are having difficult understanding basic concepts as well as counter-intuitive concepts.

Abstract—There has been an increasing use of e-learning tools in higher education, which has resulted with a larger demand for assessment of their quality. This study proposes a statistical model to evaluate the e-learning system effectiveness from the users' perspective specifically within blended learning environments. The proposed statistical model uses six e-learning success factors extracted from relevant literature. These are, Information Quality, System Quality, and Service Quality Learners Attitudes, Supportive Issues, and Instructor Quality. A survey instrument based on proposed model was developed and applied to Middle East Technical University (METU), Ankara, first year students who are actively using Net-Class e-learning system as a supportive tool in their computer literacy course. The survey instrument was tested for reliability and validity using confirmatory factor analysis (CFA). Structural Equation Modeling (SEM) statistical analysis was used to validate the research model. The results show that, each dimensions of the proposed model had a significant effect on the learners' perceived overall satisfaction from an LMS. Findings of this research will be valuable for both academics and practitioners of e-learning systems.

I. INTRODUCTION

Rapid developments in information technology (IT) have generated potential changes to teaching and learning [1]. Learning has been dramatically changed in the last decades. The development of network technology provides highly dynamic communications, multimedia tools make learning easier and convenient to use, databases offers several channels to create efficient platforms, information technologies serves better learning environment. Specifically, rapid advancements in internet technologies have resulted in significant impact on the learning industry. Consequently, the trend of using web-based or electronic learning as learning and/or teaching tool is now rapidly expanding into education [2]. Therefore, e-learning applications have become highly popular and applied

by several universities. A quote that belongs to Lockee, Moore, & Burton (2007) says that “*Only by evaluating the effectiveness of e-learning programs, we can justify their use and continue to develop their quality*” [3]. Hence, there is an important necessity for evaluation of every e-learning system [4-5]. The main contribution of this research is to bring previously build e-learning success criteria together and build statistical model based on those criteria. For this purpose, in this study, we have used previously used e-learning assessment metrics and survey created by Ozkan et.al. 2009.

In this paper, an *E-Learning System* or a *Learning Management System* (LMS) has been considered as a special type of an Information System (IS). An e-learning system or an LMS can be defined as “*the use of electronic devices for learning, including the delivery of content via electronic media such as Internet, audio or video, satellite broadcast, interactive TV, CD-ROM, and so on*” [6]. *Blended learning* or *hybrid learning* refers to “*learning events that combine aspects of online and face-to-face instruction*” [6]. Online learning can be defined as an option “*for students who wish to learn in their own environment using technology and/or the Internet*” [6]. The terms “*e-learning*”, “*online learning*”, “*computer-based learning*”, “*distance learning*” and “*web-based learning (WBL)*” are interchangeably used by researchers, and that approach will also be taken in this study.

The rest of the paper is organized as follows: Section II reports background information. Section III focuses on the research model and hypotheses. Research methodology is presented in Section IV. Section V deals with testing the hypotheses by statistical analyses and proposes new hybrid research model based on users' perceived effectiveness to use the e-learning system. The findings of this research help to develop more efficient LMSs with less effort and also provide insight into the best way to define e-learning success criteria for future research in this field.

II. RESEARCH MODEL AND HYPOTHESIS

A comprehensive e-learning assessment model has been developed to evaluate e-learning system success from users' perspective as depicted in Figure 1 [21]. The theoretical grounding for this research derives from existing information system success models such as DeLone & McLean's updated IS success models. Rather than using the existing DeLone and McLean's (D&M) model as it is, authors in [21] have extended it by integrating other dimensions related with e-learning. The final model has unique properties such as *course content*, *instructor*, *instruction quality*, and *learner attitudes*. If there were no extensions, the D&M IS Success model would be insufficient to assess an LMS effectively despite the fact that an e-learning system is a type of IS. Authors in [21] proposed HELAM (Hexagonal E-Learning Assessment Model) e-learning assessment model as a base, it has 6 dimensions:

- a) *System Quality*
- b) *Information (Content) Quality*
- c) *Service Quality*
- d) *Instructors Quality*
- e) *Learners Attitudes*
- f) *Supportive Issues*

System Quality: System Quality typically measures the performance of the system. One of the key dimensions of the DeLone & McLean's IS success model is "system quality". System Quality is an important indicator to measure an LMS's success. Moreover, nearly all of the researchers dealing with LMS success define system quality as a significant factor for user satisfaction [7] - [8] - [5] - [4] - [9] - [1] - [2] - [10] - [11] - [21].

Information (Content) Quality: Content Quality measures the appropriateness and effectiveness of the delivered information in LMS. This dimension is also one of the dimensions of the DeLone and McLean's IS Success Model, named as "Information Quality". Interactive instructional design is an essential factor for learning satisfaction and success [12] - [13] - [21]. Additionally, Shee and Wang [13] stated that learners place great value on content.

Service Quality: Pitt, Watson & Kavan stated that "commonly used measures of IS effectiveness that focus on the products rather than the services of the IS function [14]. Thus, there is a danger that IS researchers will mismeasure IS effectiveness if they do not include in their assessment package a measure of IS service quality" Also, DeLone and McLean reported that there is a significant relationship between an effectiveness of an IS system and service quality [15]. They define service quality as "up-to-date hardware and software", "responsive IS employees", "knowledgeable IS employees who do their job well". In addition, this study included other indicators for an effective e-learning service such as 'empathy'.

Instructors Quality: Several researches indicate the quality of an instructor as an important determinant for an

effective LMS [9] - [12] - [4] - [16] - [2]. Webster et. al. concluded that, it is not the technology but the instructional implementation of the technology that determines its effects on learning [1]. They also proposed that, instructors' attitudes toward a technology, teaching styles, and control over the technology will affect the learning outcomes [1]. Holsapple, et. al. proposed that instructors' attitudes toward technology-mediated distance learning systems be included in evaluations of these systems [8].

Learners Attitudes: Learners attitudes toward an LMS is considered as an important factor for creating an effective LMS by several researchers [5] - [1] - [9] - [7] - [2] - [10] - [8] - [4] - [11] - [21]. It is evident from these studies that to design effective e-learning environments, it is necessary to **understand target group**. Liaw, Huang and Chen have shown that the two learner characteristics, *perceived enjoyment* and *usefulness*, are positively related to intention to use an LMS [2].

Supportive Issues: The five dimensions, explained above, have been identified to be directly related to LMS success. However, there may be other factors affecting learners' attitudes which indirectly affect the success of an LMS, such as popularity of e-learning systems, general educational trends, technological developments, ethical and legal issues, environmental issues, i.e., geographically diversity, socio-economical level, diverse backgrounds. All these indirect factors have been included within the "Supportive Issues" dimension [21].

Levy in his "Assessing the Value of E-Learning System" book, divided e-learning components into seven categories. He stated that none of these components can create meaningful learning features without proper integration of all of them. He proved that these categories are all interrelated with each other [22]-[23]. Similarly, Khan underlines the correlations within the LMS factors [12]. In the light of all previous literature given above, this study emphasizes that examining these interrelations has become crucial to achieve an effective e-learning environment. Therefore, in this study, in addition to the six dimensions proposed, other interrelations among these six dimensions have also been tested. Any significant relationship found between any two dimensions has been added to proposed research model which is presented in Figure 1.

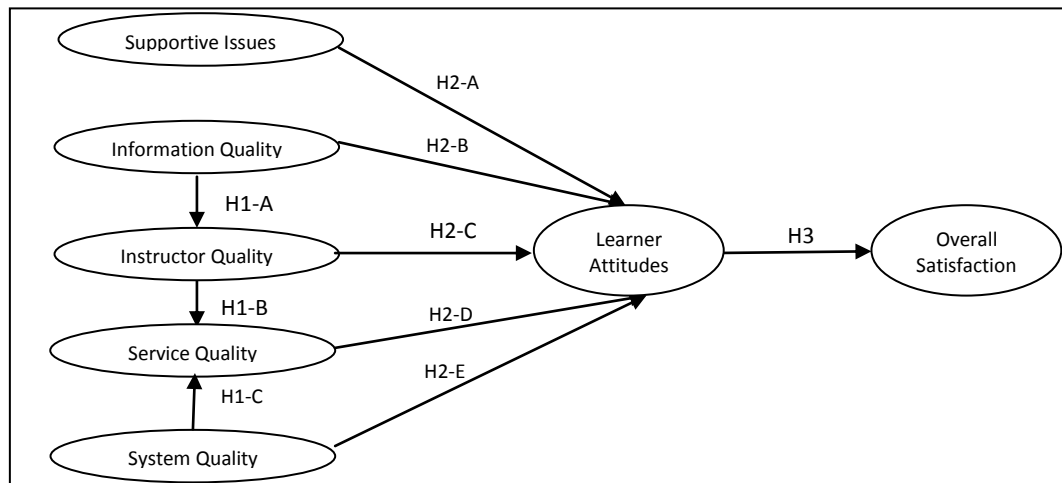

Figure 1: Proposed Research Model

The relations in the proposed research model have lead to the following set of hypotheses:

- H1-A: The quality of information is directly and positively related to instructor quality.
- H1-B: The quality of instructor is directly and positively related to service quality.
- H1-C: The quality of system is directly and positively related to service quality.
- H2-A: The quality of supportive issues is directly and positively related to learner's attitudes.
- H2-B: The quality of information is directly and positively related to learners' attitudes.
- H2-C: The quality of instructor is directly and positively related to learner's attitudes.
- H2-D: The quality of service is directly and positively related to learner's attitudes.
- H2-E: The quality of system is directly and positively related to learners' attitudes.
- H3: The quality of e-learning is positively related to learners' attitudes toward LMS.

III. METHOD

A. Measures – Survey Instrument

In this study, quantitative assessment methods have been used to build a statistical model for evaluating the effectiveness of an e-learning system. This research study uses a survey instrument developed by in [21]. This has been used to collect data from learners about their perceptions of the impact of the blended learning environment and LMS in regards to their benefits and satisfaction level. After developing the survey instrument based on critical e-learning success factors in the literature, the authors [21] were conducted a pilot study with the proposed survey with 30 Middle East Technical University students who were enrolled on the course entitled "IS100 Introduction to Information System Technologies and Applications". Additional to pilot

study, the survey developers applied the survey to students at both undergraduate and graduate levels who are users of a web-based learning management system, U-Link, at Brunel University. On their study, they applied several reliability and validity tests such as criterion-based predictive validity to assess the efficacy and effectiveness of the survey instrument's parameters in predicting learner's satisfaction, for that they used R square statistical methods. The R squared value of the survey is 0.963, which is very good indicator that the survey is likely to predict learners satisfaction.

The survey consists of two main parts. The first part aims to gather demographic data about the learners, and the second part, which is about learners' LMS experiences, is divided into six sections each of which corresponds to each proposed statistical model dimension. These are (1) *System Quality*, (2) *Information (Content) Quality*, (3) *Service Quality*, (4) *Instructors Quality*, (5) *Learners Attitudes*, (6) *Supportive Issues*. In this part, 5 point likert-type scale items have been used to collect data. Items are anchored from 1 to 5, where 1 indicates strong disagreement and 5 indicates strong agreement. All responses were guaranteed confidentiality.

B. Participants and Data Collection

The survey instrument was distributed online because the use of computer-assisted data collection can significantly improve the reliability of the data as it eliminates the human data entry step that includes some natural human errors.

Table 1 - DEMOGRAPHIC CHARACTERISTICS OF RESPONDENTS (BOTH ONLINE AND BLENDED LEARNING NETCLASS USERS)

| | Frequency | Percentage |
|--|------------|--------------|
| Gender | | |
| Male | 96 | % 44.23 |
| Female | 121 | % 55.76 |
| Age | | |
| Under 21 | 168 | % 77.4 |
| Over 21 | 49 | % 22.6 |
| Computer Usage Habits (per day) | | |
| <i>Spend time on using a computer/Internet (per day)</i> | | |
| Less than 1 hour | 31 | % 14.3 |
| Between 1-3 hour | 105 | % 48.4 |
| Between 3-5 hour | 58 | % 26.7 |
| Between 5-7 hour | 15 | % 6.9 |
| Between 7-9 hour | 3 | % 1.4 |
| More than 9 hour | 5 | % 2.3 |
| <i>Spend time on using a computer/Internet for educational purposes(per day)</i> | | |
| Less than 1 hour | 92 | % 42.4 |
| Between 1-3 hour | 100 | % 46.1 |
| Between 3-5 hour | 18 | % 8.3 |
| Between 5-7 hour | 4 | % 1.8 |
| More than 9 hour | 3 | % 1.4 |
| f Spend time on using U-Link (per day) | | |
| Less than 1 hour | 189 | % 87.1 |
| Between 1-3 hour | 17 | % 7.8 |
| Between 3-5 hour | 9 | % 4.1 |
| Between 5-7 hour | 2 | % 0.9 |
| Total | 217 | % 100 |

The survey was applied to students studying at Middle East Technical University (METU), Turkey. A total of 800 individuals participated in the survey. Out of those who participated in the study, usable data was obtained from 217 (~27% of the sample size) undergraduate Level 1 students who were enrolled on a computer literacy course entitled “IS100 - Introduction to Information System Technologies and Applications” at Middle East Technical University. IS100 course is a basic level computer literacy core course designed for all first-year students throughout the university. In this course both *blended learning*, and *online learning* style was used. As the learning environment, **NetClass** learning management system is used (<https://online.metu.edu.tr>). The same survey instrument was applied to both groups. 160 responses were obtained from blended users and 57 responses were obtained from online learners. Table 1 lists the respondents’ demographic characteristics, including gender, age and computer usage levels.

IV. RESULTS

The Structural Equation Model approach was used to validate the research model. This approach was chosen because SEM is a statistical technique for testing and estimating causal relationships using a combination of statistical data and qualitative causal assumptions [17]. Specifically, “SEM provides a great flexibility in estimating relationship among multiple predictors and criterion variables which allows modelling with unobservable latent variables; it estimates the model uncontaminated with measurement errors” [18]

A. Measures Reliability and Validity

Before running the Structural Equation Modeling model, each survey instrument was tested for reliability and validity using **confirmatory factor analysis (CFA)**. The model included 29 items categorized under proposed research model dimension. All the items’ factor loadings were greater than recommended level which is defined as 0.80 by [17], the greater factor loading indicates that similar items which measures the same hypothesis are producing similar scores. Factor loading is also a prerequisite requirement for SEM which was guaranteed by high item loadings.

According to Joreskog et.al., (1996), χ^2 (the ration between χ^2 and the degrees of freedom) provides direct statistical evidence for the test of model goodness of fit [17]. The observed normed χ^2 for measurement model was 2.24 ($\chi^2 = 4093.09$, $df = 1822$), which is smaller than 3 recommended by [19]. Other than chi-square various goodness-of-fit indexes were tested and summarized in the Table 2. All indexes shows good fit for the measurement model. Proposed model’s indexes are higher than recommended level, CFI is 0.91, which exceed the recommended cut-off level of 0.9 [17]. The root mean square error of approximation (RMSEA) is 0.076, which is below the cut-off level of 0.08 recommended by [20]. However, GIF index is slightly lower (0.78) than the recommended level which 0.8 [17].

TABLE 2 - GOODNESS-OF-FIT MEASURES

| Fit Indexes | χ^2 (Chi Square) | χ^2 / df | GFI (Goodness of Fit Index) | CFI (Comparative Fit Index) | RMSEA (Root Mean Square Error of Approximation) | P |
|--------------------|-----------------------|---------------|-----------------------------|-----------------------------|---|-------------|
| Recommended Values | - | ≤ 3 | ≥ 0.8 | ≥ 0.9 | $\leq 0.05 - 0.08$ | 0.00 |
| Model’s Values | 4093.09 | 2.24 | 0.78 | 0.91 | 0.076 | ≤ 0.05 |

B. Model of Interest (Structural Equation Model)

The results of structural model analysis are displayed in Figure 2. The structural model correlates the dimension with each other for instance information quality is linked to instructor quality. The statistical results showed that *system quality* positively affects *learners’ attitudes* toward used LMS. The result $R^2=0.69$ provides support for H2-E. Moreover, *information quality* significantly affects *instructor quality* ($R^2=0.67$) supporting H1-A. From H1-B and H1-C, *service quality* is positively affected from *instructor quality* ($R^2=0.40$) and *system quality* ($R^2=0.45$). Additionally, *service quality* ($R^2=0.30$), *instructor quality* ($R^2=0.66$), *information quality* ($R^2=0.40$) and *supportive issues* ($R^2=0.39$) has positive effect on *learners’ attitudes* which supports H2-C, H2-D, H2-A respectively. Lastly, *learners’ attitudes* toward an LMS is highly correlated with **overall user satisfaction** from used LMS ($R^2=0.70$) which supports H3.

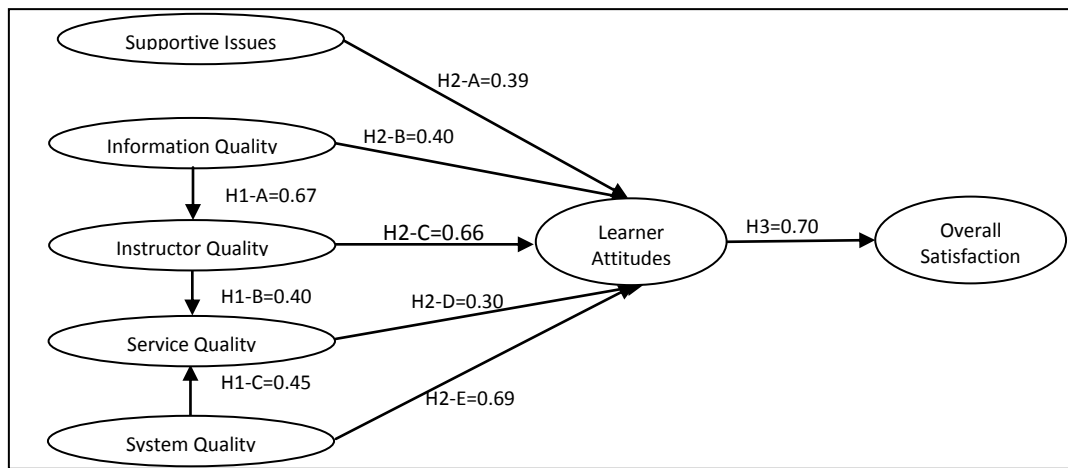

FIGURE 2. RESEARCH MODEL WITH STRUCTURAL EQUATION MODEL (SEM) RESULTS

V. CONCLUSION

This study attempted to propose a statistical model for evaluating e-learning within the higher education environment. The research in this paper sought to empirically test the constructs of this proposed conceptual model via a survey instrument and to demonstrate which were critical for e-learning systems effectiveness, particularly when implementing a computer literacy course. The instrument was validated and it has been proved that all six dimensions of the proposed e-learning evaluation model were important for the implementation of a computer literacy course via a learning management system. This study contributes to the e-learning literature with an instrument providing a roadmap for practitioners and researchers to better understand how e-learner's perceived satisfaction can be increased and how the use of learning management systems can be improved. In addition to this study, future studies may extend this model through adding other dimensions in parallel with changes in the e-learning field. Another future expansion would be to check the validity of the causal research model on different learning management systems.

Work in Progress: A Semantic Annotation Scheme for Concept Maps

Viviane Gomes da Silva

Federal Institute of Education, Science and Technology Amazon, viviane@ifam.edu.br

Alberto Nogueira de Castro Jr

Federal University of Amazonas, alberto@ufam.edu.br

Abstract – Concept Maps (CM) are custom-made graphical representations whose understanding (and therefore socialization and reuse) depends on adequate explanation by the author and so their main advantage is also their main constraint: the freedom to represent concepts and relationships between them in any way, mostly in idiosyncratic and not understandable ones. In this paper we show how information on meaning and application contexts of a Concept Map can be represented and how it would be added to a learning object database ordinarily accessed by teachers and students. We use a freely available CM editor and from the XML textual representation of a map, metadata are defined with additional information on its meaning as defined by the author and on the contexts in which it has been used. That representation of an annotated map is then incorporated into a functional learning objects database (a LO category that includes software developed for educational purposes). This scheme for semantic annotation has been analyzed through a case study with students from a Software Development Tech course, who reported their impressions when creating, socializing and reusing maps with FLOCOS database environment.

Index Terms – Concept Maps, Semantic Annotation, Learning Object, Metadata.

INTRODUCTION

Learning strategies and support materials are key issues for education in its various forms and has motivated a search for computer-based resources that might assist students and teachers to gather and organize information and share knowledge about any subject. In this context, Concept Maps (CM) are resources worth to exploit. CM are graphical tools able to communicate, represent and demonstrate knowledge about a particular topic, activity, text or any other object of analysis. This tool can be used both by teachers and by students and in areas like Science, Technology, Engineering and Mathematics (STEM) they can help to visualize abstract concepts and to grasp meaning in a stepwise way. CM can be used, for example, as a way to organize contents, to support evaluation, and to represent relationships and sub-relationships between concepts of a same area.

The goal of this work was to support CM reusability and facilitate their understanding through semantic annotation. With the adaptation of a Learning

Object (LO) repository to meet CM characteristics, we have presented a standard metadata fit to that task.

CONCEPT MAPS AND LEARNING OBJECTS

Through concept maps, domain-specific knowledge can be visually organized in different ways, one of which is a hierarchical structure with the focus concept at the top of the map. This focus concept leads into ‘child’ nodes defining their relationship to the main concept. CM, broadly conceived, are network diagrams in which concepts (nouns) are nodes and the relationships between concepts (verbs) are links.

CM allow their authors to choose different types of representations and use different vocabulary. However, such flexibility and freedom can produce semantic problems and ambiguities. The central difficulty in this challenge is the identification of an “adequate” or “relevant” map during a user search. CM are idiosyncratic, their custom graphical representation of author’s understanding of contents depend on an adequate explanation by those authors. Therefore, its main advantage is also its main limitation. The freedom to represent concepts and relationships becomes somehow a challenge to socialization and reuse. Consequently, there is a need for “commented” CM embodying information about context of use.

Learning Objects are structured and organized by metadata standards, making their search through current web tools more efficient. Since this is not the case with CM, we propose to structure them with standard LOs metadata and to add semantic annotation for their understanding and proper use. In the following paragraphs we describe how this is done.

METADATA

In order to add more information and flexibility to LO representation, we have adopted a novel standard for metadata, the Metadata for Functional Learning Objects (MFLO), implemented in [2]. As MFLO does not have enough resources to represent a using scenario by the object author – a relevant need for a proper CM description, we have adapted its structure using an ontology domain so that it would be able to add semantic annotations.

CASE STUDY

In order to evaluate suitability of metadata for structuring and organizing information from CMs, a case study was carried out with students of the 5th

period of a technology in software development (TSD) course at the Federal Education Institute of Amazonas (IFAM). These students had a good knowledge on software requirements analysis and were asked to: (i) learn about standard CM, (ii) develop specific CM, (iii) interpret and access other people CM and (iv) search CM attending to specific parameters.

As many students were familiar with metadata they were able to describe the metadata within their CM. However, doing the same thing with CM from other authors was described as “a very complex task”. The same situation happened when reading the CM’s key-concept, in other words, the starting reading point of the CM was difficult to find in CM that were created by other authors. Regarding the search for CM of other disciplines, many students stated that it was difficult to find CM even when searching for resources in other languages. Students said that even if a CM was found they often were not able to understand it. As a result of analysis on findings like these, several elements were removed and some were added to standard MFLO.

METADATA FOR CONCEPT MAPS

Data from the case study supported identify what of elements better added “semantic information” to a CM and how we structure them in a way that facilitate access and reuse.

The resulting metadata, called ‘MFLO-CM’ could then be used in a semantic annotation scheme showed in Figure 1.

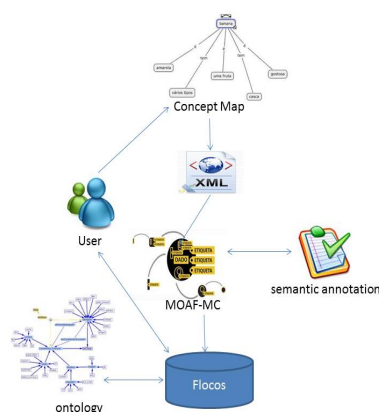

FIGURE 1
A SEMANTIC ANNOTATION SCHEME USING MFLO-CM

The scheme shown in Figure 1 has been implemented as a web-based software tool to support annotation of concept maps produced through a freely available CM tool called CMapTools¹. That editor has a plug-in tool that produces a XML equivalent for the original diagrammatic form of a CM. This linear representation of the CM was then transformed in a semantic-annotated learning object using MFLO-CM structures, described using a domain ontology and added to a freely available LO repository.

¹ <http://cmap.ihmc.us/>

ADDING CM TO A REPOSITORY OF LEARNING OBJECTS

The purpose of a repository is to facilitate the reuse of educational resources stored in learning management systems (LMS), learning content management system (LCMS), content portals (for an example, in search of digital library systems), or any application or software designed to access learning objects.

There are several public-available LO repositories, some maintained by research or higher education institutions, other by the Ministry of Education and other by private organizations. In order to test feasibility of the annotation scheme proposed here, we adapted FLOCOS (Functional Learning Object Collaborative System) – a LO repository developed by a research organization and used by teachers in real-world situations [1]. FLOCOS is a collaborative system to build FLOs described through the MFLO metadata. The users interact in the MFLO metadata generating new objects, or maintaining the existing ones. Through its update with the structure of MFLO-CM presented here, this repository can now manage and store all kinds of CM and provide them for their reuse.

A proof of concept, we have selected 24 concept maps produced by teachers and students from several science and technology courses carried on at IFAM, based on different contexts and purposes, and used the scheme shown on Figure 1 to make them available on FLOCOS.

CONCLUDING REMARKS

This paper describes a way for concept maps have incorporated information about their creation and intended used, and be integrated into repositories of functional Learning Objects. A case study was developed for requirements elicitation of metadata structure that was then used in a web-based software tool integrating a CM authoring tool and a learning object repository. Tests shown that this annotation scheme allowed CMs to be stored, accessed, organized and be available for reuse just like other LO. Structured authoring information also will allow CM to have their devising context make explicit.

Work in Progress: Management of online assessments as a replacement for exams

Dr Andrew Maxwell
Faculty of Engineering and Surveying
University of Southern Queensland
Toowoomba, Australia
andrew.maxwell@usq.edu.au

Abstract— Whilst online Learning Management Systems (LMS) environments are rapidly becoming commonplace and a justified means for supporting learning and teaching, courses are often unable to be entirely taught online due to the necessity for traditional paper-based examinations, usually of significant percentage weighting of the total course grade. In this paper, the author describes the preliminary development of procedures and workflows for managing online assessments as a replacement for these traditional examination conditions, seeking to reduce examination stress and increase assessment validity. An in-development software suite, based on a LMS log-file pre-filter mechanism and behavior identification heuristic engine, is introduced to assist with identifying online compliance and collusion.

Keywords— component; online assessment; examinations; examination stress; instruction compliance

I. INTRODUCTION

Engineering course assessments have typically consisted of set assignments concluded with a final written paper-based examination. Whilst this classical model is still valid, it is seeing re-invention particularly where courses are offered through online and mobile environments. The shift to online-compatible assessment-structures has obvious utility and technologically enables alternative assessment strategies. The aim of this paper is to demonstrate example methods in the management of one particular course where less traditional means are used, examined by the author. Within this course the assessment model transitioned away from classical assignment/exam approaches to incorporate an entirely online-exam. Although this transition afforded reinvestigation of assessment metric opportunities, it presented several challenges particularly ensuring academic integrity of the assessment responses. Whilst there is presently debate regarding the nature of online academic misconduct [1], experience shows that this is still of concern and worthy of consideration.

II. EXAMPLE COURSE

The presently ongoing course used in this case study is a 3rd year level electronic measurement course where students are required to demonstrate understanding of abstract concepts in their own-words pertaining to measurement science, and instrumentation principles through insightful interpretation of provided course materials as opposed to direct fact recall. This particular course requires a strong grasp of technical English. The student cohort studying this course is often diverse with students from Australia, Malaysia, Singapore and other Asia-Pacific nations. As a result, technical English comprehension

could not be assumed, as suitable ‘academic language’ may not yet have been sufficiently developed. It has been previously identified within this course that there was a significantly increased risk of examination stress caused by English interpretation and dissemination of technical concepts [2]. Additionally whilst assessment items were designed to be strictly individual submissions, some benefits were afforded through group discussion of the content. This presented a conflict within this course regarding the duality of specifically allowing student group discussion, participation and peer learning, whilst maintaining clear individual learning opportunities and metrics, and required monitoring and moderation. Because of these inequities, a solution was sought to ensure assessment compliance under these conditions.

A. Previous Assessment Structure

Prior to 2006, the final course assessment was based upon traditional metrics and a final written exam, worth a significant proportion of the total course marks (60%), was required to be sat at examination centers around Australia, and internationally. This examination required students to describe, in three hours, abstract conceptual interpretations of the course content, in English. The negative effects of examination-stress have been previously extensively reported, for example [3], showing in principle that this was a significant factor in poor student performance. A variety of techniques can consequently be applied to reduce stress and anxiety permitting closer examination of learning objectives [4]. These include: varying the assessment styles; relying less on memory for assessments; enabling greater expression of assessment experience; and relaxing time requirements for given assignment or examination test items.

B. Revised Assessment Structure

From 2006 onwards the previous examiner for this particular course transitioned all assessment to be entirely online based. The exception to this was physical construction assessments used to provide practical application of the theoretical concepts, for which there was no online equivalent. As a result of this online offering, the course assessment was modified to more closely incorporate improvements in reducing stress and language deficiencies. Consequently the following changes were made: preliminary formative quizzes used to train students in quiz answering techniques; increasing the time allowed for online assessment; providing memory support (open-book material); and replacing the traditional written exam with a significant open-book 24 hour timed

online quiz. These changes however necessitated the introduction of additional management to ensure academic compliance and integrity. From 2009 onwards the course assessment was updated to further consider stress and language issues, and improved course assessment management was introduced incorporating additional workflows, and improved assessment compliance monitoring.

III. ASSESSMENT MANAGEMENT REQUIREMENTS

A. Allowing plenty of time for answers

In moving to an all-online timed examination, the main aim was to reduce the effects of traditional examination stress. One fundamental issue with this approach, using the traditional LMS, was an inability to satisfactorily verify that individual effort was being assessed, and that real-time plagiarism was not occurring. Clearly face-to-face examinations permit verification of identity and enforcement of strict conditions. Whilst there are existing products for enforcing online examination conditions, for example [5], these were considered costly and outside the scope of achievability within this course. During the initial transition to online assessment, simple identity checking was performed through manual monitoring of the logfile data and comparing student response styles with acquired stylistic writing data from student's previous submissions. This was however a laborious and time consuming task, even when supported by phrase-matching and anti-plagiarism software available within the LMS [6].

To overcome this issue, the final online examination-assessment was re-configured with 20 different, but objectively similar, 'versions' of the final online assessment having being appropriately moderated to ensure equal academic opportunity across all variants offered. Each assessment was split into two parts; one involving numerical calculations able to be computer marked and graded automatically; and a second descriptive writing part allowing students to demonstrate a detailed understanding of the course concepts which was graded manually. These examinations were run over a 5 day period, configured to start in batches from both 9am and 7pm, available to students from the start time till 24 hours afterwards before closing. Flexibility in scheduling was offered, where students were able to pre-select which time slot offering they would attempt, affording them flexibility to optimize their own study or work schedule and account for when they best performed academically (for instance, day or night). Prior observations within the course between participants allowed assessment versions to be allocated to time-slots where the risks associated with potential plagiarism could be reduced. In order to provide increased confidence in these observations, custom software was created to automate modeling of student interactions, potentially permitting automation and allowing for significantly larger class sizes.

B. Behaviour Heuristics – 'PlagRemover'

This software was developed to offline-process the existing logfile data available within the LMS. These individual log entries captured the metadata for each web resource requested and identified; the user; the resource being accessed; the specific resource action; and the time/date stamp of access. *PlagRemover* then permitted complex filtering and reformatting of this data to enable more flexible and specific

queries to be answered. For the analysis used within the example course, this software was configured to identify co-located students sharing common Internet connections, or working within collaborative study groups (having similar internet protocol address ranges). Critically, the aim was not to victimize students for prior group behavior, but to instigate positive examination conditions that encouraged professional responses from students. As the custom software required prior data-sets to determine these relationships before the final assessment, prior online assignments of a smaller nature were utilized and analyzed. From the output of the software, co-located students at risk of plagiarizing were allocated individual or differing assessment batches to facilitate exam condition compliance.

IV. DISCUSSION AND CONCLUSION

An aspect for further development is investigating additional compliance options where students are checked against a list of actions required of them, including dates or deadlines for each action. This has direct utility in large classes, where automation could immediately identify disengaged students, who are not completing tasks or using the LMS appropriately, and target these students for assistance. At present, despite being an offline process, potential is seen in facilitating this functionality as a built in module within the LMS permitting real-time analysis of these logs. This has potential to yield more advanced and meaningful heuristics and immediate awareness of online student behavior. This immediacy has further benefit to the management of automated online examinations where student actions, either spatially or temporally, can be analyzed in real-time permitting automated corrective actions, or halting of the examination conditions, thus replicating in software some of the manual or visual checks that occur in other online examination integrity systems. Also of importance is the investigation of student awareness of these compliance systems and its effect on student performance during these assessments.

In conclusion, this work-in-progress presents the ongoing investigation of processes to maintain academic integrity for substantial online exams within the online teaching environment. Preliminary results conclude that LMS interaction analysis in conjunction with positive online examination conditions can assist in ensuring assessment validity and compliance.

Exploring Student Understanding of Parallelism Using Concept Maps

Greg Lammers and Cordelia M. Brown
School of Electrical and Computer Engineering
Purdue University
West Lafayette, IN
glammers@purdue.edu, brown83@purdue.edu

Abstract— This work explores the conceptual understanding attained by students in the area of parallel computing. Parallelism is continuing to grow as an important topic area in computer engineering and computer science. Even as it increases in popularity, only a limited amount of research has been done to determine how well students construct their knowledge of the field. This work aims to begin exploring the structure of parallel computing as understood by undergraduate computer engineering students. A small group of students was selected to create concept maps that illustrate their understanding. These maps have been used in many different areas of science and engineering. The maps were then analyzed and compared to a reference concept map developed by a group of computer engineering faculty. The results of this analysis revealed that students in this sample demonstrated a limited knowledge of parallelism and concurrency through the organization of their concept maps. The analysis of the concept maps also provides evidence that there is a moderate level of understanding of the challenges to implementing and controlling concurrency. However, the linkages created in the maps reveal students' misinterpretation of the goals of exploiting parallelism.

Keywords—Parallel computing, parallelism, concurrency, concept maps, conceptual understanding

I. INTRODUCTION

Parallel computing continues to gain interest as processor manufacturers have begun including more cores on their products. Increased demand for heterogeneous computing solutions has also created a need for engineers who understand the principles of parallelism. These trends have led to renewed discussion about how and when to introduce parallelism in an undergraduate computing curriculum. At the same time, it is necessary to evaluate the effectiveness of methods for teaching parallelism. This work aims to discover the knowledge structure that students in a traditional curriculum develop.

It is not sufficient to simply examine the understanding that students have of individual concepts related to parallelism. Rather, the links between concepts must also be studied. This study uses concept maps for this purpose. It is the first component in a multi-part study that also uses a concept inventory. The end goal of this study is to produce recommendations for integrating parallelism into an undergraduate curriculum. This part of the study, however, is focused only on examining what knowledge structure students

generate when educated in a curriculum that introduces parallelism and concurrency in the operating systems and architecture courses. The study was conducted at Purdue University, West Lafayette, Indiana with approximately twenty self-selected participants.

II. EXAMINING A PARALLEL CURRICULUM

Though parallelism is enjoying somewhat of a resurgence in computing curricula, concerns over its inclusion began decades ago [1]. In this recommendation, ACM detailed the importance of parallelism within a systems programming course and a computer architecture course. At this point, these were seen as the two avenues for introducing parallelism and concurrency to students.

The computer science education community continued to follow this model for some time. Bell noted in 1982 that “The subject of parallelism (or concurrency) has seen little light outside books and courses on operating systems” [2]. This was reflected to some extent even in 1994, when a major survey was completed that examined different universities’ approaches to courses on the topic [3]. This is still the way that the computer engineering department in this study views parallel computing in its curriculum.

Other universities have attempted novel ways to introduce parallelism into their curricula. One of these models is to introduce parallel thinking into the first year computer programming course [4]. This prevents any misconceptions that may arise from learning serial programming in depth before proceeding to parallel programming, but it can be difficult to create programming exercises of appropriate difficulty. However, introducing parallelism so early allows for integration of parallel topics throughout the entire curriculum.

Natural avenues for including parallelism are programming and algorithms courses. A course in data structures can be very naturally enhances to discuss thread-safe queues, for example. More advanced concepts such as GPU programming can also be included, as in [5]. Full integration throughout the curriculum beginning at the first year offers the greatest coverage of parallelism but raises concerns over what is pushed out to make room.

Another approach to including parallelism in an undergraduate curriculum is by offering a course devoted to it.

Many efforts have been made in this area (e.g. [6], [7]). Typically, this course is introduced late in a student's academic career and provides the opportunity to complete a large-scale software or hardware design project. Such a model misses out on opportunities for preventing sequentially-dominated thinking. However, whether this is a major concern is an open question. To help answer it, the computer science and engineering education communities need to better understand how students in these scenarios develop their understanding of parallelism.

III. CONCEPT MAPS

A limited amount of work has been done on examining student understanding of parallelism. Eccles completed a study on novice understanding of parallelism using schema theory and the card-sorting experiment [8]. This study has similar goals but uses concept maps to explore student understanding instead.

Concept maps were first introduced by Novak and Gowins in the early 1980's [9]. The goal of these graphic organizers is to represent a subject's understanding in a graphical, easy to understand format. A myriad of uses for these maps have been developed, including for teaching and assessment. Concept maps help to reveal the structural nature of one's understanding, which can provide valuable insight into how best to organize material in a curriculum. A typical concept map includes propositions as well as links between these propositions.

Two features of concept maps include their semi-hierarchical structure and labeling of links [10]. The term semi-hierarchical conveys the notion that links in a concept map often represent a hierarchy, but may also appear between propositions at the same depth or across very different depths. The labeling of links means that the graphical representation of some sort of relationship includes a label that describes the relationship. The validity of these links and their labels is an important factor in determining the 'quality' of a given concept map.

Novak and Gowins initially were hesitant to position concept maps as a tool for assessment, but recognizing the potential, they provided one method for evaluating student-generated maps. Based on Ausubel's learning theory, this scoring method is detailed in Table I. From this table, it is relatively apparent that a key determinant in the score of a concept map is the inclusion of cross links. Significant cross links show an ability to synthesize relationships within a content domain, an important indicator of learning.

Another method for scoring concept maps has been developed that relies on comparison to an expert-developed criterion map [11]. This method analyzes three metrics: proposition validity describes the number of relationships that are valid, regardless of relevance to the selected domain. Saliency is defined as the proportion of valid propositions to the total number of propositions, and congruence is the proportion of valid propositions to the total number of possible valid propositions from an expert concept map [11]. This scoring system incorporates part of Novak's method in the proposition validity score, but the other two scores assess different dimensions than Novak's component-based system.

A third method allows for more judgment in evaluating concept maps by providing a holistic rubric for assessment [12]. This approach examines three factors that are a combination of those used in the previous two methods. A correctness dimension is very similar to the congruence score that is part of the previous methodology. A score for organization is likely to correlate with the hierarchy dimension of the component scoring method (at least for subject domains that are, in fact, hierarchical), and the comprehensiveness score combines the congruence and saliency scores of the criterion-comparison method.

The engineering education community has begun to embrace concept maps as a learning tool [13]. Even more research has been done in the sciences. This tool has also seen some use within computer engineering [14]. Applying what has already been learned in these arenas can help create a more organized parallel curriculum.

For a more thorough review of the literature pertaining to concept maps, see [15].

TABLE I – Component Scoring for Concept Maps [9]

| Category | Scoring |
|--------------|--|
| Propositions | 1 point per valid relationship |
| Hierarchy | 5 points per valid level of hierarchy |
| Cross-links | 10 points per valid and significant cross link 2 points per valid cross link |
| Examples | 1 point per valid example |

IV. EXPERIMENT METHODOLOGY

1) Selection of Participants

In order to best answer research question (1), participants needed to be chosen who had completed courses in Operating Systems and Computer Architecture.

TABLE II– Procedure for Administering Instruments

| Activity | Description | Time Allotted |
|--|---|---------------|
| Introduction | Subjects were informed of their rights as participants | 5 minutes |
| Word association | Presented with the word 'Computer', participants were asked to create a list of as many related words as possible | 5 minutes |
| Introduction to Concept Maps | A brief lecture was given on the idea of a concept map and how to create one | 10 minutes |
| Word association | To help students generate their list of terms, the word association exercise was repeated with the term 'Parallel Computing' | 5 minutes |
| Concept map construction | Students were asked to generate a concept map for parallel computing using the terms developed in the previous exercise. Pencil and paper were used to construct the maps to eliminate training time for a computerized mapping program | 35 minutes |
| Concurrency Concept Inventory administration | Subjects completed the multiple-choice Concurrency Concept Inventory using pencil and paper. | 1 hour |

For convenience, these students were selected from the computer engineering program at Purdue University. Students were recruited using in-class visits and e-mail. The students first targeted were those in the capstone design course, as these students were the most likely to have already completed the OS and architecture courses. These students were told that they would be participating in an experiment to help aid researchers in their understanding of the students' views on parallelism. They were not told of the nature of the instruments they would be completing. These students were offered monetary compensation for their participation in the study.

2) Administration of Instruments

Students volunteered for a two-hour block of time in which to complete concept map generation and concept inventory administration. In order to provide the students with enough information to complete a concept map, part of this time period was set aside for training. A modified version of the procedure utilized by Ruiz-Primo was used to prepare students for the concept mapping process [11]. This process is outlined in Table II.

Because the goal of this work is to analyze the nature of student understanding of parallelism and not necessarily to fully evaluate the teaching program, students were asked to generate their own concept lists. This exercise provided an additional artifact for examination as well; for students who did not have a strong understanding of parallelism, the list of terms could be examined to determine which foundational knowledge may have been lacking.

3) Scoring of Instruments

The student-generated concept maps were scored by a set of reviewers following the scoring methods described in section III. The concept map developed for the Concurrency Concept Inventory was used as the criterion map for scoring methods that needed such a device. Reviewers' scores were compared and subjected to inter-rater reliability metrics to determine the validity of the scoring procedures. Qualitative observations were annotated and compared to numeric scores to arrive at conclusions regarding student understanding.

V. RESULTS AND CONCLUSIONS

Sixteen students participated in the experiment. All but one were male. Relevant information on the coursework of the population is provided in Table III.

TABLE III – Coursework Experience

| Courses Taken | Number of Students |
|--------------------------|--------------------|
| Both OS and Architecture | 5 |
| OS only | 1 |
| Architecture only | 5 |
| Neither | 5 |

The intraclass correlation coefficients for average measures are given in Table IV. The average of the three reviewers' scores is used throughout the remainder of this paper.

TABLE IV – Intraclass Correlation Coefficients

| Scoring Method | Intraclass Correlation |
|----------------|------------------------|
| Component | .795 |
| Criterion Map | .889 |
| Holistic | .791 |

Raters were largely in agreement for the criterion-map based scoring, while opinions deviated more noticeably for the other two methods. Looking into the component based method, different reviewers had divergent opinions on what levels of a hierarchy were to be considered valid.

Figure I and Table V show the relative scores for three different populations for each scoring method. From this chart, it is apparent that, as one would expect, scores for students who had never before seen parallelism covered in their coursework scored very low. These were Electrical Engineering students completing a microcontroller-based capstone design course. Their exposure to Computer Engineering concepts came during first-year programming and an upper-level microcontroller course.

Interestingly, students who had not completed the Operating Systems course (but had taken Computer Architecture) achieved higher scores on average. The small size of each sample is largely culpable for this; two of the students in the Architecture-only group had outside experience working with projects that made practical use of parallel design or programming. Figure I also shows that criterion-based scoring and holistic scoring agree more closely regarding the relative performance of each group.

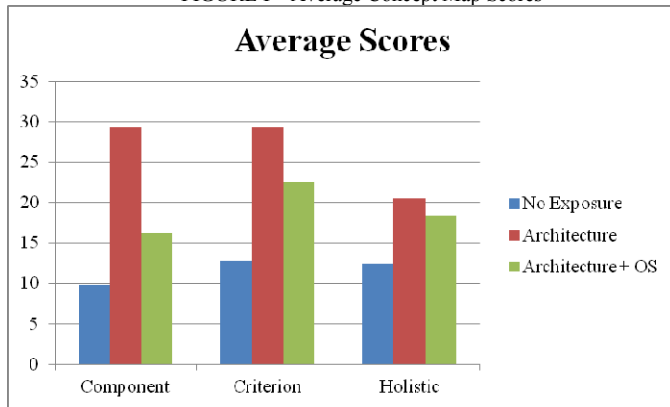

As a gauge of students' metacognitive abilities regarding parallelism, Figure II charts each student's self-reported confidence in their understanding of parallelism with the three concept map scores obtained. A linear regression identifies the trend in evaluating how well students rated their own abilities. The low R^2 values indicate a poor relationship between concept map score and student-provided confidence level. This indicates that students are not able to accurately judge their ability to apply principle of parallelism. Alternatively, they may be poor concept mappers or concept mapping does not accurately reflect their understanding in this instance.

TABLE V – Concept Map Scores

| Score | Average | Std. Dev. |
|-------------------------------|---------|-----------|
| Component – No exposure | 9.73 | 9.03 |
| Component – Architecture only | 29.40 | 12.64 |
| Component – Both courses | 16.20 | 2.85 |
| Criterion – No exposure | 12.73 | 8.66 |
| Criterion – Architecture only | 29.40 | 9.70 |
| Criterion – Both courses | 22.60 | 5.91 |
| Holistic – No exposure | 12.40 | 2.61 |
| Holistic – Architecture only | 20.60 | 2.70 |
| Holistic – Both courses | 18.40 | 2.19 |

One conclusion of this work is that students show a wide variation in their abilities to represent parallelism concepts in a concept map. This may change when the experiment is repeated with the change that students begin the concept mapping process with a list of terms instead of generating their own lists.

FIGURE I – Average Concept Map Scores

It is difficult to draw any conclusions on actual understanding of parallelism based on the scores obtained from the mapping process. The small sample size and high standard deviation of scores prevent any significant statistical observations.

While the scores do not necessarily paint a full picture of the level of understanding attained by students, some themes did emerge from the analysis of the map. Students with exposure to operating systems concepts typically included methods for concurrent processing, such as locks and synchronization, in their concept maps. This is to be expected, since the OS course emphasizes these constructs.

Student maps indicated a difficulty in understanding the difference between parallelism and concurrency. One map, for example, linked the two concepts together with a double-headed arrow, indicating an equivalence relationship. While often used interchangeably, concurrency focuses more on nondeterministic events being processed simultaneously. This is in contrast to parallelism, which aims at extracting as much performance as possible from a program by decomposing it into multiple components that can execute simultaneously. None of the concept maps generated showed an understanding of this distinction.

Figure III gives the distribution of concept mentions over the sixteen maps. Several observations can be made here. First, students acknowledge the shared memory and threading models for concurrency much more readily than distributed memory. Even the students who mentioned distributed memory models showed a deeper understanding of the other two models by including additional propositions and hierarchical levels related to shared memory and multithreading.

Students did not organize their parallelism concept maps by type of parallelism. In fact, no maps mentioned the differences between instruction-level, task-level, and data parallelism. Maps were more typically organized by identifying the challenges involved in implementing concurrency control and grouping subconcepts under each type of challenge. The benefits of parallelism, such as higher performance and reduced power usage, were explored at a more shallow level than the challenges.

It is also important to note that many more students mentioned the terms ‘hardware’ than ‘software’. Indeed, the focus of many maps was on hardware implementations that exploit parallelism. This is likely attributable to the large number of students in the sample who had completed the architecture course.

The observations made regarding the organization of maps reflects the limited knowledge of parallelism and concurrency of graduating students. By focusing solely on hardware and shared memory models, students misinterpret the goals of exploiting parallelism. A shift to a performance-oriented approach may yield benefits in expanding the breadth of student knowledge. While students seem to grasp many of the challenges in implementing and controlling concurrency, a renewed focus on algorithm performance, types of parallelism, and the relationship between hardware and software should be implemented to prevent the misconceptions discussed to this point.

FIGURE II – Score by Confidence Level

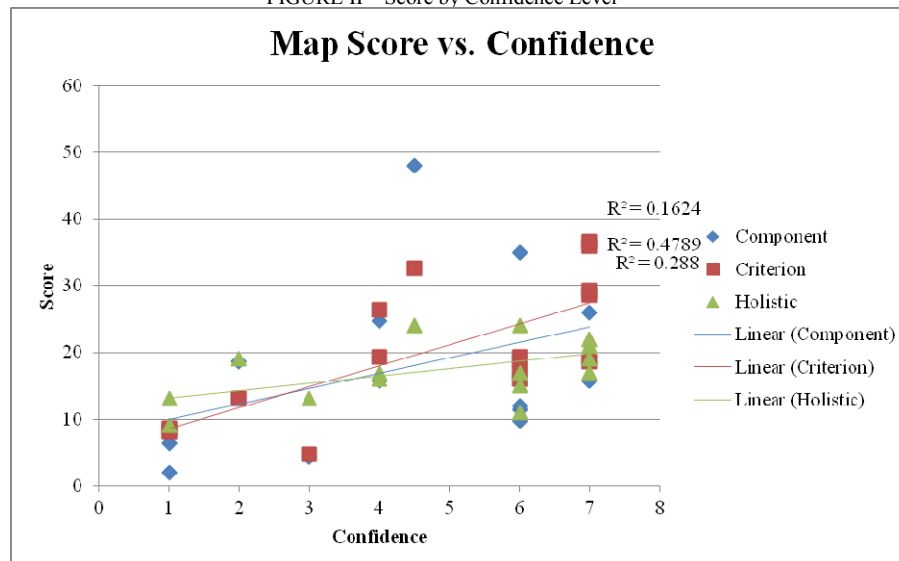

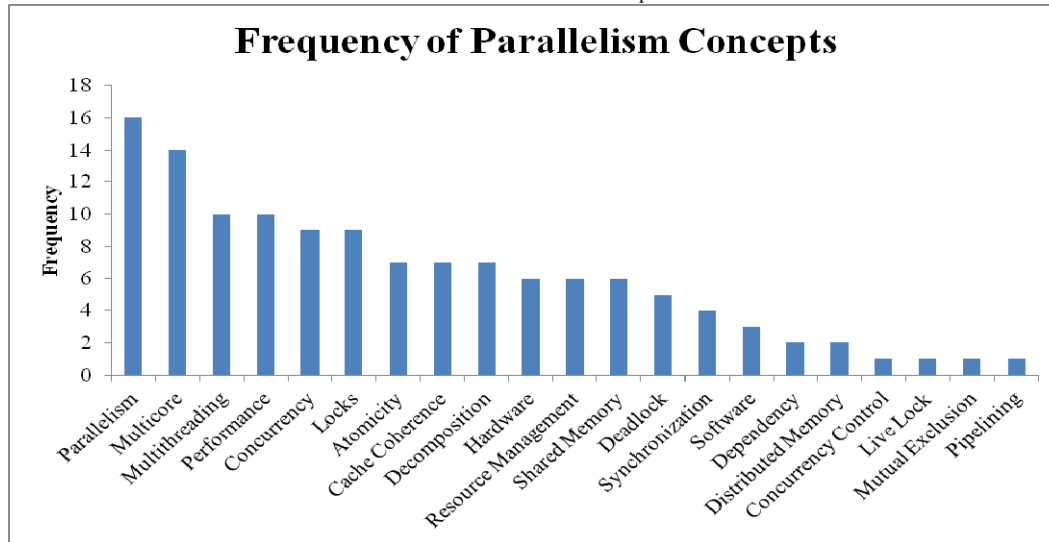

FIGURE III – Distribution of Concept Mentions

VI. FUTURE WORK

The students who completed this experiment also completed a concept inventory developed to analyze understanding of parallelism and concurrency [16]. The scores achieved on this inventory will be compared to the concept map scores. The sets of scores will also be compared to scores achieved by students who attempt the mapping process with a list of terms in hand. Lastly, the results of these studies will be used to make recommendations on when and how to integrate parallel computing into a traditional undergraduate computer engineering curriculum.

ACKNOWLEDGMENT

Funding for this work was supplied by NSF Award #0722212. The authors would like to thank the students who volunteered their time to participate in the study.

A Mastery-Based Learning Approach for Undergraduate Engineering Programs

Jennifer M. Bekki & Odesma Dalrymple

Department of Engineering
Arizona State University
Mesa, AZ, USA

Caitlyn S. Butler

Department of Civil and Environmental Engineering
University of Massachusetts
Amherst, MA, USA

We report the results of an action research study in which a modified mastery-based learning approach was implemented in three undergraduate engineering courses: engineering statistics, LabVIEW programming, and environmental engineering. In this paper, we describe both the action research and the modified mastery-based learning approach that was implemented. Findings from the analysis of data on student performance, and student and faculty perceptions of the approach are presented. In addition, we discuss our recommendations for modifications to the approach that could be used in future implementations.

Keywords: *action research, mastery-based learning, assessment, undergraduate engineering*

I. BACKGROUND AND INTRODUCTION

It is well documented that students' relative academic placement within their peer group is fairly constant, even across many years [1]. The same phenomenon is observable at the university level, where students who do well in their freshman year are often the students who continue to do well throughout the degree program. Moreover, in most class settings, a student who is a *fast* learner may be perceived as a student with high aptitude for the course material. A student who is *slow* learner, though perhaps perceived as having a low aptitude for the subject matter, may only need more time to learn the material.

Mastery-based learning is a pedagogical approach designed to help address these issues. Mastery-based learning was developed by Bloom and is based on two key ideas. First, it incorporates John Carroll's theory that student aptitude reflects a rate at which topics can be learned rather than an ability to learn topics. In addition, it incorporates the understanding that the idealized learning environment takes place when a single tutor is paired with a single student [2]. It has been shown to be effective in reducing the variability in student learning within a class, particularly improving the performance of students who require additional time to learn some of the topics.

When compared to traditionally taught courses, students in courses taught with a mastery approach attain higher levels of achievement and had more confidence in the material [3], [4]. One survey of mastery-based learning programs demonstrated that, on average, implementing mastery-based learning increased final examination scores by about 0.5 standard deviations in colleges [4]. Students who needed more time to master the course content experienced greater gains from the

mastery-based approach. The average improvement in scores of high aptitude students is 0.40 standard deviations; the improvement of low aptitude students is 0.61 standard deviations [4].

In the most traditional form of mastery learning, course content is delivered in units of instruction, which correspond to student learning competencies. Students are provided with attempts (as many as are necessary, theoretically) to demonstrate mastery of each learning competency and are then presented with feedback. If mastery is not demonstrated, the feedback provides guidance on learning progress and provides specific corrective activities to target the conceptual gaps the student needs to bridge. Enrichment activities that provide opportunities for students to tackle more advanced topics can be given to those who quickly master course topics.

Though this method has been widely applied at the K-12 level [3], [4], fewer studies have tested the approach at the college level [5]. In the university setting, the learning environment is more tightly constrained by limited instructional time. Additionally, larger class sizes make the traditional mastery-based learning style difficult to implement. This paper presents a modified-mastery based learning approach that deviates from the traditional implementation in that the cycle of formative assessments and feedback to master the material is finite. In three courses, content was divided into course-specific competencies. The implementation of this approach in two sections of a sophomore engineering statistics course, a one-credit LabVIEW course and a senior-level environmental engineering elective is presented below.

II. DESCRIPTION OF ACTION RESEARCH PROCESS

In the engineering department where this research occurred, faculty are encouraged to engage in scholarly teaching. Inspired by Ernest Boyer's [6] concept of the scholarship of teaching, this "involves a broad set of practices that engage teachers in looking closely and critically at student learning for the purpose of improving their own courses and programs"[7]. Action research is a methodological framework that is well suited for this type of inquiry. In its simplest form, action research is a systematic, self-reflective study undertaken by an individual to understand and improve his/her practices [8]. The study described in this paper was conducted using a specific type of action research: collaborative action research. The three co-authors: Jennifer, Caitlyn and Odesma; all from the same department at the time of the research, partnered as co-

researchers to explore common solutions for improving the learning experiences of students in their respective courses.

A. Starting Point

Following the steps outlined by Capobianco, Horowitz, Canuel-Browne, and Timarchi [8] and shown in Figure 1, the researchers began their collaborative inquiry by first identifying a shared starting point. Jennifer, who teaches a sophomore level statistics course, identified her concern with students' ability to deal with stochastic results outside of the statistics class. Her prior observations made her question whether her current instructional approach helped students learn some topics deeply enough to transfer to another setting, or facilitated the learning of the mechanisms, but not necessarily the application of the concepts. Caitlyn, who taught courses in the civil and environmental engineering focus area and would be teaching a senior-level environmental engineering elective for the first time, was concerned about the difficulties students in environmental engineering have contextualizing the non-technical elements of their work. Odesma, who taught courses in the electrical focus area and would be teaching a 1-credit LabVIEW course to sophomore-level students for the first time, was interested in understanding how to individualize instruction for different learners in a large class. This was of particular concern to Odesma given her prior experience observing the discrepancies among engineering students' prior programming knowledge and confidence.

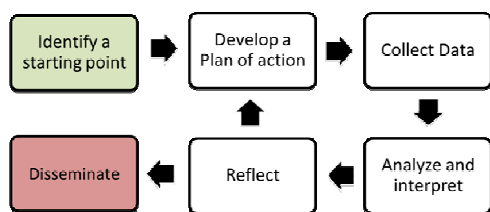

Figure 1: Steps Involved in Action Research [7]

The results of the starting point brainstorming activity, previously described, steered the team towards pedagogical and assessment solutions. Based on their prior familiarity and experience with mastery-based learning, this approach emerged as a potential candidate to address each researcher's concern. For Jennifer, the modularized curricular structure could allow for specific competencies to be included that address selection of appropriate statistical concepts and the application of the concepts in real problems. The affiliated assessments of mastery could then allow her to monitor students' performance in these competency areas (as well as all others), and provide corrective feedback to students who don't attain the competency. The feedback could potentially allow students to continue to improve and eventually demonstrate mastery at a later point in the semester. For Caitlyn, adding competencies related to the non-technical aspects of the course, which were weighted equally to the technical aspects of the course, could help students value the non-technical in the same way they value the technical components. As competencies, she would be able to monitor students' performance on both aspects (i.e., technical and non-technical), and provide corrective feedback when mastery is not attained. For Odesma, the multiple demonstrations of

mastery and individualized feedback, specifically related to the student's performance on the competency, could allow for a more personalized learning experience. In addition, the enrichment assignments could allow students who progress faster to continue to enhance their knowledge without needing to advance the entire class, or stifling their growth.

There are a significant number of research studies and how-to texts on mastery-based learning [9]. However, most of the examples are based on a K-12 context. There are few documented instances of the use of mastery-learning in college-level classrooms, and no instances related to the teaching of engineering subject matter. Given the differences between K-12 and tertiary-level learning environments, the typical individualized mastery-based learning approach did not seem practical for the researchers. A structured, feedback cycle was needed to make the approach fit in a 14-week course with a manageable amount of additional effort and preparation on the part of faculty, also managing research and service agendas. It was critical to preserve the distinguishable features, such as iterative, customized, formative assessment, to lead to improved student achievement, particularly in the problem areas identified by each researcher. From this shared challenge the starting point of the action research study emerged.

Starting point: We would like to institute a modified version of mastery-based learning in our respective engineering courses that: 1) preserves its distinguishing features (i.e., modularized according to competencies, multiple chances to demonstrate mastery, corrective feedback, and enrichment activities) and 2) will be implemented with a manageable amount of additional effort and preparation. We also hypothesize that the implemented approach will lead to high student achievement.

B. Plan of Action

Following the identification of a starting point, the next step in the action research cycle is the development of a plan of action to be piloted. This plan also includes the identification of a strategy for collecting data on the outcome of the action. The co-researchers worked together to define a mastery-based learning model that they could each use in their respective courses. The model differed from the traditional mastery-based approach in two ways that we considered necessary for effectively implementing a mastery-based approach in a higher education-based setting:

- 1) There were a fixed number of chances available to students to re-demonstrate mastery of a competency. Only two chances were given to demonstrate each competency, and a condition was placed on receiving the second chance.
- 2) Evidence assignments were introduced to provide an opportunity to practice competencies and receive formative assessment, similar to a typical use of homework assignments.

A full description of the mastery-based learning model that was piloted follows and is also shown in Figure 2.

Competencies: As part of this approach, the technical content and skills students were expected to learn in each course were divided into instructional units, called competencies. Competencies were aligned with previously established course learning objectives and departmental learning outcomes. The number of competency areas defined for each course is shown in Table 1. For each course, the students' final grade was determined by the number of competencies mastered by the end of the semester.

TABLE I: SUMMARY OF COURSES

| COURSE TOPIC (CREDIT HOURS) | STUDENT LEVEL | NUMBER OF STUDENTS | NUMBER OF COMPETENCIES |
|----------------------------------|------------------|--------------------------|---------------------------|
| ENGINEERING STATISTICS (3) | SOPHOMORE | 69 | 21 |
| LABVIEW PROGRAMMING (1) | SOPHOMORE | 44 | 4 |
| ENVIRONMENTAL ENGINEERING (3) | SENIOR | 15 | 33 |

Evidence Assignments: To help students prepare for competency assignments, in-class instruction was supplemented with additional learning activities that provided students with multiple opportunities to apply their understanding of the topics associated with the competency area(s) and get feedback on their performance. These assignments took the form of question(s) on a homework assignment or an in-class activity. The term, "Evidence Assignments," was used since these assignments provided evidence of the students' attempt to learn the topics, and their success or lack thereof with using the prescribed instructional approach. Completing evidence assignments on time ensured that students received timely feedback on their performance and suggestions for remediation when needed. Their performance on evidence assignments was not counted towards the final course grade.

Competency Assignments: Mastery of a competency is demonstrated through students' performance on competency assignments. These assignments can take the form of question(s) on a quiz or exam, an in-class activity or project. Each student received at least one opportunity to complete each competency assignment. Mastery was achieved when competency criteria are met. For example, one competency in Environmental Engineering was "Student can write balanced chemical reactions". The competency is mastered when the student correctly balances a chemical reaction. A passing score on a competency assignment translates to a prescribed number of competency points. If a student does not attain a passing score on his/her first attempt, he/she may get a second opportunity to re-demonstrate the competency at a later time. Second opportunities were only given to students who attempted all evidence assignments associated with the competency. Before a student re-demonstrates mastery, he /she will get feedback on his/her performance on the first competency assignment taken and suggestions for remediation, i.e., other approaches for learning the concepts.

Enrichment Assignments: Once a student demonstrates mastery of a competency, he/she may have the opportunity to

complete an optional associated enrichment assignment. These assignments present a challenge above and beyond the course material, and are designed to challenge and help extend students' understanding of the related topics. For example, in the statistics course, a course competency required students to be able to determine the probability of a random variable taking on a particular value from a normal distribution with given parameters. The associated enrichment activity supplied students with two data sets of unknown distribution, asked them to identify which of the two was normally distributed, determine the parameters of the distribution, and then estimate the probability of a random variable from that distribution taking on a particular value. Enrichment assignments were also assessed on a pass/fail basis. A passing score on an enrichment assignment translated to a percentage of a competency point. To attain an A+ in any of the courses, students had to complete some enrichment assignments successfully, in addition to achieving almost all other course competencies.

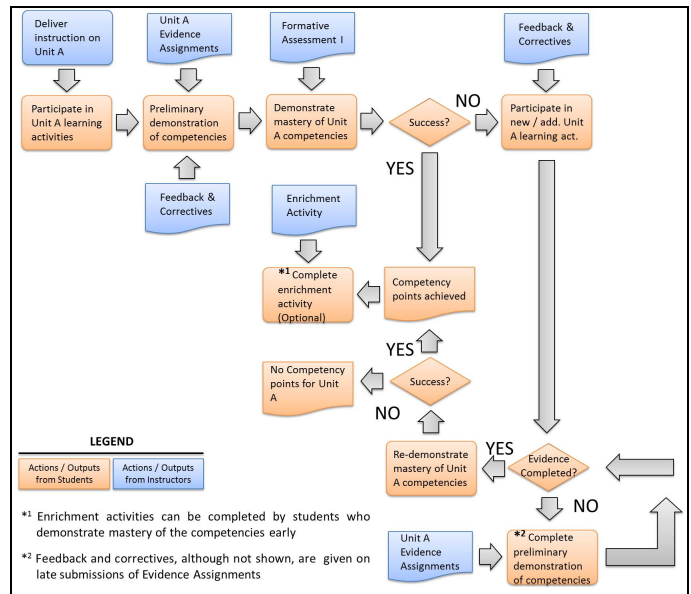

Figure 2: A Course Unit in a Typical Mastery-Based Learning Format

B. Reflection in the Action Research Process

An additional important part of the action research process is the ongoing and frequent reflection undertaken by the researchers, both individually and collaboratively. The action research process is iterative, and reflection facilitates the development of a critical awareness and deeper understanding of the action taken [8]. With each iteration, the action can be tweaked and improved. The researchers used journals to capture their weekly reflections based on observations made related to the course. They also met every two weeks to discuss and share interpretations of their experiences, and to strategize improvements to their actions.

III. DATA COLLECTION

To evaluate the described approach, several sources of data were collected, including student and faculty perceptions of the approach and student achievement data. The study was

approved by the Institutional Review Board at Arizona State University.

A. Student Perception Data

In each of the three classes, student surveys were administered multiple times to gather data about the students' perceptions of the approach. Surveys were administered in the two 3-credit hour classes four times (after 0%, 25%, 50%, and 100% of course competency assignments had been given) and in the one-credit hour class three times (after 0%, 50%, and 100% of course competencies assignments had been given to the students). The survey consisted of seven questions intended to measure student perceptions of both their understanding of effectiveness of the approach. Response options were arrayed on a five point Likert-scale ranging from strongly disagree to strongly agree (midpoint = neither agree nor disagree). The questions of this type are given below:

- Question 1: I understand the system by which I am being assessed in this course
- Question 2: I like the system by which I am being assessed in this course
- Question 3: I am aware of my current status (as related to course progress) in this course
- Question 4: The feedback I receive on Evidence Assignments is useful.
- Question 5: The frequency of feedback I receive on submitted assignments is sufficient for me to continue making progress toward demonstrating course competencies.
- Question 6: This class allows students with my learning style to succeed.
- Question 7: I am confident that after this course is over, I will be able to appropriately apply the skills that I am learning in this course to another situation.

Additional survey questions solicited open ended responses from students regarding the corrective feedback they were receiving, their learning style, and general suggestions about the approach.

B. Faculty Perception Data

Perceptions of the three participating faculty members were captured through weekly journaling.

C. Student Achievement Data

Student achievement data was based on the competency achievement of students in each class during the semester. Specifically, data was recorded by class on the percentage of competencies ultimately achieved, the percentage of competencies achieved on the second try, and the number of bonus assignments completed. The total number of competencies achieved gives a high level view of student performance, the number of competencies achieved on the second try gives an indication of how the feedback and extra time contributed to student success, and the bonus assignments provide data on whether students were able to demonstrate a higher level of learning for particular competencies.

IV. ANALYSIS AND INTERPRETATION

A. Student Performance Data

An objective of the mastery-based approach is to improve the number of students who master the majority of competencies within a course. While we do not have baseline data to compare to, Table II provides the summary data of the percentage of students who demonstrated mastery of at least 75% and at least 90% of course competencies in each of the three courses. As Table II illustrates, at least 70% of students in each of the classes demonstrated mastery of at least 75% of the course competencies, which is an encouraging result. Of note is that the percentage of competencies demonstrated does not necessarily map to course grade (different competencies can be worth different amount of points toward the course grade).

TABLE II: COMPETENCY ACHIEVEMENT BY CLASS

| COURSE | STUDENTS EARNING AT LEAST 75% OF COURSE COMPETENCIES | STUDENTS EARNING AT LEAST 90% OF COURSE COMPETENCIES |
|-----------|--|--|
| EGR STATS | 75.36% | 43.48% |
| LABVIEW | 79.55% | 61.36% |
| ENV EGR | 73.33% | 60.00% |

A particularly important result is the number of competencies that were earned on the second administration of a particular competency assignment. These second opportunities represent chances for students to have acted on the provided corrective feedback, and/or for the students who learned a particular competency at a slower pace, to demonstrate mastery. Table III shows the average percentage (and standard deviation) of competencies demonstrated on the second attempt for students in each of the classes. The data in Table III shows that students would have earned between 18% and 21% fewer competencies if the second chance (and associated corrective feedback) had not been provided. In a traditional assessment approach, this would likely have resulted in a significantly lower summative assessment for the course.

TABLE III SECOND CHANCE COMPETENCY ACHIEVEMENT

| COURSE | AVERAGE % OF COMPETENCIES EARNED ON SECOND TRY (STANDARD DEVIATION) | MAXIMUM % OF COMPETENCIES EARNED ON SECOND TRY |
|-----------|---|--|
| EGR STATS | 18.71% (9.22%) | 42.90% |
| LABVIEW | 21.21% (20.4%) | 66.67% |
| ENV EGR | 18.02% (9.00%) | 29.73% |

The final presented measure of student achievement is the number of enrichment assignments successfully completed by students in each of the courses. The statistics, LabVIEW and environmental engineering courses each had a total of 4, 2 and 4 enrichment assignments respectively. In all courses, the average number of completed enrichment assignments per student is less than one. A much larger number of students

submitted enrichment assignments. The assignments, however, were designed to require a higher level of learning of a particular topic; as such, many students did not earn credit for bonus assignments submitted.

B. Perception Data

In addition to student achievement, we also aimed to develop an approach that was well-received by both participating faculty and students. In the following sections, the analysis of the data from the student perception survey, and from the faculty journals, are presented. The numerical and qualitative data from the student perception data are presented separately

1) Student Perceptions

a) Numerical Data

The numerical data from the student perceptions survey is presented by question (question numbers correspond to those presented in Section III A) in Table IV, which gives survey results based on responses from students in all classes. A response of “1” indicates a response of “Strongly Disagree” while a response of “5” indicates a response of “Strongly Agree”. Of special interest to us is the change in responses across the multiple administrations of the survey. The implemented mastery-learning approach is a fairly different assessment approach from what they had experienced in other classes, and it is more complicated. As a result, we expected student perception of the approach to improve as the semester progressed and their understanding of the system got better. Table IV shows that for all questions, there was a positive change in the average student response. Also of note is that changes in the average responses between administrations of the survey become smaller with subsequent administrations. By the final administration of the survey, the average response was at least 4.10 to all questions, indicating that the students were satisfied with their understanding of the approach, their knowledge of their course performance, the feedback with which they were provided, and the knowledge they were learning in the course.

TABLE IV: NUMERICAL SURVEY RESULTS – ALL STUDENTS INCLUDED. RESULTS INCLUDE THE AVERAGE (AND STANDARD DEVIATION) FOR EACH OF THE SEVEN QUESTIONS. THE NUMBER OF RESPONDENTS IS SHOWN WITH THE PARANTHETICAL N VALUE.

| | 1 (N=74) | 2 (N=60) | 3 (N=30) | 4 (N=68) |
|----|-------------|-------------|-------------|-------------|
| Q1 | 4.04 (0.97) | 4.48 (0.72) | 4.73 (0.45) | 4.69 (0.53) |
| Q2 | 3.86 (1.12) | 4.03 (0.95) | 4.11 (0.98) | 4.11 (1.06) |
| Q3 | 3.77 (1.25) | 4.42 (0.96) | 4.53 (0.73) | 4.53 (0.66) |
| Q4 | 4.00 (1.35) | 4.19 (0.98) | 4.30 (0.95) | 4.56 (0.70) |
| Q5 | 3.90 (1.40) | 4.35 (0.95) | 4.23 (0.97) | 4.49 (0.73) |
| Q6 | 3.71 (1.36) | 4.13 (1.04) | 4.23 (0.86) | 4.20 (1.00) |
| Q7 | 3.81 (1.17) | 3.97 (1.11) | 4.17 (0.87) | 4.10 (0.90) |

b) Open Response Data

An informal analysis of responses to open ended questions yielded several trends in student opinion. These trends, along

with representative comments are presented here. The majority of student responses indicated that they were happy with the approach and the efforts made by the instructors in implementing the approach. Comments such as the representatives below support the positive numerical survey results:

- “I love it! It feels like I am succeeding and actually completing something whereas the ‘usual’ grading system feels like you start out with an A+ and slowly lose your grade instead of starting at 0 and progressing to an A+”
- “[I] Enjoy this learning style. I feel as though I have been given ample opportunities to succeed, and if I don’t, I am given the feedback to correct my thinking”

In addition to an overall satisfaction with the approach, four primary themes of student concerns emerged from the informal analysis of the open-ended survey responses: confusion about the assessment process itself, a desire for improved relationship between evidence assignments and competency assignments, frustration and acknowledgement with the importance of organization in implementing the system, and a dissatisfaction with the “pass/fail” notion of demonstrating competencies.

As mentioned previously, the comments about confusion on the process by which they were being assessed were not surprising to us. And, as was mirrored by the numerical survey results, the comments were less frequent in later administrations of the survey. Comments such as those below, however, do highlight the importance of spending time explaining the approach regularly during multiple class periods at the beginning of the semester.

- “It was really confusing in the beginning – I got behind because I did not understand this teaching approach”
- I think, initially the make-up method was confusing for most students. [Clarification] on this process would benefit future classes”

The concerns brought up by students about the relationship between evidence assignments and competency assignments are also important. Clearly, both types of assignments should tie back to the competency definitions themselves, and faculty implementing this approach in the future should pay special attention to ensuring that to be the case. Additionally, some of the student concern may have stemmed from a misunderstanding of the competency definitions themselves. Reminding students regularly to read the competency definitions may be helpful in allowing them to understand in advance the specific topics on which they will be assessed. Some representative comments from students follow.

- “The evidence assignments do not really prepare you for the competency assignments. We had to self-teach ourselves in order to get through the competencies.”
- “Competency tests should [not] introduce unfamiliar units or situations. Because there is only a single evidence assignment, the test should not be tricky in any way”

The third common concern raised by students was with regard to their observations that faculty organization of the course is more critical in this system than in a more traditional system. The students are exactly correct that faculty organization and timing in this type of mastery-based approach is critical. With a large number of competencies, the timeline for giving evidence assignments followed by ample time to apply corrective feedback before giving a competency assignment (and then giving at least one more competency assignment later in the semester) does not allow a lot of flexibility. In each of the classes, there were points at which this created some difficulties, evidenced by student comments such as:

- “Organization makes or breaks the system”
- “Evidence assignment due dates seem meaningless”

Finally, a number of students reacted fairly strongly to the fact that each competency is either “demonstrated” or “not demonstrated” for a particular assignment, giving the feel of a pass/fail type grading system. Ultimately, the competency based system actually gives students the chance to “fail” without incurring a negative impact on their summative course grade, but some students did not like the fact that they didn’t gain any partial credit toward their final course grade for efforts they had put into competency assignments. Some representative comments to this effect follow:

- “The one thing I would change is that if a student gets most of the questions right, they get the competency”
- “Right now it’s all or nothing...I think that’s very wrong”
- “Give some credit for all the assignments. Otherwise, it becomes too much of a pass/fail type system”

Each faculty member made the determination of what was required to “demonstrate mastery” of a competency on a particular assignment, and this was tied to the definition of the competencies themselves. In some cases, multiple concepts were tied up in a particular competency (e.g. interpret significance of a regression model and evaluate the validity of model assumptions), causing students who successfully demonstrated mastery of part of the competency but not the other, to not get “credit” for mastery. In future offerings of the course, these two-part competencies should be split to award student accomplishment of each individual learning objective.

2) Faculty Perceptions

During the action research project, faculty perceptions of the process were recorded in weekly journal entries. Each of the participating faculty members observed and noted specific successes and areas for improvement about the process from her specific class. However, of greatest interest were the several themes present across all classes, which are highlighted next. Journal entries were shared in our biweekly meeting and common themes were identified as a group, as is common practice in an action-based research project.

- The modified mastery learning approach provided a good structure for the course. For example, in-class

activities that counted as evidence assignments resulted in a higher engagement in these activities than in previous course offerings (in which the activities were not directly tied to course grades).

- Students who took advantage of the system succeeded. Moreover, the students who were the most engaged benefitted the most from the mastery based approach.
- Providing the individualized corrective feedback dramatically increased the typical workload for a faculty delivering a course.

V. SUMMARY AND CONCLUSIONS

This paper presented an action research project that resulted in the creation and implementation of a modified mastery-based learning approach in three undergraduate engineering courses. The collected data demonstrated that the approach resulted in high student achievement and also general satisfaction about the approach from participating students and faculty. Data on student and faculty perception did suggest some areas for improvement, including developing a more efficient way for faculty to deliver feedback and more careful coordination between competency definition, evidence assignments, and bonus assignments.

Future work on the approach will include a formal investigation of the effectiveness of various feedback mechanisms, a focused effort on developing approaches for making the feedback cycle more efficient for faculty, while still being useful and meaningful to students, and more rigorous evaluation of the impact of the approach on student achievement.

How does Academic Preparation Influence How Engineering Students Solve Problems?

Sarah J. Grigg and Lisa C. Benson

Department of Engineering and Science Education
Clemson University
Clemson, SC USA
lbenson@clemson.edu

Abstract—In first year engineering courses, students possess a wide range of academic preparation such as their exposure to various mathematics courses and pre-engineering programs. Additionally, students bring perceptions about their abilities, and have already begun practicing preferred methods of analysis and documentation. Understanding how students with different backgrounds develop problem solving skills in first year engineering programs is of critical importance in order to close achievement gaps between diverse populations.

This study examines how students solve engineering problems and identifies variations based on student factors of gender, ethnicity, mathematics preparation and achievement, and prior engineering experience. Solutions for three problems from 27 students were analyzed ($n = 68$ solutions). Students worked out problems using custom-designed software that digitally records ink strokes and allows researchers to associate codes to the problem solution at any point, even in portions of the problem solution that would not have been available without the use of this technology, such as in erased work.

Differences in how students solve problems were assessed based on the prevalence (or absence) of elements and errors in the problem solving process, which were evaluated using task analysis. Results indicated that pre-engineering experience did not have a significant impact on successfully solving problems; however, having completed a calculus course was significantly related to successful problem solving. Future research will expand the study population to a larger sample of first year engineering students across multiple semesters, identifying key strategies that are absent for students with low mathematics preparation, and to investigate relationships between prior academic preparation and indicators of metacognition.

Keywords— *problem solving; first year engineering; academic preparation*

I. INTRODUCTION

Engineering students must apply basic mathematical skills and reasoning to solve problems, ranging from arithmetic manipulations to analysis of variables. However, the level of mathematic and engineering preparation they bring to their first-year courses vary widely. Often instructors find that students do not have the prerequisite knowledge needed or

have strong enough analytical skills to learn new concepts successfully. The instructor may even feel it is necessary to review prerequisite material to the entire class before continuing to new concepts, which can restrict the amount of material that can be covered in a course.

In view of the one-way migration pattern from engineering majors [1], it is important to identify factors that cause students to withdraw from or fail to succeed in engineering courses. Here we examine problem solving proficiency as a potential factor. Engineering students from underrepresented groups such as females and minorities have been shown to have distinctly different engineering education experiences [2]. Research indicates that males seem to exhibit more advanced problem solving performances than females [3] and that females doubt their problem solving abilities more than males [4]. Research on the mathematical problem solving of minority students has shown that they suffer a larger dropout rate from engineering than all other students [5] and exhibit a lower success rate solving non-routine problems, even though their solutions indicate proportional skills levels [6]. Malloy defined non-routine problems as those “that could be solved with multiple strategies, could be solved with holistic or analytical strategies, and required inferential, deductive, or inductive reasoning [6]. This definition of non-routing problems describes contextual “story” problems in a typical first year engineering course. If this trend is evident in first year engineering problem solving, it could shed light on a potential factor attributing to the higher than average withdrawal rate for under-represented minorities. Understanding how students with different backgrounds develop problem-solving skills in first year engineering programs is of critical importance in order to close achievement gaps between diverse populations.

When students work through problems, they construct an interpretation of the concepts being taught using pre-existing knowledge [7]. For meaningful learning to occur, a learner must make sense out of the information presented and have relevant conceptual knowledge to anchor new ideas [8]. A learner’s framework of relevant concepts allows him or her to solve problems efficiently and successfully. When this prior knowledge is lacking or inappropriate, the learner has difficulty solving the problem in the intended manner [9].

This study investigates the relationship between how students solve problems and their prior academic experiences,

specifically prior mathematics courses and any pre-engineering experience such as involvement in FIRST or Project Lead the Way. FIRST is a program that encourages students ages 6-18 to build science, engineering, and technology skills through designing, building, and programming robots [10]. Research suggests that students who participated in FIRST Lego League showed increases in confidence and overall technological problem solving performance [11]. Project Lead the Way is a Science, Technology, Engineering, and Mathematics (STEM) education curricular program geared toward middle and high school students. Its goal is to develop critical-reasoning and problem-solving skills [12]. Research suggests that students who participate in Project Lead the Way have higher achievement in reading, mathematics, and science [13].

II. METHODS

A. Engineering Problems

This study examines problem solving solutions from students enrolled in a first-year undergraduate engineering course. Solutions were captured for three different problems typical of those given in a first year engineering course. Three problems covered topics of 1) efficiency, 2) circuits, and 3) pressure. All problems had 1) a constrained context, including pre-defined elements (problem inputs), 2) allowed multiple predictable procedures or algorithms, and 3) had a single correct answer [14]. All three problems were story problems, in which the student is presented with a narrative that embeds the values needed to obtain a final answer [15].

The first problem involved a multi-stage solar energy conversion system and required calculation of the efficiency of one stage given input and output values for the other stages [16]. The second problem required students to solve for values of components in a given electrical circuit. This problem, developed by the project team, also contained a Rule-Using/Rule Induction portion (a problem having one correct solution but multiple rules governing the process [15]), where students were asked to determine an equivalent circuit based on a set of given constraints. The third problem involved total pressure calculations and required students to solve for values within the system, and convert between different unit systems [16]. None of the problems required the use of calculus to solve. Example solutions for each problem are shown in Figures 1-3. Sixty-eight solutions were analyzed.

B. Participants

There were 27 participants, 6 females and 21 males. Twenty-three of the participants were Caucasian. Seven of the students had prior engineering experience through extracurricular activities. In terms of mathematics preparation, 4 of the students' highest mathematics course was Pre-Calculus, 3 had taken AP Statistics but no Calculus, 11 had taken AB Calculus, and 9 had taken BC Calculus.

Handwritten solution for Solar Efficiency Problem:

$$\eta = \frac{P_{out}}{P_{in}}$$

Stage 1: $P_{in1} = 2000W$, $\eta_1 = 41\%$, $P_{out1} = P_{in1} \cdot \eta_1 = 2000W(41) = 820W = P_{in2}$

Stage 2: $\eta_2 = ?$, $P_{out2} = \frac{P_{in2}}{\eta_2} = \frac{820W}{.45} = 1822W$

Stage 3: $\eta_3 = 37\%$, $P_{out3} = \frac{P_{in3}}{\eta_3} = \frac{1822W}{.37} = 4924W = P_{out2}$

Final answer: $\eta_2 = 45\%$

Figure 1: Solution for Solar Efficiency Problem

Handwritten solution for Equivalent Circuits Problem:

Circuit diagram: A 12V source connected to three resistors in series: R_{eq1} , R_{eq2} , and R_6 .

Calculations:

$$R_{eq1} = \frac{1}{\frac{1}{R_1} + \frac{1}{R_2}} = \frac{1}{\frac{1}{20} + \frac{1}{30}} = 12\Omega$$

$$R_{eq2} = \frac{1}{\frac{1}{R_3} + \frac{1}{R_4} + \frac{1}{R_5}} = \frac{1}{\frac{1}{40} + \frac{1}{50} + \frac{1}{60}} = 15\Omega$$

Final equivalent circuit: $R_{eq} = R_{eq1} + R_{eq2} + R_6 = 12\Omega + 15\Omega + 20\Omega = 47\Omega$

Current: $I = \frac{V}{R} = \frac{12V}{47\Omega} = 0.255A$

Figure 2: Solution for Equivalent Circuits Problem

Handwritten solution for Pressure Problem:

Diagram: A rectangular block of height $h = 25'$ and width $W = 20'$.

Calculations:

$$P_T = P_{hydro} + P_{atm} = \rho g h + P_{atm}$$

$$\rho = \frac{P_T - P_{atm}}{g h}$$

$$\rho = \frac{405300 Pa - 202650 Pa}{9.8 \frac{m}{s^2} (7.6 m)} = 2720.86 \frac{kg}{m^3}$$

Figure 3: Solution for Total Pressure Problem

C. Technology used to Capture Problem Solving Processes

Problem solving data was obtained via students' completed in-class exercises using a program called MuseInk, developed at Clemson University [17, 18]. This software was used in conjunction with tablet computers that were made available to all students during the class period. Students worked out problems in the MuseInk application, which digitally records ink strokes and allows researchers to associate codes to the problem solution at any point, even in portions of the problem solution that would not have been available without the use of this technology, such as in erased work. Solutions were coded using the coding scheme developed by Grigg and Benson to describe cognitive and metacognitive processes, errors, and strategies revealed in student work [19].

D. Statistical Analysis Methods

To investigate differences in how students solve problems, statistical analyses were conducted to assess differences in 1) the presence of problem solving elements, and 2) the frequency of use of problem solving elements. Evaluations assessed student factors including gender, ethnicity, and prior academic experiences such as pre-engineering experience and highest level of mathematic course taken.

Repeated measures ANOVAs were conducted to determine if significant differences existed in the presence of task elements, errors, strategies, or answer state that are attributable to student factors of gender, ethnicity, pre-engineering experience, or mathematics preparation. Repeated measures ANOVAs were also conducted to evaluate differences in the frequency of task usage among problem solutions to further explore how problem solving solutions vary between populations. Only significant effects of student factors are reported. P values of 0.05 were utilized as the significance level.

III. RESULTS

Analysis was conducted on 54 codes of process elements, errors, strategies, and solution accuracy. For codes related to process elements, the basic structure set forth in the coding scheme by Wong, Lawson, and Keesee was used within the categories of knowledge access, knowledge generation, self-management [20]. For codes relating to errors, a structure derived from error detection literature in accounting, was used to classify errors as conceptual and mechanical errors [21, 22] with an added classification of management errors to capture errors in metacognitive processes. Strategy codes were obtained from a subset of strategies that appeared most applicable to story problems from the compilation described in "Thinking and Problem Solving" [23].

A. Assessment of students' use of problem solving features

Results were evaluated for all codes of process elements, errors, strategies, and solution accuracy for the collective sum

of problem solutions, hence repeated measures ANOVAs were utilized to account for variations attributed to the problem. If the code was associated to a problem solution at least once, that code was determined as present, even if the work was later modified to eliminate its presence in the final solution.

The level of academic preparation of female students was quite different from that of male students. Of the female students in the study, only 33% had calculus experience compared to 86% of male students. Additionally, none of the female students had pre-engineering experience compared to 33% of male students. Therefore, it should be noted that differences found in terms of gender may be due (at least in part) to differences in level of academic preparation. This will be explored in future data analysis that includes a larger sample population of students.

Findings revealed significant differences that are attributed to gender. Females were more likely than males to explicitly write out equations and then plug in values in separate steps ($p = 0.035$), and had a higher occurrence of incorrectly deriving unit ($p=0.002$). Additionally, females' solutions were more likely to indicate the use of lower level strategies such as a "guess and check strategy" ($p = 0.030$) or a "plug and chug strategy" ($p=0.53$) while males' solutions were more likely to indicate the usage of advanced approached such as a "chunking strategy" ($p = 0.048$). Males exhibited a higher level of mastery, as they were also more likely to obtain a correct solution. Full results are shown in Table 1.

TABLE 1: SIGNIFICANT EFFECTS OF GENDER BASED ON REPEATED MEASURES ANOVAS

| Process Analysis Measure | F ratio | p value | Mean (Female) | Mean (Male) |
|----------------------------|---------|---------|---------------|-------------|
| Plugged values in equation | 4.62 | 0.035 | 1.00 | 0.77 |
| Incorrect unit derivation | 10.75 | 0.002 | 0.20 | 0.04 |
| Plug and chug | 5.23 | 0.026 | 0.53 | 0.23 |
| Guess and check | 4.95 | 0.030 | 0.33 | 0.11 |
| Chunking | 4.08 | 0.048 | 0.07 | 0.30 |
| Correct Answer | 13.23 | 0.001 | 0.13 | 0.64 |

The level of academic preparation of minority students was roughly equivalent to that of the remainder of the students. Of the minority students in the study, 75% had calculus experience compared to 78% of non-minority students. Additionally, 25% of minority students had pre-engineering experience compared to 26% of non-minority students. Therefore, it is reasonable to assume that differences found based on ethnicity are not attributable to prior academic experiences of completing a calculus class or participating in a pre-engineering program.

Very few significant results were found based on ethnicity. The only significant findings were that minority students had a larger number of solutions that did not utilize units throughout the problem solving solutions ($p<0.001$) and with correct answers but with incorrect units ($p=0.003$). Full results are shown in Table 2.

TABLE 2: SIGNIFICANT EFFECTS OF ETHNICITY
BASED ON REPEATED MEASURES ANOVAS

| Process Analysis Measure | F ratio | p value | Mean (Caucasians) | Mean (Minorities) |
|-----------------------------|---------|---------|-------------------|-------------------|
| Missing Units Throughout | 15.87 | 0.000 | 0.00 | 0.20 |
| Correct but Incorrect Units | 9.28 | 0.003 | 0.05 | 0.20 |

In terms of prior academic preparation, there were only a few significant findings that supported claims in the literature that pre-engineering programs enhance problem solving performance. There were no significant differences found for success in the classroom overall, or for correct problem solving solutions. Significant differences revealed that differences were mainly based on format of solving problems; students that had pre-engineering experience had a larger number of solutions where they identified prior knowledge ($p=0.018$), documented algebraic steps ($p=0.018$) and explicitly identified their final answers either by boxing in their answer or writing out the conclusion in sentence form ($p=0.030$). Full results are shown in Table 3.

TABLE 3: SIGNIFICANT EFFECTS OF PRE-ENGINEERING EXPERIENCE
BASED ON REPEATED MEASURES ANOVAS

| Process Analysis Measure | F ratio | p value | Mean (With pre-engineering Experience) | Mean (Without pre-engineering Experience) |
|--------------------------|---------|---------|--|---|
| Identify prior knowledge | 5.89 | 0.018 | 0.12 | 0.02 |
| Document math | 5.91 | 0.018 | 0.94 | 0.65 |
| Identify final answer | 4.93 | 0.030 | 0.88 | 0.61 |

A more extensive set of differences were revealed between students based on mathematics preparation as distinguished between students with and without calculus experience. It was revealed that students who had not yet taken a calculus class beyond pre-calculus committed more errors and had more rework than students with calculus experience. Solutions from students without calculus experience were more likely to utilize labeling or renaming ($p = 0.012$), have incorrect unit

TABLE 4: SIGNIFICANT EFFECTS OF CALCULUS EXPERIENCE
BASED ON REPEATED MEASURES ANOVAS

| Process Analysis Measure | F ratio | p value | Mean (With Experience) | Mean (Without Experience) |
|---|---------|---------|------------------------|---------------------------|
| Labeling / Renaming | 6.75 | 0.012 | 0.38 | 0.75 |
| Incorrect unit derivation | 5.94 | 0.018 | 0.04 | 0.19 |
| Incorrect unit assignment | 4.34 | 0.041 | 0.04 | 0.19 |
| Using incorrectly generated information | 4.69 | 0.034 | 0.17 | 0.44 |
| Missing units throughout | 6.74 | 0.011 | 0.00 | 0.13 |
| Correct Answer | 7.61 | 0.008 | 0.62 | 0.25 |
| Correct but Incorrect Units | 6.45 | 0.014 | 0.04 | 0.18 |

derivations ($p = 0.018$), have incorrect unit assignment ($p = 0.041$), use incorrectly generated equations ($p = 0.034$), have missing units throughout the entire attempt ($p = 0.011$), and have answers that were correct but in incorrect units ($p = 0.014$). Similarly, students with calculus experience were more likely to obtain correct answers. Full results are shown in Table 4.

B. Assessment of frequency of use of problem solving features

As a means of validating the results found based on the presence of codes, the same evaluation was conducted based on differences in the frequency of codes. When assessed by frequency of codes, fourteen of the eighteen significant differences remained with eight additional significant effects.

Most differences were found for effects based on gender, with one discrepancy and four additional effects. Based on frequency of use, there was not a significant difference in the number of times males or females plugged values into equations. This may be explained by males iterating through more instances of plugging in values within the same problem than females (eg. trying more combinations of possible solutions.) Additional effects found that females solved for intermediate values more frequently than males ($p = 0.035$), identified more known values, ($p = 0.029$), and identified more errors ($p = 0.006$) though this may be due to committing more error such as more frequently using incorrectly generated information ($p = 0.034$). These additional effects support the results indicating that females showed a tendency of using lower level strategies. Full results are shown in Table 5.

TABLE 5: SIGNIFICANT EFFECTS OF GENDER
FOR FREQUENCY OF USE OF PROBLEM FEATURES

| Process Analysis Measure | F ratio | p value | Mean (Female) | Mean (Male) |
|---|---------|---------|---------------|-------------|
| Solve intermediate values | 4.65 | 0.035 | 3.27 | 2.17 |
| Identify known value | 5.00 | 0.029 | 2.80 | 1.42 |
| Identify errors | 8.17 | 0.006 | 6.20 | 3.87 |
| Incorrect unit derivation | 10.75 | 0.002 | 0.20 | 0.04 |
| Using incorrectly generated information | 4.70 | 0.034 | 0.80 | 0.32 |
| Plug and chug | 5.23 | 0.026 | 0.53 | 0.23 |
| Guess and check | 4.95 | 0.030 | 0.33 | 0.11 |
| Chunking | 4.09 | 0.048 | 0.07 | 0.30 |
| Correct Answer | 4.51 | 0.038 | 0.33 | 0.85 |

Only one additional significant effect was revealed based on ethnicity with no discrepancies; minority students more frequently assigned units incorrectly ($p=0.030$). This finding also supports the original analysis by revealing another significant effect related to the use of units. Full results are shown in Table 6.

TABLE 6: SIGNIFICANT EFFECTS OF ETHNICITY
FOR FREQUENCY OF USE OF PROBLEM FEATURES

| Process Analysis Measure | F ratio | p value | Mean (Caucasians) | Mean (Minorities) |
|-----------------------------|---------|---------|-------------------|-------------------|
| Incorrect unit assignment | 4.93 | 0.030 | 0.07 | 0.30 |
| Missing units throughout | 15.87 | 0.000 | 0.00 | 0.20 |
| Correct but incorrect units | 9.27 | 0.003 | 0.05 | 0.20 |

For students with pre engineering experience, there was one discrepancy and one additional effect uncovered. While the relationship to documenting math was not evident when assessed based on frequency, it was revealed that students with pre-engineering experience more frequently ignored problem constraints ($p=0.004$). While this finding is surprising, it reiterates that pre-engineering experience does not ensure that students' solutions will be procedurally or conceptually correct. Full results are shown in Table 7.

TABLE 7: SIGNIFICANT EFFECTS OF PRE-ENGINEERING EXPERIENCE
FOR FREQUENCY OF USE OF PROBLEM FEATURES

| Process Analysis Measure | F ratio | p value | Mean (With Experience) | Mean (Without Experience) |
|-----------------------------|---------|---------|------------------------|---------------------------|
| Identify prior knowledge | 5.90 | 0.018 | 0.18 | 0.02 |
| Identify final answer | 6.54 | 0.013 | 1.29 | 0.76 |
| Ignored problem constraints | 8.77 | 0.004 | 0.47 | 0.10 |

For students with calculus experiences, significant effects for labeling / renaming and incorrect unit assignment disappeared when assessed by frequency; however, two additional significant effects of calculus experience emerged. Students without calculus experience both erased work ($p = 0.024$) and identified errors ($p = 0.003$) more often than students with calculus experience, though this may be due to the higher frequency of specific errors. Therefore, these results also support the original analysis. Full results are shown in Table 8.

TABLE 8: SIGNIFICANT EFFECTS OF CALCULUS EXPERIENCE
FOR FREQUENCY OF USE OF PROBLEM FEATURES

| Process Analysis Measure | F ratio | p value | Mean (With Experience) | Mean (Without Experience) |
|---|---------|---------|------------------------|---------------------------|
| Erasing work | 5.33 | 0.024 | 1.33 | 2.53 |
| Identify errors | 9.67 | 0.003 | 3.71 | 6.41 |
| Incorrect unit derivation | 6.46 | 0.014 | 0.03 | 0.18 |
| Using incorrectly generated information | 5.26 | 0.025 | 0.27 | 0.88 |
| Missing units throughout | 5.74 | 0.020 | 0.00 | 0.12 |
| Correct Answer | 6.16 | 0.016 | 0.86 | 0.35 |
| Correct but Incorrect Units | 5.69 | 0.020 | 0.04 | 0.18 |

IV. DISCUSSION

This analysis revealed several significant differences in how students solve problems and revealed that differences of male gender and calculus experience were related to a higher probability of successful problem solving attempts, though none of the populations tested showed significant difference in terms of overall course grade.

While course grades did not indicate a difference in achievement between male and female students, females seemed to struggle with problem solving more than males. Solutions completed by females were more likely to contain instances of incorrectly derived units and lower level strategies to approach the problems and solutions completed by males were more likely to result in a correct final answer. Units seemed to present more problems for students who did not have calculus experience (with more instances of incorrect unit assignment, missing units throughout, and having answers with incorrect units) and minority students (with more instances of missing units, and answers with incorrect units). However, it seems that females and students without calculus experience are at least aware of their performance deficiencies, as both had a higher frequency of identifying errors.

Therefore, this analysis revealed some targeted needs of specific student populations within this particular first year engineering course. While these results do have similarities to those found in the literature, these results are not necessarily generalizable to the entire population of first year engineering students. However, other instructors could utilize the methodology described in this paper as a means of identifying areas of instructional needs of students in their own classes.

V. CONCLUSIONS

This study supports current literature that shows significant differences based on gender in terms of how students approach problem solving, and supports the literature that shows a lack of significant differences in how students from different ethnic backgrounds solve problems (with the exception that students in this particular group struggled with consistent use of units). While research conducted on middle school students showed that minority students struggle with non-routine problems, this was not evident in this study. It is possible that engineering students (or at least the engineering students that participated in this study) have strengthened their problem-solving skills through advanced mathematics courses. Future research will investigate the interconnectivity of predictor factors using regression models to control for certain effects (such as gender and ethnicity) while exploring the impact of academic preparation.

The results of this study suggest that while academic preparation in the form of pre-engineering experience significantly influences how students solve problems, it did not indicate a significant impact of the probability of success in this course overall or in successfully solving problems. However, academic preparation in the form of previously completing a calculus class (but not necessarily grade) was associated with successful problem solving. This brings into question whether

there is something about going through a calculus class that has bearing on problem solving success, such as a familiarity with conducting more complicated sets of procedures, or whether it is the students' natural mathematical abilities that have enabled them to get into a calculus class at an earlier age that has the greatest impact. Future analyses will compare results of a mathematics placement test that is given to all incoming freshmen at our institution in order to test whether mathematical skill level is a better predictor of success than the highest level of mathematics course completed.

Future research will also expand the study population to a larger sample of first year engineering students across multiple semesters, identifying key strategies that are absent for students with low mathematics preparation, and to investigate relationships between prior academic preparation and indicators of metacognition.

ACKNOWLEDGMENT

This work could not have been completed without the support of the National Science Foundation, the willingness of the students to participate in the study, as well as other researchers who had a hand in the research process including Michelle Cook, Catherine McGough, Brandon Olszewski, Jennifer Parham-Mocello, and David Bowman.

Understanding Industry Experiences: From Problem Solving to Engineering Students' Learning Gains

Jacquelyn K.S. Nagel[‡], Olga Pierrakos[‡], Anna Zilberberg[§], Sean McVay[§]
School of Engineering[‡], Center for Assessment and Research Studies[§]
James Madison University
Harrisonburg, VA, USA

Abstract— This paper reports the findings from surveying a diverse group of undergraduate engineering students (N~100) who participated in summer industry experiences. The goal was to capture and understand (a) the nature of industry experiences and (b) students' learning outcome gains (cognitive and affective) during these industry experiences. Ultimately, we aim to understand how students learn in real-world problem solving contexts in order to transfer such learning and such experiences into the engineering classroom. In undergraduate curriculum, well-structured problems with known solutions acquired through preferred solution methods are encountered more frequently than ill-structured problems. The linear process of problem solving teaches students a procedure to be memorized, practiced, and habituated, a process that emphasizes getting answers over making meaning. Real-world problem solving, though, commonly encountered in industry experiences suffused with complex and ill-structured problems, foster cognitive development of essential, problem-based, and globally competitive problem solving skills. Although industry experiences offer many benefits and enable engineering students to begin the practice of solving real-world complex problems, there is limited research on students' learning outcomes and skill gains as a result of participating in such experiences. Further, there is a lack of understanding of characteristics of the problems or projects that students work on. Our research serves to address these limitations.

Keywords- Industry Experience; Complexity; Structuredness; Complex problem solving

I. INTRODUCTION

Industry experiences, which are highly promoted and supported by Corporations and other agencies, offer many benefits for our students and present a great opportunity for them to learn essential and globally competitive skills. Benefits include: (a) gaining real-world experience in professional engineering environments; (b) having the opportunity to apply skills and knowledge learned in the classroom to real-world problems; (c) working with state-of-the-art processes, equipment, and tools; (d) learning how to work in teams in a professional atmosphere and improving communication skills; (e) developing self-confidence and a positive attitude about future career options; and (f) improving their opportunities for post-graduation jobs. Employers can also benefit from the arrangement by hiring high-performance individuals. Industry experiences not only provide meaningful practice for engineering students, but also deepen a student's understanding of the profession and the workplace. Our overarching research

goal is to understand *what students learn* during industry experiences as a means of also understanding *how students learn* and *how they use and transfer complex problem solving skills* in new settings. Our goal is to capture and understand both (a) the nature of industry experiences in regards to problem solving and (b) the students' learning outcome gains (cognitive and affective) during these industry experiences. Industry experiences can vary widely depending on the work a student is assigned, however, analysis of the typical project stages and overall project difficulty (in terms of complexity and structuredness of the project) allow aggregate data to be collected and comparison of different industry experiences. Complexity gives us insight into the cognitive load imposed on the problem solver and takes into account the required domain knowledge to solve the problem, the intricacy of the solution path, and the depth of integration of varying domains [1]. Structuredness pertains to how well a problem is defined or identified as well as how well the problem solving process is structured in terms of the methods and analysis used [1]. The research questions guiding this effort were:

(1) *What is the nature of (industry experiences) in regards to complexity and structuredness?*

(2) *What are engineering students' learning outcomes during industry experiences?*

In addressing these questions, we hope to not only contribute to our understanding of industry experiences, but also measure what students are learning during an industry experience. Having developed a pre and post industry experiences survey, comprised of both qualitative and quantitative items, we collected data to better understand the layers of problem solving of industry experiences, the structuredness and complexity of such experiences, as well as students' learning outcome gains. By understanding these real-world and authentic experiences, we hope to gain insight into translating the cognitive and affective learning gains offered by industry experience into pedagogical practice at the undergraduate level [2,3].

Empirical and anecdotal evidence supports that industry experiences benefit students in a concrete manner [4], however instruments and knowledge of the outcomes acquired, and to what degree, is still understudied. Researchers at Kettering University developed an instrument that includes questions assessing the extent to which a cooperative education experience aligns with the Engineering Criteria (EC2000)

outcomes as well as questions about the company, and the supervisor [4]. The results support the multi-faceted benefits of cooperative education with 7 of the 11 outcomes having a response over 80% [4]. In a similar vein, researchers at Virginia Tech developed and implemented National Engineering Students' Learning Outcomes Survey (NESLOS), also derived from ABET a-k criteria, to understand how cooperative experiences help to make better engineers. [5]. The survey categorized outcomes by technical, professional, and personal, and revealed that the industry experience resulted in student growth in all three areas. Although some studies have looked into the overall positive impact (such as earnings and grade point average) of industry experiences [6-8], the bodies of knowledge and learning outcomes from being involved in industry settings have been insufficient. Our research serves to address this limitation.

II. METHOD

A. Theoretical Framework

A systematic and integrated analysis of industry experience problems was undertaken through application of the theoretical conceptualization of problem difficulty by [1]. The hierarchical structure of problem difficulty is comprised of two subcategories: 1) problem structuredness and 2) problem complexity. Structuredness encompasses the interdisciplinarity, dynamicity, heterogeneity of interpretations, number of unknowns (intransparency), and number of viable solution paths for the problem (competing alternatives) [1]. Structuredness is a dimension that measures how well a problem is defined or identified and how well the problem solving process is structured in terms of the methods and analysis used. Complexity encompasses the breadth of knowledge, attainment level of domain knowledge, relationally complex thinking (relational complexity) and intricacy of the path taken to arrive at a solution [1,9,10]. Complexity is a dimension that looks into the required domain knowledge to solve the problem, the intricacy of the solution path, and the depth of integration of varying domains. In a sense, complexity lets us gain insight into the cognitive load imposed on the problem solver, whereas structuredness relates to the depth of the problem itself that the problem-solver must understand.

B. Item Development and Data Collection

The theoretical framework outlined above guided the development of the survey items to capture and understand (a) the nature of industry experiences and (b) students' learning outcome gains (cognitive and affective) during these industry experiences. The items were developed by members of an interdisciplinary research team comprised of experts in engineering, engineering education, psychology, and measurement. Two of these research team members also had engineering industry experience.

Items on the survey were designed to address problem difficulty parameters and student learning outcomes. A total of 11 items were developed and administered to understand the complexity and structuredness of industry experiences. **Table I** presents the type of survey items used to measure each problem difficulty parameter. Seven questions assessed complexity and

four questions assessed structuredness. The survey included a mix of both Likert scale and open-ended items, allowing for qualitative (QUAL) and quantitative (QUAN) data, and thus offsetting the limitations inherent in both. In this paper we only present quantitative data. The NESLOS survey [4] was used to capture students' self-evaluation of their learning during an industry experience. Overall, the survey emphasizes assessing perceived knowledge and skills of: (1) problem-solving, (2) writing and communication, (3) teamwork, (4) organization and project management, (5) science, technology, engineering and math, and (6) interest and engagement in the project. Additionally, the NESLOS data are mapped to the ABET a-k criteria to demonstrate how the industry experience met accreditation objectives. The resulting survey instrument went through several iterations before administration. A concurrent nested strategy commonly used in mixed-methods research [11] was employed in this study. This strategy allowed for interpreting both types of data simultaneously in a single research study.

TABLE I. MAPPING PROBLEM DIFFICULTY PARAMETERS TO ITEM TYPE

| Problem Difficulty Parameters | | Item Type |
|-------------------------------|---|------------|
| Complexity | Breadth of Knowledge | QUAL |
| | Attainment of Domain Knowledge | QUAN |
| | Intricacy and Relational Complexity | QUAN |
| Structuredness | Dynamicity, Heterogeneity, Intransparency, Competing Alternatives | QUAN, QUAL |
| | Interdisciplinarity | QUAL |

Students who participated in a 2011 summer internship took the online survey shortly after completing their internship. The results from the quantitative post-internship survey items pertaining to problem characteristics (difficulty and complexity) and perceived cognitive and affective gains, are presented in the current study. Participant identifier information could not be collected to ensure participant anonymity.

C. Student Participants

Of the 107 students who participated in a summer 2011 internship industry experience, the following backgrounds were represented: engineering (N = 97), technology (N = 6), science (N = 8), other (N = 1) (Note that students could select more than one discipline). The majority of students were rising seniors (N = 70). The remaining students were rising juniors (N = 19), rising sophomores (N = 5), and first year graduate students (N = 9). There was also one third year graduate student, one Ph.D. student, and one international student.

Out of 77 participants who provided their gender, 50 (65%) were male and 27 (35%) were female. Out of 77 students who provided their ethnicity information, 71 (92%) were Caucasian, 4 (5%) were Asian-American, 2 (3%) were African-American, and 1 (1%) was Native-American. Out of 77 students who self-reported their GPA, 15 (19%) had an A (4.0) average; 29 (38%) had an A- (3.7) average, 22 (29%) had a B+ (3.3) average, 8 (10%) had a B (3.0) average and 3 (4%) had a B- (2.7) average.

III. RESULTS AND DISCUSSION

In this section, our focus is on understanding the nature of industry experiences and what students learn during industry experiences. More specifically, we aim to better understand these experiences through the lens of problem structuredness and problem complexity. Data analysis of the quantitative items was aggregated and descriptive statistics were tabulated and graphed to facilitate interpretation.

A. Complexity and Structuredness of Industry Experiences

We begin examining the complexity of industry experiences by addressing the breadth of knowledge required to work on and solve such problems. The next set of survey items were designed to give us insights into the intricacy and relational complexity of industry experiences. More specifically, we wanted to decompose the typical project completion process to gain insight into the intricacy of the solution path length and the relational complexity of the process. The following seven major stages of an industry experience project defined by the research team are:

- Identifying and understanding the project
- Establishing project goals, requirements, and constraints
- Coordinating resources to complete project tasks
- Gathering information or collecting data to complete project tasks
- Analyzing results and making conclusions or recommendations
- Managing the project (planning, timelines, budgets)
- Documenting (technical reports and presentations)

Utilizing these seven stages, Likert scale items were included in the survey and were focused on measuring the perceived percentage of time that students spent on each of the project stages, the degree to which these stages were defined for the students, as well as the inherent difficulty of conducting each project stage. The results from the items related to percentage of time that students spent on each of the project stages are summarized in **Fig. 1**. It is evident that the students spent half of their time on three stages: collecting data, analyzing results and making conclusions, and identifying the project. These numbers align with expectations of interns who are treated as trusted members of a team. Tasks that students spent less time on were likely those they received help with. The project stage that students seemed to spend the least amount of time on was project management.

In regards to students' ratings of difficulty of conducting the seven project stages, based on a scale of 1 to 10 (1 – very easy to 10 – extremely difficult), we observed from **Fig. 2** that students' overall mean ratings varied from 3.78 to 5.47 (sd ranged from 2.06 to 2.41). The three project stages with the highest difficulty ratings, all above 5, were collecting data, analyzing data and making conclusions, and coordinating resources. The data in **Fig. 2** correlates to reported time spent in each project stage. Stages perceived as less difficult are

where students spent less time. Stages perceived as the most difficult are where students spent most of their time. The three stages in between, documenting, coordinating resources, and identifying the project, were likely not difficult on a conceptual level but required time to learn company procedures and policies, thus taking a moderate amount of time.

Another survey item that provided insight into the complexity of an industry experience asked students to rate on a scale of 1 to 10 (1 – not at all challenging to 10 – very challenging) how challenging the industry experience was overall. Student responses to this survey item are summarized in **Fig. 3**. Overall, the data revealed that the mean rating for all students was 6.81 (sd = 1.62), with about 73% of the students giving a rating of 6 or above (i.e., challenging range); these results suggested that industry experience was perceived as a rather challenging experience for students. Qualitative responses, not shown here for brevity, confirm that students perceive the industry experience to be challenging but also rewarding.

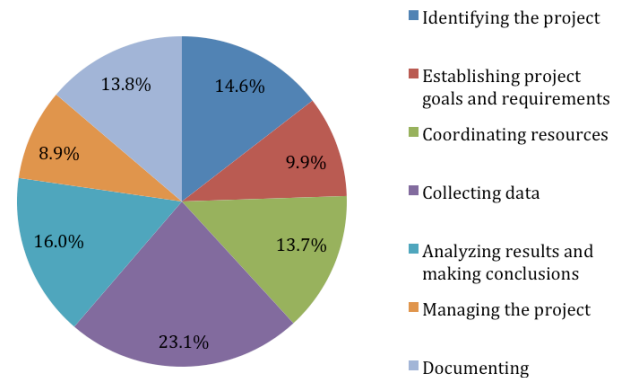

Figure 1. Percentage of time spent on each project stage ($N = 85$).

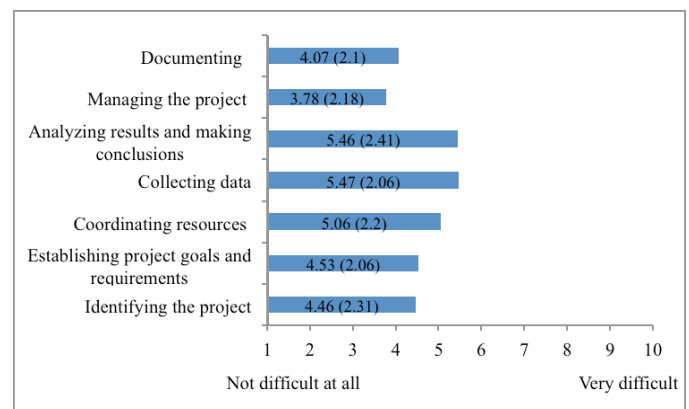

Figure 2. Bar chart of students' mean ratings (standard deviations) of how difficult each of the project stages were ($N = 81$).

The categories of structuredness are coupled in many ways, particularly dynamicity, intransparency, heterogeneity, and competing alternatives (as shown in **Table I**), therefore it was very difficult to operationalize these into survey items that capture each parameter individually. However, multiple survey items, Likert scale and open-ended, were developed to provide insights about the structuredness of industry

experiences. We begin examining the structuredness of industry experiences by examining how well the project stages are defined or identified.

Students were also asked to rate how well-defined each of the seven project stages was on a scale of 1 to 10 (1 – not well-defined at all and 10 – extremely well-defined). Descriptive statistics (mean values and standard deviation) are summarized in **Fig. 4**. Students’ mean ratings varied from 5.88 to 6.91 (sd range from 2.30 to 2.88). From the data we can estimate the percentage of students who gave a rating of 6 and above (i.e., well-defined range) in comparison to students who gave a rating of 5 and below (i.e., ill-defined range). From this estimation, we observe that the majority of students (73%) rated the project stages to be in this well-defined range (6 or above). These results suggest that not only were all seven project stages rated fairly consistently (i.e., one project stage did not appear to be more well-defined than another), but that overall these stages were fairly well-defined for the students. Internships, which are typically offered during the summer months and can range from 8-12 weeks in length, provide short-term projects for students to work on. As student participants are seen as interns, projects and tasks given are generally expected to be more structured or well-defined than ill-structured allowing for more time to be devoted to practical application of engineering concepts.

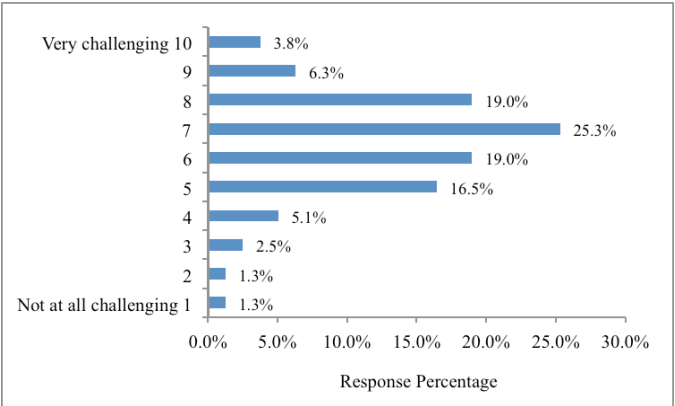

Figure 3. Response percentage for survey items pertinent to challenge of the Industry Experience (N = 79).

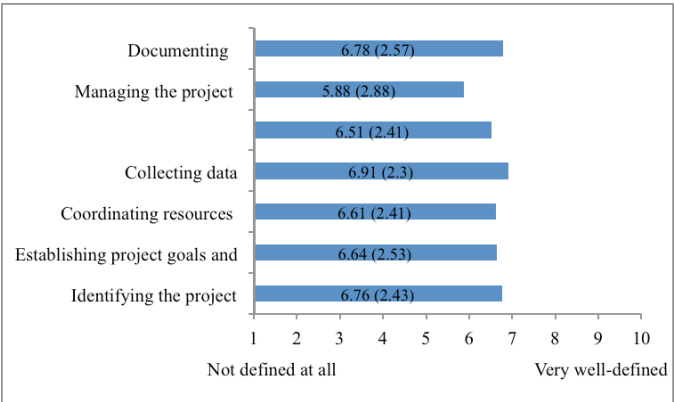

Figure 4. Bar chart of students’ mean ratings (standard deviations) of how defined each of the project stages were (N = 85).

Further, **Table II** shows the data from four survey items that gave us insight into the complexity and structuredness of the problem solving process during the industry experience. The first four items listed speak to the complexity of the problem solving process and the results suggest that about 83% of the students perceived the amount of knowledge and skills that needed to be gained to complete their projects was substantial, but the difficulty of this knowledge and skills was about average. There were also four items, designed to capture the dynamicity and intransparency of the solution path, pertaining to structuredness of the problem solving process. These results suggest that a good amount of the knowledge and skills that needed to be gained to complete the project was provided and also a good amount of instruction on the steps and path to complete the project were also provided to the students. Overall, these results suggest that although students perceived the problem solving process during industry experiences to require a substantial amount of knowledge and skill gains (i.e., requiring a substantial amount of cognitive load), students also perceived that there was a good amount of direction and instruction on these knowledge and skill gains. The problem solving process in industry projects seems to be quite complex, but also somewhat structured. For engineering interns or even entry-level engineers, this model seems to be appropriate.

B. Cognitive and Affective Learning Gains During Industry Experiences

In regards to learning outcome gains, NESLOS was used to assess over fifty learning outcomes relevant to problem solving. **Table III** shows the top ranked learning outcomes based on 70% of the students rating the learning outcome with a response of 4 (correlating to *More than adequate ability*) or a response of 5 (correlating to *High ability*). Responses of 4 and 5 are desirable as they further support the benefits of an industry experience. The results show that the highest learning outcomes for students pertained to: (1) oral and writing communication skills (ABET criteria g); (2) personal growth (confidence, intellectual growth, taking ownership of learning, leadership) (ABET criteria i, f); (3) applying computational, numerical, and experimental tools (ABET criteria k); (4) applying engineering design skills (ABET criteria c); (5) understanding the global and societal impact of engineering solutions (ABET criteria h); (6) collaborating with others and effectively working in a team (ABET criteria d); (7) solving engineering problems (ABET criteria e). Overall, it is evident from these results that students have substantial learning gains as a result of participating in industry experiences. It is interesting that the findings are representative of the skill set that Corporations are looking for in engineer hires.

Students were also asked to reflect on the STEM and other (i.e. affective) knowledge they had prior to the industry experience and the knowledge gained through participating in the experience. **Table IV** illustrates students’ responses to the questions asking them to evaluate the extent of knowledge in the STEM areas before and after the industry experience, as well as the difficulty of that knowledge. An additional

question asked students to evaluate the extent of other or additional skills knowledge before and after the industry experience. The knowledge category of other allows for the measurement of affective learning gains, which include personal and professional topics such as technical writing and presentation, project management, teamwork, learning, and decision making. A scale of 1 to 10 (1 – none and 10 – Extreme Amount) was used. The results suggest gains in knowledge across all measured areas. The highest of these is engineering knowledge. This aligns with expectations as students are working on new projects that require application

of prior knowledge as well as synthesis of field or new engineering knowledge. The second highest gain is other knowledge, which further reinforces that real-world problems, such as an industry experience, do lead to affective learning gains. In terms of knowledge difficulty, engineering knowledge appeared to be the most difficult and mathematics knowledge appeared to be the least difficult. These results suggest that industry experiences do indeed challenge students to not only apply knowledge they have gained during their undergraduate careers, but also to continue learning and gain new knowledge in multiple areas.

TABLE II. RESPONSE TO ITEMS CHARACTERIZING THE PROBLEM SOLVING COMPLEXITY AND STRUCTUREDNESS OF THE INDUSTRY EXPERIENCE

| Survey Items | N | Likert scale | Mean | % Response of 4 or 5 |
|--|----|--|------|----------------------|
| Items pertaining to project complexity (a higher rating implies more complexity) | | | | |
| How much knowledge and skills did you have to gain to complete the project tasks during your Industry Experience (IE)? | 79 | 1 – “None” to 5 – “A lot” | 4.13 | 83% |
| How difficult was this knowledge and skills that you had to gain to complete the project tasks during your IE? | 79 | 1 – “Very Easy” to 5 – “Very Difficult” | 3.10 | 23% |
| How many ways could the project tasks be completed during your IE? | 79 | 1- “Very Few” to 5 – “Many” | 3.11 | 45% |
| How difficult were the steps or path to complete the project tasks during your IE? | 79 | 1 – “Very Easy” to 5 – “Very Difficult” | 3.11 | 27% |
| Items pertaining to project structuredness (a higher rating implies more structure) | | | | |
| How much of the knowledge and skills needed to complete the project tasks were provided during your IE? | 79 | 1 – “None” to 5 – “A lot” | 4.16 | 67% |
| How defined or explicit were the knowledge and skills needed to complete the project tasks during your IE? | 79 | 1 – “Very Defined” to 5 – “Very Undefined” | 2.81 | 83% |
| How much instruction on the steps or path to complete the project task did you receive during your IE? | 79 | 1 – “None” to 5 – “A lot” | 3.58 | 46% |
| How defined were the steps or path to complete the project tasks during your IE? | 79 | 1 – “Very Defined” to 5 – “Very Undefined” | 2.87 | 84% |

TABLE III. DESCRIPTIVE STATISTICS FOR NESLOS BY A-K ABET CRITERIA (N = 78).

| NESLOS Learning Outcome | ABET a-k Criteria |
|--|-------------------|
| Convey ideas verbally and in formal presentations | g |
| Demonstrate strong leadership skills | i |
| Demonstrate confidence in oneself | i |
| Convey technical ideas in formal writing and other documentation | g |
| Apply computational and numerical tools (e.g., programming, modeling and simulation software) to solve engineering/scientific problems | k |
| Collaborate with others when working on engineering/scientific projects | d |
| Take new opportunities for intellectual growth or professional development | i |
| Recognize intrinsic interest in learning/intellectual curiosity | i |
| Generate multiple and alternative solutions/concepts | c |
| Understand the impact of engineering solutions in societal and global contexts | h |
| Demonstrate strong organizational skills | f |
| Formulate and justify the need and relevance of a problem or project | e |
| Apply experimental tools (e.g., machining, instrumentation) to solve engineering/scientific problems | k |
| Demonstrate originality and independent thinking | i |
| Set and pursue her/his own learning goals | i |
| Design a product, process, or system to meet desired needs | c |
| Recognize contemporary scientific, engineering, and technology issues | j |
| Recognize knowledge transfer between real-world engineering/scientific problems and coursework | h |
| Reach beyond oneself (challenge himself/herself to new limits) | i |
| Effectively manage conflicts that arise when working on teams | g |
| Recognize the need for lifelong learning | i |

TABLE IV. EXTENT TO WHICH PARTICIPANTS POSSESSED KNOWLEDGE IN THE STEM AREAS

| | Average Rating of Knowledge Possessed (St. Dev.) | | | Difficulty of Knowledge (St. Dev.) | N |
|--------------|--|----------------|--------|------------------------------------|----|
| | Before IE | After IE | % Diff | | |
| S | 6.26 (1.93) | 7.93 (2.00) | 27% | 5.22 (2.21) | 27 |
| T | 6.13 (2.01) | 7.87 (1.63) | 28% | 5.4 (2.35) | 45 |
| E | 5.81 (2.22) | 8.02 (1.41) | 38% | 6.16 (2.02) | 63 |
| M | 8.19 (1.97) | 8.52 (1.89) | 4% | 3.81 (2.14) | 48 |
| Other | 6.04 (2.40) | 8.24 (1.38) | 36% | 5.37 (2.64) | 49 |

IV. CONCLUSION

In this paper, industry experiences were investigated to gain insight into the nature of such experiences in regards to complexity and structuredness, as well as to gain insight into students' perceived learning gains. The hope is that this research can aid engineering educators in understanding real-world engineering practice from industry and translating such practice into the engineering classroom. Our findings indicate that industry experiences:

- engage students to continuously learn new knowledge and skills. The dynamically changing learning environment challenges students, but also enables them to learn important problem solving skills.
- are moderately structured with most of the project steps being well-defined, but most project stages are still considered to be challenging to very challenging.
- enable students to apply STEM knowledge, but also gain a substantial amount of new STEM knowledge. This is especially true for engineering knowledge.
- enable students to grow technically, cognitively and affectively through the practice of multiple cognitive operations in the context of a continuously changing and dynamic team environment.
- involving a significant amount of teamwork and mentorship were important factors in a successful project and experience.

Our motivation was to understand the nature of industry experiences as a means of translating and integrating real-world problem solving into the classroom. Problem based learning pedagogies can serve as the framework for this transferability. According to educational researchers [8], classroom problem-based learning experiences should be ill-structured with a moderate degree of structuredness, authentic by being contextualized to real-world workplace settings, complex enough to be challenging and engaging to students' interests, adapted to students' cognitive development and prior knowledge, and amenable to problem examination from multiple perspectives. Industry experiences do in fact meet these criteria for ideal classroom problem-based learning experiences.

Future work includes analysis of qualitative responses via thematic coding, triangulation of qualitative and quantitative data, and analysis of team and mentor data. Open-ended and Likert scale items related to teamwork and mentorship will be analyzed for correlations to project complexity and structuredness as well as student learning gains. We expect that classification of real-world industry-based problems will lead to an understanding and characterizing of complex problem solving domains and processes. Once further analysis is complete recommendations for transferring real-world complex problem solving (based on industry problems) in engineering undergraduate and high school courses as well as K-12 outreach settings will be made.

ACKNOWLEDGMENT

The authors would like to acknowledge the support of the National Science Foundation Award #EEC-0846468 (NSF CAREER—"Characterizing, Understanding, and Integrating Complex Problem Solving in Engineering Education"). We would also like to thank the students who participated in this study.

Work in Progress: Outreach Assessment: Measuring Engagement

An Integrated Approach for Learning

Lizabeth Schlemer, John Oliver, Katherine Chen, Sofia Rodriguez Mata, Eric Kim
Cal Poly, San Luis Obispo

Abstract— The Learn By Doing Lab (LBDL) at Cal Poly, San Luis Obispo is an on-campus laboratory where 5th through 8th grade students are taught by undergraduates who may be planning a careers in teaching. The two populations - elementary students and undergraduates - are equally important in the process. Since 2008, the lab has seen over 4000 elementary and junior high students and over 100 undergrads have participated. In most outreach assessment the number of individuals participating is an important metric, but this last Spring we experimented with a more in depth measure of effectiveness. As in any learning experience engagement in the process is an essential ingredient. Although there are several methods of measuring engagement, we chose to observe the activity of the participants as a proxy for engagement. Two industrial engineering (IE) undergraduates who themselves have been exposed to the topics of work sampling and observation studies had an opportunity to improve professional skills through this application. This involvement of undergraduates is consistent with the LBDL and Cal Poly's motto of "learn by doing." These two students, who are also co-authors, spent multiple hours coding and randomly sampling the of the elementary and junior high students as well as the undergraduate teacher's activities. Not only did the IE students discover important insights for the LBDL they also learned how to apply work sampling in a research setting. This paper discusses the integrated learning environment and the next steps involved in these undertakings.

K12 outreach; observational studies; integrated leaning

I. INTRODUCTION

A quandary in K12 outreach activities is the effectiveness of the events. Whether it is a hands-on laboratory like we have at Cal Poly or informal science activities, the effectiveness is often measured by the number of individuals participating [1,2]. Sometimes there is a self-report survey given, but the reliability and validity of such instruments is hard to determine. We tried an observational method that has been used successfully in other educational settings [3].

Initially we wanted to explore the observational method to see if any insights could be gained regarding student learning or the design of the activities. We also thought this could be used in other educational settings. As we explored this method it seemed similar to "work sampling" [4], a method of determining time standards in the Industrial Engineering (IE) practice. Students in our IE program are exposed to this technique but the chance to practice this method is limited. Given this, we recruited two students (co-

authors on the paper) to help develop the assessment method as a work sampling task.

There are two groups of interest in the LBDL. The first is the K12 students (we refer to these as "K12 students") who visit the lab and the second group is the college students (we refer to this group as "TA's") who take the class to explore the possibility of a career in teaching. Both of these groups were observed.

As we progressed we saw that there were actually three goals of this study. As we initially desired, the first goal was to measure engagement in the outreach activity for both the K12 students and the TA's. The second was to practice this method of assessment so we could use it in other settings. The third goal was to provide an opportunity for IE undergraduates to hone their skills in a technique used in their field. This paper starts with a brief description of the LBDL activities and then discusses the three goals. We also will touch on the unique integrated nature of this study.

II. DESCRIPTION OF THE LBDL ACTIVITIES

The LBDL is an on-campus laboratory where 5th through 8th grade students are taught by undergraduates who may be planning careers in teaching. Since 2008, the lab has seen over 4000 elementary and junior high students and over 100 undergrads have participated. The activity in this specific study involves the building and testing of a wind turbine. TA's begin the one hours session with a short discussion about engineering practice. The TA's then work with small groups of K12 students to develop an efficient wind turbine. The turbines are tested using a fan to determine the blade configuration (i.e., size, shape, and pitch) that generates the maximum voltage. Students are encouraged to test and adjust. The activities are repeated twice a day with a different group of K12 students. A successful activity has students talking and testing in a fun active environment.

III. WORK SAMPLING AND OBSERVATION STUDIES

Work sampling is a technique used by IE professionals to determine work content. The study is designed using random samples and statistical analysis to determine the approximate rate of occurrence of the activities. The output from the technique is a statistically confident definition of proportion of occurrences. This is very similar to the engagement observation studies described in the literature.

A. Reflection by the IE Students

“Learning the concepts of work sampling within lecture was quite different from applying it to the Learn by Doing Lab. The objective and procedure to obtain results were given to us in our courses, but in the LBDL there weren’t predefined procedures for work sampling. As a team of two, we discussed the best ways to record data, observe the subjects, and analyze the information. This freedom worked positively in allowing us to fortify our previous knowledge of work sampling and statistical analysis. The research was truly a “Learn by doing” example as it allowed us to test our proposed research methods and learn what worked and what did not. Seeing the material in lecture is one thing, but being responsible for the research and observation was truly beneficial for me. Before, my knowledge was adequate, but now I feel much more comfortable in applying my skills to real world situations. I can see that work sampling cannot only be applied in factories, but really in any situation.”

B. Next steps

The transfer of knowledge from lecture to research activity, in this case the LBDL, was a valuable experience. We plan on having undergraduate students to participate in this type of research activity in the future. There are many areas of observations that are of interest and knowing how this helped the students more thoroughly understand work sampling technique encourages us to use it in the future.

IV. OBSERVATION TO MEASUREING ENGAGEMENT

To define the observational categories we spent time watching activities. This lead to five different categories for the TA’s: Working, listening, interacting, traveling and idle. For the K12 students three categories were used: Working, focused watching, and idle. We set up a schedule of random observations for a total of between 15 and 20 observations during the two hours of activities each week. There were between 12 and 16 TA’s each day and between 30 and 40 K12 students. It was important to take the observations in a random fashion to maximize statistical validity. The data was collected and analyzed for insight into the activities.

A. Reflection

Several insights came from the studies. First the process of observing is not straightforward. We had to make adjustments in the process after the first week. The categories were initially not defined with enough detail. In addition tracking all subjects was difficult. In hindsight having two observers scoring and tracking, would have helped the validity of the study. We considered video taping the labs for both a visual record and for validation of observational judgments.

B. Next steps

As we continue to develop these studies we will have two individuals observe and score the subjects. Although it might be ideal to videotape and watch the videos to develop scores, it would make this tedious activity even more so and we feel the interest level for the researcher would fall.

We are using these observational techniques for other studies on engagement, including a random study of classroom activities across campus and in studies that contrast innovative teaching to traditional lecture.

V. EFFECTIVENESS OF THE LBDL ACTIVITES

The observational studies themselves lead to several insights into the outreach activities. In order to statistically test the comparisons we ran Chi-Square goodness of fit tests. All reported differences had a $p=.001$ of lower, but we would feel more comfortable if we had had multiple observers to validate the observations.

A. Reflection

- The younger K12 students spent more time watching while the older students spent more time working
- The second group of K12 students each day had higher proportions of working. This may have been due to a kind warm-up or practice for both K12 students and TA’s.
- The lower ratio of K12 student to TA’s the higher the proportion of working time.
- When there were more females in a group the group spent more time working.
- The TA’s were noticeably more active in the activity when the children were younger probably because more explaining was necessary.

B. Next Steps

As we refine our ability to observe the insights gained will help to develop more effective outreach activities.

VI. CONCLUSIONS

The LBDL provided an exceptional place for us to practice aspects of integration. We integrated the IE student’s curriculum into an observational study on engagement in order to develop insights into activities that help engage K12 student interest in STEM activities. As we progress in our practice in these areas we believe we will be able to develop effective measure of engagement while encouraging technique development through educational research.

Development of a Design Task to Assess Students' Understanding of Human-Centered Design

Roy B. Melton, Monica E. Cardella, William C. Oakes, Carla B. Zoltowski
Purdue University
rbmelton@purdue.edu, cardella@purdue.edu, oakes@purdue.edu, cbz@purdue.edu

Abstract— *In this paper, we describe our process for creating a design task to assess students' understanding of human-centered design. The development process involved conducting a series of pilot tests, with analyses of the data from each prior pilot motivating revisions made to the next versions of the assessment design task. This paper is a formative look at the seven iterations of the design task that have been administered. We will discuss the information we gained about the students' understanding and the design task itself and how it informed the revisions. We will also discuss student perceptions of the design task, features of the design task that helped or hindered eliciting, and capturing, the participants' design process and major breakthroughs in the task development process.*

Keywords—assessment; human-centered design; design task

I. INTRODUCTION

Developing a human-centered approach to design is vital to appropriately preparing graduates for the globally competitive workplace. The National Academy of Engineering's report on the Engineer of 2020 challenges engineering educators to consider both the demands currently being placed on our recent engineering graduates, and the world in which they will practice [1]. Human-centered design (HCD) has been shown to increase productivity, reduce errors, reduce training and support costs, improve people's acceptance of new products, enhance companies' reputations, increase user satisfaction and reduce development costs [2,3]. One of our concerns is the process of teaching HCD and the assessment of the student learning. An important facet of education is assessment; it allows instructors to provide feedback to students on their learning. To this end, we are creating a design task to assess students' knowledge about, skills in doing, and feelings toward HCD. This assessment tool could be used not only by instructors, but also by researchers to plot out the turning points in students' understanding of HCD over time as well as to investigate the impact of various pedagogical interventions. However, in order to create a valid assessment of students' understanding of HCD, it is important to begin with a theoretical understanding of the construct we want to assess [4]: in this case, HCD.

Our theoretical understanding of our construct, human-centered design (HCD), is based in what has been published on HCD and empirical research study. From the literature, HCD is a design process in which there is a purposeful focus on the end users, clients and stakeholders throughout the design process. Key principles of HCD are: the active involvement of users, a clear understanding of the user and task requirements, and

iteration of design solutions [3]. IDEO, a global design and consulting firm, believes the HCD process begins by, "examining the needs, dreams, and behaviors of the people we want to affect with our solutions" [5]. Therefore, in order to assess students' understanding of HCD, we must evaluate, and capture, the design process that students demonstrate to complete the design task. Another important phenomenon to elicit is how students are making their design decisions and what informs those decisions [6].

From the literature, we also can learn from other design researchers' efforts to assess students' understanding of design, [7-11], although previous assessment efforts have not explicitly focused on aspects related to a HCD process. To address this gap, a recent empirical study was undertaken to identify and describe dimensions of variation in students' understanding of HCD [12, 13]. From this study, [12, 13], we learned that there are seven qualitatively different ways in which students experience and understand HCD:

- 1) *As a technology-centereed process*
- 2) *As service*
- 3) *As a process of gathering user information that is inputed into a linear process*
- 4) *As a process of keeping users' needs in mind*
- 5) *As design in context*
- 6) *As commitment to users' and stakeholders' needs*
- 7) *As empathic design*

These categories (or ways of experiencing/understanding HCD) differ in terms of students' understanding of their users as well as the level of their design skills and ability to integrate the knowledge [13]. The third through seventh categories are nested hierarchically, where moving from the third category to the seventh represents a more comprehensive understanding of HCD or designing for others [13]. Two categories that were distinct and not included in the main nested hierarchy of categories: those whose experiences lacked design processes (service) and those who did not appreciate the knowledge, experiences and perspectives of the users or the value of involving the users in the design (technology-centered).

II. METHODS

To date, seven pilots have been administered to more than seventy undergraduate participants ranging from first-year students to seniors that included engineering and non-engineering majors. All of the pilots to date have been done

This work was made possible by a grant from the National Science Foundation (EEC 0935077). Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

with undergraduate EPICS (Engineering Projects In Community Service) students. Participants also ranged from students participating in EPICS for first time to students with several semesters completed in the EPICS course. The EPICS design course was targeted because it is a service-learning course that emphasizes an HCD process to achieve the wants and needs of the users and stakeholders. Additionally, the EPICS program is open to all undergraduate majors from first-year to senior undergraduates. Such diversity was sought out because one goal of the assessment task is that it be discipline neutral or able to be used across engineering, technology and computing majors. One of the aims of this project is to be able to categorize participants, as done in the previously mentioned empirical study in which participants' experiences were defined and placed into one of the seven distinct categories, where each category represented one way of experiencing HCD [13].

Participants were mainly recruited through course announcements. With the exception of one round of pilot testing, participants worked individually for approximately one hour on the design task packet. The "design task packet" consisted of a scenario assignment in which, "rather than solving the technical or design problem presented in the scenario, students are asked to describe how they would go about finding the solution to the problem" [14]. The types of activities participants were asked to complete evolved from critiquing and creating Gantt charts, to creating visual representations, filling out a detailed table, and completing reflection questions. The types of data that were collected, depending on the pilot, consisted of what participants wrote down to solve the design task, any drawings and sketches, critiqued and/or participant created Gantt charts, informal group discussions, and finally a table and reflection questions (to be discussed later). Participants only wrote or drew on the design task packet they were given and the packets were collected at the end of the one-hour time limit.

To analyze the artifacts, we examined the data for evidence of the HCD principles, as stated earlier: the active involvement of users, a clear understanding of user and task requirements, and iteration of design solutions [3]. Desired forms of iteration include involving users and stakeholders at multiple points or throughout the design process or gathering information from stakeholders and details about stakeholders' needs multiple times throughout the design process. Additionally, we looked for evidence that decisions were being based on stakeholder needs and stakeholder feedback. The analysis process also involved trying to place participant responses into one of the seven categories presented in [13]. Being unable to place a participant response in a distinct category meant that the design task either a) was not able to elicit data that would indicate their understanding of HCD or b) could not effectively capture the participants' design process. Thus, improvements were made in following pilots.

III. DESIGN TASK DEVELOPMENT

An overarching goal for the development of the design task was to not only assess students' understanding of HCD, but also to practice HCD ourselves. The "scenario" we attended to was to create a design task assessment that would be a

discipline neutral, in-class assessment to be used by any educator or researcher to assess students' understanding of HCD. Thus, some of our stakeholders include: engineering educators, researchers, and students. These stakeholders will continue to be included in our design process through conversations with expert engineering educators and students, and iterative rounds of collecting data from students. In all, we conducted seven rounds of pilot testing. Each round yielded unique insights into a) the question of how to measure and elicit design understanding and b) students' understanding of design and their perception of the design task itself.

In pilots one through four participants worked individually on the design task and they were asked to either 1) create a Gantt chart that would describe the steps they would take to complete the challenge presented in the scenario or 2) critique a Gantt chart and then produce their own Gantt Chart. The task of critiquing a Gantt chart was inspired by Bailey's investigation into design process knowledge [10]. We created two different scenarios, the "Natural Disaster" and the "Soap Box Derby." The Natural Disaster scenario had a broader scope and the Soap Box Derby scenario was situated in a design course project that other students had previously worked on. The process of developing the task has revealed interesting findings and provided insights into how students react with different instructions and design scenarios.

A. Pilot One (9 participants, all engineering majors)

In pilot one we used the Natural Disaster scenario. The intent was to provide a situation that was accessible and motivating to all disciplines. We also intended to put "humans" at the center of the design task in an attempt to elicit a human-centered (versus primarily technological) design response. The scenario read as follows:

"A natural disaster has occurred on the west coast of the United States. A vast majority of residents have lost their jobs and homes. You, and the design company you represent, are being considered to be placed in charge of the recovery effort to identify and develop solutions that will restore the livelihoods of the residents. Carla S. Helpful, a local resident, will be your guide and help you find the resources you need, whether it is materials or people. The economy of the town you will be responsible for is heavily dependent on tourism, seafood, and the natural landscape of the area. To be selected as prime project managers for this job you have to describe what your activities would be for the first month as well as providing concepts that your team would deliver to the community in the coming months. Use a Gantt chart to plan out the activities to be done for the first month."

We provided blank Gantt charts for participants to use. The artifacts collected included the design task packet: any notes participants made on blank areas of the paper, and the completed Gantt charts. We purposefully left "livelihood" undefined and didn't indicate what kind of natural disaster had happened. This was done in an effort to encourage participants to seek out stakeholders and to inquire as to what their needs would be. However, from the discussion after the task was done and examining the artifacts, it appeared that participants took the role of first responders such as FEMA (Federal

Emergency Management Agency) or the American Red Cross. Four of nine responses were focused on getting temporary housing, food, and clean up. This was most likely due to the wording of the scenario and the one month timeline given to plan for (in pilot four the Natural Disaster scenario was slightly adjusted). From discussions with participants, because of the scenario wording participants felt that they would be arriving to the affected area just after a natural disaster hit and thus it was an emergency and participants had to act quickly. These participants focused on managing the disaster and made design decisions based on their own understanding of the situation and not by gaining an understanding the stakeholders. Other participants, five of nine, focused more on rebuilding the economy. These participants exhibited more information gathering activities and had more breadth of considerations than the first responder group. However, all participants seemed to focus on project management instead of design. Regardless of which group the participants fell in, it was still impossible to place participant responses in of the seven distinct categories experiencing HCD [13]. This version of the design task did not elicit information which would facilitate our characterization of their understanding of HCD.

B. Pilot Two(8 participants- 4 engineering, 1 graphic design, 1 computer graphics technology, 1 computer science, 1 chemistry)

In pilot two participants were given the Soap Box Derby scenario. We choose this scenario because we wanted to see what effect of narrowing the scope of the project would have on eliciting a HCD response. The Soap Box Derby scenario is situated in a design course and was an actual EPICS project that we felt students could relate to. The timeline for completion in the scenario was a semester (five months) instead of one month as in the Natural Disaster scenario. The scenario was developed from a study designed to assess moral decision making [15]. In line with our goal of making a discipline neutral assessment, they created scenarios that were “general, universalizable ethical issues, broadly constructed” [15]. The scenario read as follows:

“You are the team leader of an EPICS team that will be delivering a finished project this semester. Your team has designed a new Soap Box Derby car that opens the race to children who have physical and cognitive disabilities by allowing an adult to ride in a backseat and maintain full control of the car. By allowing an adult to ride in a backseat and maintain full control of the car you have enabled children to participate in the Soap Box Derby racing event who previously could not have done so safely. Based on suggestions from the parents, you have added spring tension to the child’s steering wheel in front in order to simulate the feeling of driving and make the child’s experience more realistic and fun. The child will not have the ability to control the car, only the illusion of control. However, your team assumes that the children would like to have total control of the soap box. To help solve this dilemma, and create a consensus between all parties, you decide to interview the special needs caregivers, who are responsible for the children while the parents are at work. It is clear that in order to get this project completed and delivered this semester your team may have to redesign the soap box to

meet the needs of all the stakeholders involved, as well as manage the potential public relations issues surrounding any controversial design decisions. Unexpectedly, before you are able to do any interviews, your advisor informs you that he has to leave town and will not be back until the end of the semester. Your advisor informs you that: ‘Your task is to redesign the Soap Box Derby car this semester. Create a Gantt chart to describe, in detail, the activities to be completed during this semester leading up to delivery of a finished project. Include the specific design decisions you would make and the different roles your teammates would take.’ ”

We provided blank Gantt charts for participants to use. The artifacts collected included the design task packet: any notes participants made on blank areas of the paper, and the completed Gantt charts. In comparison to the first pilot, we were able to observe good indicators of HCD thinking such as participants including more iteration with stakeholders in their design processes. In seven of eight cases, evidence was present (but not conclusive evidence) that lead us to believe that design decisions were being governed by stakeholders’ needs and feedback. However, none of the participants saw a need to meet with the actual organizers of the event, which would show more a breadth of considerations. Also, we started to notice participants using umbrella terms such as “stakeholders” instead of specifying who they meant: parents, children, etc. Participants would also neglect to indicate what was meant by “feedback.” Feedback from whom, and about what? This would all be valuable information that would further aid in evaluating responses. Trying to have participants give more detailed responses became a reoccurring theme. Finding out how to elicit more detail from participants was discovered in later pilots. However, this scenario did seem to elicit a more HCD response than the Natural Disaster scenario. Participants took on the role of designer in this scenario more than did the participants who worked on the Natural Disaster task.

C. Pilot Three(8 participants-4 engineering, 1 general communication,1 physics, 1 computer information tech, 1 information systems)

In pilot three we used the same Soap Box Derby scenario but asked participants to first critique a given “completed” Gantt chart and then create their own. The additional instructions stated, “First, critique the design process given to you by a fellow teammate describing any improvements you would make or activities you would keep. You may also shade in areas of the process to lengthen time or to show concurrent actions. Then, create your own Gantt chart considering if you had unlimited resources and people.” Additionally, in reference to the Gantt chart given we asked, “what is good about this process and why?”, and “what would you do differently, and why?” This procedure is similar to the investigation into design process knowledge [10]. In similar fashion to the [10] study, we included design process strengths and weakness in the Gantt chart given to the participants. Some of the weaknesses were: no stakeholder involvement throughout the process, design decisions were based on team assumptions, and lack of breadth of context. The strengths of the design process were: iteration, testing, and brainstorming. However, the iteration was not done with the stakeholders. It was purely technical

iteration (something akin to troubleshooting): design, test, and redesign cycle. As in the other pilots, we provided blank Gantt charts for participants to use. The artifacts collected included the design task packet: any notes participants made on blank areas of the paper, the critiqued Gantt charts, answers to the questions, and the participant completed Gantt charts. From the artifacts collected we saw that half the participants did address at least one of the weaknesses. For five of eight responses, it was still hard to determine if design decisions were governed by consideration of all stakeholders. Also, when participants would make corrections to the Gantt chart given, some improvements would not always be copied over to the Gantt chart they created. This created a disconnect in participant performance and added difficulty in determining a participant's thinking. When compared to the first two pilots, where participants had to create Gantt Charts from scratch, there was also less detail or less explanation of the activities to be accomplished that were entered onto their Gantt charts. We attributed the reduced detail to participants mimicking the low level of detail in the Gantt chart we gave them. When comparing the effect of providing a Gantt chart to critique versus having participants solely creating a Gantt chart from scratch, participants would give more detailed responses which included discussing activities on the Gantt chart or giving overall explanations of their plans or their point of view of what needs to be accomplished. In this pilot, participants stuck to answering the questions in reference to critiquing the given Gantt chart from a fellow "team member."

D. Pilot Four (13 participants-10 engineering, 1 undecided, 1 film and video studies, 1 computer graphic technology)

In the fourth pilot we addressed some of the issues we saw with the initial Natural Disaster scenario. We stated that first responders had already been in the area for months and were preparing to leave and that the focus had shifted from immediate relief to stabilization. We also introduced a funding agency which participants had to present their strategy to, a strategy "that will lead to the generation of concepts that would be further developed in the following months." The modified Natural Disaster scenario also included a "completed" Gantt chart for participants to critique and then to create their own, with the same additional instructions as given in pilot three. However, the Gantt chart activities were different and situated in the Natural Disaster scenario. The strengths were meeting with residents to determine initial needs and brainstorming. The weaknesses of the Gantt chart given were iteration, testing, and minimum stakeholder involvement like never presenting ideas to residents. We provided blank Gantt charts for participants to use. The artifacts collected included the design task packet: any notes participants made on blank areas of the paper, the critiqued Gantt charts, answers to the questions, and the participant completed Gantt charts. After collecting and analyzing the data, not everyone picked up on the weaknesses of the given Gantt chart. Participants still seemed focused on project management. Four of thirteen only presented their results to the funding agency. Another four of thirteen participants were solely concerned that some activities could be done concurrently and/or earlier on the timeline. On the other hand, there were ten of thirteen responses that had a more breadth of consideration than the first pilot, exhibiting at least

one of the following: talking with FEMA and the American Red Cross organizations, presenting ideas and getting feedback from residents or considering infrastructure issues not mentioned in the scenario. The detail in the responses was also slightly better than the third pilot, which may have mirrored the more detailed description of the activities in the Gantt chart given. Still, the Soap Box Derby scenario elicits more data that would help indicate participant understanding of HCD than the Natural Disaster scenario. From this point on, we concentrated on refining and perfecting the Soap Box Derby scenario.

E. Pilot Five (12 participants-10 engineering, 1 computer science, 1 computer and information technology)

In pilot five we experimented with another format for capturing participants' design processes because we noticed weaknesses in solely using a Gantt chart. We decided to have participants demonstrate their design process on a calendar. A calendar was provided that showed each day during the entire semester. This change was also motivated by the informal discussions with participants from the previous pilots. During the discussions the participants talked about how they would plan their personal activities or schoolwork. Using a calendar was one method that surfaced often. Also, for this pilot we had participants work in groups of two to four. This was done in an effort to mimic true design practice where designers work in teams and not individually on projects. Participants were given the Soap Box Derby scenario, same as in pilot two, and were instructed to work in teams and report back using the semester calendar. Once the artifacts were examined, the level of detail and the richness of the responses were much less than any of the previous pilots. Moreover, because of working in groups, it was impossible to know who the design task was assessing. Did each member have an equal role? Or who contributed the most?

Analyzing the artifacts collected from pilots one thru five we learned that the Soap Box Derby scenario elicited a more HCD response than the Natural Disaster scenario. This was evidenced in being able to see more HCD principles manifested in the artifacts from the pilots where the Soap Box Derby scenario was used. Also, having participants create a Gantt chart from scratch provided a more detailed response from participants and a richer artifact to evaluate. We also noted some of the limitations of the Gantt chart. We could not tell how participants perceived the stakeholders and what types of information they were getting from stakeholders. Furthermore, it is often difficult to say for certain if we are witnessing iteration or concurrent actions from the Gantt chart. This would all help us further evaluate participant responses. Thus, we decided that we needed something to complement the Gantt chart or an alternative form for capturing the participants' design process.

F. Pilot Six (10 participants-all engineering)

For pilot six we wanted to address some of the limitations of the Gantt chart, such as being unable to tell: how participants perceived stakeholders, the type of information participants were getting from stakeholders, and if we were witnessing iteration of concurrent actions. Also, we wanted to combat the use of umbrella terms such as "testing", "stakeholders", and

“feedback” which were limiting the level of detail and prohibiting further understanding of participant responses. Therefore, we created Table 1 for participants to fill out that would supplement the weaknesses of the Gantt chart. The table is similar to the Gantt chart in that the individual activities to be accomplished are listed vertically in the left-most column. However, the addition of the three other columns allows us to uncover more of the participant thinking than a Gantt chart.

TABLE I. TABLE TO SUPPLEMENT GANTT CHART

| What tasks must be done? (List tasks individually) | What information will you need to be able to do this task? | What or who is the source of information? | Why is the task being done? What is the purpose of the task? |
|--|--|---|--|
|--|--|---|--|

The Soap Box Derby scenario was also adjusted so that it would not lead participants to indicate that they would interview stakeholders (when this is something they normally would not include in their design process) and statements explicitly stating that one of the objectives was to get a consensus between all stakeholders were eliminated. That is, statements such as, “To help solve this dilemma, and create a consensus between all parties, the team decides to interview the special needs caregivers” were eliminated. Also, participants were given the option of creating a flow chart or flow diagram instead of using the blank Gantt chart given. Giving participants the option of using the Gantt chart or creating a flow chart or flow diagram was motivated by discussions with colleagues at the Frontiers In Education (FIE) conference in 2011. They commented on the “confining nature of the Gantt chart.”

After analyzing the artifacts it became clear that implementing the table was a valuable step in the right direction. The information contained in the table supplemented the information collected in the Gantt chart. Not only did participants list their activities on it, but they also had to include explanations of why each activity was being done and with whom. Responses on the table were extremely easy to interpret and made explicit what participants planned on doing and why they were doing the various activities. The umbrella terms mentioned before were not as much of a concern as before because with the table, if one column was unclear the others would help to clarify an activity. However, based on the information from the Gantt chart and table, it was difficult to place participants in the higher categories of description of experiencing HCD, or the “more comprehensive ways of experiencing human-centered design” [13]. To place participants in categories such as “commitment to involving stakeholders to understand perspectives” and “empathic design” there needed to be more unpacking of a) how participants saw the importance of stakeholders and b) participants’ attitudes towards stakeholders.

G. Pilot Seven (13 participants-11 engineering, 2 computer science)

Pilot seven represents the culmination of all of the improvements and insights gained by conducting and analyzing pilots one through six and also reflects feedback from a special

session at FIE 2011. As stated before, after conducting pilot six the usefulness of the Gantt chart was called into question. Although the Gantt chart elicited some information that helped to characterize participants’ understanding of HCD, it lacked specific and motivational information. In addition, from discussions with expert design educators at the FIE conference, it was suggested that the form of the visual representation should be left open to the participant instead of presenting a Gantt chart. This was also evidenced from examining the artifacts from previous pilots, where some participants would make drawings or sketches on their own without instruction. Therefore, the Gantt chart was removed and replaced with blank space for participants to create any sort of visual representation. Also, as learned from pilot six, the table should be supplemented with questions that expose how participants view stakeholders and their attitudes toward them, along with how important participants felt the stakeholders’ needs were to be incorporated into the design. Consequently, we created reflection questions. The reflection questions were given after the design task was completed and collected. Reflection and self-monitoring can be forms of learning effective design practice [11]. Thus, completing the reflection questions along with the design task would possibly skew the results. Participants could presumably look through the task, see the reflection questions and that would affect how they would complete the table. The reflection questions are: 1) As a designer, what do you feel is important to consider when doing design? 2) What does it mean to do design well? How do you measure success? 3) Do stakeholders have a role in the design process? Describe why, or why not? And 4) What if you had unlimited access to children, parents, experts etc., what would you want from them? How would you include them in the design process? The version of the Soap box Derby scenario for pilot seven is as follows.

“It is the first day of the fall semester (or quarter). You are the team leader of a design team that will be delivering a finished project this semester. Your team has designed a new Soap Box Derby car that opens the event to children who have physical and cognitive disabilities by allowing a professional driver to ride in a backseat and maintain full control of the car. Soapbox derby cars are towed to the top of a small hill and they “race” by coasting down the hill on a straight track. While there are no turns in the course, the cars have steering to maintain control of the cars. In a traditional Soap Box Derby car, the child is by him or herself and steers the car. By allowing an adult to ride in a backseat and maintain full control of the car your team has enabled children to participate in the Soap Box Derby event who previously could not have done so safely.

“Your team has studied other designs for children with disabilities and these designs either have no steering for the child in the front seat or they have added spring tension to the child’s steering wheel in order to simulate the feeling of driving and make the child’s experience more realistic and fun. In either case the child can not actually control the car, the child only has the illusion of control. The question has been raised if the design should allow children who are capable of steering to do so with the driver being able to override the child. The information that you have at this point does not point in one direction or another. Your team’s advisor confesses that she/he

is not an expert in this area and has deferred to the team to determine the best design. Your advisor has stressed, however, that the new design has to be finished this semester. As the team leader, you are asked to develop a plan to get the design right and to make sure it is finished this semester (or quarter).

“Fill out the table given to describe, in detail, the activities to be completed during this semester (or quarter) leading up to delivery of a finished project. Include the specific design decisions you would make and the different roles your teammates would take. The blank space provided on the following pages is for you to use as you see fit. You can create a visual representation (flow chart, flow diagram, Gantt chart, or other picture) to show the sequencing and/or relationships of the activities or simply use to get your thoughts together.”

The pilot seven process of collecting artifacts consisted of presenting the participants with the Soap Box Derby scenario, and instructing them to create any form of visual representation, and then to fill out the table provided. Once participants finished the design task, in which they were allotted fifty minutes to complete, participants were then given the reflection questions to answer, all done individually. The entire process took usually less than one hour for participants to complete both the design task and the reflection questions; about the length of a typical class session. With this version of the HCD assessment, by analyzing the design task and reflection questions we are able to categorize participants' demonstrated understanding of HCD.

IV. CONCLUSION AND NEXT STEPS

The results from the pilots demonstrated that using a scenario that is situated in a design course, allowing participants to create their own form of visual representation along with the implementation of the table and reflection questions, is an effective way of eliciting a human-centered design response and capturing a detailed design process from students. With the Soap Box Derby scenario we are able to elicit a designer response and not a first responder or project manager response. With the table, we are able to elicit enough detail to categorize participants. The artifacts show that many times participants create flow diagrams that, sometimes, show the sequencing of events, something that may have been lost by not using Gantt charts. Even when participants do not create flow diagrams the visual representations can demonstrate HCD principles such as iteration with the stakeholders, although not always. The table effectively captures these features that are not shown in the diagrams. The reflection questions provide valuable insight and often elicit responses that are not captured by the table or the diagram related to participants' attitudes toward the role and importance of stakeholders.

Fittingly, the development of this assessment took a human-centered design approach. With the students or participants being one of the stakeholders, we first had to understand how they would interpret the design task and what scenario would elicit data that would indicate their understanding of HCD. With design educators and researchers also being stakeholders,

we sought them out to get their feedback as the task was being developed. The next phase is the development a rubric for consistently scoring participant responses. In the same fashion of human-centered design principles, educators' and researchers' needs are at the center of our process. The rubric must be easily understood and can be used by any educator or researcher. Developing the rubric will be done in conjunction with validating the design task by conducting follow-up interviews with participants. Follow-up interviews will follow a similar protocol as illustrated in [13].

ACKNOWLEDGMENT

We would like to thank Patrice Buzzanell, Jennifer Turns, Judith Zawojewski, Craig Titus, and James Huff for sharing their time and vast knowledge.

LILES System: An Educational Engineering Application in Linguistics and Cognitive Science

A Novel Interdisciplinary Paradigm

Abstract— This study shows how employing cognitive visualization in a specific engineering application can foster learning. It provides recent experimental analysis of an innovative language-learning support system that is based on a new approach to the study of kanji, our "Learner's Visualization (LV) Approach". Our research examines how intermediate and advanced students use visualization to cognitively deconstruct (divide) kanji in different ways as they study. We analyze these differences with a new learning support system, our LILES system. The LILES (Learner's Introspective Latent Envisionment) System, guides learners to choose from a set of possible "kanji deconstruction layouts" (layouts showing different ways a given kanji can be divided). Throughout the learning experience, the system assists learners in updating their "kanji deconstruction level" (the average number of parts they visualize within kanji according to their current cognitive processing). The analysis proves that there are cognitive differences: advanced learners deconstruct kanji into more parts ("blocks") than intermediate learners do, and while both improve their kanji deconstruction levels with the LILES system, there is a more significant change in intermediate learners. For students of engineering, this study provides an excellent example of the practical implementation of systems design in an effective language-learning support system.

Keywords- educational engineering applications; learning support system; visual cognition; kanji deconstruction level; cognitive maps

I. ENGINEERING EDUCATION AND LEARNER INDIVIDUAL PREFERENCES

A. Learning styles in engineering education

Felder found that learning styles of most engineering students and teaching styles of most engineering professors are inconsistent in several dimensions. He observed that most engineering students are visual, sensing, inductive, and active, and some of the most creative students are global. On the other hand, most engineering education is auditory, abstract (intuitive), deductive, passive, and sequential. In this sense, there is a mismatch that leads to poor learning performance, teaching frustration, and a loss to society of many potentially exceptional engineers [1].

B. Learner individual preference and cognitive visualization

Furthermore, it has been suggested that individual differences between learners also play an important role. For example, Plass and Homer analyzed the role of individual differences on cognitive load in multimedia learning [2]. They found that the role of learners' preferences and abilities is significant in their learning process. The focus of the present study is to evaluate the role of *preferred visualization* in cognitive deconstruction to determine what features may promote learning. Increasing the techniques in an instructor's repertoire would lead to a teaching style that is both effective for students and comfortable for the professor. In this way, the above mentioned intrinsic mismatch will naturally decrease.

C. Intermediate and advanced learners

While in our previous study we examined the case of beginners [3], this paper examines and contrasts the case of intermediate and advanced learners in order to find further and comprehensive implications and suggestions for improving the design of future educational web-based programs based on cognitive science that could be used as experimental computational models in engineering courses.

II. STUDY OF A COGNITIVE MODEL BASED APPLICATION

A. Aim of the study

The aim of this study was to implement a learning support system that makes it possible to analyze the cognitive way in which kanji students visually divide or "deconstruct" kanji during the learning process. This system, the Learner's Introspective Latent Envisionment System (LILES system), is based on our novel approach to kanji-learning called the Learner's Visualization (LV) Approach. This research is original in that it analyzes the cognitive differences between intermediate and advanced learners as they study, with a focus on how many recognizable "blocks" or parts they visualize on average within unfamiliar kanji. Our findings have shown that *beginning* learners tend to progress from visualizing many small blocks within each kanji to visualizing just a few larger

blocks per kanji (although this does not necessarily lead to advanced students visualizing entire kanji as just one recognizable block) [4]. This study strives to determine the cognitive differences that may exist in the way intermediate and advanced learners visually deconstruct kanji, especially while learning new kanji using the LV Approach. In this paper, we discuss our experimental results and summarize the main contributions this study makes to the field of kanji-learning.

B. Further Motivation

We are further motivated by the crucial need to determine not only what specific factors account for better learning results, but also how this happens. Doing so, we could certainly establish how to enhance future learning systems with cutting-edge educational engineering applications in accord with the most recent findings.

III. KANJI BACKGROUND

A. Kanji writing system research

The Japanese writing system is comprised of a unique blend of scripts: kanji (which are derived from Chinese characters), two kana syllabaries (which are phonetic), Roman letters and Arabic numerals. This offers fascinating questions for research, and kanji has been the main topic in numerous studies. In one work related to the present study, Tollini remarked on the importance of understanding how Westerners “see” kanji, especially during the initial stage of the learning process [5]. He stated that Westerners recognize kanji based on visual recognition laws different than those employed by the Japanese [5]. According to the work of Takagi, the complexity of recognizing a kanji can be reduced if learners visually break down the kanji into smaller parts, and organize them [6].

B. Kanji learning approaches

Radical approach. This method uses “radicals” (in Japanese, 部首 bushu) as the key elements of any kanji, grouping kanji according to radicals present within the characters. Limitations of this approach lie in the heterogeneity of the different groupings and in the fact that there are variations on the radicals’ shapes.

Frequency-based learning approach. This approach is based on Monbusho’s Educational Kanji Chart (教育漢字の学年別漢字配当表). Its main drawback is the fact that some kanji are taught without taking into account their visual components. For example, “eat” (ta-beru, ku-rau/SHOKU) (食) is taught in the second grade, but its component, “good”(yo-i, RYOU) (良) is taught in the fourth grade. Teaching a kanji without previously teaching its elementary parts is common but may not be efficient for foreigners.

Component approach. This approach emphasizes learning the building blocks of kanji. All the parts of a kanji are identified as components. A component is a set of strokes which keeps the same visual shape. For example, 歌 is composed of the components: 可 and 欠; another example, 東: “木 and 日” or “田 and 木”. Components are associated with a pattern, which defines the relative position of them.

Learner’s visualization approach. This novel approach proposed by Inostroza involves three elements: 1. the learner’s visual cognition, 2. multiform “deconstruction” of kanji, and, 3. block analysis/synthesis [3]. The first element, the learner’s visual cognition, is the way in which a learner visually divides a kanji into parts or “blocks”. The second element is the set of all the possible options of how that kanji could be divided or “deconstructed” into blocks, from the highest number of small blocks down to just one block (which would be the entire kanji itself as a single block). The third element is the analysis/synthesis cognitive strategy embedded in the approach which allows the user to analyze the given kanji by selecting any block inside it for further study, or to synthesize that block with a bordering one inside the same kanji, suggesting a larger block to be considered that combines the two smaller ones.

IV. COGNITION BACKGROUND

A. Cognitive processing of kanji vs. kana

Neuropsychological research has shown that when one reads Japanese, the kana and kanji scripts are processed by different areas of the brain. Usui et al found that kana and kanji are both processed in the LBTA (the left basal temporal area, also called the left inferior posterior temporal lobe), but, the two scripts are processed in different areas of the LBTA [7]. Interestingly, kanji is processed in the same area of the LBTA that is responsible for recognizing and naming pictures and objects. This suggests that the visual shapes of a kanji play a key role in the reader’s cognitive processing, which is congruent with neuropsychological literature [8]. Nakamura et al found increased activity in this area of the LBTA during the acts of visually fixating on kanji, physically writing kanji, mentally writing kanji, and mentally recalling kanji words [9]. Ino et al concluded that the brain processes kana and kanji in different areas of the LBTA because of the quite different characteristics of the two scripts and the mental tasks required to read them [10].

B. Cognitive maps and kanji visualization layouts

Cognitive maps are a method our brain uses to accumulate and store knowledge (primarily spatial information) in the so-called “mind’s eye”. The brain links related visual concepts in a mental network (a “map”) to facilitate their accessibility. This reduces cognitive load, and thus enhances recall and learning.

V. RESEARCH QUESTION AND LILES SYSTEM

A. Research question

This study is primarily focused on identifying whether or not there is a cognitive difference in intermediate and advanced learners as to their “kanji deconstruction visualization”.

B. Existing kanji learning systems vs. the LILES system

To this day, there are no kanji learning systems currently in use that facilitate the analysis of how learners update their kanji deconstruction level, which is the purpose of this study. With the exception of the LV System that we have developed, no existing system is based on the Learner’s Visualization (LV)

Approach, which guides learners to explore and update the way they deconstruct (visually divide) kanji [3]. Therefore, to pursue our study we have adapted our previously implemented Learner's Visualization (LV) System in a way that would allow us to analyze learners' behavioral results, with the goal of eventually explaining how the LV Approach facilitates learning. We have named this system the LILES System, where LILES stands for Learner's Introspective Latent Envisionment System, to convey the concept that when learners visually deconstruct kanji into layouts of blocks (groups of strokes) and update their preferred deconstruction layout via this system, learners *envision* (see or picture in their mind) possible deconstruction layouts in an *introspective* way (given to examining one's own perceptual experience), bringing to fruition new ways to visualize each kanji that are *latent* in every learner's mind.

VI. LILES SYSTEM IMPLEMENTATION

We have implemented the LILES system as an adaptation of our LV System, which is based on our LV Approach to kanji learning. A brief functional description of the LILES System is as follows: While learning kanji using the LILES System, it encourages learners to explore a predefined set of "deconstruction layouts" for each kanji, and in doing so it guides learners in visualizing alternate deconstruction layouts which differ from the layout the learner initially preferred to visualize. The learning process, illustrated in Figure 1, can be summarized as follows: (boxes "a", "b", "c" etc, refer to the boxes attached to the figures): The system shows a certain kanji with its corresponding meaning, (boxes "a" and "c"), for example, the kanji for "to be surprised, to be astonished" = "odoroku" (驚). Below the kanji, the system shows a set of predefined possible deconstruction layouts into which the kanji can be divided. The user first selects the deconstruction that best matches the way he would naturally divide that kanji according to his own personal visual cognition. After selecting his deconstruction of choice, the system then allows the user to examine and learn more by clicking on the zone of particular blocks, (box "b"), within his chosen deconstructions as well as blocks within all the other possible deconstructions. When a user clicks on the zone of a block, (box "b"), the system gives relevant information about it, (box "d"). The system then suggests that the learner consider a new, larger and more complex block, (box "e"), which is constructed based on the block selected by the learner combined with an additional block also present in the same kanji, bordering the selected block. The new assembled block becomes a "superblock" in the kanji in study. While the user is working on the kanji 驚 and examining the block 苟, the system suggests the construction of a new block "敬", combining (苟) with adjacent block (攵), and shows some examples of other kanji that include this more complex superblock. Learners can explore any of the examples just by clicking on one of them. The core of the technique lies with the recommendation of a "next complex block". For example, if the learner selected the block '苟', the "next complex block" suggested by the system is '苟+攵' = '敬'. Alternatively, at the bottom of the learning environment users can choose to explore other kanji that include the block they selected, (box "f"). The kanji the user

has studied kanji appear at the top of the screen in case she wishes to review them, (box "g").

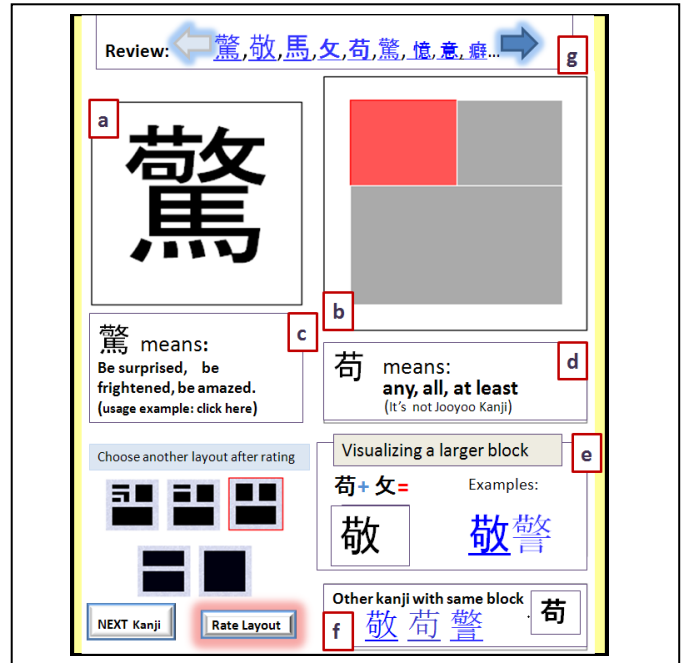

Figure 1. Functionality of the LILES system

VII. EXPERIMENTAL ANALYSIS WITH THE LILES SYSTEM

Experimental analyses were conducted via our LILES System to obtain necessary values for analyzing the possible cognitive difference in kanji deconstruction level after using the LV approach-based learning support system. A brief description of the experiments is as follows.

A. Evaluation questions

"Do intermediate and advanced learners deconstruct kanji differently?" "Does the LV Approach assist both intermediate and advanced learners equally in updating their personal way of visualizing kanji?"

B. Evaluation method

For the learning session learners used our LILES System, an implemented web-based system which is an improved version of our Learner's Visualization (LV) System. Learners were randomly assigned to one of two variants: the Control Group (G1), which used the kanji-learning software with only one possible deconstruction layout offered per kanji, and the Experiment Group (G2), which used the same software but with a function that allows the learner to choose her deconstruction layout of preference from a group of predefined possible layouts for each kanji.

C. Participants

A total of 96 university students of 17 different nationalities were evaluated and classified as "intermediate level learners" (48 students) and "advanced level learners" (48 students) following the criteria of the vocabulary knowledge scale developed by Paribakht and Wesche [11]. The mean length of

formal study (i.e. under a program with a plan, a goal and a way to measure progress) for intermediate students was 371 hours, and 537 hours for advanced students. The participants were exclusively speakers of languages that use an alphabetic script.

D. Instructional materials

□ **Global selection.** The kanji database obtained from the Asahi Newspaper published between 1985 and 1998 serves as the basis for the global selection: a total of 6,355 kanji out of almost 49,000 kanji included in the 13-volume Morohashi Dai Kanwa Jiten. The distribution of this database (being X =number of strokes) was obtained in Tamaoka's study. Its negative hypergeometric distribution has as parameters: $K=24.6877$, $M=6.8335$, $n=41$, $DF=26$, $(X)^2=45.63$, $P=0.01$, $C=0.0072$ [12].

□ **Specific selection.** The specific selection criterion was visual complexity which was found strongly positive correlated with the number of strokes [13]. This criterion was chosen based on the importance of form, stressed by Tollini [5], in the selection of kanji to be taught. The rating data was based on the negative hypergeometric distribution of the 6,355 kanji. From this database only a set of 200 were selected (73 percent belonging to the *jōyō* kanji list issued on October 10, 1981, and the remaining 54 kanji were the most common non-*jōyō* kanji that are either: (a) useful as building-blocks for other kanji (e.g. 吾, 勿, 頁, etc) or (b) very common in names (e.g. 藤, 岡, etc)). The sampling kanji were randomly selected proportionally to the distribution of the database, i.e., frequency of each value (number of strokes). This set of 200 kanji is called in this study: "database kanji" = dk .

□ Kanji deconstruction and deconstruction layouts.

Nara's study previously established a tentative set of kanji parts that non-native students see in kanji [14]. However, as different foreigners may have different ways of deconstructing kanji, in order to have a more comprehensive range of possible deconstruction layout options, a preliminary experiment was conducted. The goal was to obtain an experimental and open-to-consideration set of those kanji deconstruction layouts that are visually salient to nonnative learners. This experimental set has been elaborated based on the survey done in Nara's study on kanji visual salient parts [14]. Compared with Nara's survey which had only four participants, our survey was conducted with fourteen non-native speakers of Japanese who had enrolled in the Tokyo Institute of Technology's Japanese language course (7 intermediate learners and 7 advanced learners). They were given 200 randomly selected *jōyō* kanji and were asked to write down all the possible deconstruction layouts they visualize in each kanji that make sense according to their personal visual cognition, indicating at the end their preferred layout. The results showed that advanced learners tend to visualize substructures within a given kanji in a different way than intermediate learners do. The majority of the time, participants preferred to deconstruct the given kanji into 2 or 4 blocks (Intermediate students: mean=2.97, SD 'standard deviation'=0.71; Advanced students: mean=3.35, SD=1.33;

Global: mean=3.16, SD=1.062). The number of deconstruction layouts created per kanji mainly varied between 4 to 6 different layouts (mean=4.73, SD= 1.32).

□ **Unknown kanji selection per groups.** As the study examines the ability to visualize *novel* (unknown kanji selected according to preliminary test) kanji, the characters used in the target items were chosen kanji that are typically not well known. In order to confirm selection of *novel* (unknown) kanji to be used in the learning session of the experiment, a kanji test was given to all participants: Preliminary Test. Categories I and II of this preliminary test define a *novel* kanji. See details in sections VI-F and VI-G.

□ **Time for learning selected kanji.** All participants were instructed to learn the list of 100 kanji in 60 minutes.

E. Design

The experiment was design to evaluate the comparison of the means of kanji deconstruction level between intermediate and advanced learners. It was conducted as follows:

• Pre-tests:

1. Preliminary Test: 50 minutes for checking vocabulary of dk (database_{kanji} of 200 kanji) and building a database of 100 *novel* kanji.
2. Pre-test for Experiment: 25 minutes for selecting layouts for each of the 100 *novel* kanji (followed by a 7-minute break).

• Learning session:

3. Group 1: 60 minutes exploring one layout per kanji (100 *novel* kanji in total)
4. Group 2: 60 minutes exploring the different deconstructions layouts of the 100 *novel* kanji (with a 7-minute break).

• Post-tests:

5. Post-test for Experiment: 25 minutes for choosing the participant's final preferred visual deconstruction layout for each of the 100 *novel* kanji.

The design of the experiment was as follows:

Type of experiment: Research Experiment, 2x2x2 ANOVA Design. Three-way ANOVA with one RM (repeated measure). The RM factor has 2 levels.

Dependent variable: "Kanji Visualization Score" (KVScore), or "kanji visual deconstruction score", the mean number of blocks into which the user chooses to deconstruct given kanji).

Independent variables (factors): The two levels (Pre-Post) of the RM (within-group) factor called Tests. The two between group factors were Groups (Control Group or Experimental Group) and, Learners (Intermediate or Advanced).

Goal: Compare the performance achievements between beginning and intermediate learners.

F. Instruments

▽ *Kanji Visualization Test (KVT)*. A test with maximum score 1.00 was designed to measure the dependent variable, kanji visual deconstruction level, referred to as *Kanji Visualization Score (KVScore)*.

▽*Calculation method of KVT*. The dependent variable was calculated based on the mean of the normalization of the number of blocks mentally visualized per kanji. We used the formula $score_{sk} = (B - n + 1)/B$ where $score_{sk}$ represents the score in a given kanji, B represents the maximum number of blocks in that kanji, and n expresses the number of blocks mentally visualized per kanji. Consequently to visualize a kanji as a whole unit scores 1 point, and the mean of all the $score_{sk}$ makes the kanji deconstruction level in a learner.

△*Kanji Test(KT)*. As a preliminary test, a kanji vocabulary test was conducted. A careful criterion was included in order to correctly build a database of 100 *novel (totally unknown)* kanji.

△*Calculation method of KT*. Learners were presented with a list of target kanji and asked to choose their level of knowledge for each kanji according to the following self-reporting categories based on an adaptation of the Vocabulary Knowledge Scale (VKS) [11]:

- I I do not remember having seen this kanji before.
- II I am sure I have seen this kanji before, but I am also sure that I do not know what it means.
- III I think I know this kanji. I have seen it before, and I think it means ____.(translation or synonym)
- IV I know this kanji. It means ____.(translation or synonym)
- V I can use this kanji in context: ____.(Write an example).
(And please also do section IV)

Total score is calculated based on: Categories I and II represent score of 0.0 and 0.05 respectively. Wrong responses in levels III, IV or V lead to a score of 0.05. A score of 0.1 is given if there is a good response in category III, and 0.2 in category IV. For category V, a score of 0.3 is given if the kanji is used in the correct context but with incorrect usage and no translation is provided (and 0.4 when translation is provided). A score of 0.5 is given when translation was provided and the kanji has been used in the right context and with accurate usage, even if other parts of the sentence may have errors. It is worth mentioning that in the learning session participants learn only *novel* kanji from the set of kanji called “database”= *dk*.

G. Instructions and procedure

The sequence of instructions for the participants was:

• Pre-tests:

1. *Preliminary Pre-Test (Kanji Test, KT)*: All participants received 200 characters= *dk*, and they were asked to answer the Kanji Test (explained in section IV-F). Participants were instructed to check appropriately instead of guessing about their knowledge of kanji. When they checked either (I) or (II), the respective kanji were selected for the experiment, generating a pool of *novel* kanji for the experiment= *sn*. Learners were given 50 minutes for the test. In this experiment, the resulting pool of novel kanji was always over 100 kanji.

2. *KVT=Pre-test for Experiment*: Learners were given 25 minutes to choose their initial preferred deconstruction layout from a predefined list of possible deconstruction layouts for each of 100 novel kanji. The kanji used were randomly selected from the pool of novel kanji.

• Learning session:

3. *Control Group*: Learners were given 60 minutes to learn the set of 100 novel kanji *without* having the option to explore alternate deconstruction layouts for each given kanji. They were instructed to study each kanji by exploring the *blocks* of their sole *preferred layout* that was displayed beside each kanji. Learners need to explore at least half of the *blocks*.

4. *Experimental Group*: Learners were given 60 minutes to learn the set of 100 novel kanji from the LILES system *with* the option to *explore* alternate deconstruction layouts per kanji.

• Post-tests:

5. *Post-test for Experiment*: Learners were given 25 minutes to choose their final preferred visual deconstruction layout from a pre-defined list of possible layouts for each of the 100 kanji in study.

VIII. RESULTS

A. Cognitive processing of kanji vs. kana

All statistical analyses were performed using the PASW (Predictive Analytics SoftWare) Statistics 18 software version (the SPSS version between 2009 and 2010). The descriptive statistics results are summarized in Table 1. A comparison of the improvements of *KVScore*, by Learner and by Group, between pre-test and post-test was analyzed. Analysis of variance (ANOVA) was used to assess the changes in *KVScore*. However, prior to the ANOVA test, Levene’s Test for Equality of Variances was performed in order to assess the assumption that the population variances are equal. The Levene’s test was negative, i.e., not positive ($P > 0.05$): $P > 0.589$ for data for Experiment, meaning the variances in the groups were equal (homogeneous, i.e. homogeneity of variance).

TABLE I. RESULTS FOR EXPERIMENTAL GROUPS

| Factors | | | <i>KVScore</i> |
|----------------|-------------|--------------|----------------|
| <i>Learner</i> | <i>Test</i> | <i>Group</i> | <i>Mean</i> |
| Intermediate | Pre | Experimental | 0.647 |
| | Post | Experimental | 0.746 |
| Advanced | Pre | Experimental | 0.57 |
| | Post | Experimental | 0.64 |

The results of the ANOVA show that there is an interaction between all factors. This three-way interaction shows that two-way interactions vary across levels of the third variable. Additionally, since all of the factors in this three-way ANOVA are dichotomous (2 levels), there was no follow-up tests to perform on significant main effects. The dependence of *KVScore* differences between intermediate and advanced learners on Group factor (Control Group/Experimental Group) and Test factor (Pre-test/Post-test) was reflected in a significant Learner x Group x Test interaction in an overall ANOVA of these data, $F(1, 18) = 31.58, p < 0.001$. Our results further indicate that this three-way interaction was due in part to the presence of a significant Learner x Group interaction, $F(1,$

184)= 45.17, $p < 0.001$. The results are significant at the 0.1 percent of significance level. Therefore, one would reject the null hypothesis, concluding that there is strong evidence that the expected values in the groups differ.

As illustrated in Figures 2, as to kanji visualization level, although both the Control Groups and the Experimental Groups achieved better scores, the benefit was more significant for the Experimental Group learners who studied via our Learner's Visualization Approach. To sum up, ANOVA results of the comparison in scores for both groups of learners (i.e. intermediate and advanced learners) shows that their means are statistically different with the use of the LV Approach.

IX. DISCUSSION

Our results provide evidence that between intermediate and advanced learners, there are differences in the way they visually deconstruct kanji. Besides, although there is a significant *KVScore* ("kanji deconstruction level") improvement in both groups of learners, a statistical analysis to the improvement means shows that it is more significant in intermediate learners. This study began with a previous finding showing that the LV Approach assists beginning learners in accelerating their natural progression towards perceiving individual kanji in fewer numbers of blocks (as learners gradually gain the skill to recognize larger and more complex blocks within each kanji, they no longer need to "divide" that kanji into smaller blocks in order to recognize the blocks) [4]. However, this does not mean that the initial tendency of visualizing fewer blocks would reach a total holistic achievement. On the contrary, it is expected that advanced learners would eventually decrease their *KVScore* [15].

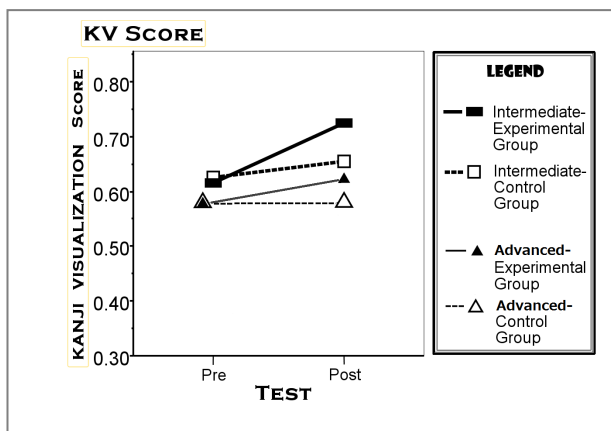

Figure 2. Comparison of KVS cores obtained in Pre-tests and Post-tests, by Learner and by Group factors

X. CONCLUSION AND FUTUREWORK

The educational technique of our LILES System lies in its strategy to help learners, through exploration of deconstruction layouts, to visually deconstruct kanji in ways they have not previously experienced. In doing so, LILES appears to foster learners' cognitive processing of self-generating memory aids that mentally link substructures (blocks) and the kanji that contain them, facilitating learning progress. As Felder stated, global learners should be given the freedom to devise their own methods of solving problems rather than being forced to adopt

the professor's strategy. Active learners do not learn much in situations that require them to be passive [1]. Research has shown that most students of engineering are active learners who learn best when allowed to harness their own creativity in tackling real challenges. Budding engineers would be better served by a more varied curriculum that allows them ample opportunity to actively experience tackling actual engineering challenges, rather than asking them to learn through passively absorbing facts and information. In today's modern world, we are constantly surrounded by innovative ideas in every field, discipline, and market. Our LILES System addresses the challenge of how to create a more effective learning support system in the field of foreign language education, specifically for learning the Japanese writing system, kanji. We believe LILES serves as an excellent example for engineering students of how systems design can be creatively applied to the latest research in most any field to produce an innovative and effective new learning tool or product.

Standards-Based Grading:

Preliminary Studies to Quantify Changes in Affective and Cognitive Student Behaviors

Abstract—Assessing student learning is a key component to education. Most institutions assess learning using a score-based grading system. Such systems use multiple individual assignment scores to produce a cumulative final course grade, which may or may not represent what a student has learned. Standards-based grading offers an alternative that addresses the need to directly assess how well students are developing toward meeting the course objectives. The course objectives are the focal point of the grading system, allowing the instructor to assess students on clearly defined objectives throughout the course. The system assesses how well students become proficient in the course objectives over the duration of the course. This study extends the use of standards-based grading at the K-12 level into the realm of undergraduate science, technology, engineering, and mathematics (STEM) education. Five STEM courses pilot tested the integration of a standards-based grading system to investigate how it impacts affective and cognitive student behaviors. The results suggest that a standards-based grading system increased student domain-specific self-efficacy, was perceived as valuable, and helped students develop more sophisticated beliefs about STEM knowledge.

Keywords – standards-based grading, assessment, student behaviors

I. INTRODUCTION

The traditional system to assess student performance in science, technology, engineering and mathematics (STEM) at the higher education level is a summative score-based grading system. Summative grading provides students and teachers alike with a cumulative score on a series of independent measures (e.g., homework, quizzes, and exams). While this assessment does provide a score associated with student performance, the system does not directly assess student development towards achieving the overall course objectives. The summative assessment instead minimizes what was intended to be measured, true student learning.

Standards-based grading is an alternative approach to assessment of student performance and learning. The system involves the direct measurement of student development towards achieving specific, clearly defined course objectives. Student development is tracked throughout the duration of a course using a standards achievement report rather than one-time individually scored assignments. Final course grades are then determined based on students' overall development toward achieving the course objectives, rather than being

based on how well the students' performed on independent (and often unconnected) assignments. The benefit to this approach is that it provides clear, meaningful and personalized feedback for both students and educators regarding student learning.

Although this approach has gained popularity at the K-12 level, there have been no empirical studies to date that analyze the effects of standards-based grading on undergraduate education. The following study discusses preliminary results gathered from an investigation of standards-based grading in undergraduate STEM courses. Our analysis focuses on how the grading system impacts affective and cognitive behaviors of students. Affective behavior was measured by assessing changes in students' self-efficacy and the value they place on standards-based grading. Cognitive behavior was measured by assessing students' epistemological beliefs of STEM knowledge. The intended goal of measuring affective and cognitive behavior is to identify how a grading system impacts the learning of both technical and personal/professional skills. The following paper will present: 1) the overall design and structure of the standards-based grading system and 2) a discussion of measured changes in student affective and cognitive behaviors resulting from the standards-based grading system.

II. STANDARDS-BASED GRADING

Grading systems have been used since the late 1700s to determine whether or not students are meeting relevant academic goals within their courses [1]. Most science, technology, engineering and mathematics (STEM) educators within higher education use the traditional, summative score-based grading system. These grading systems rely on assigning scores to multiple student assignments, which are subsequently summed and issued as a final course grade according to a predetermined scale. The system as it stands does not encourage instructors to stay true to the preset course objectives. As a result, course objectives become unconnected with the process and often are not mentioned beyond the course description and course syllabi [2]. This grading approach inherently fails to meet the conditions for sound assessment of student work and learning [2-4]. The final course grades that students eventually earn only display how

well the students performed on completing a series of separate course assignments.

A new approach is to directly measure the quality of students' proficiency towards achieving well-defined course objectives through *standards-based grading (SBG)*. SBG was first developed during the 1990s when all US states reformed public K-12 education by setting academic standards for what students should know and be able to do [5,6]. SBG utilizes a student standards achievement report (SAR) to track and provide feedback regarding individual student learning and development (a snapshot example is shown in Table 1). More detailed information regarding the standard achievement report is provided in the following reference [7]. Student development towards achieving the course objectives is directly tracked throughout the duration of a course, rather than simply assigning one-time individual scores to student work. The system allows for changes in their development levels to be directly reflected over time. Final course grades are then determined based on students' development towards achieving the course objectives according to an established grading policy.

Educators gain numerous advantages when they use standards-based grading, including but not limited to:

- clear, meaningful and personalized feedback,
- connections between assessment and the predetermined course objectives,
- fairness and transparency in the grading process, and
- a highly effective tool for program assessment [2].

When students are given useful feedback, it provides them with an opportunity to gain insights into their personal learning and development. The content they will learn throughout the semester shifts from being unclear to extremely transparent, which makes students aware of what to expect from the beginning. This provides fair and transparent grading that emphasizes the quality of their current work alone, regardless of how other students in the course perform or on the student's previous levels of development [2]. This in turn promotes the encouragement of student learning and

continuous improvement by placing responsibility for learning on the students themselves [5]. Standards-based grading can also provide detailed feedback for maintaining academic rigor and for assessing with great precision courses, curricula, and entire institutional programs.

Beyond the theoretical advantages, SBG provides tremendous ease of implementation and flexibility regardless of the institution, the course topics or objectives, the instructor, or even pedagogy. Instructors employing a traditional lecture-style approach and those using more progressive, even un-tested pedagogies can easily tailor the SBG system to meet their needs and expectations as necessary. The author's personal experience using SBG in our own classes suggests that the SBG system is even less time consuming to implement than traditional, score-based grading systems. Assessments of student work for each course objective can occur as often as an educator wishes to assess his or her students. Educators can use a one-time evaluation (e.g., homework, examinations, portfolios, a standardized test, etc.) or they can give students multiple opportunities to demonstrate development, i.e., the time allotted for student learning can be fixed or variable. There is also flexibility in how final course grades are determined. For example, a grade of 'A' could be earned if the students' overall average development ranges between 3.7 and 4.0, or if the students demonstrate strong development on a certain percentage of the course objectives. How the grading is best implemented into a course is completely up to the instructor.

Based on feedback obtained from our initial pilot studies [7] and this current study, we have developed a preliminary list of guidelines, or best practices, for implementing the standards-based grading system. In order to successfully implement SBG into your course, we suggest the following:

- establish well-defined course objectives and list them on the course syllabus,
- establish a clear course grading policy and a clear set of assessment rubrics and guidelines,
- develop a detailed standards achievement report and share it with your students at the beginning of the

TABLE I. SNAPSHOT EXAMPLE OF AN INDIVIDUAL STUDENT STANDARDS-ACHIEVEMENT REPORT (SAR)

| Standards Achievement Report (John, 02/15/2012) | | | | | |
|--|---------------|---------------|-----------|-----------|-----------|
| Development Towards Achieving the Course Objectives | Homework 1 | Homework 2 | Quiz 1 | Exam 1 | Quiz 2 |
| 1A: Understanding the concept of stress in a body | 2 | 2 | 2 | 3 | 3 |
| 2A: Analyzing members subjected to axial forces | 2 | 2 | 3 | 3 | 4 |
| 3A: Analyzing members under combined loads | - | - | 2 | 2 | 3 |
| Overall Average Development | 2 | 2 | 2.3 | 2.7 | 3.3 |

course, and

- center the course lectures, assignments, and schedule on the standards achievement report.

These theoretical and observed benefits of SBG in K-12 learning environments provide a foundation for our investigation of SBG in STEM undergraduate courses.

III. RESEARCH DESIGN

A series of pilot studies have been conducted to assess the effectiveness of standards-based grading in STEM courses. Students at two diverse institutions – one small private institution and one large public institution – were taught a variety of STEM courses ranging from engineering design to mechanics of materials to computer interaction design. A total sample of 120 STEM students in five different classes taught by four different instructors was obtained for this study. The impact of standards-based grading was assessed through an analysis of student affective and cognitive behaviors.

A. Affective Behavior

1) *Self-Efficacy*: Self-efficacy, or an individual's confidence about their ability, is shaped by experiences, social persuasions, and physiological states [8]. The resulting self-efficacy an individual possesses plays a large role in what tasks are undertaken and the expectancy for success. An individual's performance or behavior is therefore mediated by how efficacious they are in their ability to successfully complete tasks. It is important to measure self-efficacy before and after our standards-based grading intervention to assure that the grading system is not negatively impacting STEM confidence and achievement. This is particularly important for women in STEM who tend to out perform their male counterparts even though they display lower self-efficacy toward their abilities [9-12]. The inclusion of a measure of self-efficacy will provide a gage of how self-efficacy impacts student development and learning in a standards-based grading system.

2) *Value*: Our second measure of affective behavior assesses the value students place on standards-based grading. According to Expectancy Value Theory, behavior is a function of the value one places on achieving a goal [13]. The interest, attainment, utility, and cost associated with perceived individual value impacts the effort and level of responsibility put forth [14-16]. It is our belief that standards-based grading increases the value students place on learning, which consequentially encourages them to put forth more effort. An increase in effort is likely to increase a students' level of responsibility toward learning. The overall measurement of value will provide insights into whether or not the standards-based grading system impacts students' desire to be more responsible toward their education.

B. Cognitive Behavior

Understanding comes from an ability to learn through an active process of constructing a knowledge base from personal experiences [17]. As we gain knowledge, we increase our

ability to find and use it [18]. The understandings we have of a given context come from the adoption of schemata, which consist of the mental representations we use during perception and comprehension. How we learn and adopt new information is influenced by our preconceptions of the world and our metacognitively defined individual learning goals [19].

The SBG system is designed to more accurately measure what students actually understand after the courses. Instructor bias for the system precludes this research from using final course grades to assess student understanding. Instead, we will measure cognitive behavior through epistemological beliefs, or the beliefs we hold about the nature of knowing and learning. The analysis of epistemological beliefs provides a unique view of cognitive gains through the identification of how naïve or sophisticated the students' understanding is [20-21]. Course grades are too often representative of what a student was able to memorize during a course. By measuring epistemological beliefs, we can capture students' general understanding of what it means to actually know something in STEM.

IV. RESULTS

Changes in self-efficacy and epistemological beliefs were evaluated through the use of a pre/post-analysis. Instruments were developed, modified, and validated to assess the specific course objectives and the general domain of STEM. Our assessment of value was given as an added post-analysis component to analyze student perceptions of the unfamiliar standards-based grading system.

A. Self-Efficacy

The base instrument used to measure self-efficacy for each individual STEM course was a modification of a previously validated instrument used to measure engineering design self-efficacy [22]. The task-specific nature of self-efficacy requires an individual assessment of each course based on the course objectives. The base engineering design self-efficacy instrument was modified by each of the course instructors to create a course/content-specific survey. The self-efficacy item development was paired with the development of course objectives to ensure that the survey items and course objectives are clear, concise, and appropriate for the course. Individual pre/post course evaluations revealed self-efficacy toward the course content to improve for all students on all items regardless of subject matter (Table II).

TABLE II. SELF-EFFICACY AVERAGE SCORES.

| Course | N | Average Self-Efficacy | |
|-------------------------|----|-----------------------|------|
| | | Pre | Post |
| Engineering Design | 60 | 71.4 | 86.1 |
| Modern Web Applications | 18 | 15.7 | 81.7 |
| Interaction Design | 5 | 18.9 | 82.3 |
| Elements of Design | 20 | 64.9 | 84.6 |
| Statics | 14 | 40.8 | 93.4 |

A paired-samples t-test revealed increases from pre to post in self-efficacy to be significant to at least the $p \leq 0.05$ level for each individual item. This suggests that the pilot courses improved students' confidence toward the specific course topic.

B. Value

The instrument to measure value was developed specifically for this study. Developed items were theoretically based on Expectancy-Value theory and were presented using a 4-point Agree/Disagree scale. Items were first tested to ensure validity and reliability of the instrument. Three factors emerged from a factor analysis: 1) Interest/Attainment Value, 2) Utility Value, and 3) Cost. An overall Cronbach's α of 0.888 was found for the instrument, which is acceptable by social science research standards [23].

Students overwhelmingly responded with high interest/attainment value and utility value regarding SBG; low cost was also observed (Fig. 1). Written comments supported the quantitative findings and provided great feedback:

"The feedback is great and very explicit – this is a good system for educational growth."

"The primary benefit from standards-based grading was the clear statement and emphasis of learning outcomes. The direct correlation between my course grade and the course objectives forced me to pay attention to what I should be taking away from the course."

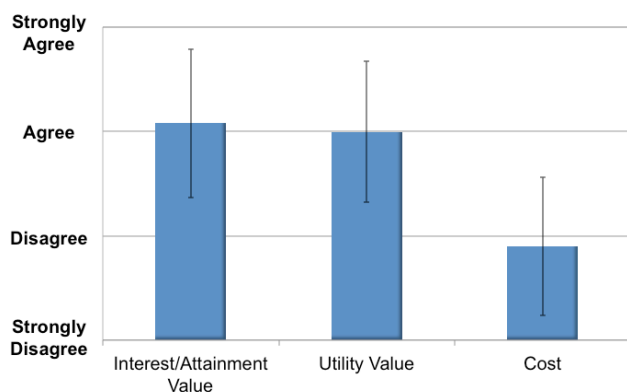

Figure 1. Average student scores for the three major areas of value of standards-based grading.

C. Epistemological Beliefs

The measure of epistemological beliefs was recorded before and after the standards-based intervention using a modified version of the Epistemological Beliefs Assessment for Engineering (EBAE) [24]. This measure identifies appreciated changes in epistemological beliefs.

The modified EBAE was presented using a 4-point Agree/Disagree scale. The items were first tested for validity using a factor analysis, which identified four factors: certainty, simplicity, source, and justification of knowledge and knowing. A Cronbach's α of 0.576 resulted. This value is below the acceptable level of 0.7, but was deemed viable for the pilot study. A pre/post analysis of epistemological beliefs

was conducted for the pilot cohort of students, who on average began their course of study with a far greater propensity for naïve beliefs about STEM, but later exhibited more sophisticated beliefs at the conclusion of their courses (Fig. 2). A paired-samples t-test revealed these increases to be significant except for their belief about 'professional opinions' and 'reciting information being equivalent to understanding.' These generally positive changes were all significant to the $p \leq 0.001$ level.

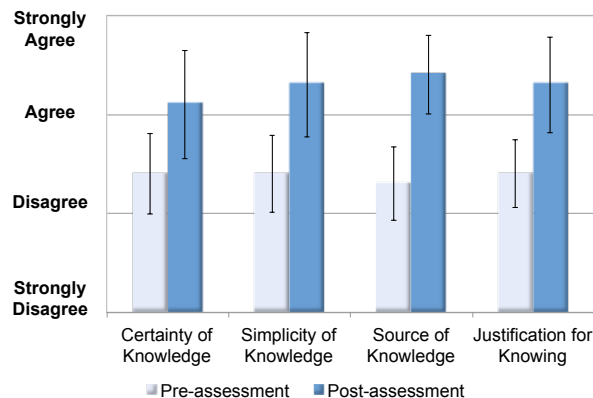

Figure 2. Average student scores for the four major areas of epistemological beliefs

V. DISCUSSION

Our preliminary analysis included an assessment of affective and cognitive behaviors for students participating in a standards-based grading system. We discovered that self-efficacy increased, epistemological beliefs became more sophisticated, and students found the intervention to be interesting without negatively impacting their learning.

The change from a traditional score-based system is intended to change student behaviors, while also helping students to improve their learning. The results suggest that the system does attend to these goals, but it is recognized that the foreign nature of the system causes some students undue stress and confusion. New systems that are unfamiliar to students may be beneficial, but until students open up to the new system and accept something different, the change may not have the intended impact. The observed benefits warrant that further analysis be conducted. The behaviors of the students participating in a standards-based grading system should also be compared to those of students participating in other grading systems to ensure the behaviors are not the same across classes.

VI. LIMITATIONS & FUTURE WORK

This preliminary study is a first step in providing reasoning to formally study and implement standards-based grading in undergraduate STEM courses. The study identified some deficiencies in the current instruments that will be addressed in our future analyses. First, the self-efficacy instrument will be tailored for each course and consist of two components:

1. A general item pertaining to the course, and

2. A set of items that specifically address the course objectives.

The general item will be used to compare courses that may have the same title, but vary in their execution. The implementation of such an approach will allow for more seamless comparison between courses.

The first time use of the value instrument was extremely successful for a newly fabricated instrument. The instrument was shown to be valid and reliable for the study sample. Further validation and reliability analysis will be conducted in future studies to ensure these trends persist.

The instrument to measure epistemological beliefs will continue to be modified to improve the overall reliability of the items. Our alpha value was below the acceptable level, but close enough for us to gain some preliminary insights into students understanding of knowing.

We will also add additional assessments beyond our current affective and cognitive behavioral instruments. Our future investigations of this system will keep a close eye on whether the system reduces student stress and concern over trying to get an 'A'. The current findings provide a solid foundation for more advanced assessments including a comparative analysis of standards-based grading versus traditional score-based grading and the impact of the grading system on the scholarship of teaching and learning.

VII. CONCLUSIONS & IMPLICATIONS

Standards-based grading represents an alternative to traditional score-based grading in STEM undergraduate courses. Our study suggests that implementing this alternative approach will positively impact students' affective and cognitive behaviors. Specifically, we discovered that self-efficacy increased and epistemological beliefs became more sophisticated after participating in a standards-based grading course. Students also displayed high interest, attainment, and utility value while not costing them valuable time and effort in order to learn.

The overall results of this study suggest standards-based grading to be a viable option for undergraduate STEM courses. The implications for switching from the traditional score-based grading system are not insurmountable and worthwhile if students continue to demonstrate improved confidence and knowledge. It is our desire that by switching to an SBG system we can help transform undergraduate STEM assessment by guiding learning with salient course objectives.

ACKNOWLEDGMENTS

The authors would like to thank the instructors and the students who participated in these preliminary studies.

Abstract—An online simulated Smith chart is designed as an aid to train students to perform impedance matching exercises and to easily follow amplifier design procedures. The tool enables the instructor to conduct classes remotely to a group of students in a broadcasting mode. Students have participated actively and regularly in the online Smith chart tool and their reactions have been positive.

Keywords—component; formatting; style; styling; insert (key words)

I. INTRODUCTION (HEADING 1)

Microwaves have played a considerable role in recent advances and developments in human civilization. As a backbone of modern communication systems, microwave engineering covers the application of knowledge and judgment to the development of components, devices, circuits, and systems involving the generation, transmission, and detection of microwaves. Teaching a microwave engineering course at the undergraduate level in universities worldwide requires instructors to devote a substantial amount of time to equip students with the necessary knowledge and skills to design circuit and systems using modern microstripline technology [1-5]. The course relies heavily on the use of Smith chart to carry out calculations of impedance and reflection coefficient associated with the standing-wave pattern created by multiple reflections of the waves on the transmission line. In addition, the complete design of a microwave amplifier, which occupies a considerable portion of the course, can be completely undertaken using the Smith chart. This requires calculation of several variables, based on the scattering parameters of the amplifier, and to follow rigorous procedures that lead to the ultimate goal of designing input and output matching networks. The procedures include plotting on the Smith chart a number of stability, gain, VSWR and noise figure circles which consequently allow the student to visually select a combination of appropriate conditions and design requirements.

However, working on the Smith chart directly using traditional paper version is tedious, elaborate and time consuming and extremely difficult to attend to every student in the class. In large classes, it is common for students to set idle or talk to each other while the instructor is busy with other students, which may eventually disturb the class. These problems may be solved with the help of teaching assistants or with the use of interactive boards or Tablet PCs. Practical, technical and financial considerations make these solutions difficult to adopt effectively. Although software packages for

designing using Smith charts are readily available, none may be programmed to allow on-line designs to be performed [6-8].

A computer-simulated Smith chart has been designed as a tool to provide online session operating at a broadcasting mode, to allow the instructor to conduct classes remotely to a group of students and give them access to the online session where they will have a screen that shows the entire instructor's work. The tool was incorporated into an open - source blended - learning environment for the microwave engineering course offered at the Communication Engineering Department in Princess Sumaya University for Technology.

II. MICROWAVE AMPLIFIER DESIGN

In the design of a single stage microwave amplifier with certain S-parameters, it is usually assumed that the transistor is driven by a source with impedance, and that its output is connected to a load, as shown in the schematic of Fig. (1).

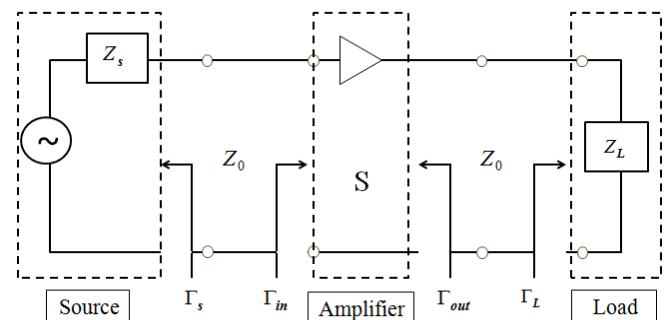

Figure 1. Schematic of a typical single stage transistor amplifier

Using appropriate signal flow diagram and applying Mason's rule to obtain the output/input transfer function, the transducer power gain can be obtained, thus [9]:

$$G_t = \frac{(1 - |\Gamma_s|^2) |S_{21}|^2 (1 - |\Gamma_L|^2)}{|(1 - S_{11}\Gamma_s)(1 - S_{22}\Gamma_L) - (S_{12}S_{21}\Gamma_s\Gamma_L)|^2} \quad (1)$$

where Γ_s and Γ_L are the source and load reflection coefficients respectively. The operating power gain, defined as the ratio of the power available from network to that delivered to the load, is given by [9]:

$$G_a = \frac{|I - \Gamma_s|^2}{|I - S_{11}\Gamma_s|^2} |S_{21}|^2 \frac{I}{|I - \Gamma_{out}|^2} \quad (2)$$

while the available power gain, defined as the ratio of the power available from source to that delivered to the network, is given by [9]:

$$G_p = \frac{1}{1 - |\Gamma_{in}|^2} |S_{21}|^2 \frac{1 - |\Gamma_L|^2}{|1 - S_{22}\Gamma_L|^2} \quad (3)$$

where the reflection coefficients at the input and output are described by [9]:

$$\Gamma_{in} = S_{11} + \frac{S_{12}S_{21}\Gamma_L}{1 - S_{22}\Gamma_L} \quad (4)$$

$$\Gamma_{out} = S_{22} + \frac{S_{12}S_{21}\Gamma_s}{1 - S_{11}\Gamma_s} \quad (5)$$

The stability of the amplifier may be described by circles at the input and output with radius and centre given by:

$$r_s = \frac{|S_{12}S_{21}|}{|S_{11}|^2 - |\Delta|^2} \quad (6)$$

and

$$c_s = \frac{(S_{11} - \Delta S_{22}^*)}{|S_{11}|^2 - |\Delta|^2} \quad (7)$$

while for the output stability circles, the radius is given by:

$$r_l = \frac{|S_{12}S_{21}|}{|S_{22}|^2 - |\Delta|^2} \quad (8)$$

and the centre is:

$$c_l = \frac{(S_{22} - \Delta S_{11}^*)}{|S_{22}|^2 - |\Delta|^2} \quad (9)$$

where the delta factor is $\Delta = S_{11}S_{22} - S_{12}S_{21}$.

The noise performance of the amplifier is also investigated in a similar manner and circles for certain values of noise figure are calculated and plotted on the Smith chart such that the centre and radius are respectively given by [9]:

$$c_{ri} = \frac{\Gamma_0}{I + N_i} \quad (10)$$

$$r_{ri} = \frac{1}{1 + N_i} \left[N_i^2 + N_i (1 - |\Gamma_0|^2) \right]^{\frac{1}{2}} \quad (11)$$

where Γ_0 is the noise reflection coefficient and r_n is the normalized noise resistance, and:

$$N_i = \frac{F_i - F_{min}}{4r_n} |I + \Gamma_0|^2 \quad (12)$$

where F_{min} is the minimum noise figure of the transistor.

Generally, a simple small-signal microwave amplifier design procedure begins with choosing suitable bias conditions for gain, linearity, noise, etc. The biasing parameters will then set the small signal S-parameters of the transistor. The next step is to determine the delta factor and stability factors as well as the values of radius and centre of the stability circles at the input and output and to plot them on the Smith chart to see if the amplifier is unconditionally stable or potentially unstable. Constant gain circles, operating power gain circles, available power gain circles and noise figure circles can be all easily plotted in the chart once their centres and radii are calculated according to the equations above. Once the designer chooses the gain, noise and VSWR values, matching networks (MN) at the input and output are selected to transform the source and load to impedances that will provide the required design parameters as shown in Fig. (2).

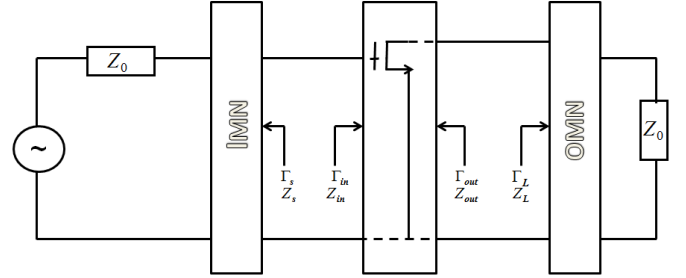

Figure 2. Schematic of a typical matched single stage transistor amplifier

III. ONLINE SMITH CHART

The Smith chart, created by Philip Smith in 1939, is a simple transformation of the equation that relates the reflection coefficient to the load impedance terminating the transmission line, given by:

$$\Gamma = \frac{Z_L - Z_0}{Z_L + Z_0} \quad (13)$$

where Z_0 is the characteristic impedance of the transmission line. Simple mathematical manipulations show that this transformation results in a series of resistance or r-circles and reactive or x-circles, where r and x are the normalized resistance and reactance and the resulting plotting of these circles is known as the Smith chart shown in Fig. (3).

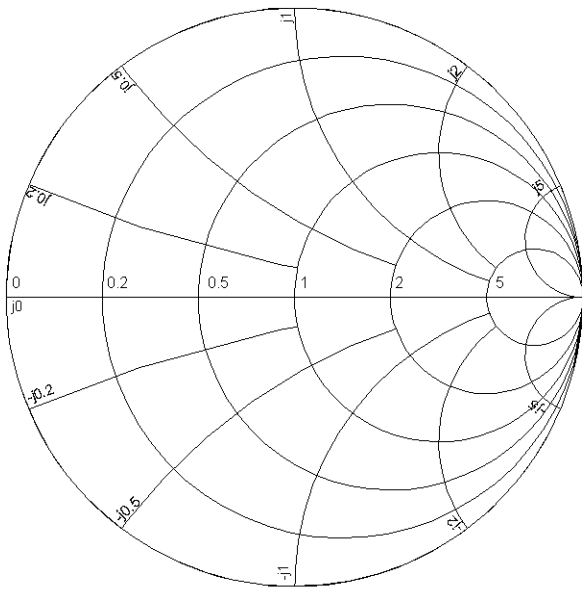

Figure 3. Simple Smith chart

The Smith chart is a useful graphical aid to the circuit designer that has been used extensively in recent years for the design of high-frequency transistor circuits employing strip transmission lines on high-frequency substrate materials. This graphical method is particularly effective for the design of microwave transistor amplifier which facilitates the demarcation of stable and unstable regions of operation on the chart, thereby allowing the proper choice of gain, noise-figure and VSWR and hence input and output matching networks for the desired mode of operation.

An online Smith chart was designed and launched at www.smithsimulator.com. The tool provides a simple interface to implement various applications such as impedance transformation, matching and microwave amplifier design. The tool also provides an online session operating at a broadcasting mode which allows the instructor to conduct classes remotely to a group of students and give them access to the online session where they will have a screen that shows the entire instructor's work. This allows the instructor to open and transmit a session to students who can follow a step-by-step procedure for plotting any required circle required in the design of the input and output matching networks. First, an interface page where S-parameters of the transistor are inserted, and then, according to a special menu, stability, constant, operating, available power gain and noise circles are selected and plotted.

The platform access simulator was designed with C# backend coding to function online via an ASP active page. This is considered as one of the most powerful web development methods. The programme was coded in such a way as to easily enable future development by creating each part of the system as an individual entity. The core of the system is the chart "object" since it is the part that should be used and called after making the appropriate calculations to display the results. This part does not do any calculations by

itself but rather accepts parameter from other functions that include a center of a circle, its radius, angle, and its description. The chart object is continuously refreshed to show the newly added circle. Some core functions are provided currently in the simulator as constant gain, stability circles, and demonstration circles. Other functions/circles can be added by user using the chart API. This may include the matching function which can be used to move/transfer from a point to another in the simulator. The interaction between this function and the chart object is made possible through API. This function can be considered as a part of the chart object itself, and the user cannot make such function using the API.

IV. RESULTS AND DISCUSSIONS

The eSmith chart was used over a period of 4 semesters in the academic years 2010-2012. It was constantly developed by the students themselves in order to improve its functionalities and to make it suitable for the purposes of teaching the "Microwave Engineering" class and to enhance its efficiency. Initially, students were trained to design a microwave amplifier following a step-by-step procedure using traditional hard copy Smith charts. Once they master these procedures, more complicated examples were solved using the eSmith chart. In this way, a complete comprehension of microwave amplifier designs was achieved. Fig. (4) shows a snapshot of an example of the stability circles and constant-gain circle of a transistor with specific S-parameters.

Other features were added to the system to improve the user experience such as allowing a student to save results in her/his own user history to be able to go back later to records and check out the results. In addition, the system was designed to support multiple classes/instructors each with a unique set of students. Using this feature, students were able to submit their work to the instructor by one-click. In such case, the instructor will receive an email with the student results and an image copy of the chart in the same manner as the in the process of saving history.

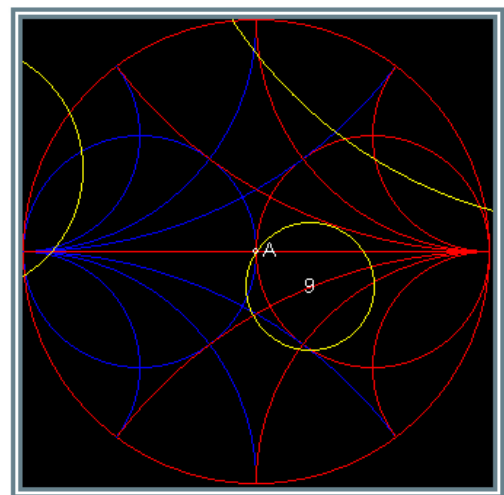

Figure 4. An online version of the eSmith chart with stability and a constant gain circles plotted

One of the main exciting features embedded is the broadcasting mode. This allows the instructor the opportunity to offer online lectures in to broadcast mode and to present classes remotely to online students as shown in Fig. (5). The instructor starts using the simulator by notifying students in the class in their main student page about an active broadcasting session. The functionality of the simulator in the broadcasting mode is no different than what students use, but just lacking some features like emailing, and saving to history.

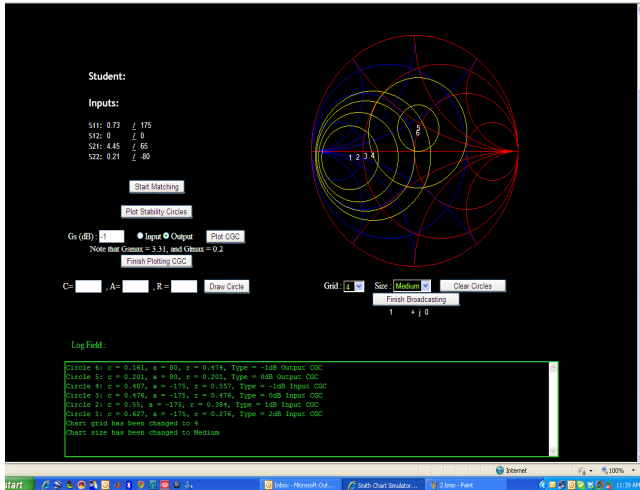

Figure.5. An online lectures in a broadcast mode

The feedback of students on the use of the eSmith chart was investigated through an online questionnaire conducted over the period of 4 semesters in the academic years 2010-2012. The questionnaire consisted of 8 questions aimed to cover a wide range of subjects posted online at www.psut.edu.jo/surveys. The following questions about the students experience in using the eSmith chart in a Microwave Engineering course were used for the survey:

Q1: The eSmith chart was well arranged and easy accessible.

Q2- The design procedures were clearly followed.

Q3- The eSmith chart helped making microwave amplifier design fast and efficient.

Q4- The eSmith chart was very valuable in the learning process.

Q5- Using the eSmith chart was a comfortable experience.

Q6- There was many difficulties in performing eSmith chart designs.

Q7- The eSmith chart has actually increased my interest in the course.

Q8- Overall, do you support the use of the eSmith chart in teaching the Microwave Engineering course?

The survey included 160 students enrolled in an undergraduate Microwave Engineering course, and the results of the survey are illustrated in Fig. (6), where the X-axis represents the question number and the Y-axis represents the overall percentage of the sample for each answer. As shown in the graph, there was a good agreement among students that they feel comfortable using the eSmith chart which helped making microwave amplifier design fast and efficient with clear design procedures. Over 80% of the respondents found

the eSmith chart valuable in the learning process and would support its use in teaching the “Microwave Engineering” course. Only 30 % of students faced difficulties in performing eSmith chart designs mainly due to internet connectivity, user-interface friendliness and accessibility. This low percentage was due to the fact that the system was designed by the students themselves who were constantly consulting each other during the design process.

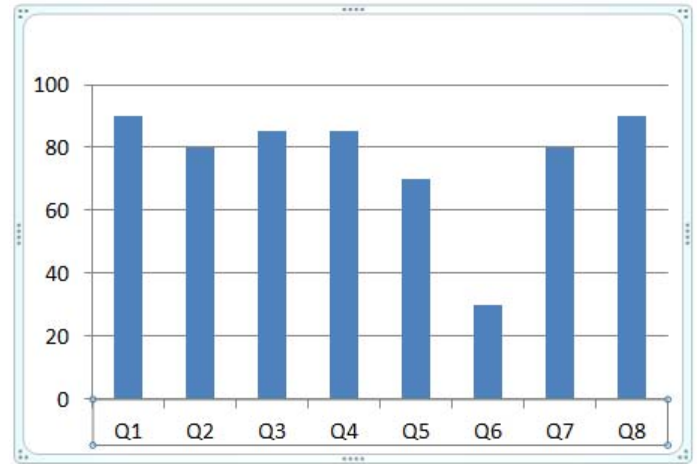

Figure 6. Results of the survey

The students’ perception of the proposed method seems positive and encouraging by their active and regular participation and reactions which shows that the eSmith chart is a user friendly that has a fast learning curve which may be useful to incorporate in a collaborative distance learning environment. Attempts for combining in the class and online technologies for teaching the microwave engineering course will continue to provide teachers and students with an active and participative role in the learning process.

Abstract - The Amazon region is characterized by its low population density, with one large city, the capital Manaus, and the remainder of its population distributed in small and less economically developed towns. Most of these towns suffer from huge geographic isolation, as these are scattered in the forest and their access are only through rivers. With all these difficulties, taking education to this population consists of a real and daily challenge. To provide an opportunity for students of this region to enter into an upper-level course, one of the solutions devised by the Federal University of Amazonas, through its Center for Distance Education (CDE) was the creation of undergraduate courses in non-face mode. CDE project consisted of organizing headquarters, called poles, to receive courses in Administration, Public Administration, Fine Arts, Biology, Agricultural Sciences and Physical Education. This paper describes this educational experience and presents the structure of the pedagogical model supported by technology (PMT) which allows this scenario to become reality. The innovation of this model is to allow the 1,618 students, distributed in 17 different poles, assisted by CDE, to keep pace with their course through a structure of logistical and technological support adapted to their reality. Resources offered by a Course Management System (CMS), tutors and other specialized tools that support off-line activities make it possible for higher education to reach the most remote regions of Amazon.

Keywords - distance education; pedagogical model supported by technology

I. INTRODUCTION

Distance Education (DE) is a teaching modality, applied to any level of education, in order to extend the possibilities of access to knowledge, democratizing access to education. In DE, according to [1], “students and teachers are in different locations during all or most of the time they learn and teach”, providing benefits that create more flexibility to the student in terms of time and place of study.

In Brazil, a country with extensive territorial dimensions, with its strong economic inequality and cultural diversity, distance education is gaining importance and challenges, with many initiatives and incentives from the government. In this context, higher education institutions have implemented and adapted their models of distance education according to their reality and students needs.

This paper presents a DE model implemented by the Center for Distance Education (CDE) of Federal University of Amazonas, highlighting its physical infrastructure and personnel, its installed poles and associated pedagogical model. Some preliminary results of CDE along its five years of existence are presented.

II. CENTER FOR DISTANCE EDUCATION STRUCTURE

The Center for Distance Education (CDE) [2] is a supplementary unity of the Federal University of Amazonas (UFAM). CDE is responsible for providing initial and continuous education in undergraduate and graduate courses to many cities in the state of Amazonas. These courses are offered in distance mode and rely on technological and pedagogical support from a well structured and capable team. This team is responsible for applying information and communication technology in educational process.

The board of CDE has five coordinators to support the courses: Administrative, Design, Pedagogical, Undergraduate and Technology. About 50 direct employees work at its headquarters in Manaus.

CDE offers courses since 2007 and currently offers undergraduate courses in the following areas: Administration, Public Administration, Fine Arts, Biology, Agricultural Sciences and Physical Education. Besides those, the post-graduate courses are: Production of Teaching Materials for Distance Education, Public Administration, Municipal Public Management and Health Administration. All courses are free.

The undergraduate courses are distributed in 17 different poles. Fig. 1 shows the state of Amazonas and each town that has a pole. Manaus, the capital, is located in the northeastern part of the state. Amazonas is the largest Brazilian state, and the 9th largest country subdivision in the world. Its area is larger than Germany, France, United Kingdom and Japan all together.

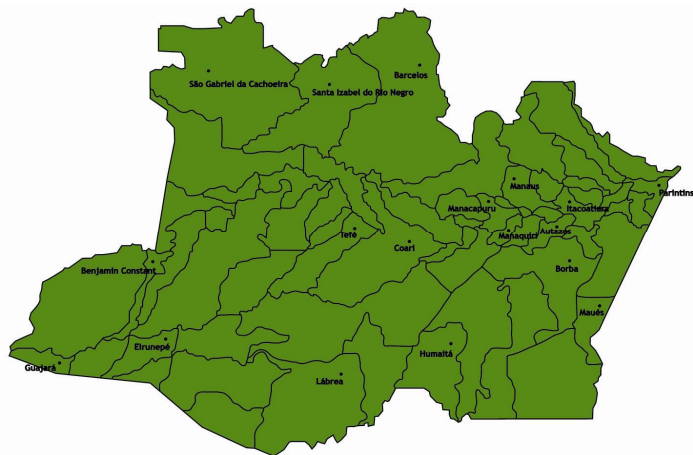

Figure 1. Amazonas state with its poles

Most towns suffer from huge geographic isolation, as these are scattered through the forest and its only access is by river. This situation makes population access to basic services, as Education, a difficult task [3].

| Distance between Manaus and poles | | |
|-----------------------------------|------|------|
| City | km | Mi |
| Manauquiri | 67 | 42 |
| Manacapuru | 102 | 63 |
| Autazes | 161 | 100 |
| Borba | 215 | 134 |
| Itacoatiara | 329 | 204 |
| Maues | 356 | 221 |
| Parintins | 420 | 261 |
| Coari | 463 | 288 |
| Barcelos | 496 | 308 |
| Tefe | 672 | 418 |
| Santa Izabel do Rio Negro | 772 | 480 |
| Sao Gabriel da Cachoeira | 1064 | 661 |
| Humaita | 1544 | 959 |
| Guajara | 1570 | 976 |
| Benjamin Constant | 1628 | 1012 |
| Labrea | 1672 | 1039 |
| Eirunepe | 5138 | 3193 |

Table 1. Distance between Manaus and poles.

Table 1 shows the distance between the capital and the poles. These data refer to distance by river.

In order to have a better vision of the dimension of the context, we present the courses offered in the different poles along with the number of the students, as it can be seen in Table 2. CDE currently has 1,618 students distributed in six undergraduate courses. Most students are in distant poles. Headquarters in Manaus also serves as a pole for three courses: Biology, Physical Education and Public Administration.

| Total active students – undergraduate 2011 | | |
|--|--|----------|
| Course | Poles | Students |
| Administration | Coari Labrea Manacapuru Maues | 106 |
| Agricultural Sciences | Coari Labrea Manacapuru Manauquiri Maues Santa Izabel do R. N. Tefe | 260 |
| Biology | Benjamin Constant Coari Humaita Itacoatiara Manaus Parintins São Gabriel da C. | 353 |
| Fine Arts | Coari Labrea Manacapuru Manauquiri Maues Santa Izabel do R. N. Tefe | 206 |
| Physical Education | All 17 poles | 453 |
| Public Administration | Coari Itacoatiara Labrea Manacapuru Manaus Maues | 240 |
| Total | | 1,618 |

Table 2. Distribution of courses and students.

III. PEDAGOGICAL MODEL SUPPORTED BY TECHNOLOGY (PMT)

According to [4], a pedagogical model adapted for distance education should seek for new paradigms in teacher-student relationship. Pedagogical, organizational and technological elements of this model should be harmonized so that learning happens interactively, collaboratively and autonomously.

CDE has a differential model of distance education which adapts to the reality of the poles to which undergraduate courses are offered. As large geographical distances from its

Due to these difficulties, PMT was structured considering the CMS, the administrative and logistical support of both coordination of undergraduate courses and technology of CDE in Manaus, the technical and pedagogical support of tutors, and specialist support of teachers. Fig. 2 shows the PMT in a simplified manner, outlining the teaching-learning process proposed by CDE. It is interesting to note that actors can interact with each other through the CMS and that, despite the hierarchical representation, the structure allows students, tutors and teachers to act collaboratively across lines of interaction.

Therefore, we note in PMT that there is harmony and cooperation between educational and technological elements, taking this model to capture, holistically, all the needs of CDE students. According to [7], teaching-learning models that combine these elements make up a new method within the concepts of different pedagogical proposals. This theory is called “blended learning” [7] and presents many advantages when there is a need to include features such as multimedia technology and virtual classrooms, as support for traditional learning approaches.

In [8], blended learning is defined as the “effective integration of various learning techniques, technologies, and delivery modalities to meet specific communication, knowledge sharing, and informational needs.” Thus, the innovation of PMT of CDE is right in the integration of features that are common to face-to-face education and distance education models, within the context of Amazonian reality.

IV. PRELIMINARY RESULTS

Undergraduate courses offered by CDE are still ongoing, and the forecast is that at the end of 2012, the first groups of courses in Administration, Fine Arts and Agricultural Sciences will graduate the first students. However, we can already analyze some preliminary results of the effort to take higher education to remote regions of the Amazon.

Because it is the case of distance education courses mediated by technology, dropout rates and failure are within the expected [9] and dropout rates are not directly related to the proximity of the pole with headquarters in Manaus, and consequently, better ease of internet access. As an example, and to illustrate these statements, Fig. 3 shows the percentage of students who passed the course, were not approved and the dropouts in Administration course, placing the poles in order of increasing distance from the headquarters in Manaus.

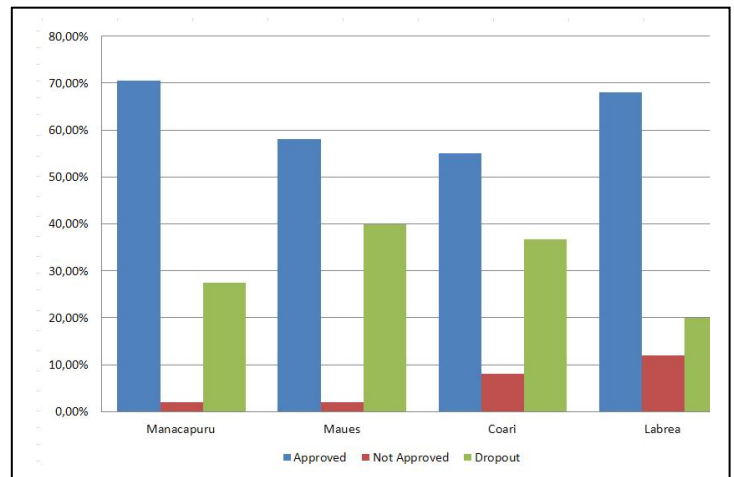

Figure 3. Index of Administration course

The Administration course was one of the first to be offered by CDE and needed adjustments during the course development. The presentation of an undergraduate course based on a mode different from the traditional was new to the poles and the students took a while to adapt to the pace of the demands of distance education.

At the beginning of the course, the major difficulty faced by these students was the paradigm shift from face-to-face to distance education. Distance education requires discipline and an autonomous construction of knowledge [1], making use of collaborative and interactive tools and resources. Furthermore, the insertion of the CMS as a learning support environment forced the students to acquire and enhance knowledge in basic informatics and internet use in their daily studies. In the first module, the scores were relatively low, being necessary adjustments and reassessments of the methods to avoid mass failure. One of the strategies was to offer summer school to the students who failed in some discipline. Other strategy was to be more flexible on deadlines and number of activities. From the middle of the course on, these problems disappeared and the levels of approval and failure are similar to courses offered in face-to-face mode [11][12].

V. FINAL CONSIDERATIONS

Population in remote regions usually suffers with precarious infrastructure and difficulty of access to basic services as Education. Distance education seems to be one of the solutions, although effective implementation is a real challenging task. On the other hand, it is really grateful to be part of this important process.

At UFAM, CDE has tried to do it with a pedagogical model supported by technology and a committed team. The model aims to give all necessary support and conditions to the students that cannot be always online. This model is based on

¹ GESAC – Program financed by federal government to digital inclusion in remote regions of the country [9].

blended learning theory to provide an educational solution supported by technology and combined with conventional educational schemes.

Surprisingly, opposite to what situation would suggest, distance does not seem to be a determining factor in performance, as it can be seen by preliminary results.

Even with an appropriate pedagogical model supported by technology, it seems that the intrinsic difficulties of distance education, such as autonomy and self organization, remain an important issue to be considered. Even in traditional education these are important aspects that sometimes students do not develop.

Future works may be on trying to motivate students to become more active learning through adaptive techniques.

VI. ACKNOWLEDGEMENTS

We are grateful to the CDE staff that kindly provided all the necessary information, in special, to the director, Prof. Dr. Gabriel Arcanjo Santos de Albuquerque.

Abstract – Nowadays, the use of remote laboratories is a common feature in order to get students involved in practical experiences. This is particularly important in distance learning environment. The regular practice is to develop a particular laboratory, required by the student competence's curricula. Usually, this involves a lack of methodology or a standard procedure so, new developments must be done to include new laboratories, additionally so many “manual” procedures are required. RELATED (REmote LABoratory Extended) it's used to solve these issues. In this paper, a practical experience of the structured development process of a virtual laboratory, using RELATED framework, will be presented from the point of view of students. This virtual laboratory is a simple signal generator. This signal generator will be used to generate a reference position for the height of the ball of an electromagnetic levitation system in a control experiment. Finally, responses of surveys made by students will be presented, in order to get satisfaction results of using/development of virtual/remote laboratories using RELATED.

Index Terms - remote experimenting, virtual and remote laboratories, software development, services and facilities, practical experience

II. INTRODUCTION

Acquiring qualitative knowledge is one of the most important things in control engineering education [1-3]. Giving students a taste of real situations, the behavior of measure instruments and how does the control action work, is a vital aspect nowadays. All these things can be done with laboratory experiments although it can be tricky with a large amount of students or in distance learning environment, as it is proposed by UNED (National Distance University of Spain) in its official degrees.

The idea is for the students to be able to perform real experiments [4-5], in real time, on real equipment, but over the Internet. This idea is in fact a widely discussed issue. In this general context there are many works, but all these remote and virtual laboratories are punctual efforts of different research groups. The use of the software and

hardware of different universities is not contemplated in any case, not taking advantage of the work previously carried out by others. This is to say, a lack of methodology or a standard for the construction of networks of virtual/remote laboratories based on previous developments. Also, services and facilities for all of these laboratories are not present.

RELATED framework [6] proposes a structured methodology of remote/virtual labs development and, also, provides common facilities as user management, booking, basic visualization (trend graphs and direct interaction using interactive variables), data logging and experimental session's control. A RLAB (Remote LABoratory) system is defined using a formal specification (which is LEDML, based on XML). The main component is an experiment, which is defined on the laboratory XML specification. To integrate a laboratory as a RLAB system is only necessary to develop local access to laboratory equipment using Java technology and the “module” paradigm. These modules, which are run-able entities, are started by the RELATED facilities in order to get/set data from/to the laboratory equipment. This data will be sent over Internet to the RELATED client too.

As users need graphical interfaces in order to understand and operate with the remote/virtual labs, RELATED framework provides the concept of “view”, which is a coded entity with the purpose of showing widgets and other GUI components. RELATED also provides built-in graphical user interface facilities, defined in a basic way, as it will be shown in the next sections.

In the next section, the fundamentals of RELATED will be shown. Also, it will be shown how a laboratory can be described in terms of its components. This section will show the development cycle and the facilities which are automatically part of the framework. In Section III, the magnetic levitation system will be presented in order to apply the development cycle using RELATED methodology (Shown in section IV). In Section V, student's development procedure and results are explained and showed, and how their results are used as the building of a remote experiment using the remote levitation lab. In Section VI, results of a survey performed by students are detailed. Finally, conclusions will be presented in section VII.

II. RELATED BASICS

RELATED provides a structured way of developing remote and virtual laboratories, focusing in lab definition and built-in facilities. To achieve this objective, these are the steps which are defined in the methodology:

A. Defining laboratory structure

Structuring the lab is one of the main tasks a developer/teacher must do [7]. There are three main components in RELATED which are necessary to describe the laboratory:

a) *Modules*. They are the basic part of development and provide virtual/physical access to lab data. They are “black boxes” used to describe the component as a set of input/output variables. This paradigm allows the interconnection of modules, being possible to flow data between a module and others. Developers must provide read/write function to get/set data for these variables.

b) *Views*. They provide the visual information to the final user (students, teachers, etc.). GUI can be included in these views. These views use data from modules to update the experiments state, and it is possible to send to modules values changed in the GUI (Graphical User Interface).

c) *Experiments*. They define the behavior expected from the lab, so one or more experiments can be defined on the lab. Basically, it is possible to define an experiment by stating the set of modules and views that will be used in the experiment. Any convenient combination of modules and views can be used as an experiment.

In order to get a full description of lab’s components, a description file based on XML must be defined. In Fig. 1, the levitator example (explained in the next sections) is shown. Fig. 2, 3 & 4 show detailed components definition for a module, view and experiment in the remote lab.

B. Developing coded entities

Once the labs components are defined, a full implementation of modules and views must be coded in order to assign the attribute/tag `<implementation>` to these entities. To “pack” the modules for RELATED runtime use, it’s mandatory to create a jar file with a main class implementing the IRLABModule java interface, which define several restrictions needed to integrate the module with RELATED.

C. Publish laboratory

With the XML definition (laboratory structure) and implemented modules and views, the next step is to “publish” the lab (and its experiments) in the RELATED Web Server. For doing this and application is provided (RLAB Publish Application) in order to validate the XML file and publish the laboratory. In Fig. 5, the RLAB Publish Application shows how the XML for levitator system has been correctly parsed and published on RELATED Web [8].

Once the laboratory is registered on main server, the lab is available to registered users, who have authorization, in the RELATED Web Server. Managers of laboratories can

add permissions of use to the registered users in the RELATED web server, using authorization system associated to every laboratory published.

Figure 4. Ball Position Control Experiment

D. Run Experiments

The experiments can be started through the RELATED Web Server simply clicking on the experiment name. A JWS (Java Web Start) application will be downloaded and, if the Internet navigator is properly configured, the login control facility will start automatically (Fig. 7). User login data

must be filled in order to show the experiment control panel (see Fig. 8).

The experiment control panel provides automatically some facilities as:

- *Booking slot time*: For every experiment, a slot time is assigned to avoid multiple concurrent users. It is represented on the upper left corner of the experiment control panel, using a three color state clock. Green represents free time for using experiment, yellow indicates less than 10% of the booking time and red color is used to indicate the finishing of slot time.
- *Experiment time*. Values of experiment starting time and actual time are presented to users in order to know time evolution for its experiment.
- *Graphical trends*. In order to add this feature, there is the possibility of adding special <paint> tags in the experiment definition. It is possible to group several variables into the same tag, which is useful for related variables. The graphical trends are presented in the lower left part of the Experiment Control Panel.
- *Interactive variables*. Usually a view is used to change some variables in one or more modules but, in simple experiments it is possible to define a set of variables which can be modified directly from the Experiment Control Panel. There is a special tag (<interactives>) for doing this. The interactive variables are usually presented on the lower right corner of the Experiment Control Panel.

Once the experiment control panel is shown, users have to press the “Start experiment” button in order to run it. After pressing the “Start experiment” this button changes for a “Stop experiment” button. In order to stop the experiment, users need to press this “Stop experiment” button.

III. LEVITATOR ON-SITE LABORATORY

Quanser [9] has on-site didactical equipment called MAGLEV (MAGnetic LEVitation system), see Fig. 9(a). This equipment provides a magnetic field in order to get an steel ball levitating in air. The MAGLEV system consists in a rectangular enclosure which has three distinct sections.

First, there is a solenoid coil with a steel core, which provides the magnetic field. In second place, there is a chamber, with white walls, where the magnetic ball suspension takes place. And, in third place, there is a bottom place where a photo-sensitive transistor (with conditioning circuitry) measures ball position, also it has offset and gain potentiometers for proper calibration. There is a cylindrical post inside the middle chamber, which is empty in the inside, where the phototransistor is situated.

The MAGLEV system provides two experiments to be carried out: coil current control and ball position control. Both of them are based on the assumption that students will run these experiments in the same “location” as the

equipment is laid. It’s necessary to do some modifications in order to get a real remote lab.

The next section will show how it is the MAGLEV reconfigured and the control software is reused using the RELATED framework.

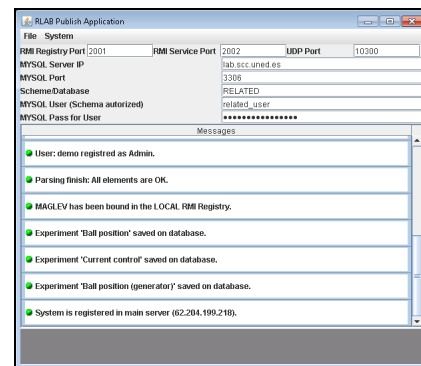

Figure 5. RLAB Publish Application

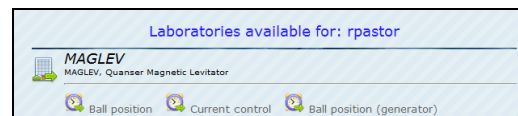

Figure 6. RELATED Web Server: Laboratory list for an user.

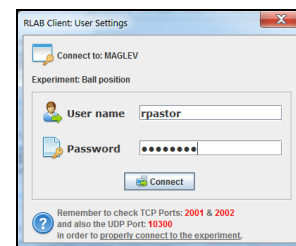

Figure 7. User login in the client application.

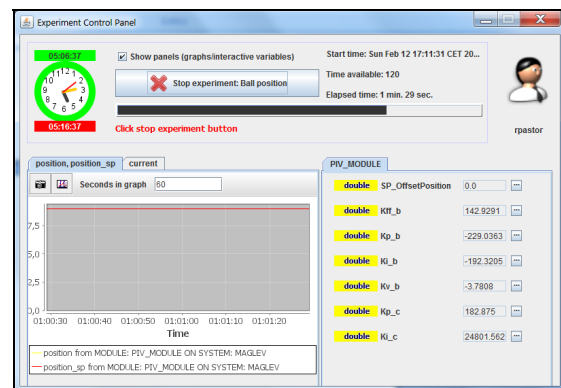

Figure 8. Experiment Control Panel

IV. REMOTE LAB FOR LEVITATOR

In order to reconfigure the on-site lab hardware, the first step is to avoid manual procedures associated with the on-site experiences. The main problem occurs when the ball falls outside the post. The solution is to surround the post with a plastic cylinder, in this way the ball never falls out. The next step is to define MAGLEV laboratory and to

reconfigure software procedures, as it is explained in the next sub-sections.

A. Laboratory specification

They are needed two modules for the two types of control experiences.

a) *PI_MODULE*: Coil current control experience which has several variables like coil current, voltage, command signal, and so. It is based in a PI (Proportional-Integral) controller, which parameters are named K_{c_p} and K_{p_i} .

b) *PIV_MODULE*: This is the ball position control experience, and the controller it's a bit more complicated than the anterior module. It's based in a feed forward plus velocity controller, and it has also the PI current loop control. Like the previous one, it has all the typical variables like coil current and so, and the specific ones of the controller (K_{ff_b} , K_{p_b} , K_{i_b} and K_{v_b}).

Also, two auxiliary modules are used: one associate to a signal generator for setpoints (*SG_MODULE*) and another associated to the video streaming (*VIDEO SERVER* module) which allows getting a real time image of the MAGLEV system. Additionally, to get a more detailed view of the remote MAGLEV system, two "views" are defined: one to represent the MAGLEV system (see Fig. 11(b)) and another to view a real time image of the steel ball.

Finally, a set of experiments can be defined using these last modules and views:

a) *Current control*: This experiment represents the coil current control experiences and its definition includes the use of *PI_MODULE* & *VIDEO SERVER* modules and the two views (*ImageViewer* and *MAGLEV Virtual View*).

b) *Ball position*: In this case, the modules which are used are *PIV_MODULE* and *VIDEO SERVER* module.

c) *Ball position (generator)*. Similar to the above experiment, but also include the *SG_MODULE* module in order to use the signal generator for the ball position.

B. Modules development

QUANSER provides QUARC software, which are composed of several modules, including some based on Matlab/Simulink models. As the Simulink models are implemented for on-site experiments, they need some modifications. The model needs to be modified with network specific blocks which allow get/set information from the model (see Fig. 10).

C. Views development

There are two views defined in the XML file. One of them is the virtual view [10] for MAGLEV system (see Fig. 9 (b)). The other view is associated to the video streaming of images from a network camera. Really, the view is supported by the use of the *VIDEO SERVER* module.

D. Final steps

Once the development steps are done, the final step is to publish the MAGLEV laboratory in the RELATED Web Server (as it was mentioned before, in section II).

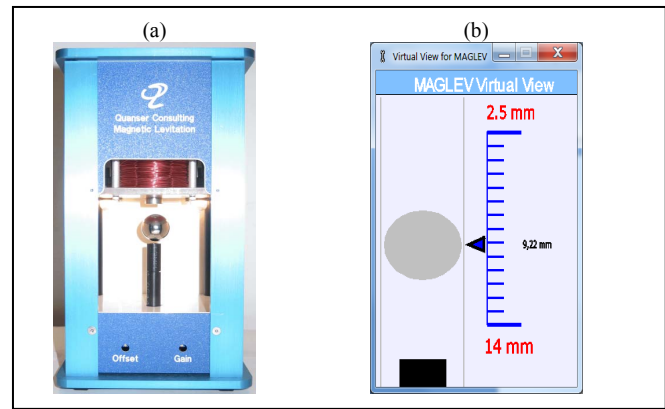

Figure 9. MAGLEV System: Real (a) and Virtual (b)

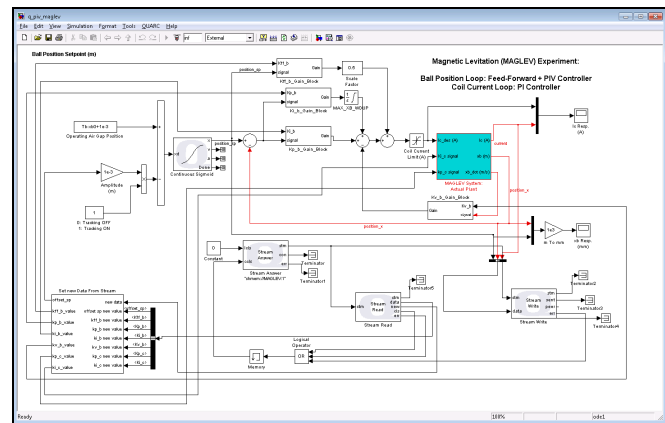

Figure 10. Re-Configured Simulink Model with network support.

V. STUDENT'S VIRTUAL/REMOTE LAB.

The practical experience which must be carried on by students has two different parts: development of a virtual signal generator and integration of the virtual lab with the remote lab (levitator). Students are enrolled in the subject called *Distributed Systems* on the Computer Science Degree at the National Spanish Distance University (UNED).

A. Development of the virtual lab.

In this part, first, students must familiarize with the publish process of a RELATED lab. For this objective it is used a predefined lab with its code available for the students (a simple random generator of 4 values). Next, they must develop a module for the signal generator and a simple view to change type, frequency and amplitude of signal generator. The development process is based on the procedures explained in Section II, in a similar way but more simple than the levitator system development. Fig. 11 details the developed view by student and the output computed in the RELATED client application.

Once the virtual lab is developed, a module component is available for reusing in other laboratories (module corresponding to signal generator). So, the next step in the practical experience is its integration with a remote lab (the MAGLEV system).

B. Integrating the virtual lab as a remote lab.

In order to create and publish the student's remote laboratory, the only task which must be done is the modification of the virtual lab XML specification (all the code is developed). This modification includes the definition of an experiment (<experiment> tag marked in green in Fig. 12) called "Remote experimentation". It is defined in a similar way that the virtual lab developed in the previous section, but the experiment must include references to the corresponding module in the remote lab (called MAGLEV). These references are located in the experiment definition:

- 1) First reference corresponds with the inclusion of a <run> tag which defines the remote execution of the PIV Module of MAGLEV system (this module get/set access to the data generated by the real equipment). It is marked in red in Fig. 12.
- 2) The second reference must be included in order to connect the output of the signal generator module with the set point for ball height defined in the remote module. This is done by using the <out> tag inside the <run> tag associated to the inclusion of the signal generator module in the experiment (to execute during the experiment). It is marked in blue in Fig. 12.

No more development must be done, so students simply need to publish the new remote lab. In Fig. 13 it is shown the views associated to the remote experiment running. As part of the experiment, a real time video image is presented to the user (represented as a module/view, and developed for the MAGLEV system). Again, reusing the code provides an efficient way of development of virtual and remote laboratories.

VI. STUDENT'S OPINION

Once the practice experience with virtual/remote laboratory is over, students must perform a survey used to get development/services satisfaction information. This survey is mandatory and it has 16 questions, classified in 4 main areas (questions/areas/ratings are shown in Table 1). The survey was performed by 78 students from 188 enrollment students in the subject. Due to the university's regulations, students can deliver the practical homework in two dates (February 2012 and September 2012), so only the first date surveys are included in this paper.

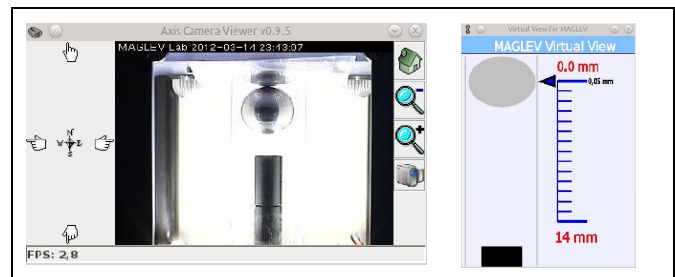

Figure 13. Running the remote experiment with visual feedback.

As it is shown in Table 1, the overall satisfaction and curricula adequacy ratings is over 4 points, so students describes RELATED as a useful tool for the learning process. Also, from ratings data can be concluded that reliability/quality of software must be improved, specially the development documentation for a RELATED laboratory.

TABLE I. QUESTIONS AND RATING

| Question (scored 1-5) | Code | Average rating |
|--|------|----------------|
| Overall Satisfaction (A1) | | 4.3 |
| It was interesting to develop the virtual/remote labs? | Q1 | 4.5 |
| Would you use this system in other subjects in the degree? | Q2 | 4.1 |
| Would you recommend the use of RELATED in a professional environment? | Q3 | 3.5 |
| What's your overall satisfaction rate about the practical experience developed? | Q4 | 4.8 |
| Development/Services facilities (A2) | | 4.0 |
| Consider the process of developing a virtual lab with RELATED, do you think it has been easy? | Q5 | 3.6 |
| Consider the publish process of laboratories, do you think is a simple procedure? | Q6 | 5.0 |
| Consider the development facilities provided by RELATED, do you think the learning process of these facilities is low? | Q7 | 3.9 |
| Consider the documentation about development/services facilities, do you think is enough to make the practical experience? | Q8 | 2.9 |
| Consider the services set provided by RELATED (data logging, booking, finding and accessing to laboratories), do you think that are appropriated to the virtual/remote labs development? | Q9 | 3.8 |
| The client runtime is intuitive and easy to learn | Q10 | 4.3 |
| Consider the used elements on views providing a visual feedback, do you feel that you are using a real on-site laboratory? | Q11 | 4.6 |
| Reliability/Quality of software (A3) | | 3.5 |

| | | |
|--|-----|------------|
| The modular approach in components (modules and views) separation facilitates the development of reusable laboratories. | Q12 | 4.5 |
| The number of errors found in the RELATED development facilities has been low or nonexistent. | Q13 | 3.0 |
| Code specification for modules and views is simple and clear. | Q14 | 3.0 |
| Curricula adequacy (A4) | | 4.4 |
| The practical experience allows me to learn more about the subject's learning objectives | Q15 | 4.2 |
| The learning objectives for the practical experience are a subset of the subject's learning objectives, expanding my knowledge of the subject. | Q16 | 4.6 |

VII. CONCLUSIONS

RELATED provides a standardized way of developing remote/virtual laboratories and useful services and facilities (users management, booking system, etc.). The clean separation between data and presentation (modules and views) has several advantages, but the main is the software reusing (code develop for this lab or others). In the case of the MAGLEV system, on-site practical experience software is reused and also, previous developed modules/views (for example, the video server and image viewer) are included with no extra development cost.

With these features, students can develop their own virtual and remote laboratories, using the structured methodology of RELATED. The "module" paradigm allows to students develop their own code, and integrate with "real" experiments simply creating/modifying the XML specifications which defines the behavior of systems/experiments. Survey's results from students indicate that the approach is easily adopted with minimum effort and it will be useful on practical experiences with other subjects.

Abstract—A new model for building and measuring analog electronic circuits has been developed and validated in the area of remote laboratories. The goal of the proposed solution is to facilitate and improve the set-up, maintenance and update of the hardware used during the configuration, control and measurement of the instruments and experiments included in the lab. The experimental setup does not reduce the performance of the lab, allowing the users to carry out the same actions and activities as they were in a hands-on laboratory. Therefore, thanks to this new paradigm users can practice through Internet and transparently to the hardware that makes possible the remote configuration of the experiments obtaining the same results as in a hands-on lab

Keywords—component; instrumentation and measurement education, remote engineering education

I. INTRODUCTION

Practical exercises and experiments are fundamental in any technical discipline either in educational or investigation areas. To achieve that, the easier way to implement these activities is to go to hands-on laboratories, which offer real equipments and experiments. However, sometimes many of these experiments require special and expensive instruments or the number of needed equipments is not enough for all the potential users due to their size or maintenance requirements.

At a scenario like this, virtual laboratories or remote laboratories can play a key role in the teaching of specific areas of technical subjects such as analog electronics. While virtual laboratories can be used in certain experimental activities in which the simulation may be enough, they are not as effective as the laboratories in which users can play and interact with real equipment [1], according to the learning-by-touching or active learning approaches. Moreover, according to the Accreditation Board for Engineering and Technology (ABET), practical exercises should help the students to achieve a set of competences that virtual labs cannot satisfy [2].

Therefore, the manual remote laboratories (or simply remote laboratories) try to reproduce remotely and as faithfully as possible the actions that the user carries out at

local laboratories. Thus the advantages that these technology platforms of learning can provide respect for others are:

- Ubiquitous access to experiments through an Internet-based communication.
- They can play a complementary role to the theoretical sessions and classroom practices, so the student can return again and again on the learned concepts and practice by their selves.
- Remote labs help to improve the performance of the available equipments, increasing the accessing time 24d/7h.

Starting with these premises and on the basis of our experience in distance learning using WebLabs [3], on the particular topic of analog electronics remote labs, technical contributions can be made in the following aspects:

- Enable users to build electronic circuits such as if they were in a hands-on laboratory.
- Obtain consistency and reliability in the measurements are taken in a remote way.
- Make easy the maintenance and scalability of the laboratory regarding the instruments and experiments.

This paper describes a model for the design of a control, measurement and configuration system of electronic circuits to be deployed in remote learning platforms. Users can build real circuits and carry out measurements on them with typical instruments of an electronic workbench: oscilloscope, function generator, power supply and digital multimeter.

From the analysis of the role that remote experimentation can play in the practice of electronics, we introduce the application area of development of the proposed model, describing its main technical aspects concerning its implementation.

According to the described model, a prototype has been developed and deployed in a remote laboratory. In this way, the effectiveness and reliability tests can be carried out to check the validity of the model as a tool for remote prototyping and interactions

II. EXPERIMENTAL REMOTE SCENARIOS

Remote labs are currently deployed to allow users to interact with real physical systems. In the field of analog electronics, different approach has been developed:

- Remote labs in which user can control special instruments to carry out specific experiments. One example of these labs is the iLAB Microelectronics Device Characterization Lab [4].
- Remote labs in which the user can make practical exercises only with predefined or prebuilt experiments. This is the case of the ISILab [5].
- Remote labs where the user manages to modify certain predefined parameters in the Circuit Under Test (CUT) as in the RemotElectLab [6]
- Remote labs in which the user have the chance of building a CUT from the beginning using discrete electronic components as in the VISIR or NetLab [7][8].

Each one of these remote labs presents particular characteristics in its design and development which defines its use and application environment. Thereby, depending on the deployed control and measurement system, user can define and implement a complete CUT and instruments setup or he is restricted to monitor and visualize how the experiments are executed without any interaction activities.

The scope of the work presented in this paper is focused exclusively in the control and measurement system of the experiments of the labs. We do not have considered other systems that are critical in the design and development of a remote lab, such as the client or server's functions in charge of users and connections management. These issues have been discussed in deep in other works [3], so in the following sections and on the base of previously referenced works, we present a model to build, control and measure electronic circuits using real components and regular instruments.

III. REMOTE CONFIGURATION AND CONTROL SYSTEM

We define a control, configuration and measurement system as a set of technologies and developments that make it possible that the user to be able to build and measure an electronic circuit and setup the available instruments in the real lab remotely. Thereby, users can carry out experiments through Internet transparently to the required hardware and software infrastructure and bring off the same actions as they were in a hands-on lab.

In the above scenario, one of the problems that usually appears is that the hardware architecture and systems developed to succeed the remote experimentation might introduce errors in the measurements. These failures may happen because local experiments need additional hardware to replace the manual actions that the user would perform if he was at the local laboratory and to make the experiments accessible via the network.

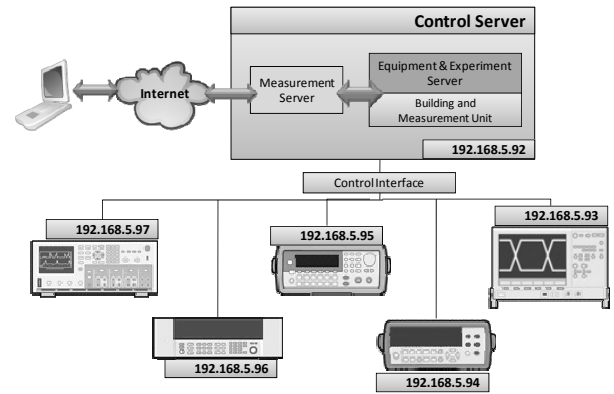

Fig. 1. Configuration and Control System architecture

Furthermore, in a typical remote session several users interact with the experiments at the same time and see the results of their own configurations and actions. So the control and measurement system has to manage different requests concurrently and in a short time slot to maintain the coherency of the system and the real-time feeling.

From the maintenance and scalability point of view, control algorithms defined and deployed at the Control Server should be transparent to the interface used to communicate the server with the experiments and independent from specific restrictions about the control of the instruments that depend of the manufacturer. These characteristics help the administrator of the lab to replace the experiments and instruments in case of updates or malfunction cases.

In summary, the main features which the proposed remote control, measurement and configure system brings are:

- 1) Allow users via Internet to create electronic circuits using real components and connections.
- 2) Through this remote system, user can setup real instruments and carry out measures performing the same actions as he was manipulating them by hand.
- 3) The measurement system brings the same results as obtained in a hands-on lab. To achieve that, the systems that make possible the remote control do not put significant errors in the acquired measures.
- 4) The proposed model is completely based on deploying regular instruments so it does not require specific equipments that could complicate the setup, maintenance and scalability of the lab.
- 5) Even in a concurrent scenario, the system is able to manage the request of each user in a short period of time, having the user the feeling of being controlling the experiment in real time.

These functionalities are regarding only to the control of the hardware of the lab: instruments and CUT. This control is based on the architecture shown at Fig. 1. It consists on a Local Access Network in which the Control Server and all the instruments are connected. The Control Server gathers the algorithms in charge of managing the communications and controlling all the equipments connected at this Instrument Network.

TABLE I
SPECIFICATIONS OF PROPOSED MODEL COMPARED WITH OTHERS

| Remote Lab | Independent of Instruments | Easy to add Experiments | Build CUT | No Proprietary Solutions |
|------------------------|----------------------------|-------------------------|------------|--------------------------|
| NetLab | No | Yes | Yes | Yes |
| RemotElectLab | No | No | No | No |
| ISILab | Yes | Yes | No | No |
| VISIR | No | No | Yes | No |
| LEDFE | No | No | No | No |
| iLab | No | Yes | No | No |
| Proposed Design | Yes | Yes | Yes | Yes |

IV. DESIGN AND IMPLEMENTATION

The choice of appropriate software architecture is key to obtain an easily scalable, maintained and managed control and measurement system.

If the solutions adopted in others remote labs are analyzed [8][9][10][11][12], we can find out different alternatives that provide each lab with different resources. That is, both the designed architecture and the developed algorithms determine the actions of the user in the lab and how the maintenance and updating tasks will be performed. In this regard, we obtain the Table I, in which it is shown how none of the analyzed solutions satisfies simultaneously all the specifications that we want to meet with the proposed model.

Therefore proposed design aims abstracting the control software from the hardware of the laboratory, both the instruments and the CUT. In this way add or replace components or equipments is simple and does not require a recodification of the software, keeping any benefits and possibilities of the remote lab closest to a hands-on one.

The result is an adaptable software architecture independent from the instruments and CUT and an Instruments and Experiments Control System that enables the remote implementation and test of the CUT without errors in the results offered to the users.

A. Adaptable software architecture

As it has been shown at Fig. 1, the functions of the Control System are divided in two logic entities. We have focused only on the functions related to the hardware control, so the Equipment and Experiments Server is the entity in which we have developed the proposed model.

We have chosen LabVIEW to develop the algorithms of this server basically because it is an instruments control oriented language that provides a set of services and applications that makes easier the access to specific functions to control the instruments through a communications interface. These functions are given by the instruments' drivers, so with the aim of satisfying the specifications described in Table I regarding the instruments, we have used IVI drivers. Thanks to these drivers, compatibility problems among instruments

due to the use of SCPI commands or VXIPlug&play drivers are avoided.

In the algorithms of the control software there is not any reference to specific instruments, only global variables are used to address the control commands of the instruments. These variables are called "Logical Names" which are valid for any family instrument defined by the IVI Foundation Specification (<http://www.ivifoundation.org/>). Once instrument's IVI driver is setup, the Driver Session is pointed to the Logical Name used in the algorithm and then the instrument can be controlled.

The control software of the communications interface, so even though in this model LXI has been the selected interface, other technology can be used based on the needs of each system. Along with IVI drivers, we have used the features of the Virtual Instrument Software Architecture (VISA) to abstract The selection of LXI has been due to the characteristics previously defined, but also because all the instruments that provide LXI interface can be controlled by IVI drivers. That is, if we deploy LXI instruments in the lab, on one hand we will benefit from the features of the Ethernet interface and on the other hand we could use the functions and services provided by the IVI drivers that make easier the software development.

To sum up, thanks to use IVI drivers we make transparent the control software of the instruments and using VISA, we get the same effect regard to the control and communications interface. The result is an adaptable, standard and easily scalable software architecture.

B. Instruments and Experiments Control System

This system is deployed in the previously defined Building and Measurement Unit, so it is the set of hardware and software technologies in charge of implementing physically the designed circuit by the user in the web client and of carrying out the measures according with the remote configuration of the instruments.

As it has been defined above, the main element is the 8x16 (8 rows and 16 columns) switching matrix. This configuration is obtained through the combination of the matrixes provided by the two modules that are connected in two slots of the mainframe. The resulting matrix is shown at Fig. 2.

The probe tests of the instruments are connected from C16 to C9 columns whereas the electronics components are plugged in the remaining columns. In this first approach only two-pins components are used, but the system is ready to manage components with more than two-pins as transistors or integrated circuits.

If it is required to increase the dimensions of the matrix, only one module has to be plugged in the free slots of the mainframe and provide one more expansion module to connect their matrixes to the existing ones. These modules do not carry any logic because they are built using only connectors, wires and sockets to place the electronic components (Fig. 3).

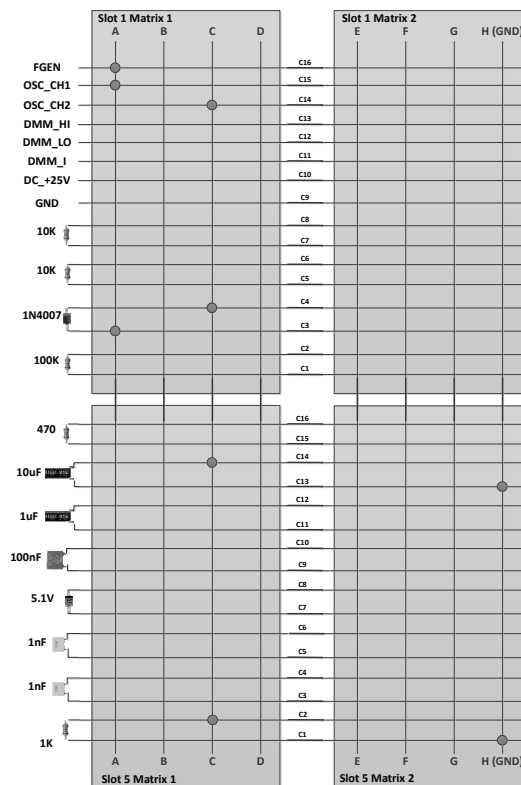

Fig. 2. Resulting switching matrix

In the Fig. 3 the upper and lower sides of the prototypes of these modules are shown. In the image on the left the sockets for the components can be seen at the top and the instruments connection points are at the left of the same image. At the bottom, the DB50 connectors used to connect these modules to the mainframe are also shown. The white connectors at the top are used to interconnect the matrixes through their rows, obtaining the matrix at Fig 2.

Regarding the control software of this system, the main thing to note is that it is included in the application that controls the rest of the instruments. As this model is not based on a proprietary solution, the control of the switching matrix is done with its IVI driver. The only thing that the control algorithm needs is two configuration files. These files are easily configured by the administrator of the system because he does not need to understand how the matrix works or how it has been designed:

- Circuit description files: using these files, the administrator determines the CUT that the user can implement in the lab. As a teacher in a real lab, these files specify how the components can be interconnected in the experiments. These files allow the administrator to limit the CUT in a practical session and avoid harmful circuits as shortcuts that could damage the lab.
- Components location file: this file describes where a component is plugged in the switching matrix. In example, this file defines that the 10uF capacitor is plugged at column 14 and 13 at matrix 1 of the module that is connected at the slot 5 of the mainframe

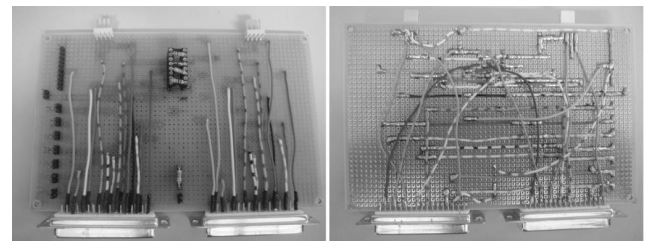

Fig. 3. Expansion Modules

Based on the information provide by both files, the algorithm that controls the mainframe generates the commands that open or close the corresponding relays at the switching matrix. The output of these actions is the CUT designed by the user at the web client.

One of the specifications of the proposed model is that the measurements taken remotely must be the same as those offered by the instruments locally. Considering that we need a switching matrix and the expansion modules which are not part of the CUT, we shall now proceed to measure the error resistance introduced by these elements in the experiment.

To characterize this error we have used a DMM to apply the 4-wire resistance measurement method. The values obtained in random points at the switching matrix are shown at Table II. The average of these results is 0,310Ω or 0,320Ω if the expansion modules are considered. We can affirm that the combination of the CTU and the expansion modules does not introduce considerable parasitic resistances in the CTU

Thanks to the configuration of the switching matrix, the parasitic resistances are placed in serial to the CUT components, so because of their small value, the introduced error is manageable, either in the measurement of resistances or in the voltage or current measurement because the voltage drop in a 0,320 Ω is really small.

In short, the use of a commercial switching matrix that is controlled as other instrument allows the user to build, setup and carry out measures in a remote way, performing the same actions as in a hands-on lab. We validate the results of these measures at Section IV

TABLE II
INSTRUMENTS AND EXPERIMENTS CONTROL SYSTEM CHARACTERIZATION

| Colum-Row | Slot | Matrix | Relay Resistance | Relay + Expansion Module |
|-----------|------|--------|------------------|--------------------------|
| C4 – R7 | 5 | 2 | 0,281Ω | 0,311Ω |
| C12 – R6 | 5 | 2 | 0,318Ω | 0,320Ω |
| C9 – R5 | 5 | 2 | 0,317Ω | 0,324Ω |
| C16 – R1 | 1 | 1 | 0,315Ω | 0,321Ω |
| C2 – R3 | 1 | 1 | 0,317Ω | 0,322Ω |
| C14 – R4 | 1 | 1 | 0,316Ω | 0,327Ω |

V. PROTOTYPE

A prototype for the proposed model has been developed with main objectives of validating its effectiveness as control and measurement system and setting up a framework to evaluate its performance in a real analog electronic remote lab.

This prototype allows the users to interact with electronics components and carry out measurements using a set of real instruments: oscilloscope, function generator, multimeter and power supply. As the scope of the proposed approach does not include a web client, in this prototype the one developed at the VISIR project has been deployed [12]. This web interface offers a set of front panels of all available instruments in the lab as well as a virtual breadboard in which the users build the CUT that later will be implemented physically using the switching matrix.

The others systems that are required to obtain a complete and functional remote lab are provided by the WebLab-Deusto.

With this software and communications architecture, we have provided the prototype with the following instruments:

- 33220A Function generator
- 34410A Digital multimeter
- DSO5012A Oscilloscope
- N5746A Power supply
- 34980A Mainframe with two 34932A switching matrix modules.

Once the instruments are deployed, these are connected by the LXI interface to a hub that also connects the computer in which the Control Server applications run.

VI. VALIDATION

The objectives of the validation phase are:

- 1) to check that the remote measurement and control system does not introduce errors respect the results obtained in a hands-on lab.
- 2) to verify that the system time response is suitable even when the measures are carried out in concurrent mode.

A. Measurements validation

In this test we want to validate that if a CUT is created remotely using the same components as in a hands-on lab, the measurements carried out using the proposed model are the same. To perform this probe, first we have made the measures in the local labs using a breadboard and some discrete components. After that, we have removed the components from the breadboard and placed them in the designed switching matrix. The measures also have been carried out with the same instruments in both scenarios. These are the test bench experiments:

- Periodic signal characterization: the oscilloscope has been connected directly to the function generator.
- Serial resistors configuration: some resistances area connected in serial. The equivalent circuit is measured using the digital multimeter.

- Parallel resistors configuration: some resistances area connected in parallel. The equivalent circuit is measured using the digital multimeter
- Voltage measures: using a voltage divider configuration.
- Current measures: in a 3 resistors network.
- Frequency circuits characterization: using a half wave-rectifier with a filter at the output and a function generator and the oscilloscope.

These experiments have been performed by ten users, some of them without skills in electronics. In the same way, some of them have never used a remote lab before. In this scenario, each user had to practice with 6 different experiments. The order of the experiments was random, so the control and measurement system had to set up different CUT and instruments in concurrent mode. The obtained measures are shown at Table III.

Analyzing these results, it can be said that:

- In the periodic signal measures, the remote system offers almost the same frequency values. In the amplitude measures, there is a little deviation.
- In the measurement of resistors configuration, the remote system provides valid results, taking into account that the tolerance of the resistances are the same.
- In the measurement of voltage and current, the remote system is a stable, providing results that are almost the same in both remote and manual scenarios.

B. System time response

The goal of this test is to estimate the system time response when users are acceding to the lab in a concurrent mode. We have developed a software application in Java that simulates until 60 users' requests at the same time.

TABLE III
REMOTE AND MANUAL MEASUREMENTS IN REAL EXPERIMENTS

| Experiment | Manual Measures | Remote Measures | Error % |
|---|------------------------|------------------------|---------|
| Periodic Signals $F_1=1\text{KHz}$; $V_1=20\text{V}$ | 999Hz | 999.4Hz | 0.04 |
| | 20.1V | 19.99V | 0.54 |
| Resistances Serial Conf. $R_1=1470\Omega$ | 1456 Ω | 1462.4 Ω | 0.43 |
| Resistances Parallel Conf. $R_1=448\Omega$ | 445.6 Ω | 447.2 Ω | 0.35 |
| Voltage Divider $V_1=12.59\text{V}$ | 12.59V | 12.59V | 0 |
| Current Measures $I_{T1}=6.911\text{mA}$ $I_{T2}=308.9\mu\text{A}$ $I_{T3}=30.89\mu\text{A}$ | $I_1=6.912\text{mA}$ | $I_1=6.947\text{mA}$ | 0.50 |
| | $I_2=307.9\mu\text{A}$ | $I_2=307.1\mu\text{A}$ | 0.25 |
| | $I_3=30.69\mu\text{A}$ | $I_3=30.59\mu\text{A}$ | 0.32 |
| Frequency Circuit $F_1=50\text{Hz}$; $V_1=5.6\text{V}$ | 50Hz | 49.99Hz | 0.02 |
| | 5.6V | 5.45V | 2.67 |

TABLE IV
SYSTEM TIME RESPONSE IN MILLISECONDS

| Users | Easy Circuit | | Medium Circuit | | Complicated Circuit | |
|-------|--------------|-----------------|----------------|-----------------|---------------------|-----------------|
| | VISIR | Proposed Method | VISIR | Proposed Method | VISIR | Proposed Method |
| 10 | 408,5 | 777,1 | 444,7 | 1129,4 | 631,7 | 1189,4 |
| 30 | 1195 | 2019,6 | 1287,4 | 3235,6 | 1874,4 | 3554,3 |
| 60 | 2347,9 | 4803,5 | 2662,2 | 6341 | 3679,9 | 6919,3 |

Each one of these requests includes a CUT configuration and instruments setup. Depending on the number of the connections that the switching matrix has to perform, the system time response is different so we have use three different CUT configuration: a simple circuit that consist on only connection, a medium circuit that implements a circuit with 2 components and a complex circuit that uses 3 components. The results of these experiments are included at Table IV. The obtained time responses have been compared with the times response of the VISIR lab in order to compare both control models. All the values are given in milliseconds.

If the circuit complexity or the number of simultaneous requests is increased, the system requires more time to response to the user's requests. Also it is noticed how the VISIR system is considerably faster than the proposed system because if a complex circuit must be implemented, its time response is less than the time required by the proposed model to build a simple circuit. According to [9] if a user has to wait more than 7 second, he will lose his attention an interest in it, so the system time response may be considered valid because the user will not be more than 7 seconds waiting for his answer. Anyway this feature should be improved in following developments.

VII. CONCLUSION AND FUTURE WORK

Control and measurement systems commonly used in remote labs must have some performance and reliability features closest as much as possible to those obtained in a manual laboratory.

We have presented a model to control and measure electronics circuits using real instruments through Internet using a remote lab. The model has been validated using a complete and operative prototype. The main advantages of the proposed model are that it can be easily update and its adaptability to new experiments and instruments. Its modular design guarantees the possibility of adding new instruments and components to the CUT easily without software or hardware reconfiguration. In short, the software is transparent to the experiments of the lab. The main features of the proposed model are:

- It is an scalable and open structure to add new instruments and components.
- It uses only commercial instruments. No proprietary and complex solutions are developed
- Using IVI and VISA technologies allow to make the control application independent from the hardware and the communications interface.
- Reliable measurements can be carried out because the hardware in charge of building the circuits do not introduce errors in the obtained results.

Regarding to future work, in one hand the system needs to improve the time response in concurrent mode. On the other hand the configuration of the switch matrix is one of the existing possibilities, so new configurations can be studied

Abstract—The paper presents our preliminary work on developing a remote hardware development lab using mixed reality technology (mRLab). The mRLab allows a group of students to remotely and simultaneously work on a VHDL project with an FPGA development board. All lab objects are created in 3D and an interactive layer on the 3D objects is added to host learning information along with caveats to assist learning.

Keywords—Mixed Reality; FPGA; Education; Remote Lab

I. INTRODUCTION

Large classes in the Computer Architecture and Organization curriculum are becoming more common as colleges and universities face budget restrictions. However, universities teach this core curriculum in computer science (CS) or computer engineering (CE) programs without any hands-on lab practices, with antiquated equipment, or with labs in which lab equipment is frequently damaged and drastically hinders student learning [1]. While remote labs have been studied over the past decade, how to reflect high fidelity of a remote lab is still a problem. Proposed in this project is a mixed reality enhanced remote lab (mRLab) which attaches real hardware such as field programmable gate arrays (FPGA) development boards for students to perform labs through a thin client or mobile devices. The mixed reality technology is used to overlay teaching materials on top of a board image and dynamically interact with students [2]. The network connected mRLab makes it possible to be broadly disseminated, and allows students to conduct labs at anytime and anywhere. The mRLab will enable students to interact with others online to create a sense of working together.

The mRLab is composed of a network connected computer, a set of FPGA development boards, a web server, and a series of supporting software. FPGAs have been widely used for prototyping digital systems and implementing proprietary embedded systems in industry. They offer a great opportunity for students to gain hands-on experience. However, our experience shows that: 1) FPGA development boards are easily broken if not operated correctly, 2) Time for software to translate a design to the FPGA chip is lengthy, 3) Few instructors have expertise in FPGAs, and 4) Lab materials are difficult to repeat in other institutions.

The mRLab was developed to overcome the aforementioned problems. The subtle settings on the board are presented in a different layer of the board image using mixed reality technology which guides students to a correct setting as if they were working on a real board. Students are able to avoid wrong configurations on their boards. This mixed reality also provides a high fidelity response of the remote lab with minimal network bandwidth. For example, a real-time image of the onboard display and LEDs is sent back to the students. Converting a design to configuration bits in FPGA involves synthesis, place and route, and a series of optimization, each of which demands computing resources. Practically, a successful hardware project requires at least tens of compilation rounds to get everything right. Shifting the computation to a high performance server will shorten the compilation time and enhance student learning. By packing together FPGA development boards and the supporting software tools in a server, the learning environment becomes consistent for every student. This will rule out unnecessary problems such as system related issues. The identical learning environment enables students to share their experience, and exchange ideas. The integration of hardware, software, and labware will allow instructors at any institution to repeat the developed curriculum at a minimal cost.

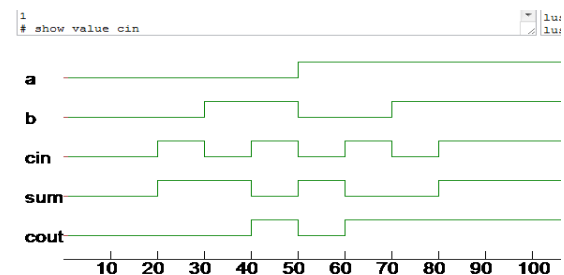

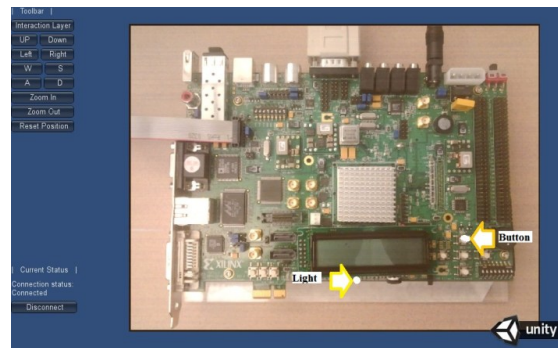

II. OVERVIEW OF THE MRLAB

The mRLab follows normal client/server architecture with open sourced or free software. This setting would allow the mRLab to be repeated and deployed in other universities with minimal support. Figure 1. depicts the overview of the mRLab architecture. The server is equipped with an FPGA development board and configured with support for hardware development. It provides services for users to synthesize, simulate, implement, and program a hardware design to the FPGA board. The simulation result is sent back to the user's browser via simulation waveforms. The response on the FPGA board including switch/light status is converted to 3D objects to be displayed on user's browsers. Virtually, a network device such as smart phones, mobile devices, laptop or desktop computers may connect to the server for receiving the service. This setting allows students to work on a project at anytime and anywhere. Moreover, a group of students may work on a project remotely and simultaneously. Students may share the

Work in Progress: STEM-Based Computing Educational Resources on the Web

Tatiana Ringenberg and Alejandra J. Magana
Purdue University, tringenb@purdue.edu, admagana@purdue.edu

Abstract – This work in progress explores the landscape of computing learning resources and environments found on the web together with teaching and learning materials that can facilitate the integration of “computational thinking” into the K-12 classroom. In specific, this paper focuses in finding and describing existing learning environments that integrate computational thinking into a STEM discipline together with lesson plans, activities and other curricula.

Index Terms – Computational thinking, STEM, learning resources, supplemental materials.

INTRODUCTION

Computing is increasingly used to extend the capabilities and therefore findings of scientific research. For example, computing has further enabled scientific breakthroughs by facilitating researchers through computerized instrumentation and detailed simulations to generate, visualize, and understand large amounts of scientific data that have radically allowed new understandings. In tandem with the pervasive role of computing in science and engineering, there is a growing recognition of the importance of computational thinking.

Computational thinking [1] has been recognized as a collection of understandings and skills required for new generations of students proficient not only at using tools, but also at creating them and understanding the nature and implication of that creation [2]. Computational thinking refers to the combination of disciplinary knowledge (e.g., physics, biology, nanotechnology) [3] with thought processes (e.g., engineering thinking, quantitative reasoning, algorithmic thinking, systems thinking) involved in formulating problems and their solutions so that the solutions are represented in a form that can be effectively carried out by an information-processing agent [4]. This requires using a set of concepts, such as abstraction, recursion, and iteration, to process and analyze data, and to create real and virtual artifacts [5, 6].

This paper explores the landscape of computing learning resources and environments found on the web together with teaching and learning materials that can facilitate the integration of computational thinking into the K-12 classroom. The guiding research question for this study is: *What is the landscape of web based resources that fall under the definition or are identified as resources that promote computational thinking?*

METHODS

We followed the approach created by Bagiati and colleagues [7] to identify resources that can be described as promoting computational thinking in STEM disciplines. We started by identifying a list of resources mentioned on national reports and in portals that compile resources related to computational thinking. The next step was to identify additional resources on the web. These resources were found using a combination of the following search terms in Google: “computational thinking”, “science”, “technology”, “engineering”, “math”, “STEM resources”, “simulations”, “lessons”, “supplement”, “K12”, “animations” and “teaching”.

Our analysis, and also the primary focus of this work in progress, consisted of identifying the primary type of instructional method and specific type of instructional planning provided in each of the identified websites [8]. For instructional method we identified whether the resources included demonstrations, discussions, simulations, games, drill and practice, discovery, problem solving, hands-on experiences and so on [8]. For instructional planning we identified those supplemental materials consisting of motivation, orientation, information, application or evaluation activities accompanying the learning resource [8].

RESULTS

Results from this study identified 64 resources that were classified as STEM-based computational educational resources, with 59 resources that can integrate computational thinking in the K-12 classrooms to support learning in other STEM disciplines. Percentages of resources found per each discipline were as follows: 32% fell in the *Science* category, 26% fell in the *Technology* category, 23% fell in the *Math* category and 19% fell in the *Engineering* category.

As described earlier, the identified resources were then classified according to the primary instructional method. Table 1 depicts the number of resources found for each instructional method. Resources utilizing multiple instructional methods were also noted.

TABLE I
TYPE OF INSTRUCTIONAL METHOD

| Instructional Method | Number of Resources |
|-------------------------|---------------------|
| Simulations | 21 |
| Programming environment | 6 |
| Games | 5 |
| Videos | 7 |
| Illustrations | 6 |
| Animations | 9 |
| Lectures | 4 |
| Books | 4 |

As shown in Table 1, eight different types of instructional methods were identified. Simulations refer to working representations of reality describing a model that may require some input parameters and then are executed by the learners. Programming environments refer to computing environments that embed a programming language mostly used for creating interactive stories and games. Games refer to electronic and interactive media played by means of manipulating images. Videos were defined as the reproduction of visual images. Illustrations refer to static pictures and drawings while animations refer to a sequence of images to create the illusion of movement. Lectures were defined as notes or presentations. Finally, books refer to electronic compendium of written materials.

TABLE II

| TYPE OF INSTRUCTIONAL PLANNING RESOURCE | |
|---|---------------------|
| Instructional Method | Number of Resources |
| Lesson plans | 17 |
| Learning modules | 14 |
| Tutorials | 8 |
| Activities | 17 |
| Sample code | 8 |
| Curriculum link | 7 |
| Assessments | 8 |
| Homework assignments | 2 |

We also identified if the resource included any supplemental material that could serve as instructional planning resource. Table 2 depicts the kinds and amounts of supplemental materials identified. Lesson plans refer to structured goal and objectives provided to teachers for a specific day's topic. Learning modules are organized collections of content that can range from a single lesson (i.e. a week-long activity with the goal of learning a single concept) to an entire curriculum (sets of week-long activities encompassing interrelated concepts, principles, procedures and problem-solving at for a specific course or grade level). Tutorials refer to instructions, in text or video form, which provide a teacher with a guide on how to integrate a particular resource into the classroom or how to use a particular resource. Activities refer to in-class interactions designed to teach students through doing. Activities are generally short term and cover a single concept. Sample code refers to code provided, by the resource, for a particular programming language. The goal of sample code is to teach by example. Curriculum links refer to ties made from the resource to a standard and accepted curriculum. Assessments refer to quizzes and tests that are used to gauge learners' progress. Assessments are generally monitored by the resource and results are provided to the teacher. Homework assignments refer to work that is given outside of the classroom to reinforce concepts learned in the classroom.

DISCUSSION AND CONCLUSION

Our research to date provides an in depth view of (a) available web-based STEM resources, (b) primary tools used to teach STEM and (c) supplemental instructional tools used by teachers to integrate the primary instructional tools. From the graphs and statistics listed in this paper, some

trends can be suggested. As more of an observational note, independent STEM resources are very difficult to find. Though there are several resource portals, many of them have either the same information or outdated and abandoned resources. Resources not found in portals are difficult to find. For instance, they had to be encountered through the right combination of search terms. This led to an abundance of unusable resources that had to be quickly sifted through and discarded. Central, up to date, resource hubs are needed to make finding computational thinking resources easier for teachers to find.

Though there were several K-12 resources, many of them were more geared towards the high school level. Very few resources were designed strictly for use in the K-8 range. Most of these resources combine multiple branches of STEM. In fact, math and engineering resources are significantly more likely to exist in combination with other STEM resources than without. Science resources were the most prevalent of all of the STEM resources.

There are almost 20 more occurrences of supplementary resources than there are of the primary tools. Further analysis shows that simulations are the only significant source of primary instructional tools. Though there is an abundance of simulations at 21 total occurrences, the other primary instructional tools are somewhat lacking. In the future, we will look further into the other primary instructional tools to understand this gap. It is possible that this gap exists due to the nature of STEM. Even though simulations were the most prevalent primary resources, they were the least explained. There were hardly any tutorials or guides on how to use the simulations. This leaves learners guessing at functionality at times.

FUTURE WORK

We are working on creating a compendium of all these resources that will be provided as part of an extended version of the paper. This catalogue will include the following information: (a) name of the website, (b) URL, (c) description of the website, (d) audience for the website such as grade level, (e) particular STEM discipline associated with the website, (f) identification of supplemental materials (e.g., lesson plans) for each of the websites, (g) learning objectives associated with the website, and (h) any evidence of assessment or educational research associated with the materials presented on the website. Any websites created for specific groups (such as females) will also be noted. Finally, we will also identify the scope of the instructional planning supplemental resources such as whether the learning resources consist of comprehensive curriculum for a course length experience, lesson plan providing specific guidance to instructors, or short learning activity that can supplement a class [7]. In resources that have limited supplemental materials, we will also explore the concept of communities. Often, lesson plans and activities are posted on forums and websites not linked to the respective resource. We will identify and qualify the communities used to teach these resources.

Work in Progress: An Intelligent Tutoring System for Improving Student Learning in a Sophomore Engineering Dynamics Course

Yongqing Guo and Ning Fang
Department of Engineering Education
Utah State University
Logan, Utah, USA
ning.fang@usu.edu

Abstract—This paper presents our ongoing efforts toward developing an Intelligent Tutoring System (ITS) to improve student learning in a sophomore engineering dynamics course. An ITS module was developed to guide students applying the Principle of Work and Energy to solve particle dynamics problems. Pre-post tests, each including six technical questions, were administered to 74 engineering undergraduates who took a dynamics course in a recent semester. The assessment results show that the developed ITS module helps students master dynamics concepts and associated calculations.

Keywords: *Intelligent tutoring system; engineering dynamics; assessment; student learning*

I. INTRODUCTION

Engineering dynamics is a high-enrollment, high-impact, core course that nearly all mechanical, civil, aerospace, and biomedical engineering students are required to take. This sophomore gateway course covers a broad spectrum of foundational concepts and principles and is a fundamental building block for many advanced studies in subsequent courses. However, many students fail dynamics. In the standard Fundamentals of Engineering examination in 2009, the national average score on the dynamics exam was 53% [1]. In a recent survey conducted at Utah State University, students were asked to share their perspectives about the dynamics course. More than 60% of the students surveyed used phrases such as “much harder than statics,” “extremely difficult,” “very challenging,” and “I am afraid of it.”

An Intelligent Tutoring System (ITS) is an innovative learning tool that receives growing attention in the engineering education community [2]. In the ITS, students solve technical problems with the guidance of a virtual tutor. Students can ask the virtual tutor questions or request hints on what to do next during problem solving, similar to what occurs in a real classroom environment where students ask a human tutor questions or request hints. Research evidence [e.g., 2, 3] has shown that the ITS can significantly improve student learning, especially in large classes where instructor-student interaction and one-on-one tutoring time are limited due to class size. The ITS also enables students to learn anytime (24/365), anywhere (with access to Internet), and at their own pace.

The authors of this paper have performed an extensive literature review using a variety of popular databases, including the FIE conference proceedings (1995-2011). The results showed that all the existing ITSs (e.g., Cycle-Talk, Genetics Tutors, and Politeness Tutor [3]) were developed for courses such as computer-aided modeling and design, forensic biology, circuit analysis, mathematics, and physics. No ITS was developed for any engineering dynamics courses.

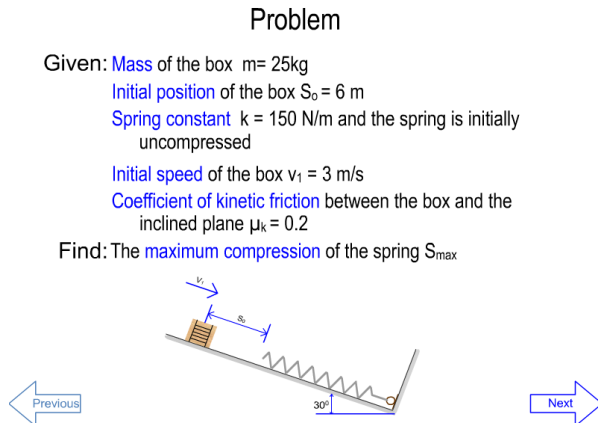

This study is the first attempt to develop and assess an online ITS for an engineering dynamics course. As a pilot study, we have developed an ITS module to help students learn how to apply the Principle of Work and Energy to solve particle dynamics problems. The ITS module was implemented in a dynamics course taught by the second author of this paper. However, no control group was involved in this pilot study yet. Student learning gains were calculated through pre-post tests that each included six technical questions. The central assessment question is: To what extent did the developed ITS module help students learn how to apply the Principle of Work and Energy to solve particle dynamics problems?

II. DEVELOPMENT OF AN ITS FOR ENGINEERING DYNAMICS

The ITS module was developed using the Cognitive Tutor Authoring Tools (CTAT) [3], one of the most popular tutor authoring software developed at Carnegie Mellon University for authoring tutor behavior. The CTAT provides a set of specialized tutoring widgets to create computer graphical user interfaces (GUIs) in Adobe Flash in a drag-and-drop manner. In the present study, the CTAT was employed to create example-tracing tutors. This type of tutors can be created quickly without programming, but requires problem-specific authoring. An author first demonstrates (to the virtual tutor) example solutions, generalizes the recorded examples, and annotates them with hints and feedback messages [3].

The ITS module developed from the present study contains a set of hints carefully designed to provide students step-by-step guidance, ranging from drawing a free-body diagram to solving mathematical equations. Thus, students not only understand what dynamics principle and associated equations should be used, but why and how they are used. Fig. 1 shows one of the computer GUIs of the ITS module, which guides

students through each of the following steps: 1) draw a free-body diagram; 2) calculate the total work done; 3) determine the initial and final kinetic energy; and 4) apply the Principle of Work and Energy to finally solve the problem. The ITS module contains a total of 13 hints that were developed based on students' common misconceptions. As an example, Fig. 2 shows one hint to help students calculate the work done by weight. The hint states, "The displacement is determined from its initial position, so it is $S_0 + S_{\max}$, not S_{\max} ."

• Work done by weight : $W_w =$

A. $mg(S_0 + S_{\max})\sin 30^\circ$ C. $mgS_{\max}\sin 30^\circ$
B. $mg(S_0 + S_{\max})\cos 30^\circ$ D. $mgS_{\max}\cos 30^\circ$

• Work done by the frictional force : $W_f =$

A. $f(S_0 + S_{\max})$ C. $-f(S_0 + S_{\max})$
B. $f(S_0 + S_{\max})\cos 30^\circ$ D. $-f(S_0 + S_{\max})\cos 30^\circ$

• Work done by the spring force : $W_s =$

A. $\frac{1}{2}k(S_0 + S_{\max})^2$ C. $-\frac{1}{2}k(S_0 + S_{\max})^2$
B. $\frac{1}{2}kS_{\max}^2$ D. $-\frac{1}{2}kS_{\max}^2$

• Initial and final kinetic energy : $T_1 \& T_2 =$

A. $T_1 = mv_1$, $T_2 = 0$ C. $T_1 = \frac{1}{2}mv_1^2$, $T_2 = T_1$
B. $T_1 = mv_1$, $T_2 = T_1$ D. $T_1 = \frac{1}{2}mv_1^2$, $T_2 = 0$

The displacement is determined from its initial position, so it is $S_0 + S_{\max}$, not S_{\max} .

Previous Next Done

Figure 2. An example hint.

III. DATA COLLECTION AND ASSESSMENT RESULTS

The developed ITS module was recently implemented in an engineering dynamics course. Pre-post tests were administered to 74 undergraduates, the majority of whom were from either mechanical and aerospace engineering majors, or civil and environmental engineering majors. After the pre-test, the module was uploaded to a website that students had access to, so students could run the module 24/7.

The pre-test and post-test each included six technical questions. Questions No. 1 to 5 involved one or two dynamics concepts and associated calculations. Question No. 6 required that students "synthesize" all they had learned in the previous steps to determine the final answer to the problem. Student learning gains were calculated for each student by using:

$$\text{Learning gain} = \frac{\text{Post-test score (\%)} - \text{Pre-test score (\%)}}{100 (\%) - \text{Pre-test score (\%)}}$$

Fig. 3 shows the learning gain of each student. The majority of students had positive learning gains varying from 33% to 100%. Eight (out of 74) students had negative learning gains because their post-test scores were lower than their pre-test scores. The class-average learning gain was 39%.

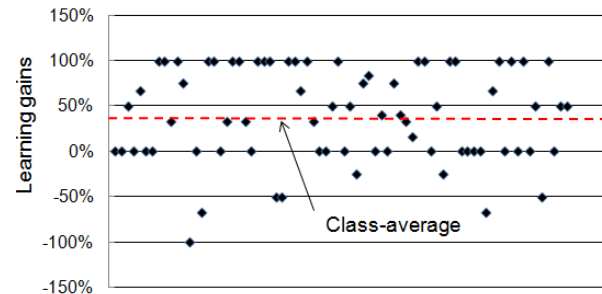

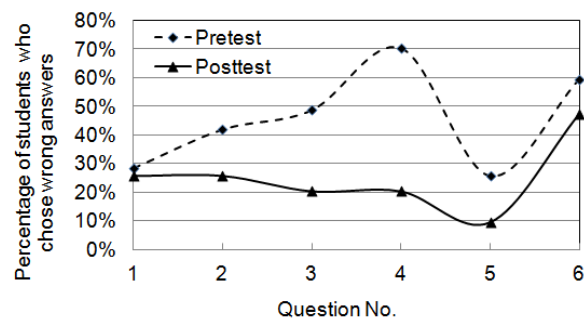

Fig. 4 shows the percentage of students who chose wrong answers for each of the six technical questions used in the pre-post tests. Except for Question No. 1, the ITS module improved student learning on all questions (Nos. 2-5) that involved one or two concepts and associated calculations. However, it is still a challenge to use ITS to improve students' skills for knowledge synthesis (Question No. 6).

IV. CONCLUSIONS

An ITS module was developed to help students learn how to apply an important dynamics principle to solve problems. The assessment results show that the ITS module helps students master dynamics concepts and associated calculations.

Abstract—Society's dependency on information technology has drastically outpaced educational curricula and the opportunities that universities and higher education institutes provide to students from both technical (e.g., computer engineering, computer science) and non-technical majors. To increase the opportunities for all students to learn how protect themselves as individuals and others as professionals from numerous cyber threats the focus of this work is to identify gaps in engineering curricula and present novel approaches to fulfill the growing and diverse needs of cyber security education.

The overall objective of this paper is to make security education accessible, relevant, and tangible across educational curricula, as well as to provide the framework to extend these efforts beyond university classrooms and into community colleges and high schools. While the predominant focus, research, and innovative practices in the area of cyber security have focused on technical students at the university level, this work instead concentrates on the demographic of students that desire to learn about cyber security without having to major in computer engineering, for example. In this paper we present a three-tiered framework that provides breadth and depth to security education across multiple education levels. This all-encompassing framework for security education includes providing (1) formal literacy-based training for students of all backgrounds, (2) inquiry-based learning through security- and technically-focused student groups and activities, and (3) classical technical-based initiatives. For each of these respective areas, previous research and efforts are discussed as well as the innovative practices that we have developed to address identified educational gaps.

Index Terms—security education; security literacy; inquiry-based learning;

I. INTRODUCTION

As peoples' lives and careers have become increasingly reliant on computers and the Internet, terms like "cyber attack," "hacktivism," "phishing," and "malware infection" have entered into the national lexicon and, rightfully so, as these undesirable events have become a part of everyday life for many. This dependency on information technology has drastically outpaced educational curricula and the opportunities that universities and higher education institutes provide to students from both technical and non-technical majors. To increase the opportunities for all students to learn how to protect themselves as individuals and others as professionals from numerous computer- and network-based threats, this work identifies gaps in both institutional and engineering curricula and presents novel approaches to fulfill the growing and diverse needs of cyber security education.

On one end of the spectrum, there exists an enormous gap between the diversity of students from both technical and non-

technical backgrounds that are interested in learning practical computer security knowledge and the courses or organized opportunities formally offered to students. If addressed at all, this gap is often filled with top-10 tips, advice lists, and security awareness campaigns. In this respect, as educators, we collectively need to move beyond promoting security awareness and begin teaching computer security literacy and best practices that provide context for students, enabling comprehension, application, and analysis of this material. On the other end of the spectrum, students of technical backgrounds are often afforded a limited set of course options that focus directly on computer security topics and many of these courses are only available as junior or senior electives. While fundamental aspects of security are often addressed as part of a general computer engineering or computer science curricula, often these topics are not covered in sufficient depth for students to achieve higher levels of cognitive learning. Thus for a large demographic of both technical and non-technically focused students, there are significant and unaddressed educational needs.

To address the mounting cyber crime epidemic, which is now fast approaching illegal drug trade in cost to the world economy [16], a wide range of students must be engaged and this broad engagement cannot be completed with limited awareness campaign or narrowly focused technical curricula. The overall objective of this paper is to make security education accessible, relevant, and tangible across educational curricula, as well as to provide the framework to extend these efforts beyond university classrooms and into community colleges and high schools. While the predominant focus, research, and innovative practices in the area of cyber security have focused on technical students at the university level, this work instead concentrates on the demographic of students that desire to learn about cyber security without having to major in computer engineering, for example. In this paper we present a three-tiered framework that provides breadth and depth to security education across multiple educational levels. This all-encompassing framework for security education includes providing (1) formal literacy-based training for students of all backgrounds, (2) inquiry-based learning through security- and technically-focused student groups and activities, and (3) classical technical-based initiatives. For each of these respective areas, previous research and efforts are discussed as well as the innovative practices that we have developed to address identified educational gaps.

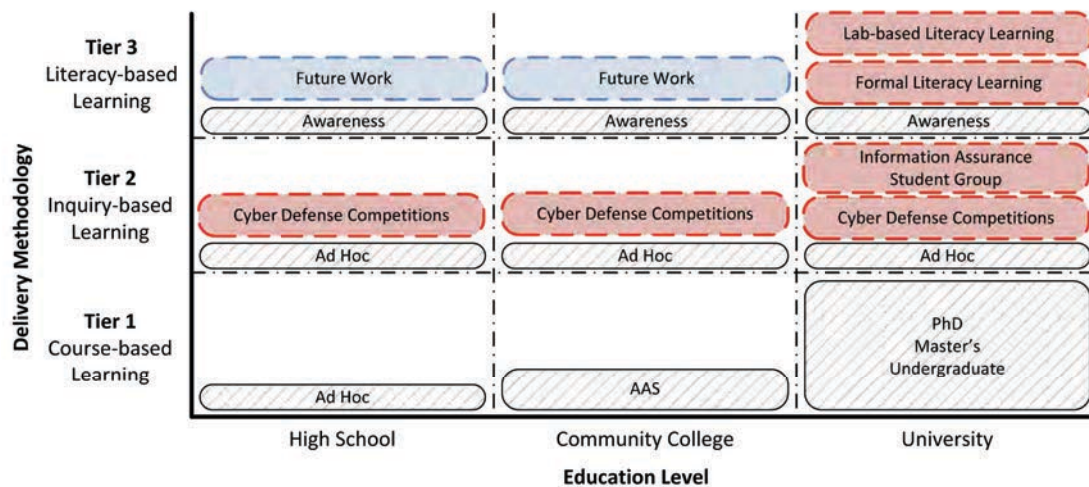

Fig. 1. Gap Detection for Cyber Security Education

II. GAP DETECTION

The remainder of the paper is organized as follows. Section II provides a gap assessment in current security education. Section III provides a literature review for the predominant body of security education research and innovation. Sections IV and V present innovative approaches to addressing the identified gaps through inquiry- and literacy-based learning, respectively. Finally, Section VI discusses conclusions drawn from this work.

As is often the case in the world of technology, innovation tends to out-pace security. The same general statement is true of university curricula and the collective efforts of security educators, researchers, and professionals in respect to addressing the educational needs of their respective communities. While positive advancements have been made in select areas, the broad analysis of security education opportunities afforded to all students presented in this section highlights that there is much work to be done. In order to truly affect change in the way students view and understand computer security, it is our belief as engineering educators that solutions must encompass more than just technically-focused students and instead target a broad audience. This section will explore the current state of computer security education taught at the university, community college, and high school levels. The three-tiered approach presented for the delivery methods of educational content will serve as the organization for the remainder of the paper.

Figure 1 presents a two-dimensional assessment of current security education efforts and innovations. The x-axis denotes the education level (i.e., High School, Community College, University) and the y-axis represents the methodology used to deliver educational content. Populated within the array shown in Figure 1 are past and current security educational efforts (denoted by diagonal slashes) and the current gaps that are being addressed (denoted a solid blue shading) and future work

being proposed (denoted a solid blue shading) at Iowa State University.

Each identified tier and corresponding educational level represents different motives and learning objectives for each of these respective bodies of students. The learning motives for students that gravitate towards the stated delivery methodologies (course-based, inquiry-based, literacy-based) are as follows:

Tier 1 - Course-based Learning - The focus of course-based learning at both the university and community college levels is to provide students with the educational foundation and security skill-set with which to enter the cyber security workforce and/or continue learning through advanced degrees. High school students that are fortunate enough to be afforded the opportunity to study security-focused classes often have the desire to continue the pursuit of technical and security focused degrees and employment opportunities after graduation.

Tier 2 - Inquiry-based Learning - Inquiry-based learning [3] allows students to explore cyber security issues and resolve problems by reviewing learning materials about cyber security, evaluating what they know, seeking out additional information about specific problems, and coming to a conclusion or resolution based upon evidence they have gathered. The focus of all activities is on critical and logical thinking, as well as exploration of creative and alternative solutions [15]. It is an effective way to shape students' ability to apply their knowledge, search for new information, and critically synthesize material. Students studying cyber security in this manner gain valuable hands-on experience in mitigating cyber security threats and develop a valuable understanding of practical cyber security knowledge and skills.

Inquiry-based learning provides two types of opportunities for students. First, since computer-related courses are nearly non-existent in high schools across the U.S., it allows high [28] school students a non-threatening environment to

explore the topic of computer security without the restrictions and pressures of a graded course. Secondly, for community college and university students, it provides a way to engage in practical and hands-on experience that is either augmented by students' current coursework or in lieu of any computer security coursework. The open-ended nature of inquiry-based activities enables students of all backgrounds and knowledge levels to explore and learn at their own pace and as well as in teams.

Tier 3 - Literacy-based Learning - Students desiring to pursue literacy-based learning options are in search of practical computer security knowledge. Whether these students have technical or non-technical backgrounds, the goal of these students is to gain a firm understanding of security concepts, the identification of security threats, the purpose, strengths, and weaknesses of security mechanisms, and to develop confidence in the execution of security best practices.

These three delivery methods presented in Figure 1 provide a range of opportunities for students of all backgrounds to explore and learn about computer security. Although each of these methods is necessary, individually, none are sufficient to truly address both the educational desires and needs of all students.

III. TIER ONE: COURSE-BASED LEARNING

The predominant focus of current security education is taught in traditional classroom and lab settings by means of course-based learning. The programs or degrees that facilitate these security-focused courses are typically housed in computer engineering or computer science departments and often require that students first pass a number of technical prerequisites. However, as is argued in this paper, this traditional delivery method and its corresponding restrictions precludes students from non-technical backgrounds the opportunity to learn about computer security in a formal setting. Past research, innovation, and both course and curriculum development have focused heavily on course-based learning. This section presents a brief review of these works to better understand the current climate of computer security education across multiple education levels.

As seen in Figure 1, course-based and security-focused learning initiatives have been primarily addressed at the university level through multiple levels of degrees. Efforts such as [1] have created a two-semester program that enables undergraduate students to learn about the technical components of cyber security through focused learning modules and laboratory environments. Similarly, Hazeyama et al. proposed a learning environment for software security education [10]. Others have sought to develop lab environments [7], simulations [17], analysis frameworks [18], [19], and reconfigurable course modules [2], [27] to facilitate technical learning of specific and hands-on cyber security topics. More novel approaches include the use of Second Life [24], hacking competitions [4] and capstone design courses [9].

Technical security education is also becoming a more common component of community college curricula [8]. National

Science Foundation sponsored efforts like CyberWatch [6] are committed to improving cyber security education and have a primary focus on community colleges by providing support for curriculum development, faculty professional development, student development, career pathways, and public awareness. Opportunities are also provided to high school students by means of structured cyber defense games [5] and ad hoc courses or extra curricular activities.

Because the predominate bulk of the cyber security work force is technical in nature, the educational opportunities that support this career path have followed a similar technical emphasis. Although technical course-based initiatives are necessary, they are not sufficient to address current cyber security problems as they provide little opportunities for students of non-technical majors or for those who do not wish to pursue a career in cyber security with an opportunity to learn. As a result, an objective of this paper is to address the gaps in Figure 1 by presenting alternative methods for students to learn about cyber security.

IV. TIER TWO: INQUIRY-BASED LEARNING

Inquiry-based learning is the backbone of cyber security outreach programs offered by Iowa State University. In our implementation of inquiry-based learning in cyber security, students are given access to learning materials, as well as a set of questions to explore and open problems to solve. They are then asked to provide solutions to challenges presented to them based upon their own exploration, additional resources they find, and experimentation. The materials provided focus on security-based concepts for designing, implementing, configuring, securing, and protecting a network, its servers, and end users from a diverse set of realistic threats.

At Iowa State University, we use inquiry-based learning as the primary delivery method of cyber security learning for high school [13], [20], [23], community college [21], and four-year university students [12], [14]. The most popular inquiry-based learning activities are the four annual cyber defense competitions (CDCs) that we host each year. In a CDC, students design, configure, and maintain a set of servers and a network in a secure manner prior to the competition. Such efforts are performed through inquiry-based learning and not by means of formal security courses. The culmination of this learning is a day-long competition in which students work to prevent security breaches and to remediate any exploits that occur at the hands of hackers (i.e. grad students) while maintaining a fully-functional network for their end users.

The experience participating in a CDC provides valuable hands-on experience with cyber security that goes beyond anything a student could learn in a classroom. For both the high school students and the college undergraduate students that do not have access to formal cyber security education, these events give them experience in an area of which they had little or no previous knowledge. For students with previous coursework experience in cyber security, a CDC allows them to move beyond what they have learned in the classroom by putting theoretical concepts into practice.

In addition to the CDCs, Iowa State University has an Information Assurance Student Group (IASG) [22] for undergraduate students in any major who are interested in cyber security. The need for such a group was spurred by the lack of security courses offered for lower-division undergraduate students. While upper-division undergraduate students may take the offered graduate courses in Information Assurance (IA), the lower division undergraduate students do not have enough hardware, operating systems, or networking background to fulfill the prerequisites to enroll in these graduate courses. Therefore, for many lower-division undergraduate students, their enthusiasm and interest in cyber security are “put on hold for two to three years while they work through the general engineering curriculum that would allow them to take formal IA and computer/network security courses in their senior year. For those students who have interest in cyber security, these two to three years of engineering foundation building present significant obstacles and disincentivizes them to continue to pursue IA as a focus. The creation of IASG was one answer to keeping students who desire to pursue careers in cyber security engaged during their undergraduate coursework. IASG now has a membership of more than 130 students who attend weekly meetings in which upper-division undergraduate and graduate students deliver content and provide hands-on activities in an inquiry-based learning environment. Meetings are a combination of lecture content, demonstrations, discussions and hands-on activities where the students can explore and create their own solutions to cyber security topics and problems for a given weekly topic.

As illustrated in the gap analysis presented in Figure 1, the use of inquiry-based learning and CDCs affords students two valuable opportunities. First, for high school students who have no access to computer-related courses, it provides an opportunity to explore cyber security as an educational path in a non-threatening environment. Second, it allows students who are studying cyber security, at the high school, community college, or four-year level, to experience hands-on, practical applications of theoretical security topics. For those students in colleges and universities that do not have access to formal courses due to lack of prerequisites, such as lower-level undergraduates, it provides an avenue to keep these students engaged and excited about pursuing a career in cyber security.

V. TIER THREE: LITERACY-BASED LEARNING

For students of all education levels, the most immediate and tangible sources with which to learn about practical computer security knowledge is through the formulation of top-ten lists [25], awareness campaigns [26], and disparate collections of websites and online articles. As a result and as depicted in Figure 1, these past efforts have predominantly focused on providing general awareness of many cyber security issues. While awareness is undoubtedly important, simply being aware of a problem is inherently limiting. Even though tip lists and *awareness* campaigns provide knowledge, they lack the context and depth for students to achieve comprehension, application, or analysis of the material. The goal of literacy-based

learning is to elevate a student's knowledge beyond that of simply being aware of the problem so that students and future professionals are able to successfully consider their actions and new events in the context of security and subsequently make informed decisions as to what they should or should not do to protect their personal and private information as well as safeguard their reputations.

At Iowa State University, we have addressed this gap in security education by developing a course entitled “Introduction to Computer Security Literacy.” The specific purpose of this 8-week, 16-lecture course is to provide both students from *technical and non-technical* majors with the opportunity to formally learn about the many facets of practical computer security knowledge. An emphasis is placed on technical and non-technical majors because previous research on this topic has discovered that despite the perceived advantage of students from technical majors (i.e., computer engineering, computer science, management information systems), students from non-technical majors are, on average, on an equal playing field with their non-technical cohorts when it comes to practical cyber security knowledge [11].

Because the goal of practical computer security is to provide security context to students concerning activities they already engage in on their computer and/or the Internet, the course topics and objectives of the corresponding lectures strive to keep the content focused and at a tangible level for all to learn. Below are the course topics covered and a brief description of the learning outcomes for each:

- **National Cyber Security** Understand our society's and nation's dependence and reliance computer computers, networks and security.
- **Password Threats** Identify and state the threats, methods, and corresponding motivations of how attackers and malware learn passwords.
- **Password Best Practice** Recognize the importance of having a secret, strong and unique passwords in the context of password threats.
- **Cryptography** Understand the purpose, strengths, and limitations of cryptography, especially as found in wireless networks and HTTPS.
- **Malware** Conceptually grasp how malware infects a computer, how it propagates and the objectives of malware once it established a foothold.
- **Defense-in-Depth** Learn how the coupling of firewalls, antivirus software, data backup, patches, and user education provide security protection as well as the purpose, strengths and limitations of each individual component.
- **Surfing the Web** Discover the many web-based threats and resulting security mechanisms that focus on web-based content.
- **Social Engineering/phishing** Learn and recognize social engineering techniques and how these attacks are manifested in emails, ads, and social networking content. Student further learn the skill of dissecting URLs in the context of security.
- **Wireless Networks** Through demonstrations, student are

presented with the threat of sniffing and subsequent mitigation techniques for both users and administrators of wireless networks.

- **Social Networking** Recognize that content is not truly private as well as understand the benefits and consequences of public information sharing.

Based on these high-level topics, the need this literacy-based course addresses is answering the question “why?” for students and to give students the proper context to better understand the purpose, strengths, and limitations of security mechanisms and best practices as well as the manifestation and motivation of the many threats that lurk on the Internet. To achieve this overarching goal, the stated learning outcomes of the course are:

- Define computer security terms and mechanisms
- Describe fundamental security concepts
- State computer security best practices
- Describe the strengths, weaknesses and limitations of security mechanisms and concepts
- Give examples of common security threats, threat sources and threat motivations
- Explain their role in protecting their own physical and non-physical computing assets
- Discuss current events topics and read security articles in the popular press
- Assess computing actions in the context of security

What makes this course particularly effective at accomplishing its stated course outcomes is that students have the opportunity to apply the knowledge learned in lecture immediately when they leave the classroom and begin to interact with their computing devices. Furthermore, this constant interaction with technology increases the students repetition leading to the goal of synthesis so that students can act in a safe manner when presented with a novel situation. Lectures are also incorporated with current event topics so that students can see a direct connection to what they are learning in the classroom, often with an event that has occurred within days of the presentation of the lecture content.

Having taught this class 10 times to over 250 students, the gap that this literacy-based course addresses is clear. There exists a vast amount of students that heavily rely on computers and the Internet and the number of opportunities that they can go forth and learn how to use these technologies safely. Universities and community colleges provide a number of literacy-based learning opportunities in the areas of financial planning, health and wellness, research methodology and utilizing a library. It is time that academic curricula evolve with technology and afford students the same type of opportunities to learn practical computer security knowledge.

A. Lab-based Literacy Learning

Throughout the development and delivery of the Introduction to Computer Security Literacy, it has become apparent that the effectiveness of this literacy-based course would be greatly enhanced by an accompanying lab. As a result, we are

currently developing lab-based components to accompany the previously discussed course topics to provide students with hands-on experience and to increase their understanding of threats, security concepts, and how to better understand and interact with their computing environment in the context of security. The following topics and descriptions summarize the future work in this area and the lab-components that are being developed:

- **Lab 1: How the Internet Works** - Through the use of tools and commands such as `ipconfig/ifconfig`, `ping`, `tracert/traceroute`, `nslookup`, and `wget`, students will discover the very basic workings of the Internet including IP addressing and routing as well as the purpose of the Domain Name Services. The synthesis of these concepts will exemplified through the use of browsing the web. The objective of this introductory lab is to develop the foundation of concepts and use of tools to provide context for future lectures and labs.
- **Lab 2: Passwords** - To better understand password threats and reasoning behind choosing strong and unique passwords, student will learn how to create password hashes and subsequently use password cracking tools to discover the limitations of password hashes.
- **Lab 3: Cryptography** - Building on cryptography lecture, student will get hands-on experience with both symmetric key and public-key cryptography in order to understand the purpose, strengths and limitations of cryptography in modern day computing.
- **Lab 4: Firewalls, backup, antivirus, patches** - Using their own laptop computer, students will discover the settings and security best practices to keep their own computer environments current, secure, patched, backed up.
- **Lab 5: Web browser technologies** - In addition to features that are inherent to a web browser (saved passwords, HTTP, private browsing, cookies, cache, etc.), student will explore the functionality and purpose of a number of popular web browser add-ons such as link scanners, ad blockers, and script blockers.
- **Lab 6: Wireless security** - Student will learn first-hand how to configure a wireless router as well as the perils of sending data over an unencrypted network connection. Further, building on the tools learned in Lab 1, the concept of Network Address Translation will be discovered and discussed.
- **Lab 7: Social Networking** - By means of course-registered social networking accounts, students will gain a working knowledge of the implications of various social networking platforms. Students will further perform a public-data analysis of themselves using popular search methods.

In addition, as shown in Figure 1, we have also engaged in preliminary efforts to expand literacy-based learning in both community college and high schools. The current challenge exists in finding engineering faculty and/or teachers

that have a deep understand of security, stay abreast of current security issues, and are able to express such knowledge to a diversity of non-technical audiences.

VI. CONCLUSION

As a result of society's dependence on information technology coupled with a lack of focus on security education, it is our strong belief that the educational gaps identified in this work need to be addressed by security practitioners, educators and researchers. While there will always be a need for course-based learning methodologies targeted at technically-focused students, this paper provides evidence that both literacy-based and inquiry-based learning methods can effectively address current security shortcomings. While course-based education provides a direct route for those highly interested in cyber security, inquiry- and literacy-based learning allow many students who may have never considered cyber security as a career an opportunity to explore this career track. Providing less formal inquiry-based learning provides students an opportunity to explore cyber security as a career option and evaluate whether it holds interest for them. Furthermore, students who participate in literacy-based learning can also be inspired to pursue the topic of cyber security further through inquiry-based or course-based learning methods. Even if the students who participate in inquiry- or literacy-based learning do not select to formally pursue cyber security as a career option, these students have broadened their knowledge of cyber security and provide much needed security-conscious employees, whether as business professionals, software programmers, or design engineers.

ABSTRACT

This paper presents the results of a comparison study using the Visual VIPERS interface, a graphical interface which can be applied as an educational tool for novice computer vision students. The goal of the study was to evaluate the change in usability of the interface after the addition of a monitor tool, which can be used to view intermediate image results at specific stages of an algorithm. A user study was conducted in which participants were asked to find an error in a pre-assembled algorithm. Results indicate that participants using the older version of the interface (with no monitor tool) took, on average, less time to find the error than participants who used the monitor tool. However, interview responses indicated a greater level of understanding of the algorithm from participants who used the monitor tool. Interview responses also demonstrated a clear desire from users of the old interface for the addition of a debugging tool (such as the newly introduced monitor tool). Our belief is that participants using the monitor tool performed a more thorough search of the algorithm, and thus gained a greater understanding of how the algorithm operated, while attempting to determine the source of the error.

Index Terms: Education, Graphical User Interface, Computer Vision.

I. INTRODUCTION

Computer Vision is an exciting and information rich field. Human motion analysis, object identification, remote sensing, technical diagnostics, autonomous vehicle guidance, biomedical imaging (2-D, 3-D, and 4-D) and automatic surveillance systems [1] are a few of its applications.

The main goal of this field is to duplicate or mimic the human visual system with algorithms that understand images by extracting information from an image for a particular purpose, such as controlling an autonomous vehicle.

The prevalence of computer vision in areas of research and development as well as in corporate and consumer technologies, has created a wide range of career opportunities for engineers, computer scientists, and for other types of experts, such as psychologists. As a result, the amount of computer vision courses offered in universities is growing. However, learning computer vision algorithms can be very challenging for students new to the field. There are many well written and clear textbooks in this area, and qualified professors to teach the material. Nonetheless, education in the field of

computer vision suffers from a lack of alternative teaching tools. This underlies the importance of products such as Visual VIPERS, a graphical user interface implementation for the Video and Image Processing Environment for Real-time Systems (VIPERS) C++ library, designed for use by students learning computer vision.

Section I-A will discuss challenges faced when studying and teaching computer vision. The remainder of this paper is structured as follows: Section II summarizes work related to education in computer engineering. Section III will give an overview of the Visual VIPERS interface. Section IV introduces the methods of our study. Section V illustrates the results obtained using the Visual VIPERS interface. Section VI provides conclusions and a discussion of possible directions for future work.

A. Challenges of studying computer vision

The field of Computer Vision is exciting and diverse, but it also possesses its own unique challenges. Some challenges of studying and teaching the field of Computer Vision, according to [1] include: Loss of information from 3-D to 2-D, interpretation of images, and noise. The level of prior programming experience acquired by each student also plays a large role in their learning performance. Each of these will be discussed in detail below.

1) *Loss of information from 3-D to 2-D:* When a photograph is captured with a digital camera, one dimension is lost in this process. In other words, a photograph is a 2-D (x - y plane) representation of a 3-D real world environment (X - Y - Z volume). This is a geometric property which can be approximated by a pinhole model. The pinhole model corresponds to projection geometry. In other words, the projection transformations that occur while a camera takes a picture “maps points along rays but does not preserve angles or collinearity” [1]. This means that objects in an image that are close to the camera, may appear similar to objects far from the camera. Therefore, we need some sort of reference point or context to measure the size of objects.

2) *Interpretation of Images:* Humans have no problem interpreting images. We base our interpretation of images on *top-down* and *bottom-up* processing. *Top-down* processes refers to interpreting images based on knowledge we already have about what we are looking at, whereas *bottom-up* processing refers to data-based processing where we base our interpretations on

images of incoming data. The problem is that humans do not just use one or the other means of processing information. Rather, we combine *top-down* and *bottom-up* processing for different scenarios. We make these discussions unconsciously, and as such, it is difficult to develop algorithms that mimic these complex but primitive processes. It has been noted by the Computer Vision community that a "quantitative representation of human perception with scientific basis has been a problem unsolved for a long time" [2].

3) *Noise*: In computer vision, as with more general image analysis fields, noise is regarded as an undesirable by-product of the image capture process, which causes distortions in the image that can obscure the desired relevant information. Noise is most commonly characterized by random variations in the brightness or color of an image. This can lead to reduced quality in measurements obtained from an image using computer vision methods, or in extreme cases (when high amounts of noise are present) can make such measurements impossible. It is important to accurately measure features in images if we aim to interpret an image accurately. However, it is often impossible to completely eliminate the presence of noise. This fact speaks to the necessity of mathematical tools that can manage the uncertainty associated with noise [1].

4) *Programming Experience*: The above points are only a few challenging factors that may intimidate undergraduate students in pursuing and education in this field. For these reasons, alternative teaching tools are in great need for undergraduate students who are interested in the field of computer vision. Typically, computer vision courses are offered as an upper-level undergraduate or graduate level course at most post-secondary institutions. This is due to the technical requirements which often necessitate the need for numerous prerequisites, such as calculus, image processing, data structures, linear algebra, and numerical methods. In many cases, computer vision is taught using a "traditional style", which involves lectures that teach theory and concepts combined with assignments that offer practical experience by asking students to implement specific algorithms in order to complete a given task.

Students new to the field often find that there is a steep learning curve, as they are required to learn a large amount of theory, combined with specific implementation details for each algorithm. In addition, they must be able to implement these algorithms in the given programming environment required by the course, such as C++ or MATLAB, which in some cases may also be new to them.

Course content in computer vision is inherently visual, thus intuition would suggest that course material should be more approachable than other courses where material is more abstract. However, theoretical concepts and algorithms are often discussed in lectures with little or no demonstrations or exercises. Krotkov from Carnegie Mellon University, Pittsburgh, PA, said in his statement at the 1996 CVPR panel [3]: "As every computer vision scientist knows, it is difficult to understand how a particular algorithm works without actually applying it on various images, using various parameters. It is

hard to convey this experience to the students using only a few images. Even more difficult is trying to demonstrate to the students how algorithms that operate on video sequences perform."

II. RELATED WORK

Teaching computer vision topics should, ideally, be tailored toward the students learning styles. LEGO MINDSTORMS robots were introduced as hands-on educational tools that provided students feedback on effectiveness of using LEGO MINDSTORMS robots [4]. Learning through the senses, as a hands-on teaching style, can have positive results on students. For example, learning while doing something that requires their senses (i.e.: Sight) [4], ensures that the course material is being absorbed on multiple levels. In [4], they used a hands-on approach to learning robotics and embedded systems design. In addition, a hands-on approach is an alternative way to hold the attention of students at the introductory level in computer science and engineering faculties. Barnes [5], suggests that "LEGO MINDSTORMS models are a particularly convenient way to build physical programmable models without having to know anything about hardware". Since this approach uses the RCX processor, students can program in JAVA, a common computing language. Robotics inspired projects can provide students with programming options other than a desktop [6]. Many current and past students would likely agree that hands-on learning is invaluable. The motivation to learn increases when students are able to comprehend the final outcome of all their hard work. The ability to apply one's knowledge towards building robotics is exciting and challenging for student. This motivation and drive, however, is unfortunately curtailed by some practical factors. For example the high cost of robotics-inspired projects in undergraduate computer science departments is not reasonable, at \$5,000 per robotics kit in the early 1990s [6]. Therefore, even though the hands-on approach to learning computer programming is desirable, it is not always the most cost efficient alternative.

As a hands-on approach seems intuitive when learning with robots, a visual approach to algorithm design would seem intuitive for computer vision, given the inherently visual nature of the field. As discussed in section I-A4, this is normally not the case, but there are some cases where visual methods of development have been employed.

The use of image graphs have improved efficiency when searching for desirable rendering parameters for a dataset of medical images [7]. They provide a visual means of representing the data exploration process. An image graph begins when a user accesses a given image. When they change a rendering parameter (i.e.: Color map, rotation, opacity, zoom, sampling, shading) a new version of the image is created. Different image results form the nodes of the graph, while changes in parameters form the edges of the graph. If the user reverses a parameter change and decides to change a different parameter instead, this is depicted by a branch in the graph from the original image. Successive parameter changes form a path in the graph. In this way, the image graph represents a record of

all parameter changes made (and intermediate images created) before arriving at a final result, and also maintains a record of alternative parameter choices that were explored but discarded. This ability to view intermediate steps in development can be very useful for collaborators, enabling them to view the entire development process at a glance and see not only the design choices that were kept, but also those that were abandoned.

Graphical user interfaces designed to aid people in developing computer vision algorithms have received little attention from the computer vision community. According to Lomker et al. [8], building a good computer vision system should be characterized by: ease of use, online parametrization of algorithms, flexible visualization of processing results, simple integration of 3rd party libraries, and rapid prototyping through reuse of existing algorithms. The literature is vast regarding how GUIs work, but the focus is on functionality rather than usability. Little attention seems to be paid to the requirements listed above. Attention is instead focused on aspects such as the number of implemented functions, or increased computational efficiency through parallelization of algorithms. The authors also note that, there seems to be no vision-related graphical environment that has been widely accepted by the vision community, although attempts have been made.

One example of a vision-related graphical environment is VisiQuest, by AccuSoft. VisiQuest is a collection of data and image analysis software tools that allows for fast development of applications regarding imaging tasks for areas like document imaging, photo processing, or medical applications. This visual programming environment gives users access to functions and algorithms simply by the click of a button. Similar systems have been created by MVTec., a manufacturer of machine vision products, which has created ActivVisionTools and HALCON. HALCON has a library of more than 1600 operators for blob analysis, morphology, matching, measuring, identification, and 3-D vision. ActivVisionTools has tools that are based on the HALCON library. These two software products have been used in the semiconductor industry, inspection application, and surveillance systems. The iceWing architecture is used in [8] due to its ability to quickly display intermediate results. In addition it allows for easy and flexible modification of parameters. Regarding the ability to quickly view intermediate results of an algorithm, iceWing enables multiple windows to display results. This system helps in developing and testing algorithms, and it has the ability to build more complex algorithms. iceWing has been used in areas like camera configuration or camera grabbing, gesture recognition, and interactive object learning.

Only one previous attempt was found for the creation of a graphical user interface with the specific goal of aiding students in the design and implementation of computer vision algorithms. This interface, referred to as a visual programming environment for the distributed image processing (VPEDIP), was based on the synchronous data flow (SDF) module [9]. The interface uses a directed data flow graph for the workspace, in which computational elements (i.e. functions) are represented by nodes. Edges connecting the

nodes represent data flow paths. In addition to the workspace, the interface includes a list of icon buttons on the left side, which allow the user to edit and execute their algorithm. The message window and server icons are located on the bottom part of the interface. The message window displays processing and error information, while the server icons indicate the status of servers in the network. While the VPEDIP interface demonstrates a strong attention to computational efficiency and functionality, little or no attention seems to have been paid to evaluating the usability of the interface. This could serve as an example that previous works in the field of interface design for computer vision have focused almost exclusively on the functionality of designed interfaces, and not on usability. This underlies the need for such studies to be performed.

The Visual VIPERS interface is a novel environment for computer vision students to explore algorithms through a modular architecture, where each module instance performs a pre-specified task [10]. This system is ideal for universities and students because it is open source, and it gives students hands on experience building algorithms and visualizing intermediate results. This interface allows for software systems design and prototyping, which is a shift from algorithm development [10]. The Visual VIPERS interface will be described in more detail in the following section.

The primary contribution of this study will be an evaluation of the usability of the Visual VIPERS interface for novice users. We attempt to assess the benefits of providing users with a visual means of interacting with algorithm designs, and thus underscore the need for further advancement in this area (usability evaluation for educational tools).

III. VISUAL VIPERS

One approach to facilitate computer vision education is to develop design tools which allow students to gain more hands-on experience with how computer vision algorithms operate, and how their operation is affected by changing parameters. The Video and Image Processing Environment for Real-time Systems (VIPERS) C++ library is designed for use by students and researchers in the computer vision field. Visual VIPERS is a graphical user interface designed for the VIPERS library, which consists of a modular architecture. The interface provides a user-friendly environment for students studying the development of computer vision algorithms.

Figure 1 presents the Visual VIPERS interface, which allows users to select functions (modules) to include in their algorithm simply by dragging them into the workspace. Any function-specific parameters can be set by selecting the appropriate module in the panel on the right side of the interface. The user can then connect the inputs and outputs of the modules as needed to form a larger algorithm. The interface includes an additional feature, called a monitor. When enabled, the monitor is displayed in a separate window from the rest of the interface, as shown in Figure 2. Using a drop-down menu the user can select a specific module in the workspace that they wish to track with the monitor. When the algorithm is executed, the monitor window will display the output for

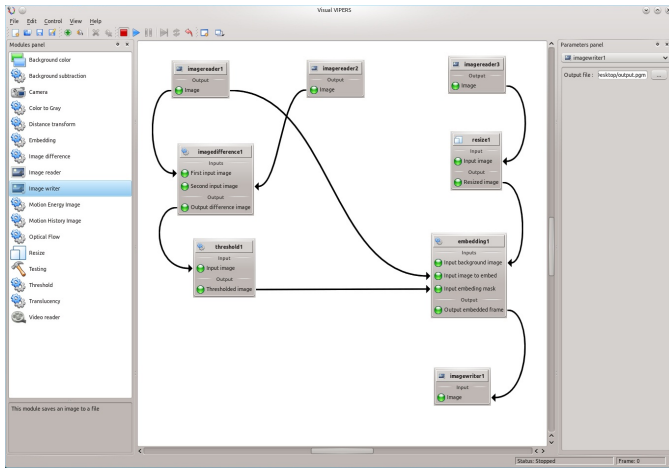

Fig. 1. VIPERS Interface, which illustrates what the participants in this study were presented with.

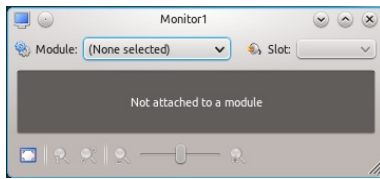

Fig. 2. VIPERS Interface monitor in its initial state, before selecting a module's output image to display.

the selected module. The user can create as many monitor windows as they wish, and assign them to display the output of various modules.

The monitor feature is believed to have greatly increased the usability of the Visual VIPERS interface. It gives students a fast, easy method to view the data flow, in image format, at each stage of their algorithm. This is useful for gaining a greater understanding of the underlying concepts that they are applying. It is also a useful tool for debugging, as it makes it much easier to detect when the output of a particular module is not what was intended. This ability to visualize both the correct and incorrect operation of an algorithm will help students to develop a better intuition both when designing and debugging algorithms.

By using Visual VIPERS to implement computer vision algorithms, students are no longer required to program (and debug) functions in detail before implementing their algorithm. This allows more time for students to experiment with their final algorithm by changing parameters and observing the results. By eliminating the need for advanced programming experience, it is also possible that the prerequisite requirements could be lowered, opening up the course to students who possess little programming skill.

In our study, we will perform a comparison study of two versions of the Visual VIPERS interface: one with the monitor feature enabled, and one with the monitor feature disabled. We hypothesize that the addition of the monitor tool will promote

a greater understanding of how algorithms operate, and will help students to locate errors in an algorithm more quickly. We will validate the usability of the Visual VIPERS interface by assessing the ease of use for students to identify a error in a pre-assembled algorithm. Our assessment is based on a combination of qualitative and quantitative findings.

IV. METHOD

Eleven participants (ten male, one female) were selected from a population of university students enrolled in computer vision and/or engineering program (undergrad or graduate level) at the University of Victoria.

Participants were assigned randomly to either the monitor or no-monitor group. At the start of each session the participant was given an introduction to the important components of the interface. They were then presented with a pre-assembled algorithm which appeared in the workspace of the interface.

The algorithm took as input 3 images. Images A and B were pictures of the same scene, consisting of a desktop with several objects placed on it. The scene in image A possessed one object not present in image B (a whiteout bottle). Image C was a picture of a completely different scene, consisting of a tabletop with two objects placed on it. The purpose of the algorithm was to perform image differencing followed by a threshold on images A and B in order to create a binary mask of the whiteout bottle. This mask was then to be used to copy the whiteout bottle from image A, and paste it into image C. The correct output of the algorithm would therefore be an updated version of image C with the whiteout bottle added to it (See figure 3).

An error was introduced to the algorithm in the form of an incorrect threshold value used to create the binary mask. The threshold was set to a lower value, which resulted in a mask that covered almost the entire image, save for a few sparse pixels. Instead of copying only the whiteout bottle from image A, the mask copied nearly the entire image, which was then used to almost completely overwrite image C. As a result of this error, the output took the appearance of image A, with what appeared to be noise consisting of sparse pixels (See figure 4). These sparse pixels were the few remaining pixels from image C not overwritten by the masking process.

Figure 1 shows the pre-assembled algorithm that the participants of this study were presented with. The purpose of the algorithm was described, and participants were shown the current (incorrect) output of the algorithm as well as what the correct output should look like. Participants were then instructed to identify the error in the algorithm. Subjects were timed during their completion of the task, and each session was recorded using a video camera for further analysis.

After completing the task, participants answered a short verbal questionnaire. Once the final questionnaire was completed, participants were debriefed about the purpose of the study.

V. RESULTS

The completion times for the monitor and no-monitor group can be seen in Table I and a plot of the data can be seen

Fig. 3. Correct output of the algorithm, which participants in this study were presented with.

Fig. 4. Incorrect output of the algorithm, which participants in this study were presented with.

in Figure 5. The no-monitor group appears to have a shorter completion time.

When reviewing interview responses, there was a noticeable overlap observed between the participants' feedback and comments. All participants had positive feedback on their overall experience with the interface, with the lowest rating at 3.5 out of 5, with 1 indicating that they found the interface hard to use and 5 indicating that they found it easy to use.

| Monitor | No-Monitor |
|---------|------------|
| 6 | 3.5 |
| 7 | 4 |
| 8.5 | 5 |
| 12 | 11 |
| 13 | 12 |
| | 12.5 |

TABLE I
TASK COMPLETION TIME (MINUTES).

All participants expressed a high level of satisfaction after testing. Participants had several constructive criticisms for possible interface changes. One common comment was that people had difficulty selecting a linkage line. More specifically, they found it difficult to select a linkage by clicking

it. They expected to be able to modify a linkage simply by dragging and dropping it, which was not the case. Another expectation many of the users had was the lack of help menus or examples of module operations, which are common in other programming environments. Lastly, participants from the no-monitor group expressed a desire for some sort of debugging tool to show intermediate results.

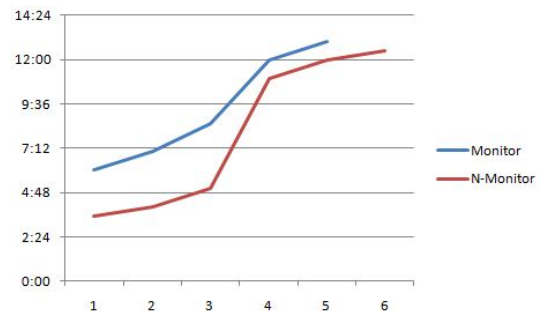

Fig. 5. Participants task completion time (minutes).

VI. DISCUSSION

Results indicate that participants who made use of the monitor tool typically took as much, if not more, time to complete the assigned task than those who did not have access to the monitor tool. This might seem counter-intuitive, given that the monitor tool is intended as an aid to help with debugging of algorithms. However, it was observed that having access to the monitor tool resulted in participants studying the visual output of the algorithm more thoroughly while searching for the error. This is not a reflection on the monitor group's ability to find the error, it simply shows that the time taken to find an error is not necessarily representative of a participant's level of comprehension for the task. The monitor group demonstrated a better comprehension of the algorithm, likely because they spent more time studying it with the aid of the monitor tool. This was noticeable when participants were asked to explain the operation of each stage of the algorithm. We observed that the monitor group was able to express the rationale behind each of the algorithm stages, whereas the no-monitor group simply stated the basic objective of each algorithm stage, with little justification for the necessity of each step.

All participants had a positive reaction to a graphical design interface used to build computer vision algorithms. Many made the comment that they wish they had a tool such as this for algorithm design. It is interesting to note that the no-monitor group commented on the lack of a debugging tool with similar operation to that of the monitor tool. This demonstrated a desire from users of the interface for the ability to scrutinize the algorithm functionality more closely.

Participants were instructed to notify us when they felt confident that they had found the error in the algorithm. However, later we discovered that many participants attempted to fix the error in addition to identifying the error. This may

account for some of the longer times that were observed. A participant may have found the error in 3 minutes, but then had taken up to 13 minutes to fix it before reporting that he was finished. Interview responses indicated that some participants were not certain of the precise nature of the error until they had corrected it. In other words, they needed to fix the error in order to confirm for themselves that they had indeed found the error.

The task itself was tailored toward a novice user. However, due to its simplicity, participants felt that they were unsure of how to rate the entire interface. This is because the participants felt that they had not been sufficiently exposed to the VIPERS interface in terms of its functionality. Our motivation for the simplistic algorithm was based on the fact that we did not want an error which was so complex that it required a significant amount of background knowledge in computer vision in order to find it.

Lastly, we felt that recording interactions with the interface would have been useful for allowing us to realize exactly how participants made use of the interface and its tools. For example, we observed one participant in the no-monitor group reconnecting modules to create additional image outputs. Essentially, this allowed the participant to simulate a debugging tool such as the monitor. In this way, we may have discovered discrepancies between what participants said they did, and what they actually did during the study. It would be interesting to see if the monitor group interacted with the interface differently than the no-monitor group. We felt that the interview questionnaire may not have revealed these interactions if they were present.

VII. CONCLUSION

In this study a comparison was done between two versions of the Visual VIPERS interface. The first version possessed a monitor tool which participants used to view intermediate results of a pre-build algorithm. The second was an older version of the interface, which did not have the monitor tool. A user study was performed, in which participants were asked to find a error in a pre-built algorithm using one of the two interface versions. We found that there was a noticeable difference between the two groups in terms of the time taken to complete the requested task. The no-monitor group had an average completion time of 9.3 minutes (st.dev.=3.07) while the no-monitor groups took an average of 7.1 minutes (st.dev.=4.07). We feel this difference may be due to the monitor group using the monitor tool to do a more thorough search for the error. Based on interview questions all participants gave positive feedback regarding their overall experience with the interface.

Work in Progress: Building Bridges in Our Backyards:

Engineering, Service Learning, and Our Elder Neighbors

Lynn Andrea Stein and Caitrin Lynch
Franklin W. Olin College of Engineering
Needham, MA USA
las@olin.edu caitrin.lynn@olin.edu

Abstract—A novel partnership with community organizations serving older adults creates the opportunity for engineering students to practice design in a meaningful and unfamiliar but local service learning context. Students benefit from contextualization and user-centered design lessons typical of foreign design projects. Community members gain significant relationships and pride through these interactions.

Keywords—service learning; engineering design; community

I. BACKGROUND: DESIGNING FOR PEOPLE

Service learning – an increasingly popular approach to engineering design projects – motivates students, connects engineering theory to practice, and attracts diverse populations who may find the human connection more compelling than whiz-bang technology [1][2]. Many recent engineering service learning efforts focus on the needs of the developing world, communities whose experiences and needs typically differ from those of the participants. [3][4]. These experiences have the additional benefits of pushing students to recognize the importance of user needs and context: the field of *appropriate design* takes into account the needs and context in which the solution must work, and not all users and contexts resemble those of the engineering student. Indeed, the very unfamiliarity of the developing-world can be an important and eye-opening catalyst to student learning. Thus, appropriate design projects teach students about engineering, leverage their interest in solving real problems and serving real needs, and motivate engineers to appreciate the importance of a human-centered and contextually informed perspective.

Unfortunately, connecting with user populations in the developing world is often expensive, logistically complicated, and therefore infrequent. Some service learning projects are instead based in local communities, including work with nearby community development organizations [5], partnerships with rehabilitation institutes [6], or engagement with not-for-profit organizations [2]. These experiences provide many of the benefits of appropriate design, though often without the radically different context of the developing world: students can extrapolate from their own needs, desires, and contexts to those of the clients they are serving, leading them to dismiss rather than appreciate the importance of understanding clients.

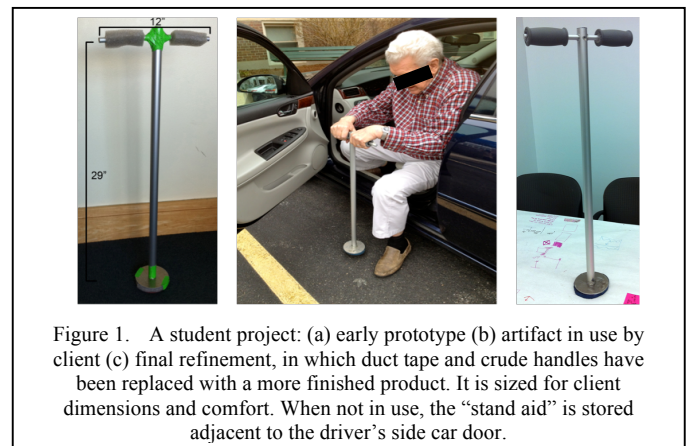

In this paper, we present our experiences in an engineering design service learning course that engages a compelling and unfamiliar population close to home: senior citizens in our own communities. Students in our semester-long project course experience ethnographic and pedagogic benefits of designing

for an unfamiliar population while simultaneously building meaningful and often transformative community connections.

II. ENGINEERING FOR HUMANITY

Engineering for Humanity, an interdisciplinary engineering design and anthropology course at the Franklin W. Olin College of Engineering, is a semester-long partnership between the college and the Councils on Aging in two neighboring communities, Needham and Wellesley Massachusetts. Each year, older community members are recruited to partner with our students in a series of discovery, design, and community-building activities. The Councils on Aging play a crucial role in recruiting and providing ongoing support to our elder partners – beyond what the College and our students might normally undertake – thereby helping to ensure that the experience is a rich and rewarding one for our volunteers.

During the semester, our students and their elder partners engage in a series of activities crafted to bring them together and to create a community. Initially, these include a set of every-day activities, such as grocery shopping, luncheon, or a trip to the movies, in which the community is built and students also learn (through conversation and observation) about difficulties and triumphs of our partners' lives. Next, students synthesize what they have learned into project ideas, refining these briefs into robust, targeted, and manageable projects through consultation with experts and co-design with our elder partners. A series of standard design stages – specification, prototyping, testing, refinement – are accompanied by visits with our partners for feedback, continued learning, and continued community building, including guest speakers and media of mutual interest. By end of semester, several of our

This project received support from the Metrowest Health Foundation and from the Franklin W. Olin College of Engineering Innovation Fund.

volunteers have received specific, custom-designed artifacts intended to solve particular problems (see Figure 1, Table 1). All of our volunteers report increased sense of belonging and value gained from being a part of this community.

III. OUTCOMES

A. Impact on Students:

Beyond the expected benefits of a hands-on engineering design curriculum, this service learning experience is transformative for our students. In end-of-semester surveys collected in the first year of the course, all students expressed an increased understanding of the everyday lives of elders and pointed to specific attitudes or assumptions that changed during the semester. In addition, approximately one-third of students involved expressed a specific change in career trajectory or major activities as a direct result of the class, including one who intends to explore a career in occupational therapy and several others who will focus on issues of aging or work with elders. Evidence in the current – second – course offering suggests that this trend of impact on life plans continues; by the conference we will be able to report on these outcomes as well.

Increases in everyday understanding are evident in student bloggings (a required course activity). For example, course activities provide first-person authentic experiences for students to experience some of the physical disabilities that may be associated with aging. After watching a fellow-student enter a bathroom in a wheelchair, a student reflected: *The door is really heavy to push open plus there is a slight lip to enter.... Sue couldn't get in by herself.... Thinking about it, I've never seen a bathroom door anywhere with a handicapped button. How does society expect people in wheelchairs to be able to get into bathrooms?* After wearing earplugs during a discussion, another student told her elder partner that she had perceived a “barrier” between herself and the rest of the world. Her partner, who experiences a range of physical disabilities related to a neurological illness, noted that this is how he always feels. The student later reflected on opportunities that enable membership rather than alienation for elders.

In another case, a student drew design-related lessons from her observations when observing an elderly couple grocery shopping: *The man was using a cane and following a woman (who I assume was his wife) who was leaning on a cart. The man was helping the woman to push the cart along. That made me think about how carts are designed. They are big and bulky, and relatively hard to maneuver. The man was trying to use a cane and push the cart, which was a real struggle for him. The woman didn't have the strength to push the cart herself. Perhaps we could make a smaller cart that is easier to turn and requires less strength to handle. But then, would an elderly person want to use this special cart, or would that again be a problem because of their desire to remain the same – unchanging over the years and never 'growing old'?*

B. Impact on Community Partners:

Eight months after the completion of the first run of our course, an independent evaluator interviewed the community volunteers from that semester. The evaluation report notes: *All participants looked back upon the program as an extremely positive experience. The elements that remained important to*

TABLE I. ENGINEERING FOR HUMANITY SYLLABUS

| Unit 1: Empathy and Ethnography | | |
|---|--|--|
| Partner interactions: Lunch, Shopping, Every-day activities | Design Activities: Goal-Setting, Contextual Inquiry | Guests/Field Trips: Assistive devices, Occup. therapy |
| Unit II: Lives: From People to Project Definition | | |
| Partner interactions: Co-Design, Design reviews | Design Activities: Synthesis, Translation, Brief Development | Guests/Field Trips: Designers |
| Unit III: Supported Independence: Many Versions | | |
| Partner Interactions: Fall prevention workshop | Design Activities: Prototyping, Testing, Iteration | Guests/Field Trips: Assisted Living, Community Centers |

them were most commonly, the students, involvement with something meaningful, attention paid to them, and connecting with others.... One respondent commented, "It was one of the best things I have ever done." Further, these participants describe the experience with pride and describe the course itself, as well as participation in the design project, as a positive influence in their lives.

The outside evaluator is currently measuring impact of Year 2 of the course on the new batch of volunteers. Because one of the goals of this project is to improve the quality of life and emotional wellbeing of the community partners, we are using tools to measure social isolation, feelings of loneliness, meaning in life, and overall satisfaction with life., including pre, mid, and post-semester measures of the volunteer's perceptions of the program and themselves. The preliminary report of Year 2 mid-year interviews includes significant volunteer enthusiasm about the personal importance of this program. As the evaluator noted in informal communication to us: *They are really interested in finding some way to continue this type of engagement, and also with the specific students. Bonds seem to be made so quickly with this program.*

ACKNOWLEDGMENT

The authors gratefully acknowledge the many, rich, and diverse contributions of our students, community volunteers, and partners at the Needham and Wellesley Councils on Aging, the MetroWest Health Foundation, and neighbor organizations that work to improve lives of older adults in our communities.

Abstract—Three educational institutions in South Dakota are collaborating to develop pre-engineering courses to increase the enrollment and success of students transferring from Oglala Lakota College (OLC) to 4-year bachelor degree programs in science and engineering at South Dakota School of Mines and Technology (SDSMT) and South Dakota State University (SDSU) through a grant from the National Science Foundation Tribal Colleges and Universities Program (TCUP). In addition to the development and delivery of these courses, an aggressive summer schedule of service learning projects has been incorporated into the program. The objectives of these projects is to provide a hands-on introduction to science and engineering topics, promote community involvement and service, and to stimulate student interest and motivation to pursue these fields of study. This paper describes the activities of the OLC/SDSU/SDSMT Pre-Engineering Education Collaborative (OSSPEEC) program and two service learning projects related to civil and geological Engineering. Results indicate a high level of mentor involvement and coordination at each institution is an important component to a successful experience for the students. The first year of the program also indicates that student collaboration, variety in project related activities, and active community involvement help support student motivation and interest in their science and engineering related activities.

Keywords—service learning; pre-engineering education; constructivist philosophy

I. INTRODUCTION

The Pre-Engineering Education Collaborative is an effort by Oglala Lakota College (OLC), South Dakota State University (SDSU), and the South Dakota School of Mines and Technology (SDSMT) to develop a pre-engineering curriculum that will enable students graduating from OLC with associate degrees to continue their degrees in 4-year engineering programs at the junior level. Summer research and service learning projects are incorporated into the program to provide a hands-on introduction to science and engineering topics, promote community involvement and service, and to stimulate

student interest and motivation to pursue these fields of study. The specific project goals are: 1) Establish collaborative offerings of gateway and bottleneck courses that occur in the first two years of engineering curricula coupled with on-reservation hands-on laboratory experiences and recitation sessions at OLC, 2) Transform classical engineering program curricula to follow the constructivist philosophy of learning through vertical integration of the first two years by incorporating service-learning and research project learning experiences, 3) Increase the pre-engineering and engineering recruitment, retention, and graduation rates for South Dakota Native American students.

At a time when the United States is facing unprecedented global economic competition, not enough young people are preparing to enter the critical Science, Technology, Engineering, and Mathematics (STEM) fields. Encouragement and support for enrollment and retention of qualified US citizens in STEM fields is critical to the long-term success of the US economy [1]. The gap between the demand and availability in the area of engineering is particularly striking for Native communities. Nationwide, Native Americans represent about 1% of the US population and about 0.5% of engineering enrollment. In South Dakota, where Native Americans represent about 10% of the population, disparity within engineering programs is even greater. In 2009, Native Americans represented about 2.1% of engineering enrollment at SDSMT and 1.5% of engineering at SDSU. The low retention rate of Native American college students may be partially responsible for disparities in engineering disciplines. The overall Native American college student retention rates were between 7% and 25% in 1995 [2], with the lowest retention rates in STEM disciplines. Tribal colleges, which tend to have higher overall retention rates for Native American students, still have lower overall retention rates when compared to state institutions.

University-level curricular materials have typically been designed to improve understanding of topics in a linear but not interrelated or integrated fashion. The linear cognitive development model [3] has become a very popular and well used model within STEM disciplines, while Bloom's Taxonomy [4] has provided the active-voice language for developing, assessing, and evaluating the success of STEM programs of study in the linear cognitive development model [5]. STEM curriculum design has also typically followed the linear development pattern of a Piagetian [3] theoretical framework [6]. That is, material designed to specifically improve understanding in one area typically is not assessed for its impact on other areas.

In contrast to the Piagetian learning model, other researchers [7] focused on the structure of the field explaining that the "grasping of the structure of a field" is understanding it in a way to permit many other meaningful relationships to be established. Student learning experiences need to be facilitated in a manner that allows them to construct complex interrelated understandings of STEM fields. The development of knowledge is a complex process including stimulation, reflection, abstraction, and experimentation [6] [8]. In general, constructivist pedagogy emphasizes the importance of knowledge gained through experience [9]. Also, it has been stressed that one of the most important ideas is that students must construct their own knowledge structures and that basically correct preconceptions can be used to help the student learn [10]. Thus, the integration of learning activities is important because mastery of the fundamental ideas of a field involves both the grasping of general principles and the development of an attitude toward learning and inquiry, guessing and hunches, and the possibility of solving problems on one's own [7].

Although hands-on learning experiences are ubiquitously considered to be platforms for enhancing conceptual understanding [11], little consideration has been given to optimizing the timing of the hands-on experience in the overall learning scheme as explained in Kolb's theory. It has been shown that poor knowledge retention in hands-on laboratory experiences can be explained by inefficient activation of the prehension dimension of Kolb's learning cycle [9]. Kolb's learning theory distinguishes between apprehension and comprehension as independent means of grasping knowledge while intention and extension are independent modes of transforming experience. These four modes are equally important to contributing to the learning process. Traditional teaching models for STEM education that have relied on Piaget's model emphasize theory taught in classical lectures followed by reflection through written exams.

The OLC/SDSU/SDSMT Pre-Engineering Education Collaborative (OSSPEEC) is made possible through a grant from the National Science Foundation (NSF) Tribal Colleges and Universities Program (TCUP). OSSPEEC relies on an integration of activities including the traditional classroom setting and individual homework assignments delivered face-to-face or at a distance combined with laboratory, service learning, and research internship experiences on the reservation. The initial collaborative learning activities are used to establish the prehension necessary for the

transformative learning experience to occur in the project based internship experiences, while the structure of the learning experience enables the student to develop a risk-taking attitude toward learning and inquiry, toward guessing and hunches, and toward the possibility of solving problems independently.

OSSPEEC was initiated with objectives focused on enhancing the capability of OLC to deliver the first two years of a Bachelor of Science degree program in engineering. The collaborative offering of these courses by OLC, SDSU, and SDSMT will result in students completing a 2 year AA degree in Science, Engineering and Math (SEM) at OLC with the ability to transfer to a 4-year degree program at the junior level. All eight of the proposed classes have been offered at least once and improvements for subsequent offerings are being made.

The OSSPEEC program, which began in Fall 2010, initiated eight service-learning projects during the summer of 2011. This paper describes 2 projects related to Hydrogeology and the restoration of a Veteran Wall, their relationship with pre-engineering courses, and engagement with the community beyond the participating academic institutions. A discussion of identified challenges and successful methods that will be implemented during the continuation of the projects in future semesters is also included.

II. SERVICE LEARNING AND PRE-ENGINEERING COURSEWORK

Results of the OSSPEEC program to date include the successful initiation of eight service-learning projects (Table I) and the delivery of eight SEM courses using a variety of delivery methods during the 2011 summer and academic year (Table II). Of the sixteen undergraduate students leading these projects and enrolled in the SEM classes, three were from SDSMT, three from SDSU, and ten students from OLC.

Many of the service learning projects provided a discovery phase that complemented the material in the SEM courses delivered. In particular, the hydrogeology and Memorial Wall projects introduced students to relevant concepts in the Geology for Engineers and Materials and Laboratory courses, which will be further developed when the projects continue during the summer of 2012. These projects consisted of three students from SDSMT and two students from OLC and are described below to demonstrate the integration between classroom instruction, laboratory, and project experiences.

A. Hydrogeologic Mapping

One of the project-based service-learning activities during the first summer was the initiation of a detailed hydrogeologic unit map of the Pine Ridge Indian Reservation and the White River watershed (Fig. 1). Compilation of this type of map will provide a powerful tool and information source that can be used for analysis of source waters for drinking, recreation, irrigation, wildlife, riparian ecosystems, and other vital purposes. It also will provide information on the mechanics of the local hydrogeologic system, especially with respect to ground water and surface water interaction and to the location and behavior of aquifer recharge areas for Reservation water supplies.

TABLE I. PROJECT LIST

| | |
|--|---|
| Memorial Wall | Restoration of a Memorial Wall honoring World War I and II veterans. |
| Hydrogeology | Compile existing geologic maps and identify existing ground water data sources. |
| Wind Energy at OLC | Review existing meteorological data and replace damaged anemometers for future monitoring. |
| Pine Ridge Aquatic Ecology | Development of a physical and biological assessment program to measure non-point source pollution impact in Pine Ridge Reservation streams. |
| White River Uranium | Survey for uranium and arsenic hot spots in streams and springs to develop a more comprehensive sampling program. |
| Heavy Metals/Plants | Measurement of bio-uptake of heavy metals in traditional food plants. |
| Surveying and Detention Pond Design at OLC | Survey and design of water detention pond to reduce peak flows and erosion. |
| GIS Support Projects | Download existing base data in support of Aquatic Ecology, Hydrogeology, and Uranium projects. |

TABLE II. PROGRAM CURRICULUM

| | |
|-------------------------------------|--|
| Principles of Environmental Science | Lecture developed by SDSU and OLC and offered in hybrid-distance mode. |
| Surveying and Laboratory | Lecture developed by SDSU and OLC and offered in hybrid-distance mode with an onsite laboratory component. |
| Freshman Design Experience | Developed by OLC and SDSMT, and offered in hybrid-distance mode with an onsite service-learning component. |
| Sophomore Design Experience | Developed by OLC and SDSMT and offered at OLC with an onsite service-learning component. |
| Statics | Developed and offered by OLC. |
| Geology for Engineers | Lecture and field trips developed by OLC and SDSMT and offered in hybrid-distance mode. |
| Materials and Laboratory | Lecture and laboratory offered at OLC by SDSMT faculty including professional material-testing certifications. |
| Computer Aided Design | Developed by SDSU and OLC and offered in hybrid-distance mode. |

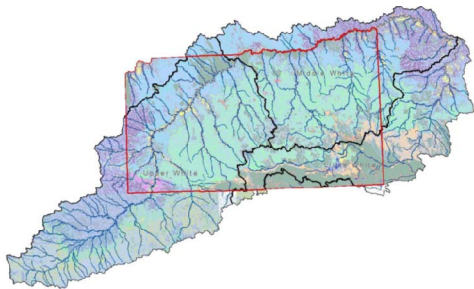

Figure 1. Geologic units within the White River watershed and the Pine Ridge Indian Reservation. Red outline denotes Reservation boundaries.

B. Restoration of a Veterans Memorial Wall

Community members in Wanblee, SD were interested in repairing a Veterans Memorial Wall located on the school grounds. As shown in Fig. 2, settlement has caused the wall to lean and many of the names are deteriorating due to weathering. Two students from SDSMT and one from OLC

used the opportunity as a service-learning project during the summer of 2011. Students visited the site and met with community members, including descendants of John High Horse, who coordinated the original construction. The students discovered the wall was originally constructed in 1947 [12] and contains the names of over 230 Native American Veterans that served in World War I and II. The names are carved in sandstone panels and are embedded in a concrete wall. Sometime during the late 1970's, the wall was moved by helicopter to its current location in front of the Crazy Horse School in Wanblee.

The components of the wall in need of repair include the sandstone panels, where portions of the lettering have eroded (Fig. 3), the deteriorated concrete wall (Fig. 3), and foundation settlement. After investigating several repair and restoration options and receiving community feedback, a final strategy was identified. The less-durable sandstone panels will be replaced with cast-in-place concrete, the deteriorated concrete will be

patched, and the material surrounding the foundation will be excavated to raise the foundation to a level position.

Figure 2. Veterans Memorial Wall, Wanblee, SD

Figure 3. Sandstone and concrete damage

C. Assessment

Students completed pre-program and post-program service learning surveys at the start and end of the summer program respectively. At the start of the summer program, students were asked to indicate the magnitude of their agreement or disagreement with eight statements about service learning. These same statements were slightly modified in wording to reflect activity completion, and students again indicated the magnitude of their agreement or disagreement at the end of the summer session. Participating faculty also completed the post program service learning survey at the end of the summer. A ninth statement was added for the post-program survey asking students and faculty to indicate the magnitude of their agreement or disagreement with a statement about the effort that they had made throughout the summer for service learning reflection. Reflection was generally accomplished through private journals maintained by the students. The eight questions asked at the beginning of the summer along with the reflection question and summary statistics for the sample results are presented in Table III for the pre- and post- student surveys and for the post-faculty survey.

III. DISCUSSION

A. Project and Course Integration

The Hydrogeology project provided an excellent opportunity to expose students to compilation of fundamental geologic and hydrologic data, and to the importance of this type of scientific information to their communities with respect

to the quality and quantity of water supplies on the Reservation. These topics provided a connection with the relevance to their daily lives and to the well-being of their communities. The students could clearly see the benefits and importance of the concepts that they were learning in the Geology for Engineers course which improved their level of comprehension of the fundamental geologic and hydrologic principles. Activities in continuing projects will include more intensive field experiences in mapping geologic contacts and geologic structures such as faults and folds, and measurement of stream flow gains and losses due to interaction with different geologic formations and features.

Investigating the repair strategies for the Memorial Wall introduced students to the topics of strength, durability and the constitutive materials in concrete (i.e. water, cement, aggregates) in addition to properties of the soils supporting the foundation. These material-related subjects were covered in the most recent course delivered through the OSSPEEC program during the 2012 Spring semester. Properties of aggregates were covered to understand the effects of particle-size distribution on the strength of concrete and settlement of foundations on poorly graded/organic materials. Laboratory exercises included determining soil sample size distributions, and designing concrete mixtures. A test batch of concrete was made and cylinders and beams were cast for strength testing.

The initial exposure of the concrete and soil in the Memorial Wall project, followed by the Materials and Laboratory course has provided students with an application-based experience for soils and concrete. Knowledge gained through the laboratory and classroom instruction will enable the students to design the concrete mixture for the foundation and wall repair, cast and test representative specimens and will increase their sense of ownership for the project.

B. Assessment Results

Data from the student and faculty surveys provided some initial insights into the developing OSSPEEC service learning component. Overall, the data from the OSSPEEC faculty indicated strong preferences (magnitude of the mean) and consistent responses (small standard deviations). A strong and consistent preference to learning by completing hands-on projects as opposed to traditional classroom learning (statements 1 and 2) was obvious. The faculty were also strongly and consistently positive about the outcomes of the service learning projects (statements 3, 4, 5, 6, 7).

The students are not as homogeneous in their responses. Some of them were just starting in engineering, may not have been sure of engineering as a program of study choice, and may have been unfamiliar with service learning concepts. The students did indicate a preference for hands-on learning versus traditional lecture style classrooms which became stronger and more consistent after participating in the summer projects (statements 1 and 2). However, the students did become more positive about classroom learning through the summer, also. The students' expectation that they would be able to apply their previous course work to the summer project experience was confirmed (statement 3), and their participation in community service learning projects became more regular (statement 4).

TABLE III. SERVICE LEARNING SURVEY SUMMARY

| Question No. | Question | Pre-Student Survey | | Post-Student Survey | | Post-Faculty Survey | |
|--------------|--|--------------------|---------|---------------------|---------|---------------------|---------|
| | | Mean | Std Dev | Mean | Std Dev | Mean | Std Dev |
| 1 | I like to learn by doing hands-on projects. | 1.08 | 0.29 | 1 | 0 | 1 | 0 |
| 2 | I prefer to learn in the classroom rather than through field projects. | 3.50 | 1 | 2.86 | 0.69 | 4.25 | 0.96 |
| 3 | I expect my summer projects to apply to what I have learned in the classroom. | 1.67 | 1.07 | 1.57 | 0.79 | 1 | 0.82 |
| 4 | I regularly participate in community service projects. | 3 | 1.60 | 2.57 | 0.53 | 1.25 | 0.50 |
| 5 | I hope to better understand the customs of others through my summer experiences. | 1.50 | 0.80 | 1.57 | 1.13 | 1 | 0 |
| 6 | My summer projects have the potential to make a lasting difference. | 1.17 | 0.39 | 2 | 1 | 1 | 0 |
| 7 | My summer projects may help local communities in important ways. | 1.25 | 0.45 | 1.71 | 0.95 | 1 | 0 |
| 8 | I expect my summer projects to challenge some long held beliefs. | 2.92 | 1.16 | 2.86 | 1.07 | 2.50 | 1.29 |
| 9 | I made a genuine effort to reflect about my work this summer. | | | 1.29 | 0.49 | 1.25 | 0.50 |

1=AGREE, 2=SOMEWHAT AGREE, 3=NEUTRAL, 4=SOMEWHAT DISAGREE, 5=DISAGREE

The students' hope to better understand other customs was not confirmed through the summer program and the standard deviation of their response also increased (statement 5). The hope that their summer projects would make a lasting difference, and that they would be able to help communities in significant ways (statements 6 and 7) were also not confirmed. The expectation that the summer experience would challenge long-held beliefs was confirmed (statement 8).

Although the students' responses for statements 5, 6, and 7 did not show improvement through the summer program and indicated increasing disagreement, they were still in the "somewhat agree" range rather than moving to a neutral or negative position. The faculty responses were in complete agreement for these statements. The student responses may have been indicative of the fact that they were gathering field samples and data and completing laboratory analyses throughout the summer, but had not yet had the opportunity to move on to a design or implementation phase of the project. The faculty responses may have indicated that they could see the long range possibility or probability of design and implementation more clearly.

C. Successes and Challenges

The courses offered through the OSSPEEC Program have resulted in a number of successes and challenges. The Geology for Engineers course was offered through hybrid delivery which was very beneficial to reducing student travel time and therefore improved student participation. Like other geology classes, field trips were enjoyed and appreciated by the students and were an important component of the class. The field trips sparked the most interest from the students and future course

deliveries will attempt to integrate more field work with classroom exercises. The course was co-taught by faculty from SDSMT and OLC and scheduling adjustments were necessary. Future efforts for this course include improving the correlation with the content of Introduction to Geological Engineering offered at SDSMT to increase student preparation for transferring to this program.

The Materials and Laboratory course was offered at OLC, which increased travel for instructors and students, however the face-to-face lecture and laboratory exercises were beneficial. A valuable component incorporated into the class were two certification programs, where students took written and performance examinations related to aggregate and concrete field testing. These exams resulted in 80% and 20% pass rates respectively and will qualify students for field-testing summer internships. Future offerings of this course will incorporate hybrid-delivery for the lecture to improve course efficiency. Additionally, a recitation session will be considered to help students with writing lab reports.

The organization of activities for the courses described above was an important component to a positive learning experience for the students. Challenges included the logistics of lectures, laboratories, and field activities between students and instructors from two institutions located 80 miles from each other and a third institution approximately 300 miles away.

The service-learning projects were also successful in many ways. The association of these projects with the community was an important component. For the hydrogeological project, a realization of the potential benefit to the water quality

heightened student appreciation and motivation for pursuing these subjects. The excitement from the Wanblee community for repairing the Memorial Wall emphasized the significance of student efforts. Observations from the summer projects suggest that a high level of mentor involvement and coordination at each institution are an important component to a successful experience for the students. The first year of the program also suggests that student collaboration, a variation in project related activities, and increased community involvement help maintain student motivation and interest.

Improvements in organization of all summer activities would lead to greater productivity and student satisfaction. Finally, a mid-summer evaluation of all projects and team activities will be implemented so that appropriate changes can be made for achievement of summer objectives.

IV. SUMMARY

The OSSPEEC program is a collaborative effort between OLC, SDSU, and SDSMT to develop pre-engineering courses at OLC. Through the first summer, 18 students and eight faculty mentors have been supported to initiate eight service-learning projects. Completing the second year of the program, eight courses have been developed and offered through hybrid-delivery from the three institutions. Two of the service-learning projects related to civil and geological engineering have complemented the Materials and Laboratory and Geology for Engineers courses which will benefit the continuation of these projects during the summer of 2012. The hybrid course delivery has shown to be an effective instruction method and is well suited for the long distances between institutions. The service-learning projects have resulted in high levels of student engagement and appreciation for societal benefits as well as the potential for pursuing careers and research in science and engineering.

ACKNOWLEDGMENT

This material is based upon work supported by the National Science Foundation under Grant No 1037797, which the authors gratefully acknowledge. The authors would like to thank Oglala Lakota College for generously hosting many of the summer activities. Recognition is made to undergraduate project participants; Shane Herrod, Tyler Corbine, Lester Richards, Kimberlynn Cameron, and Dave Fisher. Special acknowledgement is also made to Bryant High Horse and Ron Randall for providing valuable information related to the Memorial Wall project. Service learning surveys were developed and administered by Joanita Kant, graduate administrative assistant.

Work in Progress-HOMER: An Educational Tool to Learn About the Design of Renewable Energy Systems at the Undergraduate Level

Anthony Pérez-Santiago, Miguel Reyes-Carrasquillo, Eduardo I. Ortiz-Rivera, *IEEE Member*
Electrical and Computer Department, University of Puerto Rico at Mayagüez

Abstract—This paper is about how the uses of computer software's are such valuable tools for undergraduate engineering education, specifically in the design and analysis of renewable energy systems. Right now, there are many programs in the area of design of renewable energy systems, some more complexes, others user-friendlier and others too simple. For this work, the software HOMER (Hybrid Optimization Model for Electric Renewable) has all the tools necessarily to make a good work and it is not too complicated for undergraduate engineering students without previous knowledge in the area of energy systems. As part of this work, three educational modules were developed. The first module is about how to use and interact with HOMER. Second, how to design a residential photovoltaic system to lower energy cost. The last module can be considered as a guide on how to use renewable energy to secure a sustainable grid. The paper presents the technical skills gained by the students using the software HOMER. Finally, undergraduate students had the exposure to non-technical engineering skills, like economic feasibility, logistic and decision on energy security.

I. INTRODUCTION

With fuel constantly raising its prices and the energy demand growing every day, there is no doubt that renewable energy systems are quickly becoming the most popular alternative source of clean energy. Many countries, especially islands, are dealing with energy problems, because of the dependency of liquid fuels, derivate of the petroleum [1]. Professionals, especial students that will be the next generation of professionals start to think and act to solve this problem.

Undergraduate engineering students with professionals and non-professionals alike should be aware that there are several available resourceful software that simulate hybrid energy systems to provide a cost efficient solution for the high priced fuel demands. By interacting and learning to use these software students are exposed to new non-technical engineering skills like economic feasibility, logistics and decision on energy security. With no previous knowledge of these systems, students will be able to simulate and get a feasible projection on the benefits renewable energy systems have to offer [3].

The software used for this presentation is called HOMER. Homer energy is a program that simulates and analyses a hybrid power system that can include generators, cogeneration, solar photovoltaic, batteries,

turbines, wind, hydropower, fuel cells, biomass among other inputs [4]. HOMER beta version can be downloaded at <http://homerenergy.com/>. With a simple registration to the website one may be able to download and use the beta version for a free trial. Once downloaded, users can start designing and simulating hybrid energy systems [5]. Homer also makes an analysis of the energy supply by the system in every hour of the year (8,760hours) and compares it with the electric demand. The program studies the costs of all the equipment necessary in a project, bringing the opportunity to know if the project is going to be cost-effective.

The inclusion of renewable energy systems could provide an additional added value to the HOMER analysis by providing a more realistic simulation. Also, to obtain a realistic simulation or to be sure that the simulation done is adequate for a specific geographic region, it is important to follow the codes and standards of interconnection for a specific geographic region. For example "Freeing the Grid 2011" reports the practices in solar systems in the U.S. which gives some recommendations to the states that need to improve their net-metering and interconnection practices. Net metering policies are a simple billing agreement that ensures solar customers receive fair credit for the electricity their systems generate during daytime hours [2]. Interconnection practices are rules and processes that customers must follow to connect their distributed generated systems to electric grid.

The next sections of this paper will show to the potential users how to interact and learn about energy systems through simple simulations using HOMER software. Since HOMER is an excellent tool for the designing and learning of renewable energy systems because of its user friendly methodology, any undergraduate engineer student could use it without any or little previous knowledge in the area of energy system. Also, it will be discussed how HOMER can bring technical skills related to energy systems to undergraduate students or professionals interested to learn and expand their knowledge in the area of energy systems. Finally, an example of how HOMER could be integrated as part of an existing energy systems curricular sequence. For this example, the authors will use the energy systems curricular sequence that it is used at the University of Puerto Rico-Mayaguez [6].

II. INTERACTING WITH HOMER SOFTWARE FOR RENEWABLE ENERGY SYSTEMS

A. Equipment to consider

Once the program is open the user may start by pressing on the add/remove button on the upper left corner of the page. This button enables the equipment to be considered for the simulation. For this paper in particular we will explain some of the most basic and common equipments used in renewable energy systems.

Photovoltaic panels, wind turbines, converters, batteries, generators are among many of the systems to be considered. The type of load used is one of the most important inputs since it determines the energy demand of the system that wants to be considered. A deferrable load will be used when the charge is constant, otherwise a primary load will do when the charge varies from time to time. Renewable energy systems have the option to be connected or secluded from the grid. For grid tied systems we have the option of net metering to sell back the excess generated energy to the electric authorities.

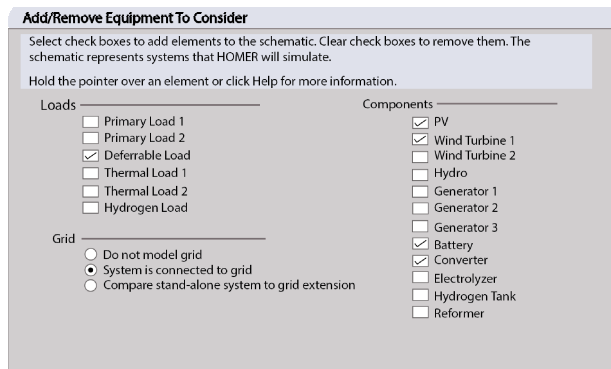

Fig.1: Equipment to consider

The following schematic represent basic PV-Wind Tied Connected System. All the components that this system has will be explained.

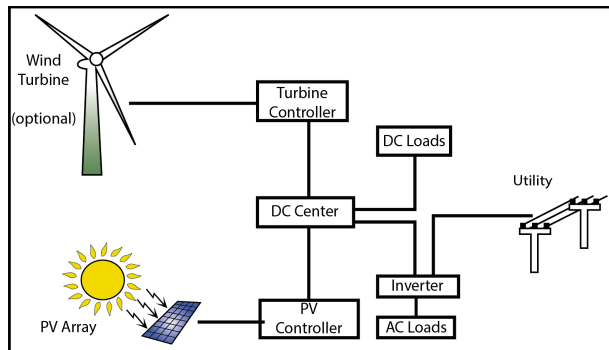

Fig.2: System PV-Wind Tied Connected System

B. UTILITY

The grid (utility) is another name for the electric authorities that supply the energy demand to houses, buildings, industries, etc. When using HOMER, the user must gather the information necessary to determine the cost of energy of the country or area where he or she resides since it varies. This may be done by checking the electric bill of the establishment where the renewable energy system wants to be installed.

Required inputs for grid (utility):

- Cost of energy. (In Puerto Rico, currently 0.29 \$/kWh [7])
- Sellback price for excess generated electrical charge, also known as Net Metering (0.075\$/kWh based on Energy policy Act of 2005 [8])
- Net metering option. (Calculated monthly or annually).

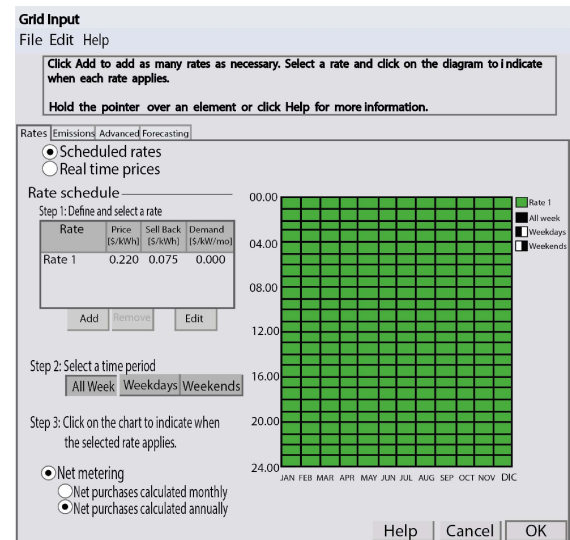

Fig.3: Utility inputs

C. Solar Resource

The solar resource is where we enter the coordinates of the area where the photovoltaic panels are going to be installed (latitude and longitude). The time zone of the country where the system will operate is also an important factor.

The software itself has its own database that gives the annual average radiation [9]. After all inputs are correctly entered it can be determined if it's worth installing photovoltaic panels as a renewable solution for the load based on the average hourly radiation. To have a substantial use for the photovoltaic panel it is necessarily from 5 to 6 hours of annual average radiation.

D. Wind Resource

The wind resource is little bit more complicated than the solar resource since the software doesn't have a database for wind speeds because of their variation and inconsistency [10]. To determine the wind speed we require an anemometer to measure the average annual wind speeds for the area of study and determine whether it is convenient or not to install wind turbines. Other inputs such as the height of the anemometer and the areas height above sea level are required for the study.

E. PV (photovoltaic panels)

PV's come with a set of properties to fill in. The output current must be in DC (direct current). The lifetime of the panels is usually from 20 to 25 years. The degrading factor varies from 80% to 85%. The slope is the angle at which the panels are mounted with respect to the ground. The azimuth is the angle at which the panels are deviated from south to west.

For the photovoltaic panels the required inputs are:

- The size of the panel array
- Cost of the panels
- Operation and maintenance cost
- Replacement cost

PV's can be classified in three types: mono-crystalline cells, poly-crystalline cells and amorphous cells. Each one have it's own efficiency: mono-crystalline around 25%, poly-crystalline less than 20% and amorphous cell only 10%. But as higher the efficiency, higher is the cost. The program do not let the user to choose between this types, so the user have to take the decision on what type of PV the system will have.

PV Inputs
File Edit Help

Enter at least one size and capital cost value in the Costs table. Include all costs associated with the PV (photovoltaic) system, including modules, mounting hardware, and installation. As it searches for the optimal system, HOMER considers each PV array capacity in the Sizes to Consider table.
Note that by default HOMER sets the slope value equal to the latitude from the Solar Resource Inputs window. Hold the pointer over an element or click Help for more information.

F. Wind Turbines

HOMER has a list of commercially available wind turbines to use for simulation. Important information about wind turbines that must be included is the height of the wind turbine tower and the lifetime (usually from 20 to 25 years).

The required inputs for wind turbines are:

- Quantity of turbines
- Initial cost
- Replacement Cost
- Operation and maintenance cost

Wind Turbine Inputs
File Edit Help

Choose a wind turbine type and enter at least one quantity and capital cost value in the Costs table. Include the cost of the tower, controller, wiring, installation, and labor. As it searches for the optional system, HOMER considers each quantity in the Sizes to Consider table.
Hold the points over an element or click Help for more information.

G. Converters

Converters are a necessary tool to have when working with photovoltaic panels and wind turbines [11]. Since these systems produce an output DC current, converters can work as both inverters (transform current from DC to AC) or rectifiers (transform current from AC to DC) to meet the necessary electrical energy demands of the power supplied. House hold items usually work with AC power supply.

Required inputs for converters:

- Size of converter
- Capital
- Operation and maintenance
- Lifetime
- Efficiency
- Replacement cost

Converter Inputs
File Edit Help

☒ A converter is required for systems in which DC components sense an AC load or vice-versa. A converter can be an inverter (DC to AC), rectifier (AC to DC), or both.
Enter at least one size and capital cost value in the Cost table. Include all costs associated with the converter, such as hardware and labor. As it reaches for the optimal system, HOMER considers each converter's capacity in the Sizes to Consider table. Note that all references to converter size or capacity refer to inverter capacity.
Hold the pointer over an element or click Help for more information.

Fig.6: Converter inputs

There are many types of converters commercially available [11]. Some of the most popular ones are:

Static-Phase Converters: These are the first phase converters that have been around for the longest time. Their uses are limited since they do a good job when working with small motors. Static-phase converters do not convert one-phase power to three-phase power, nor do they generate three-phase power. These converters will not power any type of machinery with three-phase circuitry.

Rotary-Phase Converters: A rotary-phase converter is designed to power larger equipment and higher HP motors, and a single unit can provide a continuous reliable source of three-phase power to more than one machine. These converters are a popular choice when a continuous source of three-phase power is needed. A rotary-phase converter uses its own motor to generate the third, high leg of power as well as passing on the other two legs of power provided by your single-phase power source.

H. Economics

HOMER applies the economic inputs of each system it simulates to calculate the net present cost of the project [12]. Required inputs:

- Annual real interest rate percentage
- Project lifetime in years

Other inputs are left blank by default since they don't affect the outcome of the simulation.

I. Calculation and Analysis of Results

After all inputs and resources are entered we press the calculate button to obtain the feasibility study and economic analysis. The program will analyze and

compare all the variables of the systems entered. Depending on the NPC (net present cost), we can determine the capital of each option given and decide if the system is right for the energy demand. By pressing on the sensitivity results the program will present a list of the best configurations for each of the different energy prices entered on the grid.

By double clicking on any of the results a new window will open with the details of the configuration. To compare one configuration with another and determine the time, the configuration will pay for itself the user must click on compare. To obtain a summary of the configuration selected the user must click on HTML report.

III. SIMULATION: RESIDENTIAL PV SYSTEM FOR PUERTO RICO

The cost of electricity in Puerto Rico has reached its highest peak in the last few years since the prices of fossil fuel keep increasing. By this means we have resorted to other methods like renewable energy systems to reduce energy cost. A photovoltaic system interconnected with the grid (utility) is consider for this simulation since Puerto Rico is an island that receives an average of 5 to 6 hours of sun radiation.

The primary load AC required by a residential is 15,000 Watt(hr)/days. The residential is located in Mayaguez, Puerto Rico and it specific location is: 18° 12' north and 67° 8' west; this is necessary to obtain the average sunlight per hour that the system required. To obtain the size of the panels it has been divide the primary load over the average sunlight radiation of the area. To determine the cost of the panels it is necessary to multiply the size of the array by 5 dollar per watt. The cost of the inverter can be determined by multiplying the size of the array by 1 dollar per watt. HOMER does not let the user enter additional expenses like wires, fuses and installation [12]. To take into consideration this additional cost they must be added to the cost of the panel array by adding the cost of the panels and converter and multiplying that value by .2(20%). It is very important to consider this additional cost, to obtain a good projection of the project's total capital.

IV. RESULTS

After all the information was entered the calculated button is pressed to obtain the results and see what the most economically feasible system for the simulation is. The results came up with two options: the stand alone grid system and the photovoltaic panels with converters interconnected to the grid. The NPC (net present cost) for the standalone grid was about \$21,000 and for the renewable energy system about \$25,000. The panels weren't the most cost efficient solution by a matter of a few thousand dollars.

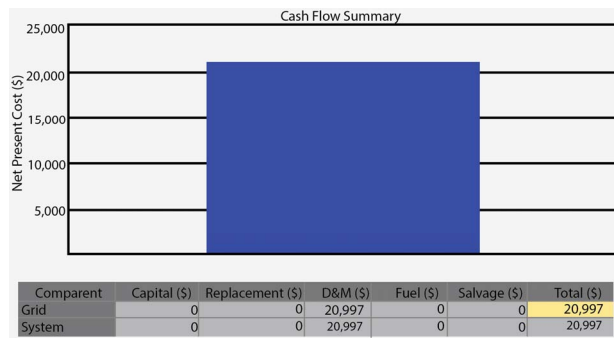

Fig.7 Cash flow for stand alone grid

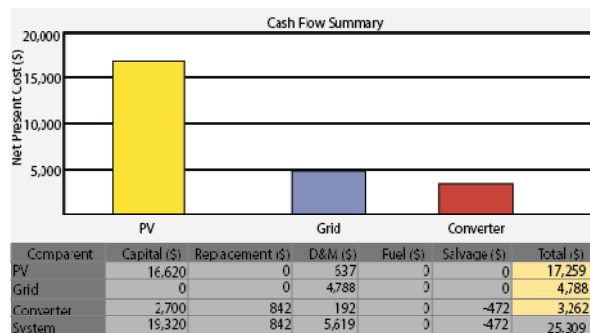

Fig.8: Cash flow for PV and converters interconnected with grid

After this simulation, another simulation was made using the same system but cutting in half the prices for the equipment of panels and converters since. This was done because the government provides incentives for the uses of green energy, to lower prices for communities and other establishments. The new simulation resulted with the renewable energy system being better energy solution for the residential with a NPC of \$15,464 and as a matter of fact being \$6,000 less than the grid stand-alone. The grid remained with the same price since the costs of energy of the electric authorities remain constant.

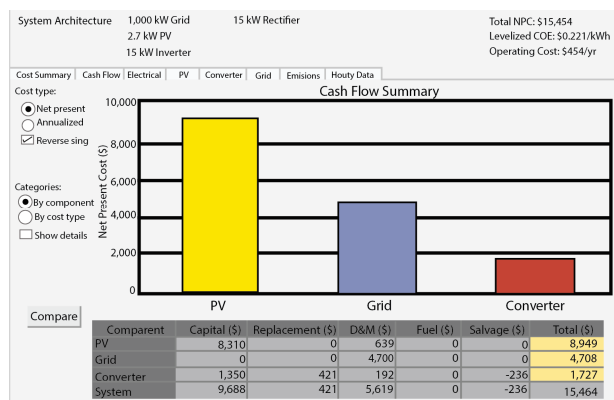

Fig.9: Cash flow for PV and converters after government incentive

V. HOMER FOR UNDERGRADUATE EDUCATION

This generation has a lot of responsibility on finding new alternatives resources of energy production. Everything that we use and do requires energy. Unfortunately the ways that countries generate the electricity are affecting the world. The reason is that the majority of the systems use fossil fuels and this resource emits gases that produce pollution to the ambient. Another disadvantage of the fossil fuel is that can be found only in certain countries. This is a problem because they control the prices and right now fossil fuel specially the petroleum is in a very high cost. Hence it is necessary to find the way to produce our own energy.

One way to produce our own electrical system is using renewable energy. Some types of Renewable energy are: solar, wind, ocean, biomass, hydropower, fuel cells, etc. These resources can be found naturally, so almost every country is capable to use it. Sometimes it is a little complicated to understand renewable energy systems, especially if the user does not have a background in energy systems. For our convenience a lot of programs are developed to help people understand this complex systems and even any student at undergraduate level is capable to use it.

Homer is a great program that simulates and analyzes renewable energy systems. This research was developed without a full knowledge in the area of energy systems, but as soon as the program HOMER was put into good use the research purpose became easier. The program helps the user answer some basic questions like: Which technology is more efficient in terms of cost? What renewable resource is more suitable for the system?, and What requirements each system needs?. For example the lifetime of the components, the slope of the PV's with respect to the ground, the height of the wind turbines with respect to the ocean level and other basic questions. These details are necessary in the simulation and a lot of users do not know about it.

One important aspect of HOMER is that it allows simulating all the combination of equipments and variables. The benefits of this software is that gives the opportunity to see how the outputs vary at every hour, it lets users enter multiple values in some inputs, and also enter more than one components size (the program choose the best one).

VI. SKILLS DEVELOPED BY THE STUDENTS

After interacting and learning to use HOMER software, undergraduate students and all users alike will be expected to gain resourceful non technical skills that will help them in their career and future studies. Some of the skills expected to learn during research are:

- Ability to apply economic analysis and provide feasible solutions to lower cost of energy for different establishments.
- Ability to design hybrid energy systems, components, and processes to meet the necessary energy demands.
- Ability to identify, formulate, and solve engineering problems using techniques learned in previous courses.
- Ability to learn about local codes and standards related to interconnection and net-metering.
- Apply logistics and make good decisions on energy security.
- Knowledge of how energy systems work and operate. Their purpose and what economic benefits they come with.

VII. UPRM'S CURRICULAR SEQUENCE ON ENERGY SYSTEMS AND HOMER

At UPRM (University of Puerto Rico Mayaguez) it has been developed a list of courses in the area of power systems that can include the program HOMER. Table 1 shows the UPRM's curricular sequence on energy systems where HOMER can be a useful tool as part of the class. An introduction of circuit analysis is necessarily to understand the electrical behavior of the devices that will be used for the simulated project. Additionally in a class of power system it could be done a simulation and analyze how much power is required by the system. Also in a class of power electronics can make a simulation and analyze the amount of energy that is going to be delivered to some devices. HOMER can be used in for undergraduate research and design projects that involve energy systems. The UPRM students have the opportunity to takes these courses and apply all the knowledge acquired by using HOMER.

VIII. CONCLUSION

Homer is a useful program that can really help undergraduate student in the area of designing of renewable energy systems. This is because it is a very easy program that anyone with basics knowledge in the area of energy system can use. The program demonstrate that with just a little tutorial on how to use the program any person, specially undergraduate students, are capable to design renewable energy systems without a bachelor's degree or a master degree. Instead it prepares students with useful tools to successfully start a master degree.

It is very important to encourage student to learn to use this kind of programs that works with renewable energy. Because by taking advantage of tools like this everyone can learn and adapt new solutions to fix the problems the world faces nowadays and have a better tomorrow. How we use energy today will determine the way we live in the future.

| Course | Course Name | Description |
|-----------|--|--|
| INEL 3105 | ELECTRICAL SYSTEM ANALYSIS I | Analysis of direct current and alternating current linear electric circuits; laws and concepts that characterize their behavior. |

Special Session: IEEE Real World Engineering Projects: Discovery-Based Curriculum Modules for First-Year Students

Stephen Williams, Anita Vasavada, Jacques Nicolas Beneat, Gregory Cappuccino, David Lin, Warren Rosen, Eric Carr, Kirk Reinkens, Mingrui Zhang, Francesco Amoroso

MSOE, Milwaukee, WI; Washington State University, Pullman, WA; Norwich University, Northfield, VT; University of Calabria, Rende Cosenza, Italy; Washington State University, Pullman, WA; Drexel University, Philadelphia, PA; Drexel University, Philadelphia, PA; Washington State University, Pullman, WA; Winona State University, Winona, MN

Abstract – This special session is organized to provide an interactive forum for the introduction of a set of new curriculum modules developed under IEEE’s Real World Engineering Projects (RWEPP) program. The modules, which are representative of a larger collection of curriculum modules available to the public via an open-access RWEPP web portal, are designed for use in the first-year engineering and computer science classroom, and are hands-on, team-based projects that emphasize the societal impact of the work that engineers do.

After a brief introduction to the RWEPP program and the showcased curriculum modules, the authors of the modules will work one-on-one with the audience providing tutorials on the laboratory activities associated with their modules in a highly interactive, simultaneous mode. Audience members can learn in-depth about the modules that interest them most. Each project will have its own demonstration table, with posters of information and hands-on demonstrations and / or videos. This will allow for audience members to interact directly with the authors, and to try out the same sorts of activities that are proposed for the students.

Keywords – laboratory instruction, first-year students, curriculum development, engineering education.

SPECIAL SESSION AGENDA

The special session will begin with a 10 minute overview of the Real World Engineering Projects program, followed by a brief (10-minute) introduction to the projects and a short question and answer session. The bulk of the session (60 minutes) will be used for one-on-one, interactive, live project tutorials by the authors of the curriculum modules, set up “poster-session style”, i.e., with simultaneous, informal presentations by the authors. Each project will have its own demonstration table, with posters of information and hands-on demonstrations and/or videos. This will allow for audience members to interact directly

with the authors, and to try out the same sorts of activities that are proposed for the students. This will give audience members a strong sense of how the activities might work at their own institutions, and an opportunity to talk directly with the authors about their own experiences with the project in the classroom.

SESSION GOALS AND EXPECTED OUTCOMES

The IEEE RWEPP program’s ongoing goal is to develop an on-line, open-access library of high quality, hands-on, team-based curriculum modules for use in first-year college courses in electrical engineering (EE), computer engineering (CE), biomedical engineering (BE), electrical engineering technology (EET), and computer science (CS). These curriculum modules are designed to be used by faculty members around the world who teach first-year students in introductory laboratory courses. The modules are designed as stand-alone units each covering about two weeks of instruction, so that faculty can pick and choose the modules they like to build a course that meets their needs. The curriculum modules are specifically designed to be discovery-based, and to illustrate real-world contemporary problems whose engineering solutions benefit society.

The RWEPP approach to first-year instruction is expected to help with retention of students, by clearly demonstrating the relevance of fundamental engineering and science concepts to real-world, contemporary problems, and by showcasing the impact that engineering has on society. Students are guided in discovering the importance of a contemporary problem in a way that will excite their interest in creative solutions. The modules make use of activities that allow students to discover key concepts about engineering science and design in a hands-on way; they demonstrate how and why technical methods work, rather than simply providing a recipe for a solution. The societal impact focus of the modules is expected to help in the retention of all students, and particularly women, by providing the students with opportunities to understand how their own future work might help others.

The goal of this special session is to showcase new curriculum materials that have been developed for first-year

students under IEEE's Real World Engineering Projects (RWEPP) program. The curriculum modules being presented are representative of a larger set of modules available on-line via the RWEPP portal, www.realworldengineering.org. The expected outcomes of the session are that attendees:

- Will be encouraged to use the curriculum modules in their own classrooms.
- Will engage in discussion about the importance of relaying to their students the benefit to society of what engineers do.
- Will exchange information on learning methods that successfully engage first-year students and support recruitment and retention of those students.
- Will be made aware of future opportunities to contribute to IEEE Educational Activities Programs curriculum development efforts, particularly through grants from future rounds of the RWEPP program. This awareness will help the RWEPP "gain momentum" in building and strengthening its library.

HIGHLIGHTED RWEPP PROJECTS

Vehicle Passenger Safety: Exploring Whiplash Protection Systems

Anita Vasavada, Kirk Reinkens

Students will design and evaluate an active head restraint system.

- Learning about whiplash injury, and characterizing a physical model of the human head-neck system.
- Evaluating the physical model in the context of neck injury testing, and designing a head restraint which can limit head movements during a collision.
- Characterizing a motor and specifying commands which can move the head restraint appropriately when an impact occurs.
- Evaluating a sensor which will activate the motor before an impact occurs.
- Testing the ability of the entire active head restraint system to limit head motion during a simulated rear-end collision.

Design of a Guitar Tab Player in MATLAB

Jacques Beneat

In this project work with several MATLAB programs to look at the effects of frequency and modeling of signals. The project has two models. In the first module, the students use several MATLAB scripts to discover the effects of sampling, the frequency spectrum of signals, and the modeling of a harmonic signal such as that of a guitar string. In the second module, the students make use of the modeling efforts of the first module to implement a realistic guitar tab player.

Coping with the Emerging Energy Demand for Charging Plug-in Electric Vehicles

Gregory Cappuccino

In this hands-on project, student teams will be engaged to cope with the real-world problem arising from the increasing demand for charging Plug-in Electric Vehicles from the electrical energy distribution grid. By means of MATLAB simulations, each team will analyze the effect of multiple quasi-contemporary charging requests on the electrical grid, hence discovering how, as the number of users to be charged increases, either the grid collapses or the user requests may not be entirely fulfilled. The class will discover how smart energy dispatching strategies and smart battery charging methods may mitigate or completely overcome the discussed problems. The class will also be asked to reflect on how the traditional "dumb" grid infrastructure should be modified to allow each proposed solution to be really implemented, finding out the necessity of developing a smart grid capable of interacting with vehicles.

Remote Surgical Robotics: Control Systems and Human-Machine Interfacing

David Lin, Kirk Reinkens

This project focuses on optimizing a prototype remote surgical robot which has force-feedback capabilities. The objective is to detect the surface of a gelatin brain by tactile perception through the robot. Students explore the tradeoff between sensitivity and range while considering human factors as design constraints.

Microcontroller-based Smart House for Improved Energy Efficiency

Warren Rosen, Eric Carr

In this project the students will program a simple microcontroller to measure temperature and control functions such as heaters or coolers in a prebuilt smart house. The house is made of a foam shell electric heater, thermoelectric air conditioner and an attic fan with vent.

Image Processing Algorithms for Identifying Gulf Oil Spill

Mingrui Zhang

This project is to teach computer science students algorithm design as a problem-driven process. Students are asked to develop image processing algorithms to locate oil spills on satellite images and implement them in a Java-based software application. Working on their projects, students will learn to analyze the problem, inspect sample images and identify patterns, design algorithm(s) and validate algorithm(s). Ocean color satellite images are pre-processed and provided with this project.

Special Session:

Connecting with Community:

Empathy, Experience, and Engineering with Elders

Lynn Andrea Stein and Caitrin Lynch
Franklin W. Olin College of Engineering
Needham, MA USA
las@olin.edu caitrin.lynch@olin.edu

Abstract—A hands-on special session at the Frontiers in Education conference introduces an experiential exercise in empathy. Participants will use prostheses to simulate some of the physical disabilities that often accompany aging, then attempt everyday activities to better understand how engineered artifacts – and engineering design choices – can facilitate or hinder these tasks. The “empathy exercise” introduced here is suitable for inclusion in a wide range of engineering classrooms. It draws student attention to the importance of end user understanding and increases student understanding of the connection between engineering decisions and societal impact at a visceral level.

Keywords- *interdisciplinary; broad competencies; empathetic engineering*

I. SESSION GOALS

Engineering is ultimately about solving problems *for people*. Participants in this special session will both experience and potentially take home a specific active learning technique that helps students to bridge between the technical work of engineering and the human needs of its ultimate beneficiaries.

Participants should leave this session equipped to integrate a people-centric experiential class session into their (engineering design) classes and/or with new ideas and techniques for connecting their course content to the end users who are the ultimate beneficiaries of their students' work.

II. SESSION DESCRIPTION

This hands-on session will focus on a set of "empathy exercises" intended to bridge the too-common gap between engineering problem-solving skills and the needs of those whose problems are ostensibly being solved. How do design decisions that engineers make affect the lives of those who use their designs?

In this session, participants will

- experience some of the physical limitations associated with aging;
- explore the ways in which engineered artifacts can facilitate or complicate tasks; and
- gain a visceral understanding of the connections between engineering design and human needs.

The session will also provide opportunity for participants to discuss ways to incorporate this session or similar activities into their own classrooms.

During the session, participants will use a variety of props to simulate disabilities commonly associated with aging: reduced vision, mobility, dexterity, and auditory and tactile sensation. Equipped with age-simulation props, participants will attempt a range of activities of daily living and assess the impact of disability on the activities. They will explore how

Figure 1. A student and volunteer transfer pills into containers while simulating the restricted dexterity typical of arthritis.

This project received support from the Metrowest Health Foundation and from the Franklin W. Olin College of Engineering Innovation Fund.

existing tools either aid or complicate tasks, depending on the sensitivity of their design. (How do various vegetable peelers work when wearing gloves that simulate arthritis? How do cataracts impact the ability to read information on a pill bottle?)

Session participants will be asked to evaluate and reflect upon their experiences, much as our students and community volunteers do. Associated discussion will introduce the course and context in which the authors use this exercise, highlight our partnership with elder members of our community, draw explicit connections to engineering education, and aid participants in planning ways in which this exercise could be incorporated into their classrooms.

III. SESSION AGENDA

The session will open with a ten minute overview including a preview of core activities, background in which the facilitators use the material, and suggestions as to what to look for/think about during the experiential activity.

The experiential portion of the activity will occupy the central fifty minutes of the session. Room layout will be highly structured with multiple stations, each involving an impairment and a set of tasks, for participants to rotate among. At each station, sample tasks will allow directed but open-ended exploration.

Following this core activity, participants will spend up to thirty minutes in facilitated groups (with structured worksheets to stimulate discussion):

- (a) reflecting on experiences and learning
- (b) connecting this experience to home institution classes
- (c) planning take-home tasks and adaptations of this material

IV. ANTICIPATED AUDIENCE

This session is directed at faculty members who teach engineering classes that are in principle connected to end user needs, such as design, capstone or cornerstone curriculum, as well as first-year engineering survey classes. All disciplines are welcome and some examples will be chosen from the worlds of software, electronics, mechanics, and building/infrastructure design.

V. EXPECTED OUTCOMES/FUTURE WORK

This special session will have two primary outcomes:

- (1) Creation/adoption of user-centered empathy experiences in participant campuses. These activities will help students to connect engineering curriculum to the end users

who are the ultimate beneficiaries of their work. Instructions for replication of this activity will be provided and available for adaptation.

- (2) Feedback on the activity -- both during the session and

Figure 2. A community volunteer tries on a vision-restricting prosthetic.

from subsequent adopters -- will improve this material and increase its effectiveness and adoptability. The facilitators will continue to use this activity in our course, to develop it further, to package instructions for adoption elsewhere, and to support collaborative development of this material by others.

In addition, this special session will create a community that shares this experience, enhancing incentives to adopt in classrooms and creating new ways of adapting this and similar experiential learning activities.

VI. JUSTIFICATION AS A SPECIAL SESSION

This activity is fundamentally experiential and would make limited sense as a paper or panel. The key insight in this activity is gained by participating. Instructors will also benefit from seeing how their students might experience and learn. As an experience, it is novel and engaging for a wide and diverse range of participants.

ACKNOWLEDGMENT

The authors gratefully acknowledge the many, rich, and diverse contributions of our students, community volunteers, and partners at the Needham and Wellesley Councils on Aging, the MetroWest Health Foundation, and so many of the neighboring organizations that work to improve the lives of older adults and all members of our communities.

New Pedagogic Challenges in Engineering Education

Michael E. Auer

International Society of Engineering Education (IGIP)
Villach, Austria
president@igip.org

Danilo Zutin

Dept. Engineering & IT
Carinthia University of Applied Sciences (CUAS)
Villach, Austria
D.GarbiZutin@cuas.at

Abstract— Never has the speed of development in the area of engineering been as accelerated as it is today, as we observe the enormous and driven growth of the area of engineering. Today's tendencies require concerted new efforts in engineering education - or in other words, the importance of pedagogy in the field of engineering is growing enormously. These changes strongly demand new didactic and pedagogic paradigms. The International Society of Engineering Education (IGIP) offers to contribute to the relevance and pedagogical aspects related to developing educational concepts in engineering education. (Abstract)

Keywords- *Engineering Education, pedagogy, didactics, IGIP, challenges*

I. IGIP AND ENGINEERING EDUCATION

IGIP has almost a 40-year tradition of contributing to engineering education and its members and many activists have contributed to making IGIP a leading global engineering association. IGIP presently has a worldwide membership of about 1.750 members (individual, affiliate, institutional). More than 1.100 professionals all over the globe at this moment bear the title of "IGIP International Engineering Educator - ING.PAED.IGIP". IGIP also works in good partnerships with international associations as IFEEES, IEEE Education Society, SEFI, and IELA, to name just a few.

The aims of the International Society for Engineering Education - IGIP are:

- To improve teaching methods in technical subjects
- To develop practice-oriented curricula that correspond to the needs of students and employers
- To encourage the use of media in technical teaching
- To integrating languages and the humanities in engineering education
- To foster management training for engineers
- To promote environmental awareness
- To support the development of engineering education in developing countries

It is important to consider that humankind has never faced such a rapidly changing and dynamic global environment which demands so much of engineers as we are witnessing today.

And as our environment changes, it is imperative we better learn to adapt, which requires us to question and, when necessary, be open to changes regarding our:

- Educational systems
- Pedagogy
- Methods and processes

Never before have the challenges in education and pedagogy been as challenging as today. Never has so much been demanded of engineers. The work of ASEE, IGIP, IEEE ES, and other associations focuses on improving the quality of Engineering Education. But what is exactly is engineering?

"Engineering is the discipline, art and profession of acquiring and applying scientific, mathematical, economic, social and practical knowledge to design and build structures, machines, devices, systems, materials and processes that safely realize a solution to the needs of society." [1]

A short definition of engineering might be: "Exploiting basic principles of science to develop useful tools, objects and processes for society." This means that engineering is the link between science and society, which can include almost anything that people come into contact with or experience in real life. The concept of engineering existed long before recorded history and has evolved from fundamental inventions such as the lever, wheel, and pulley, to the complex examples of engineering we witness today. But today, there are two actual tendencies:

First, we can observe an enormous (and accelerated) growth of the area of engineering.

Besides the traditional fields of civil engineering, construction engineering, electrical engineering, etc. new engineering disciplines have been created and more are in the process of creation. Some examples of recently created areas of engineering include:

- Software Engineering
- Data engineering
- Medical Engineering
- Neuro Engineering
- Gene Engineering
- Social Requirement Engineering, etc.

And new tasks requiring new competencies within traditional engineering disciplines have grown in number and complexity:

- Online Engineering
- Remote Engineering
- Virtual Engineering
- Reverse Engineering

On the other hand, we can observe a terrific decrease of the life cycles of technical (or engineering) products (and processes or technologies too!).

For example, how many years did it take for the following products to reach a market audience of 50 million?

- Radio 38 years
- TV 13 years
- Internet 4 years
- iPod 3 years
- Facebook 2 years
- Tablet PC (iPad) 1+ years

The field of engineering has never suffered such reduced times to bring their innovations from concept to market. Competition in the field of technology is now measured in weeks.

Both of these realities require a concerted effort to evolve engineering education into what today's reality is demanding of practicing engineers. In other words, many traditional educational models and practices are no longer functional. For this reason, the importance of pedagogy is growing at an enormous pace. The need to innovate and apply new paradigms to the teaching-learning process is an absolute necessity.

II. NEW QUESTIONS OF TODAY'S AND FUTURE ENGINEERING EDUCATION

There are especially serious changes in the social position of learning:

- According to some estimates, more than 80% of all learning occurs on the job rather than in tertiary and post-tertiary education!

Learning in the future has to be an integrated part of the job! Moreover: Learners in the workplace are not only consumers of learning resources, but often also developers and resource providers. Learners are also teachers who participate in the development of content and often in its delivery as well. This new model provides new challenges related to the integration of learning and work. [5]

Data from Australian and Portuguese surveys show that engineers tend to spend the majority of their working week (around 60%) engaged in activities which involve interaction with others (meetings, supervision, writing reports, etc.) and only around 40% is devoted to technical engineering activity.

- There are also new organizational aspects in engineering education [6]:

On the one hand, engineering issues, either in industrial products or in engineering projects, are quickly becoming increasingly complicated and most of these issues cross disciplinary lines.

On the other hand, the working environment is becoming more and more internationalized due to the globalization of the world economy. Products are fabricated by worldwide cooperation and manufacturing resources are linked by international supply chains. Nowadays, engineers have to know how to work in multi-cultural environments with people from different countries.

This means the next generation of engineers will need to possess the ability to work seamlessly across cultures, have outstanding communication skills and be familiar with the principles of project management, logistics, and systems integration.

- To face current real-world challenges, higher engineering education has to find innovative ways to quickly respond to the new needs of engineering education, and at low costs.

This means it is necessary to improve the agility of engineering education in the future. One of the approaches in this direction is the creation of virtual educational units.

All these trends result in new questions and the resulting need to evolve educational practices, especially in Engineering Pedagogy. Some of these important questions to consider include:

- What learning approaches have to be used to effectively response to these changes?
- What are the pedagogies that provide the most effective learning experiences for engineering students of the 21st Century?
- What learning skills in engineering education need to be developed and how can engineering teachers succeed in guiding their students to achieve them?
- What pedagogical approaches have been found to support the different phases of the present life-long learning continuum, or is more research necessary?
- What are the approaches that enable competence in leadership skills in a multi-cultural working environment, and what is the best way for these competencies to be delivered?
- Ambient technology is becoming a reality. What does ambient learning in Engineering Education look like? How can it be designed, delivered and assessed?
- How can engineering education support individualized and personalized learning to compensate for individual differences (learning styles, learning strategies, learning preferences, field dependency, etc.)

These are some of the reasons why the relevance and importance of engineering pedagogy is growing so enormously.

III. IGIP'S INTERNATIONAL ENGINEERING EDUCATOR TITLE

This paper, up to now, has attempted to show that dramatic changes are necessary in engineering education and that these changes strongly demand a new look at the didactic and pedagogic concepts that presently form the basis of engineering education. IGIP offers a space for professionals to look into, debate, and put into practice different concepts related to engineering education.

IGIP has established a prototype curriculum for engineering pedagogy which is already used in several countries. In contrast to ABET, FEANI, or EUR-ACE, IGIP is not an accreditation body for engineering curricula. By passing the curriculum as proposed by IGIP in any accredited or other institution worldwide, IGIP states that a given engineering educator with an ING.PAED.IGIP title has all the competencies needed to teach to the highest standards with the best available teaching technologies. Interested engineers can continue their education in accordance with the IGIP Curriculum and obtain a diploma that will provide the knowledge and skills necessary for engineers to become better teachers. IGIP, worldwide, already has 46 approved educational centers and more than 1100 approved "International Engineering Educators" (ING.PAED.IGIP).

The IGIP model's point of departure is that individual engineering lecturers initiate and are responsible for teaching and learning concepts that train engineers and technicians. The quality and success of engineering studies are decisively influenced by teacher competencies in the area of pedagogy as pedagogical skills represent a network of knowledge and skills that transmit knowledge and experience, much like Web 3.0. For this reason, technology and educational practice must go hand in hand when we are dealing with the education of engineers.

Engineering educators expand their typical engineering subject competence by acquiring teaching and learning skills in theoretical and practical coursework corresponding to the objectives of the ING.PAED.IGIP model. Students taking engineering education training should acquire the necessary professional skills which technical teachers must have to be able to exercise their profession effectively and creatively.

The proven IGIP engineering education curriculum is based on the knowledge of traditional pedagogy in philosophy and the liberal arts, but with respect to the particular character of the technician and the analytical-methodological approach in the fields of engineering science.

After many years of experience in industry or research, engineers who are appointed as teachers at a technical school or university are influenced by their professional careers. Their way of thinking is determined by the precision of the technology they work with, by their work with quantifiable and measurable events and objects. The influence of their discipline and the "language" of engineers must be taken into account in

engineering pedagogy education, and they must penetrate the engineering education curriculum.

The ING.PAED.IGIP is a registered program which certifies a certain educational level for teachers, trainers or instructors. Any engineering educator who passes the curriculum at any IGIP accredited training Centre for International Engineering Education, and whose education, training, and professional experience meet IGIP standards, may apply to be registered as an "International Engineering Educator - ING.PAED.IGIP".

The qualification profile of a specialized engineering pedagogue is based on two pillars:

- Engineering qualifications which were earned through a recognized and/or accredited engineering study program plus relevant professional experience
- Educational qualifications in engineering pedagogy acquired in the course of a comprehensive educational program

The engineering pedagogy program is generally an independent course of studies taken after an engineering program. However, it can also form an integral part of engineering degree programs. Already existing educational programs for engineering pedagogues can be accredited by the IGIP. Importantly, to be accredited, they must meet the accreditation criteria defined by IGIP.

The goal of IGIP accreditation is to insure that graduates of the accredited engineering pedagogical programs are well prepared to perform their teaching duties in engineering subjects and meet the criteria required to become International Engineering Educators, ING.PAED.IGIP. Another goal is to promote quality assurance, quality improvement, and modernization of engineering pedagogy programs and to create public awareness of the high quality of the IGIP program for engineering pedagogues. Accreditation is a voluntary process which educational institutions must apply for through the responsible IGIP national monitoring committees.

The accreditation criteria defined by IGIP for a program for engineering educators are:

- Organization of the program
- Entrance requirements for the first year students
- Skills/abilities of the graduates
- Engineering pedagogical curriculum
- Lecturers and professors
- Institutional resources
- Quality control and feedback

IV. COMPETENCES IN ENGINEERING PEDAGOGY

An "ideal" teacher with a technical background should acquire the necessary professional competences of an engineering educator. These general professional competences consist of two main groups:

- Technical expertise
- Specific engineering pedagogical competencies.

Educational theory offers different lists of competences [7]. The IGIP concept of engineering educational competences is to be summarized as follows:

- Pedagogical, psychological and ethical competences
- Didactical skills and evaluative competences
- Organisational (managerial) competencies
- Oral and written communication skills and social competences
- Reflective and developmental competences

Other categorizations might operate with the terms “technical expertise”, “pedagogical competences”, and “human competences”. Some authors substitute the term “competences” by “virtues” [8].

Technical Competences

It is assumed that the candidate has acquired a high level of technical knowledge while studying engineering and has met the requirements as defined by the “Fédération Européenne d'Associations Nationales d'Ingénieurs – FEANI” for registration as a European Engineer – EUR ING. An engineering diploma and at least one year of professional experience in engineering are also required.

Pedagogical, Psychological and Ethical Competences

It is assumed that engineering pedagogues create a positive working and learning atmosphere, see the students as learning partners in a relationship characterized by mutual respect, effectively employ group-dynamics, and stimulate engaging interaction between themselves and students and among the students themselves, using a variety of strategies. Furthermore, engineering pedagogues use student input and provide students the space necessary to promote creativity, support students in developing their professional identity, stimulate “value-orientation” in the students and are aware of their own ethical point of view (within the field of conflict between humans, society, and the environment) which permits them to better conduct themselves as professionals in the different fields of engineering.

Didactical Skills and Subject Expertise

Engineering pedagogues use engineering pedagogy models of the teaching process to create their own lessons, develop their own personalized teaching style and strategies to promote the flow of information, and observe the components of the six-dimensional education space in their own teaching and relate these to the selected teaching method. They select eclectic teaching methods and strategies, e.g. laboratory didactics and project work, and follow up by rethinking and reevaluating their teaching methods and strategies with their colleagues and students. They set clear teaching goals, select suitable materials, and structure them appropriately. They find illustrative explanations and develop clear manner of communicating content and actions. They integrate new technologies and methodologies into their teaching practices. They are comfortable using what may be called the “classic” teaching media and effectively employ “new” teaching media (e.g. learning platforms, etc), taking into account the individual

differences and learning strategies of students in a more personalized learning process (e.g. intercultural differences). They make effective use of student experiences as teaching points, effectively building on these experiences and, therefore, stimulating students to translate personal experiences into practical working theories. They advise students on how to develop their portfolios and stimulate students to include their experiences into the learning process, all the while being responsible for their actions and self-assessing themselves as professional engineers.

Evaluative Competences

Engineering pedagogues develop instruments for (self-) assessment of professional engineering skills and evaluate their students using both quantitative and qualitative means to continually monitor, assess, and record student progress during the learning process.

Organizational / Managerial Competences

Technical teachers create an adequate physical and virtual learning environment, poses time management skills for their own work, observe relevant laws and are aware of educational policy, administer all relevant data adequately, and can work “on the fly” if necessary.

Communicative and Social Competences

Engineering pedagogues work as part of trans-disciplinary teams, making their own vision of teaching explicit and effectively relating it to the visions and concepts of their colleagues. They contribute to the development of guidelines and visions of their own profession and to the modernization process of teaching. They have or create relevant regional or (inter)national networks that contribute to knowledge in the field of engineering pedagogy and effectively communicate it to their peers. They also communicate satisfactorily both orally and in writing in a variety of contexts and are competent in scientific writing.

Reflective and Developmental Competences

Teachers with a technical background appreciate new developments (e.g. new technologies) and readily integrate them into their teaching, systematically rethinking their own teaching strategies and their teaching behaviors, making their own learning process transparent to students and colleagues. They are also willing and in the position to initiate IGIP accreditation and register as an “International Engineering Educator - ING.PAED.IGIP”.

The IGIP “Recommendations for Engineering Pedagogy Studies” (in short IGIP Curriculum) are described in detail in [10].

Interested institutions and engineers, teachers, and students are welcome to contact one of the 23 IGIP National Monitoring Committees or the IGIP headquarters in Austria.

CONCLUSIONS

Technical university teaching has often been perceived as a poor cousin to research. Few technical universities require any specific technical teacher education for their academic staff. Interestingly, this is the only level of learning where academic staff receives no teacher training. Yet teaching is an art that, at least to some degree, can be taught, if the institutions of higher learning support it as an important element. The International Society for Engineering Education (IGIP) is working to assure that graduates of accredited engineering pedagogical programs are well prepared to perform their teaching duties in engineering subjects and meet the criteria for IGIP registration as International Engineering Educators, ING.PAED.IGIP. IGIP's ultimate goal, however, is to promote quality assurance, quality improvement and modernize engineering pedagogy programs and educational practices. Its intention is also to create public awareness of the high quality of engineering pedagogue programs.

Abstract— The study of students' preconceptions and how they affect their learning in science, technology, engineering and mathematics (STEM) fields is of nationally recognized importance. There are, however, various and contradictory theoretical approaches to conceptual change, and none of them have been rigorously applied in the context of engineering education. This paper is part of a larger study drawing on existing sets of data from a wide range of engineering content areas to develop a theoretical explanation of conceptual change in engineering education. In the work reported here we re-analyze students' understanding of concepts about axially loaded members (from mechanics of materials) and Boolean logic (from digital logic). Previously published analyses of these data argue that the context of a problem or question effects students' reasoning about that concept. These contexts can range from the presence or absence of figures or diagrams to the social contexts of the problem. We explored three potential theoretical explanations for the context-sensitivity of student reasoning: (1) a perceptual cues theory, (2) a domain specificity theory, and (3) a language-based theory. It is argued that these competing theoretical explanations do not contradict each other as much as they overlap, and potentially productive syntheses of the theories are proposed as directions for future work.

Keywords- *conceptual change; Mechanics of Materials; Digital Logic*

I. INTRODUCTION

The study of students' preconceptions and how they affect their learning in science, technology, engineering and mathematics (STEM) fields is of nationally recognized importance [1]. Beyond the agreement to identify and address students' preconceptions, however, there is little consensus about the nature of preconceptions or even what is meant by the term "preconceptions." The progress of empirically based research in addressing these calls depends on a more rigorous description of what is meant by preconceptions, what is meant by learning, and how one interferes with the other.

Within conceptual change research, preconceptions are assumed to be functionally equivalent to accepted conceptions acquired through formal learning, but differ only in content [2, 3]. In this paper, we will distinguish between the acquisition of new knowledge (the creation of new knowledge structures) and conceptual change (changing the substance of preconceptions to accepted conceptions).

In some cases the benefits of new knowledge is obvious, or not strongly contradicted by preconceptions – students' life experiences rarely lead them to doubt that gravity causes an acceleration of 32.2 feet per second per second, for example, so this knowledge is easily acquired. Common life experiences do contradict, however, that an object in motion tends to stay in motion. Learning Newtonian physics therefore requires students to reevaluate life experiences and ways of thinking as well as acquire the individual bits of knowledge being proposed in class (e.g. the equations of kinematics). This type of learning is conceptual change and is typically much more difficult to achieve than acquiring facts like the acceleration due to gravity [4].

Despite overwhelming evidence as to the importance and frustrating lack of conceptual change in traditional education [5], a number of vitally important questions remain contentious and difficult to answer. Why is conceptual change difficult? What are the actual processes that underlie it, and most importantly, what can educators do to promote it in their classrooms? In the past few decades, several theories of conceptual change have been proposed, but none have been clearly superior in terms of their ability to explain observed phenomena or guide instructors in helping their students learn [4, 6]. The development of these theories is typically based on one or only a small number of science disciplines, and few of these published efforts have included engineering concepts or practices [for exceptions see 7, 8, 9]. The purpose of this paper is to contribute to the development of a theory of conceptual change in engineering.

II. BACKGROUND

The work reported in this paper is part of a larger effort to utilize existing data to develop and test a theory of conceptual change for engineering education. The data being used consists of more than 250 interviews with engineering students conducted over the past several years in the course of the coauthors' ongoing research programs. These interviews cover engineering topics that include fluid mechanics, geometric highway design, thermodynamics, and a variety of topics within both mechanics of materials and digital logic.

This paper is based on analyses of a subset of those data, specifically interviews about students' understanding of axially loaded members (40 interviews) and Boolean logic (16 interviews). We chose this subset because the methodologies and findings of the interviews addressed a similar fundamental problem, despite being developed separately. In particular, both studies emphasize the ways in which students' reasoning and conceptual understanding seemed to be context dependent – understandings change as the contexts of the interview were changed [10, 11]. For the purpose of our discussion, contexts can be different tasks, presentation styles, or social contexts.

The most prominent theories of conceptual change either do not directly address the context dependence of students' knowledge [12], or they attribute significantly different meanings to it [see for example 13, 14-16]. This question may be more important in the context of engineering education than in the broader field of conceptual change research, because engineers are expected to use the knowledge they gain during formal education through problem sets and examinations in radically different contexts in practice (e.g., design and documentation). Engineering educators in particular need to be concerned with any phenomena that seem to limit students' abilities to apply understandings in new contexts.

The purpose of this study was to develop and test theoretical explanations for why students' understanding of fundamental concepts in mechanics of materials and digital logic seem to be context dependent.

III. METHODS

A. Data Collection

As described above, the data used in this study were collected as parts of two separate studies. Results from these studies have been published previously [10, 11]. In both studies, one purpose of the interviews was to present slightly different versions of the same concepts in order to better understand how students' reasoning changed with context. In the interviews about axially loaded members, Brown and Montfort tested context dependence by presenting axially loaded members in multiple ways: two-dimensional schematic drawings, isometric sections, stress elements, and pictures of actual failed concrete cylinders. For the interviews about Boolean logic, Herman et al varied both the social contexts of the problems (e.g., people deciding on pizza toppings or following a recipe to make apple pie) and the specific tasks (e.g., to write a Boolean expression or fill in a truth table). Students were always asked about the same fundamental concepts. For axially loaded members, students were asked

about normal and shear stresses, forces and strains. For Boolean logic, students were asked to reason about common operators including if-then, if-and-only-if, OR, XOR and AND.

B. Analysis

For this paper, we report our reanalysis of the mechanics of materials and Boolean logic interviews. To focus the analysis, we chose to examine students' understanding of one set of concepts from each topic: if-then (implication) and if-and-only-if (bidirectional implication) from Boolean logic and shear force, stress, and strain from mechanics of materials. This narrowed focus allowed for richer descriptions and a more grounded coding of the data to facilitate theory development.

The interviews were primarily analyzed by researchers Dr. Herman and Dr. Montfort who have expertise in conceptual change research. Dr. Herman also provided expertise with digital logic concepts and Dr. Montfort provided expertise with mechanics of materials. Each researcher was a novice in the opposite topic. The primary analysis of each group of interviews was conducted by the novice in that topic. Dr. Montfort analyzed the Boolean-logic interviews that had been designed and conducted by Dr. Herman, while Dr. Herman analyzed the axially-loaded-member interviews which had been designed and previously analyzed by Dr. Montfort. After this preliminary, independent analysis, the researchers compared and discussed codings until agreement was reached.

This novice-led analysis familiarized the novice with the transcripts and technical content of the interviews, but more importantly, it exposed the "expert blindspots" [17] of the content expert. For example, in some cases student statements that had been coded as "incorrect" by the expert in the content area were recoded to be inconclusive due to leading or unclear wording of questions as identified by the novice in that area.

This first stage of analysis, particularly the adjustment of codes to account for blindspots, further emphasized the ways in which students' reasoning appeared to change in different contexts. We conducted a second stage of coding in which the researchers went back to the interviews outside their expertise and searched for patterns and themes [18] in students' reasoning across those questions that had been designed to probe the same concepts. In this use a "pattern" is a grouping of observations. For example, Dr. Montfort identified the pattern that students who referred to "zeros" and "ones" in solving Boolean logic word problems also tended to check their work and successfully identify errors.

The patterns identified were similarly discussed and verified by both researchers before moving to the third stage of analysis. In this stage, the two researchers proposed explanations for those patterns, and sought vignettes in both sets of interviews that supported and challenged those explanations.

We derived three explanations for the differences in student reasoning that we observed in the data. These explanations were developed iteratively through the analysis as opposed to being assumed prior to the analyses. These three explanations will be introduced in the context of the theoretical works that informed and inspired them and supported by vignettes from

the data. Although we acknowledge the foundational influence of existing theories of conceptual change on our explanations, we do not intend to be faithful to any existing theories. Rather, we will expand upon their implications in the context of engineering education.

In the reports to follow, students are identified by interview topic and a number: A1 and A2 represent two different students interviewed about axially loaded members, while B1 and B2 represent two different students interviewed about Boolean logic. Note that while each theory is supported by a single student example to allow for sufficient detail, all three theories were developed and validated across both datasets.

IV. PERCEPTUAL CUES

The perceptual cues explanation argues that students' use of knowledge is cued by physical perceptual features (e.g., visual or auditory) of the interview that prompt their use of knowledge or reasoning. Building on Minstrell's construct of facets [19] and diSessa's model of conceptual ecology [20], this explanation does not assume that students possess or use coherent domains of knowledge, but rather use pieces of knowledge as they seem relevant or related to the situation. Perceptions cue or activate individual cognitive entities (e.g. memories, facts, beliefs, equations) or strings of common thoughts (e.g. algorithms to solve common problems). In this model, conceptual change is the process of creating more consistent and useful strings of concepts and ensuring that they are cued by all pertinent contexts [21]. Evidence supporting this explanation would be instances where students' reasoning seems directly dependent on what they attend to in the problem set-up. Differences in reasoning would necessarily accompany differences in perception or attention.

A. Supporting Case

When presented with various representations of an axially loaded member and asked if shear stress was present, student A2 sometimes said yes, and sometimes no. Despite the frequency of these questions, and their reoccurrence within only a few minutes, A2 did not appear perturbed by the inconsistency.

A2 correctly identified and reasoned about shear stress when using Mohr's circle (a complex graphical analytical tool relating normal and shear stresses that many students struggle to understand), but she was less able than many students to identify the role of shear in the failure of a concrete cylinder under compression. Many students, even those who struggled to describe shear stress in axially loaded members throughout their interviews, correctly identified the 45° angle of failure (a useful perceptual cue for these students) and associated it with the maximum shear stresses under axial loading. When asked to describe the cause of failure given the same picture, however, A2 reasoned, "...it looks like it has a weakness at an angle in the member sort of like...with the grains this has a failure point but at an angle rather than something straight." When asked "what forces are present and how they are acting," A2 replied, "Well there is a compressive force. So you would have the compressive force acting. So you would have - I don't really understand what you are asking."

In this exchange, we hypothesize that her response to the interviewer's questions about the failed concrete cylinder was cued by the interviewer's description of a "concrete cylinder that failed in compression" and the testing machinery that provided that compression is clearly shown in the pictures. Understandably, then, A2's description of "what forces were present and how they were acting" began and ended with those compressive forces. Furthermore, the rough, pebbly appearance of the failure plane cued her knowledge of "grains" and "failure points," rather than the more abstracted analyses she preferred in earlier questions showing more simplified and idealized members.

Even in reference to the more simplified figures, however, A2's reasoning aligned with the problem features that were most salient to her. When presented with angled, diamond-shaped stress elements (as opposed to the more common square ones oriented parallel to the edges of the page), A2 naturally and easily discussed shear stress in reference to those elements, saying for example that there would be less stress when the elements were oriented that way "because of it being distributed over more surfaces." Reasoning based on the distribution of stress over the "surfaces" of a stress element in this way contradicts the ways stress elements are presented and used in courses, but *is* strongly supported by the visual cues presented in the problem.

A2's reliance on the perceived features of the problem extends beyond shear stress to reasoning about internal and external forces. She would reason using primarily external forces when the figures presented only members with external forces, and primarily internal reactions when those forces were drawn.

B. Challenges

As noted, certain perceptual cues did not always correlate with more difficult tasks. For example, some students were better able to discuss shear in the context of the concrete cylinder, but others were better able to discuss shear in the context of Mohr's circle. In hindsight and after extensive analysis, we can tell that A2 and students who had similar difficulties appeared to envision microscopic components (e.g. "with the grains" or "the fibers") when discussing the concrete cylinder, but these distinctions and patterns would be difficult to identify in the moment or to predict. Although the use of perceptual cues may provide a clean explanation (e.g., "students talk about what they see or hear"), it does not lend itself to predictive power of a students' reasoning ability in a specific context. We identified these themes only after analyzing the interviews several times prior to and during this study.

This theory generates some valuable questions. Why do students fixate on the things they do? Why is A2 so intuitively able to distinguish external and internal forces, but not able to distinguish forces and stresses?

V. DOMAIN-SPECIFICITY

Building on Vosniadou's "framework theories," [22] the domain-specificity explanation argues that students' reasoning and conceptual understanding is controlled by the domain in

which they situate their thinking. The domain of a question, as determined by the student, determines the concepts, procedures, and expectations that are available to be applied. Students identify the domain of a problem based on their perceptions of it. In this model, changes in students' reasoning in response to superficial changes in problem features are caused by shifts in the domain in which the student is acting.

A. Supporting Case

As an example, we will present student B7's apparent understanding of the operator *if-then* in Boolean logic. When first asked, "We're going to be talking about Boolean Algebra. Could you explain the phrase 'IF A THEN B'?" How would you describe that in common, everyday English, to a senior who is about to start CS?" he asked, "You mean programming, or more like the logic part?" In this statement, we can see that the student is negotiating which domain to use: the programming domain or the logic domain.

When told to just consider "the logic part," B7 responded with a statement that would be true in the programming domain, but not the logic domain: "Basically, if we have one condition, and we have that it's true, it follows, B. So, if expression A is valued to true, then it follows with B." When asked to write a Boolean expression to show what he meant, B7 wrote a statement in a form of computer programming pseudocode using the words "if" and "then." When asked to write it "with just symbols and variables instead of programming code," B7 wrote " $A \rightarrow B$." In attempting to encourage B7 to elaborate on what he had written, the interviewer suggested ways in which to translate the function into a Boolean expression such as "using a symbol like AND, or OR, and complements," and referring to the specific course that would have covered this material. B7 became frustrated as he was unable to express "IF A THEN B" in any other way:

B7: Well the thing is that, IF A THEN B, there's no AND's and no OR's. IF A; you just write "A." And then, "follows B."

Interviewer: Ok, ok, so what is the relationship between A and B, then?

B7: What?

Interviewer: What is the relationship between A and B, are they...?

B7: Well, B is what happens when A follows to true.

Later in the interview, B7 is asked to express the phrase "if a sandwich has turkey (t) then it must also have cheese (c)" as a Boolean expression (correctly written as $f(t,c) = t \wedge c$). He reasoned about the IF-THEN better than many students by noticing, "...it's not saying anything about C whether it has to have cheese[....] Basically what'd we'd be saying now is that we have turkey then there will be cheese, but not necessarily that if we have cheese then we have to have turkey." During this reasoning, however, B7 wrote " $c=t$ " as the Boolean expression reflecting his reasoning, which is what's known as an assignment operation in programming. When asked if " $c=t$ " is a "standard Boolean algebra expression" B7 argues that is by

explaining how the operation functions in programming: "C could be expressed as a function and it would be T. So yes."

B7's reasoning and conceptual understanding can best be explained by describing the domains within which he reasons. Initially, B7 is explicitly confused as to the domain of the interviews, confusing computer programming with the more general computer science, and not clearly understanding what the interviewer implies with the phrase "Boolean algebra." Although he tends to use programming terminology, B7 is sometimes clearly aware of the disconnect between the questions and his perceptions of the domain, as evidenced by his frustration with the first line of questioning.

We cannot simply say that B7 is thinking in the "wrong domain," however, because throughout the interview he confidently and adeptly uses many Boolean algebra concepts. Furthermore, B7 had internalized some of the nuances of *if-then*. For example, B7 manages to avoid a common mistake by immediately recognizing that if-then is one directional relationship between the presence of turkey and cheese. This apparent mastery of a difficult concept, however, is immediately juxtaposed by a comparably unusual lack of understanding of how to express the concept in Boolean algebra.

We propose that B7's conceptual difficulties with Boolean algebra are caused by his failure to create strongly defined and distinct domains. Throughout his interview, B7 tries to justify reasoning by appealing to different domains and unknowingly switching between domains. He argues that " $c=t$ " is standard Boolean expression because "C could be expressed as a function and it would be T." While this statement could be a Boolean expression, it unnecessarily appropriates a concept from the programming domain. In other words, B7 lacks the mechanisms to distinguish between two domains and assess the coherence and consistency of his reasoning from the perspective of a single domain. This missing mechanism is most obvious in the first exchange quoted where B7 and the interviewer are apparently unable to make themselves understood. They each understand the components and concepts being applied – *if-then*, A's and B's as variables that can be true or false – but they are speaking about different domains and thus lack the means to interpret each other's statements. The interviewer's repeated questions imply that B7's responses are incomplete or inappropriate, while B7's repetitions of the same phrases imply that he is unable to determine what is missing from his response; he lacks the framework, or domain, to adequately assess the appropriateness of his response.

B. Challenges

Although many students' general patterns of reasoning matched B7's and tended to correspond with questions concerning the domain (e.g. "in programming, or in logic?"), it is difficult to completely separate domain-specificity as the causal agent. Simply put, any differences in student reasoning occur in response to different questions and at different times, and could conceivably be affected by any changes in circumstances including temporary changes in affect, different physical environments, wording of questions or even non-

verbal cues from the interviewer. Even if the patterns of domain-confusion continue to co-occur with changes in student reasoning, it is unclear which causes the other. As described above, there is a feedback loop between the ways in which perceptions inform domains and domains inform perceptions. As students change their reasoning in response to different questions, is it because their perceptions are overly mediated by their domain, or because their domain is too limited by their perceptions?

VI. LANGUAGE-BASED

The language-based explanation moves outside the assumption that we can infer students' conceptual or cognitive processes, and instead focuses on the actual data being recorded: student and interviewer use of language. In this definition, language includes any form of verbal, written, or bodily form of expression including drawings, statements or gestures [23]. Instead of assuming that students' *reasoning* or *conceptual understanding* changes when the problem presentation changes, we instead focus on how their uses of language are different or consistent. The use of language includes both the communication of ideas from the participant to the interviewer and the interpretation of the interviewers' statements by the participant.

A. Supporting Case

As an example, we present evidence from student A4's interview about shear forces, stresses, and strains. Throughout A4's interview, he treats forces' and stresses' directions (i.e. in the vertical and horizontal directions or in the X- and Y-planes) as defining descriptions of their fundamental nature. For example, he defines normal forces as "forces on the X-plane." Similarly, he argues for the absence of shear stress in an axially-loaded member by reasoning that "there are no forces in the Y-plane, there are no vertical forces." It's important to note that A4 may not be merely skipping a step in describing a causal sequence, or inferring that "forces in the Y-plane" or "vertical forces" are indications of or causes of shear stress. As indicated by his use of terminology throughout the interview, he apparently treats the statement "there are no vertical forces" as synonymous with "there is no shear stress."

A4 would likely find this discursive tool to be useful in courses that build upon a mechanics foundation, because decomposition of forces into x- and y-components makes up a small but significant portion of the activities students engage in within the context of the course. In much of his coursework, A4 would not even need to be able to discursively distinguish between a force's direction and nature (i.e. normal or shear), because they so reliably correspond. It makes sense then, that he does not make these distinctions in the interview. Unfortunately, normal and shear are not synonyms for X and Y, so this discursive tool has its limits for allowing productive reasoning.

For example, A4 stated that shear stress was present in one axially loaded member, but absent in another when the only difference between the two members was the frame of reference: (in one case the x- and y-directions would align

with normal and shear stress and in the other case they would not). Despite being told it was the "same member," A4 made contradictory claims about it within a few seconds.

Interviewer: looking at that top member, are there shear forces present?

A4: No.

Interviewer: And describe your reasoning.

A4: There are no forces in the Y-plane, there are no vertical forces.

Interviewer: And so now, we are making a cut on the same member at cross section BB and just draw the resultant forces and describe what forces are present at cross section BB.

A4: It would be as it comes off perpendicular to BB which also will give it a shear. It should be down.

When discussing forces on the member with a hypothetical non-perpendicular cut in the second set of questions, A4 could discuss the decomposition of the forces into normal and shear components because the relative directions of the forces could be envisioned on a rotated XY axis, and there was therefore no need to distinguish between the direction and nature of the forces.

A4's discursive conflation of "shear" and "vertical" was apparent in his interpretations of questions, as well. Regardless of how a question was phrased, A4 used the terms "shear strain," "shear" and "strain" interchangeably to describe some deformations, again failing to make appropriate distinctions between normal and shear strains, or between strain and stress.

B. Challenges

A primary challenge for this explanation is whether we should distinguish between a students' ability to explain their reasoning and their ability to reason well. For example, a student may have limited ability to engage in discourse about their conceptual understanding in English, but may be able to discourse accurately about their conceptual understanding by making predictions, graphs, figures, or even equations. Does an inability to communicate conceptual understanding with one mode of communication imply that a student possesses detrimental preconceptions? How do we distinguish between different modes of communication and are some more valuable than others for conceptual formation?

VII. CONCLUSIONS

Although we pose these theories as three distinct theories, it may already be apparent that there is considerable overlap between these proposed explanations. Considering that each theory was derived from a different, supposedly contradictory, intellectual tradition, we believe that this observable overlap is a finding in itself. Their overlap identifies potentially fruitful areas for future research that build a synthesis of the three theories into a new and more flexible theory.

First, the importance of language holds paramount across all three explanations. Students' perceptions and domains are largely identified by the language they use. Again, this use of

the word “language” refers to all the students’ efforts at making and interpreting meaning including speaking, drawing, writing equations, and gesturing. Future research in conceptual change, and indeed future efforts to teach for conceptual change, could benefit from closer and more nuanced attention to students’, researchers’ and instructors’ use of language.

Second, the concepts that students struggled to apply in these interviews are often considered fundamental, and their misconceptions are probably directly contradicted in most relevant courses. Small changes in the ways in which problems are presented render many students unable to apply basic concepts, even minutes after they have displayed mastery of them in another context. This supports a well documented trend of low conceptual understanding among engineering students, but adds the potential explanatory factor of highly context-dependent abilities.

Third, all of these explanations go beyond the content itself to examine the contexts in which it is situated, which means the ways in which a subject is typically presented are as important as the subject itself. What is being emphasized, implied and assumed in the typical representations of digital logic or mechanics of materials? Who are the people using these subjects, and what problems are they actually solving with them? Even though they are largely implicit and tacit, these messages are communicated in the ways the subjects are taught.

Finally, we’d like to highlight the ways in which these theoretical differences are important to the practice of engineering education. It is acknowledged that students struggle to learn some aspects of Boolean algebra and axially loaded members, but the response to that problem depends on one’s understanding of the cognitive processes underlying it. If students’ understanding is limited by their perceptions, the emphasis should be on helping students expand their abilities to link perceptions to pertinent engineering fundamentals. If it is the domain-specificity of their understanding that is problematic, then explicit instruction about the boundaries, purposes and history of the subject should help. If it is rather a problem of language, then treating learning as language acquisition could facilitate conceptual change. Without an empirically based and tested theory of conceptual change in engineering education, it is difficult to even define the problem, let alone begin to solve it.

- [24]

As per an earlier study [9], since problem-solving activity was alternated with the easier activity of answering three Likert-scale questions, the efficiency with which students solved pre-test problems should have increased with alternation than without. But, the time spent per problem on the pre-test was not significantly different between the control and test groups [$F(1,254) = 2.368$, $p = 0.125$] (See Table VII). Then again, more recent literature on task switching finds that subjects take longer to perform alternating tasks than massed tasks, because of alternation or mixing cost (e.g., [10,11]). In this study, the effect of such alternation cost was not found to be significant either.

TABLE VII. TIME SPENT PER PRE-TEST PROBLEM: CONTROL VERSUS TEST GROUP

| | <i>Average (seconds)</i> | <i>N</i> |
|---------|--------------------------|----------|
| Control | 55.6843 | 145 |
| Test | 61.2365 | 110 |

C. Affective Learning

After eliminating the students who had scored 100% on the pre-test:

- There was no statistically significant difference in the prior self-confidence of the control and test groups [$F(1,229) = 0.083$, $p = 0.774$] (See Table VIII).

TABLE VIII. PRIOR SELF-CONFIDENCE: CONTROL VERSUS TEST GROUP

| | <i>Average</i> | <i>N</i> |
|---------|----------------|----------|
| Control | 2.7214 | 133 |
| Test | 2.7543 | 97 |

- There was no statistically significant difference in the post self-confidence of the control and test groups [$F(1,216) = 1.163$, $p = 0.282$] (See Table IX).

TABLE IX. POST SELF-CONFIDENCE : CONTROL VERSUS TEST GROUP

| | <i>Average</i> | <i>N</i> |
|---------|----------------|----------|
| Control | 2.0563 | 128 |
| Test | 2.182 | 89 |

- There was no statistically significant difference in the average feedback response of the control and test groups [$F(1,216) = 0.123$, $p = 0.726$] (See Table X).

TABLE X. AVERAGE FEEDBACK RESPONSE: CONTROL VERSUS TEST GROUP

| | <i>Average</i> | <i>N</i> |
|---------|----------------|----------|
| Control | 2.4164 | 128 |
| Test | 2.4498 | 89 |

So, in terms of *affective learning due to tutoring* - self-confidence and feedback about the tutor – the treatment did not result in any statistically significant difference between the control and test groups.

Earlier studies had shown that self-confidence of the students increased significantly from using the tutors (e.g., [12]). There was no significant difference in the improvement in the self-confidence between the control and test groups [$F(1,215) = 0.271$, $p = 0.603$] (See Table XI).

TABLE XI. PRE-POST CHANGE IN SELF-CONFIDENCE: CONTROL VERSUS TEST GROUP

| | <i>Average</i> | <i>N</i> |
|---------|----------------|----------|
| Control | -0.6472 | 127 |
| Test | -0.5873 | 89 |

Earlier studies had shown that female students were more likely to provide positive feedback about the tutor than male students [13]. When average feedback response was analyzed with treatment and sex as fixed factors, no main effect was found for treatment [$F(1,199) = 0.256$, $p = 0.613$] or sex [$F(1,199) = 2.45$, $p = 0.119$] and no significant interaction was found between the two [$F(1,199) = 0.278$, $p = 0.599$].

IV. DISCUSSION

Introduction of the alternate task did not result in any statistically significant difference in the scores of the control and test groups on the pre-test. It did not promote better cognitive learning or affective learning during tutoring. There could be a number of reasons for the negative results:

- Though alternation was found to be on the average more efficient than massing, differences were found among subjects in whether they could benefit from alternation, and these differences were ascribed to the subjects' ability to persevere, called perseveration [14]. So, in the current study, some students may have benefited from alternation whereas others may have been hindered by it, the cumulative effect being to cancel each other out.
- An earlier study had concluded that the effects of alternation are proportional to the dissimilarity of the alternating tasks [15]. The activity of the alternate task, i.e., answering Likert-scale questions was very dissimilar from the problem-solving activity of the main task. However, since the three Likert-scale questions were about the problem that the student had just solved, the mental task set of the alternate task may not have been dissimilar enough to accrue the benefits of alternation. Other studies suggest that the effects of alternation vary according to the types of tasks involved, e.g., mental versus motor (e.g., [16]). Both problem-solving and answering Likert-scale questions are mental tasks, which may be another reason why no benefits were found that could be ascribed to alternation.
- Earlier studies have shown that massing is more efficient than alternating (e.g., [17]) for complex tasks. The main task in this study was solving problems, which is a complex task involving multiple steps. So, as per the earlier study, alternating (test condition) should have been found to be less efficient than massing (control condition). But, no significant difference in the time spent per problem was found between the control and test groups.

- According to the research on task switching, alternation results in increased error rates as compared to massing because of switch costs (e.g., [6]). This might help explain why alternation did not produce better learning or test results in the current study. Then again, the current study contradicts task switching studies in that alternation did not impair learning or test results in any significant manner in spite of switch costs. This is all the more significant considering that the task in this study – problem-solving, is considerably more complicated than the simple stimulus-response tasks used in most task switching studies.

The current study differs from earlier studies on alternation in the following respects: it considered the task of solving problems, which consists of multiple steps, and is hence more complex than single-step stimulus-response tasks considered earlier; both the primary task and the alternation task were conducted entirely online; and the primary task was in the domain of computer programming. It is possible that under these conditions, the positive benefits of alternation cancel out the negative costs associated with task-switching. This hypothesis bears further experimentation.

The Effect of Interleaving an Alternate Task During Tutoring and Testing

Amruth N. Kumar

Computer Science

Mahwah, NJ, USA

amruth@ramapo.edu

Abstract—The effect of interleaving an alternate task during tutoring and testing was studied in the context of an online problem-solving software tutor. A controlled study was used and ANOVA was used for data analysis. It was found that introduction of the alternate task did not result in any difference in the scores of control and test groups during testing. It did not promote greater cognitive or affective learning during tutoring. Some possible reasons for the negative results are discussed.

Keywords—*alternating tasks; online learning; software tutor; computer programming*

I. INTRODUCTION

We have been developing software tutors to help students learn programming concepts by solving problems. These software tutors present a sequence of problems, have students solve them, and provide feedback from which students can learn. However, solving several problems back to back can be monotonous and exhausting. It seems intuitive that breaking up the problem-solving session and introducing alternate tasks in between could break the monotony and increase engagement. Did the alternate task, which was introduced to break up the monotony of problem-solving, help students learn better with our tutors? We conducted a controlled study to test this hypothesis.

The effect of alternating tasks has been studied under multiple terms – early studies were on *alternating tasks* (e.g., [1]); more recent studies have been on *spacing in learning* or *distributed practice* (e.g., [2]) and *task switching* (e.g., [3]). In an early study on alternating tasks, researchers compared an alternating protocol where video game-like tasks and word problem tasks were alternated, against a massed protocol in which the tasks were grouped together by type [4]. They found that alternating task protocol was more advantageous for learning and retention of both video games and word problems. Literature on spacing in learning, i.e., temporally separating learning sessions with possibly other activities in between, has shown that spacing is better for retention than massed learning wherein all the learning is done in one continuous session (e.g., [5]). Research on task switching (e.g., [3]) has looked into the factors that promote or inhibit performance when tasks are alternated. One of the key findings of this research is that alternation comes with a switch cost in both reaction time and error rate (e.g., [6]). Note that the advantage of alternation for

learning as found in research on alternating tasks is at odds with the increase in error rates due to alternation found in research on task switching. So, it is unclear from prior literature what we could expect to find on the effect of alternation on learning in the current study.

A large part of the earlier research on alternating tasks and task switching was conducted with well-defined stimulus-response tasks such as solving arithmetic problems, word problems and classification problems, also called single-step tasks [7]. In contrast, in the current study, the main task is solving problems, a task that involves multiple steps, and is hence, more complex than the stimulus-response tasks studied earlier. The problem-solving task and the alternate task were both carried out entirely online in the current study. The focus of the current study is on the effect of alternation on performance during tests and learning during tutoring – both cognitive and affective. Finally, the domain considered in this study is computer programming, which, to the best of our knowledge, has not been the subject of prior studies on alternation.

In the rest of this paper, we describe the software tutor and the protocol used for the study, followed by results of data analysis and discussion of the findings.

II. METHODS

For this study, an online software tutor was used, which deals with selection statements, which are a part of introductory computer programming. The software tutor presents problems and has the student solve them. Each problem contains a computer program that includes selection statements. The student is asked to predict all the outputs of the program, one output at a time, along with the line number of the code that generates each output. After the student submits the answer, the tutor provides two types of feedback - whether the answer is correct, and step-by-step explanation of the correct answer. Earlier evaluations have shown that the step-by-step explanation helps students learn [8]. The tutor on selection statements is part of a suite of software tutors called problets (www.problets.org).

When using the software tutor, students went through the following sequence of stages, all administered over the web, back to back and without any break:

1. **Registration** – students entered identifying information about themselves - their name, and demographic information;
2. **Pre-Survey** – students rated their knowledge about the various concepts covered by the software tutor on a 5-point Likert scale (1=Very well, 2=Well, 3=Average, 4=Not well, 5=Not at all). They responded to five different statements:

- How well do you know 'if' statements?
- How well do you know 'if-else' statements?
- How well do you know nested 'if' statements?
- How well do you know nested 'if-else' statements?
- How well do you know the boolean data type?

Their average response on these five questions was used as a measure of their prior self-confidence in the topic. Note that a numerical response of 1 corresponds to the greatest self-confidence and 5 corresponds to the lowest self-confidence.

3. **Problem-solving stage** - the software tutor presented problems to the students, had them solve the problems, and provided them feedback from which they could learn. This stage itself consisted of three segments:
 - **Pre-test** consisting of 12 problems, one per learning objective. If a student solved a problem correctly, the student was given credit for the corresponding learning objective. No feedback was provided to the student, and no more problems on the learning objective were presented to the student. On the other hand, if the student solved a problem incorrectly, feedback was presented to the student immediately after the student submitted his/her solution to the problem. Additional problems were presented on the learning objective during the subsequent segments of the stage.
 - **Adaptive practice** – during this segment, additional problems were presented to the student on only the learning objectives on which the student had made mistakes when solving problems during the pre-test. For each such learning objective, the student was presented multiple problems until the student had mastered the learning objective, i.e., solved at least 60% of the problems correctly.
 - **Post-test** - during this segment, the student was presented test problems on the learning objectives that the student had mastered during adaptive practice.

Note that if a student solved all the pre-test problems correctly, no practice or post-test problems were presented to the student. The entire problem-solving stage was limited to 30 minutes. So, the students who did not solve

all the problems correctly during the pre-test may still not have completed practice or post-test because they ran out of time. Finally, for a concept (learning objective) to be considered as *having been learned by the student*, the student must have solved the problem on that concept incorrectly during the pre-test, repeatedly solved problems during practice until the student had mastered it, and must have correctly solved the post-test problem on that concept.

4. **Post-Survey** – the software tutor administered the same instrument as on the pre-survey. The student's average response on the post-survey was used as a measure of her/his self-confidence in the topic after the problem-solving session.
5. **Feedback** – students rated the usability, ability to learn from, and usefulness of the software tutor by responding to 14 statements on a 5-point Likert scale (1=Strongly agree, 2=Agree, 3=Neutral, 4=Disagree, 5=Strongly disagree). Some of the 14 statements were "The feedback provided to my answers was useful", "The tutor helped me learn new material", and "This tutor should be made available to all the students". Note that a numerical response of 1 corresponds to the most positive and 5 corresponds to the most negative assessment of the software tutor.

In one early study of alternating tasks, when a task was alternated with an easier task, the efficiency of doing the first task was observed to increase, and when it was alternated with a more difficult task, the efficiency of doing the first task was observed to decrease [9]. Therefore, in the current study, an alternate task was used that is significantly easier than solving problems – one that involved answering three Likert-scale questions. During the problem-solving stage, the test group students were asked to answer three Likert-scale questions after solving each problem: the first to rate the level of difficulty of the problem; the second on whether the problem helped the student learn; and the last on whether the student wanted to solve additional problems of that type. Control group students on the other hand were not asked to answer these three questions – instead, they solved problems back to back. Since literature on task switching finds that alternating task protocol takes longer than massed or blocked protocol, the difference being referred to as alternation cost (e.g., [10]), the test group was allowed 33 minutes for the problem-solving stage whereas the control group was allowed 30 minutes. All the other stages of the tutor were configured identically for the control and test groups.

Registration and problem-solving stages were required of all the students. Pre-survey, post-survey and feedback stages were presented to all the students, but were optional, i.e., students could continue without responding to some or all the statements during these stages.

Data was collected in fall 2009 and spring 2010. 474 students from 18 institutions (both 2-year and 4-year) used the tutor during those two semesters. The institutions were randomly assigned to control or test group. The size N varied from one data analysis to the next due to several reasons: pre-survey, post-survey and feedback stages were optional; some students solved all the pre-test problems correctly during the

problem-solving stage; and some students ran out of time during the problem-solving stage. Therefore, in the next section, N has been included in the results of every analysis.

III. RESULTS

A. Average pretest score

The score on each pre-test problem was calculated as the ratio of the number of steps correctly identified and the total number of steps in the correct solution, resulting in a scale of 0 (incorrect) \rightarrow 1.0 (correct). Average pretest score was calculated as the average of the scores of all the problems attempted by a student. ANOVA analysis of the average pretest score from the two semesters combined showed no statistically significant difference between the control group (no alternate task after each problem) and the test group (with alternate task after each problem) [$F(1,473) = 0.670$, $p = 0.414$] (See Table I).

TABLE I. PRE-TEST SCORE: CONTROL VERSUS TEST GROUP

| | Average | N |
|---------|---------|-----|
| Control | 0.8984 | 261 |
| Test | 0.9093 | 213 |

Interestingly, when only fall 2009 data was considered, the control group scored significantly more than the test group [$F(1,219) = 4.49$, $p = 0.035$]. On the other hand, when only spring 2010 data was considered, the test group scored significantly more than the control group [$F(1,253) = 7.785$, $p = 0.006$] (See Table II).

TABLE II. PRE-TEST SCORE BY SEMESTER: CONTROL VERSUS TEST GROUP

| | | Average | N |
|-------------|---------|---------|-----|
| Fall 2009 | Control | 0.9153 | 121 |
| | Test | 0.8772 | 99 |
| Spring 2010 | Control | 0.8838 | 140 |
| | Test | 0.9373 | 114 |

So, when data from the two semesters were combined, significant and contradictory differences found in individual semesters were cancelled out.

In order to account for ceiling effect, students who had scored 100% on the pre-test were eliminated (116 students in the control group and 102 students in the test group). After this elimination, no statistically significant difference was found in the average pretest score between the control group and the test group [$F(1,255) = 0.207$, $p = 0.649$] (See Table III).

TABLE III. PRE-TEST SCORE AFTER ELIMINATING CEILING EFFECT: CONTROL VERSUS TEST GROUP

| | Average | N |
|---------|---------|-----|
| Control | 0.8171 | 145 |
| Test | 0.8260 | 111 |

There was no statistically significant difference between the control and test groups in fall 2009 [$F(1,126) = 1.329$, $p = 0.251$] or spring 2010 [$F(1, 128) = 2.115$, $p = 0.148$] (See Table IV).

TABLE IV. PRE-TEST SCORE BY SEMESTER AFTER ELIMINATING CEILING EFFECT: CONTROL VERSUS TEST GROUP

| | | Average | N |
|-------------|---------|---------|----|
| Fall 2009 | Control | 0.8373 | 63 |
| | Test | 0.81 | 64 |
| Spring 2010 | Control | 0.8016 | 82 |
| | Test | 0.8479 | 47 |

So, the statistically significant differences observed earlier between the control and test groups in individual semester data was due to the data being skewed by the students who had scored 100% on the pre-test – students who did not stand to learn from the software tutor. So, for all subsequent evaluations, only those students were considered who did not score 100% on the pre-test. For these students, the alternating task did not result in any statistically significant difference in the average test score between control and test groups.

B. Cognitive Learning

Analysis of cognitive learning applies only to the students who scored less than 100% on the pre-test since only these students were presented practice and post-test stages by the tutor. It was found that:

- During the adaptive practice stage, students in the test group solved more practice problems than those in the control group, but this difference was not statistically significant [$F(1,240) = 2.256$, $p = 0.134$] (See Table V).

TABLE V. PRACTICE PROBLEMS SOLVED: CONTROL VERSUS TEST GROUP

| | Average | N |
|---------|---------|-----|
| Control | 5.8921 | 139 |
| Test | 7.0784 | 102 |

- There was no statistically significant difference in the number of concepts learned between the control and test groups [$F(1,212) = 0.01$, $p = 0.921$] (See Table VI).

TABLE VI. CONCEPTS LEARNED: CONTROL VERSUS TEST GROUP

| | Average | N |
|---------|---------|-----|
| Control | 1.5968 | 124 |
| Test | 1.5843 | 89 |

So, in terms of cognitive learning due to tutoring – the number of concepts learned and the amount of practice needed to learn the concepts – the treatment did not result in any statistically significant difference between the control and test groups.

As per an earlier study [9], since problem-solving activity was alternated with the easier activity of answering three Likert-scale questions, the efficiency with which students solved pre-test problems should have increased with alternation than without. But, the time spent per problem on the pre-test was not significantly different between the control and test groups [$F(1,254) = 2.368$, $p = 0.125$] (See Table VII). Then again, more recent literature on task switching finds that subjects take longer to perform alternating tasks than massed tasks, because of alternation or mixing cost (e.g., [10,11]). In this study, the effect of such alternation cost was not found to be significant either.

TABLE VII. TIME SPENT PER PRE-TEST PROBLEM: CONTROL VERSUS TEST GROUP

| | <i>Average (seconds)</i> | <i>N</i> |
|---------|--------------------------|----------|
| Control | 55.6843 | 145 |
| Test | 61.2365 | 110 |

C. Affective Learning

After eliminating the students who had scored 100% on the pre-test:

- There was no statistically significant difference in the prior self-confidence of the control and test groups [$F(1,229) = 0.083$, $p = 0.774$] (See Table VIII).

TABLE VIII. PRIOR SELF-CONFIDENCE: CONTROL VERSUS TEST GROUP

| | <i>Average</i> | <i>N</i> |
|---------|----------------|----------|
| Control | 2.7214 | 133 |
| Test | 2.7543 | 97 |

- There was no statistically significant difference in the post self-confidence of the control and test groups [$F(1,216) = 1.163$, $p = 0.282$] (See Table IX).

TABLE IX. POST SELF-CONFIDENCE : CONTROL VERSUS TEST GROUP

| | <i>Average</i> | <i>N</i> |
|---------|----------------|----------|
| Control | 2.0563 | 128 |
| Test | 2.182 | 89 |

- There was no statistically significant difference in the average feedback response of the control and test groups [$F(1,216) = 0.123$, $p = 0.726$] (See Table X).

TABLE X. AVERAGE FEEDBACK RESPONSE: CONTROL VERSUS TEST GROUP

| | <i>Average</i> | <i>N</i> |
|---------|----------------|----------|
| Control | 2.4164 | 128 |
| Test | 2.4498 | 89 |

So, in terms of *affective learning due to tutoring* - self-confidence and feedback about the tutor – the treatment did not result in any statistically significant difference between the control and test groups.

Earlier studies had shown that self-confidence of the students increased significantly from using the tutors (e.g., [12]). There was no significant difference in the improvement in the self-confidence between the control and test groups [$F(1,215) = 0.271$, $p = 0.603$] (See Table XI).

TABLE XI. PRE-POST CHANGE IN SELF-CONFIDENCE: CONTROL VERSUS TEST GROUP

| | <i>Average</i> | <i>N</i> |
|---------|----------------|----------|
| Control | -0.6472 | 127 |
| Test | -0.5873 | 89 |

Earlier studies had shown that female students were more likely to provide positive feedback about the tutor than male students [13]. When average feedback response was analyzed with treatment and sex as fixed factors, no main effect was found for treatment [$F(1,199) = 0.256$, $p = 0.613$] or sex [$F(1,199) = 2.45$, $p = 0.119$] and no significant interaction was found between the two [$F(1,199) = 0.278$, $p = 0.599$].

IV. DISCUSSION

Introduction of the alternate task did not result in any statistically significant difference in the scores of the control and test groups on the pre-test. It did not promote better cognitive learning or affective learning during tutoring. There could be a number of reasons for the negative results:

- Though alternation was found to be on the average more efficient than massing, differences were found among subjects in whether they could benefit from alternation, and these differences were ascribed to the subjects' ability to persevere, called perseveration [14]. So, in the current study, some students may have benefited from alternation whereas others may have been hindered by it, the cumulative effect being to cancel each other out.
- An earlier study had concluded that the effects of alternation are proportional to the dissimilarity of the alternating tasks [15]. The activity of the alternate task, i.e., answering Likert-scale questions was very dissimilar from the problem-solving activity of the main task. However, since the three Likert-scale questions were about the problem that the student had just solved, the mental task set of the alternate task may not have been dissimilar enough to accrue the benefits of alternation. Other studies suggest that the effects of alternation vary according to the types of tasks involved, e.g., mental versus motor (e.g., [16]). Both problem-solving and answering Likert-scale questions are mental tasks, which may be another reason why no benefits were found that could be ascribed to alternation.
- Earlier studies have shown that massing is more efficient than alternating (e.g., [17]) for complex tasks. The main task in this study was solving problems, which is a complex task involving multiple steps. So, as per the earlier study, alternating (test condition) should have been found to be less efficient than massing (control condition). But, no significant difference in the time spent per problem was found between the control and test groups.

- According to the research on task switching, alternation results in increased error rates as compared to massing because of switch costs (e.g., [6]). This might help explain why alternation did not produce better learning or test results in the current study. Then again, the current study contradicts task switching studies in that alternation did not impair learning or test results in any significant manner in spite of switch costs. This is all the more significant considering that the task in this study – problem-solving, is considerably more complicated than the simple stimulus-response tasks used in most task switching studies.

The current study differs from earlier studies on alternation in the following respects: it considered the task of solving problems, which consists of multiple steps, and is hence more complex than single-step stimulus-response tasks considered earlier; both the primary task and the alternation task were conducted entirely online; and the primary task was in the domain of computer programming. It is possible that under these conditions, the positive benefits of alternation cancel out the negative costs associated with task-switching. This hypothesis bears further experimentation.

Work in Progress: Using Writing-to-Learn Methods to Improve Conceptual Knowledge in Engineering Statics

Lisa McNair and Chris Venters
Department of Engineering Education
Virginia Tech
Blacksburg, VA, USA
lmcnair@vt.edu, chventer@vt.edu

Abstract—Writing assignments were implemented in a statics course to improve conceptual understanding. The assignments required students to explain in words their solution process for specific homework problems. Quantitative analyses of Statics Concept Inventory (SCI) and course exams data showed significant improvements on the SCI in the experimental section; however, scores on course exams did not significantly improve. Qualitative data indicate that students who were dissatisfied with the process problems cite unfair grading, rather than the work, as cause, highlighting a key area for enhanced collaboration between engineering and writing faculty. These results provide empirical validation for the use of writing-to-learn assignments and validated discipline-based assessment tools such as concept inventories as a means to engage content faculty in writing assignments that support conceptual learning.

Keywords- *statics; conceptual understanding; conceptual knowledge; procedural knowledge; writing-to-learn; writing*

I. INTRODUCTION

In addition to being an important foundational course for many engineering disciplines, statics is also a troublesome course for many students. The difficulty that students face can be seen in low grades and/or high withdrawal rates, but it may also be reflected through poor conceptual understanding, even among those who successfully pass the class [1].

In Spring 2011, the authors conducted a pilot study to assess the viability and utility of using short writing assignments as a way of increasing the conceptual understanding among students in statics [2]. The pilot study was in the form of a pseudo-experimental design involving a statics course taught at a large public university with a total course enrollment of approximately 300 students. The writing assignments, referred to as process problems, asked students in the experimental sections to explain in words the process that they used to solve a particular homework problem. The process problems were assigned and collected once weekly and graded by graduate teaching assistants; all other course assignments and assessments were the same in both sections.

Quantitative data in the form of student grades and pre/post scores on the Statics Concept Inventory [3] showed significant gains in conceptual understanding (i.e., scores on the SCI) by

students in the experimental section; however, procedural knowledge (i.e., scores on tests) did not significantly improve [2]. This paper focuses on qualitative data in the form of student interviews to explain how the written process problems may have impacted student conceptual understanding and/or performance in the course.

II. BACKGROUND LITERATURE

In the cognitive view of learning, the goal of formal education is viewed as a process by which novices in a field develop knowledge and transition toward more expert thinking. Experts, especially adaptive experts, are believed to possess high levels of both quality conceptual knowledge and quality procedural knowledge [4-6]. According to Rittle-Johnson and Alibali [7], conceptual knowledge is “explicit or implicit understanding of the principles that govern a domain and of the interrelations between pieces of knowledge in a domain”, whereas procedural knowledge can be thought of as “action sequences for solving problems” (p.175).

In the mathematics education community, an ongoing debate dubbed the “math wars” [8] has not reached widespread consensus regarding the primacy and relative importance of conceptual and procedural knowledge for knowledge development in novices. However, some evidence suggests that the two types of knowledge may be interlocked, requiring that they be developed simultaneously [9]. This may have important implications especially in statics, where students and instructors often tend to focus more on procedure and may fail to develop appropriate conceptual knowledge [1, 10].

We believe that writing-to-learn assignments may provide effective ways of developing conceptual knowledge in mechanics courses like statics. By having students explain their mathematical solutions, students can make links between problem-solving procedures and course concepts. Writing may also be used to promote reflection, which can result in metacognitive thinking and adaptive problem solving.

III. QUALITATIVE DATA COLLECTION METHOD

Interview participants were purposively selected from survey responses based on their course enrollment history and their current course section. Surveys were sent to all of the nearly 300 students in Statics; 136 responded, 41 agreed to be interviewed, and 13 were selected. Interviews were conducted toward the end of the semester with students in both the experimental and control sections by Venters and another Ph.D. student outside of the research team. The interview protocol was 30-45 minutes long, was semi-structured, and featured open-ended questions related to the students' experiences, study habits, and perceptions of the course and perceptions of the process problems. Finally, all interviews contained a think-aloud portion where students were given a statics problem and asked to share their thoughts as they viewed and attempted to complete the problem; follow-up questions meant to probe their explanations of their thought processes were asked after the think-aloud was complete.

IV. QUALITATIVE DATA RESULTS AND DISCUSSION

Analysis of the interview transcripts is currently ongoing, with coding labels developed through a grounded theory process in which themes are grouped and then related to theoretical concepts of conceptual and procedural knowledge.

General opinions of the process problems were mixed; some students in experimental sections did not feel that the problems were useful to them, though they did not feel that they hurt their understanding either. Rather, many students felt that their grades were negatively impacted by the problems and disliked them for that reason along with issues of time. Even among those that expressed dissatisfaction with the problems, many reported that they felt other students would benefit from doing such problems.

Students who did like the problems and felt that they had a positive impact on their understanding were students who tended to approach the course from a more conceptual view; such students mentioned that they often read for understanding and actively tried to connect homework problems to underlying theory. In some cases, students who had unsuccessfully completed the course previously discussed their change in studying habits from that of simply solving problems to learning the material on a deeper level. Further work needs to be done to determine the extent to which the process problems may have assisted in that change.

V. CONCLUSIONS

In conjunction, the qualitative and quantitative data help to explain why and how the process problems may have supported conceptual knowledge development among students in the experimental sections. While the exams given by the instructor consisted of traditional workout problems that emphasized procedural knowledge, the students who succeeded in the class and embraced the process problems demonstrated

more metacognitive awareness of problem-solving and the importance of understanding statics conceptually. This finding raises questions for future work about the interplay between conceptual and procedural knowledge.

Abstract—This paper reports on the first phase of an Australian inter-disciplinary partnership study concerned with professional learning of experienced engineers. It is a theoretically motivated, qualitative paper that aims to produce detailed descriptions of professional learning that arise within professional engineering work. The paper uses *practice theory* to conceptualise professional learning. By using 'practices' as the units of analysis, professional learning is understood as an integral part of everyday work practices that is embodied, relational and material rather than an individual attribute. The paper concludes by suggesting that practice theory may provide organisations with an alternative perspective of workplace learning, inviting them to reconsider how professional learning is acknowledged, rewarded and fostered in organisations.

Keywords - *continuing professional development; professional learning; practice theory; qualitative research*

I. INTRODUCTION

Engineers, like all professionals, face an ever-changing work environment that requires them also to continually respond to change. Such change arises from new knowledge, new ways of doing things, new organisations and organisational cultures and other imperatives from the social, economic and political environments in which they operate. It is not only new professionals who face these types of change, but also those well established in their careers. In most organisations Continuing Professional Development (CPD), or professional learning, is charged with the task of keeping professionals abreast of change. However, we contend that conventional approaches to looking at professional learning through skills and knowledge and the development of competencies are inadequate, and that new ways of conceptualizing research on professional learning are needed.

Current understandings of professional learning are beset by difficulties. Over recent decades, at the structural level, professional bodies have been influential in establishing Continuing Professional Development (CPD) programs to encourage the continuing professional learning of engineers. These CPD programs have turned from acts engaged in by professionals for their own satisfaction to a systematised and codified set of activities that have consequences for continued registration and, in many cases, the right to practise their

profession. Responsibility for engineers' professional development has been gradually subject to more rigorous surveillance, and indeed, self-surveillance. Furthermore, because it is easier to measure attendance than almost anything else, CPD is often synonymous with participation in courses or seminars. This is counterproductive as it moves from focusing on the outcome of CPD (development) to the input (the activity). Further still, 'career episodes' used to demonstrate competence to professional associations are reliant on skills in portraying what they do in written forms, that may have little to do with competence in engineers' substantive roles [1].

Our research partner, a large Australian engineering company, echoes our dissatisfaction but acknowledges an interdependent relationship between professionals, employers and professional associations. It too is interested in generating dynamic accounts of experienced engineers' learning that will have consequences for how learning is acknowledged and rewarded, and ultimately how work might be organised in ways that foster professional learning.

A further, more philosophical, difficulty with contemporary understandings of professional learning is that it is seen invariably as something that *individuals* do. When they learn they *gain* knowledge as a 'thing' that they thereby possess to *apply* as needed at some later date. The metaphors 'acquiring' and 'transferring' learning are used without realising that they are metaphors and not descriptions of concrete reality [2]. These metaphors disconnect learning from the actual practices and contexts in which learning is developed and used, and they ignore the social dimension of learning. Our assumption is that these traditional metaphors need to be replaced with more generative ones that represent the social and situated nature of professional learning and can lead to fresh understandings of CPD. The main metaphors invoked by newer learning theories are *participation*, *construction* and *becoming* [1].

Heeding such dissatisfactions, as well as noting alternative theorisations and what they can illuminate, we have adopted practice theory. A practice approach embraces ideas of *participation* (in practices), *construction* (of knowledges) and *becoming* (professionals) and is not reliant upon metaphors of acquisition and transfer. Focusing on participation in practices also allows us to see learning as a social act in context. An understanding of practice theory in professional learning shifts

the focus from the acquisition and transfer of predetermined skills or knowledges to the *generation* or construction of them by individuals as they engage with others in the ‘bundles of practices’ [3] that make up their work. Finally, the idea of *becoming* professional recognises the enduring nature of learning and professional work. These theorisations of learning sit well with the practice approach we advocate for here.

This paper begins by discussing the practice approach adopted. It then frames an investigation of engineering practices that aims to elicit learning through notions of practice. Next it identifies the challenges of the practice approach and how it can lead to a more satisfying view of CPD that better reflects professional learning. Taking into account our initial qualitative data, it presents some initial conceptualizations of engineering practice and concludes with some remarks about the potential of the study for fruitful future research.

We are not the first to look at engineering and related professions with a practice lens. Bjørkeng, Clegg and Pitsis undertook a longitudinal study of a leadership team to provide an account of the unfolding of a practice [4]. Gherardi and Nicolini provide an account of the circulation of safety knowledges within an organisation in the building industry - developing comprehensive conceptualizations of practice in the process [5]. Suchman employs a practice-orientated approach to investigate bridge building in order to contribute to understandings of organisational knowledge and acting [6]. Each of these studies provides a helpful example of the utility of practice theorizations in empirical studies. However, while they contribute to management and organisational learning, the research reported here is specifically focused on learning and in particular the continual professional learning of experienced engineers. In this way this we position the study alongside empirical studies in health professions, community services and other fields, that have taken up theorizations of practice, learning and change [7].

II. BACKGROUND

The reported research comes from a partnership project that is investigating professional learning in one of Australia’s largest engineering organisations. The interdisciplinary team consists of researchers from two faculties at the University of Technology, Sydney — Arts and Social Sciences, and Engineering and Information Technology. The Organisational Development Program Manager from the partnering organisation is also a member of the research team.

The organisation’s remit includes work in the areas of social infrastructure and building, civil engineering, water and environment, rail, aviation, tunneling, mining, communication and energy. It employs engineers with a variety of specialties and various years of experience. It invests considerable time and money in comprehensive graduate programs for new engineers. For its experienced engineers, professional learning is recognised and rewarded against a capability framework via performance management processes.

A. Aim

The broad aim of this research is to explore continuing professional learning of experienced engineers. A more particular aim is to identify practices that underpin quality continuing professional learning by experienced engineers within the context of their typical working life.

B. Rationale

This research addresses an important problem for engineering organisations: understanding how and what experienced professional engineers learn. Our focus on experienced engineers recognises that while there are many graduate programs in place specifically for new professionals, there is a dearth of research focused on the more experienced professional. The traditional approach to professional education leaves both employers of engineers and accrediting bodies (e.g. Engineers Australia) with several different, but related, challenges to recognising and developing the capability of engineers. First, for employers like our partner organisation, there is the problem of knowing what their employees know and can do, and how they can recognise and deploy expertise effectively. Second, there is the problem of providing effective training and development opportunities for staff. This includes the challenge for employers of knowing when to provide a training response to a particular issue, and when (and how) to foster learning through work allocation or other indirect processes. Added to this, more empirical evidence is needed to indicate what might be the scope and quality of everyday professional learning, and what mechanisms can be established to account for it.

C. Methodology

The research is a theoretically motivated, qualitative study that focuses on producing detailed descriptions of various types of learning, for both groups and individuals that arise within professional engineering work. The research involves the development of a richly informative account of professional learning that will be sufficiently detailed to support in-depth analysis and theory development.

In order to distil focus for this ‘rich account’, the project comprises several phases of data collection. The first, and the one we report on here, is the *identification* phase where we analysed a range of documents, held focus groups with experienced engineers and followed up with by semi-structured interviews with focus group participants. Our purpose was to create an initial list of practices that constitute the work of experienced engineers. In the second phase we are seeking *elaboration* on the identified practices, as well as identifying any further practices that arise. To do this we are carrying out unstructured observations, as well as a second round of focus groups and semi-structured interviews. In the third phase we intend to *validate* our findings by having our descriptions of practices reviewed by members of the organisation and by looking for examples of identified practice in other sites. Again, we intend remaining open to the identification of further practices (which we will then subject to elaboration, validation and so on). In this way the methodology is both iterative and generative.

III. THEORIZATIONS OF PRACTICE

Learning in professional practice involves, *inter alia*, interactions with a variety of others in a wide range of contexts. Tangible issues commonly drive such interactions. Much of the learning arises from the exigencies of work and the challenges encountered there. What holds together all the sites, purposes and relationships is that they cohere around the notion of practice. It is what professionals practise that we take as the centrepiece of learning challenges: they undertake practice, they extend their practice, and they take up new practices. We also believe that they learn through their practice – and if this is the case, then already the *participation* metaphor appears to be more aligned to professional learning than *acquisition*.

Following what Schatzki and others term the ‘practice turn’ in contemporary theory [3], there are a variety of approaches on which to draw to enable a focus on practice to be conceptualised. From ideas commonly found in the organisational literature, Gheradi [8, 9] identified several streams of research in what she terms ‘practice-based studies’: cultural and aesthetic approaches, situated learning theory, activity theory, actor network theory, and workplace studies. These streams of research have in common a focus on practice as located, mediated and relational. Many of these theories move to a quite different kind of configuration from the conventional educator’s focus on the competences of individuals and the knowledge and skills they can acquire. Such theories allow for, or indeed insist on, a variety of relational features to be considered together. Practice is an integrating idea than links thinking with doing and people with contexts. It is useful to consider five interrelated elements of practice that may be seen across various bodies of work. First, that practice is more than the application of knowledge or product of learning but a complex process of knowing-in-practice [10]; Second, that practices are socio-material; Third, that they are embodied and relational; Fourth, that practices exist evolve in historical and social contexts; and, fifth, that practices are emergent [7].

Schatzki’s work is useful because of the idea that “bodies and activities are ‘constituted’ within practices” [11]. Practices provide units of analysis that bring together the practitioner, the material objects with which they work, their relations with others and the context in which they operate. A practice view seeks to avoid separating these as variables that might be separately manipulated apart from the whole practice. This is not to say that particular features of practices might not be foregrounded, but that they are never treated independently.

A second way Schatzki’s work is helpful is that there is an emphasis on “know-how, skills, tacit understanding, and dispositions” [11]. The focus is on what is directly connected to the ‘doings’ of a practice and the ‘sayings’ that are part of the practice. Here practice is inherently dialogical and activity-focused. The organisation of practices is social, being expressed in the connections of doings and sayings that compose them, as opposed to an individual’s doings and sayings. Doings are what people do with others and with

things, and these interact with what people say. Both doings and sayings are done with people’s bodies. However, while sayings do consist of speech, they are more than this. Sayings are differentiated from doings of practice in that a saying conveys meaning and has a semantic function whereas doings may not [12]. In this sense sayings are anything that is communicative.

Schatzki also emphasises action and structure. He defines practices as “structured spatio-temporal manifolds of action ... that have two basic components: action and structure” [13]. *Structural* elements include know-how concerning the actions or the ‘how to’ of practice; rules that specify guidance or instructions; teleo-affective structuring that explains the purposes or emotions that cause people to act towards possible ends and goals; and general understandings that may be relevant, for example, the nature of a particular kind of work. Practice *actions* are performances of people that are embedded with these structural elements. Practices thus entwine people, technologies, spaces, time and artifacts. Through these embedded structures and material arrangements, practices frame future action possibilities for both individuals and the organisation.

In short, a profession (engineering in this case) consists of a bundle of interrelated practices and material arrangements. While some practices may be dispersed (in that they can be seen in other professions) there are many that are germane to the profession. Each practice consists of activities, material ‘things’ and bodies and is purpose-focused. Within the profession there is a shared understanding of the practice. These practices are prefigured in that they have a history in the profession, yet each instantiation keeps alive the possibility for reconfiguration (i.e. change).

With this in mind a final, and perhaps more pragmatic, reason for employing a practice approach is that it offers our partner organisation a new way to think about professional learning. Aspects of practice theory may be represented to partners more straightforwardly than other conceptualisations as they can readily accept that work is made up of ‘bundles of practices’ and that it is from engaging with practices that both a need for learning as well as learning itself emerges.

IV. PRELIMINARY FINDINGS

The partner organisation’s remit of activities (its macro activities) such as project design, project and risk management, people management, design and operations, shape the activities of individual engineers (their micro activities). For instance engineers spoke about how they design/plan, diarise important events and information, seek out new information on the Internet or in documents from a range of sources, and identify important contacts for their networks – all with the purpose of carrying out project design, project and risk management, people management, design and operations.

However, it is in between these macro and micro activities, of organisation and individuals, where engineering *practices*

are revealed. These are neither organisational nor individual activities. Rather, they are *collective* practices that typically comprise an assemblage of people. Some examples of practices identified in the identification phase of the research include organisation include *toolbox talks*, *site walks* (sometimes called *pit tours*), and *design/end of month reviews*. We expand on the last two practices below.

A. Site walks

A common practice among the engineers we spoke with was the site walk (or pit tour in one instance). For example, professional engineers may undertake a site walk as part of the tender preparation phase of a project:

...most engineering jobs you can't price, unless you've seen the site. That's the most important thing. The plans only tell half the story to what's actually out there. Because the plans tell you what it's going to look like when it's finished. They don't tell you what it looks like when it starts... (Tim - Estimator)

For site engineers, the site walk is the routine way to start the day. The site engineer looks for anything that has changed overnight, e.g. excavation collapse/erosion, vandalism, protective covers dislodged by wind, rainwater damage or ponding, because the results of any of these may have to be rectified or 'made good' before any progress can be made:

We usually go for a site walk prior to the men[sic] starting the day. Go around, look for issues, especially with the weather... (Denis - Site Engineer)

A site walk might be undertaken to maintain communication with a client or as part of a project milestone meeting:

So the client and I, after the meeting, had a one-on-one walk through the job and we both expressed some concerns that we have with each others' team and made promises to each other to fix things... Then I went and walked the job again with the project manager and shared a little bit of the conversation that I'd had with my owner rep and the action items that I believed that came out of this meeting that should be addressed. (Gordon - Senior Division Manager)

B. Design/End of month Review

Another shared practice among the engineers we spoke with included is what they referred to as 'reviews'. These can take the form of 'end of month' reviews and 'design reviews'. Basically, the later are meetings between the major stakeholders. As one engineer told us:

There's quite a bit of governance work associated with a hundred million dollar job. You have to look - you have to approve payments. You have to review quality. You have to - you just got to keep up with it and since you're only down there - or I'm only down there twice a month - it's also just a very good time to make sure my client's happy. (Gordon)

Engineers with different job classifications attend design reviews at different stages of projects. For example an estimator attends the pre-construction review meetings, a project engineer may only attend review meetings that occur

during the construction stage of a project, and a site engineer may not attend a review meeting at all but will typically provide information for the project manager to take to the meeting.

So it goes through the team. So the services manager will do a review, the site manager, the engineer and then the project manager will do a final one. So we'll each sit down and do our own individual thing, get together and bounce ideas off each other, if need be - if we spot an issue. (Tim)

A related practice within this organisation was what we call the *pre-review* review (i.e. the meeting before the meeting):

So I went and met with my folks for about an hour and a half, said hello to all of them, how's things going?... Anything you want me to bring up in this meeting that I need to know about, or - probably the most important question I was asking them, is there anything that the client's going to bring up at this meeting that I don't know about, because if there is, tell me right now so I can prepare for that discussion (Gordon - Senior Division Manager)

V. DISCUSSION

A common feature of these practices is that they are strongly linked to the productive work of the engineers and almost always involve purposeful communication with a variety of others. Moreover, these others represent a range of roles within the project (e.g., clients, sub-contractors, designers, site managers, etc.). Each member brings to the instance of the collective practice particular expertise and knowledge. The practice's success is reliant on the professional diversity of group members, and the co-production of new knowledges is only possible because of each member's unique contribution.

Each of these practices shares some important features that link them to practice theories. First, all feature the *embodied* action of those involved, by this we mean that these specific engineering practices encapsulate what professional experienced engineers routinely do. For instance the 'end of month' and 'toolbox talks' are routinised organisational practices that occur in specific times and locations. Those involved bring knowledges, dispositions, working histories and their bodies. Each instantiation of the toolbox talk is shaped by the collective embodiment of its participants. The professional identities of participants is confirmed and reaffirmed within the practice, as does participants' sense of agency [14].

The practices identified here are *mediated by materiality*. Indeed, practice theory tells us that *all* human activity is undertaken in conjunction with things, and for engineers this could mean things like tools, raw materials, specifications, drawings, blackberries, mobiles, pens and diaries (to name just a few). However, less tangible things also mediate practices, for example, regulations, organisational procedures and individual and collective cultures and dispositions. All of these influence the practice in particular ways. While engineers seek to shape materials, materials hold potential to shape practice. For instance site walk participants react to a sloping soil surface in ways laypeople would not. For the layperson it

might appear as a simple pile of dirt, for the professional it can mean risk and/or the need for further action.

Such professional practices are also understood as *situated* practices, and there are many ways in which a practice is situated. It is situated in particular settings, in time, in language and in the dynamics of interactions [15]. For Kemmis, practice “has aspects that are ‘extra-individual’ in the sense that the actions and interactions that make up the practice are always shaped by mediating conditions that structure how it unfolds” [14]. These may include cultures, discourses, social and political structures, and the material conditions in which a practice is situated.

These practices are also *relational*. They occur in relation with others who practise, and in relation to the unique features a particular practitioner brings to a situation. Practice is thus embedded in sets of dynamic social interactions, connections, arrangements and relationships. Schatzki suggests that, “[o]ver any period of time, human practices link and form gigantic nets, just as arrangements are connected into immense material structure and practices and arrangements relate in myriad ways” [16].

Finally, a last commonality of these practices are that they are *emergent*. Practices exist, they evolve over time and over contexts; they change in the light of circumstances. New challenges require new ways of practising. Practices emerge in unanticipated and unpredictable ways, and in this the practitioners’ knowledge and skills are open to continual construction (and reconstruction) [17].

Learning and practice

The practices described above (along with others not described) are related to each other in the ‘bundle of practices and material arrangements’ that collectively constitute the work of professional engineers. People, artifacts, social groups and networks develop characteristics through relationships with other subjects, social groups or networks such that they are formed and structured socially [14, 18].

Practices change and evolve over time and learning is implicated in this complex processes. What Schatzki [13] calls the “practice memory of an organisation” has a powerful influence in pre-configuring practices and in defining whether ‘learning’ *per se* is or is not a legitimate activity. Particular kinds of learning practices may or may not be sustained and perpetuated in any given organisational context. This raises the issue of learning-conducive work. There is good reason to think that some workplaces are far more generative of learning than others [19]. Some forms and contexts of work, even when the same qualifications are required of practitioners, are far more demanding and lead to considerably more learning than others. After all, as far as the organisation is concerned, why would it want or need to foster more learning than is needed for the purposes of production?

So what might this mean for employers and accrediting bodies that use traditional mechanisms that capture, acknowledge and ultimately reward CPD this are reliant on static notions of learning where skills and knowledge are

acquired, transferred and/or operationalized? Preliminary findings of this practice-focused account of professional learning demonstrate dynamic and situated practices being *constructed*. Through *participation* in practices, new knowledges are being constructed, and the engineers (while already professionals), are also *becoming* professional. Indeed, this preliminary account of practices suggests that practice is not only the site of learning but learning itself.

While learning itself may be a further practice that can be examined, it might not present itself as such in many situations. It is eclipsed or occluded by practices that are of greater importance in professional work, namely, the performance of work to satisfy employers, clients and ones peers. When ‘learning’ is required, most professionals can readily construct a learning discourse, but this can tend to privilege a restricted range of activities and ways of thinking about work [20].

Yet learning is integral to the practices described above. For example, consider Tim’s comment of ‘*bouncing ideas of each other*’. It is reasonable to assume that he, and others, developed new understandings as a result of this practice. Likewise, Gordon’s comment about finding out any potential issues in the pre-review in order to prepare for the review can be construed as learning.

However, learning is not necessarily how practitioners conceptualise what they do when they practise. They see themselves as tackling a problem or meeting a challenge or exploring an issue, without using the language of learning. In one of our previous studies of workplace learning, the lack of an explicit learning discourse alongside what we identified as multiple acts of learning was notable in several of the work groups we studied [21].

Learning therefore may not be seen as a practice that exists separate from other practices. For many purposes it might not be useful to single it out for attention. Tensions arise between naming and codifying ‘learning’ that may be of value to individuals for professional registration purposes, and acknowledging learning as an integral part of work and thus a normal everyday activity that would be distorted by formalization [22]. The more integral learning is to the practice of work, the more problematic it is to treat it independently of work for official recognition.

VI. CLOSING REMARKS

We conclude this paper by saying that it appears that significant continuing professional development (i.e. professional learning) results from engaging in the collective practices that constitute professional work. We suspect that the knowledges/skills co-produced within these practices are also reflected in the micro and macro activities: the professional development of individual engineers and the development of the organisation.

In regard to the approach we have taken, there is more to be said about the benefits, issues and difficulties of interdisciplinary research. However, we save this discussion for another paper.

This paper argued for a practice approach to investigating professional learning of experienced engineers. It framed an investigation of experienced engineers' work within notions of practice [3]. Through presenting qualitative data and conceptualizations of engineering practice the paper points to the challenges and opportunities that this approach could lead to in regard to alternate understandings of CPD. Further research is needed to investigate the organisations' and accrediting bodies' capacity to acknowledge and reward professional learning in light of the practices we have identified so far. However, we maintain that the practice approach offers a fruitful lens for such research.

Work in Progress: In their own words - how “changemakers” talk about change

Abstract – We present preliminary work on “change knowledge” through a study investigating what exemplar “changemakers” understand about the process of undergraduate STEM education transformation.

Keywords – transforming STEM education; change knowledge; change agents; radically transparent research

I. INTRODUCTION

This work in progress underscores a collective view that undergraduate engineering education in the United States is a complex system in need of transformation in order to meet the rapidly changing realities of our global existence [1-3]. Prior attempts to change undergraduate STEM education have had only temporary local impact [4], a low success rate but comparable to change attempts in higher education as a whole [5-6].

Fullan, Cuttress, and Kilcher [7] claim this may due to a lack of “change knowledge,” a missing ingredient in understanding why good ideas or policies fail to get implemented or that are successful in one situation but not in another. Here, change knowledge refers to a person’s assumptions and values about the system in which they work, such as their views about the nature of engineering and the aims and process of engineering education, and hypotheses on how to work within that system to avoid barriers and ultimately enable a desired transformation. If a person applies the change knowledge they have, we call them a “changemaker”. The concept of change knowledge (1) is situated in engineering education systems research [8], (2) moves the lens from investigating the artifact being changed to the human agent that initiates a change, (3) parallels the concept of “pedagogical content knowledge” [9] because it refers to the tacit dimensions of contextualized knowledge that support effective practice, and (4) supports theories of transformative learning [10-11] that are characteristic of biographies of engineering education change agents [12-13].

Research also indicates that traditional dissemination approaches such as peer-reviewed and archival publications are not effective mechanisms for transforming educational practice [14-15]. Some argue that these focus on the “telling” and not the “doing”, making it difficult to develop a rich understanding of

research that may be transferred to other contexts [16]. In this paper, we share preliminary findings from a study that asks exemplar “changemakers” to talk about their experiences of “doing” socially beneficial change in STEM education – their motivations and inspirations, assumptions about how transformational change occurs, and experiences as “changemakers”.

II. BACKGROUND & PROCEDURES

Eight “changemakers”, STEM change agents whose impact exceeded institutional, regional, and national boundaries were interviewed. Subjects were selected through a combination of convenience and snowball sampling for variety in terms of context (academia, government, and industry) and change goals (policy, curriculum, instructional and assessment approaches). The semi-structured narrative-style interview protocol had four questions: (1) *what do you see as your greatest accomplishment?* (2) *what caused you to come to that point of view?* (3) *what caused or inspired you to pursue this [presumed change]?* and (4) *what do you think of this diagram* (a causal loop diagram as an artifact to elicit personal theories of change), *what causal links look relevant, and what do you think is missing?* Interviews lasted 45 to 90 minutes and were transcribed.

Analysis is following an inductive thematic process where patterns and themes of analysis are emerging out of the data rather than imposed prior to data collection [17]. We are using the constant comparison technique where inductive category coding is combined with simultaneously comparing observations across cases [18]. Sensitizing concepts from existing theoretical frameworks are guiding collaborative perspective taking – moving back and forth between logical constructions and the actual data in a search for meaningful patterns.

III. PRELIMINARY FINDINGS: CHANGE KNOWLEDGE

The following examples illustrate aspects of change knowledge emerging from the data.

Changemakers have a comprehensive vision regarding the system they seek to change and specifically identify transforming the way people think, as compared to what people do, as critical for success. They have developed an awareness of the fears people associate with letting go of practices that have worked well in the past,

and are able to help overcome these fears by guiding them through a sensemaking process. By naming a new participant's existing practices in a way that links to the change vision, they shift the framing of the change initiative from "letting go of prior ways of thinking" into a trajectory that participants are already aligned with.

Changemakers describe their accomplishments with humility, citing the collaborative process of change over the leadership of an individual. Changemakers focus on relationship building over information dissemination. They talk about a "different kind of leadership" that focuses on facilitating ways to find a shared vision, being able to "see the way" and help others "see the way".

Changemakers aren't interested in fighting. They recognize they have limited time and resources, and don't want to spend those resources on places and people who will be unwilling to change. They develop an ability to assess the opportunity cost of a situation and walk away if it's too high, and try to find opportunities within the existing infrastructure.

Changemakers appear to be strongly motivated by personal, often emotional, life experiences that anchor their efforts for socially beneficial change. For example, Mr. Am, frustrated by the tragedies of cancer patients, promoted the idea of sustainable chemistry to minimize the use and generation of hazardous substances; Mr. S, who described his childhood of doing hands-on jobs with real instruments, shared his experiences with how he prepares holistic and self-directed learners.

IV. FUTURE WORK

Early findings suggest dimensions of change knowledge that speak to motivations, identity formation, and assumptions about educational transformation as involving systems thinking and attending to the human dimensions of change as a social and developmental process. We are still analyzing the data and our experiences have inspired the pilot of a novel approach to change, "radically transparent research"[19], a notion inspired by the real-time transparency practices of open source communities, transformative action research [20], and ways to integrate educational research and practice. It involves inviting the broader community to observe and contribute to the process of discourse analysis and collaborative sensemaking [21], and has potential as its own change initiative, aimed at revealing, challenging, and transforming perspectives on educational change.

ACKNOWLEDGMENTS

We gratefully acknowledge our participants for engaging in this study and being willing to "go public". Aspects of this work were supported by a grant from the National Science Foundation (DUE-0817461).

Feedback Effects: Comparing the Change Resulting from Peer and TA Feedback to Student Solutions of Model-Eliciting Activities

Jacob Bishop

Logan, Utah

Matthew Verleger
Embry-Riddle Aeronautical University
Daytona Beach, Florida

Abstract—Since 2002, students in a first-year engineering course at Purdue University have participated in several Model-Eliciting Activities (MEAs). MEAs are realistic, open-ended, client-driven engineering problems designed to foster students' mathematical modeling abilities. The primary artifact produced by each team is a memo to the client describing a procedure for solving the engineering problem. Since 2007, three cycles of feedback and revision have been used in the course, with students receiving reviews from peers and teaching assistants (TAs) throughout the process. Prior to 2009, students received the first round of feedback from TAs, and the second from peers. After 2009, this order was reversed, and students received the first round of feedback from peers, and the second from TAs. This paper investigates whether the amount of change differed based on whether reviews were provided by TAs or by peers.

Using the Levenshtein distance [1], the amount of change between consecutive drafts was calculated for four offerings of two different MEAs. Each MEA was offered with both the pre- and post-2009 sequencing, allowing a clear comparison of sequencing methods. Results from this study indicate that on the first revision, the amount of change resulting from TA reviews was indistinguishable from that resulting from peer reviews. However, on the second revision, the amount of change resulting from TA reviews was significantly different (greater) than the change resulting from peer reviews. Overall, the amount of change resulting from feedback was greater when peer reviews were provided first, and TA reviews were provided second. These results suggest that review expertise is more critical in the later stages of the process of solving an MEA.

I. LITERATURE REVIEW

The review process is widely employed in academic publishing, and to a lesser extent, in classrooms. It is most often utilized to improve the quality of written work, as in essays or papers. There are two primary dimensions typically used in analyzing review: a) changes produced in artifacts, and b) author and reviewer opinions of the process. In discussing both of these, two secondary dimensions of the review process are also important: c) the expertise of the reviewer (real or perceived), and d) the power relationship of the reviewer to the author.

This paper is concerned with the application of the review process in a first-year engineering course at Purdue University involving Model-Eliciting Activities (MEAs). MEAs are realistic, open-ended, client-driven engineering problems designed to foster students' mathematical modeling abilities. A detailed description of MEAs and their development can be found

in [2], [3], [4], [5], [6]. The primary artifact produced by each team is a memo to the client describing a procedure for solving the engineering problem. MEAs are based on the models and modeling perspective first developed by Lesh et al. [7], [8]. This paper builds on previous work regarding the review process as applied to MEAs. An overview of these works is shown in Table I.

Peer and TA reviews were conducted according to guidelines contained in the MEA rubric [9]. Reviewers provided qualitative review comments and assigned the memo draft quantitative scores along multiple dimensions. It is clear from prior research involving MEAs that in at least some cases these reviews lead to improvement. This was shown by Verleger and Diefes-Dux [10], who selected a single, "exemplary" case where changes in drafts of student work could be directly attributed to reviewer comments. The challenge is to understand the extent to which review comments yield meaningful change in the author's work, and the conditions necessary that lead to this type of change. As mentioned previously, one important dimension in understanding these conditions is to examine reactions to the review process from authors and reviewers. Diefes-Dux and Verleger [11] surveyed approximately 1200 students, and compiled the results of their experiences in providing reviews to other students, and in receiving feedback from reviews provided by both peers and TAs. Cardella et al. [12] interviewed TAs involved in providing reviews to students, and documented detailed reactions from two TAs regarding the experience of both providing reviews, and the effectiveness of the training designed to prepare them for this process.

The second important aspect in studying the review process is to examine the actual effectiveness of the reviews. A first step in this process would naturally be to examine the quantitative review marks received by students for each draft of their work. However, Verleger et al. [13] showed that while expert scores held relatively high correlation with other expert scores, TA review scores have a correlation of only 0.1 with expert scores. In light of this, it is not reasonable to expect peer review scores to have a high correlation with expert scores. In short, review scores from TAs or peers are not reliable measures of MEA solution quality.

An alternative approach is to examine different versions

Table I
OVERVIEW OF THE RESEARCH ON THE MEA REVIEW PROCESS.

| Ref. | Primary Author | Pub. Date | Semester of Study | MEA Studied | N* | Dimensions of Study† | Notes |
|------|----------------|-----------|-------------------|----------------|---------------|----------------------|--|
| [11] | Diefes-Dux | 2009 | Fall 2008 | PPC, JIT, STM | ~1200 I | b | Student reactions to providing and receiving reviews. |
| [12] | Cardella | 2009 | Fall 2008 | - | 2 TAs | b | TA reactions to providing reviews. |
| [15] | Cardella | 2011 | Fall 2008 | PPC, JIT, STM | ~1200 I | b, d | Multidimensional analysis of review process. |
| [10] | Verleger | 2008 | Fall 2007 | Nano-Roughness | 1 T | a, b | Examined single piece of work that changed in response to review comments. |
| [13] | Verleger | 2010 | Fall 2008 | PPC | 584 I = 147 T | a | Showed that rubric scores are unreliable measure of MEA memo quality. |
| [14] | Carnes | 2010 | Spr 2009 | JIT | 50 T | a | TA feedback leads to more substantive changes than peer feedback. |
| [16] | Bishop | 2011 | Fall 2008 | PPC, JIT, STM | | a,c | Used Levenshtein distance to examine change. |

* I = Individuals, T = Teams, TAs = Teaching Assistants.

† a = changes produced in artifacts, b = author and reviewer opinions, c = reviewer expertise, d = reviewer-author power relationship.

of actual artifacts produced throughout the review process. Carnes, Cardella, and Diefes-Dux [14] randomly sampled 50 drafts of student work from a single 2009 MEA, and examined the changes in detail. They observed that TA feedback appeared to be more detailed, and tended to lead to more substantive changes in subsequent drafts of student work. There is also an ongoing effort to take a multidimensional approach to study the review process artifacts produced by the review process [15].

Notwithstanding these efforts, there are several limitations of the studies previously mentioned. First, many of the studies had a relatively small sample size. Second, most of the studies cited looked only at a single MEA, and did not consider possible differences in effects between MEAs. Third, the order of feedback (Peer/TA or TA/Peer) is a confounding factor that has also not been accounted for.

It is important to acknowledge that the specific courses, semesters of study, and the artifacts used to derive the results presented in this work represent some of the very same artifacts used in other publications [10], [11], [12], [13], [14], [15], [16]. Despite this overlap, the analysis here takes a much broader look at these MEAs, includes information from a larger number of the different MEAs performed, and leads to novel insights not represented in previously published work. Thus, while the present work is novel, it is also essential that this paper be interpreted in the context of the previous work on MEAs at Purdue University as previously cited.

II. PURPOSE OF RESEARCH

The purpose of this research is to compare the impact of reviews from two different sources on student solutions of Model-Eliciting Activities (MEAs). This will be measured by computing the quantitative change between drafts using the Levenshtein distance. The major hypothesis tested in this research is that feedback from reviews provided by TAs will lead to more change than feedback from reviews provided by peers. This prediction is consistent with the idea that TAs have higher ability and are capable of producing higher quality reviews. It also presumes that higher quality reviews will lead to more change in student work. Further, this prediction is

Table II
NUMBER OF STUDENT TEAMS PARTICIPATING IN MEAS FALL 2007-2009

| Semester | MEA | R1 | R2 | $N_{S,M}$ | $N_{M,R}$ | N_M | N_R |
|-----------|-----|------|------|-----------|-----------|-------|---------|
| Spr 2008 | PPC | TA | Peer | 82 | 372 | | |
| Fall 2008 | PPC | TA | Peer | 290 | | 557 | 1067 |
| Spr 2009 | PPC | Peer | TA | 142 | 185 | (PPC) | (TA/Pr) |
| Fall 2009 | PPC | Peer | TA | 43 | | | |
| Fall 2007 | JIT | TA | Peer | 402 | 695 | | |
| Fall 2008 | JIT | TA | Peer | 293 | | 880 | 370 |
| Spr 2009 | JIT | Peer | TA | 140 | 185 | (JIT) | (Pr/TA) |
| Fall 2009 | JIT | Peer | TA | 45 | | | |

$N_{S,M}$ = number of teams, grouped by semester and MEA.

$N_{M,R}$ = number of teams grouped by MEA and review source.

N_M = number of teams grouped by MEA.

N_R = number of student teams grouped by review source.

consistent with the finding of Carnes, Cardella, and Diefes-Dux [14] that feedback from TAs leads to more substantive changes in student work. In light of this, it is important to examine whether the expected general trend (that TA reviews lead to more change than peer reviews) holds for different MEAs.

III. METHOD

A. Course & Participants

This study examined data collected between the Fall 2007 and Fall 2009 semesters in a required introductory course in problem-solving and computer tools at Purdue University. Several sections, each consisting of approximately 120 students, were taught each semester. A single section of the course consists of two paired 110-minute components: a lecture component taught by engineering faculty members, and a lab component led by graduate student TAs.

Enrollment for this course was approximately 200-1200 students per semester. As students worked cooperatively to produce each memo draft, the number of drafts for each revision of student work is equal to the number of student teams participating. The number of student teams for each semester included in this study is shown in Table II.

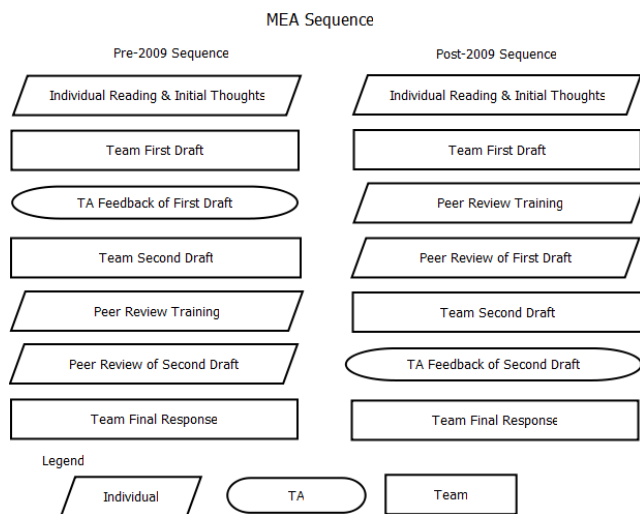

Figure 1. MEA Activity Sequence

B. MEA Order

Two MEAs were selected for examination in this study, the Purdue paper airplane challenge (PPC) MEA, and the just in time manufacturing (JIT) MEA. During the 2007-2009 semesters under consideration, three MEAs were administered each semester. When included, the PPC MEA was always appeared first in this sequence, and the JIT MEA always appeared second. Each MEA lasted 3-4 weeks.

C. Review Sequence

Since 2007, three cycles of feedback and revision have been used in the course, with students receiving feedback from peers and TAs throughout the process. Prior to 2009, students received the first round of feedback from TAs, and the second round of feedback from peers. After 2009, this order was reversed, and students received the first round of feedback from peers, and the second from TAs. The sequence of activities for these two periods as described is depicted graphically in Figure 1.

D. TA Training & TA Review Process

Before the beginning of each fall semester, graduate teaching assistants (TAs) attended a required 8-hour training, split across two days. TA training activities included instruction on MEA theory, solving an MEA, scoring seven MEAs, and scoring calibration activities. Calibration activities included a comparison of their own reviews to those provided by experts who had examined the same work, and group discussion of these differences. Emphasis was placed on appropriate use of the tools available to facilitate MEA scoring, including the MEA scoring rubric (discussed in [9]) and the instructor's MEA assessment and evaluation package.

Each semester, one TA was responsible for evaluating MEA solutions for 16-18 student teams for three separate MEAs. TAs used an abbreviated version of the MEA scoring rubric. The rubric is presented and discussed in full detail by Diefes-Dux, Zawojewski, and Hjalmarnson [9], but a brief description

is included here. The MEA scoring rubric consists of three dimensions: Mathematical Model, Re-usability/Modifiability, and Audience (Share-ability). Each dimension is scored independently, with each requiring both a quantitative score and qualitative comments regarding the team's procedure as applied to the particular dimension. Reviews typically required TAs to spend 30-60 minutes to evaluate each team draft. Reflections from two TAs of the training and review process are discussed by Cardella et al. [12].

E. Peer Review Training & Peer Review Process

Before reviewing their peers' work, students went through a review training process, as shown in Figure 1. This review training was similar in nature, but much shorter and less involved than the TA training. For this process, individual students used the Full MEA Rubric to evaluate a randomly selected prototypical student solution from a pool of sample solutions. Just as in the TA training, after students submitted their evaluation of the prototypical work, they were shown their review next to an expert review of the same memo. Students were asked to reflect on how they could improve their ability to review an MEA, and to apply these lessons in reviewing the work of their peers.

Students individually used the MEA rubric to evaluate the work of another student team. This review process was double-blind, so that neither reviewers nor the teams whose work was being reviewed knew the identity of the other. Since individuals evaluated team work, teams typically received multiple reviews of their solution from their peers, but only one when the TA acted as reviewer.

F. Measurement of Change

The measurement procedures used in this study are based on the principle of edit distance introduced by Levenshtein [1] and Damerau [17]. Edit distances thus defined can be used to compare the similarity of two strings or phrases with each other. These distances are used in a variety of applications ranging from DNA analysis to plagiarism detection. The Levenshtein distance is given by $D(X, Y)$, and computes the minimum number of substitutions, additions, and/or deletions required to transform string X into string Y . Basic units used in Levenshtein distance computations may be characters, letters, words, phrases, or any unit considered to be fundamental. We chose to use words as the fundamental unit in our Levenshtein distance calculations. Our procedure processed each draft of student work, first removing white space, then storing each word as a separate unit in a string of words that make up the draft. Like words, punctuation was treated as a separate unit.

Levenshtein distances are often normalized for a variety of reasons [18], [19]. In an attempt to represent the percent change between drafts of student work, we normalize the results by dividing the Levenshtein distance by the length of the first of the two drafts being compared. For example, in computing the normalized Levenshtein distance between drafts 2 and 3, we normalize this distance by the length of draft 2.

This is given by $C(X, Y) = D(X, Y)/|X|$, where X is draft 2, Y is draft 3, and $|\cdot|$ denotes the length of the draft.

G. Analysis Procedure

Preliminary analysis revealed that the assumptions of normality and constant error variance were not met by the raw values for the percent change response variables. For this reason, median values are reported for distance and change. Before continuing with the analysis, appropriate transformations were found using the Box-Cox method in SAS, and the recommended transformations were performed. The percent change from draft 1 to draft 3 required a log transformation, and the percent change between subsequent drafts (1-2 and 2-3) required a power transformation with an exponent of $\lambda = 0.32$. Since there were some zero-values for percent change between subsequent drafts (1-2 and 2-3), 1% was added to all scores for these drafts before transformation to make the transformation and subsequent analysis possible. This was not necessary for the draft 1-3 change. All statistical tests conducted were performed using the transformed response variables.

Drafts with a total number of words less than 30 were excluded from the analysis as these were clearly not valid products representing actual student work. No other criterion was used for data exclusion.

The data used in this analysis is summarized in Tables III, IV, and V. The analysis examined the [transformed] percent change between student drafts as a function of MEA and feedback source. The three response variables used were the [transformed] percent change from draft 1-2, shown in Table III; the [transformed] percent change from draft 2-3, shown in Table IV; and the [transformed] percent change from draft 1-3, shown in Table V. Note that original response variables in Tables III, IV, and V are given by $C(X, Y)$, $C(Y, Z)$, and $C(X, Z)$, respectively. These represent percent change between drafts. Similarly, transformed response variables are given by $C(X, Y)^{0.32}$, $C(Y, Z)^{0.32}$, and $\ln(C(X, Z))$. These represent transformations of the percent change between drafts.

IV. RESULTS

A. MANOVA Results

First, the data from all three response variables was analyzed using the multivariate analysis of variance (MANOVA) procedure in the SAS statistical package. The review order (TA/Peer or Peer/TA), and the MEA (PPC or JIT) each served as fixed two-level between-subjects factors. [Transformed] change between drafts served as a three-level within-subject response variable. This implies a 2x2 factorial design, with three response variables. A single MANOVA was used because it is more statistically powerful in testing our hypothesis, and because it allows us to compare all outputs on both MEAs considering review order with a single test.

The main hypothesis under study was to test whether the main effect of review source (TA or peer) had a significant effect on the change produced. The prediction was that it would, and this prediction was confirmed. Specifically (using

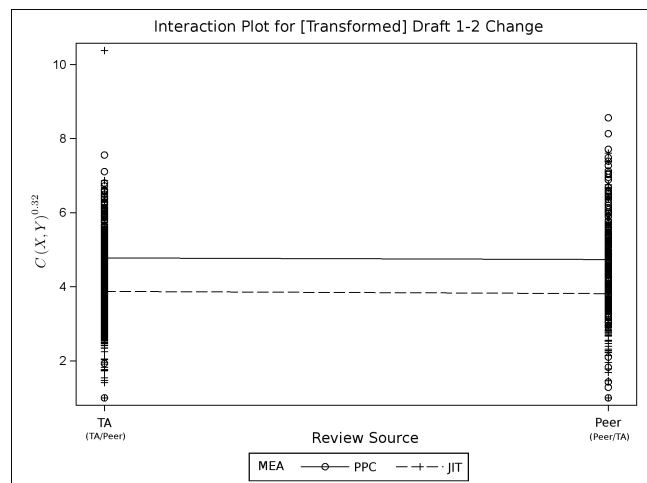

Figure 2. Interaction Plot for [Transformed] Draft1-2 Change

the Wilks lambda criteria), review source: $F(3, 1431) = 88.56$, $p < 0.0001$ was a significant main effect. Additionally, MEA was a significant main effect: $F(3, 1431) = 95.33$, $p < .0001$. The interaction effect MEA*review source was also significant: $F(3, 1431) = 7.94$, $p < 0.0001$, indicating that the effect of the review source depends on MEA. Interpretation of these effects is more clear in the context of the follow-up ANOVA tests.

Three separate 2x2 factorial ANOVAs were conducted to follow up on the initial findings from the MANOVA test. This was to determine the specific factors that account for the significance in the MANOVA. First, we examine the results of the change between drafts 1-2, then the results of the change between drafts 2-3, and finally, the overall change results between drafts 1-3. As before, review order (TA/Peer or Peer/TA), and the MEA (PPC or JIT) each served as fixed two-level between-subjects factors for all three ANOVAs. Type III Sum of Squares were used.

B. Draft 1-2 ANOVA Results

The data summarized in Table III was analyzed using a 2x2 factorial ANOVA procedure in the SAS statistical package. This ANOVA examines the results from the [transformed] change in the team-produced memo to reviews received between drafts 1 and 2. The interaction plot for this ANOVA is shown in Figure 2. The interaction effect of MEA*review source was not significant. Specifically, $F(1, 1433) = 0.85$, $p = 0.3572$. The main effect of MEA was significant. Specifically, $F(1, 1433) = 261.55$, $p < 0.0001$. The average [transformed] change between drafts 1-2 higher for the PPC MEA than for the JIT MEA. The main effect of review source was not significant. Specifically, $F(1, 1433) = 0.03$, $p = 0.8563$. This is contrary to the prediction that TA review feedback would lead to more change than peer review feedback, which was the primary focus of this analysis. Thus, for the change between drafts 1 and 2, there is no distinguishable difference in the amount of change resulting from TA and peer reviews. These results are supported by

Table III
CHANGE BETWEEN DRAFTS 1 AND 2 OF STUDENT TEAM MEA SOLUTIONS AS A FUNCTION OF MEA AND REVIEW SOURCE.

| Semester | MEA | R1 | R2 | N | median $D(X, Y)$ | median $C(X, Y)$ | mean $C(X, Y)^{0.32}$ | std. dev. $C(X, Y)^{0.32}$ |

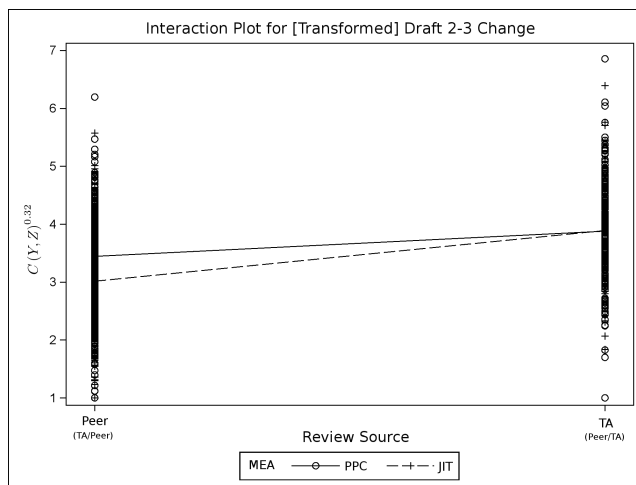

Figure 3. Interaction Plot for [Transformed] Draft 2-3 Change

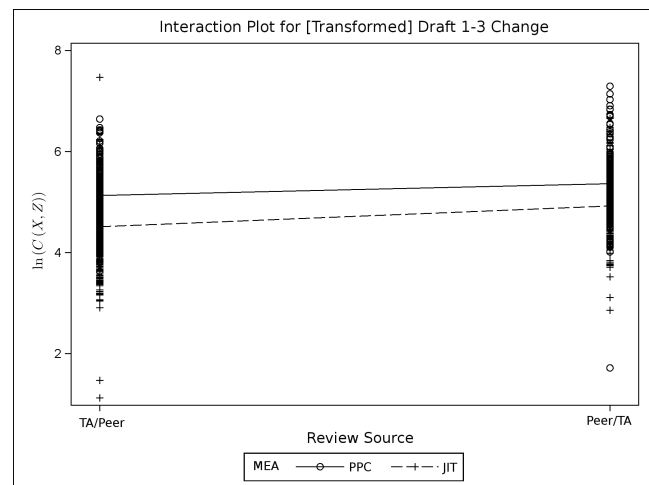

Figure 4. Interaction Plot for [Transformed] Draft 1-3 Change

a post-hoc means comparison using Tukey groupings that showed two distinguishable groups for the four LSMEANS, with group membership defined by MEA.

C. Draft 2-3 ANOVA Results

The data summarized in Table IV was analyzed using a 2x2 factorial ANOVA procedure in the SAS statistical package. This ANOVA examined the results from the [transformed] change in response to reviews received between drafts 2 and 3. The interaction plot for this ANOVA is shown in Figure 3. The interaction effect of MEA*review source was significant. Specifically, $F(1, 1433) = 22.19, p < 0.0001$. The main effect of MEA was also significant. Specifically, $F(1, 1433) = 19.68, p < 0.0001$. Post-hoc means comparisons using Tukey groupings show that the average [transformed] change between drafts 2-3 was higher for the PPC MEA than for the JIT MEA when peer reviews are followed by TA reviews, but the adjusted mean was not significantly different when TA reviews were received after peer reviews. However, this result is not particularly important, since differences are between MEAs are expected, but not the focus of any important research

question.

The main effect of review source was also significant. Specifically, $F(1, 1433) = 193.51, p < 0.0001$. This result is important, as the prediction was made that TA review feedback would lead to more change than peer review feedback, which agrees with the results of this analysis. Thus, for the change between drafts 2 and 3, the difference in the amount of change resulting from TA and peer reviews was significant, with more change resulting from peer reviews. These results are supported by a post-hoc means comparison using Tukey groupings previously mentioned that showed the adjusted LSMEANS form distinguishable groups for differences in review source.

D. Draft 1-3 ANOVA Results

The data summarized in Table V was analyzed using a 2x2 factorial ANOVA procedure in the SAS statistical package. The interaction plot corresponding to this ANOVA is shown in Figure 4. All three effects (both main effects and the interaction effect) tested in this ANOVA were significant. Specifically, the main effect of review source was significant with $F(1, 1433) = 88.39, p < 0.0001$; the main effect of

Table V
CHANGE BETWEEN DRAFTS 1 AND 3 OF STUDENT TEAM MEA SOLUTIONS AS A FUNCTION OF MEA AND REVIEW SOURCE.

| Semester | MEA | R1 | R2 | N | median $D(X, Z)$ | median $C(X, Z)$ | mean $\ln(C(X, Z))$ | std. dev. $\ln(C(X, Z))$ |
|-----------------------|-----|------|------|-----|---------------------|---------------------|------------------------|-----------------------------|
| Spr 2008 & Fall 2008 | PPC | TA | Peer | 372 | 889.5 | 168.7 | 5.13 | 0.465 |
| Spr 2009 & Fall 2009 | PPC | Peer | TA | 185 | 978 | 214.5 | 5.37 | 0.666 |
| Fall 2007 & Fall 2008 | JIT | TA | Peer | 695 | 409 | 88.6 | 4.51 | 0.563 |
| Spr 2009 & Fall 2009 | JIT | Peer | TA | 185 | 566 | 131.6 | 4.92 | 0.608 |

MEA was significant with $F(1, 1433) = 240.68$, $p < 0.0001$; and the interaction effect of MEA*review source was significant with $F(1, 1433) = 6.41$, $p < 0.02$. In interpreting these results, it is important to keep in mind the relationship between the three dependent variables. Specifically, the change from draft 1-3 is directly composed of the change from drafts 1-2 and the change from drafts 2-3. Thus, the change between drafts 1-3 represents an overall effect, made up of the change between subsequent drafts.

The significant main effect for review source indicates that the greater change in response to TA feedback, as compared to peer feedback from drafts 2-3, was sufficient to produce a significant effect in the overall measure of change between drafts 1-3. This indicates that the overall change between the initial and final drafts is greater when TAs give feedback on the second, rather than first draft. A post-hoc means comparison for this data using the Tukey method revealed four distinct groupings for the adjusted means.

V. DISCUSSION

The research hypothesis for this study was that student teams solving an MEA would change their solutions more in response to reviews provided by TAs than by peers. The results from this analysis did not support this hypothesis for reviews received between drafts 1 and 2. However, the hypothesis was supported when examining change in response to feedback received between drafts 2 and 3. If we assume that greater change between drafts is better, these results suggest that the review source is more critical in the later stages of the revision process in which teams produce solutions to MEAs. The significant interaction term found in the preceding analysis, combined with the means comparisons suggests that the magnitude of this effect depends on MEA, but the overall trend is the same for both MEAs.

Abstract— Developing and using models is an important skill employed by practicing engineers that is difficult to cultivate in students. One way to help students develop modeling capability is through feedback. Feedback has been shown to be effective in helping students close the gap between actual and desired performance. This case study investigates the effect of feedback on student teams' use of models in a three-week, open-ended, process development project in which students conducted experiments using a virtual laboratory. Feedback took place during meetings with an expert coach, termed coaching sessions. Coaching sessions of four teams were found to include a substantial amount of model-related feedback. In addition, an in-depth exploration of a single team provides insight into the impact of both directive and facilitative feedback on student modeling behavior.

Keywords—*feedback; model development; virtual laboratory; engineering education; qualitative research*

I. INTRODUCTION

While studies on the actual activities of practicing engineers are sparse, the development and usage of models is believed to be an important skill when completing open-ended, ill-structured projects. For example, studies have found that practicing engineers develop and use models to better understand and predict the behavior of phenomena [1], [2]. The perception of engineering educators and students reflects this finding by emphasizing that problem-solving is central to engineering and modeling is a key part of problem solving [3]. While modeling is an important element in engineering practice, it is difficult to develop in students. One way to help students develop modeling capability is to provide them with timely feedback. Feedback has been shown to be one of the most important tools used by instructors to help students close the gap between actual and desired performance [4].

This paper reports findings from a study of feedback in the Virtual Chemical Vapor Deposition (CVD) Laboratory Project. This authentic, industrially situated project requires student teams to optimize an industrial process within economic constraints. It has been shown to engage student teams in iterative experimental design, analysis and interpretation, and redesign [5]. Throughout the project, teams have opportunities to receive feedback on their strategy, experimental design, and performance. We believe the iterative process, combined with the feedback they receive, helps teams develop and enhance

pertinent models to use in their solution process. In this study we begin to understand how feedback given to student teams in this project helps them develop and use models. Specifically, we ask the following research questions:

- 1) To what degree does feedback given to students in the Virtual CVD Laboratory Project directly pertain to modeling? What aspects of this feedback are directive or facilitative?
- 2) What is the effect of this feedback on student teams' subsequent use of models?

II. THEORETICAL FRAMEWORK

A. Modeling

While many definitions of a model have been proposed, for brevity we limit our discussion to the definition adopted from Schwarz et al., who define a model as “a representation that abstracts and simplifies a system by focusing on key features to explain and predict scientific phenomena” [6, p663]. We focus on the qualitative and quantitative, syntactic mathematical models that students develop and use to explain and predict the CVD reactor behavior. Modeling theories describing science, mathematics and engineering professionals in practice contend that models are constructed from prior knowledge and newly gathered information and that they are refined in an iterative cycle of creation, use, evaluation, and revision. One study examined the evolution of models of chemical engineering undergraduates placed in the role of plant operators, as they performed troubleshooting in a simulated chemical plant [7]. In another study, protocol analysis was used to examine how instructional design experts used prior knowledge and experience to solve ill-structured problems [8]. This study investigates student model development and usage with respect to feedback.

B. Feedback

Feedback can be broadly defined as “information provided by an agent (e.g., teacher, peer, book, parent, self, experience) regarding aspects of one's performance or understanding” [4, p81]. Based on an assessment of hundreds of meta-analyses from 180,000 studies, Hattie concluded that “the most powerful single moderator that enhances achievement is feedback” [9, p13]. While feedback has been shown to strongly influence student performance and learning, explicit research on the effect of feedback in engineering education is sparse. Findings

from studies of first-year engineering students [10], [11] show that feedback is positively related to learning gains. These results are consistent with studies in other disciplines [12].

In general, there is limited agreement on what characterizes “effective” feedback, especially in ill-structured, open-ended projects. Hattie and Timperley [4] suggest that feedback is more effective when the feedback is related to the achievement of and progress towards specific goals and that less complex feedback may be more effective than more complex feedback. They also suggest that feedback focused on the individual rather than the task and goal is not effective. Elaborated feedback, feedback in which an explanation is provided rather than a simple “right” or “wrong,” may be more effective than a simple mark or grade. Shute contributed a literature review on formative feedback which supports these suggestions and provides tabulated lists of “things to do,” “things to avoid,” timing related issues, and learner characteristics to consider when providing feedback [13]. Feedback has previously been grouped as either reinforcing feedback or corrective feedback [14]. Reinforcing feedback, which we call affirmative feedback [15], acknowledges a correct response and may include praise. Corrective feedback has been described by Black and Wiliam to have two main functions: (1) to direct, and (2) to facilitate. Directive feedback tells the recipient what must be corrected whereas facilitative feedback, which may be more effective, provides suggestions to guide the recipient toward his/her own revisions [16]. In this study we classify episodes of discourse that contain feedback using one of these three descriptions: affirmative, directive, or facilitative. We then extend our group's use of episodes as a discourse analysis framework [19], described in the methods section of this paper, to investigate directive and facilitative feedback, and its impact on modeling, in the industrially situated Virtual CVD Laboratory Project.

III. PROJECT DESCRIPTION

The Virtual CVD Laboratory Project provides opportunities for student teams to develop and refine solutions to an authentic engineering task through experimentation, analysis, and iteration. For this project, students were placed in the role of semiconductor process engineers. Student teams were tasked with the objective of optimizing an industrially sized virtual CVD reactor, which deposits thin films on polished silicon wafers. Performance metrics include high film uniformity at the target thickness, high utilization of an expensive and hazardous reactant, and minimization of development and

manufacturing costs. If one performance metric is optimized, it is generally at the cost of another. To achieve their objective, teams must find suitable reactor input variable values (temperatures along the reactor, flow rates for two reactants, pressure, and reaction time). Their final “recipe,” one of the final deliverables, consists of a set of values for these input variables that yields the best results with respect to the performance metrics. To optimize the reactor, they must integrate prior knowledge from previous courses. The desired learning objectives for the project include both development of professional skills (e.g., working in teams, communication) and integration of core engineering science concepts (e.g., material balances, reaction kinetics, diffusion).

A typical student team devotes 15 - 25 hours to this complex, three-week project. Key project milestones and corresponding opportunities for feedback are summarized in Table 1. The feedback analyzed in this paper occurred during two 20-30 minute meetings, referred to as coaching sessions and shaded in blue in Table 1, between the student teams and a faculty member, who we call the coach. During the coaching sessions the coach acts as a mentor or boss would in industry. In the design coaching session, students must deliver a memorandum that details values for their first run variables, a strategy for subsequent runs and experimental data evaluation, and an entire project budget (in virtual dollars). In the update coaching session students must deliver another memorandum with an update on their progress. The coach asks questions to guide students to further develop their experimental strategy, models, and understanding of core content and concepts, initial variable values, and budget. Feedback is tailored to engage students in identifying gaps in their current design and directing attention to methods for addressing those gaps.

IV. METHODOLOGY

A. Participants & Setting

The twelve student participants were drawn from two cohorts in the final year of an undergraduate chemical, biological or environmental engineering program at a large public university. The project described in this paper took place as the second of three laboratory projects in a capstone laboratory course. Students were organized into teams of three and maintained their team composition throughout the course. One coach provided feedback to all student teams. This coach has coached over 60 teams in the same capstone course over

TABLE I. TIMELINE AND OPPORTUNITIES FOR FEEDBACK IN THE VIRTUAL CVD LABORATORY PROJECT

| Timeline | Key Project Information & Milestones | Student-Coach Opportunity for Feedback |
|----------------|---|--|
| Project Begins | <ul style="list-style-type: none"> Project goals are introduced Criteria for success are indicated Issued laboratory notebook | Instructor (coach) delivers introductory presentation on integrated circuit manufacturing, some engineering science background, and the Virtual CVD software interface. Also presented are project objectives and deliverables. Feedback is limited to questions and in-class interaction. |
| ~End of Week 1 | <ul style="list-style-type: none"> Design coaching session <ul style="list-style-type: none"> Variable values for first run Experimental strategy Budget | Feedback occurs during a 20-minute coaching session. The coach and student teams ask questions of each other and discuss. If initial variable values, strategy, and budget are acceptable, student teams are granted access the Virtual CVD laboratory. |
| ~End of Week 2 | <ul style="list-style-type: none"> Update coaching session <ul style="list-style-type: none"> Progress to date | Another opportunity for feedback is this second 20-minute meeting between student teams and coach. Discussion includes progress to date, issues, and path forward. |
| ~End of Week 3 | <ul style="list-style-type: none"> Final recipe Final report Final oral presentation Laboratory notebook | Teams give a 10-15 min oral presentation to the coach, other instructors, and other students. Next students entertain a 10-15 minute question and answer session that affords additional feedback. Final project feedback consists of grades and written comments on final deliverables. |

several years and has many years of thin films processing experience. The coach has also published research papers and developed courses on the subject. This study is part of a larger study on student learning in virtual laboratories.

B. Data Collection & Analysis

Data sources include think-aloud protocol, student work products, and the Virtual CVD database logs. The think-aloud protocol [18], consists of transcribed audio recordings of the four student teams (Team A, Team B, Team C, and Team D) as they worked throughout the entire project. Student work products include the following items: laboratory notebooks in which students were instructed to detail their thoughts, calculations, and work throughout the project; all memos; final reports; final presentations; and electronic files, such as spreadsheets in which students developed mathematical models. Virtual CVD database logs record the chosen variables, measurements, and timing of all experimental runs.

Episodes analysis was performed on transcripts of the design coaching session for all four teams in order to investigate the first research question. In episodes analysis, feedback in the coaching sessions is characterized by parsing transcripts into a series of episodes. Each episode in this work has a central theme that has been found to fit into one of three general categories [19], a clear beginning and end, and contains up to four stages: surveying, probing, guiding and confirmation. Some smaller episodes have also been found to be nested within larger episodes, i.e., one themed discussion takes place in the context of a larger themed discussion. Episodes were classified as either model-related or not model-related. Model-related episodes were classified as either affirmative or corrective, with corrective episodes designated as either directive or facilitative. Episodes were designated as directive if the coach explicitly requested action and facilitative if guiding took place without an explicit request for action.

To explore the impact of feedback on student modeling behavior, we chose to examine one team in depth. Because Team A had the highest number of episodes that included corrective feedback on modeling, this team was chosen for a more detailed analysis. In addition to the design coaching session, episodes analysis was also performed on the update coaching session for this team. This team's entire transcript consisted of nearly 67,000 words in 226 pages. We used an iterative approach to relate the feedback in the coaching sessions to the team's modeling activity throughout this extensive project. First, two techniques were considered simultaneously: episodes analysis, described above, and Model Maps. A Model Map, described in [20], presents a chronological, visual inventory of the solution path that a team followed. A Model Map is created through analyzing work products and think-aloud protocol transcripts. The Model Map used in this study identified transcript page numbers corresponding to each instance of modeling activity. Initial analysis was performed by comparing the model-related episodes with Team A's Model Map, focusing on modeling activity after the coaching session, in order to identify commonalities. Commonalities were further investigated by carefully examining the corresponding sections of the transcripts. A list of keywords was developed from both the

coaching session episodes and the other sections of the transcripts that were identified by Model Maps. Keywords were then used to search the entire transcript for evidence of feedback related to modeling activity.

V. RESULTS & DISCUSSION

A. Feedback Related to Modeling: A Survey of Four Teams

Examination of the first coaching session for each of four teams suggests that some episode themes are present in most design coaching sessions (e.g., citing or evaluating sources, and performing a material balance), which is consistent with previous findings [17]. While some themes are common, each coaching session is unique and carefully tailored to each team's particular strategy. It was also clear that the design coaching session often involves episodes and feedback on themes that do not pertain to modeling, such as social dynamics, instructional design, input parameters, core content and concepts, and professional skills. In this study we focus on only the model-related episodes. To examine the degree to which feedback given to students in this project pertains to modeling (Research Question 1), episodes were grouped. Initially episodes were assessed as either model-related or not model-related. Next, the subset of model-related episodes was further divided into three groups: facilitative, directive, and affirmative. The results of this grouping are illustrated in Figure 1. Teams on average had 23 total episodes. An average of 10 of these related to modeling. The distribution of the type of feedback given in these model-related episodes varied from team to team. The model-related feedback that Team A received was fairly balanced between facilitative and directive and only included two affirmative episodes. Team B had come to the meeting with common model-related episode themes adequately addressed. This preparation appears to have prepared them well for the coaching session, since with regards to model-related episodes, minimal corrective feedback was given and no directive feedback was given. By contrast, Team C had come to the meeting late, and appearing unprepared. There was even an episode near the beginning of the meeting in which the coach asked the team if they wanted to postpone the meeting until the team was more prepared. They declined. In their coaching session, they had a few long, model-related episodes and, likely due to their lack of preparedness, many shorter episodes that focused more heavily on professional skills. The model-related episodes of Team D were distributed pretty evenly between the three types of feedback investigated here.

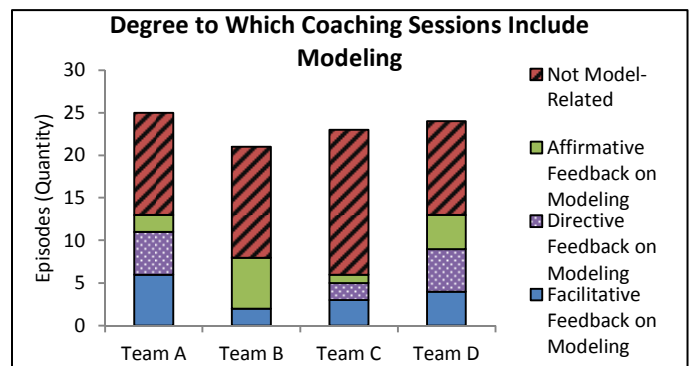

Figure 1: Episode grouping for four teams.

Considering all four teams, it is evident that different types of model-related feedback are given in these coaching sessions to varying degrees depending heavily on the teams.

B. Impact of Feedback on Modeling: A Detailed Description of Team A

In the design coaching session of Team A, two of the model-related episodes were primarily affirmations, either acknowledging or confirming student responses with no guiding or correction. Five model-related episodes contained primarily directive feedback. These five directive episodes had a central, unifying topic: choosing a method to determine flow rate values. Two were substantially longer than the other three. They guided students to realize that material balance was an appropriate method to find initial flow rate values and ended with a statement in which the coach directed the students to do so. The other three directive episodes were very brief and occurred later in the coaching session, simply reiterating the directive statement given earlier. Six episodes in the design coaching session contained primarily facilitative feedback. One was nested within the context of the two larger directive episodes discussed above. The other five facilitative episodes were centered on the topic of the impact of pressure. Within the context of pressure there are two sub-episodes: one is themed around diffusion, the other has a reaction kinetics theme. The reaction kinetics episode provides the context for a sub-episode relating the impact of reaction kinetics to industrial practice.

The update coaching session was much shorter than the design coaching session, containing approximately half as many words and only eleven episodes. In the update coaching session, all corrective feedback was facilitative, with no explicit request for action from the coach. This coaching session contained a brief episode on maintaining their laboratory notebook, multiple episodes on modeling and their experimental strategy, and concluded with discussion about the final deliverables. Two episodes were model-related, facilitative episodes corresponding to the central topics of determining activation energy and identifying the distribution of wafers in the reactor. The four central topics are elaborated upon in the following sections.

1) *Choosing A Method to Determine Flow Rate Values – Directive Feedback:* For the design coaching session, students are required to choose flow rate values for their initial run(s). Use of a material balance has previously been identified as a common method suggested by the coach to estimate or verify flow rate values in the design coaching sessions [17].

After identifying commonalities between episodes and Model Maps, and creating a list of keywords (i.e., material, mass, balance, flow, rate), the entire transcript of this team was explored in depth to look for indications of their activities prior to feedback and to examine their activities after feedback. At a team meeting the day before their design coaching session, the students expressed uncertainty in their values for flow rates. They proceeded to review literature and base one of their flow rate values on a journal article, while fixing the ratio between the two flow rate values. During a flow rate episode in the design coaching session, the coach probed the students regarding how they had selected their flow rates. They referenced a journal paper. However, the students had not

accounted for the difference in size between the reactor in the paper and the reactor in the project. The coach guided them with leading questions towards using a material balance to assess the reasonableness of their values. The students confirmed that they were able to do so. Near the end of the material balance episode the coach gave a directive statement: *"I really think that you need to do a material balance to see if that is a reasonable number."*

The students agreed. The students and coach discussed what values were needed for the calculation, specifically density, and how to acquire those values. The episode then ended. The coach reiterated the directive statement in three very brief episodes later in the design coaching session. After the coach directed the students to perform a material balance, this directive feedback was almost immediately taken up by the students; it was required before they could proceed with the project. In their team meeting directly following the design coaching session, students reflected as follows:

S1: *So, I don't know why we didn't think of this, mass balance.*

S3: *I know right?*

S3 immediately performed the calculation. Later in the meeting, another student did the calculation independently, so that they could be confident in their values. After calculating, the students expressed appreciation for the result:

S3: *Okay awesome stuff. When we get these numbers it's going to rock. I'm happy that we got these. For one I am really confused that we didn't figure this first. For two I am happy that we don't have this haphazard number no more. All the other ones are based off of things we looked up and yesterday we were just like sccms that's a good number. And we got pretty close considering we kind of guessed*

S1: *Oh no, it wasn't a randomly picked number*

S3: *Yeah it wasn't completely random but it still wasn't exactly for our process*

S1: *But it does show the fact that we were so close because if you don't account for the excess it is even closer right? It does show that these references that we are looking at have somewhat of an idea on what they're doing. I guess they are about the same size reactor*

The team was required to revise their memorandum before receiving approval to begin experimentation. They presented a revised memorandum to the coach just over an hour after the first meeting concluded. The coach checked the directive items and gave authorization. Later in the project this team used the concept of a material balance in another way; they incorporated it into their mathematical reactor model to calculate the depletion of reactant gas as it flows through the reactor.

2) *The Impact of Pressure – Complex, Facilitative Feedback:* The impact of pressure, as a central topic, was investigated similarly, with the following keywords: pressure, diffusion, and concentration. Like flow rate values, students must also choose an initial value for pressure before they can proceed with their experiments.

Analysis of the think-aloud transcript before the design coaching session revealed that students had surveyed a variety of references to find an initial value for pressure. They had also identified models of diffusion. In these early meetings the team focused on diffusion as a key to achieve one of their performance metrics, uniform film thickness. They even stated that the system was diffusion controlled and expressed a desire to develop models of diffusion. While preparing for the design coaching session, they emphasized that they wanted to convey to the coach that they have put effort into investigating diffusion, illustrated by the following excerpt:

S1: I don't know. But when we talk to him we can say that we had that, I don't know, but I want him to know we've been thinking a lot about diffusion

While pressure was not included in many of their diffusion discussions, the students explicitly related two aspects of diffusion directly to pressure. Discussions of these two aspects resulted in incorrect conclusions regarding both. Later, as the team wrote their initial memorandum they noted that they wanted to keep pressure low and that their initial pressure value was based on estimation.

During the design coaching session there was a group of facilitative episodes on this topic. An episode themed around pressure provided the context for two sub-episodes, one with the theme of diffusion and the other with the theme of reaction kinetics. A smaller episode, themed around situating the project in industry, was contained within the reaction kinetics episode. The coach began the pressure episode by directly asking the students how they determined the starting value for the pressure variable. The students cited a literature reference, and stated that they didn't think the pressure was as important as the other variables. Within the context of pressure, the team and coach discussed diffusion. During this sub-episode on diffusion, students stated that pressure should be low. The coach then asked why it would be problematic to use an incredibly low value for pressure. This prompted a discussion about the two aspects the students had previously considered, incorrectly, relating pressure and diffusion. It appears the team had a misunderstanding or incomplete understanding about the role of diffusion and the impact of pressure on the performance metrics. The team was guided to conclude that diffusion is not the only way pressure affects their performance metrics, which led to the second sub-episode.

This second sub-episode, on the concept of reaction kinetics, began with revisiting a previous question; the coach asked what other thoughts the students had about why the pressure should not be set too low. Students related pressure loosely to reaction rate. The coach focused discussion with a leading question regarding the contribution of pressure to reaction rates. The students were then guided to recognize that pressure plays a role in the concentration which in turn has an impact on the reaction rate. Within the reaction kinetics episode is another sub-episode which situated the project in the industrial context and linked the concept of reaction kinetics to its impact on high-volume manufacturing. At the end of this group of episodes, students acknowledged that if the reaction rate is slow, product will be made at a slower rate, which may pose a problem in high volume manufacturing.

Following the coaching session, the team discussed their previous understanding of pressure as it relates to diffusion and stated that they needed more information to better understand how diffusion relates to pressure. As they progressed through the project, it is clear from their discourse that they still lack a firm conceptual basis for determining pressure values. They continued to primarily reference diffusion when discussing pressure until one student, S3, created a mathematical model. Approximately one week after the design coaching session, S3 came to a team meeting with a mathematical model of the entire reactor. S3 then began to emphasize the impact of pressure on concentration and reaction kinetics, the same emphasis the coach had given in the design coaching session. This sentiment was reiterated several times throughout the meeting both in the context of trying to convey the information to the other two team members as well as trying to phrase it properly for inclusion in their update memorandum. However, S1 and S2 appear to maintain their understanding that pressure only impacts diffusion. The very last reference to the impact of pressure occurred in the team's last meeting; again S1 and S2 referenced decreasing pressure to increase diffusion, with no mention of reaction kinetics or reaction rate.

3) Determining Activation Energy –Facilitative Feedback: In this example, we show how feedback resulted in a change in a mathematical model parameter value. Prior to the second coaching session, S1 and S3 had a debate in which they discussed two options to acquire a value for one of their model parameters, activation energy: S1 wanted to calculate it from their experimental data, while S3 wanted to get it from a literature search. They chose to search for it because S3 commented that the team should keep things simple. This statement appears to reference an episode in the design coaching session on team dynamics in which the coach noted that S1 had a tendency to make things complex. S3 was also the student who was performing the bulk of the mathematical modeling and would be directly integrating the value into the model. S3 spent time independently finding model parameters, and expressed that activation energy had take “*a really long time*” to find. The keywords used to explore this topic include: activation, energy, Ea, reaction, and rate.

In the update coaching session, while discussing the team's experimental strategy, an episode directly addressed activation energy. The episode started with a student expressing uncertainty in their mathematical model parameters. The coach asked what value they used for activation energy and further probed to identify the source of their activation energy. After discovering that they had found the value at a website, the coach guided the students towards the other option they had previously debated, calculating a value from their experimental data. After this feedback, the students explicitly performed experimental runs in order to determine the activation energy experimentally with S3, the student previously opposed to this option, taking the lead and personally performing the calculations to experimentally determine the activation energy.

4) Identifying the Distribution of Wafers in the Reactor - Student-Initiated, Facilitative Feedback: Our final example is of straight-forward, student-initiated feedback. To explore this topic, keywords include: wafer, and zone. In this case, students noted a need to know the distribution of wafers in the reactor

while working on their mathematical model. The reactor has 5, independently controlled temperature zones in which the wafers are distributed. In a team meeting, prior to the update coaching session, students said “*we really need to know how many wafers are in each zone.*” They even cited that lack of information on the topic was impeding their modeling progress. They made an estimate about the distribution of wafers based on an image of the reactor; however, they also decided to ask the coach during the update coaching session. In the update coaching session, they asked and the coach provided them with the information. After the update coaching session, they immediately integrated it into their mathematical model. While this feedback was briefer than others, the students clearly had a need for the information and initiated the discussion. They were ready to receive the information and apparently perceived it as something that would help them towards their end goal.

VI. CONCLUSIONS & FUTURE WORK

Feedback on modeling is present to varying degrees in all coaching sessions that were examined. When exploring one team in depth, coaching was found to have a significant impact on the progress of the team. The first two general topics brought up concepts that hadn’t been fully explored by the team previously. One included primarily directive feedback, to which the students responded with the requested action, and later incorporated the same concept in a very different way into their project. The second included primarily facilitative feedback. The topic of the impact of pressure was complex and appears to have been incorporated by each student differently. The student who had created the mathematical model integrated it fully. The concept was required in order to develop the mathematical model. The remaining two students appear to have maintained their prior understanding more than integrating the feedback from the coach. It is possible, that because they were less involved in the creation of the mathematical model, that they did not need to further investigate the topic to proceed with the project and they did not have to reconcile what they understood with the complex interactions in the mathematical model. The final two topics were facilitative and had both been discussed explicitly by the team prior to the coaching session in which they received feedback. Feedback regarding both of these topics was fully integrated into the model development of the team.

While not discussed in depth in this paper, it appears that episodes focused on team dynamics and other themes not specifically model-related, may have had an influence on the team’s modeling activity. This warrants further investigation. In addition, modeling activity is not the only aspect of engineering practice that is elicited in this project. It has been argued that professional skills are an aspect of engineering practice that are underrepresented in engineering education and engineering education research [2]. With a similar approach to that used in this paper, we plan to investigate the development of professional skills in relation to feedback.

The Effect of Student Learning Styles on the Learning Gains Achieved When Interactive Simulations Are Coupled with Real-Time Formative Assessment via Pen-Enabled Mobile Technology

Frank V. Kowalski and Susan E. Kowalski

Department of Physics
Colorado School of Mines
Golden CO, USA
fkowalsk@mines.edu

Abstract— This paper describes results from a project in an undergraduate engineering physics course that coupled classroom use of interactive computer simulations with the collection of real-time formative assessment using pen-enabled mobile technology. Interactive simulations (free or textbook-based) are widely used across the undergraduate engineering curriculum to help actively engaged students increase their understanding of abstract concepts or phenomena which are not directly or easily observable. However, there are indications in the literature that we do not yet know the pedagogical best practices associated with their use to maximize learning. This project couples student use of interactive simulations with the gathering of real-time formative assessment via pen-enabled mobile technology (in this case, Tablet PCs). The research question addressed in this paper is: are learning gains achieved with this coupled model greater for certain types of learners in the undergraduate engineering classroom? To answer this, we correlate learning gains with various learning styles, as identified using the Index of Learning Styles (ILS) developed by Felder and Soloman. These insights will be useful for others who use interactive computer simulations in their instruction and other adopters of this pedagogical model; the insights may have broader implications about modification of instruction to address various learning styles.

Keywords—learning styles, interactive simulations, real-time formative assessment, active learning, InkSurvey

I. INTRODUCTION

Explorations of new pedagogical models have many facets and produce rich insights into how engineering education can be enhanced and invigorated. In a two-semester study, we have been investigating the effectiveness of coupling two paradigms based on active learning strategies and constructivist learning theory: using computer simulations and gathering real-time formative assessment. To accomplish this, each student used a single, pen-enabled mobile device. Elsewhere, we describe emerging evidence of the effectiveness of this coupling in undergraduate engineering physics [1] and chemical engineering [2] courses.

However, the intriguing tangential question we consider here is: are the learning gains achieved when this model is implemented greater for engineering students of particular learning styles? It could be hypothesized, for example, that this learning activity, based on a visually-rich experience and hands-on manipulation of variables, is more clearly aligned with some learning style preferences and therefore might be more successful for certain students (*e.g.*, visual, sensing, and active learners) than others.

II. BRIEF DESCRIPTION OF THE COUPLED MODEL

The coupling of interactive simulations with real-time formative assessment will hereafter be referred to as “the Coupled Model.” In this case, the coupling was implemented using one Tablet PC per student, but other types of increasingly available and increasingly affordable pen-enabled mobile devices could accomplish this as well. Thus the coupled model is economically feasible using devices provided by the institution or the students themselves.

Many engineering educators use interactive simulations (*a.k.a.* “sims,” “applets,” etc.) to help actively engaged students better understand abstract concepts or phenomena which are not directly or easily observable. There are abundant free, high-quality, web-based simulations available online, even for advanced engineering topics, and others are available in association with engineering textbooks. However, as we examine pedagogical best practices for implementing the use of these to enhance learning, shortcomings have been identified with teacher manipulation of the simulations [3], with independent student exploration of the simulations [4], and with more precise (“cookbook”) direction of student exploration [5]. It seems that students need skillful guidance from the instructor as they use interactive simulations to discover insights, and careful monitoring as they draw conclusions about new principles and abstract concepts they investigate.

Both of these needs can be met by gathering real-time formative assessment. This cornerstone of constructivist learning is most effective when students respond to open-format (vs. multiple choice) questions, as higher levels of thinking can better be probed and richer insights into student thinking can be achieved. The questions asked for this assessment provide a vehicle for actively engaging students with the course content in the context of the interactive simulation, optimizing use of class time, and increasing student metacognition. Perhaps most importantly in the Coupled Model, these questions can guide learning through timely scaffolded questioning and feedback, helping students to attain a more mature understanding of difficult concepts.

Previously, gathering real-time formative assessment to open-format questions on a time scale that made it meaningful was a daunting task [6]. Socrates did it successfully with a small group of students, but most contemporary engineering instructors do not have that luxury. However, we have developed and maintain *InkSurvey*. This free, web-based software allows students equipped with pen-enabled mobile technology to use digital ink to respond with words, diagrams, graphs, equations, proofs, etc. to open-format questions posed by the instructor. The instructor, receiving these responses instantaneously, has unprecedented real-time insight into student thinking and can reinforce correct understandings and modify misconceptions on the most immediate of time scales. There is other software, both free and commercially available, that will facilitate this, but we chose *InkSurvey* since it is designed specifically for this purpose and has been used successfully in classes with enrollments exceeding 60 students. An additional feature of this use of technology is that a single device in the hands of the student can be used for both the interactive simulation and the construction of the response; this adds to its pedagogical appeal [7].

III. LEARNING STYLES

Over the past few decades, the study of human learning styles has emerged as a well-established field within the discipline of cognitive psychology. Although many different assessments of student learning styles have been used effectively in investigating how engineering concepts and skills are learned [e.g., 8-10], we utilize the widely accepted [11] Index of Learning Styles (ILS) developed by Felder and Soloman [12, 13]. This instrument's roots are in engineering education and it is available for free online [14]. This inventory and the awareness of various student learning styles that it stimulated impacted engineering education. Indeed, by 2000, leaders in engineering education considered identifying and teaching for various learning styles to be of great importance in improving the classroom environment in undergraduate engineering classes [15].

Based on responses to 44 items in the ILS questionnaire (each one forcing the students to choose between two alternatives), every student's learning style can be placed somewhere along each of four continua. These reflect the preferred way the student perceives information (sensory vs. intuitive learning style), how sensory information is most effectively perceived (visual vs. verbal learning style), how the

student processes information (active vs. reflective learning style), and how the student progresses toward understanding (sequential vs. global learning style).

Previous studies indicate that certain learning activities are more effective for engineering students with particular learning styles. For example, when a process control course in electrical engineering was redesigned to introduce active, collaborative learning and to increase student exposure to real-life problems, including the use of advanced computer simulations, researchers found significantly greater learning gains were achieved by students with "active" and "global" learning styles [16].

IV. PROCEDURE

The goal of the course targeted for this study, "Advanced Physics Laboratory I," is to introduce students to the process of modeling in engineering and science. This is illustrated predominately using wave phenomena but also requires coverage of fundamental statistical content. The latter is introduced in the first three weeks of the course via a one week laboratory exercise along with reading, and homework assignments from the text [17]. Much of the content delivery in class is associated with computer simulations coupled with real-time formative assessment (Coupled Model).

The students enrolled in the two sections are engineering physics juniors having 3 semesters each of physics and calculus, along with courses in differential equations, linear algebra, thermodynamics, analog electronics, and a summer session in vacuum systems, optics, machine shop, computer interfacing, and electronics.

The research presented here is focused on how student understanding of content, using the Coupled Model, is influenced by learning style. For measuring learning gains, a pre-test at the beginning of the semester and a summative evaluation at the end of the semester were administered, thus determining learning of content presented via the coupled model.

Simulations involving phasors in circuits, Fourier analysis, and diffraction, along with two others in statistics, were used. The procedure for measuring learning in the phasor circuits simulation is illustrated next. Details for the others will appear in another publication.

Learning objective: to understand how phasors are used in applying Kirchhoff's voltage law to a circuit by summing time-varying sinusoidal voltages of the same frequency across the circuit elements.

Pre-test Question: "How are phasors used in circuit analysis?"

Students were asked to play before class with the simulation found here:

http://vnatsci.ltu.edu/s_schneider/physicslets/main/phasor1.shtml .

Post-play *InkSurvey* question used in class: "What does this simulation illustrate?"

Scaffolding InkSurvey question used in class: “What did you observe in the circuit simulation relative to your understanding of the phasors?”

Summative assessment question: “Explain how phasors are used in the analysis of circuits.”

Student responses were then evaluated based on their demonstration of understanding that Kirchhoff's law is satisfied at each instant of time, using the rubric in Table I.

TABLE I. SCORING RUBRIC FOR PHASOR CIRCUITS SIMULATION

| Unsatisfactory | Satisfactory | Excellent |
|------------------------------------|--|--|
| No discussion of this relationship | Discusses Kirchhoff's law in a static phasor diagram | Relates Kirchhoff's law via a phasor diagram for different times |
| Score=0 | Score=1 | Score=2 |

V. RESULTS

A. Student Misconceptions Revealed by InkSurvey

As noted above, all students were asked to run the simulation and to explain (via *InkSurvey*) what they learned from the interactive simulation relative to their understanding of circuits. Typically, students did not notice that at each point in time on the animation, the voltage across the source equals the sum of the voltages across the inductor and resistor. The instructor, reading the earliest submissions on *InkSurvey*, appropriately coaxed them to think about Kirchhoff's law and how that relates to the simulation.

Students revised scaffolding *InkSurvey* submissions as necessary.

B. Analysis of data

All assessments were identically scaled with an appropriate rubric. Next, learning gains were calculated as average normalized gains, specifically the difference between summative and pre-test assessments divided by the difference between a perfect score and the pre-test assessment. The class average learning gain for each simulation is presented in Table II. Data from students who did not attend the coupled model class session were removed from this analysis. The p values for paired two tailed t-test results with unequal variance, all less than 0.001, showed significant learning gains which were most likely not due to chance. The same conclusion (every $p < 0.001$) was reached using the Kolmogorov-Smirnov test.

To determine the effect of learning styles (dependent variable) on learning gains (independent variable) achieved using the coupled model, we measured learning styles using the ILS learning style inventory [14]. These styles are categorized in complementary pairs. A score is given for each element of the pair. For example, the instrument measures active and reflective styles (ACT-REF) each on a scale of 0-11. The other measures are sensing and intuitive (SEN-INT), visual and verbal (VIS-VRB), and sequential and global (SEQ-GLO) learning styles. Figure 1 shows the learning styles distribution for the class, offered in two sections, with a total of 41 students.

A negative scale is introduced here to more easily graph the results. Data indicating a score on the first characteristic in the learning pair is shown as negative with a more negative value indicating a stronger learning style for the first member of the pair while the positive axis records the other aspect of the learning style pair.

TABLE II. LEARNING GAINS AND CORRELATION COEFFICIENTS FOR LEARNING STYLES AND LEARNING GAINS ACHIEVED, FOR FIVE SIMULATIONS. LEARNING GAIN FOR EACH SIMULATION IS CLASS AVERAGE (SEE TEXT). TABLE SUMMARIZES PEARSON R VALUE AND ACCEPTABLE RANGE FOR 95% CONFIDENCE.

| Simulation | N | Ave.gain | ACT-REF | SEN-INT | VIS-VRB | SEQ-GLO |
|----------------------|----|----------|---------------|---------------|---------------|---------------|
| 1. Circuits | 41 | 63% | 0.02 | 0.02 | -0.04 | -0.12 |
| 95% confidence range | | | -0.28 to 0.32 | -0.28 to 0.32 | -0.34 to 0.26 | -0.41 to 0.19 |
| 2. Fourier | 41 | 67% | 0.03 | -0.004 | -0.06 | -0.05 |
| 95% confidence range | | | -0.27 to 0.33 | -0.30 to 0.30 | -0.35 to 0.25 | -0.35 to 0.25 |
| 3. Diffraction | 30 | 60% | 0.03 | 0.01 | 0.10 | -0.15 |
| 95% confidence range | | | -0.32 to 0.37 | -0.34 to 0.36 | -0.26 to 0.43 | -0.47 to 0.21 |
| 4. Std Dev Mean | 40 | 75% | 0.25 | 0.04 | .14 | -0.11 |
| 95% confidence range | | | -0.06 to 0.51 | -0.27 to 0.34 | -0.17 to 0.43 | -0.40 to 0.20 |
| 5. Least Squares | 33 | 61% | -0.13 | -0.28 | 0.03 | 0.06 |
| 95% confidence range | | | -0.44 to 0.21 | -0.56 to 0.06 | -0.30 to 0.36 | -0.28 to 0.39 |

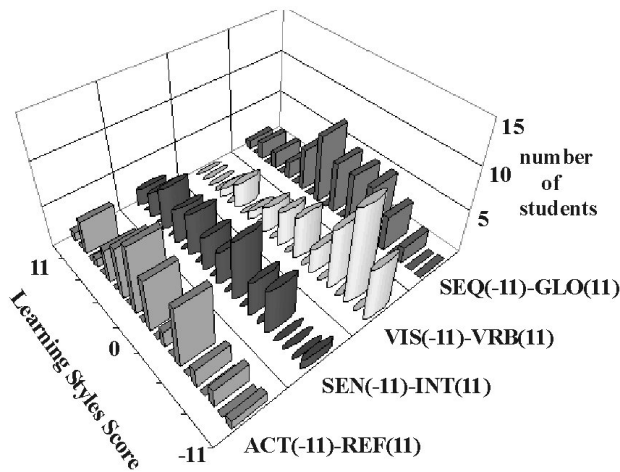

Figure 1. Learning Styles vs. Number of Students

For example, in the VIS-VRB pair, “visual” is the first term so a score further along the negative axis indicates more of a visual learning style, while further along the positive axis indicates more of a verbal style.

The independent variable, learning gain, was then correlated using a Pearson r value with each dependent variable corresponding to a particular ILS learning style and shown in Table II. The significance of each correlation coefficient is reported in Table II as a range within which the population correlation coefficient lies with 95% confidence [18].

Reliability and construct validity of the ILS learning styles measurement has been documented [11, 19, 20]. To test reliability of the learning gains measurement in this study, nine assessments (both pre-test and summative evaluations) were measured by four different raters. The inter-rater reliability was calculated based on the work of Ebel [21] using web-based software [22]. The resulting nine reliability estimates were then averaged to yield a value 0.82 with a standard deviation 0.12. The reliability estimate ranges between zero and one with the larger value indicating more reliability between raters.

C. Discussion

Although the original hypothesis at the root of this study was that the coupling of interactive computer simulations and real-time formative assessment would better meet the learning styles of some students than others, this is not supported by the learning gains data. As shown in Table II, this coupling resulted in significant learning gains for all categories of student learning styles; there is no statistically significant correlation between student learning style and the effectiveness of this pedagogical method in producing learning gains in this population of engineering physics students.

It is interesting to note that the three simulations on which students achieved the greatest learning gains (circuits, Fourier, and standard deviation mean) were also the three simulations with the greatest number of students present in class. We do not know the reasons for diminished attendance on certain

dates, but speculate that the student population present on any given day is not entirely random. This may account for the observed differences in learning gains achieved; however, the data suggest it is not a function of student learning styles.

The distribution of the learning styles of the engineering physics students included in this study did not closely mirror that previously reported in the literature for electrical [16, 23], chemical [24], bioengineering and mechanical [25], general [26] engineering undergraduate students, and others. Although all of these groups shared a preponderance of visual and sequential learning styles, the engineering physics students in this study had a greater population of students with reflective and intuitive learning styles than those consistently reported elsewhere for groups of engineering undergraduates. Nevertheless, even though the experimental group may not precisely reflect the learning styles of other known populations of engineering students, they represent a broad distribution of learning styles, as appropriate for this study.

It is greatly encouraging that this pedagogical model (coupling interactive computer simulations and real-time formative assessment) is not preferentially advantageous to any particular learning style, but rather is broadly effective across all learning styles.

VI. CONCLUSIONS

When interactive computer simulations were coupled with real-time formative assessment collected with *InkSurvey*, students achieved large and statistically significant learning gains on all five examples. These learning gains, however, are shown to have low correlation with student learning styles. The sample population used in this study has been measured to contain a broad distribution of learning styles. The reliability of the instrument to measure student learning styles has been documented, and the inter-rater reliability on measurement of student learning gains is very strong. We therefore interpret the low correlation between learning gains and learning style to indicate that the Coupled Model is effective in enhancing learning, independent of student learning style, in an engineering classroom.

Abstract—The accurate estimation of the difficulty level of the questions posed to students is essential to help them to learn more effectively and efficiently. However, it is agreed that teachers usually fail to identify the correct difficulty level of the questions, according to the answers and final scores obtained by their students. Thus, this paper examines the ability of teachers for categorizing questions by difficulty level, comparing it with the students' perception and the measures obtained by an expert system of question automatic classification. The results show that students perceive questions more difficult than teachers, except for the harder ones. In addition, teachers are only lightly more accurate (closer to the expert system), in spite of the general students' tendency to overestimate the difficulty level of less difficult questions. Although no general conclusions can be obtained about behavior and accuracy of teachers and students when they analyze the difficulty of learning material, the provided analysis could be very valuable for teachers in order to detect unclear problem statements and students' misconceptions.

Keywords—educational technology; automatic question classification; expert systems; teachers' estimation; students' perception

I. INTRODUCTION

It is very common that teachers have to estimate the difficulty level of learning material (questions, items, problems...) when they design and define assessment processes for their students. However, several studies indicate that teachers usually fail to identify the correct difficulty level of the questions, according to the answers and performance of their students [1]-[5]. Besides, if the aim of adapting assessment to students according to their knowledge level is to increase their motivation and efficiency, it is important to take into account their difficulty level perception. However, there are not many studies where the perception and estimation of difficulty level done by students and teachers are compared and analyzed in an objective way. Moreover, as it will be shown in next section, there are not definitive conclusions about the accuracy of the teachers' and students' estimations, since, beyond subjective impressions, it can depend on several factors like the type and representation format of the problem or the specific context. Thus, a more objective estimator, that specifically addresses the context under study, could be a powerful tool in such adaptive learning environments.

In order to support teachers in the difficult task of categorizing questions according to their difficulty level, an automatic classification expert system that objectively estimates the difficulty level of the questions posed through a competitive e-learning tool called QUESTOURnament has been designed. In some competitive environments like QUESTOURnament, temporal variables can play a role comparable to scoring, which is the only factor traditionally considered in automatic classification systems. The intelligent system, which is implemented by using genetic algorithms and fuzzy logic, estimates the difficulty of questions from the students' behavior when answering them in the competition and from the initial classification of these questions made by the teacher.

This paper analyzes how learning actors estimate the difficulty of the questions posed in a real undergraduate engineering course in which QUESTOURnament and this expert system have been used. Students had to answer to a number of questions posed by the teachers through the QUESTOURnament system. For each of the questions, teachers as well as students had to indicate its estimated difficulty level. Later, the expert system was used in order to measure the difficulty level in an objective way.

The rest of the paper is organized as follows. Firstly different related studies from the literature are presented and the motivations for this study are discussed. Secondly, the expert system is briefly presented. Section IV describes the experiment and data collection. These data and the objective estimations achieved by the expert system are then used in order to compare students' and teachers' behavior and accuracy when estimating the difficulty level of the questions, obtaining the results and conclusions presented in the last two parts of the present paper.

II. BACKGROUND

Different studies [4], [6], [7] show that students learn more effectively and are more motivated if posed exercises are arranged according to their difficulty level; since too difficult or too easy questions can frustrate and decrease students' motivation. However, estimating the difficulty level of questions is not an easy job. Moreover, the different studies found in the literature show contradictory results when analyzing teachers' estimations. In fact, although most of the

authors state that generally students' performance tends to be overestimated by teachers [3], [8], [9], Evans and Byrd [10] suggest that teachers perceive a difficulty level of learning material greater than students.

There are several studies analyzing the performance of teachers when they estimate the difficulty of learning material, finding that the estimation accuracy sometimes depends on the own difficulty level of the learning material. For example, Mattar [11] states that teachers are less successful at rating very difficult or very easy items. In this respect, Watering and Rijt [5] indicate that teachers tend to overestimate the difficulty of easy items and underestimate the difficulty of hard items. However, Impara and Plake [3] do not think that teachers systematically behave like this. Moreover, according to the results in [12], teachers usually classify better the difficulty level of the hardest items.

It is therefore not possible to obtain a general conclusion about the accuracy of the teachers' estimations, since the results of different studies are incongruous. In addition, even within a same context teachers can perform differently. For example, during the experience described in [12], ten teachers had to order eleven items according to their relative difficulty and the results indicate that the teachers' accuracy about the difficulty level was different between them. A similar procedure was followed in [1], in which several teachers and students evaluated the difficulty of 14 mathematical tasks by ordering them. The results show that the classifications done by teachers and students are different and that the difficulty level depends on the type and representation format of the problem.

In spite of the difficulty of this task, students sometimes are better than teachers estimating the difficulty of the learning material. Results in [5] suggest that students estimate better the items difficulty level than teachers, while [13] also finds that students perform better on judging the difficulty of items than domain experts. Results shown by Lee and Heyworth [4] indicate high correlation between the item difficulty ratios, the teachers' estimations and the students' perceptions of problem difficulty level; although students' predictions were also more accurate than teachers' estimations.

The previously mentioned studies use different methods to evaluate and compare the performance of teachers and students when classifying learning material by difficulty. For example, [13] analyses six different difficulty level estimation methods, included the students' and experts' opinion, in order to review the accuracy of these methods as compared to a large scale IRT-based calibration.

In this research, due to the open and competitive nature of QUESTOURnament, no traditional or more common methods, such as IRT (Item Response Theory), can be used to objectively calibrate the difficulty of the questions [14]. A hybrid expert system based on genetic algorithms and fuzzy logic that estimates the real difficulty of the questions posed through the tool QUESTOURnament has been designed. The estimations and perceptions of difficulty level done by teachers and students are compared and tested against this expert system, which is briefly described in the next section.

III. EXPERT SYSTEM FOR AUTOMATIC CLASSIFICATION OF QUESTION DIFFICULTY

A genetic fuzzy expert system has been designed to dynamically adapt the difficulty level of the questions posed through the QUESTOURnament system. QUESTOURnament is a competitive e-learning tool integrated into Moodle that allows teachers to organize contests, in which students must answer several questions (called challenges within the system) within a limited time. Students compete with each other in order to obtain higher scores and be at the top-ranking. This system has been successfully used in different courses [15], [16], although a component of stress, due to its competitive nature, appears almost always as main drawback.

The main aim of the expert system is to objectively estimate the difficulty level of challenges in order to be able to define a contest by groups in which students with similar skills compete together by answering questions of a difficulty appropriate to them. In this way, the stress produced in the worst classified students could be reduced and their motivation would keep higher as they would have more chances to win.

In order to implement the expert system, genetic algorithms and fuzzy logic have been used, since other common techniques, such as the previously mentioned IRT, are not valid for the contexts of use of QUESTOURnament, due to its versatility and open character [14]. The system, described in detail in [14], identifies the characteristics of the questions for each difficulty level from the actual behavior of students and adjusts the new difficulty level of each question (see Fig. 1).

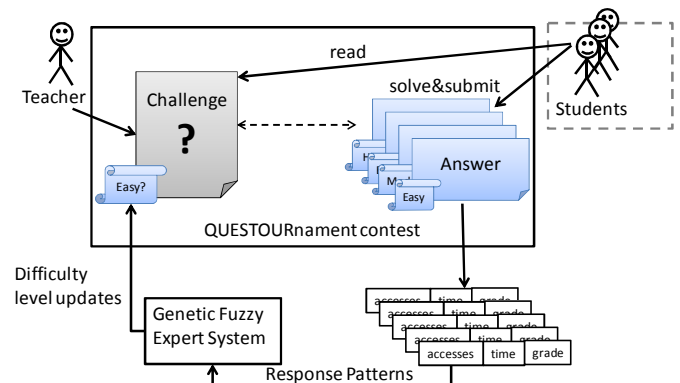

Figure 1. Diagram of the expert system for automatic classification of question difficulty

The expert system estimates the difficulty of challenges according to three levels (easy, moderate and hard) from the students' response patterns and from the initial classification of these questions made by the teacher [17].

More specifically, from Moodle and QUESTOURnament logs, three parameters are considered in the response patterns: time in minutes from the last reading of the question until the submission of the answer, grade obtained for that answer and number of accesses or readings before submitting the answer (*time*, *grade* and *accesses*, respectively). All these data make up a set of usage patterns that feed the expert system. It works iteratively and by difficulty level. In the first iteration, the questions are divided into the three difficulty levels initially defined by the teacher. Then, in next iterations, the new

classification automatically obtained in the previous iteration is used. This process is repeated until a stable situation is achieved.

For each difficulty level (easy, moderate and hard), the system uses the patterns of all the questions belonging to that level and obtains a set of fuzzy rules and membership functions of the three input variables (*time*, *grade* and *accesses*), which are used for reclassifying the questions. In the fuzzy model the membership functions of the output variable, the *difficulty*, always take the form shown in Fig. 2.

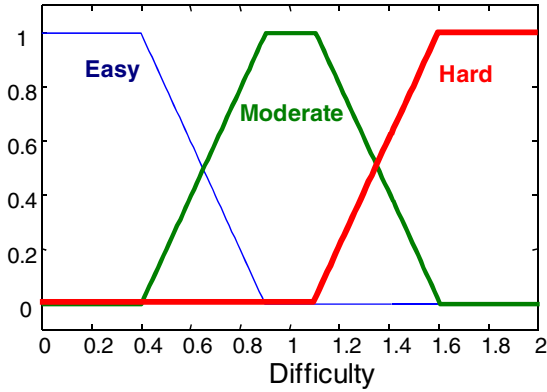

Figure 2. Membership functions of the output variable *difficulty*

Therefore, the system combines the students' behavior and the teachers' perception in order to objectively estimate the real difficulty level of each challenge. Background and motivation to design this new intelligent system, as well as a complete detailed description of it and its validation against a group of experts, can be found in references [14] and [17].

The system can be used in any engineering educational context, since it has not been designed for any specific subject. In fact, with the current version of QUESTOURnament, the challenges can be any type of questions available in Moodle question bank (essay, true-false, multiple choice...), although open answer questions was the only type available in version 1.0 of QUESTOURnament, which was the one used in the experiment described below.

IV. EXPERIMENT

A. Data Collection

The version 1.0 of the competitive e-learning tool QUESTOURnament was used in an undergraduate course of Diploma in Telecommunications Engineering given at the University of Valladolid (Spain). Thirty-eight students had to compete answering twelve challenges on IP addressing and routing. The challenges were essay or open answer questions. Assessment criteria were clearly stated and published for each individual challenge. Students had to indicate their perception of difficulty after solving each question and while they submitted the answer and participated in the competition.

The system also asked teachers to classify the challenges according to their difficulty level. Four teachers with more of ten years of experience participated in the experiment. Teachers selected one difficulty level for each challenge

according to their standard previous experience and without taking the competitive context into account.

B. Methodology

As aforementioned, when the students answered a question, they had to indicate their perception of difficulty according to a set of three values: 0, 1 and 2 (easy, moderate and hard, respectively). From these data, the average difficulty, as perceived by students, of the *j*th challenge d_j has been calculated, as in (1).

$$d_j = \frac{1}{N_j} \sum_{i=1}^3 n_{ij} \cdot D_i \quad (1)$$

where n_{ij} represents the number of learners that give feedback responses belonging to the *i*th difficult level for the *j*th challenge, N_j is the total number of learners that rate the *j*th challenge, and D_i is the challenge difficulty level quantified as 0, 1 and 2.

On the other hand, teachers were also asked to indicate their difficulty level estimation, according to the same set of values: 0, 1 and 2. The average difficulty estimated by teachers has been calculated by using the same procedure shown in (1).

Last, in order to compare teachers' and students' accuracy, the hybrid expert system that objectively measures the difficulty of the challenges has been used. Although the expert system works with three difficulty levels, it can obtain crisp numeric values that belong to two fuzzy sets in a considerable degree (for example, those values of difficulty around 0.6 belong to the easy as well as to the moderate fuzzy sets in a similar degree, as shown in Fig.2). Therefore, for a better analysis five levels have been used in this study, including those fuzzy areas found between two levels: *easy*, *between easy and moderate*, *moderate*, *between moderate and hard*, *hard*.

Finally, the membership functions shown in Fig. 2 have also been used to interpret and translate the numeric values obtained from students' and teachers' input into the corresponding linguistic values.

C. Detailed Study Objectives

This study aims at comparing the students' and teachers' perception of the difficulty level of the challenges posed in QUESTOURnament. On the basis of the literature as well as the own experience, it could be stated that students usually tend to classify questions harder than teachers. Besides, taking into account the specific competitive context of QUESTOURnament, it could be expected that teachers perform worse than students, since teachers estimate the difficulty in general terms, without considering the competitive nature of QUESTOURnament, whereas students do it immersed in the competition (as the expert system does too).

Therefore, this study tries to analyze the following two affirmations:

- The difficulty level perception reported by students will be higher than the difficulty level estimation done by teachers.

- The students' difficulty level perception against the expert system will be better than the teachers' difficulty level estimation against the expert system.

V. RESULTS AND DISCUSSION

For each of the twelve challenges posed, Table I shows the classification given by the expert system as well as the difficulty level estimated and perceived both by teachers and by students. For the expert system, the numeric value indicated between parentheses corresponds to the crisp numeric output. For the students and teachers, it corresponds to the average numeric value calculated as indicated in (1).

From data of Table I, it can be observed that students perceive challenges more difficult than teachers, except for the hardest ones. Besides, it is remarkable that none of the challenges are considered totally easy by students. Those challenges considered easier by the system are estimated as easy by the teachers but not by the students. When analyzing this, it should be contemplated that the system estimates the difficult level of questions having into account the real behavior of students when answering challenges. Therefore, students are answering correctly these questions, although they do not perceive them as easy. It should be noticed that teachers participating in this experiment tried to objectively estimate the difficulty of questions while this fact cannot be confirmed for every student. Students are inexperienced in this task and moreover they sometimes are not objective when indicating their perception. For example, the competitive nature of the context may influence the response of some students.

Therefore, for easy and moderate challenges, it seems to be true that the difficulty level perceived by students is higher than the difficulty level estimated by teachers. This same behavior cannot be confirmed for harder questions. This result did not agree on the one obtained by Evans and Byrd [10] who

suggest that teachers perceive a difficulty level of learning material greater than the indicated by students. On the other hand, the affirmation of that students' performance is overestimated by teachers cannot be confirmed as, although students perceive challenges more difficult than teachers, the output of the expert system is informing that many students are properly solving those challenges that are easy for the teachers.

The most difficult challenges according to the expert system (those classified as *between moderate and hard* or *hard*) obtain a high value in both students' and teachers' estimations, except for challenge 2, which is considered of moderate difficulty by teachers. This shows that more difficult items seem to be better classified than easy or moderate ones. In general terms, the hard questions were correctly classified by both the teachers and the students. However, the students had a tendency to overestimate the difficulty level of easy or moderate questions. Due to this behavior of students, they do not seem to be better classifiers of the challenges in this experiment than teachers, contradicting the affirmation suggested in previous section.

Finally, what it seems true is that this type of analysis can be very valuable for teachers. Data shown in table I can help them to detect special cases that should be analyzed. For example, for challenge 8 divergent classification results can be found for each of the actors; whereas the teachers consider that the question is easy, the students think that it is hard. However, the system objectively values its difficulty at the middle of the scale. Cases like this may be due to an unclear problem statement that could have confused students, thus teachers should revise the wording of that challenge. It could be also due to some important misconception not detected before. Therefore, teachers could have a powerful tool for detecting general students' misconceptions and problems formulated wrongly.

TABLE I. DIFFERENT MEASURES OF THE DIFFICULTY LEVEL: EXPERT SYSTEM, STUDENTS AND TEACHERS

| Id | Expert System | Students' Perception | Teachers' Estimation |
|----|-------------------------------------|-------------------------------------|----------------------|
| 1 | Moderate (1.08) | Moderate (0.79) | Moderate (1.00) |
| 2 | Between moderate and hard (1.51) | Between moderate and hard (1.33) | Moderate (1.00) |
| 3 | Easy (0.38) | Between easy and moderate (0.7) | Easy (0.00) |
| 4 | Between easy and moderate (0.52) | Between moderate and hard (1.28) | Easy (0.25) |
| 5 | Moderate (1.07) | Between moderate and hard (1.30) | Moderate (1.00) |
| 6 | Between moderate and hard (1.48) | Between moderate and hard (1.39) | Hard (1.75) |
| 7 | Easy (0.37) | Between easy and moderate (0.61) | Easy (0.00) |
| 8 | Moderate (1.08) | Hard (1.59) | Easy (0.25) |
| 9 | Hard (1.68) | Hard (1.70) | Hard (2.00) |
| 10 | Between moderate and hard (1.32) | Hard (1.57) | Hard (1.75) |
| 11 | Hard (1.62) | Between moderate and hard (1.46) | Hard (2.00) |
| 12 | Between moderate and hard (1.55) | Between moderate and hard (1.43) | Hard (2.00) |

VI. CONCLUSIONS

Research shows the problems that teachers have to correctly estimate the difficulty level of questions. Moreover, from literature no conclusions can be obtained about behavior and accuracy of teachers and students when they analyze the difficulty of learning material. The results of the experiment described in this paper do not provide light to the problem. Results are consistent with Impara and Plake [3] when they say that teachers do not systematically behave overestimating and underestimating the difficulty of easy and difficult questions, respectively, as it is affirmed in [5]. Besides, results do not confirm those obtained in [5], [13], [4], according to which teachers do less accurate predictions than students do, in spite of their expertise.

Results obtained in this type of studies seem to depend on different factors that should be analyzed: type and representation format of problems [1], context of the experiment, subjective reasons in the students, etc. This analysis could help researchers to understand how the difficulty of learning material could be better estimated by the learning actors as well as by automatic systems. Due to the complexity of the problem, automatic systems, such as the one described in this paper, adjusting the difficulty level of questions according to the actual students' response (which is conditioned by the specific context), are a very useful support tool for teachers and a key component for truly adaptive e-learning environments.

Abstract—The purpose of this study is to determine how introductory Project-Based Learning (PjBL) courses affect the self-efficacy of first-year engineering students. Grounded theory is used to analyze twelve interviews with first-year students about their experiences in two PjBL courses, *Engineering Design* and *Physics Laboratory*. Data indicate that students' self-efficacy within each course is correlated with the extent to which their course goal perceptions align with those intended by faculty. In *Engineering Design*, students' recognition of the faculty's intended course goals corresponds to higher levels of self-efficacy. Conversely, in *Physics Laboratory*, students' low self-efficacy is correlated with a large gap between their perceived and faculty intended course goals. Analysis further reveals that this difference in course goal perceptions may stem from the variations in the courses' contingent scaffolding. Finally, our findings suggest that students' self-efficacy may be further supported by dynamic course scaffolding that allows for an increase in students' autonomy throughout a course.

Keywords — *First-Year Engineering Curriculum, Project-Based Learning, Self-Efficacy, Course Scaffolding*

I. INTRODUCTION

Project-based Learning (PjBL) is commonly defined as a pedagogical practice or an educational experience centered around one or more long-term student-directed projects [1-4]. These projects tend to model “real-world” work situations, with a focus on group work and hands-on experiences. Unlike traditional courses, in which faculty role is largely limited to imparting knowledge on students, instructors in PjBL environments serve as mentors, offering students significant autonomy [1-4]. In engineering settings, PjBL courses are likely to focus on knowledge application as opposed to knowledge acquisition. It has been argued that this emphasis on application is necessary for the engineering profession in which changing technology and industry demands render both technical and meta-skills more valuable than specialized content knowledge [4].

In the past two decades, a number of technical institutions have incorporated PjBL as a central curricular component, often featuring it in introductory courses [5-7]. As a result, many studies to date have focused on the effectiveness of PjBL, particularly as it pertains to the first-year engineering curricula [4-8]. Yet within the body of this work, little to no research has addressed the issue of how and to which extent PjBL affects students' self-efficacy, particularly in first-year courses. Our study addresses this gap by investigating introductory PjBL courses through a self-efficacy lens [9-12].

Introduced and popularized by Albert Bandura within a larger framework of social cognitive theory, self-efficacy refers to a personal belief in one's ability to perform a specific task or achieve a desired outcome [13]. A specified context and achievement level are what differentiate self-efficacy beliefs from more general self-confidence beliefs. For example, “I'm good at math” is a statement of confidence, whereas “I believe I can solve first-order differential equations without help” is a statement of self-efficacy. High self-efficacy beliefs have been shown to be positively correlated with student interest, achievement, and persistence in engineering courses [10-12, 14-15]. Conversely, low retention in engineering has been attributed to low self-efficacy beliefs [9-12].

To describe the development of these beliefs, Bandura defined four self-efficacy sources: (1) *Mastery Experiences* are past events strongly associated with either successes or failures in performing similar tasks. Experiences with positive outcomes are likely to result in higher self-efficacy, while experiences with negative outcomes are associated with lowered self-efficacy; (2) *Vicarious Experiences* are events in which individuals compare themselves to others with regard to their task outcome; (3) *Social Persuasions* are verbal judgments about others, often relating to stereotypes or biases; and (4) *Physiological States* are physical and emotional responses – such as anxiety or stress – encountered while attempting a task.

Current literature suggests that mastery experiences are the most prevalent sources of self-efficacy in educational settings [16]. Vicarious experiences can be influential when one has little experience in a subject domain, but they are not as influential as mastery experiences. Social persuasions and physiological states occur least often, though social persuasions are found more frequently in male-dominated academic settings [17-18].

Our study utilizes Bandura's framework while adding to the current body of knowledge in the context of first-year engineering courses by asking the following questions: 1) *How do PjBL courses affect first-year students' self-efficacy?* 2) *What factors of PjBL course implementation are most relevant to establishing students' self-efficacy beliefs?*

To answer these questions, we investigate two PjBL classrooms, *Engineering Design* and *Physics Laboratory*.

II. METHODOLOGY

A. Study site

This study is part of a larger multi-site, mixed-methods research focused on first-year engineering students' experiences in PjBL courses. In this paper, we focus on one of the study sites: a small technical undergraduate institution which features PjBL throughout its curriculum. In particular, we investigate two introductory PjBL courses: *Engineering Design* and *Physics Laboratory*.

B. Student interviews and analysis

Twelve second-semester first-year students, six women and six men, participated in semi-structured open-ended interviews about their experiences in physics and engineering courses. The interviews took place midway through the semester when the students were enrolled in the courses. Students were selected using "purposive" sampling [19-20] to ensure participation in the same physics and engineering courses, as well as to ensure an inclusion of students at varying performance levels. Grounded theory was employed to analyze students' interviews [21] and pseudonyms were used to preserve students' confidentiality. Codes and memos were used to organize the data into matrices and emergent themes were identified. In what follows, representative quotes are chosen to demonstrate general themes and emerging trends.

C. Course descriptions

Though from different academic disciplines, the two courses under investigation, *Engineering Design* and *Physics Laboratory*, share remarkable similarities with respect to overall goals, as well as use of projects, teamwork, and hands-on activities, while utilizing faculty in mentorship roles. As such, both courses can be described as PjBL environments.

Engineering Design introduces students to a design process through three long-term group projects. Throughout the semester, these projects increase in length, duration, complexity, and student autonomy, while faculty support is simultaneously reduced. This is achieved through a set of intermediate deliverables which decrease in frequency and procedural/organizational specificity as the course progresses. The course also features weekly instructor-student meetings that further allow faculty to guide student teams.

Physics Laboratory is offered as a co-requisite to a lecture-based course in introductory Newtonian Mechanics. According to the course syllabus, the goal of the *Physics Laboratory* is to expose students to an evidence-based open-ended experimental process with a large emphasis on student-driven learning while faculty guidance is minimized. Students work with partners of their choosing on weekly table-top experiments. Provided with an initial open-ended problem statement, students are expected to design, build, and perform an experiment, followed by analysis that usually extends beyond the classroom. Technical writing is reinforced through weekly "tech report" summaries.

III. RESULTS AND DISCUSSION

Our data suggest two emerging trends: (1) *Engineering Design's* course implementation allows for much higher self-efficacy in comparison to *Physics Laboratory*; and (2) *Engineering Design's* course scaffolding leads to more positive mastery experiences than those in *Physics Laboratory*.

Although occasionally experiencing frustration with the design process and the overall course, students in *Engineering Design* demonstrate positive affect and convey high self-efficacy. Many students find that the design process is straightforward and easy to follow, resulting in course enjoyment and confidence in their engineering abilities. For example, when asked to describe his overall feelings about the course, Cody responds with: "The best thing about [*Engineering Design*] is that we're not doing anything extremely difficult conceptually yet. It's not scary. It's really enjoyable" (Cody, April 9th).

As a result of the course many students report an increase in their interest in engineering. Combined with enjoyment and confidence, this enhanced interest facilitates positive self-efficacy development. Some students suggest that the course contributes to their identity as engineers: "[*Engineering Design* is] really useful ... it's made me *want* to be an engineer... now I'm really happy that there's a class that I like and I can see myself doing a job in" (Carolina, April 6th).

In comparison, many students express frustration in *Physics Laboratory* that is augmented by a lack of confidence in their abilities to complete the work. Many students express a lack of understanding of the lab goals and approaches necessary to perform them: "I didn't really understand what was going on... and I was just really frustrated because... I don't know what I'm doing. I'm just doing something and I don't like to just do something... I want to know what's happening" (Isabella, April 11th).

A majority of the interviewed students echo these feelings of frustration and confusion. When asked about her overall experience in *Physics Laboratory*, Loretta comments: "I'm not that interested in physics. I knew that [since] I came here, [and *Physics Laboratory* made me realize that I] actually wasn't good at it..." (Loretta, April 10th). Loretta's quote demonstrates the powerful negative impact that *Physics Laboratory* has on many students' interest, confidence, and self-efficacy beliefs. Many other students echo this sentiment with explaining that this course lowers their overall interest in physics as a field.

Our findings indicate that the students' self-efficacy beliefs in the two courses stem, for the most part, from mastery experiences. In fact, we find that vicarious experiences, social persuasions, and physiological states have little to no effect on self-efficacy belief formation. Students associate *Engineering Design* with positive mastery experiences; they find that the course teaches valuable engineering design skills, and often describe a sense of accomplishment associated with project completion. Betty

expresses this sense of positive mastery when she describes her feelings about her work in the course: "... I've actually built this with my own hands, with the help of some other people. I've made this work, I've worked out the kinks in it. I feel that this is really the highball experience..." (Betty, April 6th). Positive mastery experiences may be attributed to completion of projects with tangible and often successful results. These mastery experiences provide students with a sense of ownership over the design process, which further contributes to the overall positive outlook on the course and engineering as a field.

Conversely, students report having negative mastery experiences in *Physics Laboratory*, which appear to stem from repeatedly poor project outcomes. Carolina explains: "I put a lot of time into making my technical reports for that class and, no matter what I do, I always get really bad data... it just seems like I put a lot of time in there and I don't think it's actually helping me understand" (Carolina, April 6th). This perceived project failure appears to contribute significantly to students' lowered self-efficacy, especially because such negative experiences often occur repeatedly.

These quotes, and many similar ones from other students, suggest that there are key differences between *Engineering Design* and *Physics Laboratory* that, at least in part, lead to significant differences in students' self-efficacy. In the next sections, we examine the correlation between self-efficacy and the alignment of students' perceptions with faculty intended course goals. We will then investigate the effect that course scaffolding has on this course goal alignment.

A. The effect of student course goal perceptions

One noticeable difference between *Engineering Design* and *Physics Laboratory* is students' perceptions of course goals. Specifically, our data indicate that students' perceptions of course goals are more aligned with faculty's intentions in *Engineering Design* than in *Physics Laboratory*. This alignment in *Engineering Design* is highly correlated with students reported positive mastery experiences which generate high self-efficacy. Conversely, in *Physics Laboratory*, misalignment of students' course goal perceptions correlates with the lack of positive mastery experiences, establishing low self-efficacy beliefs in the course.

According to the course syllabus, the primary goal of *Engineering Design* is to teach students a design process. All of the interviewed students recognize this as the course's main focus. For example, when asked what *Engineering Design* is about, Betty responds with: "[The professors] pointed out that the design process of engineering could be structured" (Betty, April 6th). What is particularly interesting about Betty's quote is that she emphasizes the professors' role in focusing the course on design as a process, suggesting explicit nature of faculty intentions. Furthermore, students recognize the value of this course goal in their academic and professional careers: "I guess what I've learned a lot about is... how the design process works and why we have a design process" (Kyle, April 10th). These representative quotes embody the high level of purpose that students attribute to the class, allowing them to

continue building upon positive mastery experiences towards high self-efficacy and agency [22].

This alignment of students' course goal perceptions with faculty intentions plays a key role in developing mastery experiences. In fact, it is because students expect to learn the design process and their expectations align with the course experience, positive mastery experiences become possible: "I think the project has really helped... [Before this class] I guess I never really understood what went into the design process" (Carl, April 8th). Of note is that even in the presence of difficulties, students maintain positive mastery experiences. Patty comments that she isn't sure how her final prototype will turn out; however, when asked about this potential failure, she responds: "I feel there is a process I'm following..., so I still feel in control" (Patty, April 8th). It is this high self-efficacy and a sense of "being in control" that allow Patty and other students interviewed to develop a sense of agency and maintain an interest in *Engineering Design* and the field of engineering as a whole.

On the other hand, in *Physics Laboratory*, very few students recognize the faculty's intended course goals. According to the course syllabus, *Physics Laboratory* seeks to teach students the basics of the experimental process. However, when asked to describe the purpose of the course, students' responses vary widely. Only a few students recognize the faculty's intentions. For example, Cody explains: "[Lab is an] introduction to taking data and keeping a lab notebook and writing out tech papers" (Cody, April 9th). However, the perceptions of other students differ. For instance, Carolina believes that the main purpose of *Physics Laboratory* is to supplement knowledge from her physics lectures: "I think the point of [the] lab is... to help you understand [physics concepts] better..." (Carolina, April 6th). Other students, such as Patty, believe that the course is about proving known physics results: "[In] *Physics Lab* you're trying to prove that [physics laws] actually work... like one of the labs was proving Newton's mechanics" (Patty, April 8th).

These varied perceptions of course goals, many of which don't align with faculty's intentions, appear to contribute significantly to the students' inability to achieve positive mastery experiences in *Physics Laboratory*. The course is designed to teach students the basics of the experimental process; it is not designed to teach new physics concepts or to have students "prove" physics laws. Nevertheless, students expect these outcomes and feel incompetent when these perceived goals do not live up to their experiences. For example, Loretta, who believes that she should be focusing on collecting "good" data, comments on a negative mastery experience: "We took the data, and that went really well, and I was like 'Oh, this isn't going to take much work. I have nice data, I have almost everything done,' and it turned out that I couldn't even get a curve for the data, and that really messed me up. I didn't even want to look at it" (Loretta, April 10th). Because Loretta's expectations for the course are limited to successful data collection, her inability to do so results in a negative mastery experience and lowered self-efficacy. Though it is possible that she still is familiarizing herself with

the experimental process, in fact achieving the intended course goals, her misaligned perceptions and expectations further lead to a lowered sense of agency in the course and potentially the overall field of physics.

B. The role of scaffolding on course-goal perception

In this section, we investigate possible reasons that underlie the differences in students' perceptions of course goals in *Engineering Design* and *Physics Laboratory*, which, as discussed in previous section, lead to differences in students' self-efficacy. This is of particular interest given that the two courses have similar foci, i.e., they intend to develop an understanding of engineering design or experimental design as a process. One possible explanation emerging from our analysis points to the differences between the levels of faculty-supported scaffolding provided for students in the two courses.

In educational literature, scaffolding is defined as temporary support structures used by faculty to aid students with the completion of a task [23]. This construct is often confused with the idea of a supportive or structured classroom environment. To differentiate scaffolding from other educational supports, Van de Pol (2010) in his meta-analysis of studies on scaffolding outlines the following three requirements. Firstly and most importantly, scaffolding must be a *positive and interactive process* with both teacher and student as participants. If students do not recognize the support structures provided by the instructor, they cannot be classified as scaffolding. This relates to the second requirement, which is *contingency* or calibrated support. The amount of teacher support must be dynamic – stronger when a student is working in an unfamiliar domain and weaker when a student gains competency. Finally, scaffolding requires *fading support and a transfer of responsibility* over time. Initial support is required to allow the student to become comfortable with the material, but Van de Pol (2010) claims that a student must become autonomous and self-regulated in order to gain true mastery [23].

We argue in this section that the *contingency* and *interactive* components of scaffolding are necessary to align student course goal perceptions with the faculty's intended goals, ultimately resulting in higher self-efficacy. In the next section, we then further propose that the *fading support and transfer of responsibility* also play a role in building students' self-efficacy beliefs.

Faculty provide scaffolding in *Engineering Design* by requiring students to submit a set of *intermediate deliverables* during the first two projects. These intermediate deliverables are a series of assignments that aid students in the design process, such as a written list of functional objectives, a work-breakdown chart, a set of design alternative sketches, etc. For example, Gloria describes her experience with the second project: “[The professors] taught us... all the little engineering tools that we’re supposed to use... and then gave us a problem statement, and told us to revise it, and [then we started to] work with due dates for every little part” (Gloria, April 9th). Because these intermediate deliverables outline the steps of the design process, it becomes apparent to Gloria that the

course is about learning design as a process. Almost every student comments on these intermediate deliverables, alluding to the important role they play in establishing the purpose of the course.

For most students, the structure provided by the intermediate deliverables is sufficient to properly align their course goal perception with those intended by faculty. However, some students require extra support to fully understand the course's purpose. These students are further supported by the *Engineering Design* faculty who, in their mentorship role, provide additional contingency structures. For example, during the second project Cody and his team rushed through many design steps, focusing more on the end product than learning of the process. Cody describes his experience and faculty intervention (i.e., contingency) as follows: “Well, on the last project our team didn’t really do as much [about] the metrics... and we were kind of excited to get on the building of it, so we kind of got slapped on the wrist for that” (Cody, April 9th). Though Cody's description of the faculty response is somewhat negative, he comments later in the interview that the purpose of the course is to learn the design process, suggesting the intervention's success. Thus, the individualized support provided by faculty, combined with the structure of the intermediate project deliverables, ensures that every student in *Engineering Design* recognizes the course's main focus.

In comparison, students in *Physics Lab* perceive a complete lack of scaffolding. Here they are given no intermediate deliverables, guidelines, or coaching, bringing about feelings of frustration, confusion, and negative affect. Kyle describes an average lab as follows: “[The professors] present you with an experiment... and give the equipment to perform an experiment, and our lab manual just kind of guides us [with respect to] how this stuff works and what you can do with it. And basically they ask us to pick an experiment and test...just take a bunch of raw data and see how your experimental values for something compare to a theoretical [framework]” (Kyle, April 10th). Rather than adapting this narrative as a focus of the course, many students perceive it as a lack of instructor support. This may be partially rooted in (1) students' expectations of an active faculty role in “teaching” the relevant content and skills; and (2) a lack of explicit guidance on the part of the faculty in the regular student-faculty meetings, intermediate deliverables, experimental techniques training, etc., i.e., *contingency*. Whatever the specific cause of this perceived lack of instructor support for each individual student (i.e., specific *contingency*), all students interviewed indicate becoming increasingly confused and misguided about the purpose of the overall course and each individual lab within the course. Thomas comments: “... I’m given the set-up for the lab, I see what it is, and there’s a premise of what it is we’re doing. But after that what it is the [professors are] actually asking me... gets a little hazy” (Thomas, April 8th). Marco shares a similar experience with *Physics Laboratory*: “You’re expected to be prepared for lab and have already read the lab instructions, so that you already know what’s going on before you’re in the lab. [So] it’s not expected that [the professors] are there to tell you how to do

it” (Marco, April 12th). This lack of contingent instructor support perpetuates students’ perception of the lack of structure in *Physics Laboratory*. According to Marco, even though students may be confused with regard to what they are supposed to be doing in lab, the faculty do not provide any assistance because of their rigid expectations of student preparation. Accordingly, this overall lack of contingency leads students like Thomas and Kyle to remain frustrated and confused about the course’s content and goals.

C. Direct effects of dynamic scaffolding on self-efficacy

From the analysis above it is apparent that scaffolding in *Engineering Design* plays an important role in establishing and aligning student course goal perceptions with those intended by faculty. However, this is not the only effect that scaffolding has on students’ experiences. Our analysis indicates that the *gradual transfer of responsibility* and *increase in autonomy* perceived by students is another factor that contributes to students’ self-efficacy. As mentioned previously, the first two projects in *Engineering Design* involve a series of required intermediate deliverables. For the third project, these intermediate deliverables are no longer required, yet students are still expected to follow the design process steps outlined in the first two projects. Student autonomy increases as their only required interaction with faculty is a weekly meeting. The explicit structure of the first two projects thus becomes implicit for the third one.

In their interviews, students appear to be very observant of this fading faculty guidance and transfer of responsibility, highlighting it as one of the main features of the course. Students not only recognize an increase in freedom with the third project, but they also realize how the structure and guidance they received in the first two projects enable them to be autonomous. Marco comments on his experience working on the third project: “Now we go into class as a group and we’re already expected to know what to do because [the professors] taught us at the beginning of the year. We are just expected to work on our own and ask them for help if we need help” (Marco, April 12th). The key insight Marco has is that the structure of the first two projects provides him with knowledge and skills underlying a positive mastery experience. This realization of competency affords the necessary self-efficacy for open-ended design problem solving.

Comparing such experiences to those in *Physics Laboratory*, we infer that the initial course structure is essential in creating mastery experiences. Specifically, *Physics Laboratory* features high levels of student autonomy and lack of structured experiences starting with the very first assignment. Arguably, it is this environment that leads to students having trouble gaining a sense of mastery, impairing their self-efficacy. Isabelle is one such student who expresses a lack of positive mastery experiences in the beginning of the course: “[The professors] should explain things more at the beginning of the course because I was really confused, and I wasn’t the only one... everybody was confused, and nobody knew what was going on” (Isabelle, April 11th). Isabelle

attributes her confusion to the lack of structure in the beginning of *Physics Laboratory*, i.e., explicit contingency and presence of too much autonomy with too little faculty support. Because she perceives the labs to be poorly (or not at all) explained, she feels unsupported in her work, preventing her from gaining future mastery experiences.

From comparing the two courses, it appears that the initial structure in *Engineering Design* may be one of the critical factors responsible for generating mastery experiences and positive self-efficacy beliefs, allowing students to pursue open-ended problems. This does not say projects with high student autonomy are detrimental to students’ self-efficacy. In fact, not only do the students report positive experiences associated with the autonomy-heavy third project, our data suggest that the *transfer of responsibility* that occurs between the second and third projects significantly contributes to the development of students’ self-efficacy.

When students talk about the third *Engineering Design* project, a common theme that emerges is the idea of real-world experience. The high levels of autonomy simulate the amount of responsibility necessary in professional practice, causing many students to compare their projects to industry-level work. Gloria compares what she is doing in this course to her expected experiences in the engineering capstone project, where students usually tackle “real world” problems: “We’re trying to go through the engineering process, manage our own time, and do it just like we would do for [our school’s capstone project]” (Gloria, April 9th). Many other students also express excitement of doing “real” engineering work in the third project. Because students, aided by their previous project experiences, feel efficacious in their ability to succeed at this professional-level project, they also gain confidence in their ability to one day work as a professional engineer: “It seems [that] what I’m doing is what engineers do on a regular basis in their jobs. It’s what they’re paid for, and I’m getting really useful experience here doing this” (Betty, April 6th). After the first two projects, students are confident in their understanding of the design process and their ability to apply it. However, it is not until the third project that they start believing in their ability to perform engineering tasks at a professional level. These representative quotes suggest that this boost in engineering self-efficacy and overall agency stems from the increase of autonomy and added responsibility the students experience in the third project.

IV. CONCLUSION

Overall, students have higher self-efficacy in *Engineering Design* than in *Physics Laboratory*. Low self-efficacy beliefs in *Physics Laboratory* stem from negative mastery experiences while positive mastery experiences in *Engineering Design* are correlated with high self-efficacy. Analysis indicates that self-efficacy beliefs within a course are significantly influenced by students’ perception of course goals, which, in turn, are determined by the amount of contingent scaffolding and dynamic nature of autonomy support provided by faculty. A lack of scaffolding within *Physics Laboratory* leads to students’ course goal perceptions

that are misaligned with those intended by faculty, and we find a high correlation between this misalignment and low self-efficacy. Conversely, a strong sense of contingent scaffolding in *Engineering Design* allows students to recognize the faculty's intended course goals, and we determine a high correlation of such alignment with students' expressed feelings of high self-efficacy. Furthermore, the dynamic nature of *Engineering Design's* scaffolding results in a gradual increase in student autonomy, which may also play an important role in enhancing students' self-efficacy beliefs. These results have important implications to the curricular design, especially in the introductory engineering courses.

Although we identified many aspects of these two courses that may affect students' self-efficacy beliefs, both the current literature and our data further suggest that other factors may be contributing to establishing and maintaining students' self-efficacy. One factor which did not play into our analysis is group work's effect on self-efficacy. Many of the interviews involved detailed discussion of group dynamics and role assignment within project teams, and further analyses are needed to explore this question. Finally, although no gender trends emerged in our analysis, literature suggests that self-efficacy in engineering settings may be gender dependent [10,15,17-18]. In future work we hope to expand our analyses to include these factors, as well as others, in order to more fully understand how PjBL environment affects students' self-efficacy.

Using Modern Graph Analysis Techniques on Mind Maps to Help Quantify Learning

Peter Jamieson

Department of Electrical and Computer Engineering

Miami University

Email: jamiespa@muohio.edu

Abstract—In this work, we use a graph analysis tool to measure how student-created mind maps reflect learning. Mind maps consist of words and connections between words, and this visual tool helps illustrate how an individual understands how these words connect together in a field. From an analysis standpoint, mind maps are graphs consisting of nodes connected by edges. In the fall of 2011, students created three mind maps over the duration of a digital system design course, and at each of the three intervals, these mind maps were created with the same 20 terms that were introduced throughout the course. Each student's mind maps were then digitally encoded and analyzed using a modern graph analysis tool called GraphCrunch II. Our results show that a simple analysis of graph density is a poor indicator of learning since this metric does not capture a graph's structure, and it is this structure that reflects meaning and understanding by the learner. Instead, a metric called relative graphlet frequency distance (RGF-distance), which is calculated by comparing a golden mind map (expert created mind map) to each of the students mind maps, is used to analyze each students understanding of how these words relate. Our results show that learner's mind maps decrease in RGF-distance over the period of the course, and this means that the students are building graphs more similar to that of the golden model. We, also, see that the RGF-distance over the set of students compared to their grades on an exam or overall grade in the course has some correlation, meaning that these mind maps relate to grades in terms of the learners understanding of vocabulary, but the correlation is not strong. The ultimate goal of these tools is to provide the learners with a method of getting automatic feedback on their understanding as well as learning progress in particular topics.

I. INTRODUCTION

Concept maps [1], [2] and mind maps [3] are useful tools in education, and they can be used both in lectures as classroom assessment techniques (CATs) and outside the classroom for the learner to express ideas in a visual form. Mind maps are words/concepts connected by lines where a line indicates a relationship between the words, and concept maps (also called knowledge maps) have similar structure except the connecting lines have directionality (indicated by an arrows) and have associated prepositional phrases that indicate how the words are related. For this work, maps are mathematically known as graphs, and therefore, we can leverage research in the understanding of graphs to help analyze mind maps.

Our focus is on using modern graph analysis tools to evaluate in class, student-created mind maps. Our goal is to help build tools that learners can use with their mind maps to automatically give them feedback on their understanding of a

topic. To evaluate a map, either the map can be evaluated by an expert observer, or the map can be compared to a golden map generated by an expert. The first of these evaluation options is very difficult for computers to perform since the computer needs some inherent understanding of the topic itself. The later is the approach used since a machine can use the golden map and compare it to the learners map without any knowledge of the subject.

To compare learner mind maps to golden maps we use a tool called GraphCrunch II [4], which is a tool developed for analyzing the similarities between proteins. This tool uses a unique method to compare graphs and is easily applicable to mind maps. Over the 2011 semester of a course on digital design, we collected student mind maps (course beginning, post exam I, and post exam II). These mind maps were CATs where students had 10 minutes to create their maps that consisted of 20 terms, and these 20 terms were introduced throughout the semester. Each student's mind maps was then digitally encoded and analyzed using GraphCrunch II. Our results show that another metric, graph density (defined later), is a poor indicator of learning since this metric does not capture the graph's structure, and it is structure that reflects meaning and understanding by the learner.

Instead, a metric called relative graphlet frequency distance (RGF-distance) [5] is calculated by GraphCrunch II. Our results, with this metric, show that the majority of learners have a decrease in RGF-distance for their maps over the course, and this means that the students are building graphs more similar to the golden map. We consider this result evidence of student's learning the vocabulary of a field and the relationships between words. We, also, see that the RGF-distance for students compared to their grades on an exam or overall grade in the course has some correlation, meaning that these mind maps reflect performance in the course. However, the correlation coefficient is not strong enough to consider using the graph analysis tool as an assessment measure.

The remainder of this paper is organized as follows. Section II reviews previous work in analyzing mind maps and introduces more details about graphs and the GraphCrunch II tool to help the reader. Section III describes the experiment, and Section IV shows our results. Finally, Section V concludes the paper.

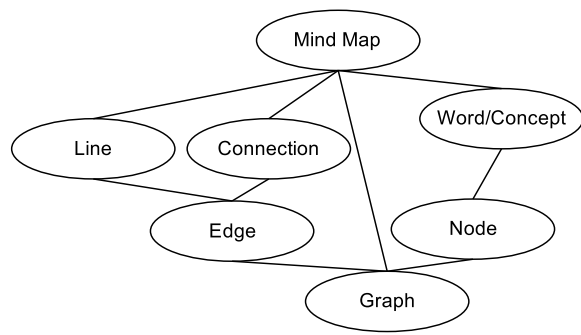

Fig. 1. Example of a mind map on the relationship between mind maps and graphs

II. BACKGROUND

Mind maps [3] are a visual tool that can be used to represent the connections between a number of concepts. These maps are useful CATs [6], and both the student and teacher can observe how concepts connect in the learners mind, which allows teachers to provide feedback. Figure 1 shows an example mind map that expresses the author's understanding of mind maps and how they relate to mathematical graphs. Basically, the words/concepts that are in a mind map are the nodes of a graph (circled bubbles), and the connecting lines between these words are edges of a graph. Concept maps [1], [2], also called knowledge maps, are more complex than mind maps since the edges are labeled with prepositional phrases. We do not analyze concept maps in this work, but they are also powerful learning tools with a valuable research literature that compliments and motivates this work. For a good introduction to concept maps, take a look at Novak's book, *Learning, Creating, and Using Knowledge: Concept Maps As Facilitative Tools in Schools and Corporations* [7].

A. Map Analysis Classifications

As described earlier, our focus is on automatically analyzing mind maps using modern graph analysis tools. To do this, we will compare student maps to a golden model; Ruiz *et al.* [8] called this type of scoring *comparison with a criterion map*. Ruiz identified another scoring mechanism called *score map*, which includes basic graph analysis techniques such as counting edges and nodes, and they describe a third option, *hybrid model*, that combines the two. Their work looks at five other studies with concept maps and categorizes them based on their scoring technique. In this work, our approach is the third choice, hybrid scoring, since we use the criterion map to assist the automated scoring.

Herl *et al.* [9] further categorize map analysis based on what the learner is allowed to do. They call maps that are restricted in construction as *closed*, which means the words and concepts are limited, and *open* maps are unrestricted. A number of researchers [10], [2], [11], have presented ways of defining closed maps for concept maps, and in our work, the mind maps are closed since we restrict the number of words/concepts that a learner can include in their maps.

B. Automated Map Analysis

As a precursor to automated map analysis, various methods of scoring a map have been proposed by researches, and a brief list of scoring metrics in the literature include the following:

- Concept map - count the number of valid propositions, levels of hierarchy, examples, and crosslinks [1] where weights can be introduced to each count ([12], [13])
- Concept map - a measure of *hierarchiness* which relates hierarchy in the map [8]
- Mind map - compare the scores on tests to the technique [14]
- Concept map - the more important a concept, the closer it is to the top of the tree [15]
- Mind map - have two independent experts score (sometimes with a rubric) the mind map on a scale two times with one week delay and compare correlation of ratings [16]

The scoring of maps has been challenged by many researchers in the literature [17], [18]. Kinchin and Hay [19] criticize the shortcomings of strict scoring of concept maps as a motivation to propose qualitative analysis of maps. Interestingly, one of their key contributions in this qualitative approach is looking for *spoke*, *net*, and *chain* like structures in a map, and these structures are internal graph structures that are captured by what will later be described as graphlets.

Early attempts at automating the analysis of maps and providing feedback focused on hint like mechanisms. A criterion map (called scaffold in these works) provides student creators with hints for their maps on what is missing and what does not belong [20], [21]. Conlon [22] built a system that used Novak's scoring mechanism and other artificial intelligent concepts to build an open concept map creation system that provided feedback to students. Our goal is study modern graph analysis tools for similar purposes.

C. Graph Analysis

We have already introduced concepts of *nodes* and *edges*. We should also mention that mind maps are classified as undirected graphs, which means that the edges do not have a direction, normally indicated by an arrow; concept maps, on the other hand, are directed graphs. In the rest of this section, we will provide a better understanding of the metrics compared as our experimental measures - density of a graph and relative graphlet frequency distance (RGF-distance). Note that mathematical formulas and definitions are provided in graph notation, but the reader does not need to understand this notation to understand this work.

The *density* of a graph is defined as the total number of edges ($|E|$) divided by the maximum number of edges that a graph could have ($.5 * |V| * (|V| - 1)$). For the graph in figure 1, the maximum number of possible edges is 21 and the number of edges is 9, so the density is $9/21$ or, approximately, 0.43. The greater this value, to a maximum of 1, means the more connectivity between the nodes within a graph.

Density measures how much connectivity there is in a graph. In terms of relating this to mind maps, we might hypothesize

that the more connected a mind map is then the more tightly related the topics are. If we compare metrics for a student map to the criterion map then we might say the closer these metrics are to one another than the global connectivity is more similar. The problem, however, is the structure of the mind map is not captured with simple metrics and students might be making wrong connections that somehow make the comparative metrics more equal.

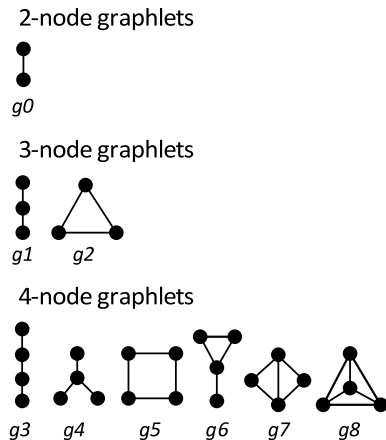

Fig. 2. Graphlets of size 2, 3, and 4

Before defining RGF-distance, we first introduce graphlets. Graphlets, formally, are “a connected network with a small number of nodes” [5] and these small graphs are non-isomorphic induced subgraphs of a larger graph. Figure 2 shows *all* the graphlets of size 2, 3, and 4. Note that the graphlet of size 1 is a single unconnected node and is not that useful.

The power of the graphlet is how it can be used to analyze a graph. The procedure developed by Przulj *et. al.* [5] is to search for all graphlets of size 3, 4, and 5 in a given graph. Based on the count of each type of graphlet, we then can construct a signature in the form (g1, g2, g3, g4, g5, g6, g7, g8, ..., g28, g29), where g1 is number of the first type of graphlet of size 3 shown in figure 2 and g29 is the count for the last graphlet of size 5. This signature can be compared to another graphs signature to get a measure of similarity, and Przulj *et. al.* used their technique to compare graphs representing biological structures such as proteins.

RGF-distance is a measure of the difference in frequency of graphlets of g1, g2, g3, ..., g28, and g29 appearing in the two graphs being compared. A detailed equation is presented in Przulj *et. al.* [5] and the reader can find the details on the calculation of RGF-distance. For this work, we must understand that GraphCrunch II will calculate this metric for us, and the smaller this number gets means the more similar the two graphs are.

RGF-distance captures the comparative structure of two graphs, and in terms of comparing student mind maps to the criterion map, we hypothesize that the lower the RGF-distance is means that students better understand the relationships

between concepts/words since their maps have more similar structure to the expert’s criterion map. This is the main hypothesis of this work.

III. SEMESTER MIND MAP EXPERIMENTAL SETUP

For our work, the goal is to automatically analyze student-created mind maps over a semester long course and observe how these students are learning the course vocabulary as reflected by their mind maps. The focus course for this experiment is a digital design course offered at the 200 level. The course starts with how transistors can be organized to make basic Boolean gates and ends at designing finite state machines using a hardware description language (HDL). From our perspective, the most challenging aspect for most students is the application of HDLs to design hardware as the language differs significantly from sequential programming languages that students are much more familiar with. However, mind maps only play a small part in understanding HDL application, and this work focuses on the students understanding of digital system vocabulary.

Table I shows a summary of our experiment. Column one describes the category, and column two and three lists the category type and specific details.

Our mind map experiments are on closed mind maps. Specifically, a list of 20 terms are provided that are introduced in the course. The following list of the 20 terms is ordered chronologically based on when the word/concept is introduced in the course. Note that by exam I, terms 1 through 15 have been introduced, and by exam II the remaining words have been presented. Also, note that the list order is randomly presented to the students. The list includes the following: Electricity, Transistor, Vdd, False, Digital, AND, Truth table, XOR, Schematic, Power, Timing, Binary, Decimal, Two’s compliment, Multiplexer, Sequential, Register, HDL, Always, FSM.

During the second class of the course, we introduce mind maps using an illustration of constructing mind maps for countries. We show how the mind map can be constructed differently depending on if we are thinking about geographical location, oil supply, or military alliances and enemies. After this basic training, we then show the list of 20 terms and give the students 10 minutes to create their first mind map. This is repeated after exam I and exam II with the same terms and the same amount of time. This means for each student who has chosen to participate (our IRB approved protocol allowed students to remove their participation agreement any time in the semester before final marks were released) could have created up to three mind maps over the semester.

To use these paper-based mind maps with graph analysis tools such as GraphCrunch II, the mind maps need to be digitally encoded. One of the digital formats that GraphCrunch uses is a simple line-by-line graph representation where two words are included on each line; the pairing of words on a line means that there is an edge between them. We built a simple key-press data entry program based on the first letters of each word to quickly encode the paper mind maps into a

TABLE I
A SUMMARY OF THE PROPERTIES OF OUR MIND MAP EXPERIMENT

| Evaluation Category | This Experiment | Details |
|---------------------|-----------------|--|
| Mind map option | Closed | Restricted to 20 terms |
| Evaluation | Hybrid | Criterion map that is used for scoring |
| Scoring metric | Various | Comparison of simple graph metrics to RGF-distance |
| Mind map creation | In class | 10 minute activity at the start of class |

digital form. Each student is given a numerical id, and each of their mind maps is encoded and a corresponding grade entry is labeled with their id. In this way, students become anonymous once all their data is in as per our IRB protocol. With the digitally encoded mind maps, the graphs are analyzed.

IV. EXPERIMENTAL RESULTS

The hypothesis is that the RGF-distance metric, which is a comparison of graph structure between student and the criterion mind maps, will decrease in value over time and show that student's mind maps reflect a better understanding of how the words and concepts in a field are organized. This learning will be examined in two ways; first, we expect that there will be some correlation between grades and RGF-distance, and second, over the course, we expect an individual's mind maps to show a better understanding of how the words/terms in a field relate. In addition to these two trends, we will first look at how simple graph metrics relate to RGF-distance assuming that these metrics can not capture structure that RGF-distance can.

A. Comparison of RGF-distance to other Graph Metrics

We speculate that the RGF-distance metric is a better metric for evaluating mind maps since it captures comparative graph structure. Here, we compare graph density to the RGF-distance metric in two ways to show that RGF-distance is more useful than simple metrics. First, for each set of mind maps the correlation coefficient is compared to the respective RGF-distance, and second, the metrics for the criterion model are compared to see if there is a relationship.

TABLE II
STATISTICS FOR THE GRAPH METRICS ON MIND MAPS

| Correlation - Density to RGF-distance | | | Golden Model Stats | | |
|---------------------------------------|--------|---------|--------------------|-------|---------|
| Course Start | Exam I | Exam II | Edges | Nodes | Density |
| -0.14 | -0.47 | -0.93 | 47 | 20 | 0.25 |

Table II summarizes this data. The first three columns show the correlation coefficients, and the last three columns show stats on the criterion mind map. In terms of the correlation coefficients between density and RGF-distance there appears to be none for the first two mind maps. However, for the post exam II mind maps, there is a high correlation. To understand if the correlation has any meaning, we look at the second aspect of analyzing this data, how does the density compare to the densities in the student mind maps. On average the density for the three sets of mind maps (0.16, 0.15, and 0.14

respectively) are all smaller than the density for the criterion map (0.25), which suggests the similarity is small. The best mind maps (as a measure of RGF-distances below 5) created in the post exam II do have the higher densities and are similar to the criterion maps density. This is not the case for the mind maps created at course start and post exam I, so we have to conclude that graph density could be a quick indicator of similarity that students could use as they create their mind maps, but by itself it is not sufficient to help students.

B. RGF-distance Relation to Grades

To examine how RGF-distance for student generated mind maps compares to scores on class exams, we will plot RGF-distance on x-axis and the exam or final grade score out of 100 on the y-axis. We will then plot a logarithmic regression line on the graph to get some understanding of the general relationship between grade and RGF-distance. Finally, we will calculate correlation coefficients between grade and RGF-distance for each time the mind maps were created to evaluate if there is a strong linear relationship.

Figure 3 shows these scatter plots. Starting with the graph in the upper left, the blue points are the mind map RGF-distance from the start of the course (n=40) compared to the student's grade, and the red points are the same but for the mind maps created post exam I (n=24).

One interesting observation is there is a shift of RGF-distance from the start of class to the first exam, which signifies that the mind maps are more similar to the criterion map post exam I. The trend line, in this first graph, suggests that there is some relationship between grade and RGF-distance, but the actual correlation coefficients are weak, -0.14 and -0.27 respectively. The second two graphs, which compare the mind maps post exam I and exam II (n=24), do not show a shift in RGF-distance between the two periods of time. This is probably due to the fact that the majority of vocabulary is introduced by the first exam and the shift would only be minor. We see similar trend lines to the first graph, and there is a high correlation coefficient for mind maps created after the first exam to the grade (-0.45 for exam II and -0.63 for final grade). However, since the number of participants and the specific participants at each stage (40 students for the class start mind map, 24 students for the post exam I mind map, and 24 students for the post exam II mind map) is different, these correlation and trend lines are only a hint of the relationship between mind map structure and grade. Interestingly, the correlation for the final mind maps RGF-distance to grades is not as high as post exam I (-0.31 for

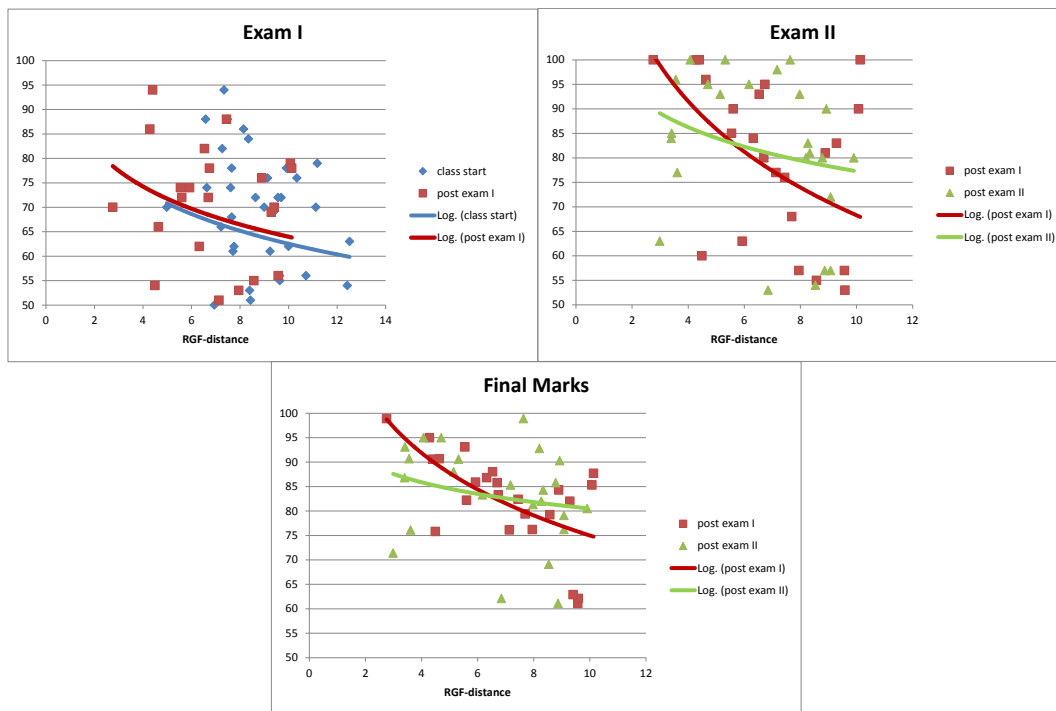

Fig. 3. Scatter plots for grade to RGF-distance on exams and overall grade with RGF-distance on the x-axis and grade point out of 100 on the y-axis.

exam II and -0.26 for final grade).

The greatest correlation is between final grades and post exam I mind maps with a correlation coefficient of -0.63. We hypothesize that mind maps RGF-distance compared to overall grade is a better comparison since the mind map is an indicator of understanding on how concepts connect, and this type of knowledge is more important to activities in the overall course, which is assessed on exams, labs, and projects. The exams, though needing an understanding of vocabulary, is more focused on testing students problem solving and design skills, which is not a good assessment of understanding how concept/words are related.

C. Individual RGF-distance Analysis

Figure 4 shows four graphs where each graph is a bin of students with a certain final grade range. Each graph shows the measure of RGF-distance (y-axis) for the students mind maps over the semester (x-axis); in the graph a line connects two points if they are for the same student and they have created mind maps at two adjacent times. Looking at all the graphs, we can see that for the most part, RGF-distance measurements decrease, meaning the student mind maps are becoming more similar in structure to the criterion map. We believe this is strong evidence supporting our hypothesis. The outliers to this trend tend to be found when comparing the RGF-distance measure from mind maps created post exam I and post exam II. Whether this reflects student confusion, poor performance on the mind map activity, or some other factor is unknown, but these trends are observable in each of the grade bins, and

therefore, is not related to students overall grade performance in the course.

V. CONCLUSION

In this work, we investigated the viability of using RGF-distance as a graph metric that could be used to automatically give students feedback on their own mind maps. We compared other simple graph metrics to verify that RGF-distance is a superior metric based on how it compares graph structure. Next, our results showed that there is some relationship between final grades and RGF-distance measured for student made mind maps compared to a criterion model. This relationship, however, was not strong, and we do not believe that mind maps could be used to assess students on activities that are not vocabulary focused. When understanding a field's vocabulary is the focus, the mind map evaluated in terms of RGF-distance could be used as a grading tool, but further exploration is needed in this area.

Our analysis of individual performance of a student over the term showed that mind maps, in general, improve over time based on a decrease in RGF-distance. This result is exciting since we could imagine a scenario where a student could use a tool over the term to see how their understanding of topic vocabulary has improved compared to their previous attempts. This type of scoring mechanism is useful to provide an overall evaluation of the mind map, but it does not provide a mechanism to provide detailed feedback to the learners.

Work in Progress: Changes in Elementary Teachers' Noticing of Engineering Pre/Post Professional Development with Engineering

Daphne S. Duncan-Wiles, Tamecia R. Jones, Heidi A. Diefes-Dux, Sean P. Brophy
Engineering Education, Purdue University
The Institute for P-12 Engineering Research and Learning
West Lafayette, IN, U.S.A.

Abstract—The addition of engineering to many state standards has created a need for effective teacher professional development. The Institute for P-12 Engineering Research and Learning (INSPIRE) facilitated summer engineering workshops for teachers in grades two to four. Participants completed the Noticing Activity, an assessment meant to gauge teachers' ability to notice and discuss engineering and its role in society. This work in progress describes the coding system being developed to analyze teacher responses. Analysis of teacher responses to the Noticing Activity will be used to determine what teachers notice about engineering in society and, later, help study how teachers discuss engineering with their students. Results from the coding will be used for programmatic evaluation and revision.

Keywords—component; Elementary Engineering, Teacher Professional Development, Assessment

I. INTRODUCTION

As the United States strives to increase the engineering literacy of K-12 students [1], the building of knowledge and understanding of engineering's vast presence in the world is critical to elementary teachers. The Institute for P-12 Engineering Research and Learning (INSPIRE) provides professional development designed to develop teachers' accurate perceptions of engineering so that they can engage in conversations with their students about engineering's role and presence in society [2]. Through INSPIRE's engineering professional development academies, elementary teachers are given an opportunity to learn about and engage in engineering activities, which ultimately leads to increasing their engineering literacy. The four stated goals for these academies prepare teachers to:

- 1) convey a broad perspective of the nature and practice of engineering;
- 2) articulate the differences and similarities between engineering and science thinking;
- 3) develop a level of comfort in discussing what engineers do and how engineers solve problems; and
- 4) use problem-solving processes (i.e. science inquiry, model development, and design processes) to engage P – 6th grade students in complex open-ended problem solving.

The goal of the Noticing Activity is to learn what elementary teachers' notice about engineering artifacts and engineers in action before and after a professional development

academy. Prior work [2] indicated that after one week long academy teachers increased their noticing of design considerations and the types of engineers that made these decisions. This paper presents a refined definition of the coding scheme for the Noticing Activity intended to measure change in teachers' recognition and articulation of engineering related goals and product design.

II. PURPOSE

The results of the Noticing Activity will aid in enhancing engineering learning for educators and students by supporting STEM instruction across the curriculum. Ultimately, such instruction will prepare future generations of STEM innovators.

III. METHODS

A. Participants

Elementary (grades 2-4) teachers' perceptions of engineering are being examined using a pre/post assessment administered to participants who attended a week-long summer engineering professional development academy in 2009 and a three-day follow-up in 2010. The first year, 2009, the participants ($n= 36$ pre, 35 post) engaged with curriculum that provided an overview of engineering. Teachers learned an iterative design process through hands-on design challenges. Teachers learned about the various engineering disciplines through the contexts of the design challenges and through a panel discussion with engineers. In the second year, 2010, a subset of the participants from 2009 (21 pre, 23 post) were engaged in activities aimed at deepening their understanding of the engineering design process, improving their ability to differentiate engineering and science, and expanding their perceptions of the role of engineers and engineering in society. Boyle, Lamprianou, and Boyle [3] revealed that teachers who participated in long-term professional development implemented greater changes to their teaching. Additionally, Garet, Porter, Desimone, Birman, and Yoon [4] indicated that time span and contact hours are two vital factors when investigating the effectiveness of teacher professional development. Our conjecture is that the repeated professional development experiences increase teachers' ability to notice and articulate engineering themes associated with products/process and the engineers responsible for making these products/processes possible.

B. Noticing Activity

Each year, participants completed a pre- and post- Noticing Activity that includes two photos of engineering; one is an engineered object (e.g. milk carton, water filtration, apple peeler), the other represents engineering in action (e.g. bioengineer in a farm field, environmental engineer testing water, and manufacturing engineer in plant). Participants responded, in a free-response format, to the following question about each photo: “From an engineering perspective, describe the object(s) or event that is the focus of this photo for you.”

IV. DEMONSTRATION OF CODING SCHEME

Researchers at INSPIRE have developed [2] and are now refining a coding system for cataloging teacher responses to the Noticing Activity. The initial coding scheme focused on factors of design and the structure, function and behavior of artifacts [2]. The revised system uses a flowchart format to better select codes defining teachers’ interpretation of photos of engineered objects and engineers at work.

The coding system has gone through four revisions with a most recent inter-rater reliability (IRR) estimate of 79%. The IRR is calculated by averaging the percentage of agreement for the coders (see an example in Table I). The total IRR is calculated by averaging the percent agreement for all coded items.

TABLE I. EXAMPLE OF IRR CALCULATION
(BOLD LETTERS INDICATE AGREEMENT)

| Coder | Codes for Response 1 | Agreement w/ other coders | Average percent agreement |
|---------|----------------------|---------------------------|---------------------------|
| Coder 1 | A, B, C, D | 75% | 68% |
| Coder 2 | B, C, D, E, F | 60% | |

Table II provides a sample of two teacher responses and the associated codes assigned. Each response provided by a teacher could earn multiple codes, depending on the information included in the response. The primary codes for objects deal with function, structure/parts, goal of the person creating the object, and design (who made it, design process steps, considerations, manufacturing). The primary codes for people deal with naming of the engineer (i.e., general engineer, specific engineer, no engineer mentioned), location of the activity, goal of the person, actions of the person, and design considerations.

V. FUTURE WORK

All participants’ pre- and post- responses for 2009 and 2010 are being coded and analyzed, and from this analysis, changes in what teachers notice about engineering and how they communicate their ideas about engineering and its role in society will be identified. Additionally, results will help answer

TABLE II. DEMONSTRATION OF CODING SYSTEM

| Response | Object/ Person | Codes and Explanation |
|---|----------------|---|
| Engineers designed this tool to improve our ability to easily and quickly peel fruits and vegetables. | Object | dwg : “Design-Who-General” code assigned when participant mentioned engineer with no specific reference to type ddg : “Design-Goal-General” code assigned when participant mentioned designing as a general goal of the person making the object. dgi : “Design-Goal-Improve Life” code assigned when participant mentioned improving our ability, therefore improving life. |
| Environmental engineer taking water samples to make sure that is safe. | Person | ns : “Naming-Specific Engineer” code assigned when participant mentioned a specific type of engineer. ac : “Action-Collect samples” code assigned when participant mentioned the engineer collecting water samples. cs : “Consideration-Safety” code assigned when participant mentioned safety as a consideration. |

questions about the effectiveness of this professional development model (intervention→ classroom implementation→ intervention→ classroom implementation). Future work will include a comparison of teacher changes and student changes (based on student assessments) to help determine the classroom impact of an engineering teacher professional development intervention.

Abstract— We present the results of a pilot study in which twenty K-12 teachers were introduced to LEGO NXT-G robot programming through a three-day summer workshop. Our aim was to give teachers the confidence and skills to start after-school robotics programs with their students. We present details on the workshop, including the approach we used to recruit teachers and an overview of the three-day course. We discuss the data gathered from the teachers following the workshop and also give our own recommendations for others who may wish to run a similar program.

Participants ranged from elementary school general classroom teachers to high school math, science, and even computer science teachers. Prior to attending our workshop, 89% of the teachers had little or no programming experience and generally were not very confident in their own ability to be able to learn how to program a robot. After completing the workshop, their confidence increased dramatically and they had a strong expectation that they would use the material with their students. A follow-up survey nine months later indicated that hundreds of students and many colleagues were impacted in the first year alone.

Keywords- *Computer Science Education; K-12 Teacher Education; Educational Robotics; Introductory Programming; Graphical Programming Languages*

I. INTRODUCTION

The U.S. Bureau of Labor Statistics projects that hundreds of thousands of new jobs will be created in Computer Science-related professions and that some of these occupations, e.g. computer software engineers, are among the fastest growing of all [1]. One would imagine that such predictions would lead to an increase in Computer Science education in US secondary schools, but in fact the opposite is true – the number of Computer Science related courses being offered in US high schools has actually seen a dramatic decline over the last several years [2].

Even if there were a sudden realization by school districts en-mass that it was imperative to introduce or increase their Computer Science offerings, there are very few teacher education programs that have the capacity or curriculum to adequately train pre-service teachers to become Computer Science teachers [2]. Part of the problem is that the K-12 educational standards for subjects like Computer Science and Engineering are not as mature as those for the more traditional

STEM areas such as mathematics, biology, chemistry, and physics [3].

Given this background, we were motivated to find a way to introduce more Computer Science concepts into non-Computer Science classrooms and after-school programs in middle and high schools. We felt that we would have the greatest impact by running workshops for teachers, who could subsequently bring back the material that they learned to their schools and affect many more students than we could hope to teach ourselves.

We chose to use the context of robotics because of the obvious appeal of the medium. Anyone who has walked into a classroom with a robot under his or her arm recognizes the power they have to attract the attention of a room full of students, be they K-12 or even post-secondary. However, some caution is warranted. A decade ago the educational robotics community was devastated when the addition of robots to an undergraduate-level computing course was found to *harm* learning [4]. The authors concluded that one critical factor was the lack of access that students had to the robots. This conclusion is supported by research into more traditional (non-electronic) classroom manipulatives which has shown the importance of giving students sufficient hands-on time with the manipulatives [5].

Fortunately, as robot hardware has become more affordable (and simultaneously more powerful!), studies have shown that when students have more access to robots they do not have a negative impact [6], and in fact there are indications that they may be beneficial [7,8].

In June 2011, we ran a pilot study in which twenty K-12 teachers were introduced to LEGO NXT-G programming in a three day workshop. The remainder of this paper describes the organization and implementation of the workshop itself as well as the results of data gathered from the teachers following the workshop and recommendations for others who may wish to run a similar program.

II. PREPARING FOR THE WORKSHOP

A. Finding an Engaging Context

Because we anticipated that the majority of our teachers would not have a specific need for computer science in their curricula, we wanted to give them a clear vision of how they

This program was supported by a Google CS4HS grant, <http://cs4hs.com/>

might use this material beyond the classroom. Thus we titled the program “Start Your Own Robotics Club: Robot Programming for Absolute Beginners” and included material on the FIRST LEGO League (FLL) Robotics program for 9 to 14-year-olds. Our hope was that after our workshop they would have the confidence and skills to start FLL clubs at their schools.

Many of the teams that participate in FLL competitions are based in after-school clubs and coached by teachers. FLL teams compete in two parallel activities: the research project and the robot game. In the research project, students explore an actual problem that scientists and engineers are trying to solve. Students develop their own solutions to the problem and present the results of their work to judges at the FLL event. In the robot game, students build a robot out of LEGO components, and program it in one of two specialized languages to move autonomously on a themed playing field to score points.

Of the three key tasks involved in FLL competitions: research, LEGO design, and programming, we felt it was likely to be the programming component that secondary school teachers will be least prepared to teach. Further, it was easy to imagine that many teachers would find the prospect of learning to program on their own too intimidating to consider coaching a team.

We ourselves have been involved in running an FLL event for many years now and have been impressed with the quality of work that the children do in preparation for the event and with enthusiasm and energy that they bring with them. Beyond our anecdotal observations, formal studies of the FLL program have shown that FLL increases student interest in science & technology, improves their understanding of how science can be used to solve real-world problems, and increases other important skills including teamwork, leadership, and planning [9].

B. Selecting Robot Hardware and Software

The LEGO Mindstorms robots [10] are the only robots approved by FLL, and the NXT-G software is one of only two FLL options, and these factors did have some influence on our choice of platform and software. We considered the ability to use FLL as a context to be an advantage, however this was not by any means the most important factor in our choice of this hardware and software – we could have easily decided to use an “after school robotics club” theme without any mention of FLL.

The Mindstorms NXT robots have many advantages for the middle and high school market. First and foremost, they are fairly robust – driving off a desk may (or may not) result in an explosion of LEGO bricks and beams around the classroom, but permanent damage is much less likely. The sets also come with an interesting assortment of sensors that work surprisingly well, and while it is hard to call the NXT robots inexpensive, they are relatively affordable and many schools have already purchased a few. Finally, while they may not be familiar with robotics or programming, most middle and high school teachers have at least some experience with traditional LEGO, which, we hoped, might reduce the “intimidation factor.”

The LEGO NXT can be programmed in a wide variety of languages [11], but as was previously mentioned, FLL only supports the two official languages supported by LEGO. Again, this did influence our choice of the NXT-G language, however much more important was our desire to use a visual programming language (following the scratch model) because we felt that would be less intimidating to teachers than a text-based language. Both NXT-G and LabVIEW (the other language supported by LEGO) are visual languages, however NXT-G is considerably simpler and thus we felt it was the better choice

C. Attracting Teachers to our Program: Minimizing Anxiety and Maximizing Value

1) Minimizing Anxiety: Removing the “Intimidation Factor”

It is our belief that anyone qualified to teach STEM (Science, Technology, Engineering, and Math) subjects at the secondary school level is highly capable of learning the basics of programming. However we are also very cognizant of the fact that many skilled math and science teachers have a fear of all things computer science – unfortunately we’ve heard statements like “computers just don’t like me” all too often.

Thus we took great care from the very beginning to emphasize to teachers that they would not be overwhelmed by our workshop. All of our literature emphasized that teachers would be learning a visual programming language and that no prior programming experience was required. We even subtitled our workshop “LEGO Mindstorms Programming for Absolute Beginners.”

2) Maximizing Value

We were fortunate to be the recipients of a Google CS4HS grant [12] to support our workshop. While we could have offered the workshop to the teachers free of charge, we chose instead to charge them a fee, but to give those who completed the three-day workshop a LEGO robot kit to bring home with them which alone was worth more than the cost of registration.

III. WORKSHOP DETAILS

A. Participants

Twenty teachers participated in our workshop. 17 of the 19 teachers who responded to our exit survey reported that they had little or no programming experience prior to attending our workshop.

While we originally advertised this workshop for middle school teachers, we attracted a much wider range. The teachers taught the following grades:¹

| | | |
|---------------------------|----------------------------|-----------------------------|
| 4 th grade: 4% | 7 th grade: 20% | 10 th grade: 6% |
| 5 th grade: 8% | 8 th grade: 18% | 11 th grade: 10% |

¹ Some teachers teach multiple grades, each teacher was counted once for each grade they taught, percentages are rounded to the closest integer value.

| | | |
|-------------------------------|---------------------------|--------------------------------|
| 6 th grade: 16% | 9 th grade: 6% | 12 th grade: 10% |
|-------------------------------|---------------------------|--------------------------------|

The teachers taught the following subjects:²

| | | | |
|----------------------------|---------------------------------------|----------------------------|----------------------------|
| Math: 42% | Elementary: 8% | Computer Science: 4% | Pre- engineering: 4% |
| General Science: 12% | 6 th grade resource: 4% | Physical Science: 4% | Special Ed: 4% |
| Chemistry: 8% | Biology: 4% | Physics 4% | Technology: 4% |

B. Duration

Our 3 day workshop ran from 8:30 a.m. to 5:00 p.m. In the exit survey, two of the teachers indicated that they felt the days were very long (though we also had comments that the length was just right or even too short). Our days were much longer than many other teachers' workshops run at our university; those typically run from 8:30 a.m. to 1:30 p.m. or 3:00 p.m.

We have a certain reluctance to shorten the length of the day simply because it is very difficult to imagine what we might cut. One obvious way to shorten the day would be to reduce the significant time (roughly 2 hours per day) we had allocated for breakfast, lunch, and breaks. We had intentionally put these extended breaks into our schedule in order to offer the teachers many opportunities to meet and interact informally with their colleagues so that they might form relationships that they could use during the school year, but are considering reducing them in future workshops.

C. Academic Topics

1) NXT-G Programming

As would be expected, roughly 75% of the academic time in the workshop was spent on NXT-G programming. This included lessons on simple outputs (displaying pictures and text on the NXT's small LCD screen and controlling motors), sensors (using the touch and light sensors), and programming concepts (loops, event handling, conditionals, functions, and variables).

2) FIRST LEGO League "Prep School"

Half of the remaining academic time was spent discussing topics relevant to those interested in starting FIRST LEGO League (FLL) Clubs at their schools. In addition to an overview of the FLL program, we included modules on the art of LEGO design, coaching students as they plan and carry out their research project, and preparing students for the judging process.

D. Other Ways to Integrate Computer Science into the Classroom

Each day, we gave teachers a break from robot programming by offering an introduction to another tool that they might find useful in their classrooms or in after-school programs. Our focus was on tools that they could use in their classrooms without having to buy additional hardware. We presented two other programming environments, Scratch [13, 14] and Alice [15, 16]. We also introduced Computer Science Unplugged [17] as an easy way to introduce Computer Science topics in their classrooms without needing a single computer.

E. Workshop Format

We used a variety of formats to teach the academic topics, including:

1) Interactive Robot Programming Lessons

These begin with a brief introduction to a topic, followed by a series of step-by-step programming examples that the instructor would walk the teachers through (the teachers would follow along by programming their own robots in parallel with the instructor). These lessons would conclude with time for hands-on exercises for the teachers to try individually or in small groups. Undergraduate teaching assistants were on hand to help keep the lessons moving by helping out when individuals got stuck.

2) Lectures

The FLL topics were presented as a set of short lectures during which teachers were encouraged to interrupt with questions. The "other ways to integrate Computer Science into your classroom" talks were lectures with some hands-on components.

3) Hands on Differentiated Instruction

Teachers were provided with sets of exercises of increasing difficulty and encouraged to pick the exercises that they felt were most appropriate. Faculty and undergraduate teaching assistants were available to help as needed.

4) Demonstrations

At the end of the workshop, the teachers demonstrated their favorite programs to each other.

IV. GATHERING DATA

A. The "Exit Survey"

At the end of the workshop we asked participants to complete an on-line survey which included detailed questions about their experience. Teachers were given the option of including their email address in the survey or remaining anonymous. Nineteen of the twenty teachers participating in the workshop completed the survey. Throughout this paper we use the term "exit survey" to refer to the data gathered from this survey.

² Some teachers teach multiple subjects, each teacher was counted once for each subject they taught, percentages are rounded to the closest integer value.

B. The "Follow-up Survey"

In March 2012, roughly 9 months after the workshop, we emailed our workshop participants and asked them to complete another on-line survey which was completely anonymous. Eleven of the twenty participants completed this survey. Throughout this paper we use the term "follow-up survey" to refer to the data gathered from this survey.

While we wish we could have had a better response rate, our rate of 55% is actually quite respectable – the teachers had no incentive to complete the survey, and one teacher reported that he was unable to access it – his school blocked access to the survey web site!

We are considering a variety of ways to improve follow-up responses in future workshops. Options include simply letting teachers know during the workshop that we'll be surveying them later and asking for their help, making the course textbook be an extra that they receive only if they agree to do their best to fill out the follow-up survey, or actually offering them an incentive at the time of the follow-up survey.

V. EVALUATING THE EFFECTIVENESS OF THE WORKSHOP

In this section we discuss our goals for the workshop and use the data from the exit and follow-up surveys to evaluate our success in achieving them.

A. Goal: Increase Teacher Confidence

As mentioned earlier, a major goal of this work was to demonstrate to the teachers that they were capable of learning and teaching this material. 89% of our teachers had little or no programming experience before attending our workshops. We mistakenly neglected to ask them about their confidence in teaching Computer Science concepts, but we did ask them two related questions on the exit survey, specifically:

"Prior to taking this class how confident were you that YOU would be able to learn to program a robot?" Result: **2.68** on a scale of 1 ("Not at all confident") to 5 ("Very confident")

"Now that the workshop is over, how has your confidence changed?" Result: **4.21** on a scale of 1 ("Much less confident") to 5 ("Much more confident").

B. Goal: Impact at least 100 students in the 2011/2012 school year

The results of our exit survey indicated that our teachers were anticipating impacting between **327 and 469+** students in the 2011/2012 academic year alone.³

Expectations immediately following a summer workshop such as ours can certainly differ from the actual results achieved during the school year when teachers have much less time and many more demands of their time and energy. We must admit to being somewhat nervous when we sent out the

follow-up survey, but that anxiety was quickly replaced with excitement as the data came in:

- Approximately **200** students have been exposed to this material in the classroom.
- Approximately **70** students have been exposed to this material outside of the classroom.
- The teachers anticipate that approximately **75** additional students will be exposed to this material during the remainder of the school year.
- The teachers also introduced the material to almost **20 non-students** (other teachers as well as principals and other administrators).

Of course, these data are based on the 55% of teachers who chose to respond to our follow-up survey. It is difficult to imagine how to extrapolate these results to the full set of teachers. One might imagine that the teachers who did not respond were the ones who did not use the material. It seems unlikely that all 9 of the remaining teachers did not expose a single additional student to the material. We expect that was true for some, but probably not all, particularly since the survey was completely anonymous. Indeed 3 of the 11 teachers who did respond reported that they were not using any of the material this year. Of those three, two indicated that this was because of school-related issues beyond their control. Furthermore, as was mentioned above, at least one school district blocked access to our survey web site.

C. Goal: Integrate Computer Science Topics into both the School Day as well as Extra-Curricular Activities

As the numbers above indicate, teachers are using this material in and out of the classroom. We were actually surprised by the ratio reported by the teachers: we anticipated that teachers would find it difficult to integrate our material into their classroom curricula, and thus the majority of the students impacted would be in after-school clubs. In fact, there are almost three times as many students being exposed to this material in the classroom!

D. Goal: Improve Teacher Attitudes Towards Computer Science

Attitude towards computer science is very difficult to measure quantitatively and we are working to improve our survey questions for subsequent workshops to better assess this question. Nevertheless, one thing is clear from the data - the teachers were very pleased with our program. In response to the following question on the exit survey: "How strongly do you agree or disagree with the following: Overall, I found this workshop to be worthwhile," we scored **4.68** on a scale of 1 (Strongly disagree) to 5 (Strongly agree). Additionally, in response to the question "Would you recommend this workshop to a colleague?" we scored **4.79** on a scale of 1 (Not likely at all) to 5 (For sure!)

We hope that the teachers' attitudes towards computer science have indeed improved, and that they have passed this on to their students.

³ We asked teachers to report how many students they expected to be exposed to the material next year. They were offered the following sequence of choices: [0, 1-5, 6-10, 11-20, 21-30, 31-49, 50+]. The number that selected each range, respectively: [0, 2, 2, 7, 5, 1, 2]

VI. RECOMMENDATIONS

Given the astonishing impact that one small workshop can have, we hope that others will follow our lead and establish similar workshops in their communities. In this section we discuss some of the techniques and tools that we used in our workshop that we think worked particularly well.

A. Hardware

We gave each teacher a LEGO Mindstorms Education NXT Base Set [18] along with the NXT-G software [19]. We strongly prefer the education set over the commercial set because it comes with a well-designed storage box and includes diagrams explaining how to store all the parts in an organized way. While this may seem at first seem to be a trivial detail, in practice it is so important for classroom use that we felt it essential to include this recommendation in this paper. The Education Base Set also includes a rechargeable battery pack which is important for anyone who doesn't have access to a vast supply of AA batteries.

The primary disadvantage of the Education Base Set is that the software is sold separately.

B. Student Teaching Assistants

We had 5 Computer Science undergraduate students that we hired to work with the 20 teachers during all of the lecture and hands-on periods. During the lectures, it was quite common for a teacher to say things like, "wait, what do I press?" or "my screen looks different" or "mine won't download." Without the student TAs this would have been very disruptive and slowed us down a lot. Instead, the TAs jumped in as needed and clarified and/or solved most problems very quickly. The teachers gave them rave reviews:⁴

"They were great very helpful, they told you how to fix a problem but left you to do it so that you learned but if you could not get it they showed you how to fix it."

"They were amazingly nice, professional, fun and patient!"

"Very knowledge and always willing to help. Did not make you feel stupid."

C. Teachers Programming their own Robots in Parallel with the Instructor

Because we targeted our workshop at teachers with little or no programming experience, having them actively follow along seemed essential to giving them early confidence. Teacher comments on the exit survey indicate we succeeded:

"[The first day was a] great intro day, not too scary!"

"This was a very fun day. Speakers and students made it seem possible to master programming."

D. Hands-on Differentiated Instruction

By the end of the first day it was very clear that some of the teachers, perhaps due to prior experience, natural ability, or

even confidence level, were keen to work on more difficult problems, while others wanted to take things very slowly. So that night we modified the day 2 hands-on exercises to offer the teachers a wide range of options – everything from "try to rewrite the programs we wrote in lecture on your own without peeking at your previous solutions" to "try one of the advanced FIRST LEGO league challenges." We had teachers at both extremes. This worked so well we repeated it on day 3.

"For me, I felt the unstructured time was great for all of us to work on our own projects. I would have been completely lost if it weren't for your wonderful TA's."

"Really enjoyed having time to work on our own and program our own stuff."

E. Mid-Course Surveys

We asked teachers to fill out mid-course surveys twice on day one (at lunch and late afternoon) and in the afternoon on day two. The surveys had four simple questions: two about the pace of the workshop, one asking if there were any unanswered questions, and the final one asking for any other comments. While mostly they served to reassure use that, on the whole, things were going well, we did get the occasional question or suggestion that was useful.

F. One Robot Per Participant

This is obviously expensive, and we were particularly fortunate that our grant funds enabled us to give each teacher their own robot to use at the workshop and bring back to their school afterwards. Having one robot per participant was not only useful during the lessons – the most enthusiastic teachers could bring the robots home in the evening to explore further. Even more importantly, teachers had the robot at home all summer to prepare for classes and clubs in the fall.

G. Building the Robots Prior to the Workshop

Each teacher was given a pre-built robot at the start of the workshop. While there is certainly a learning curve to working with LEGOs, even with detailed instructions and experience building the same base multiple times, we found the process time consuming. Had we left this task to the teachers we would have lost several hours that were better spent focusing on programming.

H. Giving each Participant His or Her Own Flash Drive

We handed out flash drives every morning and collected them at the conclusions of day one and two so we could add material. During the workshop this meant that they had quick and easy access to sample code, executables (including a full version of the Scratch programming environment), and workshop slides. Of course they took the drives home with them and now have a record of everything we did in one convenient place

I. Each Teacher Bringing His or Her Own Laptop

We advertised the workshop as "laptop recommended," planning on loaning one to any teacher who didn't bring one along. In retrospect, there is a huge value to the teachers going

⁴ Minor grammatical and spelling errors have been corrected in teacher quotes throughout this document.

home with the software and all of their programs on their personal laptop, and we're very pleased they all brought one. In addition, one teacher brought a netbook whose screen was too small to display all of the panels on the LEGO NXT-G software window making it (initially) unusable. We loaned her a laptop and one of our TAs managed (with significant effort) to find a way to display the different panels in individual windows. Had the teacher not brought her netbook to the class, she would have assumed that she couldn't use the LEGO software on a small screen. Instead, the whole class learned that there is a solution to this problem, and we posted the solution on the web so that they (and others) can find it in the future.

VII. CONCLUSION

It is quite remarkable that a single small workshop can have such a significant impact on a community. Twenty teachers who were, as a group, very unsure about their ability to learn to program robots left after three days with dramatic increases in their level of confidence. These teachers brought the material back to their schools, and by the end of *this academic year alone* several hundred students will have been exposed to the material, along with tens of other educators and administrators.

We hope that this paper will encourage others to develop similar workshops. Perhaps together we will be able to change the way computer science is introduced to young people, and that eventually computer science will become a significant part of middle and high school curricula across the country.

Abstract—TERMS (Transitioning Engineering Research to Middle Schools) is a Research Experience for Teachers (RET) project that targets the middle school teachers who teach the students most at risk for losing interest in science, engineering, and mathematics. As most students advance through middle school science classes, their attitudes toward science and math become more negative. The middle grades are a critical period for students, representing the period most beneficial to provide engaging academic opportunities. The TERMS project strived to develop curriculum and experiences for the middle grades by placing the teachers into a community of practice. The research component of the project was enhanced over three years; the teachers wrote research papers, developed research boards for science fairs, and gave research presentations. The program has improved teacher perceptions towards engineering research and teaching. This is evidenced by a survey that was adapted from one available to the RET network. The survey looks at the satisfaction with the RET experience, the extent that the faculty mentor met RET expectations, the success of the RET experience, the impact of the RET program on the RET personally, level of engagement, and learning experiences. Research results are provided from additional surveys that examine teacher perceptions towards research and science and mathematics teaching through the context of engineering.

Keywords- Middle level, research experience, teacher perceptions, community of practice

I. INTRODUCTION

The motivation for engaging some of OSU's most productive faculty in K-12 engineering educational experiences stems from critical needs at both national and local levels. Nationally, calls to action—i.e. Rising Above the Gathering Storm [1]—strongly urge policymakers to strengthen and build the United States' research infrastructure. These reports paint grim pictures of the country's technological and economic future if steps are not taken to improve and diversify STEM education. It is clear that in training the scientific workforce of the 21st century there must be more collusion among all stakeholders in education. The faculty members involved in STEM are passionate in believing action must be taken. At the local level it is becoming a high priority to increase recruitment of students entering the engineering program, particularly females and ethnic minorities. This project - Transitioning Engineering Research to Middle Schools (TERMS) - helps to foster sustainable long-term solutions to recruiting and

diversity issues. A key question is how to best create a sustainable pipeline of qualified and diverse students into a program focused on retaining them once they enter. TERMS is synergistic with, draws from, and builds on other engineering education efforts at OSU. These include *Engineering Students for the 21st Century*, an undergraduate department level reform; several CCLI awards that focus on bringing research into the classroom; and locally funded programs for K-12 schools.

TERMS addresses needed development of human resources in the state of Oklahoma by creating a network of teachers across the state who engaged students in technical subjects. This aspect of professional development is critically needed in middle schools since national standards are moving away from a teacher-oriented format focused on topics towards inquiry oriented science learning. TERMS created, tested, and disseminated age-appropriate, inquiry-based course materials aimed at middle school audiences. These course materials will focus both on transitioning research into the classroom, the engineering design cycle and emergent phenomena.

II. DESCRIPTION OF TERMS

The TERMS project is a combined REU (Research Experience for Undergraduates) and RET program that engages teachers in middle grades (6th-9th) and undergraduate engineering students in research. Teachers and undergraduate students were matched with a faculty mentor on a coherent, focused research project. All research emphasized a single theme - how engineers understand, design, fabricate, and test materials and structures whose overall properties are determined by collective interactions of their parts or *emergent phenomena*. Each research team transitioned the results of their research to projects that can be undertaken in the middle school classroom; training in how to enable this transition is a key component of TERMS.

TERMS is built around four distinguishing features. The first aspect of this project is that TERMS targets the middle school teachers who teach the students most at risk for losing interest in science, engineering, and mathematics. As most students advance through middle school science classes, their attitudes toward science become more negative and their interests decrease most in the seventh grade [2-5]. The middle grades are a critical period for students, representing the period most beneficial to provide engaging academic opportunities.

Focusing on teachers and students in the middle grades targets a population which is not being served by existing local activities. While there are several programs focusing on students and teachers in high school—*Project Lead the Way* [6] for example—there are few designed for lower grades. TERMS additionally focuses efforts on student populations—women and under-represented minorities—who can add diversity to OSU’s engineering program. One key question is whether it is appropriate for 6th through 9th grade science and math teachers to undertake focused research experiences. To address this concern TERMS builds on a large body of prior knowledge and experience that has shown teachers in the middle grades can be successful in transitioning research experiences to educational activities [7-13]. Additionally TERMS paired teachers with undergraduate REU students (apprentice engineers) who have experience with instrumentation and engineering applications teachers may lack.

A second distinguishing feature is that TERMS focuses on a coherent, timely, and important research topic that falls in Pasteur’s Quadrant [14] addressing both basic science and application. *TERMS research focuses on how to engineer materials and structures whose behavior is determined by the collective interactions of their parts.* This is an active research area at OSU with programs in biological and medical materials, photonic materials, and colloidal self-assemblies. Facilities and experience exist locally to provide a needed breadth and depth of research experiences. Research on developing conceptual understanding [15] has shown that misconceptions about “direct” processes are easier to correct than misconceptions about “emergent” processes. It is also known that it is more difficult to correct a misconception when the correction requires a shift between ontological domains—i.e. direct to emergent—than if it remains in the same domain [16]. By focusing on research that emphasizes understanding emergent processes TERMS better equips teachers to understand then teach students ways to understand the interdependent processes vital to complex systems.

The third unique aspect of TERMS is that participants were taught effective ways to transition research into the classroom by engineering faculty who have successfully done so. The cohort of teachers and REU students devoted approximately one day each week to creating inquiry-based projects appropriate for K-12 students that are drawn from their research. OSU had a very successful NSF Department Level Reform project—*Engineering Students for the 21st Century* (ES21C)—that developed a process for taking research into undergraduate classes. Engineering faculty familiar with this process drew upon examples from existing undergraduate laboratories to teach key aspects of the process to participants.

Finally TERMS was informed by in-depth analysis of others’ RET experiences to address key elements of a successful research experience. An independent evaluation of RET participants [17] suggests specific improvements to the RET program that TERMS addresses. These include:

- Involvement of low income school districts and drawing several teachers from a single school district. TERMS

focused on local school districts, many that serve low income and Native American populations.

- Development of ongoing collaborative relationships that extend beyond teachers time on campus and supported by detailed orientation and professional development sessions at the start of the RET experience.
- Research faculty mentors that are engaged and interested in helping develop low cost curricular materials for K-12. The use of these faculty mentors as well as undergraduate students that help to serve as research translators were to improve the experience of the teachers.

III. THEORETICAL FRAMEWORK AND RESEARCH QUESTION

The community of practice framework [18-20] suggests that a group can be created with the goal of gaining knowledge specific to a field. Lave and Wenger [18] specifically looked at how apprenticeships help people learn. It is through the process of shared common experiences and information that group members can learn from each other and understand the specific field. Placing the teachers in a research lab as a team and providing them authentic experiences can generate a rich learning and understanding about engineering as they gain relevant expertise. Therefore, having the teachers participate as a community of practice (i.e. an engineering research team) can help teachers’ understanding and perceptions of engineering and therefore their confidence and perceptions of teaching engineering to middle school students.

This framework gives rise to the main study research question for this paper: Does the placement of teachers into a community of practice – teachers in engineering research teams – improve their perceptions of engineering and of teaching engineering?

IV. STUDY CHARACTERISTICS

This study involves 6th-9th grade teachers in combined research and K-12 content development. The program consisted of pre-visit preparation, a six week summer research experience, and follow up academic interactions between RET teachers, OSU faculty, REU students, and middle schools students. The undergraduate students and the teachers formed a team to allow for appropriate translation of the laboratory experiments to the classroom. Additionally, curriculum was developed for the middle level classrooms. The teachers for the program are math, science and technology teachers from rural and Native America districts in Oklahoma. The most recent cohort (from summer of 2011) also had two preservice teachers involved as well as two high schools students (that are entering college in the fall of 2011).

This particular study of the TERMS project is to examine the perceptions of teachers about engineering and teaching engineering. To develop teachers’ confidence, one day each week was devoted to the professional development of the teachers. During this time, the teachers were engaged in the development of several deliverables to develop information for students and curriculum for their classrooms. These included lesson plans, flyers, pamphlets, videos, and implementation calendars. The lesson plans were developed to transition the

research to their classroom, the flyers, pamphlets and videos were to provide project information to superintendents, principals, other teachers, students, and parents about the project. The implementation calendars were developed to see when exactly teachers were covering engineering in their classrooms.

As the research component of the program was enhanced, seven research specific tools were focused on (see Figure 1) to help the teachers gain confidence in research skills and to help them communicate their research results to a variety of audiences. The first deliverable that the teachers had was a lab book where they documented the activities accomplished in the lab. The teachers also maintained a journal where they recorded thoughts and comments about their research and curriculum implementation during the entire year. The teachers prepared a narrative that examined the effectiveness of the summer research program, the effectiveness of their curriculum unit, and the impact on their students. The teachers of the 2011 cohort prepared professional quality research papers that have been compiled into a research compendium. Finally, the teachers prepared research posters for their classroom, power point presentations, and science fair boards. The completion of their research projects plus these deliverables provided confidence and experience to the teachers.

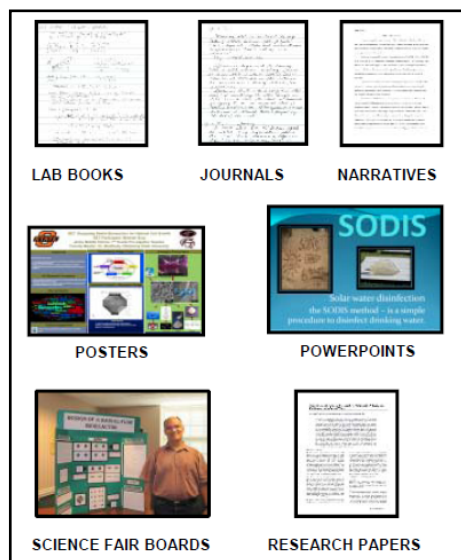

Figure 1. Teacher Research Deliverables

V. STUDY DEMOGRAPHICS

The TERMS program commenced in 2009 and had three cohorts (2009/2010, 2010/2011, 2011/2012). The teachers were selected from districts with low socioeconomic status and a large number of ethnic students. The teachers themselves came from multicultural backgrounds.

2011-2012 Teacher Demographic Information:

N= 8 In-service (5 MS/JH mathematics and 3 MS/JH science teachers) and 2 Pre-service Science
Mean Age – 39 (ages range from 28 to 50)
Years Teaching – 12 (five with 10 or more years and 3 between 5 to 9 years of experience)

Gender – 6 females and 4 male

Ethnicity – 7 Caucasian, 1 Asian, 1 Hispanic, and 1 American Indian

Misc: All but one person was traditionally certified. The one non-traditionally certified has been teaching for 14 years.

2010-2011 Teacher Demographic Information:

N= 8 (4 MS/JH mathematics and 4 MS/JH science teachers)

Mean Age – 38 (ages range from 28 to 48)

Years Teaching – 8.6 (three with 14 or more years and 5 with from 1-9 years of experience)

Gender – 7 females and 1 male

Ethnicity – 6 Caucasian and 2 American Indian

Misc: For two of the eight teachers, teaching is their 2nd career. 3/8 teachers are not traditionally certified in a BS program - (BS degrees in HPER, Animal Science, and Physical Therapy) (all 3 teaching MS/JH science; these BS degrees tend to require strong science backgrounds). 2/8 teachers have a BS degree in Elementary Education (both teaching MS mathematics). The remaining 3/8 teachers have a BS in either secondary mathematics or science.

2009-2010 Teacher Demographic Information:

N= 6 (3 MS mathematics and 3 MS science teachers)

Mean Age – 38

Years Teaching – 9 (one with 28 years and the others from 1-8 years of experience)

Gender – 5 females and 1 male

Ethnicity – 5 Caucasian and 1 American Indian

Misc: For two of the six teachers, teaching is their 2nd career. 4/6 teachers are not traditionally certified in a BS program. (BS degrees in History, German, Agriculture, and 1 not reported). The remaining two have a BS degree in Elementary Education.

VI. RESULTS AND DISCUSSION

Tables I, II and III give results from three surveys. These surveys were administered after the six week summer research experience. While the number of participants in each cohort is small (N=6, 8, 8 for 2009, 2010, 2011 respectively), an analysis by each cohort allows for the examination of overall changes in teachers' perceptions over the three study years. After analysis of year one data, researchers determined they needed additional information on the effect of the RET experiences thus the survey's whose data is reflected in tables I and II were developed. Thus, for these two instruments only two years of data is reported.

The teacher self-evaluation instrument shown in Table I was developed by the researchers as a way for teachers to reflect on their experiences and provide researchers with information on what teachers felt they had gained from the RET experience. To gain a better picture of the teachers RET experience, at the completion of the 6 week experience, teachers were asked to evaluate their experience by ranking the extent to which they believed they had developed insights or made contributions to their faculty mentors research. The instrument contained ten 5-point Likert-scaled questions (1=strongly disagree to 5=strongly agree) with each question followed by a comment section where teachers could further elaborate on their choice or their thoughts on the question.

The results shown in Table I show a high confidence and perception after the six week summer research experience for both cohorts for nine of the 10 statements. The two cohorts from 2010/2011 and 2011/2012 gave similar high results for all elements with the exception of question 3, “I contributed to my faculty mentors research project.” The increase of 1.7 points for the 2011/2012 cohort comes from the increased emphasis on research over the development of large curriculum units and the focus on writing high quality research papers.

TABLE I. TEACHER SELF EVALUATION OF RESEARCH EXPERIENCE FOR TWO COHORTS (2010/2011)

| Question | Average Rating (2010 N=8/ 2011 N=8) |
|---|---|
| I developed insights into the process of scientific research. | 4.8/4.9 |
| I developed an appreciation of the daily work of a scientific researcher. | 4.8/4.8 |
| I contributed to my faculty mentors research project. | 2.5/4.2 |
| I believe that I improved my science skills during the RET experience. | 4.6/4.9 |
| I demonstrated an increased enthusiasm toward science as a real world activity. | 4.8/4.8 |
| I accepted constructive criticism in a professional manner. | 4.8/4.7 |
| I adjusted to the challenges of the laboratory environment. | 4.8/4.8 |
| I believe that my lab placement was worthwhile for me as a teacher. | 5.0/5.0 |
| I shared ways that my faculty mentors research could be used in my classroom. | 4.9/4.5 |
| I believe that my experience persuaded my faculty mentor that this program as worthwhile for them and for myself. | 4.9/4.7 |

Strongly disagree (1) to strongly agree (5)

Further examination of the results in Table I show, that the teachers gave high ratings for developing insight into the process of research, appreciation for what researchers do, challenges of laboratory research, and application of the research to the classroom. The application of the research to the classroom is particularly noteworthy as this is the overall goal of the Oklahoma State University RET, to translate research to the middle school classroom. The teachers felt that the lab placement was worthwhile for them and also felt that the faculty mentors found the program valuable. This comment is worth noting because the faculty members that have been involved in the program have been truly engaged in the process and it is good that the teachers recognize that the faculty feel the program is worthwhile. The faculty mentors were selected specifically based on their experience with K-12 students and teachers, undergraduate research and other characteristics that made them particularly well- suited for this program.

Table II represents another self-developed post program survey with 25 questions that focusses on the teacher's assessment of the overall program. This instrument has questions that pertain to teachers perceptions of their confidence and understanding related to RET experiences. The first section deals with teachers perceptions of a change in their skills or understanding as it relates to RET experiences. Section

2 questions pertain to teachers' perceived confidence and understandings of what engineering is about. Section 3 questions pertained to how they perceived their abilities and skills as they pertained to working with their students. On this instrument, teachers rated their responses on a 6-point (1=strongly disagree to 6=strongly agree) Likert-scale.

TABLE II. TEACHER SELF EVALUATION OF PROGRAM FOR TWO COHORTS (2010/2011)

| Question | Average Rating (2010 N=8/ 2011 N=8) |
|--|---|
| I am capable of contributing to engineering research. | 4.8/5.7 |
| My skill in interpreting results of an experiment has increased. | 4.4/5.3 |
| My ability to analyze data has increased. | 4.3/5.3 |
| My confidence to conduct engineering research has improved. | 4.9/5.7 |
| I am confident in my understanding of the techniques and instrumentation used in engineering research. | 4.9/5.1 |
| My ability to integrate theory and practice has increased. | 4.4/5.0 |
| My faculty mentor was extremely helpful. | 6.0/6.0 |
| I am confident in my understanding of how engineers work on real-world problems. | 5.1/5.4 |
| I am confident that I understand the engineering design process (cycle). | 5.1/5.4 |
| I understand emergent phenomena. | 5.1/4.5 |
| I have a better understanding of how engineers think. | 5.0/5.1 |
| I understand the role science plays in engineering. | 5.5/5.4 |
| I understand the role mathematics plays in engineering. | 5.5/5.3 |
| I often do engineering work in my own life. | 4.3/4.6 |
| Engineering is a social profession. | 5.0/5.5 |
| Most engineers work alone. | 2.0/1.6 |
| My confidence to share engineering process with middle school students has improved. | 5.4/5.9 |
| I have a better understanding of how engineering can be incorporated into the MS curriculum. | 5.4/5.5 |
| I have a better understanding of how engineering concepts tie to math and science PASS. | 5.3/5.3 |
| Middle school students aren't capable of learning engineering. | 1.1/1.2 |
| I am confident that I can share a variety of engineering careers with my middle school students. | 4.5/5.1 |
| I am confident that I can develop curriculum involving engineering concepts for my middle school classroom. | 5.5/5.3 |
| I am confident that I can help other teachers incorporate engineering concepts into their classroom instruction. | 5.0/5.2 |
| I am confident that I will be better prepared to answer those “where will I ever use this” questions. | 5.0/5.5 |
| If given the opportunity, I would repeat this experience. | 5.5/5.6 |

Strongly disagree (1) to strongly agree (6)

For almost all of the questions in Table II, the 2011/2012 cohort had higher confidence and understanding than the 2010/2011 cohort. This again comes from the increased emphasis on research and research paper writing over extensive curriculum development.

For the questions on research (the top seven of table II), the teachers rated the program and their ability highly. The largest differences between the two cohorts are seen for question 2, “I am capable of contributing to engineering research” (0.9

difference), question 5, “My ability to analyze data has increased,” (1.0 difference), question 6 “My skill in interpreting results of an experiment has increased” (0.9 difference), and question 9, “My confidence to do conduct engineering research has improved” (0.8 difference). See bolded items in Table II. Again the teachers rated their faculty mentors highly and this was the highest rated element of these seven questions.

The next nine questions of Table II deal with the teacher’s confidence in understanding engineering and emergent phenomena. For both cohorts their confidence and understanding of engineering was high. The program particularly focuses on understanding emergent phenomena and the design cycle, and this emphasis translated to teacher confidence in these areas. The teachers also appreciate how science and engineering play a role in engineering and how engineers work on real world problems.

The final nine questions of Table II focus on the translation of the research into the middle school. The highest rated question is that the teachers have improved confidence in sharing the engineering process with their students. They understand how engineering can be incorporated into their classroom and have the confidence to do so. They see how engineering can address the Oklahoma Standards (PASS – Priority Academic Student Skills). The teachers feel that they have the knowledge to share engineering careers with their students. Additionally, they feel that they have the ability to help other teachers introduce engineering into their classroom. They have the confidence that their students can learn engineering as well. Finally, they rated the program very highly and would repeat the program if given the opportunity to do so.

Table III shows the results for a post survey that was developed by the RET network (www.retnetwork.org). This survey is a 52 item survey that asks questions about a variety of components of the program. Table III presents 27 of the questions that look at confidence and attitudes particularly related to research and teaching. This post survey was given to all three cohorts. The results show an increase in post teacher attitudes and perceptions over the three years as formative assessment was used to improve the program. Most of the 2011 responses to the questions were the highest for the three years.

The first section of Table III contains questions on the impact of the RET program on the teachers personally. The highest rated question was for “It stimulated me to think about ways I can improve my teaching.” Also rated highly was “I believe I will be a more effective teacher” and “It increased my motivation to see out other experimental professional development activities.” The RET experience gave the teachers confidence to become better teachers. The lowest agreement was for the question about changing career paths. Of the 20 teachers involved in the program (2 of which were preservice), 18 are still in the teaching profession, one became a college advisor in the biology department, and one plans to come to OSU for graduate school in chemical engineering.

TABLE III. RET NETWORK SURVEY QUESTIONS RELATED TO SELF-EFFICACY FOR ALL COHORTS (2009/2010/2011)

| Impact of the RET Program on the RET personally | |
|---|--|
| To what extent do you agree with each of the following statements concerning the impact of the RET program on you personally? | Average Rating 09/10/11 N=6/8/8 |
| It increased my confidence in myself as a teacher | 2.5/3.4/3.4 |
| It elevated my enthusiasm for teaching | 3.0/3.4/3.5 |
| It increased my interest in research and the ways that science, mathematics, or technology can be applied | 3.0/3.8/3.6 |
| It stimulated me to think about ways I can improve my teaching | 3.1/3.5/3.9 |
| I believe I will be a more effective teacher | 3.0/3.3/3.8 |
| It increased my interest and ability in networking with teachers and other professionals | 3.0/3.6/3.6 |
| It increased my motivation to seek out other experimental professional development activities | 3.1/3.3/3.8 |
| It increased my commitment to learning and seeking new ideas on my own | 3.5/3.1/3.6 |
| It changed my career direction | 1.6/1.6/2.2 |
| Learning Experiences | |
| Q: To what extent, if any, do you feel that your experiences each of the following types of learning as a result of your participation in the RET? | Average Rating 09/10/11 |
| I gained a greater understanding of the applications of science, mathematics, or technology in everyday life | 3.3/3.8/3.7 |
| I acquired greater understanding of fundamental concepts in science or mathematics | 3.1/3.3/3.3 |
| I became familiar with new materials and equipment that I can use in my teaching | 3.0/3.5/3.6 |
| I learned about innovative ways to use standard materials and equipment in my field | 2.6/3.5/3.4 |
| I increased my knowledge of current issues in scientific or mathematical research | 3.0/3.6/3.7 |
| I gained a greater appreciation of the difficulties some students encounter when learning science or mathematics | 3.8/2.6/3.2 |
| I better understand how collaborative inquiry can be done successfully | 2.6/3.1/3.6 |
| I increased my knowledge of careers that utilize science, mathematics, or technology | 2.8/3.4/3.2 |
| Level of Engagement | |
| Q: To what extent, if any, did you engage in each of the following types of activities during the RET? | Average Rating 09/10/11 |
| I collaborated in ongoing research with regular staff from the organization | 2.7/1.6/3.4 |
| I designed and implemented my own research or investigation under supervision from a mentor | 2.0/3.1/3.7 |
| I assisted in the process of developing, modifying, or documenting applications of science, mathematics, or technology for my mentor/sponsor | 2.5/2.6/3.4 |
| I operated instruments, equipment, and other technologies | 3.2/3.8/3.8 |
| I participated in conducting research or collecting data out in the field | 2.2/3.0/3.2 |
| I read academic literature or journal articles | 2.5/3.3/3.1 |
| I wrote about the work that I was doing and shared it with my mentor(s) or other professionals at the site | 2.5/3.6/3.9 |
| I wrote a paper that was suitable for submission to a professional journal | 1.3/1.6/2.4 |
| I gave a presentation on what I learned or an activity that I developed | 2.0/3.0/3.6 |
| I accessed information from the Internet that contributed to the work I was doing | 3.0/3.5/3.5 |

1-not at all, 2-small extent, 3-moderate extent, and 4-great extent

The second section of Table III contains questions on the learning experiences provided the teachers. The highest agreement was for the statements about understanding the use

of STEM in everyday life and knowledge of current issues in STEM.

The third section of Table III presents teacher agreement for 10 questions. The highest agreement is for writing about their work. The teachers wrote a research paper. Interestingly, the teachers didn't feel as confident that the papers were suitable for submission to a professional journal. The 2011 year teachers recognized their high level of research engagement.

The results of the three surveys presented in Tables I, II and III show the ability of the Oklahoma State University RET TERMS program to increase the confidence of the teachers in their instructional abilities, their understanding and ability to translate engineering research to the classroom and gave them improved perceptions in a variety of areas.

VII. CONCLUSIONS

This research study provides results for the main research question: Does the placement of teachers into a community of practice – teachers in engineering research teams – improve their perceptions of engineering and of teaching engineering? According to the results presented in Tables I, II and III, the answer is yes. These results are specific to perceptions at the end of a six week university research experience.

For the three cohorts (communities of practice) studied, the teachers showed an increased confidence in themselves as teachers as well as an enthusiasm for teaching, allowed them to network with other teachers and have an improved perception of professional development opportunities. They also gained confidence in themselves in their understanding of engineering and their ability to teach their students engineering. They feel that they are more conversant with engineering research methods and engaged in a variety of productive research endeavors. They feel that they produced quality research results and published these results using a variety of mechanisms.

While not part of the presented study, it can be anticipated that the improved perceptions of the teachers towards their abilities and understandings of engineering will impact their students learning. If the teachers feel more confident, they will begin to engage their students in meaningful classroom experiences. This will help to address the need presented in the introduction of the paper that middle level students need to be provided with meaningful learning experiences.

Abstract—In the Northern Appalachian region around Pittsburgh, PA, many high schools do not have computer science courses, so students are not introduced to this critical subject that is needed for most technical career paths. Our unique strategy is to invite current high school science, technology, engineering and mathematics (STEM) teachers, in Pennsylvania, West Virginia, Ohio and Maryland, to participate in 3 summer workshops showing how to incorporate computing concepts into existing STEM courses. By working with teachers on how to assimilate programming and computational thinking into their classrooms we will effectively reach a large population of students in areas where computer science classes are not available. In this paper, we outline the current state of the project and some of the data we have collected. Future goals for this project include performing a rigorous evaluation of teacher impact and developing the workshop materials for wider dissemination.

Keywords: outreach, professional development, computational thinking

I. INTRODUCTION

In the Northern Appalachian region surrounding Pittsburgh, Pennsylvania, computer science is taught in very few high schools. Most students are not made aware of the potential of computing as a field of study and a career that is in demand. Our project tries a novel approach. The ACTIVATE program reaches out to high school teachers of science, technology, engineering and mathematics (STEM) teachers in the Northern Appalachian region around Pittsburgh, where many schools lack essential resources for teacher development and have little support for special programs to interest students in computing careers. According to a recent study, "it is difficult to build a successful computer science program without any knowledge of the field of computer science, or interaction with other computer science teachers." [1] By training teachers in computing principles, we hope to add computing topics to existing STEM courses to increase student awareness of computing and to build a stronger community of computing teachers across the region.

Students are often exposed to STEM-related disciplines through the Advanced Placement program. Figure 1 below shows that the number of schools offering computer science AP classes has remained stagnant over the last decade while all

other STEM disciplines have a significant increase in the number of schools offering these subjects. Figure 2 shows that, as compared to surrounding east coast states, the number of students taking the AP Computer Science A exam is lowest in the Northern Appalachian region. [2]

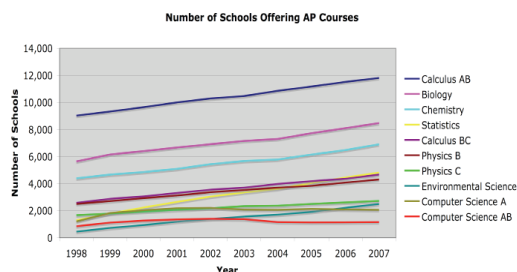

Figure 1. Number of schools offering AP courses related to STEM, 1998-2007.

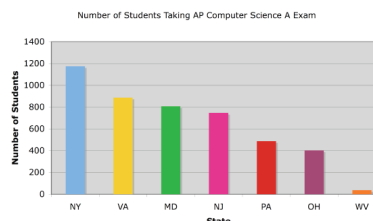

Figure 2. Number of students taking AP Computer Science A exam in Pennsylvania and surrounding states in 2007.

Low student interest in computing careers is in stark contrast with high demand for high-tech employees in this region. Pennsylvania added 6,400 jobs to its high-tech sector in 2006, making it the 7th largest cyber-state in the nation with 210,200 jobs. [3] According to a recent report (covering through 2005), the southwestern Pennsylvania region contains 805 software firms and 92 hardware firms, employing more than 16,900 people with a total annual payroll of approximately \$1 billion. [4]

II. WORKSHOP STRUCTURE

Given the gap between student interest and potential career opportunities in computing, we have developed a series of week-long intensive workshops for high school STEM teachers

in Pennsylvania, West Virginia, Ohio and Maryland, to provide training to enable STEM teachers to introduce programming and computational thinking within their curricula. In order to reach teachers at different levels of preparation and different needs, we have offered three workshops each summer since 2009: Computing with Alice, Computational Thinking using Python, and Java Programming for Math and Science.

Each workshop features four days of instruction to teach the participants the important programming and computational principles and then a fifth day where teachers create an application (using Alice, Python or Java) that illustrates integrating these concepts and techniques into curricular topics they currently teach in their classes. Through presentations and discussion, teachers are encouraged to challenge stereotypical views and to see computing as an exciting and diverse field in which both girls and boys can contribute and excel. We also provide training and guidance to participating teachers who wish to promote computing to a wider audience in events such as assemblies in their home schools and at in-service days for teachers, administrators and guidance counselors. More information can be found at <http://www.cs.cmu.edu/activate>.

III. PARTICIPANT DATA

ACTIVATE has enjoyed diverse teacher participation over its first three years. Of the 179 teachers attending these workshops, 56.4% taught in Pennsylvania, 26.3% in Ohio, 8.9% in West Virginia, and 8.4% in Maryland. A large majority (81.6.0%) taught in public school and 34.6% had more than ten years of teaching experience. As for subject areas taught, some teachers (19.0%) taught multiple subjects. The largest group of teachers teach computer science (47.5%), with mathematics second (43.6%), and science third (22.9%).

In a pre-workshop survey, respondents were asked to rate on a scale of 1 (none) to 4 (quite a bit) their previous knowledge and teaching experience with selected programming languages. More than half answered 1 (none) or 2 (very little), regarding knowledge of and teaching experience in each of the listed programming languages. There were two languages, BASIC and Java, with which computer science teachers indicated a rating of at least 3 (some knowledge and teaching experience). Overall, respondents had limited knowledge and little experience with programming prior to the workshops.

Also, respondents were asked to rate, on a scale from 1 (very uncomfortable) to 5 (very comfortable), their own comfort level with computer-related teaching practices. Over 90% rated themselves with scores 4 or 5 in encouraging students to use computers in and out of class. Also, more than half rated themselves with scores 4 or 5 in their ability to implement instructional activities designed to build students' advanced computer skills (e.g. requiring students to analyze data using software).

IV. PRELIMINARY RESULTS

At each ACTIVATE summer workshop, pre- and post-workshop surveys were given. The surveys included 13 to 15 scaled questions for which participants were to rate their ability to perform and teach concepts and skills

covered in the workshops. Across three years, 99.2% of these questions yielded pre to post increases. Increases ranged from 15.7% to 89.4% and in each year more than half of the questions showed increases greater than 50.0%.

In an effort to measure impact on participant content knowledge, a content assessment was given at the end of each workshop. In 8 of the 9 workshops, respondents mean score was over 70.0%, with highs of 86.0% in Alice (2011) and 84.4% Computational Thinking (2011). The only exception was in the Java (2009) workshop. Subsequently, the first Java assessment data led to significant changes in the Java workshop curriculum. The cumulative assessment average has increased from 65.3% in 2009, to 76.3% in 2010, and 82.7% in 2011.

A year after attending a workshop, teachers were sent a follow-up survey. Nearly all follow-up survey respondents from both 2009 (94.3%, n=50) and 2010 (97.4%, n=37) workshops indicated they plan to use workshop material in new or existing courses in math, science and computing courses. High percentages of 2009 and 2010 respondents, 88.7% (n=47) and 94.7% (n=36), respectively, *agreed* or *strongly agreed* that attending the workshop(s) gave them a better understanding of the practical use of programming. Similarly high percentages *agreed* or *strongly agreed* that the workshop(s) gave them a better sense of how to prepare students for future computer related study, 83.0% (n=44) in 2009 and 89.5% (n=34) in 2010.

Finally, follow-up interviews with workshop participants have yielded interesting findings with regard to classroom impact. In particular, respondents cite that after utilizing workshop materials and practices, their students' showed increased interest and ability to pursue additional study in computer programming, and its practical application. One participant explained the impact of her ACTIVATE workshop in particularly succinct terms: "It certainly increased my background so I could give them some perspectives about math and computers, which made a lot of connections for them because you know they live in a world of technology, animation, and computers."

V. FUTURE WORK

After one additional set of summer workshops in summer 2012, we plan to analyze all of the collected data from the four years of workshops to determine overall effectiveness of this project in updating existing STEM courses to include computational thinking, building teacher communities to share computing activities, and increasing student awareness of computing in the Northern Appalachian region.

Abstract—This work in progress paper addresses efforts to provide authentic, reflective practice in STEM education for pre-service elementary teachers through a partnership between an institute of higher education (IHE) and a public school (PS). Early results are supported by research on school-based partnerships and indicate innovations for meeting challenges to deepen and sustain the partnership for all stakeholders.

Keywords— school-based partnerships; STEM; pre-service; elementary

I. INTRODUCTION

Science and engineering education in the elementary grades is strongly supported by the National Academies of Science [1]. However, pre-service elementary teachers frequently lack familiarity with scientific ways of thinking and often feel unprepared to teach science [2]. Most elementary teachers are not science majors; many tend to view science as a difficult subject. These two factors contribute to an avoidance of teaching science at the elementary level [3]. In particular, the lack of self-efficacy in teaching science among elementary teachers has been documented by several studies [4] [5] [6]. Teachers with a high degree of self-efficacy are more likely to plan lessons with rigorous standards and not give up on poorly performing students than a teacher who has low-self efficacy [7].

Evidence from school-based partnerships between institutes of higher education (IHE) and public schools (PS) has demonstrated promise as an effective strategy for improving pre-service elementary teachers' self-efficacy to teach science [8]. For example, pre-service teachers who integrated theory and practice by planning and teaching a science lesson at a local elementary school, showed an increase in science teaching self-efficacy on the Science Teaching Efficacy and Belief Instrument-Preservice (STEBI-B) [9]. A similar study of pre-service elementary teachers found improved attitudes toward science as measured by the science attitude scale [10].

Generally the literature supports IHE/PS partnerships as successful models for teacher education. However, such partnerships often fail due to challenges related to resources and institutional structures [11].

In recognition of both the potential that such school-based partnerships hold for preparing elementary science teachers and the challenges to sustainability of such programs, this paper is the first in a proposed series that describes the interventions and outcomes of a IHE/PS partnership between a university school of education and urban elementary school in Boston Massachusetts in an effort to identify elements of an effective and sustainable IHE/PS partnership.

Problematic for the sustainability of IHE/PS school-based partnerships are the investment and commitment of both the PS and IHE faculty [12]. Both cohorts need to benefit from the collaboration. Additionally, IHE faculty are frequently reluctant to participate if their outreach efforts do not contribute to Retention, Tenure, and Promotion (RTP) [13]. Rouse and Clawson [14] identify benefits in three categories: material benefits such as salary, supplies; solidarity benefits such as rewards and recognition; and purposive benefits such as the intangible reward for helping a group achieve highly valued goals. The following paragraphs describe initial strategies that address these concerns of the IHE/PS partnership.

II. DESCRIPTION OF THE COLLABORATION

LaChance recommends that lasting partnerships begin by building trust through the accomplishment of initial successful activities together [15]. During the past three years, the IHE has funded a coach to support the PS principal, has funded a bus to transport students to the PS, and has invited PS teachers to make guest presentations in an urban education course that also is taught at the PS. During the past three years the IHS has hosted a STEM day for the PS 4th graders during which they participated in science activities designed and led by pre-service teachers in an elementary methods course. This collaboration has been low risk while serving to forge a working relationship among the IHE and PS stakeholders leading to a commitment to pilot a school-based model for university pre-service teachers at the PS.

Beginning in the fall 2011, the PS science specialist and IHE faculty collaborated to provide a clinical experience for nine undergraduate junior pre-service teachers in the elementary science methods course. The goal was to provide mentored,

Authentic science teaching experiences that foster self-confidence and knowledge of pedagogical strategies to teach elementary science effectively. Two teams of pre-service teachers were assigned to teach one third and fourth grade science class respectively. The teams were each assigned a topic based on the district's science curriculum: life cycles for grade three and animal studies for grade four. The teams were charged with creating lessons aligned with the Massachusetts Science/Technology Curriculum Frameworks using the 5E instructional strategy. The pre-service teachers began by observing exemplary models of science teaching followed by reflection on essential components of classroom inquiry. During the subsequent six weeks, each pre-service team led the elementary students through a series of three lessons and created discovery stations for the children to explore topics, collect data, and keep science notebooks in the interim between classes. Pre-service teachers received feedback following each session from the elementary science specialist, university instructor, and peer pre-service teachers.

III. DISCUSSION

Pre-service teachers from the fall 2011 cohort were given a pre and post-test of the Science Teaching Efficacy Belief Inventory version B (STEBI-B) developed by Riggs and Enochs as metric for self-confidence. Preliminary results suggest that the school-based clinical experience had a positive effect on pre-service teachers' self-efficacy. However, the small $n=9$ precludes a meaningful claim.

Focus groups with the pre-service teachers indicated that planning and teaching lessons for real elementary students was overall positive and regarded as more valuable for teacher preparation than planning lessons without opportunities to implement the lessons. The responsibility of teaching third and fourth graders added intrinsic meaning, motivation, and accountability for the pre-service teachers. Both the PS and IHE faculty agreed that the program is promising not only for the pre-service teachers and elementary students, but also for faculty at both institutions: K12 students experience a diversity of science teaching strategies, in-service teachers grow professionally through exposure to instructional methods and mentoring roles, and higher education faculty garner insight into the real-world applications of theory. The synergy also suggests the potential for research to be translated into practice, and for practice to generate research.

The preliminary findings strengthened the conviction of both IHE and PS cohorts about the potential of the partnership to benefit all stakeholders, with full knowledge that such partnerships are not without challenges. Among these are logistical issues such as travel to the school, adequate space and time, RTP, and concerns regarding material and solidarity benefits addressed by Rouse and Clawson.

With these caveats in mind, the PS principal and school of education dean as well as key faculty collaborated to address

growth and sustainability of the program. With respect to material support, it was agreed that the elementary school will provide office/classroom space for pre-service classes and the IHE will fund the renovation and provisioning of the space. The IHE has also hired a program manager to ensure a smooth flow of information between schools, oversee logistics, and manage communication among pre-service teachers, in-service teachers, and elementary students. The elementary methods science courses will be co-taught by IHE and PS faculty on-site, fostering a deeper immersion of the pre-service teachers in both science and regular classrooms and solidarity among IHE/PS faculty. Faculty at the PS will be titled at the school of education in an adjunct capacity to reward and recognize PS teachers. It is too early to gauge any impact on RTP.

As the program progresses, we propose a longitudinal study with several cohorts: pre-service teachers as they progress through student teaching and begin as practicing professionals, elementary students who participate in the program, and IHE/PS faculty in the context of material, solidarity, and purposive benefits as they relate to sustainability.

Computational Science Programs: the Background Research

Lori Carter, Ryan Botts, Catherine Crockett
Mathematical, Information, and Computer Sciences Department
Point Loma Nazarene University
San Diego, CA, USA

Abstract— There are many good reasons for an academic institution to pursue the addition of an undergraduate program in computational science. However, poor planning can lead to wasted time, money and resources, and ultimately a failed program. To create a viable program, it is essential to have buy-in from the computational faculty and science faculty, as well as the administration. In addition, it is important to understand the skill-set desired by the potential employers and graduate programs, and to design a curriculum around those needs keeping in mind the expertise of the faculty involved. This paper strives to share what was learned from over a year of background research on what it takes to have a successful computational science program.

Keywords- *Computational Science, Bioinformatics, Interdisciplinary, Curriculum Design*

I. INTRODUCTION

There are many good reasons for an academic institution to pursue the addition of an undergraduate program in computational science. Scientific disciplines, particularly biology, have recognized the need for quantitative services in their research. Computing within a context has proven to attract women, and aid in retention. There is grant money available for interdisciplinary studies in the STEM disciplines. In 2009, Computational Science was touted as one of the 5 majors on the rise by the *Chronicle of Higher Education* [1].

Unfortunately anecdotal evidence has suggested that some that start computational science programs are disappointed. Of the four participants on a SIGCSE 2011 panel discussing newly formed computational science programs, two admitted that their programs were not thriving [2]. Subsequent conversations with professors at other universities revealed similar difficulties that were attributed to poor planning or lack of buy-in from key players.

When we in the Mathematical, Information and Computer Sciences (MICS) department at Point Loma Nazarene University (PLNU) decided that we wanted to create a minor in computational science we determined to do the most thorough job possible of researching curriculum, employment opportunities, industry-desired skill sets, interest of the science faculty, possible interdisciplinary projects, and potential pitfalls. We read papers and reports, conducted interviews with people in

industry, visited labs, read textbooks, perused university catalogs and job requisitions, attended lectures, researched potential grants, and participated in numerous conversations with the scientists at our university.

This paper is designed to share what we learned about the field of computational science, how we gathered information about potential curriculum, the curriculum we have chosen based on our study, and our general strategy for the choices we made.

II. WHAT IS COMPUTATIONAL SCIENCE?

It is hard to produce a universally accepted definition of the term *computational science*. In a recent survey regarding computational science administered by the authors to a gathering of 66 mathematicians and computer scientists, only 15% were able to articulate a reasonable definition of the term. The authors have chosen to embrace a definition provided by the Society of Applied and Industrial Mathematicians (SIAM). Computational science is “*The integration of knowledge and methodologies from mathematics, statistics, and computer science to analyze and solve problems from the STEM disciplines*” [3].

Computational science encompasses sub-disciplines such as computational biology, computational chemistry, computational physics, research genetics, bioinformatics, scientific programming, and biostatistics. Computational activities in support of research in the sciences have included scientific visualization, mathematical modeling, image processing, database design and normalization, user-friendly interface design, scripting for information flow, statistical analysis, design, customization, and analysis of algorithms in support of DNA sequencing and genomics, development of parallel algorithms for modeling and processing of large amounts of data, data mining, data fusion, and design of experiments and clinical trials. The emphasis put on each of these activities may change what computational science looks like in a particular instance.

III. WHY MAKE THE EFFORT?

Encouragement for creating computational science programs is coming not only from industry, but from academic guilds on the computation side as well as on the science side. Furthermore, universities are recognizing that in addition to providing a degree that leads to an in-demand

career, there are side benefits for the institutions that house these programs.

A. Future Research Requires It

There are science-related problems that can't be solved in the laboratory alone. The prime example is the mapping of the human genome. While scientists contributed the genomic understanding, the pattern matching algorithms and computing power required was largely a result of contributions made by mathematicians and computer scientists. The volume of scientific data that can now be collected is growing rapidly, and needs to be searched, analyzed and organized. The call for computational assistance to scientists continues to expand, creating a great demand for people trained to meet the need.

B. Academic Guilds are Requesting It

In 2006 SIAM published a study entitled *Computational Science and Engineering for Undergraduate Students* in which they report on current undergraduate programs in the computational sciences, and encourage the formation of additional programs [3]. This report provides 4 reasons for the creation of computational science programs: interdisciplinary research is increasing, and will play an important role in future discoveries; it provides an opportunity to attract a more diverse student body into computing; it would train future K-12 teachers on what computing looks like in "real-life"; there are funds available for undergraduate experiences and K-12 outreach. We expand on some of these reasons in subsequent sections.

On the science side, *BIO2010*, a report published by the National Academy of Science and funded by the Howard Hughes Medical Institute (HHMI) and National Institutes of Health (NIH) strongly encourages the biology education community to include computation in their coursework noting: "while much of the postgraduate research in biology is enhanced using computational methods, biology educators have not adapted curriculum to introduce students to these computational tools" [4].

Another publication addressing the need for computation in science education is *Math and Bio 2010: Linking Undergraduate Disciplines*. This research was a joint project of the Mathematical Association of America, the American Association for the Advancement of Science and the American Society for Microbiology. They suggested that "The objective of increased quantitative education would be accomplished by introducing quantitative concepts and methods into biology courses while at the same time making biological concepts more prominent parts of courses in the mathematical and computer sciences" [5].

The Chemistry community is also aware of the need to include computation education. Computational Chemistry for Chemistry Educators is a program of the National Computational Science Institute that seeks to provide chemistry faculty with ideas for including computational approaches in the courses they teach. The focus is on using computers to help students learn chemical principles via

such techniques as modeling, data manipulation and graphing, and computer algebra systems.

C. The Institution Benefits from It

For PLNU, the initial reasons for pursuing a program in computational science were the abundance of life science companies in the region providing employment and internships, our close relationships with the scientists who share our building and the desire to provide concrete applications for our applied mathematicians and computer scientists. Additional benefits seem to be recruitment and retention of women into computer science, excellent venues for undergraduate research with available grant money to support that research, and support of the science education community which is demanding that more computation be built into its curriculum.

There is debate over whether contextualized computing education has a positive or negative effect on our students. Guzdial asserts that while contextualized teaching might not help students learn more, research shows that it does provide relevance, leading to improved retention [6]. According to this study, both Media Computation and Robot contexts have proven helpful. Science could provide another interesting context.

Recruiting students as majors in computer science has been an area of concern for many years. The concern is especially great for females. A 2006 report revealed that only 3% of all males in the freshman class intended to major in computer science, but for women, the percentage was an alarming .4% [7]. There is evidence that computational science is a way to interest more women in computational majors. A study involving over 600 high school students in pre-calculus and calculus courses included a survey asking questions about a potential major in computer science [8]. This study revealed that the number one reason female students would consider a major in computer science was if it was in the context of using it in another field. This study supported the findings by Fisher et al. that women are more interested in computing if it has a purpose [9]. Computational science provides that context and purpose. One of the first computational science programs for undergraduate students was developed as an emphasis of a computer science major at Wofford College [10]. Of the 18 students who graduated from the program between 2002 and 2007 in this small college in South Carolina, 44% of them were women.

At the time of this writing, many research funding opportunities are drying up for economic reasons. Funding for research and curriculum development in the computational sciences is a notable exception. The National Science Foundation (NSF) currently has multiple grant opportunities available for both undergraduate research and curriculum development. Funding is available from private organizations such as the HHMI as well.

IV. WHAT WILL IT TAKE?

What must be in place for a new computational science minor or major program to succeed? Research has shown

that the program must receive support from faculty members across the computational and bench science disciplines, from administration, and from local industry as providers of potential projects and internships.

A. Administrative Support

Administrative buy-in is essential. Most programs will have to be built with cooperation across science, mathematics, and computer science departments. Consequently, administration needs to work to help eliminate disincentives to these collaborations. Problems can occur with regard to teaching credit and facilities. The *Chronicle of Higher Education* reported such a problem at Oregon State University when it wanted to expand its computational physics program to other sciences. Faculty members in the other sciences were resistant because they “tended to see computational work as peripheral, and as something they would not get rewarded for at promotion and tenure time” [11]. *BIO2010* suggests “increasing recognition and rewards for faculty who teach outside of their department, possibly by allocating credit hours for teaching based on the department of the faculty member instead of the department listing the course” [4].

B. Faculty Support

Buy-in from faculty across the disciplines is crucial too. Not only will it be helpful for faculty from other departments to teach content in the program, but these faculty members will be indispensable for encouraging students to enter the program. They may also be prime providers of examples and projects.

Enthusiasm from faculty in the sciences is not as easily gained as one might expect. Computer scientists are used to interdisciplinary work because we build tools for others, scientists are not. At PLNU, faculty members from the MICS department interact with faculty members from the science departments everyday due to shared facilities. However, when we initially asked how our department could help support the work of our bench scientist colleagues, we were met with quizzical looks. Even the biologists were unaware of the copious literature in their discipline describing how they can benefit from computational support.

One particular biologist was doing cancer research which involved image processing. The processing, though redundant, was done mostly by hand. When we suggested a way to automate the process, the biologist was thrilled. Not only did he appreciate the elimination of what he saw as tedious work, he valued the increased precision of this more objective type of analysis. As the conversation continued, we discussed creating more user-friendly interfaces to the programs that they already used, script-writing to improve information flow, and other similar ideas.

C. Relationships with Local Industry

One of the top recommendations from the SIAM report was that the curriculum should explicitly include practical

experience in interdisciplinary collaboration. Internships are one of the ways to achieve this goal.

In an effort to start building the necessary relationships with those in industry and to better understand the challenges of computational and bench scientists working together, we wanted to set up interviews with people working in interdisciplinary teams at the life science companies in the area. This proved to be a more difficult task than expected. Using contact information from corporate websites led us to people who were quite confused by our request. The words “computational science” tended to cause them to direct us to the IT department. We eventually had more success by asking for scientists that used computing in their work. Still, people were hesitant to help. We gained one excellent interview via this blind contact, but the others came through personal referrals. These interviews are discussed further in section 5B.

Even with support from administration, faculty colleagues, and local industry, the challenges of working across disciplines should not be underestimated.

V. ADDITIONAL CHALLENGES

Once the science faculty is convinced that a partnership could be beneficial, there is the challenge of actually working together in research and in building an interdisciplinary curriculum.

A. Working in Interdisciplinary Teams

Communication can present a huge challenge when working in interdisciplinary teams. Each discipline has its own unique vocabulary. Even having recently reviewed biological concepts, we found ourselves having to recall definitions as we interviewed biology faculty members, causing us to miss part of the conversation. Similarly, terms that we would use in casual conversation were a mystery to our colleagues. Section 5B discusses the importance that employers place on communication skills. Practice in communicating across disciplines should be intentionally included in any computational science curriculum.

Beyond language differences are differences in how we approach research. While computer scientists and applied mathematicians may take the “let’s see what happens” approach, scientists tend to have a very pointed and narrow focus due to the scarcity of resources. Use of a sample either changes or destroys it. Consider our biology colleague working with cancerous tumors. Once he has applied the treatment to the tumor, that sample cannot be used again.

It is not essential that we understand everything about the complementary field of study. As Tyman points out “biologists do not need to be proficient in the development of algorithms, but need to understand the algorithmic process. This parallels the computer scientists’ need to understand how PCR [Polymerase Chain Reaction] works. Computer scientists need not master the process of actually running a gel, but they should be aware of the process so that they understand its limitations” [12].

B. The Challenge of the Curriculum

Curriculum is another significant challenge. Since there seems to be a lack of agreement as to the definition of computational science, it is difficult to determine what should be included in the curriculum for a related program. The authors of the SIAM report observe: “It should be noted that the successful development of a specific flavor of a computational science and engineering program depends on the structure and mission of a particular university, the collection of faculty expertise and most importantly on pragmatic considerations (i.e., which and how many courses can be approved by the institution? What are the local politics?)” [3].

Teaching resources, such as textbooks, that address the specific emphasis of a program can be hard to find. In addition, locating textbooks that appeal to, and are at the right level for both science students and computational students can be a challenge. For introductory classes, the level is not such a consideration. However, the appeal might be. Science students seem to be used to a different kind of content than computational students, with the former more comfortable with the concrete, and that later quite comfortable with the abstract.

Our approach to determining curriculum content was to consider 4 areas:

1. Skills (both hard and soft) requested by companies employing computational scientists
2. Prerequisite courses desired by local graduate programs
3. Expertise of the interested faculty members
4. Resources available for textbooks and projects

To determine the skill-set required by companies in our region, we examined job requisitions for computational scientists from employment sites such as monster.com, careerbuilder.com, and indeed.com. We made a list of both the hard (academic) skills and the soft skills requested for each position.

We thought that it would be important to focus our curriculum in a way that met the needs of the computational science industry in our area. This would be helpful for future local employment and internship opportunities. Our initial search was restricted to local employers only. Ultimately we did expand our search. In general, the skills requested were not region-specific, but rather job-specific. Searching on the keyword “computational” we found 27 biology-related positions, 7 chemistry-related, 4 physics-related, and 2 scientific programming jobs which supported the other 3 areas.

Fig. 1 displays the hard skills most requested by the 40 job requisitions examined. The most frequently requested skills on the left are generally technical skills that are relevant to most computational science positions. Molecular biology ranked highly due to the high number of biology related jobs, but chemistry positions also asked for this knowledge. The less frequently requested skills on the right side of the graph were linked more closely to specific types

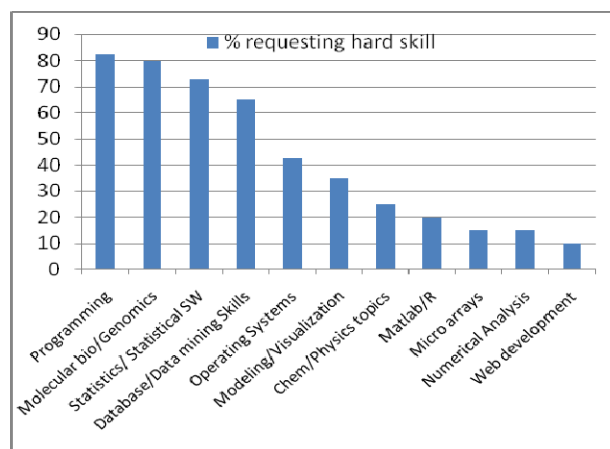

Figure 1. Hard Skills Most Requested

of jobs. For example, numerical analysis skills were linked to the computational chemistry and physics positions.

The programming category includes both high level languages and scripting languages. Many requisitions asked for either, but 45% specifically requested scripting. Another interesting distinction was in the operating system category. While almost half of the requisitions wanted strong operating systems skills, UNIX/Linux proficiency seemed to be emphasized. Skills requested less than 10% of the time, but more than once included clinical trial and experimental design (8%), machine learning (5%), testing (5%), and parallel or high performance programming (5%).

Fig. 2 presents the soft skills most often explicitly requested. Not surprisingly, communication skills top the list. Teamwork was emphasized by 42.5% of the job requisitions. 32.5% specifically mentioned the ability to work with an interdisciplinary team, reinforcing earlier observations that building interdisciplinary experiences into the curriculum is crucial.

In an attempt to confirm our findings on skill sets, and to understand better how professionals in the computational sciences worked together, we conducted interviews with those in industry. We asked about the computational aspects of their current projects, about the challenges of bench and

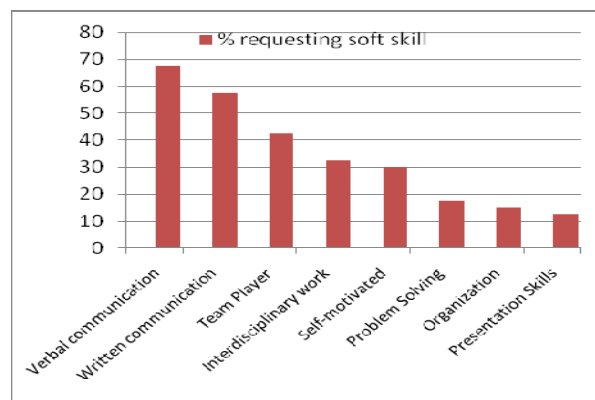

Figure 2. Soft Skills Most Requested

computational scientists working together, and for their content recommendations for the students coming both from the computational side, and from the science side. For the most part, these interviews confirmed what we had learned from the job requisitions and other sources.

Our first interviews were with a molecular biologist and a bioinformatician working together at the Salk Institute in La Jolla, CA [Singer, Sankar, personal communication]. They agreed that the number one challenge was to be able to communicate in a concise and constructive way so that each party understands the problem, possible solutions, and limitations. Typically, the computational person needs to understand the scientific problem and experimental limitations, and the scientist needs to understand computational limitations such as available analytical tools and problem complexity issues.

To that end, each of them needs to understand a little of what the other person does. The biologist was emphatic that every biology student should get a little scripting. He or she should understand basic statistics and experimental design as well as the tools and techniques (databases, motif finding software, mapping software, visualization software) available to the computational peer.

The computational counterpart should have a basic knowledge of molecular biology, understand basic biology techniques (PCR, sequencing, cloning) and tools (Basic Local Alignment Search Tool (BLAST), Bowtie), be adept at statistics, be able to analyze the complexity of an algorithm (frequently for pattern matching), and be a competent programmer in both a high level and scripting language. Much of the algorithmic software used is open source, and often customization is required. They also made significant use of MATLAB and R along with UNIX. The bioinformatician was adamant that the student have some practical experience prior to applying for a job.

Our second interview was more on the computer science side. We met with the Vice President of Wireless Health and Life Sciences and two Senior Directors at Qualcomm [Jones, Ziv, Niznik, personal communication]. Here the computational work involved the fusion and analysis of data gathered wirelessly from different biological and chemical sensors. In this case, the work required much computational knowledge with only basic biological knowledge and vocabulary. The skill-set emphasis here was strong computational expertise (programming and analytics), the ability to deal with large amounts of data, and superior soft skills. It was essential that the future employees have the ability to communicate and work in an interdisciplinary team, and to be able to think about solving problems from multiple perspectives. Once again, the need for interdisciplinary projects within the curriculum is clear.

Our final interview was with the Director of Bioinformatics and Biostatistics at the Scripps Translational Science Institute in La Jolla, CA., providing a mathematical point of view [Schork, personal communication]. This conversation focused on the importance of scripting and biostatistics. Biostatistics, we were reminded, has less emphasis on probability and great emphasis on inference

based decision making. In addition, there are limitations on the amount and types of data available. The importance of scripting for changing the format of data and for process automation was brought up multiple times. We were assured that both of these skills could be easily translated to different subareas of computational science such as cheminformatics.

Many of the computational science programs are at the graduate level, and a good number of the jobs in computational science require graduate degrees. Consequently, providing students with classes that prepare them for future education should be a consideration. The graduate programs in our area seem to focus on bioinformatics. As a result, we were encouraged to include statistics and database courses in our curriculum.

As noted in the previous section, the curriculum at a given institution will be influenced by expertise and interest, politics, and even resources. Schools with access to super computers might emphasize parallel and scientific computing. Oregon State has a computational physics program because only the Physicists were interested. At the University of Wyoming, interest came from the departments of Botany, Computer Science, Mathematics, Mechanical Engineering, Statistics, and Zoology & Physiology. At PLNU, support came from faculty in Computer Science, Mathematics, Biology, Chemistry, and Physics, and our curriculum choices reflect that.

Content in a computational science program can be created in a variety of ways. Certainly some new classes will have to be implemented. Interdisciplinary projects and research experiences will have to be devised. However, many of the classes currently in our curriculum can be retooled to include modules from complementary disciplines. A database course can use scientific databases as examples, and BLAST for searching and analysis. A Genomics course could incorporate Perl or Python to demonstrate pattern matching in searching for motifs.
