CONFERENCE AT A GLANCE

Wednesday, October 23

11:00 am – 6:00 pm	Registration Second Floor Prefunction Area
1:30 pm – 6:00 pm	Exhibit Setup Great Hall D & E
1:30 pm – 4:30 pm	Pre-conference Workshops Session A
5:30 pm – 8:30 pm	Pre-conference Workshops Session B

Thursday, October 24

7:00 am – 5:00 pm	Registration Second Floor Prefunction Area
7:00 am – 8:00 am	Focus on First-Time Attendees Breakfast Buffet Great Hall C
8:00 am – 9:30 am	Plenary Session Katherine Banks, Vice Chancellor and Dean of Engineering, Texas A&M University Great Hall A & B
9:30 am – 5:00 pm	Exhibit Hall Open Great Hall D & E
9:30 am – 10:00 am	Exhibit Hall Break
10:00 am – 11:30 am	Technical Sessions (T1)
11:45 am – 1:15 pm	HP Terman and Rigas Awards Lunch Sponsored by the Hewlett-Packard Company Great Hall C
1:30 pm – 3:00 pm	Technical Sessions (T2)
3:00 pm – 4:00 pm	Exhibit Hall Break and
4:00 pm – 5:30 pm	Technical Session (T3)
6:00 pm – 9:30 pm	Transportation to and Reception at National Cowboy & Western Heritage Museum Bus loading zone: between the Renaissance hotel and the Cox Convention Center

Friday, October 25

7:00 am – 5:00 pm	Registration Open Second Floor Prefunction Area
7:00 am – 8:30 am	Breakfast & Plenary Session Mike McCracken, Director of Online Course Development and Innovation, College of Computing, Center for 21st Century Universities (C21U), Georgia Tech Great Hall C
8:30 am – 10:00 am	Technical Sessions (F1)
9:00 am – 4:30 pm	Exhibit Hall Open Great Hall D & E
10:00 am – 10:30 am	Exhibit Hall Break
10:30 am – Noon	Technical Sessions (F2)
Noon – 1:30 pm	Luncheon Great Hall C
1:30 pm – 3:00 pm	Technical Sessions (F3)
3:00 pm – 4:00 pm	Focus on Exhibits and New Faculty Fellows Great Hall D & E
4:00 pm – 5:30 pm	Technical Sessions (F4)
6:30 pm – 9:00 pm	Reception and Awards Banquet - Ticketed Event Great Hall C

Saturday, October 26

7:00 am – 2:00 pm	Registration Second Floor Prefunction Area
7:00 am – 8:00 am	Breakfast
8:00 am – 9:30 am	Technical Sessions (S1)
9:30 am – 10:00 am	Break - Second Floor Prefunction Area
10:00 am – 11:30 am	Technical Sessions (S2)
11:30 am – 1:00 pm	Lunch Great Hall C
1:00 pm – 2:30 pm	Technical Sessions (S3)
2:30 pm – 3:00 pm	Break - Second Floor Prefunction Area
3:00 pm – 4:30 pm	Technical Sessions (S4)

WELCOME FROM THE GENERAL CO-CHAIRS

Welcome to FIE 2013!

Oklahoma has long been known as an energy producing state, so we thought it appropriate to have "Energizing the Future" of engineering and computer science education as this year's theme. The name of our state, Oklahoma, is a Choctaw word that means "land of the red people". Oklahoma is home to 38 federally recognized Indian tribes and our history is enmeshed with stories of American Indian relocation and settlement, the Oklahoma land run, and the civil rights movement. So it is fitting that FIE highlight diversity and inclusion for our future. The conference also focuses on programs that bridge disciplines, such as the successful collaborations between engineering, computing and meteorology that can be seen during the evening tour of the National Weather Center, located in Norman Oklahoma. The traditional FIE topical themes of educational innovations and research in engineering and computing education are still front and center. We hope you find many opportunities to interact with your fellow conference attendees, including taking advantage of the "catalyzing conversations" sessions.

We look forward to meeting you Thursday evening at the welcoming reception, which is being held at a unique venue, the National Cowboy and Western Heritage Museum. There are many local attractions for you to enjoy during your stay, including the Oklahoma City National Memorial and Museum which memorializes the 1995 terrorist bombing of Alfred P. Murrah Federal Building; the Oklahoma City Museum of Art which is home to one of the largest collections of glass sculpture by noted artist Dale Chihuly; the Myriad Botanical Gardens featuring 17 acres of walking paths, splash fountains, and gardens, that feature plants from climates ranging from rain forests to desserts; and the Boathouse District which hosts a U.S. Olympic and Paralympic training site for rowing and canoe/kayaking and river sport adventures. All of these venues are within easy walking distance of the hotel. The Bricktown district is adjacent to the conference venue and offers a variety of restaurants and night clubs for your dining and entertainment pursuits.

The University of Oklahoma (OU) College of Engineering is pleased to host FIE 2013. We are grateful for the support of the OU administration as we prepared for the conference. We further express our sincere appreciation to our conference sponsors and exhibitors for their financial support.

We are very pleased you have joined us in Oklahoma City and wish you a hearty welcome!

Randa Shehab
Jim Sluss
Deborah Trytten

WELCOME FROM THE PROGRAM CO-CHAIRS

We are so glad you have joined us at FIE 2013! We hope that you will find your experience here enjoyable and valuable as you participate in the broad range of paper, panel, and special sessions, workshops, and social activities that have been scheduled.

This year's conference theme is *Energizing the Future*, and that is just what we hope happens for those who have chosen to join us. If you are new to the conference, you will find sessions on a wide variety of topics related to engineering and computing education. If you have been to FIE before, you will discover new opportunities, catalyzing conversations, as well as some of the tried and true favorites in the special sessions and traditional sessions. The technical program is complemented by the Conference's networking opportunities during breakfast and lunch with a big cowboy welcome at the reception – one you won't want to miss!

Our authors deserve the credit for the continuing quality of this conference – their innovative and compelling work and their promising works-in-progress seeking your input are once again outstanding. The reviewers who volunteered their time to provide quality, constructive feedback gain our thanks.

So, may your future be energized as you enjoy your time in Oklahoma City at FIE 2013!

MESSAGE FROM THE FIE STEERING COMMITTEE

Welcome to Oklahoma City and the 43rd annual Frontiers in Education Conference. FIE has an outstanding global reputation as a premier conference on engineering education. It is known for its collaborative author network and papers from its proceedings record are regularly cited in bibliographies.

This year the conference continues its long tradition of offering an outstanding technical program. I am confident you will find many sessions where speakers will challenge you to think differently about education and how we facilitate learning in our classrooms. The General Chair, Technical Program Chairs, paper reviewers, and session chairs all play important roles in guaranteeing that the technical program remains current and is of high quality. Please take a moment to thank these people for their professionalism and volunteer service to engineering education when you meet them during the conference.

This year, I want to focus my welcome message on the process of organizing a conference. FIE is a mid-sized conference event led by a nine member Steering Committee of appointed representatives from the three sponsoring professional societies. This Steering Committee sets mission and vision for the conference including desired size, technical program specifications, and registration fee structure. The Steering Committee regularly reviews the structure of FIE as it considers growth potential. ***Have you ever thought of hosting FIE*** in your city and wondered what the conference requires for facilities? Currently, the conference is designed to:

- use four conference days typically beginning on a Wednesday in October or November,
- host approximately 600 registered attendees,
- support a technical program of 400 paper and special session presentations,
- provide breakfast and lunch to its participants to foster collegiality and networking,
- provide a welcome reception and formal awards banquet,
- be in a conference hotel that can provide at least 300 rooms per night for FIE guests, and
- be in a conference hotel that has at least nine presentation rooms, two ballrooms, and exhibit hall space.

And, ***have you ever thought of hosting FIE*** in your city and wondered what the workload and leadership requirements are? Currently, the conference uses a structure that includes:

- one or two local General Chairs that are responsible for leading the planning team,
- three Technical Program Co-Chairs responsible for papers sessions,
- a Special Sessions Chair responsible for workshops, panels, and special sessions,
- a number of International Co-Chairs responsible for participation in FIE from other countries,
- an Awards Chair responsible for the conference awards program,
- a paid publications service provider contracted through a request-for-proposals (RFP) bid process,
- a paid logistics service provider contracted through an RFP bid process, and
- hundreds of volunteer peer reviewers and session chairs.

As General Chair, the responsibility of managing this planning team requires significant time. Much of the day-to-day work falls to other people on the planning committee, but the big decisions are ultimately the responsibility of the General Chair working in collaboration with the Steering Committee. Bids to host FIE begin by contacting the Steering Committee Chair four years before the conference date. After informal conversation with the Steering Committee Chair, a General Chair prepares a formal bid package that outlines the transportation, hotel, and tourism opportunities of their location. The Steering Committee expects that a proposed General Chair will attend every FIE conference before and through their own event if the bid package is selected. The workload for General Chairs is lighter during the first two years but ramps up significantly in the final year before the conference because of multiple logistical decisions and technical program deadlines.

The Steering Committee encourages you to think about hosting FIE.

The Steering Committee has set a goal to have FIE locations for the rest of this decade decided by June 2014. We are half way to meeting that goal! Now is the time to seriously consider volunteering as an FIE General Chair and work with us to host FIE in your city. Here is the current schedule showing set locations in **bold** as well as open years and suggested locations through the rest of the decade:

- **FIE 2014 : Madrid, Spain**
- **FIE 2015 : El Paso, Texas**
- **FIE 2016 : Erie, Pennsylvania**
- FIE 2017 : open (southeast U.S.)
- FIE 2018 : open (midwest U.S.)
- FIE 2019 : open (west coast U.S.)
- FIE 2020 : open (northeast U.S.)

Please note that the regional suggestions are just suggestions. The committee ***always*** entertains bids from prospective host sites in any location regardless of the proposed year. It should be noted, however, that current FIE policy requires FIE to be in the continental U.S. or Canada for at least five years before returning to any other international venue. If you are interested in hosting FIE as a General Chair, be sure to contact me soon so that we can have a frank conversation about requirements and the bid process.

The Steering Committee works for the Societies and the member communities. We encourage you to contact any one of us to discuss the FIE conference. We can be identified by Steering Committee ribbons on our conference badges.

FUTURE FIE CONFERENCES

FIE 2014 Madrid, Spain
FIE 2015 El Paso, Texas
FIE 2016 Eire, Pennsylvania

Are you interested in hosting a future FIE conference? Leave your business card at the registration desk, and an FIE steering committee member will contact you.

CONFERENCE SPONSORS

FIE 2013 is sponsored by:

American Society for Engineering Education (ASEE)
Educational Research Methods (ERM) Division

Institute of Electrical and Electronics Engineers (IEEE)
IEEE Computer Society
IEEE Education Society

FIE 2013 is hosted by:

The University of Oklahoma

The University of Oklahoma (OU) is a coeducational public research university located in Norman, Oklahoma. The university was founded in 1890 and existed for 17 years before Oklahoma became a state. OU enrolls more than 30,000 students, has more than 2,600 full-time faculty members, and has 21 colleges offering 163 majors at the baccalaureate level, 157 majors at the master's level, 81 majors at the doctoral level, 28 majors at the doctoral professional level, and 28 graduate certificates.

The school is ranked first per capita among public universities in enrollment of National Merit Scholars and among the top ten in the graduation of Rhodes Scholars. PC Magazine and the Princeton Review rated it one of the "20 Most Wired Colleges" in 2008.

The OU College of Engineering was formed in 1909 and recorded its first graduates in the spring of 1910. It is now the largest engineering program in Oklahoma, with 1,800 undergraduate students, 450 graduate students and a 115-member faculty.

OU is also well known for its athletic programs, winning seven NCAA Division I National Football Championships, playing in four BCS national championship games since the inception of the BCS system in 1998. Its baseball team has won 2 NCAA national championships, and the women's softball team won the national championship in 2000.

CORPORATE AFFILIATES AND SPONSORSHIPS

Corporate affiliates play an important role in supporting FIE conferences. This support subsidizes the cost of the award presentations and of meal functions. We appreciate these supporters and the part they play in making the 2013 FIE conference an outstanding event.

Thursday Activities

Hewlett-Packard — Frederick Emmons Terman and Harriet B. Rigas Award Luncheon

Friday Activities

NextThought — Morning Break in the Exhibit Hall

FIE 2013 EXHIBITORS

The FIE vendor and association exhibits are a popular and rewarding tradition for both attendees and exhibitors. Exhibits will include materials, equipment, textbooks, software, and state-of-the-art tools applicable to engineering education. We thank the vendors for their financial support and contributions to making FIE 2013 a meaningful experience.

Exhibit Hall Hours
The exhibits will be open in the Great Hall D&E from 9:00 a.m. to 5:00 p.m. Thursday and from 9:00 a.m. to 4:30 p.m. Friday. As of September 5, the following companies had committed to exhibiting at FIE 2013:

EXHIBITOR	WEBSITE
Digilent	www.digilentinc.com
EMA Design Automation	www.ema-eda.com
Emona Instruments	http://www.qpsk.com/
JMP statistical discovery software from SAS	http://www.jmp.com/
Purdue Engineering Education	engineering.purdue.edu/ENE
Stratasys	www.stratasys.com
Texas Instruments	http://education.ti.com/en/us/home
Utah State University Department of Engineering Education	www.eed.usu.edu/
Virginia Tech Engineering Education	http://www.enge.vt.edu/
Zyante	www.zyante.com

Focus on Exhibits and New Faculty Fellows Poster Presentation
Attendees and participants will be encouraged to visit the exhibit area throughout the conference. In order to provide full exposure for the exhibits, a special "Focus on Exhibits" session is planned for the afternoon of Friday, October 25th, during which time there will be no technical sessions scheduled. The New Faculty Fellows will also display their posters at this time. Door prizes contributed by some of the exhibitors will be awarded during the Focus on Exhibits. You must be present to win.

EXHIBITOR SHOWCASE PRESENTATIONS

Thursday, October 24

10:00 am – 11:30 am	**Texas Instruments**	**Meeting Room 3**

Thursday, October 24

1:30 pm – 3 pm	**Zyante**	**Meeting Room 3**

Topic: Animated Interactive Learning of Programming Languages
Speakers: Smita Bakshi and Frank Vahid
Description: Zyante develops web-based animated interactive learning material for lower division computer science and engineering. These offerings enable students to "learn by doing" as they engage with animations, interactive tools, embedded coding environments, games and self-assessment questions. Available for $35, students can also download them for later use. 4000+ students at over 40 universities are using Zyante's current offerings: C, C++, Java, Python, MATLAB, Embedded Systems, Data Structures & Discrete Math.

Join the founders, Smita Bakshi and Frank Vahid, at the Showcase to learn more about the material and the teaching tools. We'll provide you with a hands-on opportunity to evaluate the material and teaching tools, including the ability to view student activity data, and to rearrange and customize the material.

Friday, October 25

10:30 am – Noon	**ABET**	**Meeting Room 3**

Topic: Future Directions for the Computing Accreditation Criteria – A Discussion with the Computing Community
Speaker: Mark Stockman, University of Cincinnati
Description: The computing disciplines continue to undergo rapid change, as evidenced in part by the current cycle of model curricula efforts in the various disciplines. Driven by the same challenges, the ABET Computing Accreditation Commission (CAC) in cooperation with the ACM and IEEE Computer Society are currently considering revisions to the ABET Computing Accreditation Criteria. For ABET to be responsive to its constituencies, criteria changes must be driven by the community. As a result, CAC, ACM and the IEEE-CS are engaged in a variety of activities designed to obtain input from the community at large so as to effect appropriate evolution within the criteria. In this session, we present an update regarding some of the proposed changes to the Computing Criteria and provide an opportunity for review, comment and general input by the session participants. The results of this session will be used as an important input to the criteria change process.

1:30 pm – 3:00 pm	**NextThought**	**Meeting Room 3**

Topic: NextThought: Frontiers in Online Social Education
Speaker: Ken Parker
Description: NextThought is creating the future of online education today. Their unique software melds social media with content and course management to create active learning experiences that engage students. This session will provide a product demonstration by a faculty member using NextThought in the classroom and give attendees an opportunity to interact with the next big thing in higher education.

PLENARY SESSIONS

Thursday, October 24, 8:00 – 9:30 am
Great Hall A & B

Speaker: Katherine Banks, Vice Chancellor and Dean of Engineering, Texas A&M University

Introduction by Kyle Harper, Senior Vice Provost and Director of the Institute for the American Constitutional Heritage, the University of Oklahoma

Dr. M. Katherine Banks is vice chancellor for engineering for The Texas A&M University System and dean of the Dwight Look College of Engineering at Texas A&M University.

As vice chancellor, Banks oversees coordination and collaboration among the engineering, academic and research programs at universities throughout the A&M System, as well as three state agencies: the Texas A&M Engineering Experiment Station (TEES), the Texas A&M Engineering Extension Service (TEEX) and the Texas A&M Transportation Institute (TTI). Banks also is TEES director, overseeing research administration of more than 4,400 projects and $142.5 million in sponsored research awards. As dean of the Look College and holder of the Harold J. Haynes Dean's Chair in Engineering, Banks leads one of the largest engineering schools in the country, with more than 11,000 students and nearly 400 faculty.

Banks was previously the Bowen Engineering Head for the School of Civil Engineering at Purdue University and the Jack and Kay Hockema Professor at Purdue. She received her B.S.E. from the University of Florida, M.S.E. from the University of North Carolina, and Ph.D. in civil and environmental engineering from Duke University. For her research, Banks has received funding from the National Science Foundation, the U.S. Environmental Protection Agency, the U.S. Department of Defense, the U.S. Department of Energy and NASA, as well as industry and state government. She served as director of the EPA Hazardous Substance Research Center, associate director of the NASA Center for Advanced Life Support, and co-director of the 21st Century Center for Phytoremediation Research, all headquartered at Purdue.

Banks is a Fellow of the American Society of Civil Engineers (ASCE) and is a licensed professional civil engineer in Indiana and Kansas. She has received numerous awards including the ASCE Petersen Outstanding Woman of the Year Award, ASCE Rudolph Hering Medal, Purdue Faculty Scholar Award, Sloan Foundation Mentoring Fellowship and the American Association of University Women Fellowship. She is the author or co-author of more than 150 journal articles, proceedings papers and book chapters. Banks has served as editor-in-chief for the *ASCE Journal of Environmental Engineering* and associate editor of the *International Journal of Phytoremediation*.

Friday, October 25, 7:30 – 8:30 am
Great Hall C, immediately following breakfast
Boogies, Boojums and Snarks: There are MOOC's Under Your Bed and in Your Closet.

Speaker: Mike McCracken, Director of Online Course Development and Innovation, College of Computing, Center for 21st Century Universities (C21U), Georgia Tech

W. Michael McCracken is a Principal Research Scientist in the College of Computing at Georgia Tech. He is the Director of Online Course Development and Innovation for the Center for 21st Century Universities at Georgia Tech. In his position at C21U he is responsible for the overall development of the portfolio of Massive Open OnLine Courses (MOOCs) for Georgia Tech. Last year, Georgia Tech fielded 16 MOOCs and will field a minimum of 10 new MOOCs, repeat 11 of them, and extend 3 of them to full semester offerings. He is also a participant in the development of the newly announced OnLine Masters in Computer Science being developed jointly with Udacity. McCracken also teaches and conducts research in computer science and software engineering. Additionally, McCracken is on the editorial board of the *Journal of Computer Science Education*.

FIE 2013 WORKSHOPS

Wednesday, 1:30 – 8:30 pm (Pre-Registration is required.)

On Wednesday afternoon and evening, FIE features workshops—highly interactive sessions selected for their timeliness and value. Workshops offer a concentrated professional development experience. The wide range of workshop topics offers opportunities for everyone from new faculty members to the most experienced educators to expand their skills and knowledge.

Conference attendees must register separately for workshops. There is a $50 registration fee for each workshop. Complete abstracts for the workshops can be found in the Wednesday schedule of the program book.

GROUP MEETINGS

Wednesday, October 23

5:00 – 6:30 pm	FIE Steering Committee Meeting	Meeting Room 14

Thursday, October 24

10 am – Noon	IEEE EDUCON Steering Committee	Meeting Room 1
4:00 – 5:30 pm	ASEE ERM Division Business Meeting	Meeting Room 1

Friday, October 25

10 am – Noon	IEEE Education Society Board of Governors meeting	Meeting Room 1
4:00 – 5:30 pm	ASEE ERM Division Business Meeting	Meeting Room 1

This is an open meeting for all members of the community to participate in the strategic planning for ERM. We will build on the conversation begun at the ASEE meeting in June. Input from that previous meeting will be used to craft a set of goals to guide ERM activities going forward.

Saturday, October 26

8:00 – 9:30 am	FIE Steering Committee Meeting Executive Session	Meeting Room 1
1:00 – 3:00 pm	FIE 2014 Planning Committee Meeting	Meeting Room 1

NEW FACULTY FELLOW PROGRAM

Each year, FIE invites new engineering and computer science faculty to submit applications for possible selection as New Faculty Fellows. A review panel of engineering and computer science faculty from assistant, associate, and full professorship levels completes a rigorous peer review of each applicant's conference paper, nomination letters and professional résumé. The fellowship provides a $1,000 grant for conference travel expenses.

The purpose of the program is to promote the involvement of new faculty in the Frontiers in Education Conference so they will be exposed to the "latest and greatest" in engineering educational practices and will have the opportunity to exchange information with leaders in education innovations. This year, FIE 2013 will provide registration and travel grants for the awardee to attend the conference.

Focus on New Faculty Fellows

Each fellow will present a conference paper during FIE 2013. Join them in their session and share your thoughts and ideas about the future of engineering education. Also, during the Focus on Exhibits session Friday at 3 p.m., the Fellows will display posters describing their interests and activities and previewing the full papers that they will present as part of the FIE 2013 technical sessions.

2013 New Faculty Fellow:

Joseph Ranalli
Pennsylvania State University - Hazleton
Session T3G
Assessing the Impact of Video Game Based Design Projects in a First Year Engineering Design Course
Joseph Ranalli (Pennsylvania State University - Hazleton Campus); Jacqueline Ritzko (Pennsylvania State University- Hazleton Campus)

CONFERENCE AMENITIES

Breakfast

7:00 a.m.–8:00 a.m. Thursday Great Hall C

7:00 a.m.–8:00 a.m. Friday Great Hall C

7:00 a.m.–8:00 a.m. Saturday Great Hall C

Refreshment Breaks ●

Morning and afternoon breaks Thursday and Friday Exhibit Hall – Great Hall D & E
Morning and afternoon breaks Saturday Second Floor Prefunction East

Lunches

Frederick Emmons Terman and Harriet B. Rigas Awards Luncheon – Great Hall C
Sponsored by the Hewlett-Packard Company
11:45a.m. –1:15 p.m. Thursday
The Frederick Emmons Terman Award is presented annually to an outstanding young electrical engineering educator by the Electrical and Computer Engineering Division of the American Society for Engineering Education. The Harriet B. Rigas Award is presented annually to an outstanding woman engineering educator in recognition of her contributions to the profession.

Luncheon – Great Hall C
Noon – 1:30 p.m. Friday

Luncheon – Great Hall C
11:30 a.m. –1:00 p.m. Saturday

Reception
6:00 p.m.–9:30 p.m. Thursday
Join your colleagues as we board busses and take the short ride to the National Cowboy and Western Heritage Museum for a reception. We will have drinks, a western-themed dinner, and plenty of time to explore the exhibits. Be sure to bring the drink tickets you received when you checked in at registration. Buses will begin boarding at 6:00 pm between the Renaissance Hotel and the Cox Convention Center on Sheridan Avenue.

New Faculty Fellows ● Exhibit Hall – Great Hall D & E
3:00 p.m.–4:00 p.m. Friday
A special session focusing on the New Faculty Fellows will be held on Friday. This session will provide an opportunity to meet this year's New Faculty Fellows, a group of new CSET educators who were selected based on an application and a full paper being presented at this year's conference. There will also be an opportunity to view their poster presentations at this time.

Focus on Exhibits ● Exhibit Hall – Great Hall D & E
3:00 p.m.–4:00 p.m. Friday
Visit the FIE exhibits and check out the latest textbooks, computer software, lab equipment, and other innovations while enjoying refreshments provided by our sponsor.

Awards Banquet ● Great Hall C
6:30 p.m.–9:00 p.m. Friday
This year's awards banquet features fine food, drink, and camaraderie along with presentation of special awards from FIE, the IEEE Education Society, and the IEEE Computer Society. There is a separate charge for the banquet.

The National Weather Center Tour
6:00 p.m.–9:30 p.m. Friday
Visit the National Weather Center and the Lawrence G. Rawl Engineering Practice Facility on the University of Oklahoma campus. The bus boards at 6:00 pm between the Renaissance Hotel and the Cox Convention Center on Sheridan Avenue. There is a separate charge for the tour.

FIE Registration Conference Desk ● Second Floor Prefunction East
Registration will be open during these times:

Wednesday	11:00 a.m. – 6:00 p.m.
Thursday	7:00 a.m. – 5:00 p.m.
Friday	7:00 a.m. – 5:00 p.m.
Saturday	7:00 a.m. – 2:00 p.m.

Hospitality Table ● Near Conference Registration
If you are looking for a certain kind of a restaurant, shop, golf course, or health club, stop by the hospitality table close to the registration area. Maps and brochures of area attractions will be available.

FIE Message Center ● Near Conference Registration
The conference will maintain a message board by the registration area. Messages received for conferees will be posted there. In an emergency, we will make every effort to locate you.

Catalyzing Collaborative Conversations
Conference Registration and rooms assigned Please stop by the registration desk to reserve a room for collaborative conversations with your colleagues. Pick a time, get a room, name a topic, and we will announce it by the Message Center and via Twitter #fie2013.

Social Media. Twitter hashtag #fie2013
Are you in the TwitterSphere? Tweet your comments on the conference, thoughts on the speakers, a shout-out for work that inspires you, time and topic for a Collaborative Conversation - use #fie2013 to share your insights with your colleagues and the conference committee.

2013 FIE CONFERENCE AWARDS PRESENTATIONS

Thursday, October 24 .... Terman/Rigas Awards Luncheon
Noon - 1:30 p.m.

ASEE ECE Division Hewlett-Packard Frederick Emmons Terman Award
IEEE Education Society Hewlett-Packard/Harriet B. Rigas Award

Friday, October 25 .... Awards Banquet
6:00 p.m. - 8:30 p.m.

Frontiers in Education (FIE) Conference Awards

FIE 2012 Benjamin J. Dasher Best Paper Award
FIE 2012 Helen Plants Award
FIE Ronald J. Schmitz Award

IEEE Education Society

William E. Sayle Award for Achievement in Education
IEEE Transactions on Education Best Paper Award
Chapter Achievement Award
Distinguished Chapter Leadership Award
Distinguished Member Award
Edwin C. Jones, Jr. Meritorious Service Award
Mac Van Valkenburg Early Career Teaching Award
Student Leadership Award

AWARD SELECTION COMMITTEE CHAIRS

Frontiers in Education Conference

Benjamin J. Dasher Best Paper Award ....Jenefer Husman
Helen Plants Award ....Cordelia Brown
Ronald J. Schmitz Award ....Arnold Pears

ASEE Electrical and Computer Engineering Division

Hewlett-Packard Frederick Emmons Terman Award ....

IEEE Education Society

IEEE William E. Sayle Award for Achievement in Education ...Lyle D. Feisel
IEEE Transactions on Education Best Paper Award ....Jeff Froyd
Chapter Achievement Award ....Trond Clausen
Distinguished Chapter Leadership Award ....Edmundo Tovar
Distinguished Member Award...Ted Batchman
Edwin C. Jones, Jr. Meritorious Service Award ....Edwin C Jones Jr
Hewlett-Packard/Harriet B. Rigas Award ....Joanne Bechta Dugan
Mac Van Valkenburg Early Career Teaching Award ....S. Hossein Mousavinezhad
Student Leadership Award...Emmanuel A. Gonzalez

Mung Chiang
Princeton University

ASEE ECE Division Hewlett-Packard Frederick Emmons Terman Award

For an outstanding young electrical engineering educator in recognition of his contribution to the profession

Mung Chiang is the Arthur LeGrand Doty Professor of Electrical Engineering at Princeton University, and an affiliated faculty in the Program in Applied and Computational Mathematics and in Computer Science. His research on networking received the Alan T. Waterman Award (2013), the IEEE Kiyo Tomiyasu Award (2012), a U.S. Presidential Early Career Award for Scientists and Engineers (2008), several young investigator awards from National Science Foundation, Office of Naval Research, and Princeton, and a few paper awards including the IEEE SECON (2013) and INFOCOM Best Paper Awards (2012). A Technology Review TR35 Award recipient (2007), his inventions have resulted in a few commercial adoptions, and he serves on several networking companies' advisory board. Supported in part by many industry research awards, he founded the Princeton EDGE Lab in 2009, which has led to multiple technology transfers as well as startup companies. He was elected an IEEE Fellow in 2012.

In 2011, Chiang created an undergraduate course: "Networks: Friends, Money, and Bytes," which lead to an open online offering with 90,000 students during 2012-2013. The corresponding textbook, "Networked Life: 20 Questions and Answers," adopted the "just-in-time" approach and received the PROSE Award in Engineering and Technology (2012) from the Association of American Publishers. The second textbook "Networks Illustrated: 8 Principles without Calculus" was at the top of bestsellers in Networking on Kindle upon its release, and became a series of "micro-ebooks." In 2013 they became the first Integrated and Individualized Book-App (IIB) that adapted to individual readers. He chaired the Princeton University Committee on Classroom Design, and founded the non-profit online education platform "3 Nights and Done" (3ND).

Chiang also initiated a Network Optimization workshop series and the Smart Data-Pricing (SDP) industry forums, and co-chaired the US NITRD Workshop on Complex Engineered Networks. He has served as an associate editor of a few IEEE journals, an IEEE Communications Society Distinguished Lecturer, and Chairman of the founding steering committee of the new IEEE Transactions on Network Science and Engineering.

ASEE ECE Division Hewlett-Packard Frederick Emmons Terman Award (continued)

About the Terman Award

The Frederick Emmons Terman Award is presented annually to an outstanding young electrical engineering educator by the Electrical and Computer Engineering Division of the American Society for Engineering Education. The Terman Award, established in 1969 by the Hewlett-Packard Company, consists of $5,000, an engraved gold-plated medal, a bronze replica of the medal mounted on a walnut plaque, and a parchment certificate.

The recipient must be an electrical engineering educator who is less than 45 years old on June 1 of the year in which the award is presented and must be the principal author of an electrical engineering textbook published before June 1 of the year of his/her 40th birthday. The book must have been judged by his/her peers to be an outstanding original contribution to the field of electrical engineering. The recipient must also have displayed outstanding achievements in teaching, research, guidance of students, and other related activities.

About Frederick Emmons Terman

Frederick Emmons Terman received his A.B. degree in chemistry in 1920, the degree of engineer in electrical engineering in 1922 from Stanford University, and his Sc.D. degree in electrical engineering in 1924 from Massachusetts Institute of Technology. From 1925-1965, he served as instructor, then professor of electrical engineering, executive head of the Electrical Engineering Department, dean of the School of Engineering, provost, vice president, and finally, as acting president of Stanford University.

Among the many honors bestowed upon him were: the IEEE Medal of Honor; the first IEEE Education Medal; the ASEE's Lamme Medal; the 1970 Herbert Hoover Medal for Distinguished Service to Stanford University; an honorary doctor's degree by Harvard; a decoration by the British government; the Presidential Medal for merit as a result of his war work; and the 1976 National Medal of Science from President Ford at a White House ceremony.

Dr. Terman was a professor at Stanford University when William Hewlett and Dave Packard were engineering students there. It was under Dr. Terman's guidance in graduate work on radio engineering that Mr. Hewlett built the first tunable and automatically stabilized Weinbridge oscillator. Partially through Dr. Terman's urging, Hewlett and Packard set up their partnership in an old garage with $538 and the oscillator as their principal assets.

Dr. Terman died in December 1982. It is in appreciation of his accomplishments and guidance that Hewlett-Packard is proud to sponsor the Frederick Emmons Terman Award.

Nancy Amato
Texas A&M University

Past Recipients

’95 Denice D. Denton

IEEE Education Society Hewlett-Packard Harriet B. Rigas Award

For increasing the participation of underrepresented members in the computing research community by promoting research experiences for undergraduates

Nancy M. Amato is Unocal Professor and Interim Department Head of the Department of Computer Science and Engineering at Texas A&M University where she co-directs the Parasol Lab. She received undergraduate degrees in Mathematical Sciences and Economics from Stanford University in 1986, and M.S. and Ph.D. degrees in Computer Science from UC Berkeley and the University of Illinois at Urbana-Champaign in 1988 and 1995, respectively. She was an AT&T Bell Laboratories PhD Scholar, received a CAREER Award from the National Science Foundation, is a Distinguished Speaker for the ACM Distinguished Speakers Program, was a Distinguished Lecturer for the IEEE Robotics and Automation Society, and is an IEEE Fellow.

She has served as an Associate Editor for the IEEE Transactions on Robotics and Automation and of the IEEE Transactions on Parallel and Distributed Computing.
She was co-Chair of the National Center for Women in Information Technology (NCWIT) Academic Alliance (2009-2011), is a member of the Computing Research Association's Committees on the Status of Women in Computing Research (CRA-W) and Education (CRA-E), and of the ACM, IEEE, and CRA sponsored Coalition to Diversity Computing (CDC). She has directed or co-directed the CRA-W/CDC Distributed Research Experiences for Undergraduates (DREU, formally known as the DMP) for more than 10 years. DREU is a national program that matches undergraduate women and students from underrepresented groups, including ethnic minorities and persons with disabilities, with a faculty mentor for a summer research experience at the faculty member's home institution. She received a University-level teaching award from the Texas A&M Association of Former Students and the Betty M. Unterberger Award for Outstanding Service to Honors Education at Texas A&M.

Her main areas of research focus are motion planning and robotics, computational biology and geometry, and parallel and distributed computing. She has graduated 13 PhD students, with most of them going on to careers in academia (7) and government or industry research labs (4), 15 master's students, and has worked with more than 100 Texas A&M undergraduate researchers and non-Texas A&M student interns, with the majority being students from groups underrepresented in computing.

She currently supervises 13 PhD students, 4 masters students, and more than 10 undergraduate and high school researchers.

IEEE Education Society Hewlett-Packard Harriet B. Rigas Award (continued)

About the Rigas Award

The Harriet B. Rigas Award is presented annually to recognize outstanding faculty women who have made significant contributions to electrical/computer engineering education. The award consists of an honorarium, plaque, certificate, and Frontiers in Education Conference registration.

The recipient must be a tenured or tenure track woman faculty member in an ABET-accredited engineering program in the United States, with teaching and/or research specialization in electrical/computer engineering.

About Harriett B. Rigas

Dr. Harriett B. Rigas (1934-1989), an IEEE Fellow, was an electrical engineer with an international reputation for her hybrid computer and computer simulation research. At Washington State University between 1966 and 1984, she was eventually both full professor and chair of Electrical and Computing Engineering School. Later she chaired larger departments at the Navy's Postgraduate School in Monterey and, at the time of her death, Michigan State University.

Her achievements in engineering research, administration, and service were widely recognized. In 1975-76, Harriett was a Program Director at the National Science Foundation and, over the years, a member of numerous panels and advisory committees at both the NSF and the national Academy of Sciences.

Professor Rigas' success was achieved within a profession and within university administrative structures where there were very few women. Her character and courage were both evident in her strong advocacy of advancement for women. She was involved both locally and nationally in the Society of Women Engineers.

Frontiers in Education Conference Benjamin J. Dasher Best Paper Award

Applying Philosophical Inquiry: Bringing Future Engineering Education Researchers into the Philosophy of Engineering Education **by Robin Adams, Alice Pawley and Brent Jesiek**
FIE 2012, T2B

Robin S. Adams is an Associate Professor in the School of Engineering Education at Purdue University. She was also a Senior Design Engineer in the semiconductor packaging industry, an Assistant Director for Research at the Center for Engineering Learning and Teaching, and the lead for the Institute for Scholarship on Engineering Education with the Center for the Advancement of Engineering Education. She received her PhD in Education, Leadership and Policy Studies and her MS in Materials Science and Engineering from the University of Washington, and a BS in Mechanical Engineering from California Polytechnic State University, San Luis Obispo. Her research seeks to empirically develop “languages for learning” in areas central to the practice of engineering – cross-disciplinarity and design – and to the practice of engineering education. A language of learning describes what it means to know, be able to do, or be as a professional and how this changes over time and through experience. It provides tools for learners to reflect upon and self-assess their own progress, teachers to design and assess learning experiences, and leaders to take action in shaping engineering education programs and policies. She conducts research in: (1) Cross-disciplinary ways of thinking, acting and being, (2) Engineering design learning trajectories and education for innovation, and (3) engineering education transformation. Dr. Adams is a recipient of a National Science Foundation CAREER award, teaching and leadership awards, best paper awards (*Journal of Engineering Education*, *Design Studies*), and publishes broadly. Her research group, XRoads, involves collaborators from a variety of disciplines to conduct research at the “crossroads” where different perspectives can connect, collide, and catalyze new ways of thinking. She also participates in many professional organizations including the American Society of Engineering Education (ASEE), American Educational Research Association (AERA), International Society of the Learning Sciences (ISLS), Design Research Society (DRS), Association for the Study of Higher Education (ASHE), and Association for Integrative Studies (AIS).

Alice L. Pawley earned her B. Eng (Chemical – Distinction) degree from McGill University in 2000, and a M.S. degree (2003) and Ph.D. degree (2007) in Industrial Engineering with a minor in women’s studies from the University of Wisconsin-Madison.

As a graduate student at UW-Madison, she worked with the Engineering Learning Center, the Wisconsin Engineering Education Laboratory, and the Center for the Integration of Research Teaching and Learning. She has served as an Assistant Professor in the School of Engineering Education and as an affiliate faculty member with the Women’s Studies Program and the Division of Environmental and Ecological Engineering at Purdue University in West Lafayette, IN from 2007 to 2012. In 2013, she was promoted to Associate Professor at Purdue. She serves on numerous advisory boards for federally funded projects across the nation, and reviews papers for the *Journal of Engineering Education*, the *International*

Journal of Engineering Education, the *European Journal of Engineering Education*, the *International Journal of Engineering, Social Justice and Peace*, *Science Education*, the *Journal of Higher Education*, *Advances in Engineering Education*, and *Engineering Studies,* and has reviewed for MIT Press.

Prof. Pawley is a member of the American Society for Engineering Education (ASEE), the National Women’s Studies Association (NWSA), the International Network for Engineering Studies (INES), the Society of Women Engineers (SWE), and the National Organization of Gay and Lesbian Scientists and Technical Professionals (NOGLSTP); she serves as faculty advisor to the Purdue chapters of ASEE and NOGLSTP. She received a NSF CAREER award in 2010 and a Presidential Early Career Award in Science and Engineering (PECASE) from President Obama in 2012.

Brent K. Jesiek earned his B.S. in Electrical Engineering (computer engineering option) from Michigan Technological University in 1998, and a M.S. degree (2003) and Ph.D. degree (2006) in Science and Technology Studies from Virginia Polytechnic Institute and State University. He is currently an Assistant Professor in the Schools of Engineering Education and Electrical and Computer Engineering at Purdue University, and is an Associate Director of Purdue’s Global Engineering Program. Dr. Jesiek draws expertise from engineering, computing, the social sciences, and humanities to investigate the geographic, disciplinary, and historical dimensions of engineering education and professional practice. He has a strong track record of grant-funded research, and in 2012 received an NSF CAREER award to study boundary-spanning roles and competencies among early career engineers. He leads the Global Engineering Education Collaboratory (GEEC), which serves as a hub for his research. An award-winning teacher, Dr. Jesiek regularly serves as instructor for courses in Purdue’s First-Year Engineering program and Engineering Education graduate program. His professional memberships include IEEE, International Network for Engineering Studies (INES), and American Society for Engineering Education (ASEE).

Frontiers in Education Conference Benjamin J. Dasher Best Paper Award (continued)

About the Dasher Award

The Benjamin Dasher Best Paper Award is given to the best paper presented at the annual Frontiers in Education Conference, as demonstrated by technical originality, technical importance and accuracy, quality of oral presentation, and quality of the written paper appearing in the Conference Proceedings. Papers are nominated for the award by reviewers.

A committee with representation from each of the organizing societies (ERM, IEEE Ed. Soc., IEEE Comp. Soc.) is formed to review nominated papers. During the FIE meeting, the committee attends presentations of the nominated papers. The committee then makes a final recommendation to the FIE Planning Committee for the Ben Dasher Award winner based on the overall quality of both the paper and the presentation.

About Benjamin J. Dasher

Benjamin J. Dasher was born December 27, 1912 in Macon, Ga. He earned his bachelor's and master's degrees in electrical engineering in 1935 and 1945, respectively, and graduated with a doctorate in electrical engineering in 1952 from the Massachusetts Institute of Technology. At MIT, Dr. Dasher worked on the electronics of instrumentation of electromechanical transducers and analog-to-digital converters. He was the author of "Dasher's method" for synthesis of resistance-capacitance two-port networks, which is found in standard textbook treatments.

While at Georgia Tech, Dr. Dasher served as a graduate assistant in 1936, then as an instructor in 1940, and became an assistant professor in 1945. While earning his PhD at MIT, he was an instructor from 1948-51. Before finishing with his PhD, he became an associate professor at Georgia Tech in 1951, was promoted to professor in 1952, and became director of the School of Electrical Engineering in 1954, where he served in that capacity until 1969. In 1968, Dr. Dasher was appointed associate dean in the College of Engineering. At Georgia Tech, Dr. Dasher served as director of network synthesis projects and transistor oscillator projects. His fields of interest included advanced network theory, electronic theory, electronic circuits, electrical engineering education, machine translation, speech analysis, and pattern recognition. He was credited for bringing undergraduate engineering education to the forefront at Georgia Tech and for increasing interactions between undergraduates and industry.

Dr. Dasher was a member of Phi Kappa Phi, ASEE, Sigma Xi, and the American Association of University Professors; he was a Fellow of both the IEEE and the Institute of Radio Engineers. He served as a regional director for IEEE and as the chair for the Atlanta section of IEEE; he was on numerous committees for IRE, AIEE, and IEEE. He served as President of the IEEE Education Group in 1970-71.

Ben Dasher organized the first Frontiers in Education Conference; it was held in Atlanta in 1971, and attracted 100 participants. There were 34 papers in six technical sessions.

Dr. Dasher died of congestive heart failure on December 13, 1971 in Houston, Texas.

Frontiers in Education Conference Helen Plants Award Best Nontraditional Session at FIE 2012

Special Session: Connecting with Community: Empathy, Experience, and Engineering with Elders, FIE 2012, Session S1A

Lynn Andrea Stein is a founding faculty member of the Franklin W. Olin College of Engineering, where she is Professor of Computer and Cognitive Science and Associate Dean for External Engagement and Initiatives. Stein's research, at Olin and over a decade on the faculty of MIT, spans the fields of artificial intelligence, programming languages, and human-computer interaction. She is a co-author of the foundational documents of the semantic web and the "mother" of a humanoid robot and an intelligent room. Stein is also active in the engineering and computer science education communities, a member of curricular advisory boards, and a frequent speaker at educational conferences on work including pioneering curricular applications of inexpensive robotics, an innovative curriculum for introductory computer science, and curricular change processes with academia. In 2009, Stein was named the founding director of Olin's Initiative for Innovation in Engineering Education.

Caitrin Lynch is a cultural anthropologist with cross-cultural expertise in labor, gender, and aging. An Associate Professor of Anthropology at Olin College of Engineering, she is also a Visiting Research Associate in the Department of Anthropology at Brandeis University. She is the author of two books, *Juki Girls, Good Girls: Gender and Cultural Politics in Sri Lanka's Global Garment Industry* (Cornell, 2007) and *Retirement on the Line: Age, Work, and Value in an American Factory* (Cornell, 2012). She is editor, with Jason Danely, of a collection of essays on aging and the life course: *Transitions and Transformations: Cultural Perspectives on Aging and the Life Course* (Berghahn, 2013). Lynch also is the producer of a documentary film "My Name is Julius" (directed by Titi Yu); see www.juliusfilm.com. Lynch strives to expose engineering students to critical analysis and identification of the burgeoning needs and opportunities in our aging world. One outlet for these efforts is in her interdisciplinary service-learning course (co-taught with faculty in engineering and design and created with Lynn Andrea Stein) "Engineering For Humanity: Helping Elders Age in Place through Partnerships for Healthy Living" (http://e4h.olin.edu/).

About the Plants Award

The Helen Plants Award is given for the best special (non-traditional) session at the FIE conference, as demonstrated by originality, session content and presentation including the use of written materials and visual aids, and participation of session attendees.

About Helen Margaret Lester Plants

Helen Margaret Lester was born in Desloge, Missouri, in March 1925, the only child of Rollo Bertell and Margaret Stephens Lester.

She entered the University of Missouri as a journalism major, but soon switched to Civil Engineering. She received her BSCE in 1945. She joined West Virginia University in 1947 as a graduate student and Instructor in Mechanics, and received her MS in Civil Engineering in 1953. She was a Professor of Theoretical and Applied Mechanics and of Curriculum and Instruction in the Division of Education at WVU. She became Professor Emeritus, Mechanical and Aerospace Engineering in 1983. From 1985 to 1990 she served as Chair of Civil Engineering Technology at Indiana University-Purdue University - Fort Wayne.

Her husband Ken Plants had been a "bureaucrat" with the US Bureau of Mines in Morgantown - a chemical engineer with great expertise in cost estimation. Some of their "courting" evenings were spent manually checking the design calculations on the Star City, WV Bridge, designed by the Dean and State Bridge Engineer. While in Morgantown, Helen was active in Trinity Episcopal Church where she served as a Vestryman and Bishop's Man. For many years she was a Girl Scout leader. Helen died in Tulsa, Oklahoma in September 1999.

From the beginning of her academic career, she was a gifted teacher and a role model for the few women students at West Virginia University at that time. Later, she became an advocate of programmed and individualized instruction. She and Wally Venable wrote series of papers on these topics and several texts: *Introduction to Statics, a Programmed Text*, (1975), *A Programmed Introduction to Dynamics* (1967), and *Mechanics of Materials, A Programmed Textbook* (1974). She established the first doctoral program in Engineering Education at West Virginia University.

In 1975, the University of Missouri at Columbia recognized her with the Missouri Honor Award for Distinguished Service in Engineering. She became an ASEE Fellow in 1983 as a member of the first class of Fellows. She also received Distinguished Service Award, Western Electric Fund Award, and was an ASEE Vice-President (1974 – 1976).

Jennifer Karlin
South Dakota School of Mines and Technology

Frontiers in Education Conference
Ronald J. Schmitz Award

For outstanding contributions to the conference series though her steering committee activities and especially her organization, coordination and management of the 2011 FIE conference in Rapid City, South Dakota

Dr. Jennifer Karlin received her undergraduate degree from Washington University in St. Louis and her Ph.D. in industrial and operations engineering from the University of Michigan, specializing in engineering management. As far as her committee could determine, she was the first person in the Industrial and Operational Engineering department to successfully defend a solely qualitative methodology dissertation. While a graduate student at the University of Michigan, she taught a senior elective and worked for the Center for Research on Learning and Teaching. Dr. Karlin is now an associate professor of industrial engineering at the South Dakota School of Mines and Technology. She teaches courses in engineering management, quality, strategy, and operational excellence in both the industrial engineering and engineering management undergraduate and technology management graduate programs. She is also the Coordinator of Faculty Development for the university.

These days, the majority of Dr. Karlin's research is in learning organizations, holistic learner development, and impact of engineering education on economic development. In 2006, Jennifer received a National Science Foundation CAREER award to continue her study of organizational and student learning, determining the relative organizational health of colleges and departments of engineering and correlating this to changes in student intellectual development. Her work has been funded by the National Science Foundation, the United States Air Force (through a congressional earmark), and the Material Handling Industry of America (MHIA).

Dr. Karlin has been active in FIE serving as conference general co-chair for the 2011 conference and an ERM representative on the FIE steering committee. She has also served as an ERM Board Member. She received the ASEE ERM Division Distinguished Service award in 2011.

Frontiers in Education Conference Ronald J. Schmitz Award (continued)

About the Schmitz Award

The Ronald Schmitz Award is given to recognize outstanding and continued service to engineering education through contributions to the Frontiers in Education Conference.

About Ronald J. Schmitz

Ronald J. Schmitz was born near Ionia, Iowa on April 25, 1934. He attended a one-room country school through the eighth grade and then, as was not uncommon at the time, decided to forgo high school and work on his father's farm. At age 18, he joined the United States Navy. He served as an Electricians Mate, spending much of his enlistment at sea and made a round-the-world cruise aboard the USS Saipan.

In the Navy, Ron found an interest in and an aptitude for technology and recognized the need for further education. He completed a GED program in the Navy and, when he was discharged, enrolled in electrical engineering at Iowa State University. He received all his degrees there, finishing his doctorate in 1967.

In the fall of 1967, he accepted appointment as Assistant Professor in the Department of Electrical Engineering at the South Dakota School of Mines and Technology in Rapid City. He was involved in various research activities and directed both masters and doctoral students, but his strongest interest was always in teaching. Ron was a consummate teacher, patient with students who were having difficulty but intolerant of sloth. He received the School of Mines Teaching Award in 1975 and the Western Electric Fund Award for Excellence in Teaching in 1981.

Dr. Schmitz was very active in the IEEE, especially the Education Society, and served as Secretary Treasurer of the Society. He was also active in ERM and attended, and contributed to, many Frontiers in Education Conferences. He served as general chair of FIE 1981 in Rapid City.

Ron was an avid hunter and fisherman, a devoted husband and father and a faithful friend. He served his church as Lector and Lay Minister and was active as a Boy Scout leader.

Ron contracted cancer in 1983 and died on July 19, 1984.

IEEE Education Society William E. Sayle II Award for Achievement in Education

Presented by name

For innovative approaches to engineering education and inspiring young people to pursue a career in engineering

Dr. Karen Panetta is a Fellow of the IEEE. Dr. Panetta received the B.S. in Computer Engineering from Boston University, and the M.S. and Ph.D. in Electrical Engineering from Northeastern University. She is the 2013 Vice-President of Communications and Public Relations for IEEE-USA. She is the Editor-in-Chief of the award winning IEEE Women in Engineering Magazine and Editor of the IEEE Boston "Reflector" Newspaper. She served as the 2011 Chair of the IEEE Boston Section. During 2009-2007, she served as the Chair for the IEEE Women in Engineering, overseeing the world's largest professional organization supporting women in engineering and science.

She is the Associate Dean for Graduate Education and a Professor of Electrical and Computer Engineering at Tufts University. She is the Director of the Simulation Research Laboratory. Her research focuses on developing efficient algorithms for simulation, modeling, signal and image processing for security and biomedical applications.

Before joining the faculty at Tufts, Dr. Panetta was employed as a computer engineer at Digital Equipment Corporation. Her research in Simulation and Modeling has won her research team five awards from NASA for "Outstanding Contributions to NASA Research" and "Excellence in Research". She is a NASA Langley Research Scientist "JOVE" Fellow, is a recipient of the NSF Career Award and won the 2003 Madeline and Henry Fischer Best Engineering Teacher Award. Dr. Panetta was also awarded a Mass High Tech All-Star by Mass High Tech Magazine. She is the recipient of the 2006 Boston University Outstanding Alumni Award and was a recipient of the "Be The Change" award from the Massachusetts Conference for Women. She is the 2009 Norm Augustine Award recipient from the National Academies of Engineering and Science, American Association of Engineering Societies. In 2010, the IEEE recognized Dr. Panetta by awarding her the IEEE Educational Activities Board, Major Educational Innovation Award. In 2011, she was awarded the "Women of Vision" award from the Anita Borg Institute and the IEEE Education Society Harriet B. Rigas Award for Outstanding Engineering Educator. In 2011, U.S. President Obama presented Karen with the NSF Presidential Award for Excellence in Science, Mathematics and Engineering Mentoring. In 2013, she was awarded the E-Week New England Leadership award and the IEEE Award for Ethical Practices.

Dr. Panetta serves on the Boston University Engineering Alumni Board and is a board member for the Center for Balance by Design. She is also a member of the ACM, AAAS, AWIS, SWE, SPHE, Tau Beta Pi, ASEE and the Society for Computer Simulation. She is the faculty advisor to both the Tufts SWE and IEEE student chapters.

Believing that real world experience is critical for engineering education, Dr. Panetta maintains consulting positions in industry and brings her experience back to the classroom. She is a Design Consultant for Tycoelectronics, M/A-Com Inc. and consults for school systems and Science Museums across the United States to inspire engineering and technology education.

Dr. Panetta is dedicated to promoting women in engineering and created the nationally acclaimed "Nerd Girls" program, where undergraduate engineers use their engineering skills to solve real world problems and serve as role models for younger students. By showing youth how engineering helps society and can improve the quality of life for humans and wildlife, Karen Panetta has connected young students with the motivation for pursuing engineering careers.

The IEEE.tv video, "Nerd Girls", which demonstrates Karen's most successful mentoring and recruiting philosophy, shows that female engineers are smart, well-rounded, talented girls. The video has won an APEX GRAND award and an Aegis Award for Best Educational Outreach video. The IEEE.tv video, "Ship the Chip" documented Karen personally mentoring 100 female students from a diversity of ethnic and socio-economic backgrounds. The participants included both physically challenged girls and girls with learning disabilities, all exploring the excitement of engineering as a team.

About the Sayle Award and William E. Sayle II

The William E. Sayle II Award is presented to recognize a member of the IEEE Education Society who has made significant contributions over a period of years in a field of interest of the IEEE Education Society. The award consists of a plaque, a certificate, and paid registration to the Frontiers in Education Conference.

Dr. William (Bill) E. Sayle received his BSEE and MSEE degrees from the University of Texas at Austin and his Ph.D. from the University of Washington. He joined the faculty in electrical engineering at Georgia Institute of Technology in 1970, just as Georgia Tech was beginning the transition from an undergraduate institution to a research university. He was the ECE associate chair for undergraduate affairs from 1988-2003 and, following retirement in 2003, served as director of undergraduate programs at Georgia Tech-Lorraine in France until 2007. Bill was a tireless advocate for students, putting in countless late night and weekend hours in addressing student issues, assigning teaching assistants, and meeting with prospective students and parents.

Throughout his career, Bill touched the lives of many people in the worldwide academic community. He was a leader and a pioneer in many areas. In the 1970s, he was a founding member of the IEEE Power Electronics Society, where he served in many leadership roles over the years. He was a champion of diversity and in recruiting underrepresented minorities and women to engineering and science, long before it became a national issue. He visited many high schools on behalf of the Southeastern Consortium for Minorities in Engineering, a role where he made many friends for Georgia Tech among high school administrators and students in the southern part of Georgia.

In his 30-year career at Georgia Tech, Bill received the ECE outstanding teacher award twice, as well as the Georgia Tech outstanding teacher award and outstanding service award. Bill lent his voice and efforts to Georgia Tech faculty governance throughout his career, serving as an elected member of Institute-level committees, the Academic Senate, and the Executive Board.

Bill was a long-time member and active volunteer in the IEEE Education Society and the Electrical and Computer Engineering Division of ASEE. He was a Fellow of both IEEE and ASEE. He was the recipient of the Education Society's 2001 Meritorious Service Award and 2004 Achievement Award and of the ECE Division's 2001 Meritorious Service Award and 2006 ECE Distinguished Educator Award. Bill was the General Chair of the 1995 Frontiers in Education (FIE) Conference, which is still remembered for its all-vegetarian menu, and received the 1996 Ronald J. Schmitz Award for outstanding service to FIE.

Much of Bill's professional career was devoted to engineering accreditation, serving at various times as member and chair of the IEEE Committee on Engineering Accreditation Activities and the IEEE Accreditation Policy Council. He participated in more than 20 visits as a program evaluator, in addition to serving as a team chair and member of the Engineering Accreditation Commission of ABET for more than five years. Bill received the IEEE Educational Activities Board Meritorious Achievement Award in Accreditation Activities in 2004.

Dr. Sayle passed away on February 2, 2008.

IEEE *Transactions on Education* Best Paper Award

***Factors That Influence Dissemination in Engineering Education*, Benjamin T. Hazen, Yun Wu and Chetan S. Sankar, IEEE Transactions on Education, Vol. 55, Issue 3, pp. 384-383, August of 2012.**

Benjamin Hazen
U.S. Air Force

Yun Wu
Auburn University

Chetan Sankar
Auburn University

Benjamin T. Hazen received the B.S. degree in Business Administration from Colorado Christian University, in 2004. He received the M.A. degree in Organizational Leadership from Gonzaga University, in 2006, the M.B.A. degree from California State University, Dominguez Hills, in 2007, and the Ph.D. degree in Management from Auburn University, in 2012.

He is a United States Air Force maintenance officer and has served on active duty continuously since 1999. From 1999 to 2002, he served as a Satellite and Wideband Communications Journeyman at Tinker Air Force Base, Oklahoma. He then managed the Engineering Laboratory in the Department of Astronautics at the United States Air Force Academy, Colorado, from 2002 to 2006. From 2006 to 2009, he served in a variety of aircraft maintenance positions at Travis Air Force Base, California. From 2009 to 2012, he participated in an advanced degree program and worked as a Doctoral Candidate in the Department of Aviation and Supply Chain Management at Auburn University. Currently, he serves as the Maintenance Operations Officer for the 916th Maintenance Squadron at Seymour Johnson Air Force Base, North Carolina. His primary research interest is in the area of innovation diffusion.

Yun Wu received the B.S. degree in Management Information Systems from Beijing University of Post and Telecommunications, China, in 2005. She received the M.S. degree in Management Engineering from Politechnico di Milano, Italy, in 2007.

She is currently a Doctoral student in the Department of Aviation and Supply Chain Management at Auburn University. Her research interests include IT innovation diffusion, cloud computing, healthcare information systems and pedagogy dissemination.

Chetan S. Sankar (M ’81-SM ‘88) received the B.S. degree in Mechanical Engineering from Regional Engineering College, Trichy, India, in 1971, and the M.B.A. degree from Indian Institute of Management Calcutta, India, in 1973. He received the Ph.D. degree in Decision Sciences from the Wharton School, University of Pennsylvania, in 1981.

From 1973 to 1974, he worked as an inventory control manager at Balmer Lawrie & Co., Ltd. He was a Research Fellow at the Indian Institute of Management, Calcutta, from 1974 to 1977. He served as an Assistant Professor at Temple University, from 1981 to 1985. He then worked as a project manager at AT&T Bell Laboratories, from 1985 to 1989. In 1989, he joined the faculty at Auburn University, where he is currently the College of Business Advisory Council Professor of Information Systems, and the Director of the Geospatial Research and Applications Center at Auburn University. He has received more than three million dollars from grants sponsored by the National Science Foundation and Economic Development Administration to develop exceptional instructional

materials that bring real-world issues into classrooms and to help communities recover from disasters effectively. He serves as the Editor-in-Chief of the Decision Sciences Journal of Innovative Education and the Managing Editor of the Journal of STEM Education: Innovations and Research. His research interests include improving instructional and pedagogy methodologies and innovative uses of information technologies to benefit the public.

Dr. Sankar has won awards for research and teaching excellence from the Society for Information Management, NEEDS, Decision Sciences Institute, American Society for Engineering Education, American Society for Mechanical Engineering, International Network for Engineering Education & Research, and the Project Management Institute.

IEEE India Council

Deepak Garg
Chair

Raghu Raman
Past Chair

Prashant R. Nair
Vice Chair

IEEE Education Society Chapter Achievement Award

For exemplary technical activities, membership services, societal activities to its members, and for outstanding leadership by Chapter officers

Dr Deepak Garg is currently faculty in Computer Science and Engineering Department of Thapar University, Patiala. He holds a PhD in Efficient Algorithm Design for Pattern Discovery. He has more than 100 publications to his credit. He is the Chair of Steering Committee of IEEE International Advanced Computing (IACC) Series of Annual Conference. He is also the chair of Steering Committee of IEEE International Conference in MOOC, Innovation and Technology in Education.

He is currently the Chair of IEEE Computer Society, India Council and the Chair of IEEE Education Society, India Council. He is the Chair of ACM SIGACT North India Chapter. He is teaching UG and PG courses and guiding PhD students in different areas of algorithms. He has executed few projects with funding from Indian Govt. His workshops on Advanced Algorithms and data structures are very popular. Currently his research areas are advanced algorithms, Theoretical Computer Science and Bioinformatics.

Prof. Raghu Raman currently heads the Center for Research in Advanced Technologies for Education (CREATE) at Amrita University, India. As Principal Investigator for multiple research projects totaling over $2.3m, Raghu's main research focus is in the area of computational intelligence for Intelligent and Adaptive Learning Systems, Virtual Interactive learning environments, and Diffusion of ICT Innovations.

Prior to joining Amrita, Raghu worked at NEC Research Labs, USA on the Intelligent Video surveillance technology using neural networks that was ultimately spun out into a new venture. Formerly, Raghu was the Executive Director of Product Development at IBM, where he provided product leadership and direction for engineering groups with full responsibility for operations and budget control of an annual budget of over $8m. Raghu holds an MBA from Haas School of Business, UC Berkeley and is the recipient of President's gold medal. He serves on the board of directors for Amrita Technology Business Incubator; as Member, Standing Committee, National Mission on Education through ICT (NME ICT) and is the past chair of IEEE Education Society Chapter, IEEE India Council.

Mr. Prashant R. Nair is the Vice-Chairman - Information Technology at Amrita School of Engineering, Amrita University, Coimbatore in South India. Since 2000, he has been on the faculty of Amrita University, where he also teaches at the Business School and Centre of Excellence in Cyber Security. Since 2008, he has been holding the administrative responsibility of Vice-Chairman for Accreditation & Quality Assurance for Amrita University. He has taught at academic programs in USA and Europe at University of California, San Diego and Sofia University, Bulgaria as an Erasmus Mundus fellow. His research interests include Application of ICT tools for Supply Chain Management & Education, Cyber Security and Internet Technology. He completed his B.E from Bharathiar University and MBA from Amrita School of Business, Coimbatore, which is ranked among the top 25 B-schools in India.

Om Vikas
Chair, Policy and Planning

Past Recipients
’06 Nordic Chapter
’07 Spanish Chapter
’08 Gulf Chapter
’09 Santa Clara Valley Chapter and Portugal Chapter
’10 Austria Chapter
’11 Spain Chapter
’12 Hong Kong Chapter

He has served on the program committee of over 60 international conferences including the IEEE International Conference on Technology Enhanced Education (ICTEE) 2012, IADIS WWW/Internet conference, and editorial board of 3 international journals including Computer Society of India (CSI)Transactions on ICT, a Springer Journal. He is presently holding several leadership roles in professional bodies like Student Activity Chair (SAC) of IEEE Computer Society, India Council; Executive Committee member of IEEE Madras Section and Member of National Student Committee of CSI. He is the Associate Site Director for ACM International Collegiate Programming Contest (ICPC), which is considered as the world championship of programming. Various Awards won include ASDF Award for Best Academic Administrator (2012) and CSI Academic Excellence award (2011).

Dr. Om Vikas possesses B Tech(EE), M Tech(EE), Ph.D.(CSE) all from IIT, Kanpur. Formerly Director/VC, ABVIIITM (Indian Institute of Information Technology & Management) Gwalior, Senior Director in the Department of Electronics & Information Technology (DE&IT, Govt of India), and Counselor (Science & Technology) in Indian Embassy, Tokyo, Japan. In DE&IT, he headed Technology Development for Indian Languages Mission and Computer Manpower Development Division. He served in TCS as System Engineer. He was visiting professor at IIT/K, adjunct professor at IIT/D & NSIT; Professor in charge CLASS project at NCERT, Director, IP Engineering College, Advisor to C-DAC, and on Academic Councils of various universities / Institutions. Currently he is Professor-Emeritus at Mahamaya Technical University.

He has vast experience of designing curricula 1-to-12 school level (Vocational & Academic) for CBSE, and UG & PG curricula – Computer Applications, Knowledge Engineering, Industrial Informatics, Engineering Education, etc. He is invited as Expert Assessor of NBA/AICTE and NAAC/UGC for assessment & accreditation of technical programmes / institutions. He is member of Organizing Committee of World Summit on Accreditation WOSA -2014. Dr. Vikas received several awards for his outstanding contribution towards IT for masses.

IEEE Education Society
Distinguished Chapter Leadership Award

For his efforts to make Colombia the 2nd largest chapter in our Society, sponsoring many activities, and being directly involved in the development of the chapter, providing meaningful service in Colombia

Jesus Alfonso Perez Gama was a tenured professor and university master fellow at the National University of Colombia, as well as director of the Master and Systems Engineering Undergraduate Program and University Superior Council Teacher representative. Currently Alfonso is the faculty engineering dean at the Foundation of Higher Education, San Jose and is also director of the International Research Group, San Jose EIDOS. He has conducted several research projects dealing with social and economic problems for tertiary education, using mathematical and computational models and artificial intelligence, which were sponsored by Colciencias, CYTED-D (Spain - V Centenary) and the Ministry of National Education and FODESEP.

Alfonso is a graduate of the Mayor San Bartolome. He also studied Electronic Engineering at the U City University of Bogota and received a Master of Science from the University of Essex, UK and a Systems Engineering Magister from the National University and Economics Graduate Program at Universidad de los Andes, Bogota. He is IEEE Senior Life Member and a member of the New York Academy of Sciences, the International Council on Systems Engineering, the International Input Output Association, the International Institute of Software Architects, Systems Engineering Colombia Association, and the Colombia Informatics Association, which he chairs.

He has received the James Rooke Honorary Scholarship, granted by British Council; the 2012 Roberto Valenzuela IEEE Life and Achievement Award; and the City University Francisco Jose de Caldas IEEE Student Branch 50 Years with Professional Excellence recognition. Alfonso was also recognized for his *A Successful Case in Superior Education: Mathematical and Computer Model for Engineering Using Propaedeutic Cycles*, which was included in the Bank of Significant Experiences in Higher Education 2010 by Ministry of National Education of Colombia.

Victor Nelson
Auburn University

IEEE Education Society Distinguished Member Award

For leadership and service on the Board of Governors; as chair of the Constitution and By-Laws Committee; and related professional contributions through publications, accreditation activities, and as an associate editor

Victor P. Nelson is a Professor and Assistant Chair of Electrical and Computer Engineering at Auburn University, where he has been on the faculty since 1978. His primary research interests include embedded systems and computer-aided design and testing of digital systems and application-specific integrated circuits (ASICs). He is co-author of the textbook *Digital Logic Circuit Analysis and Design* and IEEE tutorial book *Fault-Tolerant Computing*. He is past chair of the ECE Curriculum Committee and coordinator of the ECE Graduate Program, and served one year as Associate Dean for Assessment in the College of Engineering. He was a co-winner of the 2005 "Wireless Educator of the Year" award from the Global Wireless Education Consortium for his role as one of the developers of the Bachelor of Wireless Engineering program at Auburn University, which is the first of its kind in the U.S., and currently serves as the director of that program. He received the Birdsong Merit Teaching Award in 2000 and the Walker Merit Teaching Award in 2002 from the College of Engineering, and was named outstanding member of the Graduate Faculty in 2004.

He is a member of the IEEE Education Society, in which he has served as a member of the Board of Governors, chair of the Constitution and Bylaws committee, and previously as an associate editor of the *IEEE Transactions on Education*. He was a member of the IEEE Computer Society/ACM Task Force that developed the *Computer Engineering 2004* report on model computer engineering curricula. He is active in accreditation activities, having served as an ABET program evaluator and a current member of the ABET Engineering Accreditation Commission, and previously as a member and mentor coordinator of the IEEE Committee on Engineering Accreditation Activities (CEAA). He is also a member of ASEE, and previously served as chair of the ASEE ECE Division.

IEEE Education Society Edwin C. Jones, Jr. Meritorious Service Award

For his outstanding contributions and service as the Editor in Chief of the IEEE Transactions on Education

Charles Fleddermann is a Professor of Electrical and Computer Engineering and Associate Dean of the School of Engineering at the University of New Mexico (UNM) where he has been on the faculty for over 27 years. He also has served as Dean of Graduate Studies at UNM. Prof. Fleddermann earned his Ph.D. and M.S. degrees in electrical engineering from the University of Illinois at Urbana-Champaign, and a B.S. degree, also in electrical engineering, from the University of Notre Dame.

Dr. Fleddermann is a senior member of the IEEE, and is also a member of the ASEE. He has served as the Editor in Chief of IEEE Transactions on Education (ToE); previous to that he was an Associate Editor for the journal. He serves as an electrical engineering program evaluator for the Accreditation Board for Engineering and Technology (ABET).

His research interests are in engineering education, photovoltaics, plasma processing of electronic materials, optical diagnostics of plasma systems, and engineering ethics. He has taught a variety of courses at both the undergraduate and graduate levels, including on-line courses. He has developed and taught a course on professional ethics for engineers, and has been involved in research projects in the area of ethical issues in nanotechnology. He has also taught professional development seminars on ethics for engineers in New Mexico and elsewhere in the U.S. over the past few years. He is the author of two textbooks: the 4th edition of *Engineering Ethics,* was released in 2011; and he co-authored *Introduction to Electrical and Computer Engineering*, intended to help first-year students develop knowledge and strategies for success in the profession.

About the Edwin C. Jones Award

The Edwin C. Jones Meritorious Service Award is presented to recognize a member of the IEEE Education Society who has made pioneering contributions to the administrative efforts of the IEEE Education Society over a period of years. The award consists of a plaque, a certificate, and registration to the Frontiers in Education Conference.

About Edwin C. Jones

Professor Jones served as a Society officer from 1970 through 1976; this service included two years as president. He served as Editor-in-Chief of the *IEEE Transactions on Education* from 1982-84. Since he first became involved in the Society in the late 1960s, he has held virtually every office in the Education Society. He is still actively involved with the Education Society. Professor Jones also serves the IEEE as a member of the IEEE Committee on Engineering Accreditation Activities. Dr. Jones is University Professor and Associate Chair, emeritus, Department of Electrical and Computer Engineering, Iowa State University. Prior to joining Iowa State in 1966, he was an Assistant Professor at the University of Illinois from 1962-66. He received his PhD in 1962 from the University of Illinois; the DIC in 1956 from Imperial College of Science and Technology, University of London; and the BSEE in 1955 from West Virginia University. Dr. Jones' honors and awards include: Fellow, Institute of Electrical and Electronics Engineers; Fellow, American Society for Engineering Education; Fellow, American Association for Advancement of Science; Fellow, Accreditation Board for Engineering and Technology; IEEE Centennial Medal, 1984; ASEE Centennial Medal, 1993.

IEEE Education Society Mac Van Valkenburg Early Career Teaching Award

For his innovative teaching approach, simultaneous emphasis on disciplinary rigor and on the societal implications of engineering in his classes, and his deep commitment to inspiring engineering students to address high-value global development problems in resource limited settings

Muhammad H. Zaman is Associate Professor of Biomedical Engineering at Boston University. He also holds appointments in the Department of Medicine and the Department of International Health at Boston University School of Medicine. Prof. Zaman is also Associate Chair of Biomedical Engineering and Associate Director of Kilachand Honors College at Boston University. Prof. Zaman got his PhD in Physical Chemistry from the University of Chicago in 2003, where he was a Burroughs-Wellcome Graduate Fellow in Interdisciplinary Sciences. After his Ph.D. he was a Herman and Margaret Post-Doctoral Fellow at MIT from 2003-2006. He was Assistant Professor of Biomedical Engineering at UT Austin from 2006-2009 and moved to BU in Fall 2009. His lab focuses on developing new experimental and computational technologies for high value healthcare problems in both the developing and developed world.

Prof. Zaman is actively involved in two areas of research. The first is developing new tools and quantitative understanding of tumor formation and tumor metastasis. The second is developing robust and affordable diagnostic technologies for the developing world. He is working on capacity building and engineering education in these countries as well. Technologies developed by Prof. Zaman and his team are in various stages of implementation in multiple African countries.

Additionally, Prof. Zaman is actively involved in bringing high quality engineering education to developing countries. He is currently involved in setting up the first biomedical engineering departments at various African Universities in Kenya, Zambia, Uganda and Ethiopia. He is also a member of the technical committee of the UN Economic Council on Africa (UNECA) and co-Director of the UNECA biomedical innovation program in Africa. He contributes regularly on issues in engineering and development as a regular op-ed columnist to various newspapers and magazines including the Huffington Post and Express Tribune (one of the leading English daily newspaper in Pakistan).

Prof. Zaman’s emphasis on excellence in teaching has been a major part of his academic career. His contribution to engineering education has been highlighted by the New York Times, NPR and a number of other organizations. Prof. Zaman has won numerous awards for his research and teaching, including BU College of Engineering Early Career Research Excellence Award, Saving Lives at Birth Innovator Award, Tewkesbury Fellowship, American Society for Engineering Education Outstanding Assistant Professor Award, BME outstanding teacher award at UT Austin, College of Engineering Outstanding Teaching by an Assistant Professor Award at UT Austin and the highest award for teaching in the entire UT System, the UT System Regents Outstanding Teaching Award. He has been invited by the National Academies of Engineering to participate in both frontiers of engineering and frontiers of engineering education as well as Japan-US Frontiers of Engineering.

IEEE Education Society Student Leadership Award

For exemplary leadership in the execution of programs and continuous improvements of the IEEE Education Society Student Activities Committee (SAC) and excellent performance in the upgrading of the IEEE Technology in Engineering Education (formerly IEEE Multidisciplinary Engineering Education Magazine)

Subhamoy Mandal (StM’04, GSM’08) is currently a DAAD PhD Scholar with the Institute of Biological and Medical Imaging at TU München and Helmholtz Zentrum München. He received his MS (by research) from the Indian Institute of Technology Kharagpur, and B.E. in Biomedical Engineering from Manipal University, Karnataka, India. Subhamoy’s areas of interest are Medical Signal & Image Processing, Medical Imaging and DSP/GPU based algorithm design. His current research pertains to visual quality enhancement and development of novel methods for optoacoustic (photoacoustic) imaging.

Subhamoy is an active Member of IEEE, and is the Student Rep and AdCom member of its Engineering in Medicine and Biology (EMB) Society, and the 2010-13 Chair, IEEE Education Society Student Activity Committee (IEEE EduSocSAC). As the Chair of the EdSocSAC he was instrumental in designing and implementing the IEEE TechSym, a unique student only conference which is archived in IEEE Xplore DL. Further, he initiated the IEEE Direct to Student (D2S) and One World- One Education (1WoE), which has achieved notable initial success. Subhamoy was the Founding Chair, IEEE EMB Student Club of IIT Kharagpur, which was awarded the Best New Student Club/Chapter Award 2010 by IEEE EMBS Student and Member Activity Committee. He has been a Member of IEEE Ad-hoc Committee on Social Media Policy reporting directly to the IEEE Board of Directors, founding Chair of the IIT Kharagpur GOLD Affinity, and also actively volunteered with the IEEE Student Branches at IIT Kharagpur(Treasurer 2009-10) and MIT Manipal (2005-07).

Subhamoy has been closely associated with several corporate organizations including Philips, GE and Microsoft. During his internships with Philips and the master’s thesis, he has focused on developing low cost point of care technologies to address healthcare challenges of emerging economies. At GE Global Research his primary area of focus has been Magnetic Resonance Imaging (MRI) and its application in Brain Iron Quantification, leading to early diagnosis of Alzheimer's and other neuro-degenerative diseases.

Subhamoy’s goal is to achieve success in innovating point-of-care healthcare solutions using expertise of biomedical engineering and domain knowledge of medical sciences by synchronized efforts in a collective venture. He aims to leverage the acumen and experiences gained through his own training to encourage growth of better educational and technical training facilities in emerging economies, including the Indian Subcontinent.

IEEE Education Society Student Leadership Award

For exemplary leadership in the execution of programs and continuous improvements of the IEEE Education Society Student Activities Committee (SAC) and excellent performance in the upgrading of the IEEE Technology in Engineering Education (formerly IEEE Multidisciplinary Engineering Education Magazine)

Xinyou Zhao was born in Biyang Village, Henan Province, China in 1976. He received the B.S. degree in computer education from Xinyang Normal University, China, in 2000 and obtained the M.S. degree in Computer Science from Guilin University of Electronic Technology, China, in 2003. He was awarded a Ph.D. degree in Engineering at Graduate School of Information Systems, The University of Electro-Communications, Tokyo, Japan, in 2010.

From 2003 to 2007, he worked as a lecturer at Guilin University of Electronic Technology, Guilin, China. During May 2005 to April 2006, he was also a visiting scholar in Matsumoto Research Lab., GITI, Waseda University, Tokyo, Japan. Now he is working at ACARIC Co. Ltd as a system engineer, Tokyo, Japan. He is also a guest researcher in Advanced Research Center for Human Sciences, Waseda University, Tokorozawa, Japan. He has published more than 30 papers in national and international journals and conferences and numerous technical reports. His research interests include mobile learning, data mining with big data, intelligent tutoring system and multimedia technology.

Dr. Zhao was a recipient of the Best Ph.D. Student Award of 11th International Conference on Computers and Advanced Technology in Education (CATE 2008), Conference Presentation Grant of C&C NEC Foundation, 2008, Conference Presentation Grant of The Hara Research Foundation, 2010 and Doctoral Fellowship of Japanese Ministry of Education, Culture, Sports, Science and Technology, 2008 - 2010.

REVIEWERS

This year, FIE 2013 had over 600 papers and presentations submitted for consideration. The FIE2013 Program Committee wishes to thank the following individuals for acting as abstract and paper reviewers. The program committee asked these individuals to help control the quality of the presentations at this year's conference by reviewing the submissions for FIE2013. Their outstanding effort has helped maintain the high standard that has become the reputation of each FIE conference.

SESSION CHAIRS

The conference committee would like to thank the people that have agreed to act as session chairs at the 2013 Frontiers in Education Conference. Session chairs play an important role in ensuring the conference runs smoothly and that the technical presentations are a valuable experience for both speakers and attendees. Session chairs also have served a critical role in helping with the Ben Dasher Award process.

The primary responsibilities of session chairs are to:

- Read the session's papers in advance and recommend papers for the Ben Dasher Best Paper committee.
- Contact the authors in the session and become familiar with the authors who are presenting.
- Introduce the session and make any FIE announcements that are needed.
- Briefly introduce each speaker and paper.
- Manage audience questions, and ensure that presentations begin and end within their time slots.

The program committee would like to thank the following individuals for their efforts to help make FIE2013 both informative and successful:

Session	**Time**	**Room**	**Session chairs**	**Affiliation**
T1C: Approaches to Student-Centered Learning I	10:00 AM	Room 16	Irene Rothe	Bonn-Rhine-Sieg University
T1D: Student Beliefs, Motivation & Persistence I	10:00 AM	Room 17	Lisa Benson	Clemson University
T1E: Software Engineering, Computing & Informatics Education I	10:00 AM	Room 18	Walter Schilling	Milwaukee School of Engineering
T1F: Innovation and Entrepreneurship I	10:00 AM	Room 19	Gurdip Singh	Kanas State University
T1G: First and Second Year Programs I	10:00 AM	Room 20	Kurt Thoroughman	Washington University in St. Louis
T1H: Assessment I	10:00 AM	Room 2	Ashutosh Marathe	University of Pune
T1I: Mobile and Online Learning I	10:00 AM	Room 4	Khallai Taylor	Triton College
T2C: Approaches to Student-Centered Learning II	1:30 PM	Room 16	Melany Ciampi	Safety, Health and Environment Research Organization
T2D: Teaming and Engagement	1:30 PM	Room 17	Dietrich Romberg	Anhalt University of Applied Sciences
T2E: Computing I	1:30 PM	Room 18	Rajendra Raj	Rochester Institute of Technology
T2F: ECE I	1:30 PM	Room 19	Firas Hassan	Ohio Northern University
T2G: First and Second Year Programs II	1:30 PM	Room 20	Susan Donohue	University of Virginia
T2H: Experiential Learning I	1:30 PM	Room 2	Abhijit Nagchaudhuri	University of Maryland Eastern Shore
T2I: Mobile and Online Learning II	1:30 PM	Room 4	Jacob Bishop	Utah State University
T3C: Innovative Computing Practice I	4:00 PM	Room 16	Claudio Brito	Science and Education Research Council
T3D: Real World Influences in Experiential Learning	4:00 PM	Room 17	Elif Miskioglu	The Ohio State University

Session	Time	Room	Session chairs	Affiliation
T3E: Energy Engineering Education I	4:00 PM	Room 18	Madhumi Mitra	University of Maryland Eastern Shore
T3F: Experiential Learning II	4:00 PM	Room 19	Wookwon Lee	Gannon University
T3G: Game-Based Learning I	4:00 PM	Room 20	Amir Zeid	American University of Kuwait
T3H: Open Educational Resources and Practices I	4:00 PM	Room 2	Velvet Fitzpatrick	Purdue University
T3I: Inclusivity and Diversity I	4:00 PM	Room 4	Catherine Samuelson	University of Washington
F1C: Faculty Development I	8:30 AM	Room 16	Rachel Kajfez	Virginia Tech
F1D: Teams, Communication & Profession	8:30 AM	Room 17	Kelly Cross	Virginia Polytechnic Institute and State University
F1E: Philosophy of Engineering and Engineering Education I	8:30 AM	Room 18	Eric Pappas	James Madison University
F1F: ECE II	8:30 AM	Room 19	Dale Carnegie	Victoria University of Wellington
F1G: Game-Based Learning II	8:30 AM	Room 20	Srividya Bansal	Arizona State University - Poly Campus
F1H: Learning Theories	8:30 AM	Room 2	Dazhi Yang	Boise State
F1I: Approaches to Student-Centered Learning IV	8:30 AM	Room 4	Dejang Liu	College of DuPage
F2C: Online Learning I	10:30 AM	Room 16	Theodore Manikas	Southern Methodist University
F2D: Open Educational Resources and Practices II	10:30 AM	Room 17	John Skardon	California State University-Monterey Bay
F2E: Philosophy of Engineering and Engineering Education II	10:30 AM	Room 18	Dorothy Jones-Davis	National Science Foundation
F2F: ECE III	10:30 AM	Room 19	Aurenice Oliveira	Michigan Technological University
F2G: Faculty Development II	10:30 AM	Room 20	Geoffrey Herman	University of Illinois
F2H: Design and Assessment	10:30 AM	Room 2	Deborah Munro	University of Portland
F2I: pK-12 STEM I	1:30 PM	Room 4	Anthony Joseph	Pace University
F3C: Approaches to Student-Centered Learning III	1:30 PM	Room 16	Asad Azemi	Pennsylvania State University
F3D: Student as Learner	1:30 PM	Room 17	Mauricio Dziedzic	Universidade Positivo
F3E: Assessment Strategies	1:30 PM	Room 18	Manuel Castro	Spanish University for Distance Education - UNED
F3F: Learning Approaches in ECE	1:30 PM	Room 19	O'Connell Robert	University of Missouri-Columbia
F3G: Mobile and Online Learning III	1:30 PM	Room 20	Mahesh Banavar	Arizona State University
F3H: ECE IV	1:30 PM	Room 2	Vignesh Subbian	University of Cincinnati
F3I: Integrating Design Throughout the Curriculum	1:30 PM	Room 4	Aurenice Oliveira	Michigan Technological University
F4C: Student Beliefs, Motivation & Persistence II	4:00 PM	Room 16	Jia-Ling Lin	University of Minnesota Twin Cities
F4D: Innovative Computing Practice II	4:00 PM	Room 17	Irene Rothe	Bonn-Rhine-Sieg University
F4E: Cognitive and Affective Domains of Learning	4:00 PM	Room 18	Stephen Frezza	Gannon University

Session	Time	Room	Session chairs	Affiliation
F4F: Pathways to Engineering Degrees	4:00 PM	Room 19	Dorothy Jones-Davis	National Science Foundation
F4G: Inclusivity and Diversity II	4:00 PM	Room 20	Deborah Munro	University of Portland

S4I: Interdisciplinary Programs II	3:00 PM	Room 4	Mahesh Banavar	Arizona State University

SESSION GRID – WEDNESDAY, OCTOBER 23RD

	Room: 16	Room: 17	Room: 18	Room: 19	Room: 20
1:30 PM	W1A: Pre-Conference Workshop: Computer Engineering Curriculum Guidelines (FREE workshop - costs covered by NSF grant)	W1B: Pre-Conference Workshop: Modeling Software the Alloy Way	W1C: Pre-Conference Workshop: Programming Board Game Strategies in CS2	W1D: Pre-Conference Workshop: Why are continuous-time signals and systems courses so difficult? How can we make them more accessible?	W1E: Pre-Conference Workshop: Using Problets for Problem-Solving Exercises in Introductory C++/Java/C# Courses
5:30 PM	W2E: Pre-Conference Workshop: Refining a Taxonomy for Engineering Education Research (FREE workshop - costs covered by NSF grant)	W2D: Pre-Conference Workshop: Teaching Service-Oriented Programming to CS and SE Undergraduate Students (FREE workshop - costs covered by NSF grant)	W2C: Pre-Conference Workshop: An Online Revolution in Learning and Teaching: from e-books to MOOCs	W2B: Pre-Conference Workshop: The Erlang Approach to Concurrent System Development	W2A: Pre-Conference Workshop: Inspiring Inventive Genius in Middle and High School Students with Chain-Reaction STEAM Machines™

SESSION GRID - THURSDAY, OCTOBER 24TH

	Room: 14	Room: 15	Room: 16	Room: 17	Room: 18	Room: 19	Room: 20	Room: 2	Room: 4
7:00 am – 5:00 pm	Registration Location: Second Floor Prefunction Area								
7:00 am - 8:00 am	Focus on First-Time Attendees Breakfast Buffet Location: Great Hall C								
8:00 am - 9:30 am	Plenary Session Location: Great Hall A & B Keynote: Katherine Banks, Vice Chancellor and Dean of Engineering, Texas A&M University								
9:30 am – 5:00 pm	Exhibit Hall Open Great Hall D & E								
10:00 am - 11:30 am	**T1A: Mini-Workshop: Exploring Boyer's Scholarship of Application for Submissions to the IEEE Transactions on Education**	**T1B: Special Session: Assessing Lifelong Learning: The Role of Information Gathering and Application Skills**	**T1C: Approaches to Student-Centered Learning I**	**T1D: Student Beliefs, Motivation & Persistence I**	**T1E: Software Engineering, Computing & Informatics Education I**	**T1F: Innovation and Entrepreneurship I**	**T1G: First and Second Year Programs I**	**T1H: Assessment I**	**T1I: Mobile and Online Learning I**
11:45 am - 1:15 pm	HP Terman and Rigas Awards Lunch Location: Great Hall C Sponsored by the Hewlet-Packard Company								
1:30 pm - 3:00 pm	**T2A: Mini-Workshop: New National Science Foundation Opportunities for Improving Undergraduate Engineering Education**	**T2B: Panel: Model Collaboration for Advancing Student-Centered Engineering Education**	**T2C: Approaches to Student-Centered Learning II**	**T2D: Teaming and Engagement**	**T2E: Computing I**	**T2F: ECE I**	**T2G: First and Second Year Programs II**	**T2H: Experiential Learning I**	**T2I: Mobile and Online Learning II**
4:00 pm - 5:30 pm	**T3A: Mini-Workshop: Catching the Wave: Big Data in the Classroom**	**T3B: Special Session: DiSrUpTiOn**	**T3C: Innovative Computing Practice I**	**T3D: Real World Influences in Experiential Learning**	**T3E: Energy Engineering Education I**	**T3F: Experiential Learning II**	**T3G: Game-Based Learning I**	**T3H: Open Educational Resources and Practices I**	**T3I: Inclusivity and Diversity I**
6:00 pm - 10:00 pm	Transportation to and Reception at Western Museum Bus Loading Zone: Between the Renaissance Hotel and the Cox Convention Center								

SESSION GRID - FRIDAY, OCTOBER 25TH

	Room: 14	Room: 15	Room: 16	Room: 17	Room: 18	Room: 19	Room: 20	Room: 2	Room: 4
7:00 am – 5:00 pm	Registration Location: Second Floor Prefunction Area								
7:00 am - 8:30 am	Breakfast and Plenary Session Location: Great Hall C Keynote: Mike McCracken, Director of Online Course Development and Innovation, College of Computing, Center for 21st Century Universities (C2IU), Georgia Tech								
8:30 am - 10:00 am	**F1A: Mini-Workshop: Tools to Facilitate Development of Conceptual Understanding in the First and Second Year of Engineering**	**F1B: Panel: Building an Inclusive REU Program: A Model for Engineering Education**	**F1C: Faculty Development I**	**F1D: Teams, Communication & Profession**	**F1E: Philosophy of Engineering and Engineering Education I**	**F1F: ECE II**	**F1G: Game-Based Learning II**	**F1H: Learning Theories**	**F1I: Approaches to Student-Centered Learning IV**
9:00 am - 4:30 pm	Exhibit Hall Open Location: Great Hall D & E								
10:30 am - Noon	**F2A: Mini-Workshop: Why are continuous-time signals and systems courses so difficult? How can we make them more accessible?**	**F2B: Special Session: True Grit: Toward a Culture of Psychological Preparedness in Engineering Education**	**F2C: Online Learning I**	**F2D: Open Educational Resources and Practices II**	**F2E: Philosophy of Engineering and Engineering Education II**	**F2F: ECE III**	**F2G: Faculty Development II**	**F2H: Design and Assessment**	**F2I: pK-12 STEM I**
Noon - 1:30 pm	Luncheon Location: Great Hall C								
1:30 pm - 3:00 pm	**F3A: Special Session: What is the Role of MOOCs in Engineering Education?**	**F3B: Special Session: Defining and Assessing Engineering Ethics**	**F3C: Approaches to Student-Centered Learning III**	**F3D: Student as Learner**	**F3E: Assessment Strategies**	**F3F: Learning Approaches in ECE**	**F3G: Mobile and Online Learning III**	**F3H: ECE IV**	**F3I: Integrating Design Throughout the Curriculum**
3:00 pm - 4:00 pm	Focus on Exhibits and New Faculty Fellows								
4:00 pm - 5:30 pm	**F4A: Mini-Workshop: Hands-On Activities with Portable Electronics to Engage Students in Analog Electronics Education (lab-in-a-box)**	**F4B: Panel: Effective Recruiting for Diversity**	**F4C: Student Beliefs, Motivation & Persistence II**	**F4D: Innovative Computing Practice II**	**F4E: Cognitive and Affective Domains of Learning**	**F4F: Pathways to Engineering Degrees**	**F4G: Inclusivity and Diversity II**	**F4H: ECE V**	**F4I: pK-12 STEM II**
6:30 pm - 9:00 pm	Reception and Awards Banquet – Ticketed Event Location: Great Hall C

TECHNICAL SESSIONS TABLE OF CONTENTS

Wednesday, October 23rd

W2A: Pre-Conference Workshop: Inspiring Inventive Genius in Middle and High School Students with Chain-Reaction STEAM Machines™
5:30 - 8:30 pm
Room: 20

W2B: Pre-Conference Workshop: The Erlang Approach to Concurrent System Development
5:30 - 8:30 pm
Room: 19

W2C: Pre-Conference Workshop: An Online Revolution in Learning and Teaching: from e-books to MOOCs
5:30 - 8:30 pm
Room: 18

W2D: Pre-Conference Workshop: Teaching Service-Oriented Programming to CS and SE Undergraduate Students (FREE workshop - costs covered by NSF grant)
5:30 - 8:30 pm
Room: 17

W2E: Pre-Conference Workshop: Refining a Taxonomy for Engineering Education Research (FREE workshop - costs covered by NSF grant)
5:30 - 8:30 pm
Room: 16

SESSIONS - Thursday, October 24th

T1A: Mini-Workshop: Exploring Boyer's Scholarship of Application for Submissions to the IEEE Transactions on Education
10:00 - 11:30 am
Room: 14

T1B: Special Session: Assessing Lifelong Learning: The Role of Information Gathering and Application Skills
10:00 - 11:30 am
Room: 15

Session T1C: Approaches to Student-Centered Learning I
Chair: Irene Rothe
10:00 - 11:30 am
Room: 16

Session T2D: Teaming and Engagement
Chair: Dietrich Romberg
1:30 - 3:00 pm
Room: 17

Session T2E: Computing I
Chair: Rajendra Raj
1:30 - 3:00 pm
Room: 18

Session T2H: Experiential Learning I
Chair: Abhijit Nagchaudhuri
1:30 - 3:00 pm
Room: 2

Session T2I: Mobile and Online Learning II
Chair: Jacob Bishop
1:30 - 3:00 pm
Room: 4

T3A: Mini-Workshop: Catching the Wave: Big Data in the Classroom
4:00 - 5:30 pm
Room: 14

T3B: Special Session: DiSrUpTiOn
4:00 - 5:30 pm
Room: 15

Session T3C: Innovative Computing Practice I
Chair: Claudio Brito
4:00 – 5:30 pm
Room: 16

Session T3D: Real World Influences in Experiential Learning
Chair: Elif Miskioglu
4:00 - 5:30 pm
Room: 17

Session T3E: Energy Engineering Education I
Chair: Madhumi Mitra
4:00 - 5:30 pm
Room: 18

Session T3F: Experiential Learning II
Chair: Wookwon Lee
4:00 - 5:30 pm
Room: 19

SESSIONS - Friday, October 25th

F1A: Mini-Workshop: Tools to Facilitate Development of Conceptual Understanding in the First and Second Year of Engineering
8:30 - 10:00 am
Room: 14

F1B: Panel: Building an Inclusive REU Program: A Model for Engineering Education
8:30 - 10:00 am
Room: 15

Session F1C: Faculty Development I
Chair: Rachel Kajfez
8:30 - 10:00 AM
Room: 16

Session F1D: Teams, Communication & Profession
Chair: Kelly Cross
8:30 - 10:00 Am
Room: 17

Session F1E: Philosophy of Engineering and Engineering Education I
Chair: Eric Pappas
8:30 – 10:00 am
Room: 18

Session F1F: ECE II
Chair: Dale Carnegie
8:30 – 10:00 am
Room: 19

Session F1G: Game-Based Learning II
Chair: Srividya Bansal
8:30 - 10:00 am
Room: 20

Session F3D: Student as Learner
Chair: Mauricio Dziedzic
1:30 - 3:00 pm
Room: 17

Session F3E: Assessment Strategies
Chair: Manuel Castro
1:30 - 3:00 pm
Room: 18

Session F3F: Learning Approaches in ECE
Chair: Robert O'Connell
1:30 - 3:00 pm
Room: 19

Session F3I: Integrating Design Throughout the Curriculum
Chair: Aurenice Oliveira
1:30 - 3:00 pm
Room: 4

Session F4D: Innovative Computing Practice II
Chair: Irene Rothe
4:00 - 5:30 pm
Room: 17

Session F4E: Cognitive and Affective Domains of Learning
Chair: Stephen Frezza
4:00 - 5:30 pm
Room: 18

Session F4H: ECE V
Chair: Joseph Hoffbeck
4:00 - 5:30 pm
Room: 2

Session F4I: pK-12 STEM II
Chair: Mindy Hart
4:00 - 5:30 pm
Room: 4

SESSIONS - Saturday, October 26th

S1A: Special Session: The CS 2013 Computer Science Curricula Guidelines Project
8:00 - 9:30 am
Room: 14

S1B: Panel: Engineering Education in Countries of Portuguese Language
8:00 - 9:30 am
Room: 14

Session S1C: pK-12 STEM III
Chair: Andres Navarro
8:00 - 9:30 am
Room: 16

Session S1D: Innovative Computing Practice III
Chair: Daniel Krutz
8:00 - 9:30 am
Room: 17

Session S1E: Distance Education I
Chair: James Rowland
8:00 - 9:30 am
Room: 18

Session S1F: Innovation and Entrepreneurship II
Chair: Anthony Joseph
8:00 - 9:30 am
Room: 19

Session S1G: First and Second Year Programs III
Chair: Leen-Kiat Soh
8:00 - 9:30 am
Room: 20

Session S1H: ECE VI
Chair: Abdel-Hameed Badawy
8:00 - 9:30 am
Room: 2

S2B: Mini-Workshop: Integrate by Design: Bringing Science, Math, and Technology Together Through the Engineering Design Process
10:00 - 11:30 am
Room: 15

Session S2C: Teaming I
Chair: Amy Javernick-Will
10:00 - 11:30 am
Room: 16

Session S2D: Experiential Learning III
Chair: James Rowland
10:00 - 11:30 am
Room: 17

Session S2E: Industry Partnerships
Chair: Xiaosong Li
10:00 - 11:30 am
Room: 18

Session S2F: Ethics and Moral Reasoning
Chair: Melany Ciampi
10:00 - 11:30 am
Room: 19

S3A: Mini-Workshop: Integrating International Students' Contests with Software Engineering Courses: Lessons Learned and Best Practices
1:00 - 2:30 pm
Room: 14

Session S3C: Student Beliefs, Motivation & Persistence III
Chair: Leen-Kiat Soh
1:00 - 2:30 pm
Room: 16

Session S3D: Computing Pedagogy Research
Chair: Xiaosong Li
1:00 - 2:30 pm
Room: 17

Session S3E: Engineering in International Contexts I
Chair: Velvet Fitzpatrick
1:00 - 2:30 pm
Room: 18

Session S3G: Energy Engineering Education II
Chair: Je-Hyeong Bahk
1:00 - 2:30 pm
Room: 20

Session S3H: pK-12 STEM V
Chair: Julie Rursch
1:00 - 2:30 pm
Room: 2

Session S4F: Assessment III
Chair: Asako Ohno
3:00 - 4:30 pm
Room: 19

Session S4G: Distance Education II
Chair: Dorothy Jones-Davis
3:00 - 4:30 pm
Room: 20

Session S4H: pK-12 STEM VI
Chair: Min-Chi Kao
3:00 - 4:30 pm
Room: 2

Session S4I: Interdisciplinary Programs II
Chair: Mahesh Banavar
3:00 - 4:30 pm
Room: 4

***Abstract*— Participants of this pre-conference workshop will learn about the development of computer engineering curricula reports. They will also learn about the revision process and will have the opportunity to provide comment and opinion on drafting an update of the joint ACM and IEEE Computer Society document from 2004 titled, "Curriculum Guidelines for Undergraduate Degree Programs in Computer Engineering" known also as CE2004. The authors of this workshop welcome all participation including overall comments and targeted editing assistance from the computer engineering education community. This activity will ensure that an updated document is a forward-looking summary of state-of-the-art educational practices in the computer engineering field.**

Keywords—Computer engineering; curriculum guidelines; CE2004; ACM; IEEE Computer Society

I. Background

In early 2011, the ACM and the IEEE Computer Society created the CE2004 Review Task Force (RTF) and charged it with reviewing and determining the extent to which the document titled, "Curriculum Guidelines for Undergraduate Degree Programs in Computer Engineering" (CE2004) [1] required revision. The RTF developed and issued survey invitations to over twenty thousand industry and academic constituents in the computer engineering field. It also contacted some ABET industry program evaluators to solicit their input. Although the survey default was anonymity, over sixty respondents provided contact information indicating they were interested in further participation in the revision process.

The RTF reported on its survey of academic and industry constituents in July of 2011. Part of the report included some new or expanded technical skill areas such as system on a chip (SoC) technologies, networking, software engineering agile methods and tools, embedded system design, parallel programming, and hardware/software co-design. It also recommended specific contemporary topics to be strengthened or added while de-emphasizing other topics that appeared to be waning from the mainstream of computer engineering topics.

The RTF found that the majority of what the constituencies believe is important is already covered rather well in CE2004. However, the RTF did identify significant deviations that could guide the revision process toward a document that is appropriately forward looking given the continuing changes in the computer engineering landscape. Thus, this preconference workshop is an effort to engage the computer engineering education community in evaluating the current draft for recommended changes and in planning further revisions to the guidelines with the hope of issuing a preliminary report in 2014 or in 2015.

Additionally, the RTF recommended that the two societies form a joint committee to update and edit the earlier document and to seek input and review from the computer engineering industrial and academic communities through workshops co-located at major conferences [2,3]. At an RTF meeting in Raleigh, North Carolina, the RTF recommended that a team of volunteers lead the revision effort with interim updates as necessary. This new team or special committee would consist of at least sixteen representatives divided equally between ACM and the IEEE Computer Society. At the same meeting the RTF indicated the importance of having international representation. It also recommended that this special

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

committee should include representatives from academia, industry, government, and community college groups.

The RTF largely affirmed the contents of the CE2004 report compiled nearly a decade ago. However, the RTF recognized that several significant advances in computer engineering have occurred since that time. The special committee should make key drafts of their revisions available to a wide constituency, including all respondents to the survey who expressed interest in having further input. The special committee should make efforts to include a presence at key conferences both within and outside of the United States.

II. WORKSHOP FORMAT

Discussions and questions will be encouraged throughout this interactive workshop session. The major topics to be covered are:

- Background, goals, and timeline of the revisions effort
- Curriculum types targeted with brainstorming (*e.g.*, Should other degree types be targeted? Should the document address master's degree programs?)
- Body of Knowledge (BoK) structure, changes, size, required and elective topics, with brainstorming regarding the utility of the structure
- Seven key BoK revision areas with brainstorming in areas of participant interest
- Overview of non-technical areas addressed in the document based on the 2011 survey and the FIE'12 special session
- Small group discussions: key technical and non-technical skills needed for computer engineers graduating over the next several years. Groups will share results and the RTF will collect notes from all groups that wish to share them.
- Additional discussion of items of audience interest to include: plans for publishing the next draft, ways to involve more people, access to drafts, opportunities to provide feedback, and opportunities to lead revisions of specific sections.

III. WORKSHOP PRESENTERS

Eric Durant (Milwaukee School of Engineering) is the lead IEEE-CS member of the team and the de facto leader of the RTF. In addition to conducting the workshop, Eric will summarize the activities of the group and key changes contemplated in the current draft of the CE2004 revisions.

John Impagliazzo (Hofstra University) is the lead ACM member of the RTF team and was a member and principal co-author of CE2004 committee. In addition to participating in the workshop, John will present a brief overview of the CE2004 document, describe the evolution and components of the 2004 report, and focus on its body of knowledge.

Susan Conry (Clarkson University) is a RTF member and is the past chair of the Engineering Accreditation Commission (EAC) of ABET. In addition to participating in the workshop, Susan will discuss ways in which the computer engineering curriculum complements the current ABET criteria. She will highlight the essential elements of the criteria and show how the new curriculum satisfies those criteria.

Andrew McGettrick (University of Strathclyde) is the Chair of the ACM Education Board and the ACM Education Council. Andrew is an RTF member and was a member of the CE2004 committee. He will summarize the specific BoK changes in the current draft.

Mitch Thornton (Southern Methodist University) is a RTF member and he is a member, past chair, and past vice chair of the EPE subcommittee working group for the National Council of Examiners for Engineering and Surveying. Mitch is also the vice chair, past chair, and a member of the IEEE-USA Committee on Licensure and Registration. He will focus on the results of the surveys and contrast the suggestions received from industry with those received from academia.

Timothy Wilson (Embry-Riddle Aeronautical University) is the Past Chair of ASEE's Electrical Engineering division for the Southeast region. Timothy is a RTF member and will discuss the revisions timeline.

Modeling Software the Alloy Way

Michael J. Lutz
Software Engineering Department
Rochester Institute of Technology
Rochester, NY, USA
mjl@se.rit.edu

***Abstract*—Until recently, those who taught mathematical modeling (or "formal methods") faced daunting challenges. First, most modeling tools used seemingly esoteric notations that were hurdles for many students. Even if the notation could be tamed, the tools themselves were rarely more than syntax checkers, possibly with support for simple expression evaluation. Venturing beyond this requires understanding of proof theories and strategies well beyond that typical of other engineering disciplines. What is more, the tools worked at a much lower level than that of the domain itself; it was easy for students to miss the forest for the trees.**

The development and release of the Alloy from MIT has improved the situation dramatically. With Alloy, instructors now have a tool that supports formal structural and behavioral modeling (using C-like syntax), along with state space exploration and property verification using relational logic, predicates, and assertions The tradeoff involved - only first order systems over finite domains can be analyzed - is not problematic in practice.

The workshop will introduce Alloy - both the language and support tool - to faculty interested in formal methods and mathematical modeling. After a brief introduction to Alloy concepts, the tool and language will be explored by interactively developing a simple software system model. This approach mirrors the way Alloy is taught and used within RIT's undergraduate software engineering program.

***Keywords*—formal methods; mathematical modeling; software engineering education.**

I. Workshop Organizer

Professor Lutz has almost 40-years of academic experience in computer science and software engineering. In the 1990s he instigated and led the effort to establish the nation's first B.S. in Software Engineering at RIT. He has extensive industrial and consulting experience, which he has brought into the courses he teaches.

Professor Lutz has taught courses in formal methods and modeling for over 20 years, first in RIT's computer science program, and for the past 15 years in the software engineering program. He has used Alloy[1,2] for over a decade, and has reported on his experiences at ACM[3] and ASEE[4] conferences..

II. Topic Outline

The Context: Alloy vs. Other Formal Methods

During this time participants will install Alloy on their notebooks.

What Alloy's Analyzer Can (and Cannot) Guarantee.

Alloy Foundations: Signatures, Atoms, Sets, Relations.

Specifying constraints: Facts and Predicates.

Exploring the state space: The Run command.

Relational navigation: Joins and Transitive Closures,

Verifying properties: Assertions.

Questions and Discussions.

III. Audience (20 max)

The workshop is primarily for computer science, software engineering and computer engineering faculty using discrete mathematics to describe and analyze software system structures. Participants should bring a notebook computer (Mac / Linux / Windows) with a USB port for installation of the software.

IV. Logistics

Computer video projector system (screen or large monitor).

Programming Board Game Strategies in CS2*

James Heliotis, Ivona Bezáková, Sean Strout
Department of Computer Science
Rochester Institute of Technology
Rochester, NY, USA
{jeh,ib,sps}@cs.rit.edu

***Abstract*—This workshop presents freshman-level projects based on designing and programming player strategies for well-established board games. Unlike modern computerized games, board games are typically discrete, where the game state can be stored in basic data structures, and a variety of search techniques can be used to evaluate possible player moves. Such board games provide a natural context for many introductory Computer Science topics. The strategy component makes the project open-ended, motivating the students to keep improving their code. After appropriate background information is presented, to better understand how the project works from the students' perspective, participants will act as students, brainstorm through a variety of data structures, and develop a small part of a player module.**

Keywords—data structures; software design; algorithms; introductory computer science curriculum

I. Introduction

Well-established board games such as Quoridor [3], The aMAZEing Labyrinth [2], and San Francisco Cable Cars [1] provide excellent opportunities to teach data structure and algorithm design to students in computer science. Because of the discrete turn-taking nature of the games and the simple organizations of the game board environments, a variety of search techniques can be used to evaluate possible player moves. We have developed game engines that graphically display the current game state as they cyclically call the individual player modules to make their moves. Every student team designs and implements its own player strategy in one of these player modules. Our latest engine, for the Quoridor game, runs remotely via a web service, which has given us the opportunity to provide client-side support code for player modules written in multiple languages, currently Java and Python. We provide, in each language, a player module template into which the students put their strategy implementation.

We tested the framework at the Rochester Institute of Technology as part of the Computer Science 2 course taken by over 400 students from a variety of majors.

The participants at the workshop will gain practice developing a simple path-determining algorithm for the Quoridor game. They will also experience testing a student code in the environment of a real game engine.

The participants will receive the supporting project documentation and all necessary code modules so that they will be able to utilize the games in their own classes.

Work supported by the NSF via the TUES grant program, award 1044721

II. The True Term Project

A. Design

Through a small package on the student's computer, the student's code accesses a web-based "engine" service that displays the current state of the game back inside the student's web browser. It cyclically calls functions in the student's player module code. The student implements three functions: one that is called by the engine at the beginning of the game to initialize the player module's data structures; one that is called by the engine whenever it is that module's turn to move and that returns the chosen move of their player; and one that is called after every move, informing the module of the move so that it can update its data structures accordingly.

B. Assignment Logistics

The project is split into four separate parts to guide the students in implementing their strategies. In the first part, the students implement a function useful to the game, for example searching for the shortest path through a maze. In the second part, their software needs to be able to play as a single player in the game, computing moves that follow the rules of the game and updating data structures accordingly. The third part has them play against other players – without the need to win. The fourth part consists of designing and experimenting with a player strategy, requiring minimally that the students consistently beat an unsophisticated or random player. Many students go well beyond this base line and develop very clever strategies. At the end of the term, the students' players compete in a not-for-credit tournament.

At RIT there are problem-solving sessions scheduled at the time each new part of the project is assigned. The instructions for these sessions are part of the workshop's documentation package. Instructors use these sessions in their classes to stimulate discussions about the project among small groups of students. The groups develop rough designs on paper before they proceed to their implementations. In other courses it may be more appropriate to dictate, or at least strongly suggest, specific approaches instead. It could also be an option whether students develop and submit their coded solutions individually or in teams.

In our experience many students go well beyond what is required to pass the course. They seek out advanced computing concepts or come up with advanced approaches on their own in order to give their players an edge over other players.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

III. WORKSHOP SCHEDULE

The goal of the workshop is to offer the project materials to the attending educators for use in their own courses. One of the best ways to assess the applicability of the materials to their own classes is to get faculty to go beyond just learning about the project by experiencing the work for themselves.

In brief, the workshop will introduce the projects and discuss their relevance to typical CS2 topics, demonstrate the "engine" software and the functions the students are asked to implement, describe the four project parts in detail for the Quoridor game, present several student-implemented strategies competing against each other, and finally give the participants a chance to develop their own strategies for the chosen game. A more detailed schedule follows in **Error! Reference source not found.**. The total time for this workshop is **3 hours**.

After the workshop the participants will be familiar with the described CS2-level project, which is open-ended enough to accommodate the beginning programmer with the achievable goal of beating a random player. They should also have a fair idea of what it takes to build an engine for new games, including ones that are simpler or more advanced than the ones shown.

IV. MATERIALS PROVIDED

Participants will be provided with both the software and documentation for the project. The software includes access to a web-based engine that runs games for students, and personal copies of client support software that is easily adapted to many languages. (Currently we support Java and Python versions.) Participants also get the full set of materials for the project, including individual project part descriptions and the related "problem solving" documents. The problem solving documents are to be used in a course to stimulate discussions about the project among small groups of students. The rough designs so generated are used as starting points for the lab work.

The participants will bring home hard copies of the documents and will be given a URL where the documents, supporting software libraries, and the game engine service will be made available.

TABLE I. WORKSHOP SCHEDULE

Topic	**Time Needed (min.)**
Introduction	5
Objectives and rationale for the board game projects	20
Brief description of individual board games used in our projects, and a short discussion of the underlying data structures and algorithms	15
Detailed description of the rules of one board game	10
Demonstration of the corresponding engine	10
Description of the individual project parts	10
Demonstration of student-implemented strategies	5
Break	15
Hands-on session: participants act as students	75
Discussion	15

***Abstract*— The introductory continuous-time signals and systems (CTSS) course is widely considered one of the most difficult courses in electrical and computer engineering (ECE) curricula. This workshop is an interactive discussion about sources of difficulty and what can be done to help improve student learning and understanding. In the first part of the workshop, discussion will be sparked and encouraged through presentation of historical data and directed questions. The goal will be to advance a continually developing understanding of the problem. In the second part of the workshop, attendees will learn about hands-on activities that are being done at Bucknell and Rose-Hulman to help address what the authors think some of the issues are. Attendees will have an opportunity to attempt some of these activities, use the technology to develop their own activity, and review the activities with regard to the previous discussion about learning difficulties. Each attendee is highly encouraged to bring a laptop and will receive a USB memory stick with the software, lesson plans, materials, and background literature that support this workshop.**

Keywords—signals and systems; continuous-time; active learning; hands-on activities

GOALS OF THE WORKSHOP

The introductory CTSS course is one of the most difficult courses that students encounter in an electrical and computer engineering (ECE) curriculum. This is evidenced at Rose-Hulman over the last 10 years by drop/failure rates that are at least two times greater than any other course except electromagnetics. We have received NSF funding to explore why students find these courses so difficult and to determine effective methods for helping students grasp the concepts. This workshop offers engineering and science faculty an engaging opportunity to explore how to improve learning in introductory continuous-time signals and systems (CTSS) courses [1]. The two primary goals of the workshop are to provide:

- an interactive discussion that will try to provide as broad a perspective as possible to the question "Why is signals and systems difficult?" and,
- a hands-on experience with laboratories that developed and used at Rose-Hulman Institute of Technology and Bucknell University over the past 4 years to improve learning in CTSS courses

CONTENT OF THE WORKSHOP

While many people are developing supplemental materials for CTSS courses, very little exploration of the sources of difficulty from the student's perspective has been done[2][3]. There are many opinions and ideas with regards to these sources, but we would like to take a scientific approach to arrive at more definitive answers. Once more of these sources are identified, we can tailor the supplemental materials to be more effective. We are analyzing historical data and developing new studies to try to identify more of these issues. In addition to those studies we want to gather input from the community at large to try to get as broad an understanding of the problem as possible. The first part of the workshop will be an interactive discussion with the purpose of gathering such input. Discussion will be sparked by presenting data, current ideas, and directed questions. The results of this discussion will be used to guide the remainder of the workshop.

We have been trying to address issues that are related to lack of motivation and learning by creating application-oriented hands-on active-learning opportunities for students[4][5]. There are many examples of such opportunities described in the literature, but most of these activities make use of MATLABP®, LabVIEWP®, or DSP hardware [6]. The exercises described in this workshop are based on analog circuits and real-world applications of continuous-time signal processing and system modeling. There are certainly advantages to using software simulation tools for laboratory exercises because they are relatively inexpensive and students can perform many "experiments" relatively quickly. In fact, many of the exercises described in this workshop could be simulated entirely using such software tools. We are not advocating the elimination of these simulators, and in many cases use them for both prelab exercises and/or analysis of results. However, there is one key advantage to using hardware-based hands-on activities and real-world applications that simply cannot be obtained with software-only based activities. Practicing engineers use the theoretical and mathematical concepts from CTSS courses to model real-world

This workshop is supported by NSF grant #1140995. The authors would also like to thank Ruth Streveler at Purdue Univeristy and Shannon Sexton at Rose-Hulman for their input on data analysis and learning theory.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

physical phenomena. The overwhelming majority of students have never had an opportunity to connect those theoretical concepts with the physical phenomena that they are trying to model[2]. So it's possible that a lack of motivation could be due to a lack of understanding of what use the concepts have. While software tools can help students visualize the concepts, they are in-themselves also modeling tools. An important way for students to gain an experience of the phenomena that they are trying to model is to actually experiment with them[7]. Using a real system with real-world applications creates a degree of credibility and relevance that is not possible with software simulations. When students manipulate these systems, there is an understanding that they are changing something physical rather than simply adjusting a number.

In order to facilitate application-oriented hands-on activities, we have developed a number of laboratory lesson plans and an analog printed circuit board, the signals and systems exploration platform (SSEP)[8]. The SSEP can be configured easily to sum, multiply, filter, and sample continuous-time signals. With an onboard microphone, ECG/instrumentation amplifier, and generic signal input, a wide variety of signals can be studied and manipulated. During the workshop, attendees will be able to load the software onto their own laptop from a USB memory stick and work individually with an SSEP.

This workshop will provide a detailed introduction to the SSEP and some of the lesson plans that were developed both with and without the SSEP in mind. The attendees will then have an opportunity to run through some of the lesson plans. Time will also be given for attendees to play with the equipment and develop a mini-lesson plan of their own. Finally, in order to close the loop, attendees will then be able to provide feedback relating the activities to the previous discussion about sources of difficulty in CTSS courses.

INTENDED AUDIENCE AND NUMBER OF ATTENDEES

We expect this workshop to be primarily of interest to undergraduate electrical engineering faculty who are involved in signal processing education. We will also make the activities accessible to pre-college educators who are attending the conference. In fact, the instrumentation used in this workshop is currently being used in high-school physics courses. The examples and materials presented would also be of interest to those teaching Fourier theory in other disciplines such as physics, mathematics, and other types of engineering. We would expect to have approximately 10-15 attendees.

WORKSHOP AGENDA

I. Introduction to the workshop. **(10 minutes)**
II. Participant discussion of the initial question: Why is CTSS such a difficult subject for students? **(30 minutes)**
III. Introduction to hands-on activities being done at Rose-Hulman and Bucknell **(15 minutes)**
IV. Overview of the SSEP **(15 minutes)**
V. Supervised activities using the SSEP **(60 minutes)**
VI. Free time with the SSEP and exploration of other ideas. **(30 minutes)**
VII. Review of hands-on activities with regard to the initial question. **(15 minutes)**
VIII. Assessment of this workshop **(5 minutes)**

TAKE AWAY SKILLS

We are expecting attendees to leave the workshop with a greater appreciation for the sources of difficulty in CTSS courses and some ideas of simple hands-on activities that can be used to help make the material more approachable to the students. They will have some personal experience with these activities and knowledge about how to use the SSEP and acquire the hardware. They will be given a memory stick containing all lesson plans and software so that they could begin using these activities at their own institution. They will also be invited to attend a more in-depth summer workshop at Rose-Hulman during the summer of 2014 and to participate in an ongoing discussion of the issues.

QUALIFICATIONS OF THE PRESENTERS

Mario Simoni is an Associate Professor of Electrical and Computer Engineering at Rose-Hulman Institute of Technology. He has been teaching for 12 years including the introductory CTSS course and analog circuits. He has been teaching for 12 years including the introductory CTSS course and analog circuits. He developed the SSEP and associate hands-on activities with input from Maurice Aburdene. He has been using these activities for the past three years.

Maurice Aburdene is a Professor of Electrical Engineering at Bucknell University. He has been teaching for over 30 years, including courses on linear systems and signal processing.

Farrah Fayyaz is a doctoral student in the School of Engineering Education at Purdue University. She holds Bachelors and Masters degrees in electrical engineering from the University of Engineering and Technology, Lahore, Pakistan and taught signals and systems, digital signal processing, analog circuits and microelectronics in Pakistan for more than eight years. Her Masters research focused on identifying student difficulties in learning signal analysis. She will continue investigating students' understanding of various concepts in signals and systems for her PhD dissertation.

Using Problets for Problem-Solving Exercises in Introductory C++/Java/C# Courses

Amruth N. Kumar
Computer Science
Ramapo College of New Jersey
Mahwah, NJ, USA
amruth@ramapo.edu

***Abstract*—This workshop will help participants introduce problem-solving exercises into their introductory C++/Java/C# programming courses. The purpose of problem-solving exercises is two-fold: they supplement classroom instruction and complement the programming projects traditionally assigned in the course. The benefits of problem-solving exercises are many: they improve students' comprehension of programming constructs, their self-confidence, especially that of female students, and their coding skills. In this workshop, problets (www.problets.org) will be introduced as a tool for problem-solving exercises. They parameterize problems to deter plagiarism; provide step-by-step explanation of the correct solution to each problem, which helps students learn; and adapt to the learner's needs. They are a web-based service freely available for educational use. Problets have been rigorously evaluated, and have been adopted and used by dozens of instructors every semester since 2004. The workshop is appropriate for instructors of introductory C++/Java/C# programming courses in Computer Science or engineering. Participants are asked to bring a WiFi-enabled laptop to the workshop for hands-on experience.**

Keywords—introductory programming, problem-solving, software tutors, C++, Java, C#

I. Goals of the Workshop

Solving problems is an integral part of STEM learning. The goal of this workshop is to help participants introduce problem-solving exercises into their introductory C++/Java/C# programming courses using problets (www.problets.org), a web-based service freely available for educational use. Evaluations have shown that problets improve students' knowledge of programming constructs [1], their self-confidence in the material [2] and their ability to write code [3]. The exercises presented by problets are meant to supplement classroom instruction and complement programming projects traditionally assigned in the course.

II. Description of the Content

The workshop will be an introduction to using problets to incorporate problem-solving exercises into introductory C++/Java/C# programming courses. Topics will include a description of the software service, its history, its problem-generation, feedback and adaptation features, the introductory programming topics and learning objectives that it covers, the types of problems it presents, the benefits of using it in the introductory course, the ways in which it can be used in a course, the support provided to faculty adopters, the process for adopting and using problets in a course, and the opportunities for using problets in one's own research on teaching and learning of introductory programming. In addition, participants will get to try out problets hands-on, on different topics and types of problems, and have the opportunity to resolve technological and pedagogical issues in incorporating problets into their own course(s) at their institution.

III. Qualifications of the Presenter

The presenter is the developer of problets. Funded by grants from the National Science Foundation, he has worked on the development of problets for over a dozen years, and has been using them in his own courses all those years. He has been disseminating problets through conference presentations and NSF showcases. Finally, he has been supporting the use of problets by dozens of faculty adopters each semester since 2004, setting up the service for them, configuring problets for their needs and generating reports of student use for them.

IV. Workshop Agenda

1. Introduction, history, topics, problem types: (30 minutes)
2. Problem generation features: (5 minutes)
    - Hands-on activity – Arithmetic Expressions: (15 minutes)
3. Feedback features – Delayed, Error-flagged: (10 minutes)
    - Hands-on activity – Selection and code-tracing (15 minutes)
    - Hands-on activity - Debugging functions (15 minutes)
4. Learning objectives and adaptation feature: (15 minutes)
    - Hands-on activity – Student setup of arrays [15 minutes]

5. Benefits of using problets for students, Ways to use problets in a course – (15 minutes)
6. Adopting problets, support provided to adopters (15 minutes]
    - Demonstration – Problem and learning objective reports
7. Teaching and learning research with problets (15 minutes)
8. Questions and answers, Wrap-up (15 minutes)
9. Optional demonstrations (time permitting): Classes, Bit-wise expressions, Assignment expressions

V. Audience

This workshop would be of interest to instructors of introductory C++, Java or C# programming courses, who would like to incorporate more problem-solving, active-learning, and blended-learning activities into their courses. The material is appropriate for introductory programming courses taught in Computer Science, engineering or business schools, baccalaureate or associate's degree-granting institutions as well as high schools.

VI. Expected Outcomes

Attendees will learn how they can use problets to incorporate problem-solving and active-learning exercises into their introductory C++/Java/C# programming courses. They will get hands-on experience using problets and get the opportunity to explore pedagogical and technological issues in incorporating problets into their own courses. Evaluations have shown that problets help improve students' knowledge of programming constructs, improve their self-confidence (especially that of female students [4]), and their ability to write code in the course.

VII. Additional Information

The web site www.problets.org contains demonstration versions of various tutors, listing of the learning objectives covered by each problet, publications covering the results of evaluating problets, student testimonials, and a sample of the report provided to adopters.

Acknowledgment

Partial support for this work was provided by the National Science Foundation under grant DUE-0817187**.**

***Abstract*—In this hands-on pre-conference workshop, participants will learn about the STEAM Machines™ program, which teaches middle and high school students the engineering design process in the context of designing and building Rube Goldberg®-style chain reaction machines.**

Keywords—design; K-12; outreach; creativity; project

I. Description

A *STEAM Machine*™ (http://steamlabs.asu.edu) is a Rube Goldberg®-style chain reaction contraption that completes a simple task in an overly complex way. This hands-on workshop introduces participants to the project-based *STEAM Machines*™ program, where middle or high school students brainstorm ideas, design, and build creative inventions that solve everyday problems - like sending a text message - using chain-reaction machines. Students are challenged with learning and applying the Boston Museum of Science Engineering is Elementary® engineering design process and integrating science, technology, engineering, arts, and math concepts together in the design and construction of their machines. In addition, the program embeds students in local or geographically-distributed teams to expose them to other cultures, improve the quality and quantity of their design communication, and simulate a trans-national engineering and manufacturing environment by having students swap designs with peers. Machines designed by geographically-distributed teams have the added constraint that their parts must connect together across camp sites using communication technology, resulting in machines that start at one site, progress through a number of challenging intermediate steps, and culminate by completing the simple task such as popping a balloon at the final site. This hands-on workshop will begin with a description of the *STEAM Machines*™ program, and a video of a chain-reaction machine from a recent camp offering. Examples of how science, technology, engineering, arts, and math learning objectives are addressed by the curriculum (including 21st century skills) will be presented, along with the pedagogical techniques employed. Opportunities for assessment of knowledge, skills, and attitudes of students will be discussed. Then, results of current design-based research on the *STEAM Machines*™ program will be presented including a discussion of its effectiveness and impact. Workshop participants will have the opportunity to engage in a hands-on *STEAM Machine*™ design activity, followed by discussion and reflection on how the program could be adapted for implementation at other sites. Student pathways for participation in other engineering outreach programs will be presented, including the Rube Goldberg Machine Contest® (http://www.rubegoldberg.com). Finally, participants will receive sample curriculum resources for use in their programs.

The Erlang Approach to Concurrent System Development

Michael J. Lutz
Software Engineering Department
Rochester Institute of Technology
Rochester, NY, USA
mjl@se.rit.edu

***Abstract*— The prevalence of multi-core processors means application developers can no longer ignore concurrency and its attendant problems of data races, deadlock, safety, and liveness. Imperative languages such as Java and C, based on shared, mutable state, have added locks, semaphores and condition variables to address these problems; unfortunately, these locking approaches are notoriously error-prone.**

Functional ("single assignment") languages with immutable state have been promoted as tools to mitigate these problems. In particular, Erlang, a functional language with roots in Prolog, has been used by Erickson, Ltd., to develop robust, concurrent, fault-tolerant, communications switches (31ms downtime per year). This workshop will introduce Erlang to educators interested in the language *per se* as well as those focusing on concurrent system development. The goal is to encourage the use of both imperative and functional languages in teaching about concurrency.

Participants will install the Erlang system on their notebooks so as to engage in activities along with the organizer. Both sequential and concurrent systems - small but complete - will be developed in conjunction with the presentations. Time is allocated at the end of the workshop to discuss the pedagogical issues involved in adopting Erlang or similar technology.

Keywords—functional vs. imperative languages, concurrent and distributed systems, software engineering education.

I. Workshop Description

Until quite recently, dealing with concurrency was the domain of specialists in operating systems and transaction processing. Today, the prevalence of multi-core processers means these issues can no longer be ignored by application developers. What is more, concurrency highlights the problems of extending imperative, mutable state languages such as Java and C into this arena: synchronization and controlled access to shared, mutable state via locks and condition variables are notoriously error-prone.

Functional languages (for example, Haskell [1], Clojure [2] and Scala [3]) have been proposed as tools to mitigate some of these problems. A key characteristic of these languages is the elimination of or severe restriction on mutable state. The program effects are not caused by changing values in memory cells, but rather by sophisticated composition of pure mathematical functions. Of course any implementation on a traditional instruction set will manipulate memory, but the data structures and algorithms need only be created once; the bulk of the software is written functionally.

Erlang [4-5], a functional language with roots in Prolog, has been used by Erickson, Ltd., to develop robust, fault-tolerant, distributed communications switches. These switches exhibit “nine nines availability” (less than 32 ms of downtime per year). More recently, Erlang has incorporated symmetric multiprocessing support, allowing Erlang processes to execute with real as well as virtual concurrency. Commercially, Erlang is a key component in well-known applications such as GitHub [6] and Twitter [7], and is the language to develop the CouchDB [8] database system.

The goal of the workshop is to expose computing educators to Erlang as a vehicle for concurrent software design and implementation. With the workshop experience in hand, attendees will have the basic knowledge needed to assess the appropriateness of Erlang (and similar languages) in the context of their institution.

II. Workshop Organizer

Professor Lutz has almost 40-years of academic experience in computer science and software engineering. In the 1990s he instigated and led the effort to establish the nation’s first B.S. in Software Engineering at RIT. He has extensive industrial and consulting experience with the design and implementation of concurrent systems, which he has brought into the courses he teaches.

Most recently he has worked on Erlang-based projects with several independent study students. As part of RIT's transition from quarters to semesters, he is incorporating Erlang as part of a concurrent and distributed systems course now focused solely on Java and and its mutable state concurrency.

III. Topic Outline

Issues in concurrency: race conditions, deadlocks, livelocks.

Problems with mutable state approaches.

Functional programming concepts and their applicability to concurrency.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Erlang the Language

Erlang shell

Expressions; variables & single assignment.

Atoms, numbers, tuples, lists.

Assignment as pattern matching.

Modules and functions; pattern matched arguments.

Clauses; selection via case statement.

Recursive definitions; tail-recursive functions.

Process spawning; sending and receiving messages.

Concurrent System Development with Erlang

Processes, actors, and controlled state mutation.

Erlang: concurrency problem mitigation, not cure.

Process design heuristics and patterns.

Fault-tolerance and "fail fast".

Monitors and fault recovery.

Teaching courses with Erlang.

Projects based on Erlang.

Open discussion.

IV. AUDIENCE (20 MAX)

Computer science, software engineering and computer engineering faculty interested in functional languages and their application to concurrency. Participants should bring a notebook computer (Mac / Linux / Windows) with a USB port for installation of the software.

At the end of the workshop, participants will have:

1. Installed versions of the Erlang system and accompanying documentation,
2. Basic knowledge of Erlang syntax and semantics,
3. An overview of Erlang's approach to classic concurrency issues, with a focus on how it differs from that of imperative languages,
4. Used Erlang to create a simple client/server system,
5. Discussed the advantages and disadvantages of using Erlang in the classroom.

V. LOGISTICS

Computer projector with screen.

***Abstract*— College-level online learning took off in a big way in 2012, and is likely to impact every department and teacher in some manner. This workshop will highlight major developments in online education technology in engineering and computer science. The workshop will highlight recent online trends like flipped classrooms and MOOCs, will survey various authoring and delivery platforms like EdX and Zyante, summarize some research on online/flipped teaching, discuss methods for instructors to collaborate on delivering instructional experiences, and highlight experiences by teachers of online and hybrid courses.**

Keywords—Online education, MOOCs, hybrid classrooms, flipped classrooms, inverted classrooms, group teaching.

I. Overview

This workshop will highlight major developments in online education technology in engineering and computer science. The workshop components include:

- Overview of latest developments, including MOOCS, flipped classrooms, web-native learning material, and the growth in online courses.
- Summarizing of various authoring and delivery platforms, such as those from EdX (edx.org), Inkling (inkling.com), Zyante (zyante.com), along with other collaborative teacher and student technologies.
- Highlighting some studies of the flipped classroom model, utilizing MOOCs in traditional classes, and utilizing interactive learning material.
- Discussion of teaching roles and skills and how to effectively execute community teaching.
- Sharing of some online teaching experiences.
- Discussion on directions of the field, and ideas for teachers on adapting to the online trend.

II. Presenters

Diane Rover is a Professor of Electrical and Computer Engineering at Iowa State University. She serves as the director for two large-scale NSF-funded education related programs: IINspire LSAMP is an alliance of sixteen institutions to broaden participation in STEM; and SP@ISU is a campus-wide program to support the broader impacts work of faculty. She is also the principal investigator on NSF STEP and S-STEM grants at Iowa State that have focused on the recruitment, retention and success of engineering students. She received her B.S. in Computer Science and M.S./Ph.D in Computer Engineering from Iowa State Univ. She was formerly on the faculty of Michigan State Univ.

Yacob Astatke is Associate Chair of Electrical and Computer Engineering at Morgan State Univ. He has over 15 years experience in the design/delivery of web-based course supplements for electrical engineering courses. He directs "Foundations of Mathematics", a free online math course, offered to all pre-freshman engineering students. He also teaches the "Electric Circuits" and "Introduction to Electrical Laboratory" courses completely online using innovative pedagogy and interactive Mobile StudioTM technology. He is recipient of the 2012-2013ASEE Mid-Atlantic Distinguished Teacher Award. He received his B.S. in Electrical Engineering and Doctor of Engineering degrees from Morgan State Univ, and his M.S. in Electrical Engineering from Johns Hopkins Univ.

Smita Bakshi is CEO of Zyante, a Silicon Valley startup company developing a framework to create online interactive animated learning material, and building a community of content contributors especially for core computing and engineering topics. The web-based offerings are being used by over 2000 students at dozens of leading universities including UT Austin, UC Davis, UC Riverside, Univ of Arizona and others. She was formerly on the faculty of Univ. of California, Davis in Electrical and Computer Engineering. She received her Bachelor of Engineering from the Delhi Instit. of Technology, and her M.S./Ph.D. in Computer Science from the Univ. of California, Irvine. She also received her M.B.A from Harvard Univ. She has been a software developer and product manager at several companies including Synplicity, Intuit, Symantec, and Veritas.

Frank Vahid is a Professor of Computer Science and Engineering at the Univ. of California, Riverside. He has co-authored several college textbooks with various publishers using different publishing formats. He created the first online courses at UC Riverside, all on computer science topics, and assists with the course offerings. He is part of the Univ. of California's Online Education 10-campus pilot project. His recent focus is on creating a framework to help instructors develop interactive animated online content, and creating interactive web-native lower-division computing, engineering, and math content. He has been principal investigator on several education-focused NSF grants. He has a B.S. in Computer Engineering from Univ. of Illinois, Urbana/Champaign, and M.S./Ph.D. in Computer Science from Univ. of California, Irvine.

***Abstract*—Service-Oriented Programming (SOP) is a relatively new programming paradigm that supports the development of new software applications using existing services as building blocks. SOP has gained significant popularity in industry as it increases software reuse and productivity. As the SOP paradigm can improve modern software development, the presenters have created a course-module based approach for incorporating SOP into Computer Science (CS) and Software Engineering (SE) curricula; a course module is a distinct curricular unit such as a lab or teaching component that an instructor may incorporate into an existing course typically without requiring formal curricular approval. SOP course modules have been developed for inclusion in standard courses in many CS and SE programs; for example, an introductory SOP course module in a CS2 course while advanced modules for courses such as Programming Language Concepts, Software Engineering, or Web Services. This workshop will present basic concepts and techniques of SOP and describe how the course-module approach toward SOP can be adapted for the participants' own teaching. The typical participant would be a faculty member with some background in programming, and is interested in learning more about SOP but does need not to have prior web service programming experience.**

Keywords—service-oriented programming; service-oriented architecture; web services; computer science; software engineering

I. MOTIVATION

This workshop presents Service-Oriented Programming (SOP), which is a new programming methodology that permits the development of software applications by connecting and composing existing services [1], thus facilitating software reuse. SOP builds on object-oriented programming (OOP), as services are developed in an object-oriented (OO) fashion and then wrapped as Web services. OOP provides the basis to model and implement software components as objects, while SOP permits modeling and implementing software systems as web-accessible services, and has attracted attention from the industry as it substantially improves software reuse. SOP leverages the web's communication infrastructure to provide easier access to existing software components. Consequently, more and more companies have begun to offer their business functionalities via web services. Some search engines have been developed specifically for finding existing web services. For example, www.programmableweb.com indexes over 5814 web services and 6610 mashups (which are applications, built on web services). Other search engines, such as www.webservicelist.com and www.biocatalogue.org, list web services by application domains.

This workshop is broadly divided into two major parts. In the first part, the presenters will describe the problem areas and motivation underlying the SOP paradigm, the techniques of designing and implementing services, and the techniques for developing applications using services. Topics covered include service-oriented architecture, web services, service description and discovery, service invocation, service composition architecture, and core SOP protocols, e.g., Web Services Description Language (WSDL), Universal Description Discovery and Integration (UDDI), Simple Object Access Protocol (SOAP), and Representational State Transfer (REST). Participants will also be provided guidance to develop and deploy web services in a stepwise fashion, and be split into small groups for an activity, e.g., to compare OOP and SOP. In the second part, participants will be introduced to the developed teaching materials, including a demo of the SOP framework that exemplifies SOP techniques. Participants will again work in groups and discuss issues about how to incorporate SOP course modules into their existing courses.

This workshop is in line with the goals of FIE because it aims to introduce new software development methodology into existing STEM curricula.

II. WORKSHOP DESCRIPTION

As stated, this workshop will introduce the major concepts and technologies of SOP, and demonstrate the development of web services and SOP applications. The presenters will also share their curricula materials and experiences in teaching SOP in programming courses for undergraduate students.

Table I outlines the tentative agenda for the workshop.

TABLE I. WORKSHOP AGENDA

Event	Duration
1. Presenter and participant introductions	10 min
2. SOP fundamentals 2.1 The evolution of programming abstractions 2.2 Motivation for SOP 2.3 Service-oriented Architecture 2.4 Examples of web services 2.5 Team activity: Each group will do an exercise, for example, given a problem, provide and compare corresponding OOP and SOP solutions.	40 min
3. SOP Standards 3.1 WSDL 3.2 SOAP & REST 3.3 UDDI	30 min
4. SOP Development Environment 4.1 .NET Framework for Windows Communication Foundation (WCF) services 4.2 Netbeans + GlassFish for Java-based services 4.3 Hands-on exercises of SOP.	30 min
5. SOP teaching materials 5.1 SOP framework demo 5.2 Course module for CS2 5.3 Course module for Programming Language Concepts 5.4 Course module for Software Engineering 5.5 Team activity: Each group will do another exercise, for example, discuss how to effectively and smoothly incorporate the course modules to the targeted course.	50 min
6. SOP: Reflection & Conclusion	20 min

III. WORKSHOP LEARNING OUTCOMES

The workshop's learning outcomes are as follows:

- Attendees will explain the main issues and concepts in SOP.
- Attendees will solve a problem using SOP techniques.
- Attendees will have in-depth experience with SOP.
- Attendees will explain and apply SOP teaching materials, including the SOP framework and course modules, developed by the presenters.

Among other outcomes, the presenters will make their SOP curricular materials available to the participants.

IV. QUALIFICATIONS OF THE PRESENTERS

Of the five authors, the three who will be presenting this workshop are Rajendra K. Raj, Tom Reichlmayr and Alex Pantaleev. Professors Raj and Reichlmayr are faculty members at Rochester Institute of Technology and Dr. Pantaleev is a faculty member at SUNY at Oswego.

Rajendra K. Raj is a professor in RIT's Computer Science department, and his current research interests currently include in large-scale data management, distributed/mobile computing, security, and critical infrastructure protection. He is also interested in computing education methodologies, and is involved in program assessment, evaluation and accreditation. Dr. Raj teaches courses in database systems, cloud and large-scale data management, distributed systems, and security. Prior to RIT, he was a software designer, developer, architect and manager in the Information Technology Division at Morgan Stanley & Co., where he architected, built and managed globally distributed database infrastructures for financial applications handling big data. He received his PhD in Computer Science from the University of Washington, Seattle.

Tom Reichlmayr is an associate professor in RIT's Software Engineering department. He has extensive experience in curriculum development and cooperative learning. He has developed and coordinated an introductory software engineering course as well as advanced courses in software engineering design and process. He has actively converted software engineering courses from traditional lecture/lab format to studio classroom delivery.

Alex Pantaleev is an assistant professor in SUNY Oswego's Computer Science department that offers degrees in Computer Science, Information Systems and Software Engineering. His current research interests include service-oriented architecture, computer science education, and distributed computing, especially as it applies to computer game development. Dr. Pantaleev's work has appeared in conferences such as ASEE and ITiCSE. He has developed two new courses and redesigned several others at SUNY Oswego including CS2 and web services. He is the major creator of a new concentration in the Computer Science major at Oswego.

All presenters are experienced teachers who use active learning techniques extensively and teach in multiple settings including traditional classroom or blended settings.

Refining a Taxonomy for Engineering Education Research*

Cynthia J. Finelli
Center for Research on Learning and Teaching in Engineering (CRLT-Engin)
College of Engineering and CRLT
University of Michigan
Ann Arbor, MI USA
cfinelli@umich.edu

***Abstract*—Engineering education research is a diverse, rapidly-evolving, international field in which scholars apply the methods of educational research to address a variety of issues pertaining to teaching and learning in engineering. As the field has grown, so has the need for a standardized terminology and an updated taxonomy to map and communicate research initiatives. Refining a U.S-centric taxonomy is the focus of this workshop. Participants will engage in activities to reflect on a draft taxonomy and offer suggestions to refine it. Participants are encouraged to bring a computer, and interested participants at any experience level are encouraged to join this dialogue.**

Keywords— outline; taxonomy

I. Goals

The goals of this workshop are to:

- Apply the taxonomy to a series of related abstracts
- Engage the community in refining the taxonomy

II. Description of the Workshop

The workshop will involve opportunities for participants to use the taxonomy (through a computerized interface) to identify keywords for a series of related abstracts as well as to work with others in refining the taxonomy. The workshop will be interactive.

III. Workshop Agenda

15 minutes: Welcome and overview
60 minutes: Using taxonomy
90 minutes: Revising the taxonomy
15 minutes: Next steps and wrap up

IV. Presenter Qualifications

The author has engaged in a project to develop a U.S. centric taxonomy for the field of engineering education research. This workshop is one of multiple opportunities for community engagement.

V. Intended Audience

Interested participants at any experience level are encouraged to join this dialogue. There is no limit on number of attendees.

VI. Take Away Materials for Attendees

Participants will contribute to a dialogue to create a U.S.-centric taxonomy for the field of engineering education research.

VII. A/V Needs

The presenter requires an LCD projector and a power adaptor. She will provide her own laptop computer and all workshop materials.

VIII. Participant Fees

This project is funded by National Science Foundation, grant #1240797, and there is no cost for participants.

* This material is based upon work supported by the National Science Foundation under Grant #1240797. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

Exploring Boyer's Scholarship of Application for Submissions to the IEEE Transactions on Education

Jeffrey E. Froyd
Engineering Academic and Student Affairs
Texas A&M University
College Station, USA
froyd@tamu.edu

Susan M. Lord
Engineering
University of San Diego
San Diego, USA
slord@sandiego.edu

***Abstract*—A substantial percentage of the manuscripts submitted to the IEEE Transactions on Education as well as a substantial percentage of the papers that have been published fall within the scholarship of application as described by Boyer. The scholarship of application in electrical and computer engineering education might be briefly described as the scholarship of teaching practice in these disciplines. While this is a critical arena for electrical and computer engineering education, standards and criteria across the scholarly community for this area of scholarship have not been well established. Thus, this workshop at FIE 2013 offers opportunities for dialog about these issues. A starting point for the conversation will be the new review criteria that the Transactions has established for the scholarship of application. The intent of the workshop is to explore how authors interpret the new criteria, how authors might address the new criteria, and how support for authors can be fostered. Small groups will explore in greater depth the meaning of review criteria for the scholarship of application for education in electrical and computer engineering. Then, small groups with share their results with the large group for broader conversations.**

Keywords—Boyer's model of scholarship; electrical and computer engineering; engineering education; publishing

I. Introduction

As Boyer pointed out in his exploration of the meaning of scholarship [1], restricting description of scholarly contributions only in terms of new knowledge contributed, i.e., scholarship of discovery, ignores varieties of necessary intellectual contributions. He went on to describe at least two more areas of scholarship, i.e., application and discovery; however, describing the nature of contributions in these two areas upon which further intellectual contributions can be built has not received the attention needed to elaborate expectations so that scholars can frame their work. Thus, this workshop at FIE 2013 provides an excellent opportunity to engage an important segment of the community of potential scholars in constructive conversations about appropriate review criteria and how authors can address these criteria within this area that sees hundreds of potential annual contributions. At the end of the workshop, participants should be able to:

- Describe Boyer's three areas of scholarship and distinguish the scholarship of application from the other two areas
- Describe their ideas about criteria appropriate for the scholarship of application
- Provide ideas on how to write a manuscript that contributes to the scholarship of application

II. Criteria: Scholarship of Application

Words related to application, e.g., practice, design, create, innovate, invent, etc., might be the basis for a set of criteria. The following are the criteria for the scholarship of application in the IEEE Transactions on Education as of June 2013.

(i) Relevance/Importance/Need/Opportunity: How relevant are issues, practices and applications described in the manuscript to education in electrical engineering, computer engineering, and related fields? Are significant issues in education for electrical engineering, computer engineering, or related fields clearly articulated? Has a need for potential contributions been established? How widespread among engineering educators is interest in the issues, practices, and applications presented in this manuscript?

(ii) Intended outcomes: What were the outcomes that the authors were seeking? To what extent were the outcomes explicit and clearly stated? Did the authors just mention the course or topic or did they articulate clear intentions for instructional practices described in the manuscript? To what extent have the authors articulated intended contributions in education in electrical engineering, computer engineering, or related fields? If the authors present approaches to instruction, how well have authors articulated intended learning outcomes or objectives?

(iii) Context: Have the authors analyzed prior research related to their intended contribution? Have they identified the appropriate references? Have they situated their work within the context of prior research?

(iv) Application Design: In the scholarship of application, a key focus is on decisions that authors made as they applied existing knowledge and research. This criterion focuses on these decisions. What were key decisions that needed to be made in the process of designing approaches, strategies, tactics, activities, behaviors, and structures to achieve the outcomes? Have the authors identified and explained the key decisions that were needed for their approach? For each decision, what are alternatives drawn from the literature that were, or should

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

have been, considered? To what extent have the authors considered possible alternatives, including alternatives described in prior research? For each decision, what were the criteria used to guide prioritization among the alternatives? To what extent have the criteria that the authors use in making their decisions been clearly and adequately explained? How did the authors prioritize their alternatives, based on their criteria? Did they describe how they arrived at their decisions? Were the descriptions clear and the reasoning solid?

(v) Findings: Once the choices were made and implemented, to what extent did the activity achieve intended outcomes? Is evidence presented by the authors sufficient to support the findings? Has the evidence been analyzed and interpreted according to accepted practices?

(vi) Conclusions: What is the significance of the conclusions? Are opportunities for further innovations in practice identified? Are potential research questions identified? Are implications for broader acceptance of the applications considered?

III. Workshop Overview

Interactive activities have been designed to catalyze conversations that will advance scholarship across the community and enhance quality of papers in the Transactions. The workshop will alternate between small group dialog and large group exploration of findings reported by small groups. Small groups will explore in greater depth the meaning of review criteria in the areas of application, integration and discovery as applied to the field of education in electrical and computer engineering.

A. Schedule

An overview of the workshop schedule is provided in Table I.

TABLE I. WORKSHOP SCHEDULE

Start Time	Duration	Activity
0:00	10 minutes	Introductions: Facilitators and participants will introduce themselves, describe their purposes for participating in the workshop, and describe their familiarity with Boyer's three areas of scholarship.
0:10	10 minutes	Introduce the scope of the IEEE Transactions on Education, provide an overview of the review process for the Transactions (including timing), and provide an overview of Boyer's scholarship of application
0:20	15 minutes	Introduce Criteria for Scholarship of Application
0:35	20 minutes	**Activity:** Pick a criterion. Ask groups of 4 persons to work on approaches that manuscript authors could use to address the criterion effectively. Reports from groups will be solicited. Questions and comments will be shared.
0:55	20 minutes	**Activity:** Pick a criterion. Ask groups of 4 persons to work on approaches that manuscript authors could use to address the criterion effectively. Reports from groups will be solicited. Questions and comments will be shared.
1:15	15 minutes	**Summary:** Synthesize findings, consider next steps, wrap-up workshop

IV. Possible Prerequisite Knowledge

No special technical prerequisite knowledge is needed. All FIE participants would be welcome. Familiarity with the IEEE Transactions on Education would be desirable. Some familiarity with Boyer's model of scholarship would be helpful. Useful references include Boyer [2] and Glassick [3].

V. Workshop Facilitators

A. *Jeffrey E. Froyd, Texas A&M University, Editor-in-Chief, IEEE Transactions on Education*

Dr. Jeffrey E. Froyd received the B.S. degree in mathematics from Rose-Hulman Institute of Technology and the M.S. and Ph.D. degrees in electrical engineering from the University of Minnesota, Minneapolis. He is a TEES Research Professor in the Engineering Student Services and Academic Programs at Texas A&M University, College Station. He has been an Assistant Professor, Associate Professor, and Professor of Electrical and Computer Engineering at Rose-Hulman Institute of Technology. He served as Project Director for the Foundation Coalition, a National Science Foundation (NSF) Engineering Education Coalition in which six institutions systematically renewed, assessed, and institutionalized innovative undergraduate engineering curricula. At Rose-Hulman, he co-created the Integrated, First-Year Curriculum in Science, Engineering and Mathematics, which was recognized in 1997 with a Hesburgh Award Certificate of Excellence. He has authored over 70 papers on faculty development, curricular change processes, curriculum redesign, and assessment. Prof. Froyd is a Fellow of the IEEE, a Fellow of the ASEE, an ABET Program Evaluator, the Editor-in-Chief for the IEEE Transactions on Education, and an Associate Editor for the Journal of Engineering Education. He has served as the general chair for the 2009 Frontiers in Education Conference and a program co-chair for three other FIE conferences.

B. *Susan M. Lord, University of San of Diego, Associate Editor, IEEE Transactions on Education*

Dr. Susan M. Lord is Professor and Coordinator of Electrical Engineering at the University of San Diego. She received a B. S. in Electrical Engineering and Materials Science and Engineering from Cornell University and the M.S. and Ph.D. in Electrical Engineering from Stanford University. Author of over eighty publications, her teaching and research interests include electronics, optoelectronics, service-learning, feminist pedagogy, lifelong learning, helping military veterans transition to engineering programs, and engineering student persistence. Dr. Lord's industrial experience includes AT&T Bell Laboratories, General Motors Laboratories, NASA Goddard Space Flight Center, and SPAWAR Systems Center. Dr. Lord's research in engineering education has been supported by the National Science Foundation. She is a member of the IEEE, the Society of Women Engineers (SWE), ASEE, and Tau Beta Pi. Her leadership positions include President of the IEEE Education Society (EdSoc), Frontiers in Education (FIE) Steering Committee Member, General Co-Chair of FIE 2006, FIE 2005 Program Co-Chair, and elected member of administrative board of ASEE's Education and Research Methods (ERM) Division. Dr. Lord and coauthors received best paper awards in 2011 from the Journal of Engineering Education and the IEEE Transactions on Education. She was Guest Co-Editor of the 2010 Special Issue of the International Journal of Engineering Education (IJEE) on Applications of Engineering Education Research. Dr. Lord is an Associate Editor of the IEEE Transactions on Education and a member of the Editorial Board for IJEE.

Assessing Lifelong Learning

The Role of Information Gathering and Application Skills

Abstract – **This special session will explore different approaches to measuring and promoting lifelong learning skills in support of fulfilling ABET student outcome criterion 3.i. "The recognition of the need for, and an ability to engage in life-long learning"[1] is mult-faceted and challenging to both define and measure and is comprised of a mixture of skills, abilities, and habits, and attitudes. This session focuses on those aspects of lifelong learning associated with self-directed learning, and in particular the information gathering and application skills required for effective independent learning. As a result of this session, we will develop some shared understandings of these skills, our ability to measure them, and an agenda for future research on measuring and supporting activities related to student outcome criteria 3.i.**

Index Terms – lifelong learning; assessment; information literacy

GOALS OF THE SESSION

This session will provide examples of assessment tools that probe lifelong learning and related information literacy competencies. The special session participants will cooperatively develop criteria for measuring lifelong learning skills, which will be folded into the development of future standardized assessment instruments. Ultimately, this will improve the ability for engineering educators to measure ABET lifelong learning outcomes.

SESSION RATIONALE

Lifelong learning is one of the least understood and studied ABET criteria in terms of measuring student achievement. In a recent study, students rated their performance lowest in lifelong learning, of all the ABET outcomes, and it had the least growth in achievement of any of the criteria [2]. Many assessments of lifelong learning, furthermore, are based on student self-assessments or participation in formal post-graduate educational activities (seminars, workshops, advanced degrees). However, much of lifelong learning takes place independently and through the initiative of the engineer at a point of need [3], and these qualities are not addressed by simply inventorying educational activities attended. What is needed are assessments that probe the skills students need in order to be successful self-directed learners. This session provides an example of some such assessments and a venue for discussion to increase the educator community engagement with lifelong learning and refine and suggest assessment tools to measure the lifelong learning capacity of our students. Once we can assess those outcomes, we can better measure the effectiveness of instructional interventions and make sure lifelong learning no longer languishes as the least-achieved of the ABET criteria.

SESSION DESCRIPTION

After asking participants to reflect on their own understanding and experience working with lifelong learning outcomes, the facilitators will briefly review lifelong learning and self-directed learning theories and how they have been interpreted by the engineering education community. We will review different assessments that have been used to measure self-directed learning and information skills and explore their strengths and weaknesses. The facilitators will then discuss standardized assessments they developed as a result of an institutional seed grant that was recently funded for further development. Participants will take one of the assessments and reflect on whether they believe it measures skills associated with their perception of lifelong learning. The following discussion will help spark thinking about lifelong learning and how it can be measured, whether through refining existing instruments or the development of new approaches entirely.

SESSION AGENDA

Introductions/Warm-up Activity 15 minutes -- Instructors will introduce themselves. In small groups, participants will introduce themselves, explain what they think lifelong learning is, and give two or three examples of how they measure lifelong learning at their institutions, including at least one way they measure non-formal lifelong learning (e.g., outside of continuing education courses or advanced degrees).

Review of Lifelong Learning Literature 15 minutes – Instructors will provide context of how the education

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

community and the engineering community has historically defined lifelong learning and the characteristics, skills, and abilities of lifelong learners.

Review Types of Assessments Used 15 minutes - Discuss advantages/weaknesses of different kinds of assessments (e.g., multiple choice, performance, self-assessments), with examples of each.

Participants Take Sample Assessment 10 minutes (1st part of CELT, the Critical Engineering Literacy Test, an assessment designed by the facilitators) - This provides a concrete example of one assessment method.

Small Group Reflect on Assessment 20 minutes - Gather feedback on whether this assessment is measuring the skills and abilities students need for informal lifelong learning. What challenges did the participants have with the assessment, what did they think the assessment was measuring? Small groups will document their discussions, which will be turned in to the instructors.

Entire Group Reflection/Report 15 minutes - Opportunity for discussion, sharing information between groups. Determination of consensus skills and abilities needed by lifelong learners and appropriate assessment tools to measure them.

LITERATURE REVIEW

Lifelong learning encompasses the skills, abilities, and inclinations to learn outside the academy. While formal learning opportunities, such as workshops, seminars, and advanced degrees provide some venues for lifelong learning, the bulk of post-graduate learning occurs at point of need and in the context of authentic work-related activities [3]. These situations require self-directed learning skills, defined by Knowles as the ability to "identify their learning need, determine a learning plan to acquire the skills or abilities to meet the need, actually implement the plan, and be able to determine whether they met their learning goals."[4] Similarly, Shuman *et al.* propose that lifelong learners be able to "demonstrate reading, writing, listening, and speaking skills, demonstrate an awareness of what needs to be learned; follow a learning plan; identify, retrieve, and organize information; demonstrate critical thinking skills; and reflect on one's own understanding."[5] Costa and Kallick describe self-management, self-monitoring, and self-modifying, as the three categories of skills, with several attributes and competencies for each category [6]. Garrison substitutes motivation for self-modifying in his classification of skills [7], and the Association of American Colleges and Universities created the VALUE rubric for lifelong learning, which is comprised of the core characteristics of curiosity, initiative, independence, transfer, and reflection [8]. The common pieces in all of these descriptions of lifelong learning are an ability to determine what the knowledge gap is, how to find information to meet that need, actually apply that information, and determine if the task is complete or if more needs to be done. When the attributes of lifelong learning are summarized in this fashion, the link to information literacy skills, the ability to determine an information need, locate relevant information, and to apply it appropriately and ethically [9], can easily be seen.

Many attempts at assessing self-directed learning focus on student self-assessments [10], which mostly provide information on attitudes toward lifelong learning, or information about learning style preference [11] rather than actual habits or skills. Standard assessments of information literacy [12] are often decontextualized, so transfer of skills is more problematic. The facilitators of this session created a scenario-based assessment to provide a better indicator of student skills in a context similar to that they will experience in their professional careers [13]. They also developed a rubric-based tool for assessing authentic student work [14], in particular student project reports that evaluate not only the number and type of resources students use in their documentation, but also the quality and relevance of the information in the context of the task and the appropriateness of the application of the resources.

Although some progress has been made in the construction of appropriate assessments of lifelong learning, more work needs to be done. It is the hope of this program that participants help uncover new ways of thinking about lifelong learning and potentially new lines of research to understand the connection between different skills, abilities, and attitudes and success as a lifelong learner.

ANTICIPATED AUDIENCE

Our anticipated audience includes engineering educators, faculty, graduate students, and librarians.

EXPECTED OUTCOMES & FUTURE WORK

The results of this session will be folded into further revisions of the instructors' lifelong learning assessment tool. The tool will be made openly available to the education community by depositing it in the STEMEdHub repository. Participants will also be recruited to test the assessment at their institutions and to increase content validity of the instrument. The outcomes of the session may also spark further research into other methods of assessing lifelong learning.

AUTHOR INFORMATION

Şenay Purzer is an Assistant Professor in the School of Engineering Education and is the Co-Director of Assessment Research for the Institute for P-12 Engineering Research and Learning (INSPIRE) at Purdue University. Purzer has received her M.A. and Ph.D. degrees in Science Education at Arizona State University. She has a B.S. degree in Physics Education and a B.S.E. in Engineering. She has written journal publications on teaming and design, conceptual learning, and instrument development. Her current research focuses on design problem-solving, assessment of life-long learning, and K-12 engineering education.

Michael Fosmire is a Professor of Library Science and Head of the Physical Sciences, Engineering, and Technology Division of the Purdue Libraries. Fosmire received is MS (Physics) and MLIS from the University of Washington, and B.S. degrees in Physics and Mathematics from the Pennsylvania State University. He has written extensively about curriculum-integrated information literacy, active learning techniques, and the information habits of scientists and engineers.

Amy S. Van Epps is an Associate Professor of Library Science and Engineering Librarian at Purdue University. Van Epps received her MSLS from The Catholic University of America, M.Eng. (IE) from Rensselaer Polytechnic Institute, and B.A. in Engineering Science from Lafayette College. She has extensive experience providing instruction for engineering and technology students, including Purdue’s first-year engineering program. Her research interests include finding effective methods for integrating information literacy knowledge into the undergraduate engineering curriculum.

Ruth Wertz is a doctoral candidate in the School of Engineering Education at Purdue University. She holds a Master of Science degree in Civil Engineering from Purdue University and a Bachelor of Science degree in Civil Engineering from Trine University (formally Tri-State University). Ms. Wertz is a licensed Professional Engineering in the state of Indiana with over six years of field experience and eight years of classroom teaching experience. Ms. Wertz’s research interests include teaching and learning engineering in online course formats, and the development of information literacy in engineering students.

Green Construction in Civil Engineering Instruction

Kenneth R. Leitch, Christopher Koop, Miles Messer, and Andrew Payne

West Texas A&M University, kleitch@wtamu.edu, cdkoop1@buffs.wtamu.edu, mcmesser1@buffs.wtamu.edu, arpayne1@buffs.wtamu.edu,

Abstract – **Teaching sustainability in civil engineering curriculum fulfills ABET 2000 Outcome 3c and the codes of ethics of NSPE and ASCE. The US Green Building Council (USGBC) has published the Leadership in Energy and Environmental Design (LEED) criteria since 1998. LEED is an optional criteria in private construction and is mandated or encouraged by many federal, state, and local governments for public construction projects. Learning about LEED criteria will help to prepare civil engineers to understand how civil systems interact with and operate in a more complementary manner with the natural world as well as to reduce water, energy, and material usage. The authors describe the process of learning about the LEED v3 (2009) criteria to apply it to two existing buildings to build a scorecard. In the process of building the scorecard, the authors learned about sustainable construction techniques. Future guidance on applications of the LEED criteria across the undergraduate civil engineering curriculum is discussed.**

Index Terms – Civil Engineering, Sustainability, LEED, USGBC, ASCE, ABET, Ethics, Environment, Construction

INTRODUCTION

Incorporating sustainability into the civil engineering curriculum is consistent with ABET Outcome 3c as well as ASCE, NSPE, and ASME codes of ethics [1, 2, 3, 4]. The primary roadblock to implementation is that many of today's current engineering educators have not studied or been trained in sustainable engineering practices.

The term *sustainability* refers to the ability of the people of the present to maintain a high quality of living while ensuring that future generations will have access to the resources that they need to also maintain a high quality of life. This means that the people, businesses, and governmental organizations of today need to examine their actions in regard to production and consumption of goods and services, infrastructure, water and energy usage, and end-of-service life such that those actions maximize the quality of life and economic growth while minimizing degradation to the natural environment. The common refrain of *reuse, reduce, and recycle* summarizes the goal of sustainability initiatives.

A great source of information on sustainability in construction is the multidisciplinary US Green Building Council (USGBC). Engineers (civil, mechanical, and electrical), architects, contractors, and other stakeholders have come together with the market-driven approach of the USGBC to create the Leadership in Energy and Environmental Design (LEED) family of specifications to incorporate sustainability into construction projects. USGBC has specifications for homes, neighborhoods, new and existing construction, and schools that give guidance on how to make projects more sustainable by reducing environmental degradation, water, energy, and material usage while also making the project more conducive to human health and well-being.

Work at West Texas A&M University (WTAMU) began in May 2012 to learn about the LEED criteria. Work began by studying the LEED Green Associate (lower-level) certification materials, published by the USGBC [4]. Examinations are administered by the independent Green Building Construction Institute (GBCI). Dr. Leitch successfully passed the LEED Green Associate examination in August 2012.

The upper-level certification for LEED is specific to individual specialties in construction. For example, one specialty is in neighborhood development while another is in new building construction. Each specialty has a set of LEED criteria prerequisites that must be met before certification and scorecard values related to water, energy, materials, indoor air quality, and site location plus bonus points related to regional priorities and innovations in design. Certified buildings have 40 – 49 points, silver certified 50 – 59 points, gold certified 60 – 79 points, and platinum certified are 80 or more points.

PREVIOUS WORK

Many civil engineering programs in the United States are incorporating elements of sustainability across their curriculum, with a few examples noted here. A review by Ahn, et. al (2008) and Cottrell and Cho (2009) [6, 7] provided a list of universities incorporating elements of sustainability into civil engineering curriculum such as Pennsylvania State, the University of Florida, Texas A&M, Texas Tech, the University of Colorado, and Virginia Tech. Instructors at Lamar University [8] write about using the Shangri La Botanical Gardens and Nature Center in Orange, Texas (the first Platinum certified project in Texas) as a teaching tool. Since 2000, the Oregon Institute of Technology [9] has implemented a three-term sequence in senior civil engineering design that emphasizes sustainability by using the LEED criteria. George Mason University [10] uses the LEED Neighborhood Development criteria for its senior design project to address all major subareas of civil engineering. In 2012, Sattler et. al at the University of Texas at Arlington addressed integrating sustainability across the civil, mechanical, and industrial engineering curriculum including a multi-disciplinary senior design experience to design a biodiesel production facility [11].

SUSTAINABILITY INITIATIVE FOR THE CIVIL ENGINEERING CURRICULUM

The civil engineering program began at West Texas A&M University (WTAMU) officially in the Fall 2010 semester. WTAMU is a member of the Texas A&M system, serving the Texas Panhandle and surrounding region. The university has approximately 8,000 students with over 500 in the School of Engineering and Computer Science (ECS). The civil engineering program currently has about 50 declared majors, with the first graduates in 2013.

The sustainability initiative consists of three distinct parts. The first part was completed in Summer 2012 when Dr. Leitch and an undergraduate student developed a series of 50-min sustainability modules for several civil engineering courses which include the introductory engineering course, civil construction materials, transportation engineering, and senior design. This phase also included study of the LEED Green Associate material.

The second phase will be discussed in depth in the next section. Three students learned the LEED Green Associate Material as well as the LEED AP (Accredited Professional) specific material necessary to evaluate one remodeled and one new building on the WTAMU campus.

The third phase incorporated elements of the LEED and sustainability criteria into civil engineering senior design in 2013. Civil engineering senior design addresses multiple subdisciplines such as structural, transportation, environmental, hydrology and water resources, and construction in a group project within a 3-credit semester course. Additionally, elements of engineering finance, technical communication, ethics, and sustainability are addressed within the project.

LEED CRITERIA

The LEED scorecard is comprised of five primary categories with prerequisites and credits (up to 100 points total) and two bonus categories (up to 10 points). A brief overview is given here, but readers are urged to consult each LEED AP specific category for prerequisites and credit values.

The first major category is for *Sustainable Sites* and promotes responsible, innovative, and practical site design strategies that are sensitive to plants, wildlife, water, and air quality. LEED rating systems address project location and site design and maintenance by the following five main subtopics: location and linkages, neighborhood pattern and design, transportation facilities, storm water management, and heat island effects. Credits are earned for redevelopment efforts located near major transit services that allow for ease of walking and for mitigation of environmental damage.

The second major category is *Water Efficiency*. Efficient fixtures save potable water and reduce wastewater treatment demands. Water reuse can also result in credits. For example, a rainwater capture system can channel non-potable water (greywater) for use in irrigation of native or adapted plants (xeriscaping) and for toilet facilities.

The third major category is *Energy Efficiency*. Rising fossil fuel costs have made efficient heating/cooling systems, appliances, and low-energy electric devices important to reduce energy costs and environmental effects. An integrated process helps to identify synergy-promoting strategies in the following areas: energy demand, energy efficiency, renewable energy, and operational performance.

The fourth major category, *Indoor Environmental Quality*, focuses on building air quality, lighting, thermal conditions, ergonomics, and the effects it has on the occupants of the building. Indoor air quality can be more polluted than outdoor air, and yet, people spend about 90% of their day indoors. Indoor contaminants are generated by smoking, cleaning materials, HVAC equipment, and building materials that emit volatile organic compounds (VOCs). VOCs are defined as substances that vaporize at room temperature, and have the ability to cause health problems. Ventilation is vital in removing pollutants that enter a building. But the best way to improve indoor air quality is to reduce pollutants at the source of production.

The final major category *is Materials and Resources*. When deciding on materials for a project, the production, transportation, consumption, and eventual disposal must be taken into account. Three main points to remember in regard to materials and resources: conservation of materials, selection of environmentally preferable materials, and for waste management and reduction.

There are two bonus categories. *Innovations in Design* credits are awarded to projects that go above and beyond what is required of the LEED scorecard. Innovative strategies expand the scope of green building practice by putting new techniques, processes and products into place. *Regional Priority* credits recognize environmental issues that are unique to a locale, outside the scope of the five main categories.

CURRENT STUDY

A team of three senior-level civil engineering students was tasked with learning about the LEED criteria in the Fall 2012 semester and applying it to two structures on the WTAMU campus. The students were also tasked with studying the LEED Green Associate examination study materials and taking a mock 100-question exam. The mock exam is similar to the actual Green Associate examination, and is intended to prepare the students to take the certification examination.

The two structures evaluated were a remodeled facility (ECS Building opened in 2012) and the recently constructed Centennial Hall dormitory (opened in 2010), both located on the WTAMU campus. Construction documents and specifications were graciously provided by the WTAMU Physical Plant.

The team of students reviewed several hundred pages of documents to determine scorecard values for both buildings. These scorecards are given for reference in Figures 1 and 2, respectively. As can be seen in the scorecards, the renovated Engineering and Computer Science Building scored 32 points, eight points shy of Certified status. The new Centennial Hall dormitory scored 45 points, indicating Certified LEED status, if the university had chosen to submit the required documentation. As shown in Figures 1 and 2, most points were awarded for sustainable sites and for indoor air quality, due to the use of low VOC emitting materials. The new dormitory building was awarded significant points for its greywater system that can use rainwater for flushing toilets, saving potable water usage. Both structures also received points for reused and locally sourced materials. Some examples of sustainable features for these two buildings are given in Figures 3 through 7.

With this group of students trained in sustainable development techniques, these concepts were applied to their senior design project. This project involved the creation of a new outdoor engineering lab facility with structural, transportation, geotechnical, water resources, and environmental elements that adapt ideas from the LEED sustainability criteria.

FUTURE DIRECTIONS AND CONCLUSIONS

The immediate near term goal is to incorporate sustainability into the civil engineering curriculum, in the spirit of ABET Outcome 3c and the ASCE and NSPE codes of ethics. The authors plan to share their findings with other faculty at WTAMU. The concepts of sustainability are readily adapted in related fields such as for

mechanical engineering and engineering technology.

Sustainability is important for all engineers, but especially for civil engineers, as they are responsible for the design, construction, and maintenance of infrastructure necessarily for a high standard of living and for the economic growth of nations, such as the United States. Major engineering societies and accreditation bodies recognize the importance of sustainability. As such, civil engineering programs are beginning to incorporate elements of sustainability across the curriculum.

The LEED criteria provide a market-driven mechanism for recognizing construction innovations that promote sustainable practices. Since 1998, over 43,000 projects in the USA have been certified (more than 50,000 total worldwide), according to the USGBC database (2012) [12]. The US General Services Administration (GSA) has been directed by Presidential Executive Orders in 2007 and 2009 to utilize LEED criteria for federal construction projects [13]. Many states and cities are also implementing incentives for applying LEED strategies in public projects. The LEED project database reflects that corporations and private citizens seeking certification as well.

Incorporation of LEED criteria and concepts of sustainability across the curriculum are essential in preparing engineers of 21st century so that the engineers of the 22nd century and beyond can continue to provide a high quality of life for future citizens.

On-professional competences in engineering education for XL-Classes

Stefan Schröder M.Sc., Daniela Janßen M.A., Dr. rer. nat. Ingo Leisten, Dr. rer. nat. René Vossen, Prof. Dr. phil. Ingrid Isenhardt

Center for Learning and Knowledge Management (ZLW)
IMA/ZLW & IfU RWTH Aachen University
Aachen, Germany
stefan.schroeder@ima-zlw-ifu.rwth-aachen.de

***Abstract*— Far reaching changes in university higher education have taken place in the last ten years. Different factors, e.g. necessity of on-professional competences in engineering education, rising or vast student numbers and new technical possibilities, have influenced the academic teaching and learning process. Therefore interdependence between requirements and didactical-educational possibilities is given. Because of changed circumstances an adaption of teaching methods and concepts is required. At the same time Bologna arrogates students to be placed in the centre of the teaching and learning process and claims on-professional competences for today's students. Especially for XL-Classes this is a specific challenge. One of the questions ensuing is how to increase learning success by the use of specific didactical methods? With a research approach connecting different proven didactical concepts and considering the previously shown conditions, the concept of the lecture "communication and organizational development" (KOE) at RWTH Aachen University has been redesigned. This lecture, organized by the Institute Cluster IMA/ZLW & IfU at RWTH Aachen University, is mainly frequented by up to nearly 1.300 students of the faculty of mechanical engineering and inherent part of the bachelor-curriculum. The following practical example prospects the multi-angulation of didactical concepts and shows up innovative educational teaching.**

Keywords— engineering education; audience response system; on-professional competences; best-practice

I. Introduction

Innovative teaching techniques and concepts have been developed in the last years against the background of different factors of influence in the teaching process of higher education. This paper presents a best-practice example, which implements and combines different didactical concepts in higher education. The combination of different concepts is necessary as set out in chapter II – Challenges in context of higher education.

In the course of years multifarious didactical concepts have been created. Research reveals different human learning types and success, depending on learning environments [1]. It follows and carved out that integration of learning methods and styles is essential.

Bologna claims the design of student-centered education formats and conveyance of on-professional competences [2], which is challenging especially in large-audience courses, the so-called "XL-Classes". On-professional competences are understood as competences which enable students to deal with their theoretical specialized knowledge and prepare them for working life. These competences comprise e.g. methodological-, social-, self-reflecting- and media-skills.

By means of the lecture "communication and organizational development", organized by the Center for Learning and Knowledge Management (ZLW) of the RWTH Aachen University, it is highlighted, how and against which backdrop the lecture was subjected to a whole redesign to cope with the changed influence-factors, technical possibilities and student-requirements. This redesign is mentioned in chapter III – Redesign of the lecture 'KOE'.

II. Challenges in context of higher-education

During the last decade far reaching changes in higher education teaching took place. Different factors have influenced the design of higher education, for example conveying on-professional competences in higher education, the high number of students at German universities and (new) technical opportunities. These most important challenging factors will be elaborated in the following.

A. The challenge ‚XL-Classes'

In Germany, many Universities face the challenge of a vast number of students each semester, especially in engineering education degrees at RWTH Aachen University [3]. This challenge is tightened by the reduction of school time by one year due to a change in German educational policy. In addition to that the demand for engineers in Germany is growing [4]. More than ten years after implementing the Bologna Declaration, the higher education system in Germany has changed significantly [2]. Since then students and their learning process represent the core of the teaching and learning process. This change, also known as a 'shift from teaching to learning' [5], is a more student-centered and involvement-oriented design of teaching. 'It is characterized by innovative methods of teaching which aim to promote learning in communication with teachers and other learners

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

and which take students seriously as active participants in their own learning, fostering transferable skills such as problem-solving, critical thinking and reflective thinking' [6]. Instead of being 'content-oriented', which means focusing on the transmission of content, the design of teaching now focuses on 'learning outcomes', hence the students' learning results and the way of achieving these results. This is, however, a major challenge to lecturers of XL-Classes, as they predominantly focus on the transmission of content due to their difficulties of involving a large number of students at the same time. Therefore the question arises how a lecture can be student-oriented in XL-Classes.

B. Conveyance and promotion of on-professional competences

Due to the huge number of students attending lectures-XL-Classes have the problem of a content-oriented focus. Therefore the conveyance of on-professional competences to students in XL-Classes is often in a theoretical way. Indeed the transmission of on-professional competences plays an important role in higher education in general and particularly in engineering degree programs [7]. Not only professional knowledge is required to be the output of higher education, but also soft skills like method-, self-, organizational - and social competences are expected from today's students [8].

Against this background the required competences are considered at the redesign. From its multidisciplinary and holistic approach, the ZLW aims at designing and conducting lectures also including the transmission of on-professional competences. Thereby the ZLW tries to accomplish one major goal of the Bologna Process, which is "to create a European space for higher education in order to enhance the employability […]" [2]. Students should be educated in a way which makes them available for the employment market in a fast, efficient and adequately educated manner [9]. This means students should be enabled to convert learned knowledge in higher education in later working life [10].

C. Combination of didactical concepts

Didactical concepts are the tools of today's lecturers. Those concepts and methods are combinable and applicable in various ways. Due to the didactical diversity of methods a student-centered alignment of lectures is possible. The students learning process is further supported through didactical multi-angulation [11].

Additionally, the students obtain skills in dealing with various methods through methodical diversity (e.g. with presentation techniques). Böss-Ostendorf and Senft confirm that useful methodical diversity is a factor of success for university education, because of the multiplicity access to teaching content [12]. The reasons for integration and combination of different didactical concepts are mentioned by Flechsig [1]:

- Various learning styles and types of students with different learning success
- Diversity of study motivation and interest
- Variety of competences and fields of knowledge
- Variety of context in which learning is placed

Any didactical method aims at enforcing learning and knowledge permanently [13]. As a result a sensible combination of didactical methods and concepts to increase learning-success for students is necessary. As a consequence concepts, explained in the following, have been integrated in the lecture 'KOE'.

III. Redesign of the lecture 'KOE'

The compulsory lecture "communication and organization development" (KOE) is held every winter term. Almost 1300 students, mostly engineering students, participate in this weekly lecture. In addition a laboratory session takes place, in which students experience a simulated company situation in an authentic environment [14]. Based on the changed influence factors, which are mentioned before, and with the premise to maximize learning success and also among the maxim of sustainable teaching of practice-oriented and on-professional contents, the lecture is continuously refined and was subject to a complete redesign in the winter term 2012/2013. Existing elements were further developed and new didactic elements were implemented. The lecture's elements (shown in Figure 1) will be explained in the following.

Didactical multi-angulation of the lecture 'KOE'	
A	**Theoretical inputs and lecture modules**
B	**Practice oriented theoretical inputs through expert-lectures with professional practice**
C	**Interaction in XL-Classes through Audience Response Systems (ARS)**
D	**Learning on demand through medial preparation**
E	**Teaching and learning online portal/platform**
F	**Simulation based learning through organizational simulation**
G	**Online examination system**

Fig. 1. Didactical elements 'KOE' lecture at RWTH Aachen University

A. Theory input and lecture modules

The lecture consists of twelve modules, including the basics of communication and organization development, learning- and knowledge management concepts and intercultural aspects of global work division management as well as system-theoretical approaches and practical inputs by experts from industry. The whole concept of teaching follows a linear structure. Practical lectures tie in with earlier taught theoretical contents. Thus an ideal transfer from theory to praxis is established. At the end of every module contents are reflected and summed up. For this purpose the 'KOE funnel' is applied (Fig. 2). Both the systemic view and the different levels of a company are included. Thereby communication and organization are regarded as the most important requirements for the development of interaction between humans, technique and organization on the different organizational levels, for example within departments or project teams.

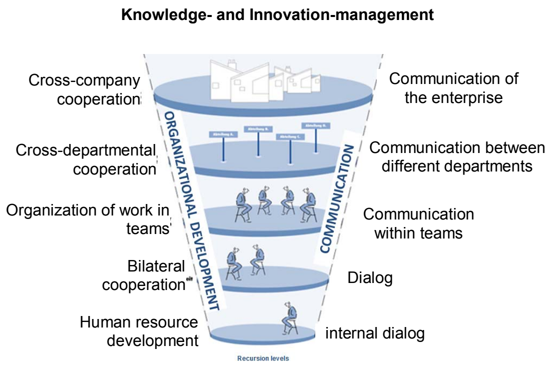

Fig. 2. 'KOE' funnel/recursion-layers [14]

B. *Expert lectures*

As already stated the lectures redesign aims for an increasing relation to practice applications and does not only focus on technical expertise. Additionally it also aims at increasing the ability of understanding the complexity of working life. The inclusion of on-professional competences in studies is not only an issue since the Bologna reform [15]. Furthermore it is important to connect the studies with professional practice, not only from the student's perspective, but also from the perspective of company representatives [16]. For this reason, it is more important to connect teaching with practical insights [15]. Based on this, guest speakers with professional industrial background give an insight into their companies and working experiences (e.g. Vodafone Group, Capgemini, p3 group, inside group of companies). For example: Lecture contents are the experiences in handling international projects as well as interdisciplinary challenges. The experts as well as the lecturer try to establish the connection between already taught theoretically contents and the meaning of communication and organization development in daily processes. In this way theories are linked to praxis and relevance is outlined. In order to solve the area of conflict between the teaching of basic sciences and practical teaching at the expense of theoretical essentials [17] the distribution of proper contents and basics is kept reasonable.

C. *Interactivity throug the application of "Audience Response Systems"*

As outlined by Prensky, that "our students have changed radically" and that "today's students are no longer the people our educational system was designed to teach" [18], (new) technologies e.g. in the form of 'Audience Response Systems' (ARS) may improve the learning outcomes of students [19]. Due to the application of an ARS, students are further involved in the education process.

The ARS is a valuable didactical element as already mentioned by Brinker/Schumacher in 2009 [20]. Capabilities to participate in a lecture are quite diverse for students, which means that they can choose particular contents, recap their knowledge, interpret, reflect and prepare for examinations. Taxonomies of learning goals, like knowledge, understanding, application and analyzing [21] [22] are addressed holistically by the use of knowledge and comprehension checks. As a result problem-solving skills can be improved. The barriers for participation are marginal. Only an end device with access to the internet is required.

To satisfy the student's demands and with the objective to enable interactions between lecturer and students [23], an ARS is used since the winter term 2012/2013. The implementation of the described system demands a redesign of the lecture with special regards to the content. Questions have to be developed that allow the students to interact with the lecturer as well as with each other. This variety of questions ranges from multiple-choice questions to the inquiry of calculation results etc. [19]. Furthermore iteration-loops, to repeat misunderstood content, can be taken into account.

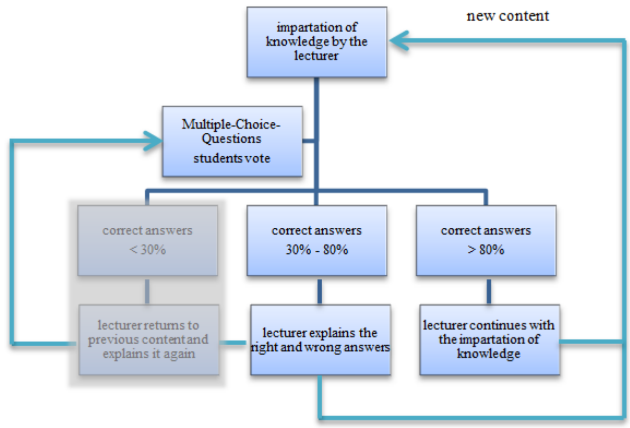

Fig. 3. Didactical concept of using the ARS [23]

Figure 3 illustrates the didactical concept of an Audience Response System, which is treated in the 'KOE'. Two fields are shaded grey, as this case is not applied in the lecture. If there are less than 30% correct answers, an explanation on the right answer is given. Provided that the content is understood (>80% correct answers), the lecturer switches to the next topic.

Evaluations of the success of the implementation of ARS in large university lectures show that the application of this "tool" has led to e.g. higher motivation of attendance, more attention of the students during class and even higher knowledge acquisition than in conventional (non-interactive) classes [19]. If and how the new didactical implementation of the media Audience Response System influences the learning process of students in the lecture 'KOE', has to be evaluated during the next terms.

D. *Video documentation*

In the winter term 2012/2013 the whole lecture was recorded by a professional camera crew, edited and afterwards provided to the students via the online teaching and learning platform L²P of RWTH Aachen University to support the learning process in auto-didactical-phases of the students. As shown in Figure 4 it is a matter of an interactive video documentation. For each module the chapters can be retrieved individually. Knowledge is thereby no longer appropriated as a lecturer-reserve, but accessible for students on demand. This form of making content available for students resembles the concept of learning on demand [25] and results in time saving potential for student learning [26]. Through this video documentation, the students can recapitulate content without any limit and at any time. Furthermore the presentation papers and manual sketches as well as animations and explanations of the lecturer are shown (see Fig. 4). The moderator works as a mediator and presents contents using different channels based on corporate learning. This way offers the possibility to review important contents and especially the preparation of exam papers could be done in a more efficient way. The result is an approach to the teaching for "individual learning", because students can decide when, where and how fast they organize their learning process [27].

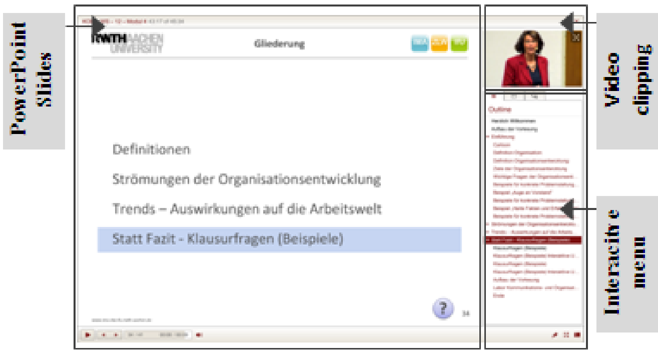

Fig. 4. Surface of the video recording of the lecture

E. Exchange and dataplatforms

As a reaction to the various influencing factors like the new technical possibilities, the teaching and learning platform L²P is used since the end of 2007. The learning platform is password secured and is just accessible for registered students.

The platform is implemented in order to provide important contents like teaching materials (e.g. lecture notes, videos and presentations of experts) and (further) literature for the students on a web based server to support time-consuming and complex teaching and learning processes [28] [29]. Additional L²P can be used to conduct surveys and simulate electronic tests.

Moreover the students have the possibility to discuss certain topics in an online forum talking to professors, mates or coaches and to obtain important clues to further arrangements. Thus discussion and dealing with lecture-content is supported and promoted. The aim is to influence the learning process to the effect that knowledge is understood by the students and can be applied. According to Palloff & Pratt the use of L²P in the lecture 'KOE' can be described as a "web-enhanced course" [30]. That implies physical as well as virtual components and thus copes with the European university-tradition in independent preparation of subject-specific content [31].

F. Laboratory tutorial

XL-Classes are faced with the challenge of a theoretical conveyance of on-professional competences to students. During the lecture 'KOE' not all contents can be taught within XL-Classes [32]. Therefore parallel to the lectures a laboratory tutorial of one and a half days takes place. The laboratory tutorial is based on the concept of 'simulation-based learning' which is a research or training method that tries to create a realistic experience in a controlled environment [33]. According to this, simulation replaces or boosts real experiences [34] and thus offers enormous advantages in mediating knowledge long-acting [34] [35]. In groups up to 40 students a foundation of a fictitious automotive company with different branches is simulated. Target systems and various strategies are developed and communication ways are defined and coordinated. An innovative vehicle is constructed under the guidance of 40 professional coaches. The basic knowledge for the realization of this task is mediated via microteaching units. In the next step, earlier learned theoretically basics are applied practically during a company simulation in order to obtain first practical experiences in organizational communication and working processes. Students try to construct an abstract concept in a theoretical framework to finally put their findings in an active experiment. The teamwork and the communication between the different branches demonstrate the importance of the lecture as well as the relation to working life. Additional to the contents of the lecture 'KOE', key skills such as team building, time management and project management are applied, experienced and trained in the simulation.

G. Online examination system

In order to examine around 1300 students efficiently and content orientated, a digital online examination system (called OPS = Online-Prüfungssystem | developed externally especially for 'KOE') is used and applied since 2007 [36] [37]. Examination questions are derived from the lectures contents and distinguished in different taxonomy levels (degrees of difficulty). Thereby the whole taxonomy-spectrum by Bloom 1956 [25] on a cognitive base is addressed to the students. The taxonomy levels are: knowledge, comprehension, usage, analysis, synthesis and evaluation. For the preparation of exam questions it is important to take into account, that the taxonomy levels are hierarchically arranged [38]. Hence the mediated competences for each taxonomy level must gain a specific manifestation before they can be applied in the next taxonomy level [39]. For example, without knowledge, usage of taught content (transfer capacity) is impossible [39].

Supported by a holistic handling of the mentioned difficulty degrees, the OPS enables to retrieve the student levels of awareness. With the help of the OPS knowledge and transfer capacity can be interrogated and evaluated electronically within a few minutes, so that no further staff is required.

IV. CONCLUSION & VISION

Each semester a university and lecture wide evaluation is stated. First evaluation results indicate that the adaption of the lecture concept and the implementation of new technical and didactic elements have a positive impact on the student evaluation of the course, especially the use of technical aids and demonstrations as part of the lecture as well as the teaching of contents by the lecturer.The average evaluation grade rises in the order of 0.5 (arithmetic average; scale from 1 (very good) to 6 (very bad)). For example the usage of devices and demonstrations in the lecture are evaluated with 1.7 (arithmetic average). The mediation of contents also has a positive trend. Lecture records as well as implementations of ARS Systems are inter alia reasons for that.

Altogether the multi-angulation of various didactical concepts can be outlined as a success for the lecture 'KOE'. This educed concept states that students are centered in educational learning process. In a next step the transferability of the redesigned concept of the 'KOE' lecture must be elaborated. Therefore indicators for a survey will be operationalized and developed.

Based on the already mentioned scientific studies of combining various methodical concepts to increase learning-success and the first positive evaluation after the 'KOE' redesign, more innovative teaching and learning methods will be developed, taken up and implemented for this purpose in the next few years.

Furthermore there is still potential for a continuous and appropriate optimization of the lecture 'KOE'. A long-term goal is to implement additional to the existing concepts the method of 'just in time teaching' to optimize and adjust lecture contents [40].

Accordingly presence lectures are not used anymore for conveying contents, but rather to motivate the students to participate and interact in the presence lecture and to discuss questions and problems with the lecture content. Therefore questions and tasks are provided online before every presence lecture. So the lecturer can see the student's results before every lecture 'just in time' and develop the lecture according to the level of awareness. This method is used to obtain feedback related to the student knowledge. This can be used in order to precisely react to the students demands on certain contents. In addition, students get to know on-professional competences while formulating their own questions as well as working on tasks independently. The continuous development of the lecture 'communication and organizational' primarily serves the goal of creating demand-oriented and target group-oriented courses for XL-Classes.

***Abstract*— This paper describes the development and integration of augmented reality content with traditional Engineering Design Graphics materials, and presents the results of a preliminary usability study conducted with Freshman Engineering students. The resources developed combine printed text and images with interactive three-dimensional content with the purpose of enhancing the understanding of technical graphics concepts and improving the students' visualization skills. In general, students had a very positive reaction when first presented with the materials and showed an optimistic attitude while interacting with the content. Additionally, augmented reality materials promote the development of self-directed learning skills and self-assessment.**

***Keywords*— augmented reality; spatial skills; engineering graphics**

I. Introduction

Engineering design graphics play a fundamental role in the engineering product development cycle. From an academic standpoint, the development of 3D spatial skills has been cited and recognized by many authors as a key factor in many scientific and technical disciplines [1, 2]. Studies have consistently shown that proper spatial skills are directly related to academic success in science, technology, engineering, and mathematics (STEM) [3-5]. Additionally, the use of CAD packages and the ability to create professional engineering drawings are common requirements both in upper-level capstone design courses and certainly in industry.

In engineering education, the development of three-dimensional visualization and spatial skills is often listed as a major objective in engineering design graphics courses. In many cases, these skills are developed indirectly, through the use of sketching or hand-drawn exercises, or as a side effect that occurs when studying topics such as orthographic projection or sectional views [6, 7]. Some approaches have used CAD applications [5, 8], multimedia [9], games [10, 11], and even virtual reality to train spatial abilities [12, 13].

While engineering design graphics are concerned with processing and describing three-dimensional information, the intrinsic nature of books and traditional printed materials is two-dimensional. This creates a learning barrier that has existed for years. On the other hand, the digital literacy and technological profiles of current students demand new and motivating teaching resources and methods that take full advantage of the existing technology [14]. Furthermore, it has been proven that the more immersive the learning process is (the more senses that are involved), the more effective and engaging the learning experience becomes [15]. In this regard, augmented reality technology can help overcome the limitations of traditional printed media, allowing students to truly visualize the concepts described on paper in full 3D.

This paper presents the use of Augmented Reality (AR) technology as a tool to enhance the delivery of traditional engineering graphics materials. For our study, printed resources, three-dimensional computer models, and visualization software were combined and integrated into a unique system intended to facilitate the learning process. The results of a pilot usability study of our system conducted with freshman engineering students are also reported.

II. Augmented Reality in Education

Augmented Reality can be understood as a variation of Virtual Reality [16]. AR is a visualization technology that combines real-time three-dimensional computer graphics with real video, creating a modified or enhanced representation of reality. Unlike Virtual Reality, where an entire world is artificially generated and users are completely immersed inside a simulation without perceiving their surroundings, AR allows users to experience a modified version of the world. In AR, virtual imagery is seamlessly overlaid onto real live footage providing an "augmented" view of reality. While Virtual Reality aims at replacing the real word with a simulated one, Augmented Reality complements or enhances the real world with virtual elements. Augmented worlds are typically experienced via computer screens, projectors, or head mounted displays (HMD).

The flexibility of Augmented Reality technologies has made possible the emergence and rapid growth of new applications. AR systems have been proven particularly effective as educational tools in different fields, including geography [17], architecture [18], medicine [19, 20], archeology [21], and geometry [22]. In medical areas, for example, AR has been used to train professionals in the use of new equipment and the implementation of new procedures, as

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

well as to teach students anatomy and biology [23]. Remarkable visualizations have also been created for archeological sites and architectural applications.

In the engineering graphics domain, studies have shown that the development of spatial abilities can be trained and improved by the use of Augmented Reality [12, 13]. In previous research, Do and Lee [24] developed an augmented reality game that used virtual LEGO blocks as a tool to analyze structures, create models, and assemble components to create complex configurations. The authors concluded that the game significantly improved the player's spatial abilities and visualization skills. In a different study by [25], the authors used augmented reality to develop resources that would help engineering students understand projections methods. Their students showed a higher level of engagement during the learning process. Various projects aimed at exploring the educational applications of AR have been promoted. Examples include CONNECT [26] and ARISE [27].

A. *Augmented Reality Books*

The concept of Augmented Reality Book has been explored by many scholars, and more recently by some commercial publishers, as educational alternatives to traditional books. When used without special AR devices, Augmented Reality books do not look any different from their traditional counterparts. Users can flip through the book and see the text and graphics printed on the pages. However, when read through the proper AR device, virtual content is rendered in real time creating the illusion that three-dimensional models are coming out of the page. The "MagicBook" is one of the most popular examples of educational books that use an AR interface to blend reality with virtual imagery [28]. Previous studies by [29] and [30] have concluded that books provide a familiar, intuitive, and accessible interface to interact with three-dimensional content, creating innovative and engaging experiences for the user.

The augmented engineering graphics materials presented in this paper are an extension of the work done by [31]. In their research, an augmented reality book was produced with the objective of improving visualization and spatial skills in engineering students. Their text, conceived as a workbook, contained traditional visualization exercises based on orthographic and pictorials representations of complex objects organized according to five levels of difficulty. The material was used successfully in freshman level courses, including remedial and intensive training sessions.

III. DESCRIPTION OF THE LEARNING TOOL

For our work, we selected two complete educational modules, orthographic projection and pictorials, from a classic engineering graphics curriculum. We developed the material incorporating augmented reality technology to both the content and the exercises.

The augmented reality system we present is low cost and easy to implement. In addition to the printed materials, only a computer with the proper software installed and a web camera are required. The "augmented" world is experienced through the computer screen. Usually this approach is known as "desktop augmented reality".

In order to activate the AR content, the user's web camera must be pointed at specific areas of the printed materials. These areas are defined by a series of square patterns, called markers (Fig. 1), which are automatically recognized by the augmented reality software. The markers are seamlessly integrated within the pages and linked to specific 3D models (Fig. 2).

Fig. 1. Examples of AR markers embedded in the graphics materials

A second marker is used to manipulate the augmented reality content, which is rendered in real time in the user's computer screen. The markers are black and white patterns used to trigger the AR content. They are recognized by computer vision techniques implemented in the software to determine the position and orientation of the marker relative to the camera.

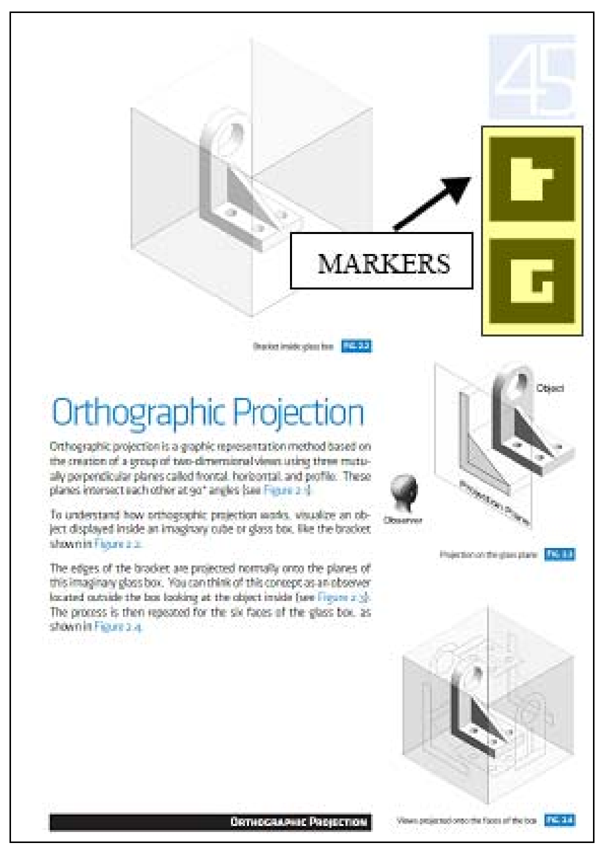

Fig. 2. Integration of AR markers within the page

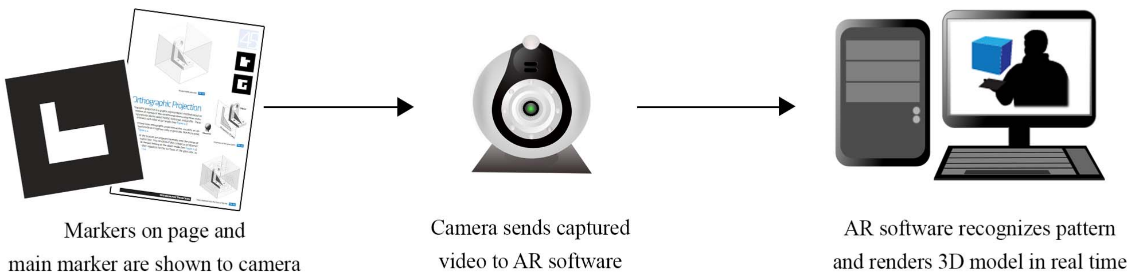

Fig. 3. AR System Diagram

Once a set of markers is recognized, the corresponding three-dimensional model is rendered over the video captured by the web camera using the calculated coordinates of the marker. The basic functioning of the system is shown in Fig. 3. Some of the AR models used in our system are shown in Fig. 4, as rendered by the software in the user's computer screen.

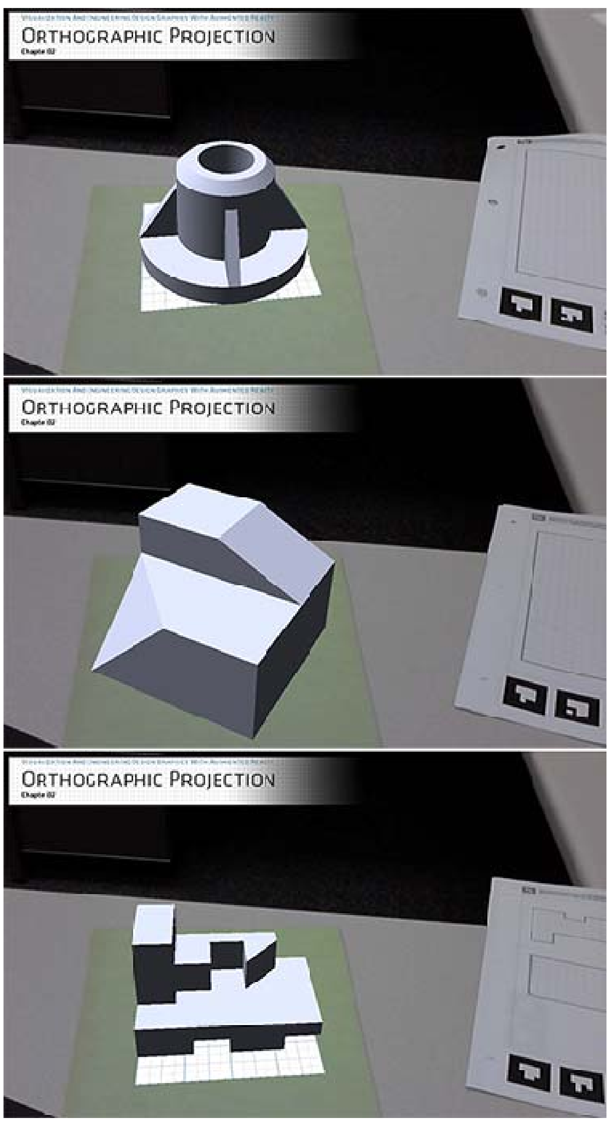

Fig. 4. Examples of AR models as seen by the users

IV. Pilot Usability Study

A pilot study of the AR system was conducted with freshman engineering students at Texas A&M University to determine whether the tool has adequate usability for its possible integration into the classroom. The study was prepared according to usability factors defined by [32]:

- Effectiveness: "accuracy and completeness." It refers to how accurately a system completes a set of tasks to achieve the desired result.
- Efficiency: "resources expended." It refers to the extent to which effort, cost, and time are well spent to perform the desired task.
- Satisfaction: "positive attitudes toward the use of the product." It refers to the extent to which expectations are met. Satisfaction is essential for keeping users motivated and engaged.

A total of 60 volunteers participated in this pilot study, all with recent training in engineering design graphics. This number widely exceeds the minimum number of participants recommended by [32] (more than 8) for usability studies.

The experiment was conducted in a computer laboratory environment, where the every participant had a computer with a web camera and the AR software already installed. Each participant was able to use and test the Augmented Reality system individually. A set of printed materials with the corresponding markers were provided and the individuals were given time to test the application and complete a series of exercises. The content of the engineering design graphics materials was limited to orthographic projection and visualization exercises.

To measure the different aspects of usability, a psychometrically validated questionnaire similar to the one proposed by [30] was distributed at the end of the exercise. A set of questions divided into two categories was presented to participants using a standard five-point Likert scale: Strongly Disagree, Disagree, Neutral, Agree, and Strongly Agree. To assign a quantitative value to these Likert items, progressive positive integer values from 1 (Strongly Disagree) to 5 (Strongly Agree) were used, which allows the use of mean and standard deviation to quantify the parameters of interest.

The questions in the first category were intended to evaluate the effectiveness and efficiency of the materials. The questions in the second category were used to test user satisfaction levels in terms of the technology. Effectiveness, efficiency, and satisfaction levels are measured using the mean and standard deviation of the data obtained from the participant's responses.

The questions presented in the first category as well as the statistical measures used to analyze the results are shown in Table I.

TABLE I. QUESTIONS AND RESULTS OF EFFECTIVENESS AND EFFICIENCY

	Question	Mean	Std. Deviation
A1	The material is presented in a clear and concise manner and the topics are well structured.	4.533	0.536
A2	The number of exercises proposed in the chapter is sufficient for the topic discussed.	4.433	0.673
A3	The examples, types of 3D models, and difficulty of the exercises are adequate to comprehend the material.	4.483	0.624
A4	It is easy to locate the examples, exercises, and markers in the pages.	4.667	0.542
A5	The manipulation of the markers/virtual objects is easy and intuitive.	4.45	0.79
A6	The Augmented Reality application is stable and works well (doesn´t freeze).	4.033	0.78
A7	The Augmented Reality application is responsive, i.e. there is no lag in the screen when manipulating virtual models.	4.1	0.858
A8	The visual quality of the three-dimensional models on the screen is adequate. The models are clear and easy to recognize.	4.5	0.597
A9	The combination of printed materials and Augmented Reality technology is easy to use and intuitive.	4.6	0.527

Both AR technology and materials scored notably high. The vast majority of participants considered that the content was appropriate and well structured, and that the AR technology worked well. None of the participants experienced major difficulties manipulating the markers or using the AR software. This observation agrees with the responses given in the questionnaire, as most students reported that the system was intuitive and easy to use.

The AR software is robust, although a few participants detected some problems with the application that caused the AR models to flicker or momentarily disappear from the screen. This can explain the low scores on questions A6 and A7. We tested the application after all participants completed the exercises and found that the lighting conditions in certain seats and the print quality of some of the markers used in the experiments were not ideal.

User satisfaction questions and results are shown in Table II. For the last question, participants were asked to score the overall quality of the materials and technology presented. Since the Likert scale used in previous questions didn't apply to this question, the items of the scale were changed from Strongly Disagree, Disagree, Neutral, Agree, and Strongly Agree to Very Bad, Bad, Average, Good, and Excellent. The numerical values assigned to the items remained unchanged.

TABLE II. QUESTIONS AND RESULTS OF USER SATISFACTION

	Question	Mean	Std. Deviation
B1	The use of Augmented Reality in an Engineering Graphics course is valuable and useful to improve the understanding of engineering graphics topics.	4.55	0.565
B2	I could complete the exercises without any help other than the Augmented Reality software.	4.033	0.843
B3	The use of Augmented Reality technology is interesting and engaging.	4.833	0.376
B4	The use of Augmented Reality provides a significant advantage over traditional written materials.	4.383	0.761
B5	The use of three dimensional tools can increase attention and motivate students to study Engineering Graphics subjects.	4.617	0.613
B6	Augmented Reality is a good tool to help students comprehend engineering graphics and improve visualization skills.	4.683	0.537
B7	The use of Augmented Reality technology can be beneficial for students in other engineering and technical courses.	4.617	0.524
B8	Overall Opinion of the material (Very Bad, Bad, Average, Good, Excellent)	4.683	0.504

The material was received with enthusiasm and the participants showed a very positive reaction. The general opinion was that AR technology is valuable, engaging, and useful in the engineering design graphics domain, particularly when visualizing challenging models. Excitement and engagement could be easily observed in the participants during the exercise, although this could be attributed to the fact that many had never used or experienced AR technology before.

The frequencies of the students responses to the questions provided in the study are shown in Table III and illustrated in the chart shown in Fig. 5. The item "Strongly Disagree" has been omitted from the chart because the frequency of such response is zero for all the questions.

TABLE III. FREQUENCIES OF PARTICIPANTS' RESPONSES

	Disagree	Neutral	Agree	Strongly Agree
A1	0	1 (1.67%)	26 (43.33%)	33 (55%)
A2	0	6 (10%)	22 (36.67%)	32 (53.33%)
A3	0	4 (6.67%)	23 (38.33%)	33 (55%)
A4	0	2 (3.33%)	16 (26.67%)	42 (70%)
A5	1 (1.67%)	8 (13.33%)	14 (23.33%)	37 (61.67%)
A6	1 (1.67%)	14 (23.33%)	27 (45%)	18 (30%)
A7	2 (3.33%)	13 (21.67%)	22 (36.67%)	23 (38.33%)
A8	0	3 (5%)	24 (40%)	33 (55%)
A9	0	1 (1.67%)	22 (36.67%)	37 (61.67%)
B1	0	2 (3.33%)	23 (38.33%)	35 (58.33%)
B2	3 (5%)	11 (18.33%)	27 (45%)	19 (31.67%)
B3	0	0	10 (16.67%)	50 (83.33%)
B4	1 (1.67%)	7 (11.67%)	20 (33.33%)	32 (53.33%))
B5	0	4 (6.67%)	15 (25%)	41 (68.33%)
B6	0	2 (3.33%)	15 (25%)	43 (71.67%)
B7	0	1 (1.67%)	21 (35%)	38 (63.33%)
B8	0	1 (1.67%)	17 (28.33%)	42 (70%)

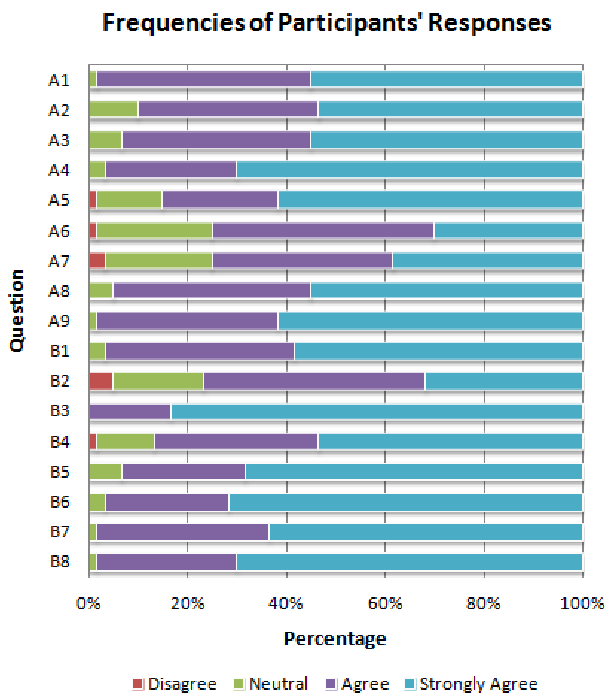

Fig. 5. Frequencies (%) of the participants' responses

A great percentage of the participants agreed or strongly agreed with the statements that AR provides a significant advantage over traditional printed resources and that AR could also be beneficial in other engineering courses, which indicate a high level of acceptance, motivation and interest in the technology. On the other hand, question B2 received some low scores, which seems to reveal that some participants see AR technology supporting traditional materials rather than entirely transforming them into self-study resources.

V. CONCLUSIONS AND FUTURE WORK

Our study has shown that the use of Augmented Reality has the potential to become an effective tool to deliver engineering graphics modules. AR technology provides an attractive and engaging new way to complement and enhance traditional teaching and learning materials (usually based on pen and paper exercises), while moving education one step closer to the technological profiles of today's students.

The system we present was designed to be low cost and easy to use. Users learn to work with the application almost immediately and the physical manipulation of the markers becomes natural very rapidly. The minimalistic interface of the software ensures the students remain focused on the actual activity they are performing without getting distracted by other elements.

As shown by the results of our usability study, the system scored remarkably high in all categories. The materials were widely accepted, with very positive reactions from the majority of the participants.

In the future, we plan to perform a comparative study to more accurately test the impact of AR technology in the students' understanding of engineering design graphics materials. Although the technology looks promising and many students and instructors have already ventured to use it (at least partially) in the classroom, we are interested in determining if there is a significant statistical difference between engineering students that use traditional materials and students that use AR-based materials.

***Abstract*—Students from China are always intelligent but lack of creativity. These are somewhat stereotypes. This is partially because of the reserved or implicit culture. In an objective point of view, it is also because of the limited education resources. In the single assessment criterion education circumstance, students chase for the high marks even without knowing their interests or aptitudes. In a 12-week open experimental course, *Optoelectronic Instrument Experiments* (OIE), we try to encourage the students to dig their aptitudes and bring them into full play to earn more credits for the course. Self-assessment and mutual-evaluation for technical proficiency, communication skills, collaboration and leadership are carried out for the final evaluation. We also communicate with the students the speciality and skill a qualified engineer needs. We hope to help them prepare themselves for engineering-related jobs in the further.**

Keywords—Project-based learning, engineering-involved courses, aptitude digging

I. INTRODUCTION

Students from China are always intelligent and shy. They are good at mathematics but lack of creativity. These are somewhat stereotypes. This is partially because of the reserved or implicit culture. In an objective point of view, it is also because of the limited education resources. The traditional teaching and assessment criterion for a good student is high marks in the examination. Struggling for the standard answer, most students do not have their interests or even their own time. This is terrible and some of the students get lost in job hunting or even their life because standard answer no more exists. They only know what they dislike, but do not know what they are fond of or good at. This is the common case in the current generation.

The purpose of education is not teaching what to do but instructing how to do things correctly and effectively. However, the “standard answer” education mode can hardly help students develop or even realize their aptitude and personality. Since self-knowledge is the basis for the choice in life, the situation should be changed gradually. Unfortunately, it is still hard to do personal evaluation and education for each college student in China. So at least one course involving and encouraging personal thoughts, trails or even failures should be arranged. It is a pity in many colleges in China such kind of compulsory course does not exist.

We have launched a project-based course Optoelectronic Instrument Experiments (OIE) in Beijing Institute of Technology since 2009 [1]. Several optoelectronic instrument systems are set as the subjects of experimental project. After learning some general topics on optoelectronic instruments and design examples, the students are grouped and each group can choose one project. They are required to develop the whole system within 12 weeks. The final assessment includes the performance of the system, the collaboration, the presentation, and etc. It is an open experiment course and there is no standard answer. In the previous years, we find that some of the students turned more enthusiastic about his major during the course; some all-around ones found their shorts and some discovered their speciality. These are all good phenomena. They proved that the course could help students improve their self-knowledge. We call it aptitude digging.

In this year we are preparing a segment which systematically emphasizes aptitude digging through the project process. The detailed methods are given in the following sections.

II. APTITUDE DIGGING PEDAGOGY AND ISSUES IN OIE

A. OIE: The Open Project-based Course

OIE is a lecture-lab course which aims to familiarize students with the principal ideas of optoelectronic apparatus design and train students to apply the knowledge to identifying, analyzing and solving problems in optoelectronic system construction. We try to expose the students to “real” engineering early. After some brief general topics on optoelectronic instruments and introduction to several successful design examples, the students are assigned to teams and each team chooses one project to implement in twelve weeks. Through the mini simulative “Cycle of Professional Practice” [2], students will learn how to integrate the knowledge and techniques they have learned previously, and use different kinds of components and devices to construct an optoelectronic instrument.

The main difference from the other project-based courses is that the OIE course is compulsory, which means every student must take this course. In our opinion, students are the products of their college. Elite education may help several excellent students to achieve huge success, but we prefer to the results that all the students turn to be qualified products. All the students who are majoring in Measurement & Control Technology and Instruments have to gain the OIE credit to get their bachelor degree. Our purpose is to help all the students in this major, at least most of them, to improve their engineering practical, personal and interpersonal skills. We are trying our best to impel them to be prepared for the real engineering environment they have to throw themselves into soon.

B. No Standard Answer in the Open Experiments

As introduced above, in OIE, we don’t set any exams or established experiments. The entire detailed target, schemes, budget, schedules are proposed and organized by the students in group. They can solve the scientific and technic problems by any means they can afford. This is similar with the situation in real engineering research environment. However, this does make it more difficult to conduct and grade them. Their questions are divergent and some of the jobs are really demanding while some are regular.

In order to technically help them better, we organized a 6-member instructor team, including full professors, associate professors and lecturers. The members are also distinct in major, which includes optics & photonics, mechanics, electronics, and computer hardware & software. We also involve experienced researchers and technicians into the course as consultants. As for the assessment of students doing jobs with different difficulties, we do the grading considering the difficulty as a factor.

What we are trying to do is to create an environment without standard answer and with diversification. We hope this will help inspire the students with creativity and confidence.

III. What's New This Semester

With the environment created as above, in this semester, we emphasize aptitude digging through the project process. We set two sections at the beginning and end of the course.

A. Self-assessment and Mutual-evaluation in the Group

The first class of OIE is arranged for team grouping. In this semester, the students are grouped "providentially". Some poker cards with funny pictures are prepared before, the total number of which equals to number of the students who have signed up for the OIE course. Every student is asked to draw a card from the poker card pile when he enters the classroom. Just when they enjoy the funny view on their cards and become curious what it is for, the grouping rule is announced. The students who got the same suits and numbers are grouped as a team.

Because it is impossible for the students to choose their partners, they have to position themselves in the group at the beginning. They also have to elect the team leader and choose the experimental topic. We organize self-assessment and mutual-evaluation section to help them visualize the process.

Self-assessment is done through questionnaire. Two choice questions are included. The aptitude related to modern engineering realization can be divided into two general categories: academic and interpersonal capability. We call them specialized skills and teamwork capability. For the specialized skills, we further classify it into

(1) optical design and optical path setup;

(2) mechanical design and system setup;

(3) electronic design and realization;

(4) programming and debugging, and

(5) others.

The first question is that *Do you know your specialized skill*? Five options are given as

A. Yes, I know. It is the above ( ) and ( ) (no more than two choices) because I had relevant experiences.

B. Yes, I know. I am good at all of them.

C. Yes, I know. I am not good at any of them.

D. No, I do not know. I am good at getting high scores in examinations maybe, but I really do not know my skills in solving real engineering problems.

E. None of the above. My opinion is ( ).

For the teamwork capability, we focus on the personal localization. We design classification as

(1) I am suitable for the team leader. I am responsible and good at organizing and coordinating teammates.

(2) I am suitable for a backbone in the team. I am responsible for my own work and willing to help other teammates, but I do not want to organize.

(3) I am suitable for a common member. I can finish my work but I am not interested in others' work. I will do what team leader asks me to do.

(4) I am not interested in this class, and I will spend as little time as possible on it.

The second question is *Do your know your teamwork capability? What is your localization among your teammates*? Three options are given as

A. Yes, I know. I localize myself as ( ) in the above. I am not willing to take other characters.

B. No, I do not know. I can be any of the above.

C. None of the above. My opinion is ( ).

After the self-assessment, students are asked to do the mutual-evaluation by sorting the teammates according to leadership, fundamentals in mathematics and physics, experiences in engineering and preliminary intention for the division. Results are made public anonymously or not according to the students' opinions. Then the division inside the group is made by the students according to the sorting results and discussion.

Members with different specialities and personalities may constitute a reasonable and efficient team. Communications based on self-knowledge and mutual-understanding may lead to success. There is an old saying in China, *knowing yourself as well as the enemy*. It is also true that *knowing yourself as well as the partner*. Students are expected to preliminarily position themselves in unfamiliar members.

In this section, most of the students showed enthusiasm in self-dissecting and mission division. Some received different opinions about their characteristics. Very few acted negatively and replied "whatever". We arranged the division according to their voting and each student was assigned a particular mission by his team.

B. Reassessment at the End of the Course

During the experiments, the students are asked to try their best to solve the problems in their own division. Up to now, they act very actively. Since this is the first time for most of them to join in a practical engineering project, overestimation and underestimation happen in almost every class.

When the students finish the scheme design and realize that all the knowledge is available from the text book, they tend to take the problem lightly and complain it is too easy. They even believe they can finish the whole system in one week. However, when they begin to assemble a specific functional device and encounter a small failure, they turn blank and complain it is too difficult. The project also turns impossible to them. This reflects the fact that they do not know how to solve practical problems and how to deal with unexpected failures. They will even become less confident in front of a failed basic circuit with only 4 components.

Facing this current situation, we try to guide them not only with technical skills but also open mind. We plan that at the end of the course, the students should evaluate all the group members including themselves again in the same aspects. The questionnaire after the whole course is similar with that before the experiments. Still two questions are included. The classification for specialized skills and teamwork capability are exactly the same. But the options are changed as follows. For specialized skills, options are

A. Yes, I know. It is the above ( ) and ( ) (no more than two choices) and I had more relevant experiences in this course.

B. Yes, I know. It is the above ( ) and ( ) (no more than two choices) and I had first relevant experiences in this course.

C. Yes, I know. I still think I am good at all of them.

D. Yes, I know. I still think I am not good at any of them.

E. No, I still do not know. I do not have the chance to try.

F. None of the above. My opinion is ( ).

For teamwork capability, options are

A. Yes, I know. I am suitable for ( ) in the above. It is proved in the course.

B. Yes, I know. I am suitable for ( ) in the above. It is a pity I cannot prove it in the course because of the grouping and division.

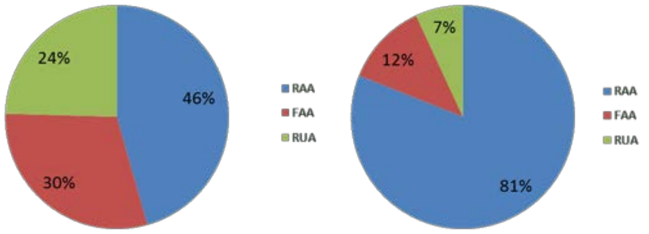
C. Yes, I know. I am suitable for ( ) in the above. I changed my mind in the course.

D. No, I still do not know.

E. None of the above. My opinion is ( ).

C. Results and Analysis

In all, 57 students took the questionnaire before and after the experiments, and we counted their answers as follows. For the specialized skills questions before experiments, Option A is taken as Real Awareness of the Aptitude (RAA), Option B and C are taken as False Awareness of the Aptitude (FAA), Option D is taken as Real Unawareness of the Aptitude (RUA), and Option E is taken as others. For the specialized skills questions after course, Option A and B are taken as RAA, Option C and D are taken as FAA, Option E is taken as RUA, and Option F is taken as others. The choices of the students before and after the experiments are counted and visualized as in Fig. 1. More than 30% of the students get better understanding and recognition of their academic aptitude.



(a) (b)

Fig. 1. Statistics of specialized skill recognition (a) before and (b) after the couse.

For the teamwork capability, similar results can be obtained. 14% of the students get better localization of themselves.

IV. Conclusion

Since self-knowledge and confidence are the basis of work and life, we launched a project-based open experimental course, *Optoelectronic Instrument Experiments*, and tried to create an environment without standard answer and with diversification. We organize self-assessment and mutual-evaluation section to help students dig their aptitudes. Currently, overestimation and underestimation happen in almost every class. We try to guide the student to establish confidence and accumulate experience during solving open engineering problems. According to the self-assessment questionnaire before and after the course, the students get better understanding and recognition of themselves in both academic and interpersonal capabilities. We will improve the mutual-evaluation process next time.

Abstract*— We applied the How People Learn framework (HPLf) in two different higher education contexts. On one hand, a first-year core course on Computer Technology, taught at the Computer Engineering Degree Program at Universitat Politècnica de València, Spain. On the other hand, two Food Chemistry related courses, taught at Universidad de las Américas Puebla, Mexico, as part of food engineering undergraduate and food science graduate programs. The goal of these works was to redesign studied courses at both universities from a lecture-based format to a "challenge-based" format by using Tablet PCs and digital ink. In order to support the studied approach, different ink-enabled software tools were utilized. Class sessions were enhanced through the usage of Classroom Presenter, a pen-based interaction system that supports the sharing of digital ink on slides between instructors and students. InkSurvey also allowed teachers to pose questions, receive instantly digital ink responses, and provide real-time formative feedback. Some other tools such as PDF Annotator and Ardesia helped instructors to review coursework and assignments and provide formative feedback as well. We studied our approach over the two last academic years by observing classes at both universities, obtaining selected student achievement indicators and conducting surveys with students and instructors.

Keywords—Tablet PC; Digital ink; How People Learn; Classroom Presenter; InkSurvey

I. Introduction

The *How People Learn* framework (HPLf) provides a convenient way to organize a great deal of information about the nature of competent (expert) performance and about ways to help students develop their own competence. This framework highlights a set of four overlapping lenses that are useful for designing learning environments. HPLf encourages that teachers promote student engagement both in and out of class, working in teams or individually, and what is more important, providing students with multiple feedback from different formative assessments.

Our challenge was to use HPLf to redesign different courses in two quite distinct contexts. Overall, the goal was to improve teaching and learning, creating learning environments that promote high quality interactive classrooms while formative assessment should be integrated in educational practices through the use of Tablet PCs and associated digital ink technologies.

Tablet PCs combine a standard notebook computer with a digitizing screen and a pen-like stylus device to produce a computer that allows users to easily input natural writing and/or drawing. Pedagogically, applications for the Tablet PC include lecture/presentation enhancement, problem-solving demonstrations, active learning support, guided brainstorming, reading, commenting, marking- up (providing feedback), and grading of student work. A review of the current literature supports the following advantages in using a Tablet PC: first, digital ink enables instructors to write "on the fly" during class as one would write on a chalkboard or on a transparency. This is especially meaningful for engineering and chemistry courses where examples and explanations are often mathematically and graphically intensive. Second, the freedom of marking-up significantly changes the way students and teachers interact. It facilitates bidirectional sharing of information, moving students beyond merely observing presentations to interacting with the material, the teacher, and each other. In addition, the use of Tablet PCs supports more efficient management of information. Dynamic working notes can be saved, while lecture notes with vivid annotations can become available for students' online viewing [1].

The rest of this paper is organized as follows. Section II describes the contexts where this approach was implemented. Section III outlines how the courses were redesigned and the ink-enabled software that supported these processes. Section IV summarizes the results on both contexts. Finally, section V draws some conclusions and outlines further work.

II. Context Description

As stated in the introduction, two different contexts have been used to validate our approach. On one side, at *Universidad de las Americas Puebla* (UDLAP), a Mexican private institution of higher education committed to first-class teaching, public service, research, and learning in a wide range of academic disciplines including business administration, the physical and social sciences, engineering, humanities, and the arts. Since 1959, the Commission on Colleges of the Southern Association of Colleges and Schools (SACS) has accredited

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

UDLAP in the United States. On the other side, at *Universitat Politècnica de València* (UPV), a Spanish public educational institution that offers modern, flexible degrees that are designed to meet the demands of society, as well as official postgraduate programs that are subject to demanding quality control systems. It has three campus sites with a total of 36,187 students, 2,843 members of teaching and research staff, and 2,396 administrative and services staff. It is the only Spanish technological University ranked among the best in the world, according to the Academic Ranking of World Universities (compiled by Shanghai Jiao Tong University).

A. UDLAP courses

Concerning case studies, UDLAP selected 2 courses, *Food Chemistry (IA-332)* and *Advanced Food Chemistry (IA-530)* which are a junior level, 3 credit required course for food engineering and nutrition BS programs and a first- semester 3 credit required course for the food science MSc program and also an elective for the PhD in food science program at UDLAP, respectively. Approximately 10-25 students are enrolled in IA-332 per semester with 6-17 food engineering students and 4-8 human nutrition students, while approximately 5-10 graduate students are enrolled per semester in IA-530; these graduate students have already a BS in food engineering, food science, biology, agricultural engineering, chemistry, or pharmacy. IA-332 and IA-530 major goal is to help students think about the way a food chemist does. Thus, students are involved in answering two key questions: i) how the composition, structure and properties (especially in terms of quality and safety) of foods are affected by chemical changes the food experiences? And ii) how the understanding of key chemical and biochemical reactions can be applied to many situations encountered during formulation, processing and storage of food?

The fundamental concepts of the studied courses are, therefore, chemical and biochemical changes of food and its effect on food composition, structure, quality, and safety during formulation, processing and storage, while encouraging students think about and apply food chemistry in the same ways experienced food scientists and engineers do.

In an increasingly collaborative, mobile and globally inter-connected environment, UDLAP envisions ubiquitous computing as a natural, empowering component of every teaching, learning, and research activity. UDLAP is committed not only to adopting and adapting technologies to all its scholarly endeavors, but also to playing an active role in their development [2].

B. UPV course

In contrast to UDLAP courses, *Computer Technology (TCO-11544)* is a first-year core subject taught during the spring term (second semester) in the Computer Engineering Degree Program that was selected at the UPV as case study. The course has 6 ECTS credits (150-180 hours). 60 hours are dedicated to face-to-face classroom work and at least 90 hours are expected as students' personal study. On average, during the last academic years, the course has dealt with 11 lecturers and more than 450 students per year, divided into 11 lecture groups and 21 lab groups. The syllabus was compiled according to national and international recommendations, the main sources being the ACM/IEEE curricula recommendations, as well as the Computer Engineering Degree Program White Paper of the National Agency for Quality Assessment and Accreditation [3].

The course is included in the field of computer engineering in ACM/IEEE computing curricula, and matches the non-computing topic of electronics as it is focused on semiconductor devices and logic families. Computer Technology topics are not generally addressed in high school programs, so that the background of UPV students on electronics is virtually nonexistent.

III. Redesigning the Courses

A major aim is to help students developing the kinds of connected knowledge, skills, and attitudes that prepare them for effective lifelong learning [4][5]. This involves the need to seriously rethink not only how to help students learn about particular isolated topics but to rethink the organization of entire courses and curricula. The ability to design courses and corresponding high-quality learning environments require that we move beyond procedural strategies and models. We also need to understand the kinds of skills, attitudes, and knowledge structures that support competent performance. Thus, for the redesigning of the courses similarly as previously described [4]-[6] we "worked backwards" as suggested by Wiggins and McTighe taking into account Jenkins model as well as the HPL framework [7][8]. Especially important was knowledge of key concepts and models that provide the kinds of connected, organized knowledge structures and accompanying skills and attitudes that can set the stage for future learning [8].

Our redesigns involved a transformation of our courses from a lecture-based format to a "challenge-based" format. We use the term "challenge-based" as a general term for a variety of approaches to instruction that many have studied, these include case-based instruction, problem-based learning, learning by design, inquiry learning, anchored instruction, and so forth. There are important differences among these approaches, but important commonalities as well. We used the HPLf as a set of lenses for guiding the redesign of the lessons, development of our challenges but also the overall instruction that surrounded the challenges [5]-[7]. Our goal was to improve teaching and learning by creating high-quality learning environments that promote an interactive classroom while integrating formative assessments into classroom practices by means of Tablet PCs and associated digital ink technologies [4][9][10].

Particularly important were opportunities to make students' thinking visible and give them chances to revise. We also noted the importance of provided opportunities for "what if" thinking, given variations on the challenge and for new problems that also involved the lesson's concepts. Attempts to help people reflect on their own processes as learners (to be metacognitive) were also emphasized. We utilized several Tablet PC associated technologies to gauge student learning in real time, provide immediate feedback, and make real-time pedagogical adjustments as needed.

A. *Ink-Enabled Software*

To support the described approach, different ink-enabled software tools were utilized.

Communication within the classroom was enhanced through the usage of *Classroom Presenter* (CP) [11], a pen-based interaction system that supports the sharing of digital ink on slides between instructors and students. Instructors connect the Tablet PC to the lecture room screen to present contents, while showing their digital ink annotations in real time. CP makes possible to broadcast these contents to students' Tablet PCs, while allowing them to personalize the instructor provided materials with typed and ink annotations that each student can make, based on discussion during class (Fig. 1).

Using the work of Angelo and Cross [12], we identified Classroom Assessment Techniques (CATs) appropriate to each section of the course and then adapted them into the Tablet PC/CP environment. Instructor utilized CATs to gauge student learning in real time and made real-time pedagogical adjustments as needed. At various points during each session, students are asked to tackle a learning activity, whether a simple exercise or a more complex problem, as in the traditional approach. In this setting, students can anonymously respond by handwriting (or typing) their solution on the Tablet PC and submitting it wirelessly to the instructor. As soon as the exercises are received, instructors can preview the student responses, select one or more to display to the class, and make annotations as they are being displayed. This option provides immediate feedback to both students and instructor about misunderstandings and enables the instructor to adjust course material in real-time based upon student answers to in-class exercises. Additionally, student responses can be saved for review after lecture by the instructor or even made available electronically to the audience. According to the instructor judgment and course design, students are asked to deliver some in-class exercises through the virtual campus platform and thus, can be used as part of the student activity score, what enables a continuous assessment.

The instructor also made use of CATs that are already features within Classroom Presenter, like the polling features (true/false as well as multiple choice questions). Students respond by clicking the corresponding answer on their Tablets. Once instructors close the poll, CP shows the corresponding results in statistical form. This strategy is also useful as a way to quickly gather formative information and in turn, to provide immediate feedback to students to help clarify misconceptions.

In order to support group work, a virtual meeting room called *Vyew* [14] was also employed. It is a browser-based group screen and desktop sharing platform that also offers group video chat and includes ink annotation and drawing tools. Therefore, it proved especially suited to help students to address team assignments, problem-solving or projects that usually requires everyone to have access to the common information as well as a more rich communication ways. *Vyew* comes with a basic free version that offers unlimited use for up to 10 people, making it more than sufficient for typical team sizes at UPV.

InkSurvey [15], a web-based tool developed specifically to allow an instructor to pose open-ended questions to students during class and receive real-time student responses was also utilized (Fig. 3). Students by means of Tablet PCs respond to these questions with their own words/sentences/paragraphs entered manually via the keyboard, or with digital ink that allows handwriting, sketches, equations, graphs, derivations, etc. Confidence level can be included if desired (as was our case). The instructor received an instantaneous compilation of web-based student responses to receive feedback in real time [2][5].

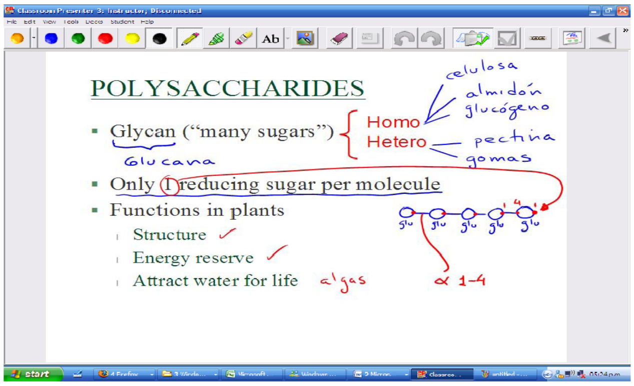

Fig. 1. Example of Classroom Presenter usage in Advanced Food Chemistry.

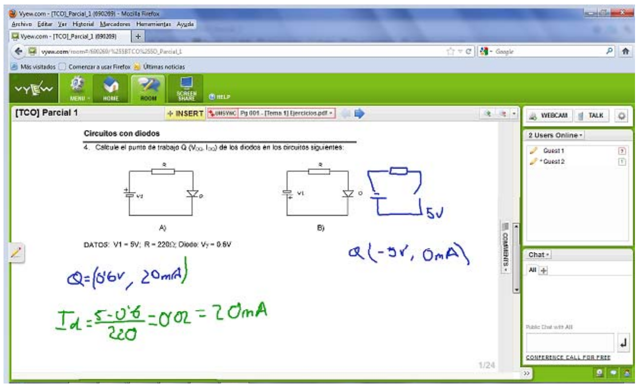

Fig. 2. Example of Vyew usage in Computer Technology.

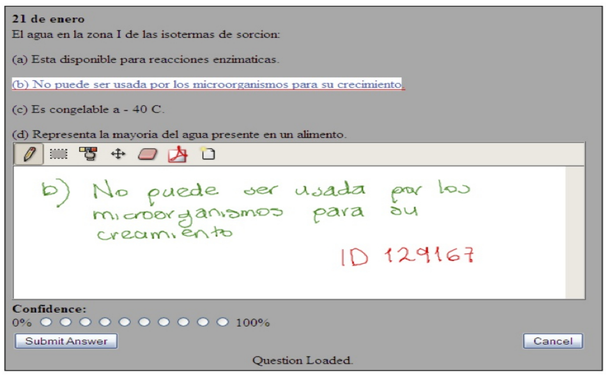

Fig. 3. Example of Inksurvey usage in Food Chemistry.

Some other tools such as *PDF Annotator* [16] and *Ardesia* [17] were used by UPV instructors to review and correct student coursework and assignments uploaded to the corresponding LMS. In the first case (Fig. 4), ink features were very helpful to make short comments on PDF documents, highlighting, or even adding drawings in order to better illustrate ideas. In case other formats or resources were delivered, a free digital sketchpad software called *Ardesia* was used to make colored free-hand annotations with digital ink everywhere, record it and return it to the student. According to White and Irons [18], these tools help faculty introduce some of the most useful types of formative feedback perceived by students and can therefore contribute to enhance their learning.

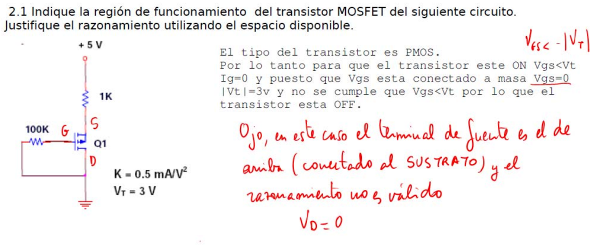

Fig. 4. Example of PDF Annotator usage in Computer Technology.

IV. RESULTS AND DISCUSSION

To measure the effectiveness of the experiences, we report here some quantitative and qualitative measures of the effectiveness of the studied approach.

A. *Quantitative measures*

In order to assess the approach presented in this paper two groups have been selected in Computer Technology (TCO in the figures) as the experimental ones, while the remaining followed the “traditional” teaching approach. As there were nine morning groups and two afternoon groups at UPV, and their features use to be different, we selected two morning groups as the experimental ones (Tablet groups in Fig. 5 and 6) in order to facilitate the comparison.

We utilized three quantitative indicators to assess UPV experiences: the student activity score (lectures and labs), the written exam scores and the final score, which was computed as the arithmetic average of the first two. In fact, these indicators represent the average score in a 10-point scale for the different groups. It is important to point out that the second one is the more reliable as all the students take exactly the same exams regardless their group. However, the definition of student activity mark and accordingly the final score can be different depending on the studied groups.

Fig. 5 shows that students in the Tablet groups had better results in the three indicators when compared both to the morning groups and to all the groups, although the difference in the written exams was the lowest. Concerning the second academic year, Fig. 6 shows that although student activity is quite similar in the different groups, in particular when we compare Tablet and morning groups, once again students at experimental groups performed better in written exams compared to the rest of the groups. Similar results were obtained in terms of pass, fail, and dropout rates. Tablet groups obtained better results in the two considered academic years; however, the differences were small.

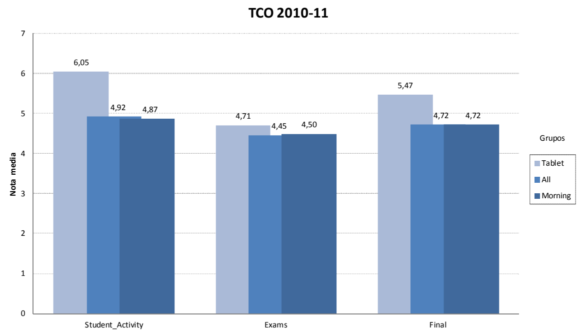

Fig. 5. Indicators for the academic year 2010-11.

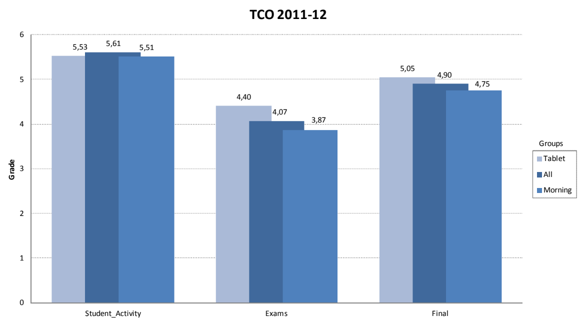

Fig. 6. Indicators for the academic year 2011-12.

Concerning UDLAP courses, in IA 332 (undergraduate) and IA 530 (graduate) were applied three quizzes, the courses were evaluated by obtaining scores of three quizzes, the third ones were part of the final exams. With the use of Tablet PCs and ink-enabled software (InkSurvey and Classroom Presenter) students improved their results in these summative assessments (final exam). In both cases, undergraduate and graduate courses, the formative assessment exercises performed with the Tablet PC and InkSurvey had a positive impact on the grades of the summative quizzes (Fig. 7).

Fig. 8 exhibits the mean scores (in a 10-point scale) of quizzes taken by undergraduate (IA332) and graduate (IA 530) students in the quizzes applied four years before implementing the use of the Tablet PCs (2005 to 2008) that were compared with results (after) obtained during the next four years (2009 to 2012) when the courses were redesigned and Tablet PC and associated technologies were utilized.

B. *Qualitative measures*

In order to examine how students perceived the use of Tablet PCs and associated technologies, at UDLAP we applied two online surveys to be answered by students (IA 332 and IA 530). The first survey was conducted at the beginning of the semester and the second one at the end. The first survey was related to the expectations of students in relation to the use of these technologies. The second survey was designed to assess the academic experience that students had with the use of these technologies. Both surveys have some open-ended questions.

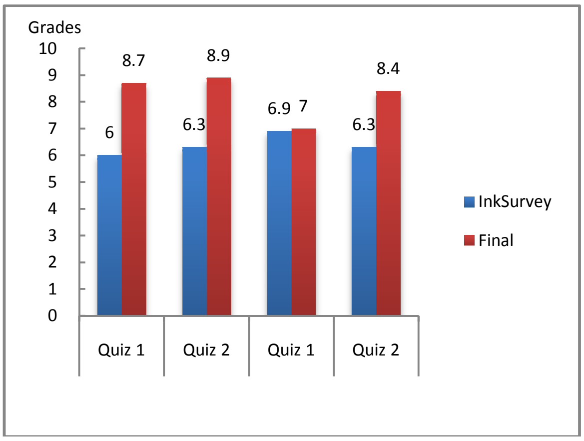

Fig. 7. Mean grades of undergraduate and graduate students in formative assessment (Inksurvey) and summative assessment (final) two first quizzes (years 2009-12).

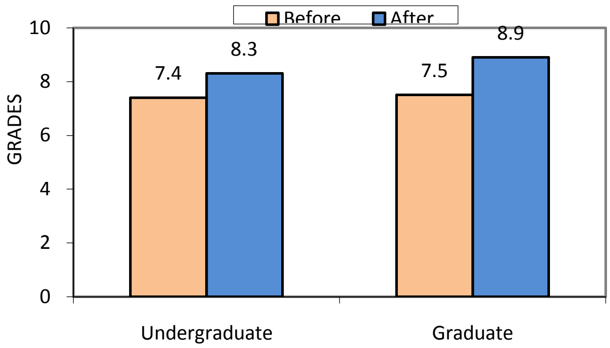

Fig. 8. Mean grades of quizzes taken by undergraduate and graduate students before (2005-08) and after (2009-12) course redesign and Tablet PC implementation.

44% of students had previous contact with a Tablet PC before UDLAP studied courses. Students responses regarding the advantages of using a Tablet PC include: to write on it and take notes on the teacher's presentations, the ability to do graphics or drawings, write with the digital pen like in a notebook, the ability to interact with the teacher and peers to exchange information or ideas; the simplicity to take notes.

The second survey indicated that students' experience with Tablet PC and associated technologies was very interesting and different. They emphasized that it was a chance to take more didactic classes, or a course that was more dynamic, interactive and not boring. They also highlighted the experience of taking notes and writing on the teacher's presentations, which allowed them both to pay more attention to the class and interact with their teacher and classmates. Furthermore, the opportunity to send questions to the teacher and interact with him was highly appreciated.

In addition, UDLAP students underlined the increasing interaction with the teacher through more dynamic activities where they could draw pictures, graphs, solve problems, etc. They also stressed that more exercises and assessments in real time were conducted and the fact that they can participate and give opinions by using the capabilities of the Tablet PC.

Another result of the use of the Tablet PC was a visible increase in the motivation of students to participate in class discussions and problem solving activities. Also, redesigning courses improved understanding and ability of UDLAP students to solve practical food chemistry problems and complete real-world engineering projects, evaluated directly in several work products made by students, such as projects, problems, homework, tests and engineering journals.

Additionally, in order to carry out a qualitative analysis of the experience held at the UPV, each student participating in the experimental groups was asked to complete a common survey, few days before finishing the term. The first part of the questions asked the students to indicate how the Tablet PC-based approach influenced some key aspects of their learning process, such as class attendance, motivation, class work, or learning achievement. The survey also included some open questions concerning pros and cons, as well as suggestions.

Fig. 9 shows that most UPV students perceive a positive influence of Tablet PCs on class attendance, class work, motivation and learning achievement, while an important percentage considered Tablet PCs a source of distraction. It is also remarkable that most of them would recommend its usage in other courses.

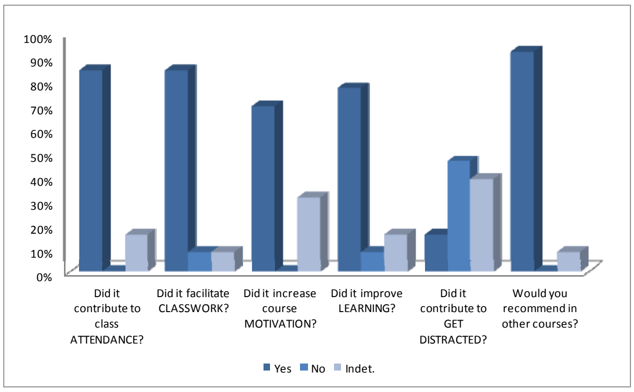

Fig. 9. UPV student post-questionnaire.

V. Conclusions

Thanks to the possibility to work in an anonymous way by Tablet PCs and associated digital ink technologies, students felt comfortable sharing their ideas with classmates, which enabled instructors to assess student understanding frequently during the process of instruction and problem solving. Formative assessments quickly identified the most common difficulties, allowed faculty to provide immediate feedback, redirect classroom activities, and/or refine instruction based on feedback received. Opportunities to make students' thinking visible were greatly enhanced, these gave them chances to revise their thinking, for "what if" thinking, as well as to help them reflect on their own processes as learners (to be metacognitive).

Students' initial conceptions provided the foundation on which more formal understanding of the subject matter was built. Further, frequent formative assessment helped make students' thinking visible to themselves, their peers, and their instructor. Facilitated by Tablet PC associated digital ink technologies, feedback (in studied courses) that guided modification/refinement in thinking increased.

Additionally, several other important impacts were achieved, particularly on instructor identifying the most common difficulties in UDLAP and UPV courses while providing immediate feedback of both written work products and oral presentations from students; helping students reflect on their own processes as learners; and instructor understanding of how through the use of Tablet PC associated technologies, student thinking can be revealed, and therefore the student learning experience in the classroom can be enhanced resulting in improvements in both instruction and student academic success.

ACKNOWLEDGMENT

We acknowledge financial support from HEWLETT-PACKARD (HP), through the HP Technology for Teaching Higher Education Grant Initiative for Latin America for the project "High-Quality Learning Environments for Engineering Design: Using Tablet PCs and Guidelines from Research on *How People Learn*" as well as through the HP Catalyst Grant Initiative for the project "Critical Support Systems to Enhance the Development of 21st Century Expertise in Engineering Students: Using Tablet PCs and Associated Technologies, the *Framework for 21st Century Learning*, and Guidelines from Research on *How People Learn*". Similarly, UPV group received an HP Technology for Teaching High Education Grant Program for Europe, Middle East and Africa in 2008: "Improving effective learning in a first-year Computer Engineering course by using mobile Tablet PC technology".

Understanding Engineering Identity Through Structural Equation Modeling

Allison Godwin, Geoff Potvin, Zahra Hazari, and Robynne Lock
Engineering and Science Education
Clemson University
Clemson, South Carolina 29634

***Abstract*—Understanding students' self-ascribed engineering identity may be one way to understand engineering choices and to help recruit new students to the engineering pipeline. In our framework, identity is composed of students' perceptions of their performance/competence, recognition, and interest in a domain. This paper outlines the creation of a model of engineering choice based on this framework. The data utilized in this analysis come from the nationally-representative Sustainability and Gender in Engineering (SaGE) survey. Distributed during the fall of 2011, the survey was completed by 6,772 college students across the United States enrolled in first-year English courses. A structural equation model was built using previously validated constructs of mathematics, physics, and general science identities. These three constructs predict an engineering identity which, in turn, influences the choice of engineering in college. The model is a step towards a better understanding of the choice of an engineering major in college.**

***Index Terms*—Structural Equation Modeling, Identity, Engineering Major Choice**

I. Introduction

Students who choose engineering after completing high school often have not been fully exposed to professional science practices, let alone engineering practices. Additionally, high school coursework is rarely differentiated for students pursuing specific STEM careers; students intending engineering careers are expected to take a similar or identical set of courses as students intending, for example, chemistry or physics careers. So the choice of an engineering major may not be a fully-informed decision. In recent years, there have been calls for more STEM graduates [1] with particular attention being paid to recruiting and retaining more engineers, but access to the engineering pipeline is relatively closed after the first year [2], [3]. One way to address the need for more STEM graduates is through an improved understanding of the factors that affect the choice of engineering and how to more effectively recruit students upon entrance into college.

A potential way to address this pivotal transition is through students' self-ascribed identity. Identity is the authoring of a self within a particular context [4]. In this case, the particular context is that of an engineering discipline. Identity is associated to a student's authorship of identity at a particular moment and how these beliefs may change or remain stable over time. The importance of understanding identity is highlighted by Brickhouse et al.: if more students are to enter science and engineering, they need to see themselves as the "kind of people who would want to understand the world scientifically"[5].

There have been calls for an increase in research on engineering identity by Brickhouse and others [5], [6]. Attainment value, which is related to engineering identity (being an engineer is related to the "sense of self"), has been found to be important for the persistence of engineering students during their undergraduate programs. Further, it has been found to be more important than interest or perceived utility to engineering persistence [7]. Other recent research on students' engineering identity has also focused on the college years, exploring both engineering and professional identity development. For example, Chachra et al. [8] studied the development of engineering identity during the undergraduate years and found a substantial dependence on the culture of engineering schools as well as students' beliefs about what constitutes engineering practice (e.g. "technical work" versus other aspects). The importance of school culture for the development of an engineering identity has also been found in other work [9].

Professional identity development has been another theme in recent years. Students who aspire to be engineers have been found to have more distinct professional and occupation-related identities, even at an early age [10], [11]. There are, however, few studies that focus on the effect of pre-college experiences and other identities on engineering identity development [10] although the importance of such factors and early exposure to engineering has been stressed [12]. Much of the prior research has acknowledged the importance of considering a multiplicity of identities, but little research has been conducted on the effect of other STEM disciplinary identities on the development of an engineering identity. Considering a multiplicity of identities is important since self-beliefs in related domains will lend to, and interact with, the development of an engineering identity. Subsequently, a focus on interwoven identities and pre-cursor identities (those beliefs that precede engineering identity development because students have had little early exposure to engineering) will help to develop a better understanding of the students who gravitate towards engineering and those who move away due to perceptions about engineering practices and performances which conflict with their views of themselves in other domains. This work is a first step toward understanding the engineering identity that precedes the choice of an engineering major in

National Science Foundation Graduate Fellowship (Grant No. 0751278), Research on Gender in Science & Engineering Grant (No. 1036617)

college, in concert with multiple STEM identities.

In the current conceptual framework, domain-specific identity is comprised of three measurable dimensions of students' beliefs: their performance/competence, recognition by others, and interest [13], [14], [15], [16]. The study of identity using this framework has proven useful in other domains but has not yet been fully applied to engineering [17]. This framework has been validated in physics and mathematics through large scale studies [13], [14]. The recognition component of identity consists of an individual's beliefs in the external recognition they receive (from parents, teachers, other students, ...) as a good engineering student. Interest in the subject material also plays a key role in the choice of engineering as a major: students should have some understanding of the realm of engineering in order to be be attracted to engineering and, hence, have the opportunity to develop an identity with respect to engineering. Performance/competence are an individual's beliefs in their ability to perform effectively (e.g. on an engineering exam) and be competent in engineering (e.g. understand engineering concepts). Traditionally, students have very few direct experience in an engineering community of practice before they make their choice of engineering as a career in the high school to college transition [18]. For this reason, multiple subject identities have been explored in this work to understand the identities that students who choose engineering in college have *before* their development of the traditionally-studied engineering identity within an engineering community of practice. These identities are important for choice of engineering in college in the path to developing an engineering identity. Previous studies have shown that students interested in engineering show interest and skill in the areas of math and science [19], [20]. Physics, when taught in a high school classroom, may mirror some engineering techniques (building bridges, analyzing statics, discussion of motion, etc.). Identities in math, science, and physics were chosen to explore the effects of these experiences on identity development for future engineers. The distinction between physics and science is subtle. Physics is part of science of course but other skills not specific to physics – say, in chemistry and biology – may be important for students interested in particular engineering majors (chemical, biomedical, environmental, etc.). Through exploring multiple subject-related identities from high school, a clearer picture of what experiences and attitudes are important for future engineers can be developed.

This paper reports on the development and establishment of an affective model which has predictive power for the choice of engineering as a college major through multiple subject-related identities. Understanding the particular identity or identities that students who choose engineering have is especially important for increasing the number and diversity of engineers in the workforce. The unique and simultaneously diverse approaches of engineers and the problem-solving strategies they employ are essential to national success in an increasingly competitive global marketplace, the ongoing restructuring of many industries, the increased use of technology in all facets of life, and the emphasis on new energy sources in the world.

The research questions explored in this paper are:

1) What is the effect of students' identities in physics, mathematics, and science (general) on their engineering identity?
2) To what extent is an engineering identity predictive of the choice of engineering as a college major?

II. Methods

In this paper, the analyzed data were collected as part of the Sustainability and Gender in Engineering (SaGE) survey (http://www.clemson.edu/~gpotvin/SaGE.pdf). This was a large-scale national study of students who were currently enrolled in introductory English courses at both two- and four-year institutions across the United States. The data collection methodology employs a cross-sectional design which relies on the natural variation in experiences and backgrounds of the student population. The SaGE project recruited institutions from a representative, stratified, random sample taken from a comprehensive list of four-year and two-year institutions, obtained from the National Center for Education Statistics (NCES). The list was divided by institution type (two-year or four-year) and stratified by institution size (small, medium, or large) into six lists to account for the size of the institution and ensured an appropriate sampling of the small but numerous liberal arts colleges across the U.S. In total, fifty schools agreed to participate in the survey. The survey was administered in each institution's "required" freshman English course to capture a sample that included both STEM and non-STEM majors. In all, 6,772 students completed the survey during the administration period in the fall semester of 2011.

The survey instrument focused on students' backgrounds, pedagogical and curricular experiences in their high school science classrooms, classroom achievement, and student attitudes toward STEM and sustainability. The goal of the study was to identify factors that influence students' attitudes toward engineering careers and to explore the connections between engineering and sustainability-related topics in students' experiences. The final version of the survey included 47 questions about students' career goals, high school science experiences, earlier math and science enrollment and achievement (including types of courses taken, the level of courses, the year courses were taken in high school, final grades, and AP test scores), student attitudes about sustainability, and demographic information. These questions primarily consist of anchored Likert-type, multiple choice, and categorical responses.

Multiple aspects of validity and reliability of the instrument were assessed. An open-ended hypothesis-generation survey was collected from 82 first-year engineering and 41 non-engineering students, as well as 83 high school science teachers (recruited via the listserv of the National Science Teachers' Association). Lending to content validity, these hypotheses were included in the survey. Questions were further refined based on feedback from assessors and the results of pilot testing in a first-year freshman engineering course. Thus, each item of the survey was further examined for face and content validity. Test-retest was also conducted to establish the reliability of the instrument.

Earlier work verified the measures of each of the identity and agency constructs [20]. Using these identity and agency measures, a structural equation model was built to reflect the identity framework utilized in this work [13]. The resulting model is shown in Figure 1. From previous work on physics and math identity [13], [14], [21], the constructs of physics and math identity were built with interest and recognition mediating the path from performance/competence to identity. The questions that ask students if they identify as a "physics person" or a "math person" were used as an overall measure of these identities. These identities predict an engineering identity that students have prior to their choice of engineering. The choice of engineering as a career is predicted by students' engineering identity.

The choice of engineering was determined by utilizing a question that asked students to "Please rate the current likelihood of your choosing a career in the following:" for a variety of science, math, and engineering careers on a Likert-type scale. A student's strongest response to any of the several engineering disciplines was used as a proxy for a student's interest in pursuing a career in engineering. This method was used in order to capture students interested in engineering in general (but undecided on a discipline) as well as students with a very well-specified interest in one or two engineering disciplines.

The students' belief model in Figure 1 was tested using the lavaan package in R [22], [23] with a subset of the SaGE data input as a correlation matrix. This matrix was imputed for missingness using an expectation maximization bootstrapping method from the Amelia II package [24]. There were 1,113 patterns of missingness found and the final sample size utilized in this analysis was 6,772. The variance of each latent variable was fixed to one. A Satorra-Bentler estimation method [25] was used to account for any non-normality in the data by setting the estimator to "MLM" [23].

III. Results

The standardized path estimates were inserted into the model pictured in Figure 1. All of the standardized path estimates were significant in the predicted direction ranging from 0.133 to 0.982 (all $p<0.001$).

Several fit indices and path significance tests were used to evaluate the model. The chi-square statistic for this model is 18,343 and is significant. Due to the large sample size, the chi-square statistic will be inflated and it can be expected to be significant without indicating a poorly fitting model [26]. The degrees of freedom reported are 685. The root mean square error of approximation (RMSEA) indicates a good fit of the model with the observed data with a value of 0.062 with a lower confidence interval of 0.061 and an upper confidence interval of 0.062. An RMSEA of 0.01, 0.05, and 0.08 indicate excellent, good, and acceptable fit, respectively

TABLE I
CONFIRMATORY FACTOR ANALYSIS ESTIMATES FOR PHYSICS IDENTITY

Latent Variable	Indicator Variable	Standardized Factor Loading	Standard Error	Item Reliability (R^2)	Construct Reliability	Average Variance Extracted
Interest	Interest in physics	0.866	0.025	0.750	0.857	0.791
	Enjoyment of physics	0.912	0.025	0.832		
Recognition	Physics recognition from family, friends	0.898	0.013	0.806	0.861	0.796
	Physics recognition from teacher	0.886	0.013	0.785		
Performance/ Competence	Confidence in learning physics	0.886	0.014	0.785	0.919	0.724
	Confidence in understanding physics	0.877	0.014	0.769		
	Can do well on physics exams	0.903	0.014	0.815		
	Understand physics concepts	0.921	0.014	0.848		
	Others ask me for help in physics	0.787	0.012	0.619		
	Can overcome setbacks in physics	0.711	0.012	0.506		

[27]. Additionally, the RMSEA is largely invariant as the sample size increases and may be a better indication of fit than the chi-square statistic [28]. For sample sizes of 500 or greater, the RMSEA is sensitive to increasing misfit. Thus it may be appropriate to use this supplementary fit statistic in the presence of sample sizes of 500 or more cases, to inform if sample size is inflating the chi-square statistic, and hence its significance [29]. Since the RMSEA is in the acceptable to good range, the model does not show significant misfit. The comparative fit index (CFI) also suggested good fit with a value of 0.920 (acceptable values above 0.9) [30]. The Standardized Root Mean Residual (SRMR) is an absolute measure of fit and is defined as the standardized difference between the observed correlation and the predicted correlation. For this model, the SRMR is 0.079 which is below the acceptable cut-off of 0.080 [31]. This model does fall within the accepted criteria for a good fitting model, taking into account the large sample size ($n = 6,772$).

IV. Discussion

The results of this analysis indicate that there is a strong connection between the development of multiple identities as a pre-cursor to an engineering identity for students just entering college. Based on the previously validated identities of physics and mathematics [13], [14], the measures for this model were found to be reliable. The confirmatory factor analysis (CFA) results supporting this claim are included. These loadings are not shown in the diagram but can be found in I, II, and III. The factor loadings ranged from 0.577 to 0.922 with the only loadings below 0.7 occurring for science identity items, particularly recognition which was less reliable. This is not surprising since the items used for science recognition, unlike math and physics recognition, were not developed specifically for examining identity.

In terms of the structural model in Figure 1, a significantly negative direct path from performance/competence to identity was found for both physics and math. This finding indicates that while performance/competence is needed to develop an identity in these domains, without interest and recognition as mediating factors, identity development will be hindered. Thus, if a person feels competent and able to perform in physics or math, both popularly considered to be difficult subjects, but she/he is never recognized or does not become interested, their likelihood of developing or reinforcing a physics or math identity is depressed. This is an important finding since self-efficacy, similar to performance/competence beliefs, is often cited as a key factor in persistence [32], [33] without a deeper examination of the nuance with which self-efficacy relates to identity. Although more nuanced examinations, such as Social-Cognitive Career Theory [SCCT]), identify the moderating effect that interest plays between self-efficacy and engineering goals (and subsequently persistence) [34], these studies may not highlight the important role of recognition by others. In our model, physics and math recognition have the largest direct effect on physics and math identity, respectively, and are therefore critically important for engineering. Although the importance of recognition has been cited in many qualitative studies of identity [17], [35], our work confirms its importance quantitatively. Furthermore, our work clarifies that performance/competence beliefs are not sufficient for identity development. In support of this finding, Marra et al. found that female engineering students in their study had positive shifts in self-efficacy while having negative shifts in feelings of inclusion [32].

Unlike the physics and math identity constructs, general science identity in our model did not include a significant direct path from science performance/competence to science identity. However, recognition and interest remain as mediating paths reaffirming their importance for identity development in all three cases. The mediating paths for recognition in the science identity block have lower path coefficients than the same mediating paths in math and physics identity development. These lower path coefficients may be due to the lower reliability of some of the measures for the recognition construct as mentioned above.

Engineering identity is strongly influenced by a student's developed physics identity (path coefficient of 0.815). This finding may not be surprising, but the relative influence of this path on engineering identity when compared to a general science (path coefficient of 0.722) or math identity (path coefficient of 0.537) is large. The larger effect of physics identity compared to math identity is somewhat surprising since the literature heavily documents the importance of mathematics outcomes to engineering performance and persistence with little reference to physics outcomes [36]. The stronger connection to physics is likely because engineering and physics content share a paradigm: heavily applying math with science. There are other parallels between engineering and physics as well – whether they are a consequence of similarities in the content, culture, or both is not yet clearly understood. For example, in terms of demographic considerations, females are under-represented in both engineering and physics at the undergraduate level whereas they are not in mathematics [37]. In addition, when students switch into or out of engineering, they often switch back or forth to the physical sciences; more often than in mathematics [38]. More broadly, however, this work shows that students' identity in physics, math, and science all contribute to an engineering identity. Finally, the path coefficient from engineering identity to the choice of an engineering major/career in college is 0.549. This loading illustrates that students' self-ascribed identity has a significant impact on their choice of engineering. Understanding these self-perceptions can help elucidate the transition between high school and college for students intending on majoring in engineering as well as allow us to account and control for these self-perceptions when examining how early college experiences in engineering might impact the choice of engineering sub-discipline and persistence.

These findings are important for the recruitment and retention of engineering students. Students attitudes about the subjects they take in high school are important and affect the career choices that they make as well as their persistence in those choices. Simply being "good" at these subjects is not enough for identity development. Students' attitudes and beliefs about their ability to perform subject-related work, the recognition of them as being good students in these areas by their peers, family and teachers, as well as an interest in the subject material are vital to engineering identity development. Additionally, professors who teach the pre-requisite or co-requisite classes of physics, math, and other important science courses for engineering majors may have an important influence on students' future engineering identities. The authoring of an engineering identity is not a one-time effort while pursuing a degree in engineering, but is a continual process [4]. A disruption of this process through poor classroom experiences in associated courses like physics, math, or other sciences can cause a decline in engineering identity and may change students' choice to pursue an engineering career in the future.

V. Conclusion

We found that students' physics, math, and general science identities are important factors for their engineering identity development. In our framework, students develop a multiplicity of identities which may interact to affect choice outcomes. Furthermore, subject-specific identities are moderated by beliefs about performance/competence, recognition, and interest. Perhaps surprisingly, performance/competence beliefs are not sufficient for identity development but require the mediation of recognition and interest beliefs to help actualize identities for students. For educators and administrators, this latter point is worth noting: there has been a historic focus emphasizing the importance of self-efficacy and related beliefs to student persistence, but this work highlights the fact that the development of students' recognition beliefs and interest may be just as critical as curricular objectives. Students who see their own identities lining up with specific disciplinary identities persist at a higher rate than those who do not [2]. For this reason, practitioners may consider fostering interest and recognizing students in their classrooms rather than simply emphasizing student acquisition of the technical skills needed to develop subject-related competencies. Developing interest and feeling recognized in a variety of subjects (math, physics, and science in general) is more important for the choice of engineering than feeling "good at" a variety of subjects. Furthermore, only developing beliefs about performance/competence in a subject area is detrimental to the formation of a subject-related identity and may decrease persistence in engineering. As we seek to increase the number and diversity of students in engineering, considering these findings is important not only for engineering education researchers, but also engineering administers and faculty. Our future work in this area will seek to incorporate into these models greater details about students' career outcome expectations and agency beliefs.

***Abstract*—Using longitudinal data from eleven institutions in the U.S., this study explores the persistence of students in the two largest engineering disciplines: Electrical (EE) and Mechanical (ME). These programs have large enrollments of students but small percentages of women. Despite these similarities, enrollment and persistence in these majors is qualitatively different. In this research, we adopt an intersectional framework and consider both race/ethnicity and gender. Our results show that ME attracts more White students while EE attracts more Black and Asian students. Hispanic men and women are attracted in similar numbers to EE and ME. Overall, ME has higher graduation rates than EE and women have higher rates than men in both disciplines. Transfer students of nearly all race/gender groups are more likely to persist to graduation than starters in the same disciplines. Black and Hispanic female transfer students are particularly successful in EE and ME, which suggests enhancing the transfer pathway as a strategy to improve diversity. The success of ME starters causes a shift in the demographic profile between starters and graduates. ME could learn from EE how to diversify its enrollment and EE could learn from ME strategies to retain its diverse students. These findings suggest that program factors affect each race-gender group differently. Therefore, the success of recruitment and retention strategies may depend on considering both the target population and the discipline.**

Keywords—electrical engineering; graduation rate; mechanical engineering; persistence; retention; stickiness; transfer students

I. Introduction

A. *Understanding pathways in electrical and mechanical engineering education is vital to the profession.*

There have been numerous calls to diversify the engineering profession [1], [2]. Electrical Engineering (EE) is one of the oldest engineering disciplines, dating back to the 1880s [3], and also one of the largest. Mechanical Engineering (ME) also dates back to the 19th century and currently has the largest enrollments [4],[5]. Thus, students in EE and ME make up a large portion of the engineering population. What do these large fields have in common? How do they differ?

Enrollment and retention in engineering degree programs has been studied extensively, and more complete literature reviews are available elsewhere [6]. In a large multi-institution whole population study, no gender gap in persistence or graduation was found for engineering matriculants with all disciplines aggregated [7]. This study focuses on extending that work to explore two engineering disciplines that enroll many students, but that have a particularly male enrollment bias. Here, we briefly review important literature on student pathways for EE and ME as well as transfer students. Unlike most studies, we disaggregate by race/ethnicity, gender, and engineering discipline. In analyses of engineering persistence, it is important to adopt a critical race theory framework [8] and consider the intersectionality of race and gender [9]. For both EE and ME, we consider the race-gender of those who start in these majors, trajectories of students, six-year graduation rates, and "major stickiness" which is a ratio of the number of students who graduate in a major divided by the number of students who ever declared in that major. The stickiness metric permits consideration of transfer as well as first-time-in-college (FTIC) students [10]. This work presents a detailed description of students who major in EE and ME based on a large amount of data. These results are intended to speak to faculty, department heads and Deans.

B. *Results of Prior Studies of Electrical Engineering Pathways.*

Despite having high enrollments of students, around the world EE has one of the lowest percentages of women students, including in the U.S.A. [5], Canada [11], and Israel [12]. Many studies of undergraduate student persistence aggregate all engineering disciplines [13][14][15][16][17]. This may often be a practical limitation imposed by the available data that results in small datasets when disaggregated by engineering discipline. There has been some work focused on EE. For example, Murphy[18] examined the paths of 34 EE majors at the Citadel and found that 44% graduated within five years in EE, 32% graduated in a discipline other than EE, and 24% did not graduate. York Young and Redlinger [19] analyzed the student flow for 23 EE matriculants at one institution over six years. They found that 14 (61%) of the EE matriculants graduated in six years. Six of these were in EE, three in Computer Science, and one each in five other majors. Humphreys and Freeland [20] found that 68% of 422 EECS matriculants at one institution were still in the major after four years. They note that women were a small fraction of the cohort, persisted in engineering at lower rates than men, and switched out of the major at higher rates than males. Lord, Layton, and Ohland studied the pathways of students in EE and computer engineering disaggregated by race/ethnicity and gender [21]. They found that although men consistently outnumber women in EE, the rates of matriculation and six-year graduation vary by race and gender. EE is the most popular choice for Asian and Black students (males and females) at matriculation, but while Asian students graduate at high rates, Black students (particularly males) are not retained. Graduation rates are lower than expected for Hispanic women in EE. By the third semester, some students of all races and genders have left their matriculation major, but others have migrated in from other majors, compensating for some of this loss. Trajectories of EE students are racialized and distinct.

C. *Results of Prior Studies of Mechanical Engineering Pathways.*

Despite the gender gap in enrollment, little research has been published on the pathways and persistence of women in ME. Only eleven of 412 articles in the International Journal of Mechanical Engineering Education use the words women, woman, gender, or female, and only seven were referring to students. One catalogued the accomplishments of outstanding women in ME [22], one explored motivating factors for women to study engineering in Ghana [23], and the rest mentioned women only in passing. Only four mentioned race, ethnic origin, or ethnicity in a relevant way. A search of conference proceedings of the American Society for Engineering Education and Frontiers in Education yielded a few single-institution studies. At Iowa State University, women's enrollment has increased from 7% to 10% since the launch of a student-run Women in Mechanical Engineering (WiME) program [24]. Tuskegee University reported a 48% six-year graduation rate in mechanical engineering for an 1991 cohort, although this number was based on enrollments rather than tracking of individual students [25]. Clearly there is a need for further discipline-specific research.

D. *Prior Studies of Transfer Students in Engineering*

Transfer students are a sizable, yet understudied, population with the potential to increase the engineering workforce and its diversity [26]. Many of these students transfer from community and other two-year colleges in which women, minorities, and economically disadvantaged students are over-represented. Community colleges enroll nearly half of U.S. undergraduates and large shares of women (58 percent of community college students), minority (45 percent), first generation (42 percent), and low-income (46 percent) students. These are the very groups that are under-represented among engineers in the U.S.—and a potential pool of recruits for engineering and other scientific fields [27]. Yet studies of engineering transfer students indicate that students who actually transfer to four-year institutions are demographically similar to those starting their academic careers at the four-year institutions, increasing the importance of understanding this population [28]. In the aggregate, engineering disciplines that do well in attracting and retaining first-time-in-college students also do well in attracting and retaining transfer students [10], but (as expected) race and gender play a role in the outcomes of transfer students [28]. Thus it is important to study the outcomes of transfer students disaggregated by race, gender, and discipline, and recent methodological developments facilitate the study of transfer students including comparisons with the first-time-in-college population [10].

II. METHODS

A. *The MIDFIELD Database and its Characteristics.*

This study uses the Multiple-Institution Database for Investigating Engineering Longitudinal Development [29], a dataset with 137,649 first-time-in-college (FTIC) students matriculating in engineering and 39,354 transfer students articulating in engineering at eleven U.S. institutions with nine of these in the Southeastern U.S. Of the U.S. engineering bachelor's degrees awarded in 2005, 1/10th were awarded by MIDFIELD institutions [30]. The MIDFIELD database includes seven of the 50 largest U.S. engineering institutions by engineering enrollment (institutions in which over 20 percent of students major in engineering, versus the nine percent national average) [31], and four of the top five producers of Black engineering graduates [30], including two that are historically Black colleges and universities (HBCUs) and two predominantly White institutions. By design, engineering students are overrepresented in MIDFIELD, which enables the analyses of subpopulations proposed in this research (by discipline, ethnicity, etc.). Students self-report gender and race, choosing among Asian, Black, Hispanic, Native American, and White (as well as Non-Resident Alien and Other, which are not included in this study). Results from the study of the MIDFIELD database are expected to generalize to the same type of institutions, large public universities with above average enrollment of engineering students, and therefore are relevant to institutions producing most engineering graduates nationally. All institutions offer degrees in Electrical and Mechanical Engineering. Since this dataset includes whole population data, statistical inference is unnecessary—all reported differences are true differences for the institutions and subpopulations studied for the time period.

B. The Population Studied in This Work.

Of the total MIDFIELD population, this work focuses on the 93,629 FTIC students and 26,350 transfer students with sufficient data to calculate six-year graduation rates during 1987-2010. MIDFIELD institutions offer several matriculation pathways [32],[33]. We study students in multiple pathways: FTIC who matriculate directly into EE and ME, students who choose these majors after completing a first-year engineering (FYE) program (where direct matriculation into specific engineering majors is not possible), FTIC students who matriculate in other majors and migrate into these majors, and transfer students who make their way into these majors.

Special methods are needed to include students in these diverse pathways in the same study. To include students enrolled in FYE programs as well as students who matriculate directly to specific engineering majors, we imputed the Semester 1 disciplinary enrollment at FYE schools. This imputed Semester 1 enrollment, Semester 1*, is calculated by allocating the total FYE matriculated population to specific majors at semester 1 in the same proportion as students choose each major after FYE. This assumes that the retention through the transition from FYE programs is the same for all engineering majors. For example, if 100 students matriculate to FYE programs, and 80 students declare a specific engineering major immediately after leaving FYE, then there is 80% retention. If 48 students declared EE after FYE, then we would impute 60 EE students at Semester 1* (48 / 80% = 60). The retention rates used in imputing Semester 1* enrollment are computed separately for each race-gender population. Throughout this paper, the term "starters" refers to the total of FTIC students who matriculated directly in a major and those imputed to start in that major. "Transfers" refers to students who earned credits at another institution before transferring to the MIDFIELD institution and were designated as transfer students by the participating institutions. Transfer students are assumed to begin in a particular semester, where for every 15 credits they transfer, their starting semester is increased by one.

In this paper, graduation is defined as having graduated by the sixth year from matriculation, following a standard of reporting by the Integrated Postsecondary Education Data System (IPEDS) [34]. The population at matriculation (Semester 1) is a useful referent and is needed for defining the persistence of the matriculating cohort. The population at Year 4 marks the point at which 90% of all students graduate, and has been used as a measure of success by Seymour and Hewitt [15] and others. Finally, graduation, as defined above, is labeled Year 6. It is important to include the Year 6 outcome in addition to the Year 4 outcome, because differences in the graduation rate beyond Year 4 have been observed when the data are disaggregated by race/ethnicity and gender [6].

To protect student confidentiality, a minimum cell size of 5 is common in practice. MIDFIELD research has generally excluded populations with fewer than 10 students from displays and analyses [35]. Although we have included Native Americans in prior work [6] [7], after disaggregating by discipline, there were not enough Native American women to include in this study. Since we could not include the women, we also excluded the Native American men.

III. Results and Analysis

A. Who enrolls in ME and EE?

Table I shows the number of starters in ME, EE, and Engineering (ENGR).

TABLE I. Number of Students Starting in ME, EE, and ENGR.

Race/Sex	ME starters	EE starters	ENGR starters
Asian Female	92	157	1124
Black Female	367	773	3555
Hispanic Female	49	51	531
White Female	1612	1020	13847
Asian Male	620	1048	4110
Black Male	1145	1823	6026
Hispanic Male	335	337	1937
White Male	12242	8942	59424
All Female	2120	2001	19057
All Male	14342	12151	71497
All students	16462	14151	90554

The ratio of the ME and EE starters in each race-gender group to all Engineering starters of the same race-gender group is shown in Figure 1, with the panels ordered by the median of the ME and EE values. For example, the top right panel of the figure shows that of all Black Males starting in Engineering, 19% start in ME and 30% start in EE.

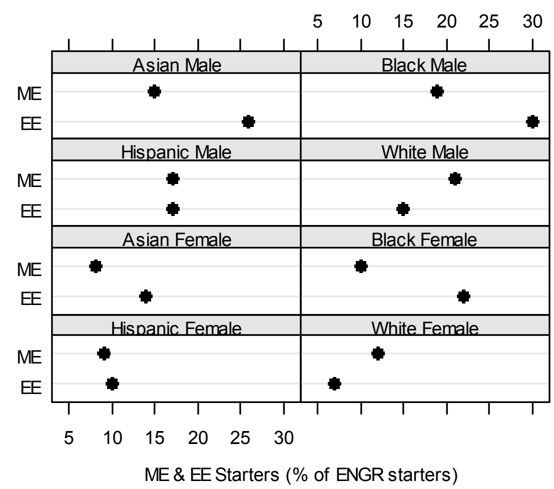

Fig. 1. Enrollment in EE and ME as percent of ENGR starters choosing the major disaggregated by race/ethnicity and gender.

As shown in our earlier work [21], Black engineering students, men and women, choose EE at the highest percentages of any group. For ME, White males choose it at the highest rate with Black males a close second. A higher percentage of White women choose ME than EE, although both percentages are below the aggregate percentage enrolling in those disciplines. In fact, White students prefer ME over EE but students in every other race/ethnic group prefer EE over ME. Asian men and women, particularly men, prefer ME over EE. The numbers and percentages for Hispanic students are very close for ME and EE. Since there are so many more White students, their story often dominates discussions.

B. Graduation Rates in ME and EE

Table II shows the numbers of starters in ME and EE remaining in the major through 6 years. With the starting numbers of Table 1, these values are used to compute the 6-year graduation rates shown in Figure 2, with the panels ordered by the median of the ME and EE values.

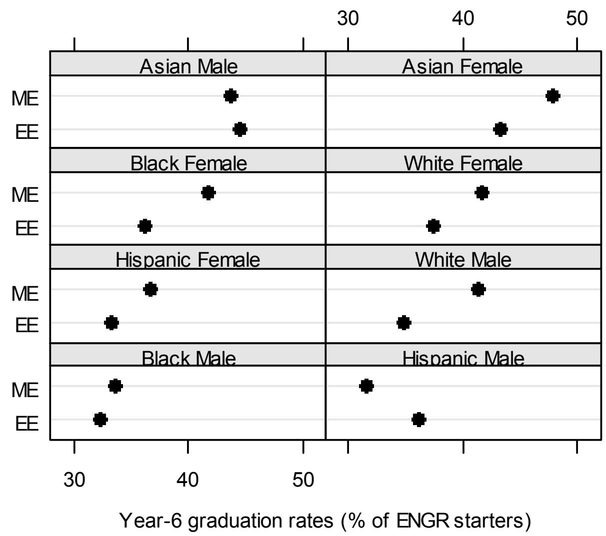

Fig. 2. Graduation rate disaggregated by race/ethnicity and gender for EE and ME starters.

Overall, students have higher graduation rates in ME than EE. This is true for all populations except Hispanic men where EE is higher and Asian men where the rates are nearly equal. The largest discrepancies are among White men and Black women; both groups have 6% higher graduation rates in ME than EE. Asian women have a 5% higher graduation rate in ME, while White and Hispanic women have a 4% higher rate in ME than EE. Black males in ME have a 2% higher rate than those in EE. In the aggregate, women have higher rates than men in both disciplines. The success of ME starters causes a shift in the demographic profile between starters (where EE has a notably higher fraction of Black females and males) and graduation rate (where ME graduates a notably higher fraction of Black females). Asian students have the highest graduation rates in both EE and ME with Asian women higher than Asian men for ME but lower than Asian men for EE.

TABLE II. NUMBER OF EE AND ME STARTERS WHO GRADUATE IN SIX-YEARS.

Race/Sex	ME Year 6	EE Year 6
Asian Female	44	68
Black Female	153	280
Hispanic Female	18	17
White Female	673	383
Asian Male	271	466
Black Male	386	588
Hispanic Male	106	122
White Male	5058	3114
All Female	888	748
All Male	5821	4290
All students	6709	5038

Note that these discussions of graduation rate are restricted to starters. These do not tell the complete story as will be shown later in this paper.

C. Trajectories of Students in ME and EE

Once students are enrolled in ME or EE, how do they fare? In Figures 3 and 4, the trajectory of students is shown for ME and EE starters and all ME and EE students. These figures are collections of time-series plots showing the number of students enrolled in EE or ME at matriculation (0), enrolled or graduated four years later (4), and graduated by six years later (6). Figure 3 shows starters only (direct matriculants in the discipline or those imputed to start in the discipline at FYE schools). Figure 4 shows the numbers of students in the major for all students, including starters, switchers, and transfers. The vertical scale (numbers of students) is logarithmic to include populations that differ by orders of magnitude. The horizontal scale (years after matriculation) is linear. In each panel, women are on the left and men on the right. Race/ethnicity is indicated by a letter. To illustrate, consider the leftmost column in Figure 3, "Women in ME (ME Students-Starters)". The lines labeled "B" and "W" indicate that in this category, White women outnumber Black women for each time period, starting at matriculation with approximately 400 Black and 1100 White women and ending at Year 6 with approximately 150 Black and 700 White women. The steeper the slope of the enrollment profile, the higher the loss of students from the discipline.

The trajectories for EE and ME starters shown in Figure 3 look similar to those for EE reported earlier [21]. Compared to EE, ME has more White and Hispanic students and fewer Asian and Black students, particularly Black women. All populations lose starters from matriculation until Year 6. Losses are rather steep from matriculation until Year 4. After Year 4, some populations level off, most noticeably Asian women and White students. Note that the steepest losses occur for Hispanic and Black students from Year 4 to Year 6. These steeper negative slopes indicate a faster attrition over this time period.

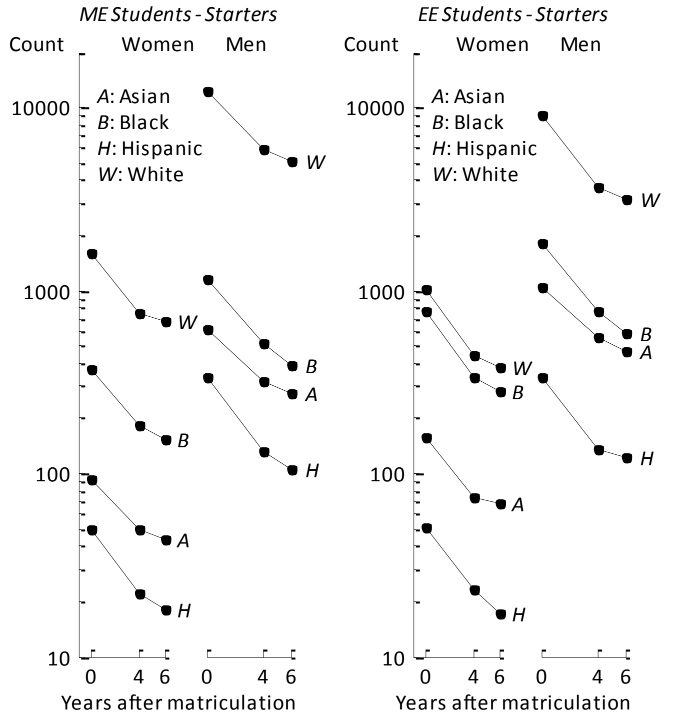

Fig. 3. Trajectory of starters in ME and EE.

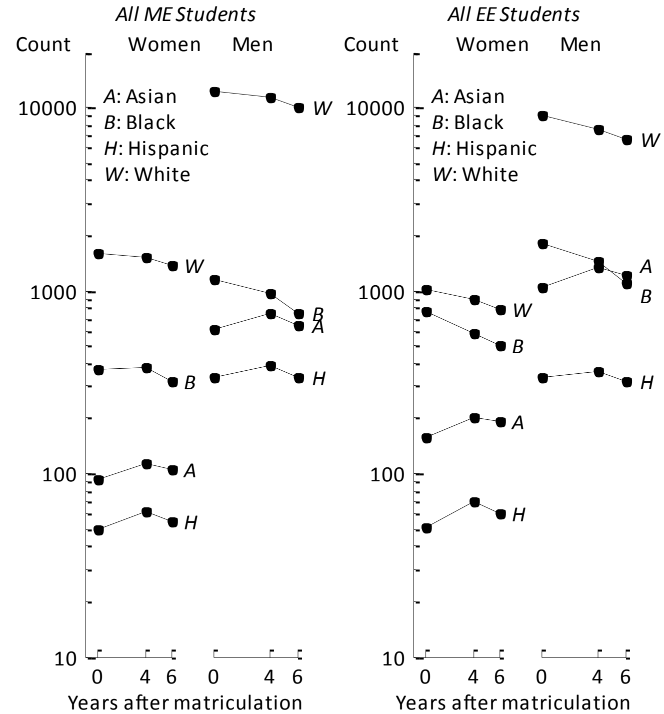

Fig. 4. Trajectory of all students in ME (left) and EE (right).

The shallower slopes of the curves in Figure 4 for all students, which include students matriculating in other majors and those who started at other institutions, show that students of each population are entering EE and ME, compensating for some of the starters who are leaving. Overall, the shapes of the trajectories for all students in EE and ME are similar. The most difference is seen for Black women. More Black women start in EE but low numbers at Years 4 and 6 suggest few transfer and switcher students. Fewer Black women start in ME but enough transfer or switch in by Year 4 to compensate for the losses of starters. Fewer White and Black students graduate in 6 years in ME and EE than started. The opposite is true for Asian students and Hispanic women suggesting the importance of transfer pathways for these populations. For Hispanic men in EE and ME, there are about the same number at matriculation as graduation.

D. Stickiness in ME and EE

Figure 5 shows the stickiness in the major for starters and transfers in ME and EE, disaggregated by race/ethnicity and gender, and ordered by the median of the values in each panel.

Starters and transfers are more likely to "stick" with ME than EE. Women show higher stickiness than their male counterparts for each race/ethnicity. White men and women have the most similar stickiness, underscoring the importance of disaggregating by race and gender so that the White population does not bias the discussion. Asian women have the highest stickiness in ME and the second highest in EE, close to the Asian men. The populations with the lowest stickiness are both men: Black and Hispanic.

Consistent with earlier work [10], transfer students tend to be more "sticky" than FTIC students. This is likely related to their having already successfully passed some engineering prerequisites and thus being more strongly committed to the major before entering our database. Transfers have higher stickiness in both ME and EE (in Figure 5, the open circles for transfer students are typically to the right of the closed circles for starters). Consistent with other studies [10], transfers in ME and EE also have much less variability across race-ethnicity and gender (the open circles are much-more aligned vertically). This is not surprising given how many sources of variance are matched among the transfer students in the study—even among the FTIC students, our sample includes students who all chose to enroll in higher education, selected one of the participating institutions, were admitted to do so, and selected engineering.

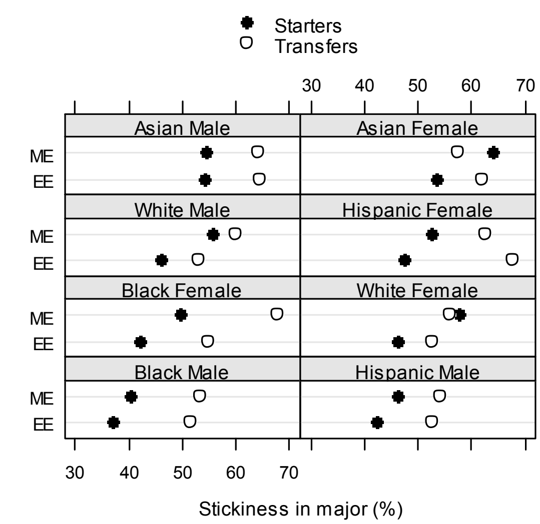

Fig. 5. Stickiness in Major of starters and transfers by race and gender.

The transfer students did all these things and additionally did so through a transfer pathway, so a reduction in variability in any outcome is predicted at least in part by the restriction of variability in the population.

Black and Hispanic women transfer students are notably successful. If transfer students have an experience similar to that of starters, we would expect populations with a high stickiness in the starter pathway to similarly have a high stickiness in the transfer pathway. Where this is not true, there is an interaction between discipline and transfer status. Hispanic female transfer students have the highest stickiness of all groups studied for EE (68%) and are second for ME (62.5%) where the Black female transfers have the highest stickiness of 68%. Success for Hispanic female transfers in engineering overall has been reported in previous research with MIDFIELD [36]. Black female transfer students in EE have a stickiness of 55%, still high but not as high as in ME. Asian transfer students continue to be successful. However, for transfers Asian men are stickier than Asian women.

IV. Discussion and Conclusions

The graduation rates studied here help understand the success of students in these disciplines, but the stickiness metric is particularly useful and facilitates the study of transfer students. Regardless of any of the challenges faced, transfer students of nearly all race/gender groups are more likely to persist to graduation than starters in the same disciplines, and some Black and Hispanic females find such success in the transfer pathway (in ME and EE respectively) as to suggest enhancing the transfer pathway as strategy to improve diversity. The emergence of these stories is a reminder to researchers and practitioners of the need to disaggregate by race/ethnicity and gender. In contrast, ME could learn from EE how to diversify its enrollment and EE could learn from ME strategies to retain its diverse students. Further work will extend this line of research to other disciplines.

***Abstract*— In order to develop critical thinkers and capable problem solvers it is important to understand the needs of today's engineering student and design instruction to meet those needs. An important component in that discussion is the degree to which students perceive themselves as adults versus child learners. The issue is important for educators; particularly those who teach senior-level courses, because research on adult learners points toward different classroom methods than those used for children. In this paper, we focus on capstone design - a course often structured to simulate a professional work experience to understand student beliefs regarding their self-perceived orientation as an adult learner and how those beliefs are related to a) their self-perceived learning outcomes and b) the value they place on forms and frequency of feedback. To examine this impact, we draw on the concept of "andragogy." This study utilizes student data from a 2011 survey of capstone students. The data includes student beliefs regarding the andragogical assumptions, self-reports of their learning, and perceptions of the capstone course. The findings support Knowles' andragogical assumptions and indicate that student learning in project-based courses have the potential to have higher andragogical orientations. These findings provide insight into the characteristics of the capstone student and provide opportunities for faculty to tailor teaching to meet student needs.**

Keywords—Andragogy, Adult Learning, Student characteristics, Design

I. INTRODUCTION

The ability to teach engineers who are capable of working effectively in a field or discipline relies on an education that is situated in a realistic and comparable environment commonly seen in project-based learning (PBL) courses [1]. A common example of these types of learning environments is representative in design courses, both at the first-year and senior levels. PBL approaches to teaching require students to exhibit a high level of motivation and advanced cognitive development, representative of an adult learner, in order to successful meet the requirements of the course.

One of the key types of teacher knowledge includes the knowledge of the student [2]. Felder and Brent [3] have acknowledged that in order to develop critical thinkers and capable problem solvers, teachers must understand the needs of today's engineering student and design instruction to meet those needs. In addition, engineering schools should attempt to improve the quality of their teaching, which in turn requires understanding the learning needs of today's engineering students and designing instruction to meet those needs. As such Felder and Brent [3] suggest the characterization of students as a promising area of study where learning style profiles, orientations to study, and levels of intellectual development of engineering students should be assessed and analyzed.

Knowles identified teachers as being critical to creating an environment supportive of adult needs. Several authors have noted that the facilitation of adult learning can be best achieved through a student-centered approach that, in a developmental manner, enhances the students self-concept and promotes autonomy, self-direction and critical thinking [4, 5]. In this sense, PBL has elements of andragogy within it and is representative of Knowles' andragogical framework [5, 6]. However the appropriate approach to teaching is dependent upon the state of the student [5].

In their work, Yoshimoto, Inenaga, and Yamada [7] identified that across three regions (Germany, United Kingdom, and Japan), more mature students preferred practical and independent learning with well-developed materials and provisions, whereas younger students preferred human contact and connection with teachers and classmates throughout the learning process. Another study indicated that age, when combined with acceptance of andragogical principles, was predictive of course satisfaction [8]; however, neither study identified how this impacted learning in the course. Overall, Clardy [9] notes that studies tend to show that andragogical approaches to adult learning and education do not perform as predicted due to a misunderstanding of the student perspective.

II. BACKGROUND

A. Knowles' Andragogy

Knowles [10] coined the term andragogy, meaning "the art and science of helping adults learn", whereas the traditional term of pedagogy is the, "art and science of teaching children" [11, 12]. Knowles approaches the concept of andragogy and pedagogy as a theory of practices that lie on a continuum, where pedagogy is at one extreme and andragogy at the other with defining assumptions for

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

each (Table 1)[12]. The assumptions for the adult learner acknowledge that they are self-directed, have many life experiences, have learning needs closely associated with social roles, is problem-centered, is intrinsically motivated, and has a readiness to learn [10].

TABLE I. PEDAGOGICAL/ANDRAGOGIVCAL CONTINUUM [10, 12-14]

Pedagogy		Andragogy
Dependent on decision of teacher	–	Self-directed learner
Few life experiences	–	Many life experiences
Learning needs dictated by teacher	–	Learning needs related to social roles
Subject/content-centered	–	Problem-centered
Extrinsically motivated	–	Intrinsically motivated

The assumptions were developed from Knowles' recognition that the concept of the learner - life experience, readiness to learn, and orientation to learning - are different when comparing a child to an adult [10]. He acknowledges that through the process of maturation a person becomes increasingly self-directed, accumulates more life experiences that provide both content and context for learning, and views education as a process to develop competence in professional areas needed to achieve life goals.

B. Faculty Perspective

A prior study of faculty perspectives identified that a large percentage of faculty view their students as being more aligned with andragogical assumptions than pedagogical [12]. In addition, those faculty who view their students as adult learners utilized more student-centered tasks and assessments in engineering capstone design courses [12]. While no differences between faculty interactions and the mechanisms for feedback based on their perspective of the students exist, faculty who view their students as adults tended to use evaluations that included self-reflection papers and focus groups more than those who view their students as child learners. In addition, faculty who view their students as adult learners, typically view their role as a mentor to guide student learning, especially with emphasis on the student becoming a self-directed and taking responsibility for deadlines.

C. Research Questions

We use Knowles framework of andragogy in the capstone course because these courses are liminal spaces in which the students are at once still undergraduates in a course working for a grade, and practicing engineers addressing pressing, open-ended design challenges in their field. The degree to which student beliefs position them as either an adult or child learner (or both) significantly impacts the value they place on styles of teaching and their learning. Therefore we pose the following research questions:

RQ1.How do capstone students perceive their andragogical orientation?

RQ2.How does a student's andragogical perspective relate to self-perceptions of student learning in the capstone course?

RQ3.How does a student's andragogical perspective relate to their value of feedback and interactions with faculty in the capstone course?

RQ4.How do student andragogical perspectives align with faculty perspectives of the students' andragogical orientation?

III. METHODOLOGY

This study is part of a national examination of expert teaching in capstone design courses [12, 15-18]. The current analysis is a non-experimental quantitative design of student responses to a self-reported survey. Prior to the students' completion of the survey, their faculty, as well as other capstone faculty in ABET accredited program, completed a similar survey and interviews about their teaching. A review of the faculty survey and interviews can be found in [15-18].

A. Participants

The participants for this study were recruited from the faculty interviews in the first phase of the study. Overall, 20 faculty at different institutions distributed the survey to their capstone students in the last two weeks of the Spring 2011 academic term. The Spring term was chosen so that students would have a full capstone course experience to reflect on; whether it was one or two terms. Three weeks after the initial distribution, a request was sent to the faculty to remind their students about the survey. By the end of the term, 208 students had completed the survey. Due to the uncertainty of which faculty administered the survey it is difficult to determine the exact response rate.

B. Data Collection

The student survey included 99 self-reported items that were separated into three main sections: course logistics, capstone experiences, faculty interactions (instructor role, frequency and form of feedback and interactions, and benefit of interactions), and demographic information (years of education, sex, race).

The demographic information also included 5 items that addressed the students self-perceived andragogical orientation. A similar item was used in the faculty survey to identify andragogical and pedagogical differences [12]. The Student – Andragogical Perspective Measure (S-APM) consisted of 5 Likert style questions with answers ranging from strongly disagree (1) to strongly agree (5):

- I have an independent concept of myself and can direct my own learning
- I have accumulated a reservoir of life experiences that offers a rich resource for learning
- I have the ability to recognize my own learning needs

- I am problem-centered and interested in immediate application of knowledge
- I am motivated to learn by internal rather than external factors

A reliability analysis of the five items revealed that the Cronbach alpha was 0.784. When examined individually, the items had a minimum Cronbach alpha of .695 indicating acceptable reliability. Construct validity was confirmed through a principal component analysis of the item responses. The analysis indicated that S-APM was most likely a unidimensional measure of andragogical perspective as the five survey items explained 54% of the variation in the results.

C. Data Analysis

Using the five individual S-APM, a composite score called the Student – Andragogical Perspective Score (S - APS) was calculated by summing the individual items. The score ranged from 5 to 25. In order to determine perspectives based on the S-APS, the student responses were separated into two groups based on the standard deviation. Participants with an S-APS of more than one standard deviation below the mean were considered to have low S-APS and those with an S-APS of more than one standard deviation above the mean are considered to have a high S-APS.

Descriptive statistics were used to address the distribution of S-APS and faculty Andragogical Perspective Scores (APS) as required by RQ1 and RQ4. A Mann-Whitney U test was used to statistically compare the medians of the low and high S-APS with respect to learning outcomes and value of feedback and interactions (RQ2 and RQ3).

IV. FINDINGS

The data identifies a clear distinction between the value that high andragogical and low andragogical students place on interactions with and feedback from faculty and their self-perceived learning outcomes. In addition, the distribution of S-APS identifies inconsistencies between faculty and student perspectives.

A. Student - Andragogical Perspective Score (S-APS)and Alignment with Faculty Perspective

The student responses from the S-APM indicate, on a 25 point scale the average and median score is 20 with a right-shifted distribution of scores. The minimum score was 13 (2 participants) and 20 participants rated their APS as the maximum 25 (Figure 1). From this distribution of responses, 69% of the responses had an S_APS within one standard deviation of the mean. The high and low andragogical responses were determined as being one standard deviation outside the mean. Therefore, low S-APS respondents were grouped with scores 17 and less and high S-APS respondents with scores 24 and higher. These groups are used to compare the differences in value and self-perceived learning outcomes.

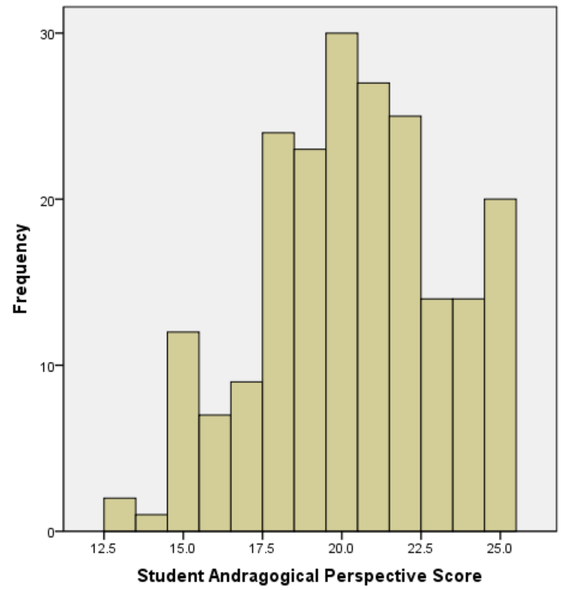

Fig. 1. Distribution of Stusdent - Andragogical Perspective Scores.

In comparison to the faculty responses identified in prior publications [12], the student andragogical perspective was higher than the faculty perception of student andragogical orientation (Table II). When examining the individual item responses, faculty and students were aligned with the student being problem-centered. The largest discrepancy between faculty and student occurred in the comparison of life experience. For this item, students considered their life experience much greater than the faculty perspective. The other items regarding the students' ability to direct own learning, recognizing learning needs, and intrinsic motivation saw less, but similar differences.

TABLE II. MEDIAN ITEM SCORES IN COMPARISON TO FACULTY PERSPECTIVE

APS Items	**Student Median**	**Faculty Difference**
Able to direct own learning	4	-1
Large amount of life experience	4	-1.5
Ability to recognize own learning needs	4	-1
Problem-centered	4	0
Intrinsically motivated	4	-1
S-APS	20	15.5

B. S-APS relation to Student Learning

The comparison of high and low S-APS respondents to their self-perceived learning outcomes indicates that students with high andragogical perspective rated their learning outcomes higher for all outcomes with the exception of written communication, concept generation, and communication with professionals (TABLE III). Where the high S-APS respondents had the greatest difference was in the learning outcomes of engineering ethics ($\Delta = 0.85$), creativity (Δ = 0.76), and responsibility for deadlines (Δ = 0.75).

TABLE III. COMPARISON OF LEARNING OUTCOMES AMONG LOW AND HIGH S-APS

Learning Outcomes	**Low S-APS Mean**	**High S-APS Mean**	
Written communication	2.97	3.50	
Oral communication	3.06	3.62	*
Project planning	3.32	3.82	*
Concept generation	3.45	3.74	
Analysis tools	3.10	3.65	*
Engineering ethics	2.35	3.21	**
Economics	2.68	3.41	*
Creativity	3.03	3.79	**
Design	3.39	4.09	**
Set goals	3.42	3.97	*
Responsibility for deadlines	3.48	4.24	**
Communicate with team	3.48	4.03	*
Communicate with professionals	3.52	3.59	
Stay engaged	3.39	4.00	*

$* p < .05$, $** p < .01$

C. Value of Feedback and Faculty Interactions

When examining the value that students place on the feedback given by faculty, the comparison of averages indicates that high S-APS respondents rated all forms of feedback statistically higher than low S-APS respondents (TABLE IV). While significant, the least difference was seen in the value that students place on electronic medium as a form of feedback. The greatest difference (Δ=.81) was seen in the value that that high S-APS respondents placed on feedback concerning their personal teamwork.

TABLE IV. COMPARISON OF VALUE OF FEEDBACK AMONG LOW AND HIGH S-APS

Value of Feedback	**Low S-APS Mean**	**High S-APS Mean**	
Written comments	3.95	4.57	*
Team technical content	3.91	4.55	**
Personal technical content	3.86	4.55	**
Team teamwork	3.77	4.37	*
Personal teamwork	3.67	4.48	**
Electronic medium	4.12	4.60	**

$* p < .05$, $** p < .01$

While feedback is clearly important to the success of capstone students, interactions with faculty encourage and facilitate the mentoring that supports student success [18]. In comparison to the large differences seen in learning outcomes and feedback, low and high S-APS respondents were similar with respect to scheduled meetings, and formal class times. In contrast, high S-APS respondents value informal interactions with faculty before and after class statistically significantly higher than low S-APS respondents. This higher value on informal interactions with faculty was also seen through a statistically higher rating of the value on electronic communication.

TABLE V. COMPARISON OF VALUE OF INTERACTIONS AMONG LOW AND HIGH S-APS

Value of Interactions	**Low S-APS Mean**	**High S-APS Mean**	
Formal class time	3.19	3.57	
Scheduled meetings	3.91	4.22	
Informal before/after class	3.14	3.97	*
Work spaces	3.20	3.82	
Large studio	3.00	3.68	
Electronic communication	3.72	4.34	*

$* p < .05$, $** p < .01$

V. CONCLUSIONS

While self-perceptions of learning outcomes and perspectives of value are limited in their effectiveness as an assessment, they provide an insight into the characteristics of the student as an adult learner. The results of this study identify the andragogical student as one who is secure in their learning and values one-one-one interaction with faculty. Their willingness to receive tailored feedback on their personal knowledge and skills supports the perspective that they exhibit a stronger sense of self-directed learning and intrinsic motivation that is characteristic of an andragogical learner.

Despite discrepancies with faculty perspective, students in their senior year place a high value on tailored instruction through feedback and interactions. From this perspective, they are open to and may excel through problem and project based learning that goes beyond the capstone course. Faculty can facilitate student learning in these environments by applying several mentoring functions [16-18]. An ability to develop interpersonal relationships and cultivate approachability with the student, *rapport*, provide students who desire one-on-one interaction the comfort to address learning needs with faculty. This rapport will yield opportunities for coaching of technical and professional engineering skills while giving faculty the opportunity to role model the attitudes and values associated with the field and key to the capstone outcomes.

Quantitative Assessment of Student Motivation to Characterize Differences Between Engineering Majors

Adam Kirn and Lisa Benson
Engineering and Science Education
Clemson University
Clemson, SC, USA 29634

***Abstract*—Student motivation is often undervalued in comparison to academic performance measures for evaluating changes in higher education. There is a need to consider the affective domain in reform, in addition to academic performance. The effect of student motivation toward short- and long-term goals on student actions is not well understood. To assess this need, two research questions are addressed: 1) What elements of a motivation instrument designed for first-year engineering students are valid for upper-level engineering students? 2) How do motivations differ for upper level students in different engineering majors? Students in their major-specific engineering courses were surveyed with the Motivation and Attitudes in Engineering (MAE) instrument, which assesses long-term goal related expectancy, and perceptions of present and future tasks/goals. Short-term task self-efficacy was assessed using items adapted from the Attitudes and Approaches to Problem Solving survey. Results based on comparisons between major, class, and grade point average (GPA) showed: 1) Higher GPA indicates significantly higher expectancies and self-efficacy; 2) Bioengineers have significantly higher expectancies than mechanical engineers; and 3) Juniors have significantly higher GPAs, expectancies, and more positive perceptions of the present than sophomores. Results indicate that students' motivations toward short- and long-term goals may influence actions toward learning.**

Keywords—attitudes; motivation; engineering disciplines

I. Introduction

Student motivation is often undervalued in comparison to quantitative student performance measures [1] in research that contributes to evidence-based curricular and programmatic changes in higher education. Evidence-based curricular changes in higher education have had limited effect on improving the state of higher education [2]. While lack of improvement in learning may be attributed to limited cognitive effects of the innovations being examined, it is more likely that these minimal learning gains are caused by ignoring students motivation [3]. Additionally, in engineering, these innovations often neglect the student-based [4] and cultural differences [5] between different majors. To enhance education there has been a call in the literature to consider the affective domain of students in addition to academic performance [1], [6]–[9]. One model for understanding how student motivation influences student learning is the Motivated Action Theory presented by DeShon and Gillespe [10]. This model posits that students are driven by goals to perform actions. In this model, student goals are situated in different levels or time scales, from goals that are more long-term and stable, to goals that are situated in the present and are temporary. The combinations of motivations toward short- and long-term goals prompt students to act. While Motivated Action Theory provides a map for student action it does not signify which paths are significant for actions that will improve student learning.

NSF Career Grant EEC-1055950

To understand the significance of paths from long- to short-term goals we must first understand students' motivations at each proposed level. Students' motivations toward long-term goals can be evaluated through Expectancy x Value theory, the expectation of how one will perform on a task and how much one values a task or its outcomes [11]. Expectancy x Value theory posits that three main criteria must be met for motivated action: a) With enough effort, the performance can be achieved; b) If achieved, performance will lead to desired outcomes; and c) Those outcomes will lead to satisfaction [11]. Work in Expectancy x Value theory has shown that students who have higher expectations will have better academic performance [12], and those who see higher value for a task will persist longer [11]. Expectancy x Value theory has been developed to examine students' motivations toward long-term goals, such as major [11].

Despite development with long-term goals, Expectancy x Value theory does not provide express consideration of the variable time scales of students' long-term goals. Not considering the temporal space of students goals limits the way in which researchers and practitioners can understand how students' motivations influence action. Husman and Lens have examined students perceptions of the future and how the future relates to present tasks [7]. Future Time Perspective theory posits that the temporal distance of student goals, paired with the perceived instrumentality of a current task, will influence student actions in the present [7]. Husman and Lens have shown that students who have stronger academic motivations often have stronger or more detailed perceptions of the future, which correlates to improved persistence and performance on academic tasks [7]. While this framework explicitly examines students long-term goals, it has had limited application in engineering [13]–[15].

While the two frameworks mentioned above explicitly consider students' motivations toward long-term goals they have not been developed to work with motivations toward short-term goals. Bandura's work in self-efficacy has been developed

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

to examine motivations toward short-term tasks [16]. Self-efficacy speaks to students specific perceptions on how they will perform on a task [17]. Self-efficacy has been shown to influence the use of learning strategies on tasks related to students' courses [18]. While self-efficacy and expectancy are correlated constructs when examining the same time scale of goals [12], self-efficacy was developed to examine short-term tasks that require a high level of granularity [19]. The granularity of self-efficacy makes it more useful for examining motivations toward short-term goals.

Different aspects of engineering student motivation will be addressed through two research questions: RQ1) What elements of an instrument designed for (and validated with) first-year engineering students are valid for assessing motivation of upper level engineering students? RQ2) How do motivations differ for upper level students in different engineering majors?

II. Methods

A. Theoretical Frameworks

Previous work with engineering students established three motivation factors related to their engineering major (long-term goal): students expectancies related to their major, perceptions of future goals and tasks, and perceptions of present goals and tasks [20]. These factors are based on two motivation theories: Expectancy based on Expectancy x Value theory [11], and perceptions of future (Future) and present (Present) explained by Future Time Perspective theory [7]. Results indicated that students with higher perceptions of the Future, or having a more positive outlook on their long-term goals, were more likely to persist in engineering than students with lower perceptions of the future [20]. In other work it has been shown that students with higher expectancies will perform better on academic tasks, and those who value tasks more will persist longer at those tasks [11]. Work in future time perspective has shown that students who have a time perspective (view of time) that is situated further in the future are more likely to persist on tasks that they are currently working on than students who have a view of time that is closer to the present [7].

In these prior studies, students' Expectancy, Present, and Future are evaluated in relation to their engineering major, and do not speak to students short-term motivations for classroom tasks such as problem solving. To better understand the different elements of student motivation we are adapting the above framework to include student motivations toward problem solving. A commonly used framework in student problem solving is expert-novice, comparing how students and experts (often faculty) solve problems [21]–[23]. This framework has been applied across many fields and has helped to elucidate the steps of problem solving that are important for success [22]. The expert novice framework was adapted into a survey and given to students to examine what parts of the problem solving process students would perform [24]. This survey administration, much like others, showed a difference between faculty and graduate students, with faculty more likely to perform expert tasks. However, this survey could not differentiate between successful and unsuccessful students due to the fact that students have yet to become experts during their time in the university system [25]. To assess student motivation in relation to problem solving, and examine the variability between students, the instrument developed by Mason and Singh was modified to examine student views of problem solving using a self-report rating of self-efficacy [19]. Confidence in problem-solving self-efficacy examined alongside motivation toward long-term goals can begin to elucidate the interactions of these two aspects of motivation.

B. Participants and Instruments

Students enrolled in major specific second year courses at a southeastern land-grant institution in fall 2012 participated in surveys assessing their views on motivation related to long-term goals and short-term goals. Bioengineering (BIOE) and Mechanical engineering (ME) students were selected for this study due to the similarities of some of the course content of the two majors yet dissimilar populations [26]. Students were given the Motivations and Attitudes in Engineering (MAE) survey, an instrument that assesses student perceptions of their Expectancy, Future, and Present [20]. This thirty-four question quantitative survey was developed and validated with first year students in a general engineering program at the southeastern land-grant institution. Examples of Expectancy items include, "I expect to do well in this engineering course" and, "I am confident I can do an excellent job on the assignments and tests in this engineering course". Present items included, "I will use the information I learn in this engineering course in the future" and, "What I learn in my engineering course will be important for my future occupational success". Future items included, "My interest in engineering outweighs any disadvantages I can think of", and "I want to be an engineer". Additional MAE items may be found in Benson et al. 2013 [20]. MAE items were anchored Likert-type items on a seven point scale from strongly disagree to strongly agree.

An additional set of twenty-three items pertaining to their problem solving self-efficacy were also developed. The problem solving items were adapted from the Attitudes and Approaches to Problem Solving survey [24], and placed on a scale from 0-100 [19]. This change allows us to examine motivation toward problem solving tasks (short-term tasks) that is distinct from motivation related to students goal of obtaining an engineering degree (long-term goals) [10]. Samples of problem solving self-efficacy items included "Drawing pictures or diagrams to answer multiple-choice engineering problems" and "Checking my work for errors when I have obtained an unreasonable solution," after being prompted with "Please rate how certain you are that you can do each of the things listed below". Additional sample items from this construct are found in Table III in the Appendix. These items were added to the end of the survey to not influence results of the original MAE items. Students were offered the opportunity to win a ten dollar gift card as incentive for participation. Extra credit was offered to BIOE students, but not to ME students due to departmental policies. A red herring item ("Please respond forty-two to this item.") was added to the self-efficacy section to determine if students were properly responding to survey items. Five students did not fill out the red herring item correctly and were excluded from analysis.

C. Analysis

All statistical analyses in this paper were completed using the software R [27]. An exploratory factor analysis (EFA) was conducted using the structural equation modeling (SEM) package to determine how the MAE survey would factor with a new student population and additional self-efficacy items. Promax rotation was used due to potential correlations of items, and a 0.4 was used as the minimum threshold. Confirmatory factor analysis was not conducted due to the novel population and insufficient sample size [28]. Internal reliability of the survey items was tested through the use of Cronbach's α [29]. Differences in motivation by major, academic class, grade point average (GPA), sex, ethnicity, and basic skills math test (BST) score were tested by using analysis of variance. The BST is an assessmentof students' pre-calculus abilities at this institution during the first two weeks of students first math class. Student scores from the BST were used due to the predictive nature of math preparation on student success [30]. Differences in GPA between majors were tested using Welchs t-test. Least squares means contrasts were run to examine the differences between juniors and sophomores and MEs and BIOEs, since these populations had sufficient numbers for standalone analysis. Least squares mean contrasts separate desired groups from an ANOVA population and test for differences while limiting the influence of the more complicated statistical model. BST score differences were analyzed for class and major using nominal logistic fit, which is used to make predictions with multiple categorical outcomes.

TABLE I. SIGNIFICANCE VALUES FOR MOTIVATION BY MAJOR, ACADEMIC CLASS, GPA, SEX, RACE, AND BST SCORE. $*\alpha<0.05$.

Motivation Factor	Expectancy	Present	Future	Problem Solving Self-Efficacy
Descriptor				
Major	0.08	0.17	0.48	0.45
Academic Class	0.02*	0.33	0.62	0.29
GPA	<0.01*	0.34	0.14	0.03*
Sex	0.32	0.99	0.94	0.65
Race	0.87	0.99	0.68	0.87
BST	0.08	0.95	0.84	0.61

TABLE II. MOTIVATION CONTRASTS BETWEEN BIOE AND ME STUDENTS AND JUNIOR AND SENIOR STUDENTS. $*\alpha<0.05$.

Motivation Factor	Expectancy	Present	Future	Problem Solving Self-Efficacy
Comparison				
BIOE v. ME	0.02*	0.43	0.98	0.15
Junior v. Sophomore	<0.01*	0.04*	0.31	0.10

III. RESULTS

Of the possible 331 students in the two courses there were 153 survey responses (46.22%), with 44 of the 195 ME students (22.56%) and 79 of the 88 BIOE students (89.77%) responding. Of the total respondents, 32.03% were female (40.5% of BIOE students and 15.91% of ME students). The sample was composed of 85.62% White Non-Hispanic, 3.27% Black or African American, 2.61% Asian, 1.31% Hispanic, 5.88% other, and 1.31% non-responding about their ethnicity. The sample had one freshman, one hundred sophomores, forty-five juniors, six seniors, and one graduate student. EFA results for this population indicated that factors of the MAE were similar to previous administrations with first year engineering students [20]. Three items within Expectancy ("I am certain I can understand the most difficult material presented in the readings for this engineering course", "The course work in engineering classes is easy", and "I am having to work harder than many of the other students in my classes"), four items within Present ("I am having fun in my major", "I get satisfaction from my coursework", "I am encouraged and supported in my studies by the engineering faculty", and "My overall attitude about my engineering department is positive") and six items within Future ("I like the professionalism that goes with being an engineer", "I feel pride when I tell others that I am an engineering major", "I must pass my engineering course in order to reach my academic goals", "Engineers are respected by society", "I have an understanding of professional and ethical responsibility", and "The grade I get in this engineering course will affect my future") did not factor in this analysis and were dropped from subsequent analysis. Self-efficacy items factored into a single construct, showing that students view the different aspects of problem solving as one process. One item from the problem solving self-efficacy section of the survey did not factor ("Handling the mathematics involved with solving engineering problems") and was excluded from the analysis. Cronbach's α were 0.93, 0.86, 0.90, and 0.95 for Expectancy, Present, Future, and Problem Solving Self-Efficacy, respectively. For each construct, items were averaged and this average score was used for subsequent analysis. A non-weighted average was used due to the imposed cutoff when conducting an EFA and the weights possibly giving rise to overvaluing remaining items. ANOVA results showed that students in different academic classes have significantly different expectancies (Table I). Students with higher GPAs also have significantly higher expectancies and problem-solving self-efficacy. No significant differences were seen based on major, sex, ethnicity, and BST both for motivation constructs and GPA.

Due to confounding from limited numbers of students in academic classes (senior, freshman, and graduate) and majors (non-BIOE/ME), least square means contrasts were run to compare MEs and BIOEs as well as sophomores and juniors (Table II). On a scale of 1 – 7, BIOEs have significantly higher expectancies (5.28) than MEs (4.83). Juniors showed significantly higher expectancies (5.53) and perceptions of the present (5.94) than sophomores (4.91, 5.61 respectively). There are differences in GPA based on academic class (p=0.04), with juniors (3.51) having a significantly higher GPA than sophomores (3.34).

IV. DISCUSSION

EFA results have shown that the MAE can be used with upper-level students with minimal modification. The results of the EFA are similar to previous administrations where the factors were Present, Future, and Expectancy [20]. Cronbach's α's for this study are all within the good to excellent ranges, indicating internal consistency of the items [29]. Problem solving self-efficacy broke out as its own factor, indicating that students view it separately from long-term goals, such as major related expectancy which has been shown to be correlated to major related self-efficacy [12]. Problem solving self-efficacy as a single factor may indicate that students view problem solving as one step or hurdle instead of a series of subcomponents. Given students prior experiences with problem solving they may be chunking the steps of solving a problem together [21], [22]. Additionally, students may be viewing the short-term task of problem solving as one hurdle instead of a series of barriers due to having time perspective set in the future [7]. Results have indicated differences between academic classes on expectancy and perceptions of the present. Differences in self-efficacy and expectancy were noted for students with higher GPAs. The influence of self-efficacy and expectancy on GPA mirrors the work of Jones and colleagues that showed that both factors are predictive of GPA [12]. While self-efficacy and expectancy have been shown to be correlated in previous work [12], these factors are potentially viewed as unique by students due to different time scales of motivations toward obtaining a degree and motivations toward solving a problem [7]. This interpretation is further supported by our comparison of junior and sophomore students: despite juniors having significantly higher GPAs than sophomores there is not a significant difference in their problem solving self-efficacy. Students with higher problem solving self-efficacy may have had more instances of mastering problem solving in the past [31]. Students with higher GPAs may have had more recognition of their mastery of problem solving, thus their higher self-efficacy. Higher perceptions of the present may indicate that students have a better developed time perspective and value their course materials more [7]. More positive perceptions of the present may also speak to increased persistence within the major and tasks related to the major [20].

Differences in present and future perceptions for all academic majors are potentially masked due to limited numbers of students in majors outside of BIOE and ME. Lack of differences between sexes and ethnicities may indicate that students who make it to major specific courses have similar motivation profiles. BST scores while predictive of student performance are not predictive of differences in student motivation for this population. The lack of differences between sexes may indicate that the instrument measures presented here are separate from other pieces of motivation such as intrinsic and extrinsic motivation which have indicated sex-based differences in other work [32] or that students who have progressed this far in their academic careers possess similar motivational profiles regardless of sex, the same explanation also applies for the lack of differences between races. The MAE survey used in this study has demonstrated that students who persist in engineering possess similar motivation profiles when compared to those who leave engineering [20]. The lack of sex differences reported here are also in contrast with results presented by Hutchinson-Green and colleagues that have indicated that females have lower self-efficacy than males in general engineering courses [31]. This difference may be due to the major-specific context in which students were surveyed influencing results. Items in the context of a students major may better relate to their long-term goals which may lead to better performance on tasks and increased self-efficacy [7], [31]. The increased time of enrollment may also allow students to develop an understanding of what their abilities are and what they are truly capable of doing.

The results of this work support the theory of DeShon and Gillespe, showing that students motivations toward multiple goals are at play. A student's goal of being a high performer, manifested through a strong GPA, may be influencing their expectations toward their major and their problem-solving self-efficacy. The group of students who have higher GPAs are also likely to be juniors who see more usefulness for their current courses in terms of reaching their goals. The interplay of motivations related to long- and short-term goals is displayed through the multiple motivations that students possess toward different tasks. These results support the Motivated Action Theory's idea of multiple levels of motivations playing into student action.

Previous work in motivation has demonstrated that students' motivational states can be influenced through instruction [6], [7], [33]. Despite the fact that these motivational states have been produced in laboratory environments, they have been shown to lead to improved learning strategy use [34] and knowledge transfer [6]. While motivation cannot be entirely influenced by instruction [10], the ability to lead students into positive motivational states could result in student actions that are more beneficial to their learning. Additionally, these results indicate that students' motivations toward short- and long-term goals/tasks are at play concurrently and may be driving student actions.

V. Conclusions

Results of this work show that the Motivations and Attitudes in Engineering Survey can be applied to student populations who have advanced beyond the first-year of their studies and can be used for differentiating student groups. Results indicate that students' perceptions of the present, perceptions of the future, major-related expectancies, and problem-solving self-efficacy are distinct pieces of students motivations. These four aspects of motivations examine student perceptions of long- and short-term tasks/goals. Students who have progressed further toward completion of their major show higher expectancies than students who have made less progress despite being in the same required courses. Additionally, juniors have shown higher perceptions of the present, potentially indicating better understanding of what they want to do, compared to sophomores. Students with higher GPAs also possess significantly higher expectancies and problem-solving self-efficacy. BIOE students have also been shown to have higher expectancies than ME students. Understanding these differences in student motivations, despite the similar entry requirements for students, can help better direct instructional change that can help motivate students in ways that are more beneficial for learning.

VI. Future Work

Results from this work only speak to a small set of motivational features that can drive students to perform. As such, future work must consider additional frameworks to describe the motivation of students pursuing engineering degrees and solving engineering problems. While we have a better understanding of how different student characteristics influence student motivation, we have yet to connect these motivations to students actions toward learning. Here students have considered their ability to perform during the different steps of a problem as one motivational construct. The types of problems and key features of the problem solving process as viewed by students were not clearly understood, as indicated by the single problem solving self-efficacy factor. Understanding the types of problems and problem features that students notice under the influence of different motivation profiles is not well understood. To gain further understanding of students' motivations toward problem solving (short-term tasks) and major (long-term goals), the results of this work will be used to group students based on motivational profiles through cluster analysis. These groups will be used to purposefully select students for interviews. These interviews will qualitatively examine students motivations toward long-term goals (major and future careers), short-term tasks (problem solving situations), and how the interactions of these two motivations influence student action (knowledge transfer). An understanding of how motivations influence student action will allow for the creation of interventions that can influence student motivations related to the learning, retaining, and using information presented in the learning environment.

VII. Appendix

TABLE III. Problem solving self-efficacy items displayed below were on a scale from 0-100. Prior to answering these items students were prompted with, "For the following items, please rate how certain you are that you can do each of the thingsbelow by writing the appropriate number." Additional examples of MAE items can be found in Benson et al. 2013 [20].

Item
Work through an engineering problem with a peer, when having difficulty solving it alone.
Go to see a teacher or TA to get help when I am not sure how to start a problem.
Check my work for errors when I have obtained an unreasonable solution.
Handle the mathematics involved with solving engineering problems.
Draw pictures and/or diagrams even if there is no partial credit for drawing them.
Determine what may be wrong with a problem solution if the answer seems unreasonable.
After solving engineering problems in which the same principle is applied in different contexts, apply that principle in other situations.
Identify the engineering principles in the problem before looking for corresponding equations.
Determine when my answer and/or work is wrong.
Think about how each term in an equation relates to the an engineering problem I have not seen before.
Solve challenging engineering problems.
Reflect on engineering principles that may apply when unsure of the correct approach to solve the problem.
Solve an engineering problem symbolically before plugging in the numbers.
Determine which approach is more reasonable, if two approaches to solve an engineering problem gave different answers.
Explicitly think about the concepts that underlie the engineering problems I solve.
Draw pictures and/or diagrams to represent the situations described in engineering problems.
Solve a multiple-choice engineering problem by drawing a picture and/or diagram.
Learn from the problem solution after I solve each engineering homework problem.
Keep working on an engineering problem even if I havent been able to solve it after 10 minutes.
Learn enough from my mistakes on tests and homework such that I do not repeat those same mistakes.
Use different approaches to solve an engineering problem when one does not work.
Solve an engineering problem with numbers instead of symbols.
Learn by solving a few difficult problems using a systematic approach.

Engineering Person-Thing Orientation: Comparisons between first-year students and practicing engineers with implications for retention and professional placement

Abstract— **Academics, industrial leaders, and policy makers seem to agree that the United States can improve its ability to attract and retain engineering talent. Efforts aimed at addressing this need vary broadly from increasing the public's awareness of the problem, to re-framing the identity of engineering, de-emphasizing its less glamorous aspects, and orienting engineering's future toward solving the world's greatest problems facing humanity. In doing so, it is suggested that engineering would be a more appealing profession to groups that are historically under-represented. The fundamental assumption of these efforts is that an improved image of engineering as a socially engaged helper of humanity will result in greater initial and prolonged interest in engineering. Research investigating engineering as a profession has found few examples of specific engineering disciplines considered socially sensitive. This may suggest engineering is a career choice better aligned with individuals who prefer working with things rather than people. This exploratory study will utilize the Graziano, Habashi, & Woodcock (2011) Person and Thing Orientation Scale to examine how these things versus person tendencies appear in engineering college students and practicing engineers. It aims to identify potential sources of differentiation for these preferences within and across the sample populations.**

Keywords—person-thing orientation (PO-TO); student retention; engineering profession; engineering identity; engineering disciplines; industry; practicing engineers

I. Introduction

The Engineer of 2020 (National Academy of Engineering, 2004), and Rising above the Gathering Storm (National Research Council, 2007) raise a sense of urgency for engineering educators to better understand industry's need for greater numbers of engineers and to elevate filling these shortages as critical for the United States economic stability. Other initiatives appear to take an adjacent tact, emphasizing the benefits of becoming an engineer rather than sounding a siren song among the profession. The Grand Challenges effort (National Academy of Engineering, 2012) portrays engineering as a vibrant discipline capable of solving the world's biggest problems, particularly those associated with improving quality of life for people.

This shift in portrayal of engineering could be important when considering how to attract greater numbers of females (and other under-represented populations) into the profession. Currently the number of females obtaining engineering degrees is virtually steady (National Science Foundation Division of Science Resources Statistics, 2011) while at the same time women receive over half of degrees issued from universities and colleges, a number that continues to grow (ASEE, 2012). In spite of efforts to reframe engineering in a more exciting and female friendly way (Giddens, et al., 2008), studies investigating females' interest in science and medicine over engineering often cite a preference among females for occupations that are helping in nature (Miller, Rosser, Benigno, & Zieseniss, 2000). In particular, these studies note a distinct preference toward occupations that engage people rather than related mechanical artifacts (Miller, et al., 2000). Interestingly at the university level, industrial engineering of all engineering disciplines is noted to attract disproportionate numbers of females, frequently for socially oriented reasons (Brawner, Camacho, Lord, Long, & Ohland, 2012).

According to Little (1968) people selectively orient to environments that are congruent with their interests and occupy that niche. Just as we can parse human interests into people and things we can parse the environment the same way. We expect people to choose environments that are congruent with their interests. This is particularly true in the United States where interests are primary motives for career choice. Science, Technology, Engineering, and Mathematics (STEM) fields are perceived as very thing oriented, so we expect that people high in Thing Orientation are attracted to STEM. In particular, engineering is commonly typified as a discipline that primarily deals with the creation and manipulation of objects as opposed to a discipline centered on interpersonal interaction or data manipulation. Based on the work by Graziano and colleagues (Graziano, Habashi, & Woodcock, 2011) an individual's

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

preference between people oriented (PO) events and activities versus thing orientations (TO) can be established. Further, in a related study (Graziano, Habashi, Evangelou, & Ngambeki, 2012), gender differences in educational major choices were highly correlated to the person and thing dimension. In addition, they found that Person Orientation may push people towards person oriented careers and drive people away from thing oriented careers, while alternatively, Thing Orientation was found to move people toward thing oriented careers while being unrelated to selection of person oriented careers. Finally, the study found that women and men high in Thing Orientation expressed more interest in thing oriented careers, an effect particularly pronounced for women (Graziano, et al., 2012). With these findings in mind, interests are therefore an important determinant of career choice when women consider entering careers that are not gender role congruent.

II. STUDY DEVELOPMENT

The goal of this study is to examine the following research questions:

1. Do first year engineering students and practicing engineers share a homogeneous PO-TO profile?

2. If different, in what ways are they differentiated?

3. Can demographic influencers (including gender) associated with PO-TO scores be observed and confirmed across both populations?

4. Are there industry sectors or engineering disciplines that demonstrate stronger orientations toward persons versus things?

5. Is there an indication that somehow the workplace creates a transformative environment for ones PO-TO profile?

Using the Graziano et. al. PO-TO instrument, this exploratory quantitative survey study will examine the interest in people and things of 400 first-year engineering students and over 150 industry professionals. The participants for this study are from two distinct pools – first-year engineering students and practicing engineers from industry, both of whom were accessed for this study through convenience sampling.

Analysis for this study will include both demographic and ANOVA statistics. ANOVA mean value comparisons across the two populations will be looking at gender, generation, and ethnicity for possible sources of person versus thing score differentiation. Within the population of engineers in practice, this study will examine the central tendency PO-TO profiles by specific engineering disciplines and industry sectors.

We predict that analysis will demonstrate more thing orientation than person orientation across both sample populations overall. In addition, we predict that within both populations, male participants will have a greater thing orientation than female participants corroborating prior research. We do not however anticipate PO-TO differentiation by ethnicity. Further, we anticipate that when compared to the professional engineers, the student engineers will display a slightly greater tendency toward thing orientation, indifferent to gender. Finally, we predict that for the practicing engineering population, PO-TO mean scores will be differentiated by industry sector, but will display no mean differences across engineering discipline.

III. DISCUSSION

Currently, our research is in the analysis and interpretation stage. Data was collected from both target populations as part of two separate research studies, and initial mean scores and demographics have been developed for each. Next steps will include the merging of individual data sets to complete the ANOVA comparisons, and begin interpretation of the results.

The value of this work for engineering educators and the professional community is three-fold. First, for researchers focused on issues surrounding retention and under-represented populations in engineering, it may illuminate another aspect of student preference attributable to their choice of engineering as a career choice. Going further, if PO-TO preferences are found to shift once engineers reach the workplace, this may help to explain why some graduates who successfully navigate and complete a rigorous traditional engineering education fail to remain in the profession long term.

Second, for those engaged in student advising and coaching in engineering education pathways, the findings of this study could encourage the use of the PO-TO instrument as another predictive tool for academic persistence. This would occur by determining alignment/misalignment between the student and the engineering profession's cultural orientation.

Finally, by investigating and developing a PO-TO profile for engineering professionals across industry sectors and disciplines, we can begin to explore how the cultural context of practice may be influencing an individual engineer's interest in people and things. Implications for this possibility could influence career placement activities for both novice and expert engineers, as research has suggested that alignment between personal and professional identity is important in the profession of engineering (Downey & Lucena, 2004). Further, understanding the person or thing orientation of an industry sector or specific engineering discipline could assist engineers of all education/experience levels make improved job selection decisions by aligning their PO-TO profile with that of potential employers. Prior to being in the position of job selection, students attempting to determine their discipline specific engineering pathway could use PO-TO profiles of engineering disciplines to inform their educational choices.

IV. CONCLUSIONS

Although the results of this study are still unfolding, the potential benefits to engineering education and the profession on whole offer significant promise. Using the PO-TO scale (Graziano, et al., 2011) across a diverse engineering population hopes to add insights related to individual preference between person oriented events and activities versus thing orientations in different contexts. Further, determination will be made as to the level of influence demographic aspects such as gender, ethnicity, industry sector and engineering discipline play.

Student engineers and engineers in general are thought to be drawn to engaging things, yet data to corroborate this persistent image is absent. Reviewing the literature for the importance of thing orientation to chose and persist in engineering, it would be beneficial to examine if engineering thing orientation can be corroborated, is constant, or changes over time. Such a finding could eventually uncover additional insights into contributing factors for why some graduate engineers never choose to engage in engineering related careers.

An understanding of such relationships could also provide opportunities for engineering educators to influence the messages and regulate/support outreach and college activities taking advantage of thing orientation to increase engineering persistence for groups that are historically under-represented including women.

ACKNOWLEDGMENT

The authors would like to thank both the student and industrial participants of this study for their time and thoughtful consideration. We would also like to acknowledge Dr. William Graziano and his early research team which has allowed this comparative study to begin to unfold to the benefit of STEM education and field of industrial practice.

Exploring the Student Experience in Low-cost Intrinsic Motivation Course Conversions

Kathryn F. Trenshaw[1], Renata A. Revelo Alonso[2], Katherine Earl[3], Geoffrey L. Herman[2]

***Abstract*—The low-cost intrinsic motivation (IM) course conversion project aims to promote the adoption of education innovations, lowering the costs of these innovations by promoting students' intrinsic motivation to learn and to invest in their own education. We have piloted and scaled the IM course conversion of a large enrollment, sophomore-level engineering course. As part of a broader evaluation, we interviewed 31 students to better understand how the IM course conversion affected students' motivations to learn. During these interviews, students described their experiences in the course as a story from the beginning to the end of the semester. Interviews were transcribed and analyzed with an open coding scheme focused on motivational and affective statements. Preliminary analysis indicates that strategic choices, positive team dynamics, and productive failures in the learning process all contribute to promoting students' intrinsic motivation to learn in both pilot and full scale IM course conversions.**

Keywords—intrinsic motivation, low cost, Self-Determination Theory, undergraduate, large enrollment, student interviews, course conversion

I. Introduction

The low-cost intrinsic motivation (IM) course conversion project aims to redesign core engineering courses so that they primarily focus on promoting students' intrinsic motivation to learn. These converted courses would require low investments of time and money for instructors to teach. Because the traditional design of engineering courses focused on teaching the "right things" or perhaps even the "right way," previous reform efforts focused on getting students to learn the course content better by changing instructors' approaches to teaching. Although a focus on instructors' teaching methods can be beneficial, we believe that it may fail to prepare students to be life-long learners who are passionate and excited to become engineers. In contrast, the IM course conversion project focuses reform on methods to promote students' IM to learn with the belief that motivated, excited learners will ultimately learn more and persist longer in their learning.

In this paper, we report on the qualitative evaluation of the pilot and full scale versions of the IM course conversion. We interviewed 31 students who had experienced the IM course conversion to understand how the course affected their motivation to learn and their interest in the course content. We are using a grounded-theory-based analysis method informed by motivation theories with the goal of developing a finer-grained theory for describing what happens inside or outside the classroom to promote students' intrinsic motivation to learn, and how different course structures change students' motivational orientations.

II. Methods

A. IM Course Conversion

Using Self-Determination Theory (SDT) as the foundational decision-making framework, we make all IM course conversion decisions to promote students' sense of *purpose*, *autonomy*, *relatedness*, and *competence* for learning the material [1][2]. We ask instructors to identify a narrow strategic core for their course content so that their courses have a stronger sense of purpose and to give students a degree of autonomy to direct their own learning. With these guiding principles, in Fall 2011 and Spring 2012, we piloted IM course conversions with a subset of students (fewer than 50 students) from a large enrollment (more than 200 students) sophomore-level core computer engineering course. In Fall 2012, we scaled this IM course conversion to engage all students in the same course. In this IM converted course, all students crafted three learning agreements in which they could choose how they would practice the course content and demonstrate their mastery of the course content. They could even choose elective topics to study. Our previous quantitative research found that students in the IM courses achieved learning gains that were comparable to students who were in collaborative problem solving courses, but IM students expressed a greater sense of ownership and support for their learning [3].

B. Interviews

After completion of the course, we asked students to share their individual experiences by participating in interviews. A total of 14 students who had experienced the pilot conversions and 17 students who had experienced the full scale conversion volunteered for interviews. We used a semi-structured interview protocol and asked students to walk us through a timeline of their experiences in the course. We analyzed the interview transcripts without an a priori coding scheme, because we found no prior studies that indicated what we might expect to find. Our open coding process focused on students' motivational and affective statements. We created, reduced, and synthesized codes with a four step process: 1) individual open coding, 2) collaborative code reduction, 3) individual re-coding based on the reduced code set, and 4) theme development. So far, we have completed the analysis of the eight interviews from the first pilot IM course conversion.

This material is based upon work supported by the National Science Foundation under Grant No. DUE-1140554. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

III. Preliminary Results

Thematic analysis resulted in four main themes which mapped to four of the motivational orientations described in SDT [4]: 1) no motivation or disengagement, which mapped to *amotivation* (AM); 2) motivation by grades or requirements, which mapped to *external regulation* (ER); 3) motivation by career or bettering oneself, which mapped to *identified regulation* (IR); and 4) motivation by learning, excitement, interest, or fun, which mapped to *intrinsic motivation* (IM). We found that strategic choices, positive team dynamics, and productive failures in the learning process commonly marked movement from AM, ER, or IR to IM throughout the students' experiences. The following quotations are from the first pilot IM course conversion only and are annotated with the motivational orientations assigned to individual phrases in braces (e.g., {IM}).

Students were identified as IM oriented when they made statements about interest in learning or enjoyment of the experience. A representative IM quotation is shown below.

> Please don't take up spots in the [pilot] by saying you want an easy A. And **those who in the past have wanted to learn more than what's in the class, who want to learn what's real life, then definitely, definitely do this {IM}**. I wish all classes were like this. (emphasis added)

Students became more intrinsically motivated to learn when working within a positive team dynamic, when given opportunities to make strategic choices about their learning, and when failures early in the course led to productive decisions later on. Selected quotations from students who started out AM, ER, or IR oriented and moved toward IM oriented are discussed below.

Positive team dynamics (*relatedness*) resulted in mutual support, greater perseverance, and increased excitement for the course. Students who described positive experiences with other team members made more IM oriented statements about the course than those who reported either neutral or negative experiences.

> We had a good group…. We split up work evenly, everyone got their work done and then we all got together and put our parts together {ER}. The only problem was when you're transferring ... files to one computer ... we all sat there and we're trying to figure out what was going on, so I think that was a good team building thing even though it kind of stunk {IR/IM}.

> Being with other people and working with other people who were also really excited about it makes me more excited {IM}.

Students were given the opportunity to choose how they would demonstrate their mastery of the course content (*autonomy*). When students based their initial choices on "getting an easy A," the final products were low quality and received negative feedback from instructors. These early failures "woke students up" and caused them to rethink their choices (*purpose*). The students' later choices centered on learning gains rather than grades and received positive feedback from instructors (*competence*).

> [At] the end of the first learning contract, we got stuck because we got very low grades {ER} ... We were very upset and we were thinking 'should we drop out of this section or not? {AM}' But then we kind of came out of that. **We shouldn't just give up {IM}** ... (emphasis added)

> Right after that exam it sorta just tanked {ER} and then just realized, "Okay. You know what? Time for the second learning contract. The second exam is something we can do, we can actually make an impact on." {IR/IM}

> But after the first one when we were designing the questions, we decided to do a design thing more, to **get more out of the course {IM}** ...The project aspect, trying to design something that really works well. To design things that work efficiently as much as a [sophomore] could probably do {IM}. (emphasis added)

We hope to elucidate these aspects of students' experiences with future analysis of the other 23 interviews.

IV. Future Directions

We are currently analyzing the second pilot and the full scale IM course conversion interviews. Future work will include qualitative results from all 31 interviews as well as classroom and team meeting observations. We will triangulate these qualitative results with quantitative surveys of both autonomy support and achieved learning gains for both the pilot and full scale conversions. We will also compare the pilot and full scale conversions.

We are studying the outcomes of IM course conversions in one large enrollment course in computer engineering for sophomores. We hope to expand the study to include conversions of courses at different levels and within different engineering disciplines in future semesters. Collaborations with chemical engineering and bioengineering are currently underway. Interest in IM course conversions has spread beyond engineering as well, with education and psychology instructors taking notice and adapting the method to their own classrooms.

Acknowledgment

We thank the instructors and teaching assistants of the course for supporting our IM course conversion efforts. We thank our diligent transcribers for their hard work.

***Abstract*— In this collaborative project with librarians, the faculty members of Nelson College of Engineering, West Virginia University Institute of Technology (WVU Tech) identify the importance of information literacy (IL) in accreditation documents and then leverage accreditation guidelines from Accreditation Board of Engineering and Technology (ABET) student outcomes to integrate IL skills from standards of the Science and Technology Section (STS) of the Association of College and Research Libraries (ACRL) into an existing software engineering course. This project was sponsored by West Virginia University Information Literacy Course Enhancement Grant. We included the full range of the university libraries' resources, expertise, and services in course planning and delivery by incorporating different IL units: an introductory talk, special workshops, library sessions and consultations with the librarian throughout the semester. As conducting researches, designing projects, and writing reports are most effective vehicles for students' learning of strategic and rigorous information retrieval and management, the class includes a group software-development project and an individual paper-writing project. We included different data collection and evaluation methods distributed throughout the semester, including Standardized Assessment of Information Literacy Skills (SAILS), a web-based tool to document IL skill levels and to pinpoint areas for improvement.**

Keywords—Information Literacy, Software Engineering, ABET outcome, ACRL Standards

I. INTRODUCTION

According to the National Forum on Information Literacy "information literacy (IL) is the ability to know when there is a need for information, to be able to identify, locate, evaluate, and effectively use that information for the issue or problem at hand" [4]. This paper describes a collaborative project between engineering faculty members of Nelson College of Engineering, West Virginia University Institute of Technology (WVU Tech) with university librarians to identify the importance of IL literacy in accreditation documents and then to leverage accreditation guidelines from Accreditation Board of Engineering and Technology (ABET) student outcomes to integrate IL skills from standards of the Association of College and Research Libraries (ACRL) into an existing software engineering course. This project was funded by West Virginia University Information Literacy Course Enhancement Grant.

In this project, we offer pedagogical innovations through unique combination of different methods of instruction delivery and class assignments. Along with traditional lectures, we offer workshops (on IL, technical writing, professional presentation, CASE Tools) and special library sessions (on orientation, search strategy, citation analysis). We also included special sessions on ethics and contemporary issues (watching related video, discussion on engineering ethics standards, intellectual property, copyright law etc). In addition to regular tests, the class includes a semester long group project, formal presentations, paper writing and multiple active learning exercises. In a group environment the students build their own software project over the semester by applying the software engineering process, methods and tools. The whole semester is divided into four phases "Communication and Planning", "Modeling", "Construction" and "Deployment". As the semester goes through each of these phases, the students gain theoretical knowledge from lecture contents, related hands-on experience from their own projects and share their experience through formal presentations. The class also has an individual project in which each student perform research on a current software engineering topic to prepare a formal report. Students work with librarians to research background material, formatting requirements and referencing others. This class allows us to compare the efficacy of design engineering projects with that of engineering reports as alternative vehicles for information literacy. While integrating the ACRL standards and ABET outcomes, we emphasized more on the professional skills including communication (oral presentation and writing), teamwork, ethics and lifelong learning. Rather than just letting them work in a team, we guide our students in group development, consensus-building, resolving-conflict, and team-leadership. Finally we demonstrate how students can become a lifelong learner by becoming proficient in broad spectrum of professional skills.

Our greatest strength is our extensive assessment effort through the whole semester. On top of regular grading through scoring rubrics and peer evaluation (on teamwork), we are performing multiple survey/tests including pre and post

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

survey, assignments on citation analysis, search strategy, plagiarism and a test called Currency, Relevance, Authority, Accuracy, Purpose (CRAAP) test [8]. We are also conducting external evaluation through Standardized Assessment of Information Literacy Skills (SAILS) test [10].

The rest of the paper will include following sections. In section II, after describing information environment in ABET's nine general outcomes for computing programs and ACRL's five standards for science and technology, we will try to relate both options. In section III we will explain the background of this project. Our efforts around five professional skills communication, teamwork, impacts of computing, ethics and lifelong learning will be narrated in section IV. Before we draw our conclusions, our different implementation and assessment strategies are described in sections V and VI respectively.

II. ABET AND ACRL

In following subsections, after briefly describing ABET's outcomes for computing programs and ACRL's standards for science and technology section, we will try to identify the relationship between these two skill sets.

A. ABET Student Outcomes for Computing Program

The Accreditation Board for Engineering and Technology (ABET) is recognized as the worldwide leader in assuring quality and stimulating innovation in applied science, computing, engineering, and engineering technology education. ABET student outcomes describe what students are expected to know and be able to do by the time of graduation. These relate to the knowledge, skills, and behaviors that students acquire as they progress through the program [3]. Criterion 3 of computing programs includes a set of nine general outcomes that all computing baccalaureate graduates should possess. The nine general student outcomes of computing programs are listed in Table 1. One aspect of the enhanced ABET criteria (2000), particularly relevant to engineering and technology is "an understanding of professional responsibility". In section IV we will walk through ABET's five professional skills communication, teamwork, impacts of computing, ethics and professional development (also known as lifelong learning).

B. Standards of ACRL's Science and Technology Section

The Association of College and Research Libraries (ACRL), a division of the American Library Association, is a professional association of academic librarians and other interested individuals [4]. It is dedicated to enhancing the ability of academic library and information professionals to serve the information needs of the higher education community and to improve learning, teaching, and research. In order to identify the 21st century information environment in computer science or more generally in engineering education, let us look at the simpler versions of information literacy standards (also described in details in Table 1) specific to science, engineering, and technology defined by the Science and Technology Section (STS) of the Association of College & Research Libraries. Here, we will also identify ways to accomplish these standards in our software engineering class.

1) Determine the nature and extent of the information

In corporate world, engineers need to find critical information from databases, technical journals, handbooks, and product catalogs to solve the problems. Defining the problem and identifying what they need to know are critical first steps that engineering students tackle. As the students themselves seem to be most receptive to IL when they are engaged in creative projects, inclusion of a workshop on IL before projects are being assigned will be very beneficial.

2) Acquire information effectively and efficiently

Engineering students (also professionals) often do their research only with the internet and overestimate their abilities in searching the internet for information. Most of them are unaware of subject-specific databases that could be better sources for more detailed information on a topic with a clearly-defined subject area. The guidance of the librarian on what other tools are available and when they are useful for a specific information need will help students to expand their skills in finding web sites, books, and journal articles via the use of a web search engine, the library catalog, and a research database.

3) Critically evaluates the procured information

A quick search of any technical topic will yield a sea of user-created information content of varying quality. The necessity of being able to correctly select, interpret, and measure the "goodness" of the information, and therefore how much it should be relied upon, becomes more and more critical. As engineering students typically value accessibility over quality when choosing information sources, it is very important to teach them how to critically evaluate material.

4) Use information effectively and ethically

Engineering ethics is one of the crucial areas in engineering education. Using media information (Report on Bhopal or Columbia shuttle incident) to discuss about ethical principles and our responsibilities to the society is a very effective technique.

5) Understand IL as a component of lifelong learning

The goal of engineering programs is to educate competent engineers. Because the working environments and experiences of engineering students will differ greatly after graduation, engineering programs aspire to teach a set of skills that will be of value in different working environments and also encourage them to engage in a life of continuing pursuit of knowledge using IL.

When we consider the implications of the IL standards, identify the information applicable to the problem at hand, find the appropriate sources, evaluate the quality of the information, apply it ethically and engage in a lifelong learning, we can see that IL is the very *essence* of engineering education and it must be incorporated in our curriculum to meet the future professional needs and success of our students.

C. The Relationship

Although ABET outcomes criteria do not explicitly mention information literacy, it is apparent that students cannot achieve many of the ABET outcomes without developing information literacy skills [5]. Some IL standards clearly overlap with ABET outcomes in communication, teamwork, impacts of computing, ethics and lifelong learning. However it is still not a common practice for the IL skills to be assessed as part of ABET outcomes assessment. As we wanted to integrate these two skill sets, identifying their relationship is crucial for our project. After carefully analyzing the skills in both sets, one can identify that these two actually can complement each other. While ACRL standards are designed around the conception that the engineers are only the consumer of the information, ABET is placing the engineers as the sole producers of information. ABET's outcomes assumes that the engineers work with data which are only generated through their own experimentation. They do not encounter the need to account for information gathered in other ways, particularly through existing information resources [5].

We identify a symbiotic relationship between these two sets. We are hoping that if the engineering faculty and librarians work together to design and develop different types of instruction methods to deliver these skills and assessment tools to evaluate, like a true symbiotic relationship, both skill sets will nourish each other. The success of these efforts will not only be the summation of both, it will be a success of multiplying factors. We strongly believe that integrating ABET outcomes with IL together can achieve far more than either can individually. In TABLE 1, we put the related ABET's outcome and ACRL's standards side by side.

III. BACKGROUND

In this section, we describe our process in integrating our IL criteria with our ABET assessment process. We will also make the case for utilizing the same class which is currently being used for assessing ABETs outcomes for a project funded by a course enhancement grant to incorporate IL skills.

A. The Development Process

In Computer Science and Information System department of Nelson College of Engineering of WVU Tech, as part of a department wide effort, we are currently preparing for application for ABET accreditation on 2014. At the beginning, we performed curriculum mapping process, where we were trying to identify core courses for performing the documented and effective process for the periodic review and revision of the student outcomes. During this process, along with our senior project capstone class (CS 461), our sophomore level software engineering class (CS 222) has been selected as a natural candidate to measure the fulfillment of a large numbers of the ABET outcomes. In early spring 2012 when the university library has announced a course enhancement grant to incorporate IL in an existing course; this software engineering class seems like a perfect candidate. Because we are already committed our time and resources to ABET preparation, we desired to integrate efforts for including information literacy standards with those of ABET in this class. After successfully securing the grant, we approached our librarians with ideas and suggestions of IL based instructional issues particularly relevant to our software engineering course. As the librarians have been providing essential instruction in IL for many years, they can assist us (software engineering faculty) in adjusting to the emerging standards by incorporating lessons of IL responsibility into an existing curriculum. Our librarians worked amongst themselves to ascertain the specific incremental instruction components that can be integrated into this particular course and provided us concrete suggestions that can be a basis for to documenting IL instructions, which in turn can facilitate documentation for accreditation reports. This collaboration between software engineering faculty and librarians has so far been a great experience in exploring the effective intersection of ABET outcomes and IL competencies, in the context of incorporation into an existing course.

Several works can be found in literature which mapped IL criteria to ABET outcomes [5, 6, 7]. Most of these work [6, 7] place IL in the "lifelong learning" (also known as continuing professional development) category of ABET outcome. We have chosen to broaden this mapping outside of lifelong learning because we believe IL skills are developed across several professional outcomes including communication, teamwork, impacts of computing and ethics. In our work, we tried to bring the bests of both worlds of ABET and ACRL by not only mapping them together, but also reviewing these skills with an emphasis on how they can be taught together. In this project, software engineering faculty and librarians are working together to develop creative ways to combine these skills. During our work we survey the literature to identify successful and promising examples of implementation of IL and successful assessment mechanisms to evaluate ABET outcomes in a class. Because each institution develops their own set of mechanisms, we did not simply adopt another's mechanism but developed our own implementations of instruction delivery and assessment tools based on our own programs need. In Table 1, along with grouping related ABET outcomes and ACRL standards together, we are also identifying our instruction implementation components and assessment tool for the related skill.

B. The Reasons to Select this Course

There are three major approaches in which IL can be incorporated into education: full curriculum reform, dedicated courses, and inclusion in existing courses. As our department is currently preparing for ABET accreditation, finding faculty time to plan and implement full curriculum change would be too ambitious for us. While the second approach seems very appealing, the pressure exerted by state legislatures and university administrators to reduce the number of hours in engineering programs, makes adding any course to the existing program an impossible solution. Hence we have chosen the third approach which can be accomplished by making changes to existing courses, a practical solution for our programs.

To identifying courses more suitable candidate for introducing IL, we performed a literature survey to see what other school are doing. Some universities reported the difficulty with introducing in-depth information literacy primarily at the freshman level. The report showed that engineering students are not, at that point, yet knowledgeable enough about their prospective fields to be able to appreciate technical literature available necessary to the successful practice of the profession. On the other hand another school reported that after using the senior project class to incorporate IL, a frequent comment from students to the faculty was "Why didn't we learn this earlier?" After careful considerations, we selected CS 222 Introduction to Software Engineering to embed IL units. We strongly believe that this sophomore level class is a natural candidate for introducing IL. The class enrollment is between 14-18 students. The class is required for computer science, computer engineering and information systems majors. The class is the pre-requisite for CS 322 System Analysis and Design Methodology which is prerequisite for CS 461 Senior Project capstone class.

IV. Professional Skills

Since the founding of the ASEE in 1893, we have witnessed the engineering education to collectively shift the focus from course content to the development of students as emerging professionals. More recently, the last two decades have paved the way for including the professional skills as learning outcomes [1]. In ABET outcomes for computing, outcomes "d – h" are identified as "professional" skills. Shuman [1] have conducted comprehensive survey on how these professional skills can be taught, or more correctly learned, and the difficult issue of assessing these skills and recognize that there is considerable research that remains to be done. In this section of our paper we will concentrate on these five professional skills, map them in ACRL standards and identify our ways to implement these in our own software engineering course.

A. Communications

The proceedings of both the Frontiers in Education conferences and the annual conferences of the American Society of Engineering Education are replete with examples of ways to integrate communication into the core of engineering education [1]. In our class we are going through the phases of software development cycle, with a concentration on oral, visual and writing communication skills. At the end of each phase, the student groups are making power point presentations to the class on their experience during the corresponding phase. In the class, each student is also working in an individual project in which each student perform research on a current software engineering topic to prepare a formal report. During the whole semester, along with traditional lectures, we offer workshops (on technical writing, professional presentation, CASE Tools) and special library sessions (on search strategy, citation analysis). Students are getting the first hand opportunity to work with librarians to develop their research skills. We believe that placing communication components to express their recently gained experience will be a good way of approaching ABET's criteria for communications in a course with significant technical content.

B. Teamwork

This team based project driven class provides our students with the opportunity to experience the dynamics of team design work from idea development to completion. During the semester, the engineering faculty member and the librarians are working closely with the students as their team members. We are hoping that our teamwork development strategies will teach our students the skills necessary to work effectively in teams like: demonstrating positive interaction, good listening skills, understanding of team roles, sharing responsibilities, helping others, soliciting member input, resolving conflict etc. For each of the four phases in the semester, students are evaluated by their own team members.

C. Ethics and Local/Global Impacts of Computing

The true test of engineering ethics education is how graduates behave in the workplace during their careers, certainly a difficult outcome to measure *a priori* [11]. Stephan [11], in questioning whether or not engineering ethics can be taught, quotes philosopher Michael Davis in giving four good things that can result if successful: students can become more aware of the ethical implications of their work, they can learn ethical standards, they can become better judges of ethical conduct, and they can become more willing to put their ethical knowledge into action. Although there is no debate about importance of ethics and contemporary issues in engineering curriculum and because of ABET requirements, much attention has focused on how engineering students perceive, articulate, and resolve ethical dilemmas in their professional life, our existence in this "Information Age" puts us in further challenges. According to Wikipedia "The Information Age, also commonly known as the Computer Age or Digital Age, is an idea that the current age will be characterized by the ability of individuals to transfer information freely, and to have instant access to information that would have been difficult or impossible to find previously." Through the internet, we are developing a new world of human knowledge and information, which has no geographical, political, social, or generational boundaries. This new world is accessible to anyone who wants, from the scientist in developed world, to the farmer in rural areas of an underdeveloped country. This new world engenders new forms of ethical issues for which old solutions to past ethical problems cannot be merely exported and mechanically re-applied. Hundreds of years of research on ethics have helped us understand how ethical ideology is related to our life when more traditional ethical quandaries are encountered. However, whether conclusions regarding traditional ethical issues apply to IT-related behaviors is unknown.

Both ABET and ACRL, criteria call for ensuring *understanding* rather than *demonstrating* that graduates are ethical [9]. Education researchers [1, 9] emphasize on evaluating students on knowledge and skills, not values and beliefs. Our librarians and engineering faculty members have worked together to develop (researched and written) pedagogical tools (for both instruction and assessment) to teach not only engineering design, but engineering ethics to expose the students to realistic situations involving unstructured problems with multiple possible answers and trade-offs. We are hoping that these will foster the development of higher-level cognitive skills in students, by enabling them to address problems that require analysis, judgment, independent thought, and critical thinking.

D. *Life Long Learning*

"It has been said that the "half-life" of engineering knowledge--the time in which half of what an engineer knows becomes obsolete--is in the range of two to eight years." [2]. In Criterion 3 of ABET's computing programs we can see "lifelong learning" as professional development (outcome "h"). Whereas for ACRL, we see lifelong learning as an integral part as standard 5, "The information literate student understands that information literacy is an ongoing process and an important component of lifelong learning and recognizes the need to keep current regarding new developments in his or her field". Although most literature [6, 7] placed IL primarily in the realm of life-long learning, we disagree. According to Shuman [1], "One will become a proficient lifelong learner as one becomes proficient in the broad spectrum of professional skills". We also believe that as students acquire all these skills in ABET outcome and ACRL standards, they will, in fact, acquire the ability to do lifelong learning.

V. Implementation

The professional skills can be incorporated into this existing course at many levels, and ways. In the initial draft we identify the opportunities to incorporate different IL units: an introductory talk at the start of the course, a special workshop and consultations with the librarians throughout the semester. During our collaboration we designed effective ways to deliver our instructions to offer the best of both worlds, ABET's outcomes and ACRL's standards.

A. ***Semester long Group Project***

Literature shows that design projects are the most effective vehicles for students' learning of strategic and rigorous information retrieval and management. The software engineering class has a group project in which the students will build their own software project over the semester by applying the software engineering process, methods and tools. This group project is two-fold: Project building and Project Demonstration. The whole semester will be divided into four phases; (1) Phase I: Communication and Planning, (2) Phase II: Modeling, (3) Phase III: Construction and (4) Phase IV: Deployment. As the semester will go through each of these phases, the students will gain theoretical knowledge from the lecture contents and related practical (hands on) experience from their own projects.

B. *Group Presentation*

At the end of each phase, the groups will make power point presentation on their experience as they went through the phase. They will also demonstrate the work products related to corresponding phase as follows: (1) Phase I: list of stake holders, question sets, list of objects, list of constraints etc, (2) Phase II: use case, use case diagrams, analysis diagram, CRC card, behavioral diagrams, design models, component diagrams, architectural diagrams, deployment diagrams, (3) Phase III: first iteration of the software, test cases and test results, (4) Phase IV: final iteration of the software.

C. *Special Workshops and Sessions*

In the class special workshops are conducted on "professional presentation", "technical writing", "UML Visual Paradigm", "information literacy". During the semester, librarians will conduct special sessions on "search strategy", "citation analysis", "software testing". The class will also include video sessions (report on bhopal or columbia shuttle incident) and active learning assignments (working in an Agile software development environment).

D. *Enterprise Architecture and Project Management Case Research (Individual assignment)*

The class also has an individual project in which each student perform research on a current software engineering research topic or software engineering process standards to prepare a formal report. Making accommodations for the students to work with a librarian to research background material for the written report will be a perfect situation. Through this assignment, the students will be graded on the quality of their research and the variety and appropriateness of the selected resources. This will also provide the students to introduce to specific journal search in on-line library catalogs and formatting requirements (like IEEE template).

VI. Assessment

Our goal is not only integrating ABET's outcomes and ACRL's standards in an existing class, but also to design an assessment plan to evaluate both. Our strength is our extensive assessment efforts which are described below.

A. ***Scoring Rubrics with Performance Indicators***

We implemented performance indicators to measure ABET's outcomes and ACRL's standards fulfillment. Then we developed rubrics with performance indicators to measure every outcome and standard addressed in this individual course. At the end of every semester engineering faculty members will evaluate program outcomes and they will also evaluate the IL standards in conjunction with the librarians. Librarians and engineering faculty both need to be prepared to make adjustments based upon results found within the cycle of assessment.

Although we are analyzing data for all outcomes and standards, because of space limitations, we are displaying our results only for presentation skills. Fig. 1 shows the percentage improvement in student's overall presentation skill from Phase I to Phase II. Here, we are analyzing the presentation skill as a team in five different criteria.

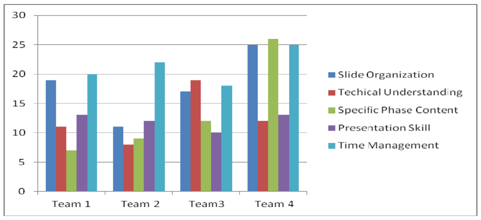

Fig. 1. Percentage improvement in student's overall presentation skills from Phase I to Phase II

B. *SAILS Test*

The SAILS test is a nationally-recognized assessment of information literacy skills [10]. The test is a knowledge test based on the ACRL information literacy competency standards for higher education. Analyzing our pre and post score demonstrate an average 17% improvement. Using the SAILS test allowed us to identify strengths and weaknesses of our students' IL skills. Although some student's achievement is quite significant, for others it was not as we expected. We are hoping this first time experience with SAILS testing will provide us direction for our course in order to better develop the IL skills of the students of our future software engineering classes.

C. *General Survey/Test on IL*

We are performing multiple survey/tests on IL including pre and post survey, assignments on citation-analysis, search-strategy, plagiarism. As an internal evaluation option (where as SAILS is the external option) we have designed pre-testing and post-testing. Because the test measures overall information literacy, pre and post testing have been conducted after a long interval of twelve weeks and demonstrated an average 31% improvement.

D. *Student Peer Evaluation*

After the presentation of each phase, the students are asked to grade their team members on demonstrating positive action, good listening skills, understanding team roles and sharing responsibility. In fig. 2 we show the improvement in teamwork skills for individual student (12 students) according to our instructor's evaluation and student peer evaluation approach. From the figure, we can see that there is significant improvement in teamwork skills for all of our twelve students.

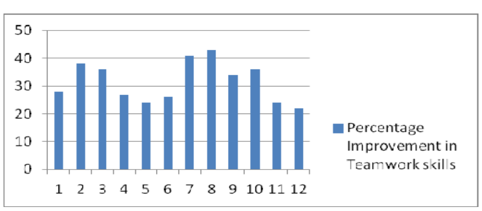

Fig. 2. Percentage improvement in teamwork from Phase I to Phase II

E. *CRAAP Test*

The CRAAP Test [8] is a useful guide to evaluating resources used by our librarians for ACRL STS standard 3. In our software engineering class, they help students to take the CRAAP test to make a case for the importance of critically evaluate the authenticity of an information source.

VII. CONCLUSIONS

In this paper we describe our experience in preparation for ABET assessment process while integrating information literacy with ABET student outcomes in a sophomore level class. This project was collaboration between software engineering faculty members with the librarians. This collaboration enabled us to deliver IL contents throughout the semester rather than in one discrete lecture and to facilitate the development of a realistic assessment plan. Unlike others work in literature [6, 7], where ABET and ACRL outcomes mapping is mostly on life-long-learning, we also dealt with other ABET professional skills like teamwork, communication and ethics. We also identified the different points of view of ABET and ACRL regarding the relationship of the engineers with the data they work with.

This project is a win-win-win situation for the students, for the librarians and for the department. With this embedded IL approach, the students will achieve an improvement not only in their perceptions of IL skills but also an improvement in their actual skills. By evaluating student IL skills, the library team can modify the existing IL instruction to focus more on identified weaknesses. At the same time, by introducing IL in our software engineering class, we get the opportunity to develop a curriculum with a stronger foundation.

ACKNOWLEDGMENT

This work was supported by West Virginia University Information Literacy Course Enhancement Grant.

TABLE 1. Mapping of ABET Outcomes, ACRL Standards along with our Implementation and Assessment Strategies

ABET Outcomes	ACRL Standards	Our Practices		
		Implementation		*Assessment*
		Role of Engineering Faculty	***Role of Librarians***	
Outcome (b) An ability to analyze a problem, and identify and define the computing requirements appropriate to its solution	**Standard 1** The information literate student determines the nature and extent of the information needed.	Assign a project to each team. Conduct *Active Learning Sessions* so the students can ✓ analyze the assigned problem ✓ identify and define the computing requirements ✓ determine the nature and extent of the information needed	Conduct General Library Session at the beginning of the semester on ✓ Available resources – Databases, Card catalog, Types of sources ✓ Non Available resources - Interlibrary loans ✓ Searching tools and techniques Special one-to-one sessions with each team	Group Project Grading Rubrics
Outcome (a) An ability to apply knowledge of computing and mathematics appropriate to the discipline **Outcome (c)** An ability to design, implement, and evaluate a computer based system, process, component, or program to meet desired needs **Outcome (i)** An ability to use current techniques, skills, and tools necessary for computing practice	**Standard 2** The information literate student acquires needed information effectively and efficiently. **Standard 3** The information literate student critically evaluates the procured information and its sources, and as a result, decides whether or not to modify the initial query and/or seek additional sources and whether to develop a new research process.	1. Introduce students to new knowledge of computing and guide them to apply this knowledge in the project 2. Work with the students during: ✓ two week long Communication and Planning phase ✓ four week long Modeling (design) phase of their project ✓ two week long Implementation phase of their project ✓ two week long Testing phase of their project 3. Conduct workshop to train students on UML Visual Paradigm 8.3 Tools 4. Work with students to develop work products including USE case, UML Diagrams, CRC Models, Analysis model and Design Model, Architecture Design, Component design	Specific Library Sessions during the semester ✓ Guide to find sample work products ✓ Guide to find standard software testing suits ✓ Recommended readings Continuing search strategy assignments Continuing one-to-one session with teams	Group Project Grading Rubrics CRAAP Test Quizzes SAILS Test
Outcome (f) An ability to communicate effectively with a range of audiences	**Standard 4.3:** Acknowledges the use of information sources in communicating the product or performance **Standard 4.6:** Communicates the product or performance effectively to others.	Conduct workshop on Professional presentation Conduct workshop on Technical Writing Develop Rubrics Provide detailed instructions with grading policy	Conduct library session on Citation Analysis Go through IEEE Template General Instruction on formatting	Presentation Grading Rubrics Research Paper Grade
Outcome (d) An ability to function effectively on teams to accomplish a common goal	**Standard 3.5:** Validates understanding and interpretation of the information through discourse with other individuals, small groups or teams,	Provide guidance in ✓ group development, consensus building, resolving conflict, and team leadership. ✓ After each phase conduct peer evaluation among team members	✓ Work as a team member to find related information ✓ Solicit input	Peer Evaluation
Outcome (e) An understanding of professional, ethical, legal, security and social issues and responsibilities **Outcome (g)** An ability to analyze the local and global impact of computing on individuals, organizations, and society	**Standard 4:** The information literate student understands the economic, ethical, legal, and social issues surrounding the use of information and its technologies and either as an individual or as a member of a group, uses information effectively, ethically, and legally to accomplish a specific purpose.	Conduct Special sessions Play video on explosion of the Challenger, the Three Mile Island Nuclear Power Plant accident, Bhopal, Chernobyl and the Ford Pinto incidents Engineering Ethics Standards Conduct discussion on Engineering Ethics	Conduct Special sessions on Intellectual property, Copyright law Plagiarism	Library work on Search Strategy, Plagiarism Citation Analysis

A taxonomy of exercises to support individual learning paths in initial programming learning

***Abstract* – Initial programming learning is known to be difficult to many students. To improve this situation it is necessary to support students learning effectively. This means that learning activities should be adapted to each student learning pace and specific needs. This is difficult considering that classes often have a large number of students. The definition of individual learning paths adaptable according to the student performance might help to improve the situation. To support the definition of learning paths it is useful to have a large set of exercises, organized according to a taxonomy that includes different dimensions and parameters relevant to the choice of appropriate exercises at any moment. To present this taxonomy is the main objective of this paper.**

Keywords – Programming education; Taxonomy; Learning paths; Programming learning difficulties.

I. INTRODUCTION

Introductory programming learning causes difficulties to many students worldwide. Various reasons have been identified [1], [2], [3], [4], [5] and several proposals have been put forward in the literature to minimize those difficulties [1], [4], [6]. However, high dropout and failure rates in introductory programming courses continue to be reported in many higher education institutions.

The heterogeneous nature of most classes is often mentioned as a cause for difficulties. It is common to find students with very different levels of knowledge, motivation, commitment and learning rhythm. Therefore, it is difficult for the teacher to follow an approach suitable for every individual student. In an attempt to reach all students, teachers often design lectures and activities to the "average student", who may not even exist in the class. To improve this situation personalized support and guidance is necessary, so that individual needs and difficulties can be addressed. However, considering the number of students that classes commonly have, it is not easy for a teacher to deal with the diversity of student's levels and needs at each moment.

To allow a personalized support to a large number of students there is a need to systematize the learning process. This systematization must take into account the individual needs and learning pace of each student, but also the main objective that the student must reach a certain level of programming proficiency.

To be successful in introductory programming courses the student must learn a set of basic concepts, the syntax of a programming language, and develop problem-solving skills using the programming language to express solutions. The introduction of the basic concepts and the language syntax is often made in lectures where a teacher presents them to a large number of students. Although this model is cost effective, it is far from ideal from a pedagogical point of view. All students receive the same information in the same format, not taking into consideration individual differences. It is usually accepted that students often have different motivation, learning strategies and learning styles [6], [7], [8], [9]. So, it is important to consider those differences when designing learning experiences. For example, some students would learn easier if there is an initial and generic presentation of the various contents, accompanied by small examples, while others would learn better if each topic is addressed separately and more profoundly, practicing it through a wide range of exercises.

The development of programming problem solving skills is the more complex aspect for novices. It demands an intensive programming experience and it is necessary to define adequate exercises at each stage. The sequence of exercises shouldn't be predefined and the same for all students. It should be adapted for each student needs and current level of knowledge. Activities that are too easy in a particular moment don't give a good contribution to the student cognitive development, but if they are too difficult for the student they may cause frustration, demotivation and dropout. In our view, it is important to propose to each student activities that create some difficulty, but that they may be able to solve, at least partially. This can contribute to raise the student motivation and self-confidence, making him/her believe that it is possible to be successful, and that solving problems is an effective way to learn.

Motivation can also be improved if the student feels improvement in his/her abilities. A possible strategy when a student is not able to solve a problem is to divide it in sub problems and propose some of them to the student. When he/she solves the sub problems the original problem can be proposed again, hoping that the student has progressed and is now able to produce a better solution. If this happens the student will notice the improvement.

To support this individualized learning experience, which implies the dynamic definition of learning paths, it would be useful to have an automatic system that may propose exercises to the student. This system would need to use a large set of exercises that should be classified in several dimensions to support the process of choosing the next exercise to a particular student, under the pedagogical principles described above. In other words we felt the need for a taxonomy to classify common programming exercises, taking into consideration the pedagogical objectives of our work. To present that taxonomy is the main objective of this paper.

In the following sections we briefly present some taxonomy proposals found in the literature, describe and fundament the taxonomy we propose, and present some preliminary evaluation of its utilization in the definition of individual learning paths.

II. RELATED WORK

Taxonomies of educational objectives are used worldwide to describe learning outcomes and assessment results, reflecting a student learning stage. Usually authors divide educational objectives into three domains: cognitive, affective and psychomotor. As described in Fuller et al. [10], some, such as Bloom's taxonomy [11], treat each of these as a one-dimensional continuum, others, like the revised Bloom's taxonomy [12] describe the cognitive domain using a matrix. Yet others, like the SOLO taxonomy [13], use a set of categories that describe a mixture of quantitative and qualitative differences between student performances. There are also taxonomies that use all three domains equally. However, existing research on the use of learning taxonomies in computer science focuses on the cognitive domain.

A very well-known taxonomy is the original Bloom's taxonomy [11]. It is a classification of the different objectives and skills that educators set for students. Skills in the cognitive domain are divided in six levels. Starting from the lowest order processes to the highest: Knowledge, Comprehension, Application, Analysis, Synthesis and Evaluation.

The Knowledge level consists in activities that demand recognizing or recalling information. Referring to the case of introductory programming, Lister and Leaney [14] report that questions on Java programming appropriate to the Knowledge level would be for example: "List the three types of repetitive structures that exist in Java." or "What kind of repetitive structures in Java are executed at least once?"

Activities in Comprehension Level consist in demonstrate sufficient understanding to organize and arrange information mentally on a given subject. At this level, the student understands what is being communicated without necessarily relate it to other issues or view their full implications. Lister and Leaney [14] report that a question about Java programming appropriate to the Comprehension level could be the translation to Java of a very specific instruction described in a textual or pseudocode format. For example, "Write a Java statement that declares a variable *x* that can contain integer values".

Activities in the Application level consist in constructing an answer through the application the previously learned information. Lister and Leaney [14] report that many traditional tasks of programming are on the application level, since they are completely specified. According to these authors a question about Java programming appropriate to the application level would be to ask students to write a class, whose characteristics are specified in detail. The specification should include the attributes and the headers of the methods. The code of each method should not be long (e.g. less than 20 lines) or algorithmically complex.

Analysis level includes questions requiring critical and detailed thinking. Bloom states that the level of analysis emphasizes the partitioning of the subject into its constituent parts, as well as the detection of relationships between them and how they are organized. Lister and Leaney [14] report that an appropriate Java programming task appropriate to the analysis level could, for example, consist in providing to the student some code that implements the standard programming Model-View-Control, and ask student to identify the pieces of code that implement the model, the view and the controller.

Synthesis level includes questions requiring the execution of creative and original thinking. It consist in join all the parts into the whole. In the case of Java programming Lister and Leaney [14] suggest that a typical exercise suitable for this level would be to decompose a problem into classes and determine the most appropriate methods for each class.

Evaluation level includes open-ended questions that allow multiple answers or solutions. According to Lister and Leaney [15] this level of the taxonomy is perfectly suited to the teaching of programming, because aspects such as clear, concise and efficient code should be valued. The authors mention that a Java programming task appropriate to the Evaluation level could consist on peer evaluation of code in terms of its effectiveness.

Bloom's taxonomy has been revised [12]. The authors changed the nouns listed in Bloom's model into verbs, to correspond with the ways learning objectives are typically described.

The SOLO (Structure of the Observed Learning Outcome) taxonomy [13] makes no reference to the learner performance cognitive characteristics or to the affective dimension. It focuses on the content of the learner's response to what is being assessed. It aims to identify the nature of that content and the structural relationships within it. The content could be designed to assess knowledge, cognitive skills or underlying values. The taxonomy can be used to establish the expected relationships between these different types of content.

The levels of the SOLO taxonomy are: Pre-structural, Uni-structural, Multi-structural, Relational and Abstract. The Pre-structural level is the least sophisticated type of response that a student can give. Reveals insufficient knowledge about a subject or little interrelated knowledge. Lister et al. [16] report that a student giving a pre-structural response to a question demanding the interpretation of a piece of code demonstrates a significant misunderstanding (misconception) concerning the topic in question or uses a previous concept irrelevant to the subject. The Uni-structural level includes answers where the student expresses a certain understanding or a minimum knowledge about some but not all aspects of a given problem. The student understands certain simple meanings, revealing a partial understanding of a particular problem within a more complex case. Usually the response of the student focuses only on one important aspect of the task to be solved. The Multi-level structure includes responses where the student expresses an understanding of several or all parts of the problem, but without an awareness of the relationships between them, treating them independently. The Relational level includes answers where the student demonstrates a level of understanding that integrates the parts of the problem in a coherent structure, using this framework to solve a given task. The student is able to use concepts that integrate a given data set comprising its application to familiar problems. The Abstract level includes answers where the student shows a level of understanding that allows the relationship between reflection and questioning the existing principles and acquaintances, so that he/she can deal with new problems [13], [17].

Fuller et al. [10] propose a new taxonomy (The Matrix Taxonomy) considered particularly useful for evaluating the learning of programming. The inspiration for this taxonomy resided in research conducted by Winslow [3] and Lister et al. [18] that indicates that the ability to understand the code of a program and the ability to produce code are two semi-independent skills. Students who can interpret programs may not necessarily be able to write their own programs. Also the ability to write code does not necessarily imply the ability to correct errors. The authors considered that Bloom's Taxonomy would be a good basis for their taxonomy that would use a two-dimensional array. The dimensions of the matrix represent the two scales of skills separately, including the ability to understand and interpret a program and the ability to design and build a new one. The levels that reference the understanding and interpretation of code are placed on the horizontal axis (Remember, Understand, Analyze and Evaluate). The levels concerning code generation are placed on the vertical axis (None, Apply, Create), both with lower levels in the lower left corner. The authors consider that, according to this taxonomy, a student may not have any skills to create code (None). Through the vertical axis we can comprehend that students cross each line through a strict sequence. For example, a student could not be able to synthesize (Create) without a certain degree of competence at the application level (Apply). This taxonomy can be especially useful for educators who need a grid to classify their students. It also illustrates the different learning paths that students can follow, as shown in a study conducted by Lahtinen [19].

However we agree with Raymond Lister when he says that "specific to the teaching of elementary programming: the lower two levels should emphasize the skill of reading and comprehending code, the intermediate two levels should emphasize the writing of small fragments of code, but within a well-defined context, and the upper two levels should emphasize the writing of complete non-trivial programs" and that "students should first be taught to read programs before they write programs" [20].

III. TAXONOMY OF EXERCISES

Our research group is involved in the development of a platform that may support novice-programming student's autonomous work. It includes several tools, such as automatic diagnosis of the student's difficulties based on the problems he/she was able to solve previously and the errors made, feedback on the current assignment, and definition of individualized learning paths based on the student's past performance. These learning paths are sequences of exercises to be proposed to the student, in order to develop his/her programming skills. Its definition is dynamic, considering the difficulties shown in each exercise by the student. To support this approach we created a database of common introductory programming assignments classified according to a taxonomy we created. It allows the selection of the next exercise to propose to a student considering his/her current level.

The taxonomy we developed maps each programming exercise in one or more dimensions, taking into consideration different aspects that we consider relevant to the classification of exercises. Some of the dimensions used were: the levels of Bloom's Taxonomy; the mathematical knowledge necessary to solve the exercise; the complexity of the control structures involved in the solution; the complexity of the exercise description and the algorithmic complexity.

A. General aspects

The definition of a taxonomy of exercises has the intent to allow an adequate classification of introductory programming exercises. This should facilitate the selection of an appropriate exercise to be proposed to a particular student in a specific moment. This is central to our objective of supporting the definition of individual learning paths for any student.

The taxonomy allowed us to structure a database of exercises that is continually evolving with the inclusion of more exercises. The work of defining the taxonomy and classifying the exercises was based on an already existing set of exercises, which was used in introductory programming courses at our department. Those exercises were structured in worksheets, each of them addressing a topic (variables and operators, conditional structures, repetition structures, functions, arrays, strings, …). In each worksheet, the exercises were organized according to the sequence they are presented and solved in lab classes. Each worksheet also included exercises proposed for the student's individual work.

We can't expect students to solve all the problems included in the worksheets, and that isn't necessary for most of them. Also, it is not feasible to create a shorter list of problems adequate for all students as their needs normally differ strongly. An exercise that is suitable for a student may be too difficult or too simple for other students. We agree with the principle of "small steps" mentioned by Hofuku et al. [21] as a way to consolidate the programming learning process. When choosing an exercise it is important to consider its cognitive requirements and compare them with the student current situation to avoid the creation of "gaps" that may hinder learning. A classification of exercises is necessary, so that it is possible to choose the right one for each student in a particular moment. That was the main objective of the definition of the taxonomy we describe in the next section.

B. Dimensions

Our classification proposal includes three dimensions in which it is possible to classify any exercise. Those dimensions are presented in the next three subsections.

1) Topics

In this dimension exercises are classified considering the programming structures necessary for their solution. The possible values in this dimension correspond to the common topics in an introductory programming course based on an imperative language, "variables and operators", "conditional structures", "repetition structures", "functions", "vectors", "arrays", "strings" and "files". This list is not closed and can be adapted to the specific strategy of any course (for example if it uses object oriented programming). An exercise may belong to more than one topic, as it should be classified in all topics necessary for its solution (for example "variables and operators", "conditional structures" and "repetition structures" if all of them are necessary to solve the problem). The topics dimension does not assume any relationship between exercises classified in the same topic in terms of complexity or relative order between them. For example, an exercise involving nested loops is normally more complex than another that uses only a simple loop, but they would both be classified in "repetition structures".

2) Complexity

In this dimension exercises can be classified considering its complexity in several parameters that may be configured by the teacher. In our work "algorithm complexity", "code complexity", "math complexity" and "cognitive effort" are considered. The first two deal with the complexity of the solution algorithm and the code that needs to be written. We decided to include the "math complexity" parameter because we often observed that student's difficulties were caused by the mathematical knowledge involved in the solution, and not in the algorithm itself [22]. The "cognitive effort" parameter aims to measure the overall difficulty of a problem, including its description complexity (in our experience sometimes students don't even understand what the problem is about). This dimension allows sorting exercises that belong to the same topic regarding its complexity in the above-defined criteria.

As our objective is essentially practical, the complexity of an exercise on any parameter is always defined in relative terms – a new exercise will be compared with one or more exercises already defined in the same parameter.

3) Levels

This dimension was thought to help in the classification of exercises by levels, following existing models. At the moment this dimension has two parameters, "Bloom's taxonomy" and "exercise level". The first allows the classification of an exercise in one of the levels of Bloom´s taxonomy, as it may be useful to use Bloom's taxonomy to set the next exercise to propose to a student and also to follow his/her evolution using this taxonomy levels. The "exercise level" parameter is intended to classify the exercise considering the type of student it addresses: beginner, intermediate or advanced (in the context of the level demanded in the course).

Fig. 1 shows the different classification that can be attributed to a particular exercise. It can be included in one or more topics, and classified in any of the complexity and levels parameters.

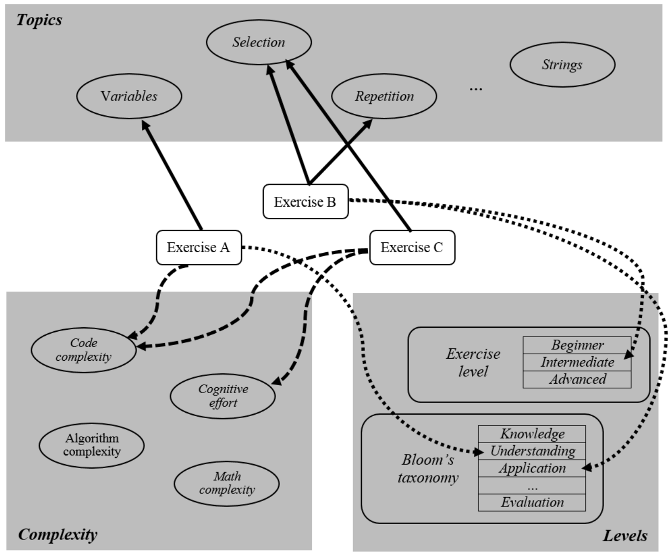

Fig. 1. Classification of exercises

C. Graph of exercises

The use of weights is very important in our approach, as they play a central role is establishing relations between exercises and in determining which one should be proposed next. The relation between exercises in a particular parameter is represented by a comparison-weighted graph.

The assignment of weights is made in comparison with the exercises previously classified and already present in the graph. When adding a new exercise to the graph it is not necessary to compare and classify it with all other exercises already present, but only to set a weight in comparison to an already existing exercise. The weight can be any integer value, positive or negative. A positive value represents that considering the represented parameter the exercise will be more difficult. A negative value represents an easier exercise, concerning the parameter in analysis. For example, considering the graph of Fig. 2, exercise A is easier than exercise B and exercise C is much more difficult than exercise B.

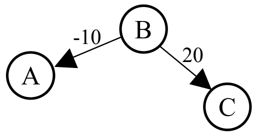

Fig. 2. Graph example

The edges are unidirectional and are defined taking into account the introduction order of the exercise. If exercise B already exists and we introduce exercise A, related with B, the direction is from B to A. In the example the weights used were multiples of 10, but other values may be used. The idea was to create a "gap" that allows posterior introduction of other exercises that are relatively easier or slightly more difficult -

for example we can use +5 or -5 to represent an exercise which is a little harder or a little easier, respectively.

Currently the assignment of weights is done manually. However we intend to create a semi-automatic mechanism that allows the assignment of weights to new exercises that are added to the graph. This tool is under development considering the "code complexity" parameter. The calculation of weight is made in two steps. First an absolute complexity score is calculated. Then the system looks in the graph for an exercise classified in the same topics having a score as close as possible. The new exercise is inserted in its neighborhood and the difference in scores is recorded. The calculation of the absolute complexity score is based on a solution for the problem introduced in the system. The code is analyzed and its data and control structures are identified. Each of them contributes to the exercise complexity score, taking into consideration its context. For example, a conditional structure may have a certain weight, but if it is inside a repetition structure its weight will be higher due to the added difficulty that this situation creates. To clarify, we may use the code in Fig. 3 as an example.

```
1:  if (x>10)
2:    x=10;
3:  for(i=0;i<10;i++)
4:    if (i>x)
5:      x=x+1;
```

Fig. 3. Code example

Considering that conditional structures have a difficulty of 5 and repetition structures a difficulty of 10, the exercise would receive 5 points for the condition in line 1 and 10 points for the repetition structure that begins in line 3. The conditional structure in line 4 receives a higher score, because it is located inside the loop. The value is calculated by multiplying a fraction of the weight of the repetition by the conditional value (5). Through a recursive mechanism it is possible to calculate a value that reflects the difficulty of each exercise.

IV. Taxonomy Application

As mentioned before, the overall objective of this work is to support the definition of individual learning paths, which might effectively help students to develop their programming skills. Of course learning depends on several factors, some of them difficult to control by the teacher. However, we think that to propose the right activities to the students in each moment is fundamental. This is especially true when students feel difficulties and it is necessary to give them other exercises, eventually slightly easier, but involving the same concepts. If there is a good set of exercises classified according to the taxonomy we propose this selection is easier and can even be automatic. In the above case, the new exercise should have been classified in the same topics, but having a lower score in some of the complexity parameters. If the student is able to define an appropriate algorithm but he/she is experiencing coding difficulties, the teacher (or an automatic system) can suggest an exercise that has a lower "coding complexity" score and identical scores in the remaining parameters.

Another approach that may be pedagogically interesting when a student feels difficulties with an exercise is to give him/her new exercises that are sub tasks of the original. If the student is able to solve them it is a good moment to stress the importance of proper planning and division of a problem in sub problems that might be easier to solve.

To test some of these ideas we designed an experiment that involved 44 students from the second programming course of the Computer Science degree of the Engineering Institute of Coimbra. During the first semester the students attended an introductory programming course, where they should have developed basic programming skills using the C programming language. In the experiment participated 13 students that didn't get approved in the first course. The degree regulations allow that students can attend the second programming course without having success in the first one. Although it is not very frequent sometimes some of these students manage to recover and get approved in the second course. Another 13 students in our sample were repeaters who had already get approved in the introductory programming course during the previous year.

The experiment consisted in proposing an exercise with some algorithmic complexity to the students. They were informed that there were several approaches and possible ways to solve the problem. They were also informed that the solution would not be given during the class, so they should try to solve the problem individually or in pairs. Teacher support would be available for doubts and difficulties they might experience. This recommendation tried to avoid a common student behavior: have a passive attitude in classes and just wait that the teacher gives the solution to pass it to their notebooks, many times without even understanding what they are writing.

The proposed exercise was:

It is intended to reduce an image to one quarter of its original size. The initial image is a two dimensional array with M × M integer values where each pixel can take a value between 0 and 9 (shades of gray). The reduced image is stored in a two dimensional array with M/2 × M/2 real values where each element (pixel) corresponds to the average of the 4 elements it replaces. For a better understanding of the statement see the example shown in Fig. 4 (in this case, for M=8):

Original matrix

0	4	9	3	6	7	2	9
9	4	7	8	3	4	7	2
5	1	2	6	3	8	6	2
7	1	4	8	7	2	0	7
4	9	3	5	2	1	5	7
5	3	4	7	8	9	1	0
2	3	5	6	7	9	2	4
2	3	4	5	6	7	8	9

Reduced matrix

4.25	6.75	5.00	5.00
3.50	5.00	5.00	3.75
5.25	4.75	5.00	3.25
2.50	5.0	7.25	5.75

Fig. 4. Matrix reduction

Write a C function to perform this operation. The function should take three arguments: address of the first element of the original array, address of the first element of the reduced array and the value M.

After the students had access to the exercise the teacher gave a generic explanation on the objectives of the exercise. Some time was given for students to start solving the problem, but only the best students were able to start doing it. The remaining students simply weren't able to try any possible way to reach a solution.

After about 10 minutes the teacher made an intervention. The students who were already solving the exercise were encouraged to continue their work in the same line. The other students received a sequence of simpler exercises where each was an evolution of the previous one. The goal was that, at the end of this sequence, the students would reach the solution of the original exercise.

The exercises / steps were:

1) Print all values in the array, row by row and column by column. For the example given, the sequence would be 0 4 9 3 6 7 2 9 9 4 7 8 3 4 7 2 5 1 2 6 3 5 6 7 8 ... 9

2) For the previous sequence, print only the values in the even rows and columns, one per line. For the example the sequence would be 0 9 6 2 ....

3) Note that the values printed in the previous step are the first element of each sample of the original exercise. Now print also the remaining values of each sample. For example: 0494 9378 67...

4) Add to the end of each line the average value of its values. For example: 0494 4,25 ...

5) Store each average value in the reduced matrix.

Although the students could initially solve the problem considering the dimension 8 (M = 8), the final solution should support any size of the original matrix. This was similar to previous class exercises where students had to create functions capable of processing arrays of different sizes. Students had the notion that they should index values using pointers to the first element of the matrices associated with an offset calculated based on the row number, column number and the number of columns per row.

The students didn't show any special difficulty solving the first step. A similar exercise had already been done before and they were able to do what was asked. Of course, each student progressed at his/her own pace, but they were all successful in this first step. All the students chose to use 2 nested loops, with two control variables ('i' and 'j'), and, inside them, a *printf* statement to print each value.

In the second step, every student immediately identified the need to increase the control variable of each loop by two. Here we noticed some problems related with the codification of the algorithm. The students that chose to implement using two 'for' structures only changed the third parameter, from something like 'i++' to 'i+2'. The teacher didn't tell what the error was. Instead, he asked each student to also print the value of the control variable. Students easily realized that the value was always the same, and that the increment statement was not doing what they expected. After this they changed the statement to something like "i=i+2" ("i += 2", "i++, i++", …).

Once again, in the third step, each student reached the solution at his/her own pace. The main difficulties were related with the need to index other values, applying some offset to the control variables without changing their values. Nevertheless, students were able to identify the necessary offsets ([i][j],[i][j+1],[i+1][j] and [i+1][j+1]). They needed some time to transform the identified offsets in a pointer arithmetic statement but didn't ask for help in this task.

The fourth step was completed with no student asking for any help. They were able to calculate the average and show the value.

The fifth step had the difficulty of identifying and calculating the coordinates in the reduced matrix. Some students realized that it was possible to increment the reduced matrix pointer. Other students needed some help to identify that a possible solution was to divide the indexers of the original matrix by 2. After this they concluded the exercise without problems.

In the end most students had the initial exercise solved and functioning as expected.

The few students who failed to solve the complete exercise were mostly those who previously lacked the minimum skills, students who had failed in the first introductory programming course, and were alone in the classroom (not in pairs). Although they were able to solve some steps within the time given, they were not able to complete all the tasks and, consequently, they were not able to solve the original exercise.

V. CONCLUSIONS

Learning to program is not an easy task for many students. It is not uncommon to find high dropout and failure rates in introductory programming courses. Although many reasons can contribute to this situation, we still believe that most students will be able to learn if an adequate support is provided.

The support necessary varies from student to student. Any experienced teacher has probably met students that learn programming easily, while others show deep difficulties even when they work and try to learn. Each student has his/her own learning rhythm and it is not wise to expect that all keep the same pace. This causes many difficulties to the teachers that have to deal with this heterogeneity in the context of large classes. In this situation it would be helpful to have a tool that might help to individualize the support given to a particular student. The work presented in this paper aims to be a contribution to the development of that tool.

A taxonomy of common introductory programming exercises is essential to the definition of individual learning paths. The classification of exercises under several perspectives allows a more adequate reaction in function of each student specific difficulties. More than insisting that the student should solve some problem or giving him/her the solution for it, it is more effective to propose different exercises, a little easier in some perspective, so that the student can improve skills and then be able to solve the original exercise.

Although we didn't mention the good students too often, the taxonomy can also help to define faster learning paths for those students, avoiding the boredom of being asked to solve many exercises that are too easy for their level.

This taxonomy can also help to promote student motivation creating an adequate balance between successes ("motivational stimulus") and failures ("positive errors") essential to a consolidated learning.

We are aware that the taxonomy will be more useful if there is a tool that uses it to automatically propose exercises to students. To have a more extensive set of exercises we are also considering following the technic used in *problets* [23], defining templates from which we can generate "new" and different exercises. That tool is currently under development at our research group.

***Abstract*—Advances in computing contribute to science and engineering discovery, innovation, and education by facilitating representations, processing, storage, analysis, simulation, and visualization of unprecedented amounts of experimental and observational data to address problems that affect health, energy, environment, security, and quality of life. In spite of the emerging importance of the role of computing in engineering, a well-recognized shortage of scientists and engineers who are adequately prepared to take advantage of, or contribute to, such highly interdisciplinary, highly computational scientific challenges is evident. This exploratory study identifies how computation is integrated in the engineering disciplines at the undergraduate level. The research question is: *How engineering professors integrate computation as part of their disciplinary undergraduate courses?* This study reports anonymous survey responses of thirty-nine engineering and engineering technology faculty members who identified themselves as integrating computation as part of their undergraduate courses. Results indicate that most of the faculty members used computation for the solution of complex calculations, for conducting simulations, and for design purposes. Further research is required in order to identify and validate appropriated pedagogical practices to integrate computation as part of disciplinary courses.**

Keywords—computation, pedagogical methods, undergraduate education.

I. INTRODUCTION

Advances in computing contribute to science and engineering discovery, innovation, and education by facilitating representations, processing, storage, analysis, simulation, and visualization of unprecedented amounts of experimental and observational data to address problems that affect health, energy, environment, security, and quality of life. Therefore, promoting computing as both a fundamental knowledge and a technical skill becomes necessary in order to develop a workforce that identifies and implements optimal solutions and rapidly adapt in order to compete in our fast-changing, global society. [1-3]. In spite of the emerging importance of the role of computing in engineering, the well-recognized shortage of scientists and engineers adequately prepared to understand and contribute towards solutions that decidedly require computationally complex and interdisciplinary efforts is evident [4-6].

Professionals within the disciplines of science and engineering have emphasized the need for a new and modern approach to educating and training the next generation of researchers that will effectively complement experimental and theoretical approaches to address problems in science and engineering [e.g., 7-9]. Computational thinking, the problem solving method that engages solutions via computing techniques, is seen as a necessary companion to the approach. Computational thinking [10] integrates disciplinary knowledge with fundamental analytical skills needed by individuals entering the workforce to meet the increasing technologically driven demands.[11]. To address these challenges, we need to integrate computation in the curriculum sooner and often.

Computing contains various sub-disciplines such as computer science, computer engineering, software engineering, information systems, computer systems, and domain-specific applications [12]. This project focuses on the latter of these, namely domain-specific applications or discipline-based computing as we will refer to it here on forward. We define discipline-based computing as an interdisciplinary approach that integrates computational methods (e.g., numerical methods such as Euler and Krylov methods), tools (e.g., MATLAB, Mathematica, Mathcad, MapleSim), and practices (e.g., modeling and simulation) of computational science and engineering with disciplinary knowledge to (a) comprehend the behavior of complex systems or (b) to predict the behavior of new designs [13]. This exploratory study identifies how computation is integrated in the engineering disciplines at the undergraduate level. The research question is: *How engineering professors integrate computation as part of their disciplinary undergraduate courses?*

This study reports survey responses of thirty-nine engineering and engineering technology faculty members who identified themselves as integrating computation as part of their undergraduate courses.

II. THEORETICAL FRAMEWORK

Pedagogical Content Knowledge (PCK), first presented by Shulman (1986), is the theoretical framework that guided this investigation. PCK is a framework that describes how teachers transform their content knowledge into a structured knowledge to then be learned by their students. Such content knowledge is blended with pedagogical methods for learning purposes [14]. Several categories of teacher knowledge are derived from this framework, including Pedagogical Knowledge, Content Knowledge, and Pedagogical Content Knowledge.

Pedagogical Knowledge (PK) refers to knowledge about teaching methods and pedagogical strategies. Content Knowledge (CK) refers to concepts, procedures, and principles that belong to a specific subject. Finally, Pedagogical Content Knowledge (PCK) refers to "an amalgam of content and pedagogy unique to a subject matter teacher. The blending of content and pedagogy into an understanding that allows the teacher to more thoroughly understand how to present a topic" [14, 15]. The relevance of PCK lies in the ability of teachers or

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

instructors to mix specific content with an adequate pedagogy for effective teaching. Some authors point out that a direct relationship exists between good teaching and good PCK [14].

To make PCK suitable for this context, the adaptation proposed by [16] was employed. This adaptation consisted of mapping how the assumptions about teacher knowledge can be adapted to expert (faculty) knowledge. Since PCK was originally designed to be used in science education, and as the respondents for this study were undergraduate engineering faculty members – as opposed to science teachers –, they can be described as content experts who do not necessarily have any pedagogical preparation. The second adaptation consisted of our own interpretation of each of the PCK constructs as applied to this specific context. CK was interpreted as the common types of disciplinary problems that faculty pose to students to solve using computation, and the software they use to attain this goal. PK was interpreted as the pedagogical and teaching methods used to introduce computation and the frequency of computation usage in the classroom. PCK was conceived as faculty descriptions of the role of computation into their engineering classroom and the most common learning outcomes instructors try to accomplish in their courses by means of computation.

Specifically in the context of engineering classrooms we have also investigated what are engineering instructors' Technological Pedagogical Content Knowledge (TPCK) for introducing computation and computational tools [17]. This research identified that participating instructors incorporated computation or computational tools for conceptual understanding while others integrated it with the goal of providing their students with computational techniques. Other instructors used a combination of both. We have also identified instructors' specific intended learning outcomes of using computation and computational tools in engineering contexts [18]. The following learning outcomes were identified: (a) To increase awareness of the potential role of computation in a particular field of science or engineering; (b) To measure materials or devices by collecting data as in a laboratory experiment; (c) To explain the cause-effect relationship of a given underlying model; (d) To test the accuracy of a given model and/or its computational implementation; (e) To validate the results or performance of the product of a design task; (f) To implement computational techniques/ methods in a modeling task. (g) To predict the results of an experiment in a design task. (h) To discriminate between different models/methods to represent a given physical phenomenon. These studies are useful because they can guide the design of learning objectives that can be turned into learning experiences

In this study we utilize PCK together with our own preliminary work on instructors' intended learning outcomes as a framework to identify how and for what purposes computation is being introduced into the undergraduate engineering classrooms.

III. METHODS

Baxter and Lederman [19] advocate multiple data collection techniques such as interviews and observation techniques, convergent and inferential techniques, visualization techniques and multi-method evaluation as effective data collection methods for identifying PCK constructs. We select a multiple-choice survey approach coupled with open ended questions to explore common approaches for integrating computation at the undergraduate level.

A. Participants, Procedures and Data Collection Method

Recruitment of participants was conducted through two different mechanisms: (1) the mailing list of the ASEE Engineering Technology Division with approximately 4000 members and (2) the mailing list of the ASEE Educational Research Methods Division with approximately 1300 members. An invitation announcement was conducted one single time through each of the above mentioned vehicles inviting faculty to participate.

A description of the purpose of the study was communicated followed by an invitation to participate in an online survey and asked to respond to a combination of nine multiple choice and open-ended questions. The URL to the survey was included and which is hosted on an online survey server. Once on the survey server, participants were provided instructions to the survey and reminded of the voluntariness and anonymous nature of the study. Then, participants were provided with the following definition of computation:

> *"Computation refers to the execution of an algorithm. Specifically in engineering computation may refer to the integration of computing algorithms and methods (e.g., numerical methods such as Euler and Krylov methods), tools (e.g., MATLAB, Mathematica, Mathcad, MapleSim), and practices (e.g., modeling and simulation) of computational science and engineering with disciplinary knowledge to (a) comprehend the behavior of complex systems or (b) predict the behavior of new designs.*

Then, participants responded the following questions:

1. Please give us a brief description of the engineering or engineering technology courses you teach at the undergraduate level in which you actually use computation. [Open-ended question]
2. What role does computation play in your teaching as part of the undergraduate courses you have described above? [Open-ended question].
3. What kind of computation software do you use in your teaching? [Options: MATLAB/Simulink, Mathematica, MapleSim, Mathcad, and Others].
4. In what form do you actually integrate computation into your undergraduate teaching? [Options: lectures, projects, homework assignments, laboratory practice, other].
5. How often do you use computation to accomplish the following learning outcomes in your undergraduate teaching? [Options: the eight proposed learning outcomes from [18] listed above].
6. How often do you have your students use computation to solve the following kinds of problems? [Options: never, rarely, occasionally, every once in a while, frequently]. (a)Satisfaction of constraints problems; (b) Minimization or optimization problems; (c) Mean-field or particle-based

dynamic systems; (d) Time-independent 1D spatial varying system; (e) Diffusion/ Electric field problems.

7. What are other typical engineering or engineering technology problems that you commonly couple with computation? [open-ended question]

8. Are there any other ideas or comments you would like to share with us about the role of computation in your teaching? [open-ended question]

Options of the multiple choice questions were derived from literature or through personal communications with four experts in computational science and engineering from materials, mechanical, civil, and electrical engineering disciplines.

Thirty nine engineering faculty voluntarily responded the full anonymous survey. Participants are from different universities and have taught at least one course in engineering or engineering technology at the undergraduate level. Most of them have experience teaching electrical, computer or mechanical engineering courses. Figure 1 shows the percentage for each disciplinary area of the courses in which participants integrated computation.

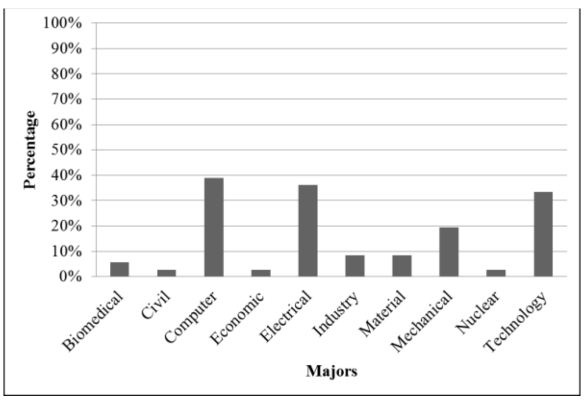

Fig. 1. Percentage of computation integrated in a course by participants vs course discipline

B. Scoring and Data Analysis.

We coupled qualitative with quantitative methods of inquiry for analyzing the data as follows.

Qualitative Data Analysis: The analysis of the open-ended questions was approached using a categorical analysis. To categorize the responses we used two main techniques called open-coding and axial-coding. During open-coding we conducted an initial level of abstraction in conceptualizing major ideas. Inter-rater reliability was conducted throughout the study. First, three researchers individually analyzed the responses to each question and then came together as a group to discuss findings. During axial-coding, we reconstructed the data to identify their explanations and relationships. This step consisted of organizing the categories and trying to find similarities. Finally, the number of occurrences for each category was counted.

Quantitative Data Analysis: Multiple choice questions related to employed pedagogical methods and software were normalized to describe the percentage for each option. Questions related to common learning outcomes and frequency of use of computation, were scored using a five-level Likert-scale. We denote the range from 0 to 4 to be the frequency of using computation. The corresponding five levels are: "never," "rarely (once or twice per semester)," "occasionally (once or twice per month)," "every once in a while (once or twice every other week)," and "frequently (more than once or twice a week)".

IV. Results

Here we present the analysis and results for each individual question. Our theoretical framework, PCK, is then reintroduced in the discussion section to facilitate the identification of themes.

A. How faculty identified the role of computation as part of their teaching of undergraduate courses?

Two themes were identified from the responses: “Activities” for integrating computation and “Learning Outcomes” associated with integrating computation.

Activities. Activities refer to actions or tasks carried out using computation through the learning process. Within this theme, the most popular role (n=19, 33.93%) was to solve complex calculations. Some of the statements that respondents used to justify its use were: *"Makes complex computations manageable"* or *"Simplification of calculations required to resolve voltages & currents in complex circuits"*

The next most commonly used activity among instructors’ responses was to represent phenomena (n= 9, 16.07%). The use of simulation tools into the classroom to represent real phenomena was broadly discussed both as an activity and as a learning outcome: *"I use these simulations to illustrate the effect of changing parameter values"*

Another use was to implement algorithms (n=8, 14.28%). Some examples of the algorithms or activities they performed when implementing algorithms include MATLAB use to execute Taylor or Newton Raphson algorithms as follows:

> *"We use MATLAB to execute algorithms such as Taylor series to estimate the sin or cos of an angle, Newton Raphson algorithm to solve a single equation in a single variable, and numerical estimates for derivatives and integrals based on sets of data such as estimating the velocity of an object based on position data"*

The fourth activity with high relevance for the respondents was the use of computation to support analysis processes (n=7, 12.50%). This activity is supported by comments whereby computation is used towards computer-aided analysis, automation of data analysis, and circuit analysis. Sample quotes include: *"Freshman level: computation to analyze data, compute statistics, perform least squares curve fit "*

The last two categories for activities identified were to solve real world problems (n=4, 7.14%) and to measure variables (n=3, 5.35%). Examples of quotes are: *"Students use MATLAB to write programs for solving the mechanical engineering problems"* and *“Students are shown the ways in which real engineers do their daily computation and documentation of it.”*

Learning Outcomes. Learning outcomes refer to learning performances that faculty members expect their students to learn or perform when using computation. This theme included five different categories. The most commonly mentioned learning outcomes were "to understand and create artifacts through the design process for specific problems" (n=10, 38.46%) and "to understand the behavior of the system by variation the parameters" (n=10, 38.46%). The first one is related to the design process. Some examples of how the respondents described this category are: *"Provides tools for upper level undergraduate studies and design work."* And *"students perform computation to automate design and analysis processes"* The second one is related to the use of simulation to understand how a phenomenon works. Some of the responses were: *"It is also used so that they can understand behavior by allowing them to change inputs and quickly see how outputs vary"* and *"Helps students understand behavior of systems."*

The next category is "to formulate, build and understand models" (n=3, 11.54%). The use of the word model/modeling was recurrent in responses like: *"I feel it is important to introduce the senior-level undergraduates to some computational modeling."* and *"I can show them how to work with each other in data gathering, data analysis, model building, and output analysis."*

The two remaining categories are, "to comprehend how computation can support time and money saving through automation and optimization" (n=2, 7.69%), and "to read and interpret a graph" (n=1, 3.85%): *"They learn how computation can save time and money and make the process of design easier, faster and more efficient."*

Finally, some of the respondents described the role of computation in terms of the relevance they perceive. Most of the respondents (n=9, 69.23%) believed that computation has a *central role* in their courses. Some others (n=3, 23.08%) gave it a *medium supporting role*, while one of them (n=1, 7.69%) thought that computation has a minor role when it is used to introduce senior-level undergraduates to some computational modeling.

B. *What are common learning outcomes associated with the use of computation for teaching and learning?*

Table I displays a descriptive analysis of a set of learning outcomes associated with the use of computation for teaching and learning. The results indicate that a small portion of the participants used learning outcomes different to those that were presented in the given options, but the variations for the frequencies of using computation are relatively large. Moreover, the most and least used learning outcomes are "to discriminate the differences between models and methods" and "to increase awareness of the potential role of computation in a particular field of science or engineering". As part of the "other" category, few respondents stated that they used computation software to introduce novice students to fundamental programming concepts and logical thinking.

C. *Which software do instructors use to introduce computation into their disciplinary courses?*

The options for the multiple choice question included MATLAB/Simulink, Mathematica, MapleSim and Mathcad. Almost fifty percent of the participants used MATLAB/Simulink as the computation software in their teaching. In addition, many respondents selected the "other" choice wherein they were additionally provided the opportunity to type in the tool name. Tools mentioned in this category included R, C++, Excel, Labview, Multisim, and calculator. Figure 2 presents the percentages of responses as related to software used by participants in their respective class (es).

TABLE I. FREQUENCY OF USE OF RELATED LEARNING OUTCOMES ASSOCIATED WITH COMPUTATION

Learning Outcome	**Never**	**Rarely**	**Occasionally**	**Once in a while**	**Frequently**
To increase awareness of the potential role of computation in a particular field of science or engineering (N=39)	n=20 51.28%	n=11 28.21%	n=5 12.82%	n=2 5.13%	n=1 2.56%
To measure materials or devices by collecting data as in a laboratory experiment (N=38)	n=6 15.79%	n=11 28.95%	n=7 18.42%	n=9 23.68%	n=5 13.16%
To explain the cause-effect relationship of a given underlying model (N=39)	n=10 25.64%	n=13 33.33%	n=11 28.21%	n=3 7.69%	n=2 5.13%
To test the accuracy of a given model and/or its computational implementation (N=39)	n=8 20.51%	n=11 28.21%	n=9 23.08%	n=9 23.08%	n=2 5.13%
To validate the results or performance of the product of a design task (N=38)	n=9 23.68%	n=9 23.68%	n=10 26.32%	n=4 10.53%	n=6 15.79%
To implement computational techniques/ methods in a modeling task (N=38)	n=8 21.05%	n=15 39.47%	n=4 10.53%	n=5 13.16%	n=6 15.79%
To predict the results of an experiment in a design task (N=39)	n=6 15.38%	n=9 23.08%	n=10 25.64%	n=8 20.51%	n=6 15.38%
To discriminate between different models/methods to represent a given physical phenomenon (N=37)	n=7 18.92%	n=8 21.62%	n=7 18.92%	n=6 16.22%	n=9 24.32%
Others (N=8)	n=2 25%	n=0 0%	n=1 12.5%	n=0 0%	n=5 62.5%

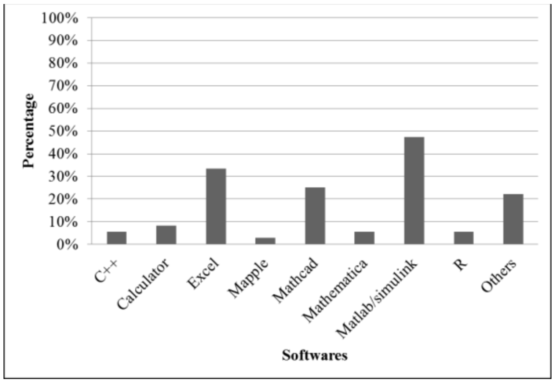

Fig. 2. Percentagesof a given software used by participants in their class(es)

D. What pedagogical methods and delivery mechanisms do participants integrate when teaching?

In Figure 3, the frequencies of the most common pedagogical methods and delivery mechanisms are shown. Lecture, projects, homework assignments and laboratory practice were most commonly used ways to introduce computation within disciplinary courses. In addition, homework assignments were the most commonly used form of integrating computation. Other forms including laboratory reports, exams and class demonstrations were also mentioned in the "other" category.

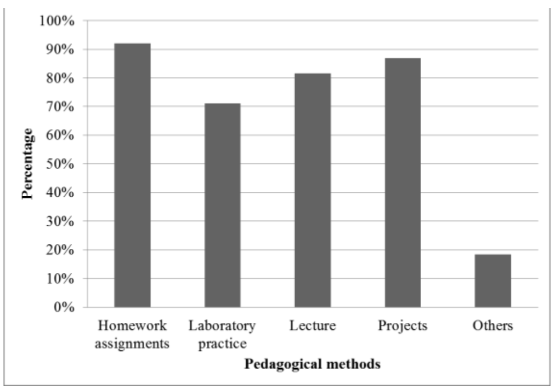

Fig. 3. Percentage of various pedagogical methods and delivery mechanisms employed by the collective set of participants

E. What is the frequency of use of computation in related assignments?

Table II demonstrates the frequency of use of computation in related assignments. It illustrates that computation was usually used in solving mean-field or particle-based dynamic systems, diffusion/electric field problems, and time-independent 1D spatial varying system problems. Problems such as energy and efficiency, physical construction, circuit analysis/design were also mentioned in the "other" category.

F. What are the most common types of engineering problems that can be solved with computation?

In examining the participants' responses, three themes emerged and are classified as: (1) Specific Application; (2) Specific Approach; and (3) Context.

Specific Application. Specific application can be defined as specific problem areas instructors focused on to solve with computation. Within the identified categories the most recurrent problem was described in multiple contexts of engineering design (n=12, 42.86%). Design of steel, concrete, wood, amplifiers, and circuits represented the most commonly used problems for this theme.

TABLE II. FREQUENCY OF USE OF COMPUTATION RELATED ASSIGNMENTS

Related Assignment	Never	Rarely	Occasionally	Once in a while	Frequently
Satisfaction of constraints problems (either chemical or mechanical) (N=38)	n=8 21.05 %	n=9 23.68 %	n=4 10.53%	n=8 21.05%	n=9 23.68%
Minimization or optimization problems (N=38)	n=3 7.89%	n=10 26.32 %	n=6 15.79%	n=10 26.32%	n=9 23.68%
Mean-field or particle-based dynamic systems (N=38)	n=2 5.26%	n=3 7.89%	n=2 5.26%	n=5 13.16%	n=26 68.42%
Time-independent 1D spatial varying system (N=38)	n=2 5.26%	n=5 13.16 %	n=7 18.42%	n=7 18.42%	n=17 44.74%
Diffusion/ Electric field problems (N=37)	n=2 5.41%	n=6 16.22 %	n=3 8.11%	n=3 8.11%	n=23 62.16%
Others (N=16)	n=5 31.25 %	n=5 31.25 %	n=1 6.25%	n=0 0%	n=5 31.25%

The next most common type of problem is automatic control (n=5, 17.86%). Some of the related responses are: "*project control problems*", "*control systems*" or "*automatic control theory*". The remaining categories are mostly broad, focusing on topics such as: statics (n=3, 10.71%); dynamics (n=2, 7.14%); strength of materials (n=2, 7.14%); electronic (n=2, 7.14%); mechatronics (n=1, 3.57%); and nuclear reactor theory (n=1, 3.57%).

Specific Approach. Specific approach refers to problems viewed as specific task to be accomplished by students using computation. The most commonly used approaches were to do simulations (n=6, 35.29%) and to solve calculations (n=3, 17.65%). They were described in statements like: *"Finding roots of equation having orders higher than 2. Laplace transform and analyzing system's behavior to a particular input signal."*

Data representation (n=2, 11.76%) was also highlighted as an important approach. Samples of quotes include: *"Plotting of experimental data vs. prediction equation"* or *"curve fitting, interpolation, presenting data graphically."* The rest of the categories were for programming (n=1, 5.88%), data collection (n=1, 5.88%), calibration of instruments (n=1, 5.88%), iterative design/analysis (n=1, 5.88%), and error analysis (n=1, 5.88%).

Context. Context can be defined as the situation of the problem in a given setting, time or space. Three categories were identified within this theme. The most common context for the problems was referred to as "real world problems" (n=6, 66.67%). Samples of responses into this category were:

"Problems that come up from their work place." Some other respondents mentioned other types of contexts for the problems such as capstone courses (n=2, 22.22%) and senior projects (n=1, 11.11%).

G. Additional Comments

We also invited the participants to offer any additional ideas or comments. Highlights from these include some of the already described uses for computation (e.g., solve calculations and do simulation), statements that emphasize the relevancy of computation, and descriptions of the difficulty of coupling disciplinary content with programming.

> *"Many of our students express being overwhelmed with the learning curve involved with learning to program...so, some students complain that they are being forced into a comp. sci. role, but their major is m.e., b.m.e., m.j.e., etc. They don't realize that all engineers may be expected to do programming at some time or another."* And *"Programming is a difficult topic to teach freshmen but I believe they benefit from the experience. It is one of their first steps toward becoming problem solvers."*

V. Discussion

In this section we discuss each question under the three categories of the Pedagogical Content Knowledge framework.

A. Pedagogical Knowledge

The main themes that emerged from the responses related to PK were: pedagogical methods, delivery mechanisms, and frequency of use in related assignments in which computation was used. The most common ways for having students apply computation were in homework assignments, project development, and laboratory practice. These results suggest a predominance of computation performed by the student was during independent work. The use of lectures and class demonstrations was the most commonly used way for presenting computation. The most frequently used computation related assignment type involved contextualizing problems in dynamic systems whereby students used simulation tools to inform the solution to their problem.

Additionally, most of the identified types of problems (e.g., minimization or optimization problems) showed an average frequency of use higher than 50% and only a small portion of the faculty members never use them. This suggests that all these related assignments are relevant for their disciplines. However, it is not easy to make a distinction for frequency of use due to the high difference among such frequencies.

B. Content Knowledge

Design process applied to real world settings appears to be the most common approach for integrating computation into disciplinary courses. These processes typically involve solving complex calculations and the use of simulations. Among these types of assignments the most commonly used software packages were MATLAB/Simulink and Mathcad. This finding can be compared with the described activities and frequent problems and contexts identified. These tools seem to be appropriate for representation, simulation purposes, and for the solution of complex calculations.

C. Pedagogical Content Knowledge

The identified PCK can be associated with participants' descriptions of the role of computation in disciplinary courses in terms of the activities they implemented. Within the identified activities, it is important to highlight that most of the described activities were related to either tasks that can help students make efficient use of their time and make complex systems manageable. For instance, solving complex equations through computation instead of solving them manually was frequently described as one way to save time. Many respondents also expressed used computation to teach students about programming or supporting computer-aided analysis. Alternatively, some of the instructors used these activities in an integrative way – an inquiry process of several stages: data collection, data analysis, modeling and validation.

The learning outcomes identified can be roughly aligned with learning categories depicted in the Revised Bloom's Taxonomy [20]. As explained in Magana et al., [18], the mapping of the intended learning outcomes indicated on how far engineering instructors wanted their students to achieve certain learning outcomes. For example, both "to understand and create artifacts through the design process for specific problems" and "to understand the behavior of a system by variation of parameters" can be equally balanced between the Conceptual and the Procedural Knowledge within the Knowledge Dimension of Bloom's Taxonomy. In this context, students may not only have to understand how something works (either design process or phenomenon) but they may have to interact at some level with it. The difference between these two learning objectives can be established at the level of interaction. While the one objective is related to the use of simulation for understanding given phenomena (Understand Level in Bloom's Taxonomy), the learning outcome related to the design process actually expects students to create a design or an artifact (Create Level in Bloom's Taxonomy).

VI. Implications for Instruction

Disciplines wherein respondents suggested they readily integrated computation are Computer Engineering, Electrical Engineering, and various Engineering Technology disciplines. Results suggest most common applications for integrating computation include automating solving complex calculations to arrive at a solution faster and more accurately, for conducting modeling and simulation, and for design purposes. Although respondents established a central role for computation into their courses, there was no strong evidence to suggest any use of computation at a deeper level or in alternative meaningful contexts such as inquiry learning or design. Considering the most frequent pedagogical methods identified, it seems students primarily engage in computing assignments as part of individual work. This process of individual work may be overwhelming for students. This is consistent with findings from Magana et al., [13] where they found that coupling computation with disciplinary knowledge is challenging for students.

Pedagogies that support a smooth integration of computation with disciplinary knowledge from a learning standpoint include implementing inverted classroom pedagogies. For example, a student comes to class having already watched the online lecture, which is available for them to watch at their convenience. During class, informed by their understanding and reflection of the lecture, perform computation in the classroom having the added benefit of learning deeper understanding from faculty and teaching assistants as well as their peers when working on group projects. Pair programming [21] is another viable pedagogy shown to have multiple benefits such as greater likelihood of students' success at course completion, their increased confidence in programming abilities, and increased participation of female and minority students when applied to computing courses [21,22].

We also advocate the use of online scaffolding to support individual work. For instance, the use of worked examples has been commonly used in the field of computer science. Worked examples are composed by a problem statement, a sequence of steps to solution and a given solution. These set of tools, usually given with a similar problem statement, allow decreasing the cognitive load by facilitating the acquisition of a certain cognitive skill [23].

VII. Conclusions and Future Work

Computation is a required skill in modern engineering; however, integrating computation with disciplinary knowledge may pose some challenges for instructors and students. Progress is being made by integrating software for scientific computation that can facilitate the solution of complex calculations, the design of processes or artifacts and understanding of complex phenomena. Suggested pedagogical methods and strategies that can support the integration of computation for teaching and learning include flipped classroom, paired programming and worked examples.

The limitations of the study relate to the small sample size. We do not know if participants who chose not to respond did so because either they decided not to participate (among many reasons) or because they are not integrating computation at the undergraduate level. However, we believe that identifying, describing and documenting how other instructors are integrating computation can be an initial fruitful endeavor to identify benefits and challenges for integrating computation with disciplinary knowledge and potential ways to overcome the latter one. Therefore, future work will consists of conducting in-depth case studies that can bring more light into the ways computation can be integrated more effectively at the undergraduate level, challenges that instructors and students face and the effectiveness of the suggested pedagogical strategies in facilitating and supporting this integration.

***Abstract*—Empirical studies are important in software engineering to evaluate new tools, techniques, methods and technologies in a structured way before they are introduced in the industrial (real) software process. Perform empirical studies in a real context is very difficult due to various obstacles, so, we intend to create a stable environment that allows us to perform reliably empirical studies with students. This paper describes a case study with 104 students grouped in seven teams that developed a software system (Web application) for a real costumer. In this study we used a model based on Use Case Points (UCP) to estimate the resources needed to develop a software system.**

Keywords—empirical studies; software engineering management; software engineering process; software quality; use case models; use case points.

I. INTRODUCTION

Empirical studies in software engineering have had a significant role in the evaluation of tools, techniques, methods and technologies before they introduced in industrial software. In the early nineties, Basili introduced, for the first time, the concept of *experience factory* [1]. These authors developed an organizational schema for collecting experiences on reuse of empirical results, for analysing them and generalizing the knowledge contained [2]. This scheme was designed based on many years of the Software Engineering Laboratory (SEL) work. Empirical studies developed within the SEL involved students from different USA universities and industry partners.

With our approach we do not intend to create a new SEL. Instead, we intend to create a space (virtual or physical) that allows us to conduct empirical studies in the software engineering area by involving students that are enrolled in our current software engineering courses (both at undergraduate and postgraduate university programmes).

To ensure compliance, in terms of cost, schedule and quality of an IT (Information and Technology) project is important to estimate the total amount of resources early in developing process. Currently, there are several methods to estimate the resources needed to develop a software system. For this propose, in our research we find *Function Points* (FP) [3], *Use Case Points* (UCP) [4] and LOC (*Lines of Code*) methods.

In our empirical study we used graduate and undergraduate students that were randomized grouped in seven teams to develop a software system. We applied the original UCP method for estimate the effort needed to develop the software system of each one teams.

Our final goal of carrying out empirical studies with students is to understand its validity when compared with the corresponding studies in real industrial settings. We intend to answer if it is adequate to use students as subjects in empirical studies? What is the better way to involve students as subjects in order to obtain valid results? Can we use the results with student in real context?

In this paper, a description of Empirical Software Engineering (ESE) using students versus professionals as subject is presented in Section 2. Section 3 describes related work with *Function Points*, *Use Case Points* and LOC (*Lines of Code*) methods. In Section 4, we present in detail the original *Use Case Points* method that we use in the next section. In section 5 we briefly describe the case study we have developed to initially assess the effectiveness of using UCP method in educational context. Finally, in Section 6 we present the conclusions and future work.

II. ESE USING STUDENTS VERSUS PROFESSIONALS

In this section, based on literature review we describe the strengths/weaknesses of using students versus professionals in the empirical software engineering context.

In the survey conducted in [5], a total of 5,488 subjects took part in the 113 experiments investigated, eighty-seven percent were students and nine percent were professionals. This survey demonstrates the importance of using students in this context.

In many studies, students are used instead of professional software developers, although the objective is to draw conclusions valid for professional software developers. The differences are only minor, and it is concluded that software engineering students may be used instead of professional software developers under certain conditions. Höst et al. have a paper where the performance of software engineering students in empirical studies is discussed and evaluated [6]. The authors emphasize two main reasons for performing this kind of studies. First, it may serve as a measure of the quality of education. A large difference in performance between professional software developers in industry and students in their last year at the university may imply that the persons leaving the university need experience and training before they are able to fully contribute. A second reason for studying the differences between students and professionals is that many empirical studies in software engineering research rely on students as subjects, although attempting to generalize the findings to professional software developers [6]. Höst et al. argue that the main reason to use students as subjects is often that they are available at universities and they are willing to participate in studies as part of courses they attend. In many cases, it is possible to combine the learning objectives of the courses with the research objectives of the studies.

Tichy refer that software graduate students are so close to professional status that the differences are marginal. The author also refer that this students are technically more up to date than the "average" software developer who may not even have a degree in computing. About software professionals, Ticky refers that they may be better prepared in the application domain and may have learnt to deal with systems and organizations of larger scale than a student. The author also argues that a theory is provisionally accepted only if it has been tested in at least two experiments by independent groups and the empirical work have a main role in this issue [7]. In educational context, we can do empirical work with students from different courses, schools and regions. Later, if possible, we can reply these experiments in industrial context.

Sjøberg et al. argue that the main reason of most subjects in software engineering experiments are students is that they are more accessible and easier to organize, and hiring them is generally inexpensive. Consequently, it is easier to run an experiment with students than with professionals and the risks are low. However, authors refer that the discussion in the software engineering community about students versus professionals seems over-simplified [8].

Jaccheri et al. refer that empirical studies are often carried out with students because they are viewed as inexpensive subjects for pilot studies. The authors also argue that, at any rate, the final goal of carrying out empirical studies with students is performing empirical studies in industrial organizations and establishing collaborations with them [9].

Svahnberg et al. refer that the students are readily available, often willing to participate, and require no or little compensation. They conducted a study where they found out that students are able to both have a personal view and express their opinion about the way it works in industry. This study was about requirement selection task where students must select which requirement that should go into a specific release of a system [10].

Carver et al. have developed a checklist that provides guidance for researchers and educators when planning and conducting studies in university courses. Initially, the authors identified the requirements that research and pedagogy place on a valid empirical study with students and after, they used this information as the basis for develop that checklist [11].

III. EFFORT ESTIMATION METHODS

There are great efforts and contributions to measure the size of a software system and estimate the effort needed to develop it. Measuring the size of a software system is different to estimate the effort needed to develop it. The first is an activity that estimates a probability of a software system size in a measurement unit while the second estimates the effort required to developing it. The relationship between the size of a software system and effort required to develop it is given by the productivity of the software development team.

Metrics are measurement methodologies whose main objective is to estimate the size of software system and assist, as an indicator, the project management of software system development. The estimated size is one of the most commonly used metrics for software size, since has direct impact on development effort and project management. It is an indicator of the amount of work to be performed and this kind of knowledge can be used to help us to estimate the cost and the lead time for the project [4]. According to Pressman, measurement enables managers to plan, monitor, improve and enhance the software process development [12].

Estimating the size of a software system is a critical development process activity. Not only does size impact the technical solution; it also impacts the project management solution [13].

The size of the software system means the amount of work to be performed in a project development. Each project can be estimated according to the physical size (which is measured through the requirements specification, analysis, construction and testing); based on the functions that the user gets, in the complexity of the problem that the software system will solve and in the reusability of the project, which measures how much the product will be copied or modified from another existing product [14] [15].

Currently, there are several metrics of size estimation and it is difficult to select the most appropriate for the size of a software project in an organization. The main metrics were developed based on the software functions such as: *Function Points* [16], *Bang* [17], *Feature Points* [18], *Boeing' s 3D Function Points* [19], *Mark II* [20], *Use Case Points* [4], *COSMIC Full Function Points* [21].

A. LOC (Lines of Code)

The first metrics of software size estimation emerged in mid-1960's, although the first dedicated book on software metrics was not published until 1976 [22]. These metrics were based on the physical size of *Lines of Code* (LOC) and were used as the basis for "measuring programming productivity and effort" [14]. This metric considers the software from the perspective of the internal structure and is applied in the final stages of the software project [23].

Ross highlights two advantages of using LOC method: 1) the possibility to estimate automatically, and 2) the ease of using historical data because most of the existing data about estimation were measured by LOC method. The disadvantages are related to ambiguity, because the metric becomes ambiguous when dealing with non-textual abstractions and the lack of significance of the measure to the end user (costumer) [13]. Besides these disadvantages Fenton and Pfleeger note that a count in LOC depends on the degree of code reusing and the programming language and can be five times higher than another estimate, due to differences in techniques of measurement of blank lines, comment lines, data declaration and statements [15]. The authors also emphasize that the LOC method penalizes small and well-designed programs, it is not adequate to non-procedural programming languages and is difficult to obtain in the early planning stages of development of a software system [15].

LOC method was a metric widely used until mid-1970. From there emerged various programming languages and consequently the need for other ways to estimate the size of software.

B. Function Points

The *Function Points* (FP) is one of the first metrics to measure the size of software with some precision. It is the most used in the industry and became an international standard in 2002 through the ISO/IEC 20926 [24]. Currently, the mapping of the *Function Points* method to estimate object oriented software projects has been widely discussed in the literature.

Function Points method was developed in the mid 70's and published in 1979 by Allan Albrecht in an attempt to minimize the difficulties associated with lines of code as a measure of software size, and to assist in generating a mechanism that could predict the effort associated with software development [3, 25]. The first version of *Function Points* aimed to be applied early in the software development process, to be related to economic productivity and to be independent of the source code or programming language.

In 1984, Allan Albrecht refined this version and later, with the increased use of the *Function Points* method, it became necessary to define a guide to interpret the original rules for new environments. Due to this need, in 1986 was created the *International Function Point Users Group* (IFPUG) [26]. From this date, the IFPUG became responsible for defining the counting rules, the training and certification of professionals interested in the application of this metric and dissemination of several historical databases of productivity of software development in industry, provided by various agencies, including the *International Software Benchmarking Group* [27]. This information enables the estimation of development time for new software projects and team productivity based on previous estimates made by the *Function Points* method [25, 28]. The *Function Points* has become the most widely used and studied metric in the history of software engineering and in late 1993 had groups of users in 18 countries [29].

The *Function Points* method aims to establish a measure of "size" of software in function points (unit of measure for software as well as the hour is unit of measurement for time), by quantifying the functions implemented from the point of view of user in a business focus and not in technical focus [25]. As the basic principle, this metric focus on requirements specification to obtain estimates of time, cost, effort and resources in early phase of software development process independently of the technology used for their implementation [30]. It provides a count indicative early in software development process without knowing details of the data model. Later in the software development process, this count becomes more accurate estimate of the complexity of functions and, at the end of software development (in the implementation phase), a detailed count is performed, obtained from the degree of complexity of the functions raised in the functional process, data model, description of the screens and reports [25, 26].

In general, organizations apply the *Function Points* as "a method for determining the size of the software package purchased; to support the analysis of productivity and quality; to estimate the costs, resources and efforts of development projects and maintenance of software" [28]. In addition to these purposes, Longstreet highlights other utilities of *Function Points* method: "define when and where to make reengineering; estimate test cases; understand the increase of scope; assist in contract negotiations; develop a standard set of metrics; and make benchmark of software" [25].

C. Use Case Points

The *Use Case Points* (UCP) metric was defined to estimate Object Oriented (OO) projects based on the same philosophy of *Function Points* and in the process "*Objectory*", where the use case concept was developed. Later, Ivar Jacobson developed "*Object-Oriented Software Engineering (OOSE)*", methodology based in use cases, a technique widely used in industry to describe and collect the functional requirements of the software. Considering that the use cases model was developed to collect the requirements based on use and users vision, it makes sense to base the estimation of size and resources of software projects in use cases [31].

Since the UCP method was selected to perform the empirical study with the students, next we present the relevant characteristics and the counting process of this method.

IV. USE CASE POINTS METHOD

The first description of the method was published by Gustav Karner [4] with the aim of creating a model that would allow estimating the resources required to develop a software system under *Objectory AB* (later acquired by Rational Software). Its influences came from the classic

Function Point method. However, after the original work, the author has not done any further publication or justified aspects of the conception of the method, thus it was being applied and adapted according to the circumstances. The method consists in calculating a metric called *Use Case Points* that give us an estimation of the size and complexity of a software project. If we know the development team productivity (to be obtained based on previous projects), we can derive an estimate of the effort required to develop the software project.

The UCPs are related to functional, technical and environmental complexity of the software project, namely the following aspects:

- The number and complexity of the actors and use cases in the system;
- Several non-functional requirements with impact on the project (e.g. performance, usability, reliability, etc.);
- The impact of the environment where the project is developed.

When applying the method, we must first calculate the complexity of actors and use cases in the system to quantify the variables *Unadjusted Actor Weight* (UAW) and *Unadjusted Use Case Weight* (UUCW), respectively. When combined with their weight, we obtain an inadequate measure of the size and complexity of the system called *Unadjusted called Use Case Points* (UUCP). The next step is to adjust this measure with a number of technical factors and environmental factors given by *Technical Complexity factor* (TCF) and *Environmental Factor* (EF) variables, respectively. These factors combined with the UUCP variable will produce the effective number of UCPs that reflect the size and complexity of the software project. In the following subsections we detail the steps needed to calculate the UCPs.

A. Unadjusted Actor Weight (UAW)

An actor is an entity that interacts with the system to achieve its goals: a person, a machine, a software application, etc. Thus, to capture these differences, each actor is classified as *simple*, *average* or *complex* and each actor type is associated with a weight as shown in Table I.

TABLE I. COMPLEXITY OF ACTORS

Category	Example	Weight
Simple	An external system through an API (Application Programming Interface)	1
Average	A user who interacts with the system through a command line	2
Complex	A user who interacts with the system through a Graphical User Interface (GUI)	3

Although we believe that a GUI is more complex than a command line or API, there are no published studies that justify this aspect [32]. The complexity of the actors in the system is given by the *Unadjusted Actor Weight* (UAW) variable, and is calculated by the sum of the products between the actors in each category with their associated weights.

B. Unadjusted Use Case Weight (UUCW)

A use case is a story about how users interact with the system to achieve their goals. There are several ways to write a use case, however, to avoid that the measurement of the number of UCPs of the software project is not affected, all use cases of the system must be written with the same level of detail. The user-objectives oriented approach described in [33] is suitable for apply the method.

Such as actors are classified according to their complexity, the use cases are also classified as *simple*, *average* or *complex* through the number of transactions containing the main course of success and alternative courses, as shown in Table II.

TABLE II. COMPLEXITY OF USE CASES

Category	Number of transactions	Weight
Simple	3 or less	5
Average	4 to 7	10
Complex	More than 7	15

It is noted that a transaction cannot be a step in the courses of use cases. Ivar Jacobson (the use cases author) defines a transaction as an action triggered by the user to which the system reacts and presents the results of its processing [34].

To calculate the *Unadjusted Use Case Weight* (UUCW) variable, each use case must be classified according to its category and the corresponding weight must be multiplied by the number of use cases the systems possesses of each category.

C. Unadjusted Use Case Points (UUCP)

After calculating the complexity of actors and use cases of the system, the respective variables must be combined to determine an estimation of the *Unadjusted Use Case Points* (UUCP). UUCP is considered an unadjusted estimation because it will be adjusted by a set of technical and environmental factors to calculate the effective value of the UCPs of the software project. The calculation of UUCP uses the following equation:

$$UUCP = UAW + UUCW \qquad (1)$$

D. Technical Complexity Factor (TCF)

The size of the software system does not depend only on its functions and the users it serves. It also depends on the quality characteristics of the system. Therefore, there is a number of technical or non-functional factors that must be considered to measure the size of the system based on what was agreed between the costumer and the supplier. A list describing all technical factors proposed by Karner is shown in Table III [4].

The impact of each factor within the project is rated on a scale 0, 1, 2, 3, 4 and 5, where 0 means that it is irrelevant and 5 means it is essential. If the factor is neither important nor irrelevant it must be rated with the value of 3. The rate of the factor must be multiplied by the associated weight as shown in Table III. The sum of all the products calculates the

TFactor value, which is used to calculate the *Technical Complexity Factor* (TCF):

$$TCF = 0.6 + (0.01 \text{ x } TFactor) \quad (2)$$

Karner based the constants 0.6 and 0.01 on the adjustment factors of *Function Points* created by Albrecht [3]. For example, for a given system with a *TFactor* equal to 42, the TCF is:

$$TCF = 0.6 + (0.01 \text{ x } 42) = 1.02 \quad (3)$$

TABLE III. *TECHNICAL FACTORS* CONTRIBUTING TO COMPLEXITY

Factor	Description	Weight
T1	Distributed systems	2
T2	Performance	2
T3	Efficiency	1
T4	Complex internal processing	1
T5	Code reusability	1
T6	Installation ease	0.5
T7	Usability	0.5
T8	Portability	2
T9	Changeability	1
T10	Concurrency	1
T11	Security	1
T12	Accessibility of others	1
T13	Training	1

E. Environmental Factor (EF)

The characterization of the software development teams is also important to obtain a measure of the size and complexity of the software project; thus there is a set of aspects related to the development environment that must be weighed. The levels of the motivation of the team or the familiarity with the software process development adopted are examples of environmental factors that must be taken into account on the calculation of the UCP value. A list describing all environmental factors proposed by Karner is shown in Table IV [4].

The impact of each factor within the project is rated on a scale 0, 1, 2, 3, 4 and 5, where 0 means that it is irrelevant and 5 means it is essential. If the factor is neither important nor irrelevant it must be rated with the value of 3. The rate of the factor must be multiplied by the associated weight as shown in Table IV. The sum of all the products calculates the *EFactor* value, which is used to calculate the *Environmental Factor* (EF):

$$EF = 1.4 + (-0.03 \text{ x } EFactor) \quad (4)$$

TABLE IV. *ENVIRONMENTAL FACTORS* CONTRIBUTING TO EFFICIENCY

Factor	Description	Weight
E1	Experience with a software development process	1.5
E2	Development experience with similar projects	0.5
E3	Experience with OOP	1
E4	Maturity in OO analysis	0.5
E5	Motivation	1
E6	Stability of requirements	2
E7	Part time workers	-1
E8	Experience with technologies adopted	-1

For example, for a given system with an *EFactor* equal to 17.5, the EF is:

$$EF = 1.4 + (-0.03 \text{ x } 17.5) = 1.+ (-0.51) = 0.89 \quad (5)$$

F. Use Case Points (UCP)

Finally, after calculating the above variables shown in the previous subsections, the last step is to calculate the effective number of UCPs of the system using the following equation:

$$UCP = UUCP \text{ x } TCF \text{ x } EF \quad (6)$$

If the team productivity is known, the UCP value can be used to estimate the effort required to develop a software system. According to Karner, each UCP corresponds to 20 hours of work [4].

V. CASE STUDY

Based on the previously described approach for calculating the UCP, a case study was developed to determine the productivity of some student software development teams.

The teams were constituted by second year students of the course 8604N5 Software System Development (SSD) from the undergraduate degree in Information Systems and Technology in University of XXX (the first University to offer in XXXX DEng, MSc and PhD degrees in Computing). The teams had between 10 and 17 people (1 team with 10, 1 team with 14, 1 team with 15, 3 teams with 16 and 1 with 17). Each team receives an sequential identification number (Team 1, Team 2, .., Team 7) and the description of the customer problem.

The teams developed a software project of medium complexity, using the *Unified Modeling Language* (UML) notation encompassed in an iterative and incremental software development process, in this case, the *Rational Unified Process* (RUP). The teams followed the guidelines established by the RUP reduced model [35, 36], executing the phases of inception, elaboration and construction according to the best practices suggested by CMMI-DEV v1.2 ML2. The project lasted 3 months. This software project was to develop a Web solution using object-oriented technologies and relational databases, to support the information system of one local costumer that provided all the information about the organization and interacted directly with the teams.

The main goal of case study was to calculate the productivity of the teams in hours/man per UCP, based on the size of each software project and in effort reported by each team. To determine the teams productivity, we have used the following equation:

$$Productivity = Effort[h] / Size[UCP] \quad (7)$$

The measurement of the functional size expressed by UUCP metric was based on the latest version of the use case model that developed by each team. Each team has chosen a different number of components to develop. The quality attributes and restrictions were also different for each team. These differences had considerable impact on the calculation of the TCF. For reasons of space is not shown the table with the weights of technical factors assigned to each of the teams. Table V presents the weight of environmental factors across all teams.

To calculate the team' s productivity we have used the real effort that each team reported to develop the software system. This effort involved hours spent within the project, as well as attending lectures related with the SSD course.

TABLE V. WEIGHT OF ENVIRONMENTAL FACTORS ON TEAMS

Description	Weight
Experience with RUP	3
Development experience with similar projects	0
Experience with OOP	3
Maturity in OO analysis	1
Motivation	3
Stability of requirements	3
Part time workers	1
Experience with technologies	3

Table VI presents the metrics collected from each development team. From this table we can conclude that the productivity factors of the teams vary between 5,6 hours to 12,2 hours per UCP. On average, the productivity factor per team is 9,36 hours per UCP. These results are directly related to the total effort accomplished in hours and the size of projects measured in UCPs.

In general, teams with more elements reported more effort. Normally, we tend to assume that the size of projects in UCPs is proportional to the functional size. However, this did not happen to all teams, as seen in Fig. 1.

This discrepancy occurs primarily for two reasons. The first indicates that the teams with more members (and reporting more effort) give more emphasis on documentation tasks (mainly the writing of reports). The other reason is due to the quality of artifacts (mainly the use case models) that are limited by the reduced experience of the teams in requirements specification. We could observe in all teams, use cases with poor quality, leading to a subjective interpretation to identify transactions in the main and alternative courses. Additionally, the majority of the use cases were classified as *simple* according the UCP method because it had few transactions.

Based on the costumer assessment, the teams with the highest software project size in UCPs had the best results, especially teams Team4, Team3 and Team7 (with the exception of the Team6). Finally, it was also found that the use case models of these teams were superior to the others.

VI. CONCLUSIONS

In the empirical study, the average productivity of the teams was based on the size of the software projects in UCPs and in total effort made throughout the all phases of the software project development. We believe that the average productivity could be used in future situations: (1) in the business planning phase of the project within the Software Process and Methodologies (SPM) course (first semester) to estimate the development effort of the project to implement in the SSD course (second semester); (2) during the implementation phase for control purposes, to calibrate the effort of every moment of the project. The results could also be packaged in database (repositories) with historical data with projects information. This data can include all measurements obtained in all project of the teams.

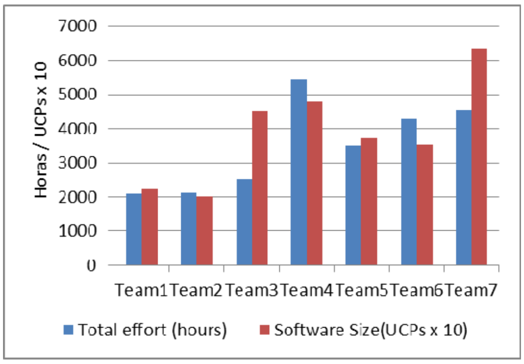

Fig. 1. Comparison between total effort and software size per team

After application of the UCP method in three real projects, Karner found that it takes 20 man hours to complete one UCP [4]. This factor has been accepted as an historically collected figure representing productivity [31, 37]. The teams involved in the case study presented coefficients of productivity more generous. This does not mean that they are super teams, but means that further research is needed to find the reason of this discrepancy. However, we believe that empirical studies involving students on these subjects are important for the scientific community and the industry.

Considering also that productivity is directly related to the effort made and with the functional size per UCP, we suggest for future editions of the SMP and SSD courses that all teams use a development tool, for example *Teamwork Project Manager* [38], in order to accurately determine the effective involved effort. We intent to assess the influence of this tool in the teams performance. As future work, the determination of the productivity of each element according the role of the RUP that he/she assumes is also an interesting experiment.

TABLE VI. RESULTS OF THE SOFTWARE DEVELOPMENT TEAMS

Description	Team1	Team2	Team3	Team4	Team5	Team6	Team7
Number of elements	10	15	16	17	16	16	14
Total effort [hours]	2094	2118	2511	5467,5	3517,5	4287	4548
Unadjusted Actor Weight (UAW)	36	27	45	42	30	21	87
Unadjusted Use Case Weight (UUCW)	170	165	365	400	300	305	570
Unadjusted Use Case Points (UUCP)	206	192	410	442	330	326	657
Technical Complexity Factor (TCF)	1,075	1,045	1,095	1,075	1,115	1,075	0,955
Environmental Factor(EF)	1,01	1,01	1,01	1,01	1,01	1,01	1,01
Software size	221,45	206,4	448,95	475,15	367,95	350,45	627,44
Use Case Points (UCP)	224	203	453	480	372	354	634
Productivity [hours / UCP]	9,36	10,45	5,54	11,39	9,47	12,11	7,18

Method for Teaching Parallelism on Heterogeneous Many-Core Processors Using Research Projects

Henrique Cota de Freitas
Department of Computer Science
Pontifícia Universidade Católica de Minas Gerais (PUC Minas)
Belo Horizonte, Brazil
cota@pucminas.br

Abstract—**Parallel programming and parallel architectures are necessary to achieve scalability and performance. It is difficult to evaluate when to teach parallelism and how to change the paradigm from serial to parallel algorithm in traditional curricula. Currently, there are efforts to introduce parallel programming since there are multi-core processors. However, there is a new chip generation called many-core processor. For instance, one processor chip can be built with 1,000 processing cores. Moreover, this type of processor is designed to achieve scalability and performance based on heterogeneous cores. How to teach parallelism to undergraduate and graduate students? Human resources are necessary to design and program parallel architectures based on this next generation of many-core processor. Therefore, the main goal of this paper is to show an experience based on research projects. The idea is to join students from different courses and levels, e.g. Computer Science, Information Systems, Computer Engineering, and Graduate in Informatics. All of them working together in order to understand all characteristics of heterogeneous many-core processors based on integrated environment composed of computer clusters and simulation. The proposed method focuses on projects convergence to teach how to extract characteristics from benchmark traces in order to simulate many-core processors based on Networks-on-Chip. Consequently, students can understand parallel heterogeneous architectures and how to program them. Main results present the number of students interested in this research field along last three years and several scientific papers published. It is important to highlight that papers have students' participation and two papers are related to education. Results reinforce the contribution of the proposed method since we have several benefits including continuous and cooperative work along more years.**

Keywords-Computer Engineering; Parallel Architecture and Programming; Heterogeneous Many-Core Processors; Education

I. INTRODUCTION

A 1,000-core processor depends on semiconductor technology and strategies to reduce power consumption [1]. It is a matter of time. The architectural challenge was the first step, and several proposals to interconnect many cores are presented by literature, mainly Networks-on-Chip (NoCs) [2, 3, 4]. Therefore, we can easily link hardware and architecture, but software [5] is also an important issue related to this new era of many-core processors [6]. There is no "dark side of the force", but what/how/where is the type of software developed to 1,000-core processor? In order to exploit many cores, software must be parallel. However, it does not make sense to run the same code of computer networks (based on complex protocols) on a small chip where resources are constraints. We have to exploit space to place processing cores or memories. On-chip interconnection is necessary for scalability; it needs to be small, simple, since it is not more important than cores (to process data) or memories (to store data). Therefore, we need to design software based on different parameters from different architectures, such as GPPs (General-Purpose Processors), ASIPs (Application Specific Instruction Set Processor), and GPUs (Graphic Processor Units). All of them can compose a unique chip called many-core, e.g. 1000-core processor. This way, parallel software [7, 8, 9] for many-core processors must be analyzed on environments composed of parallel machines (multi-core workstations, GPUs, computer clusters, etc.). Moreover, it is important to simulate and evaluate the impact of Networks-on-Chip in order to study the following issues for heterogeneous many-core processors: concurrency, synchronism, and granularity, process/thread scheduling and mapping, software performance, scalability and efficiency.

Fig. 1 illustrates the importance of parallel architectures and programming for the new chip generation. In order to exploit performance and efficiency on heterogeneous many-core processors it is important to correlate architecture and programming. The first step to software development is to know the target architecture. If architecture is parallel, e.g. many-core processor, software must be parallel. However, it does not make sense to develop software based on message passing to access shared memory. This way, it does not make sense to develop software based on shared variables to access network. Now, we can look at inside the many-core processor based on 1,000 cores in order to describe three obvious hypotheses:

- In order to interconnect 1,000 cores and move data, it has a Network-on-Chip;
- In order to store data, it has several cache memories and different organization levels;
- All cores address the same main memory;
- There are different cores for specific processing, e.g. GPU cores.

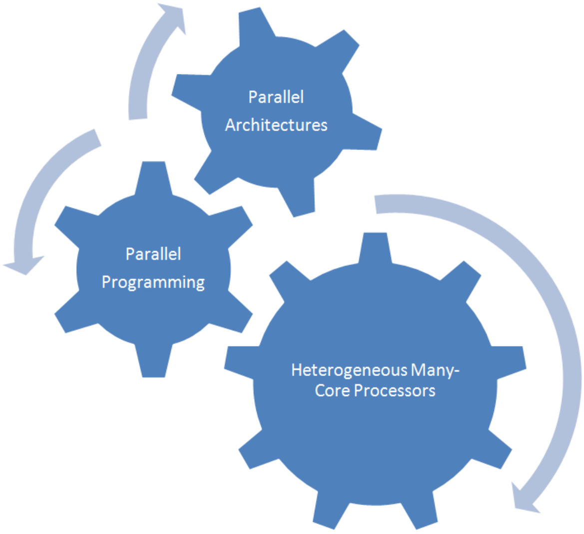

Figure 1. Parallelism and heterogeneous many-core processors

Therefore, we have a parallel heterogeneous processor that supports two programming models: message-passing and shared-variable models. However, how to program 1,000-core processor? Do we need to use both programming models? First of all, we need to understand the parallel workload model. It implies to understand all workload characteristics during processing. Parallel workload model describes parallel application characteristics (execution behavior), such as intra-chip communication intervals and patterns, shared-cache access, inter-process concurrency/dependency, and others. As consequence, it is possible to define how parallel software can exploit correctly processors in order to achieve performance, scalability and low cost. Moreover, it is possible to define how codes must be generated, for instance, packet/message size.

But, how to include all topics related to heterogeneous 1000-core processor in traditional curricula? The answer is research projects. Supported by projects, the main goal of this paper is to describe a teaching method based on parallel workload characterization and evaluation to teach parallelism. The main focus is on programming many-core processors supported by networks-on-chip. According to the scientific context, workload is based on hybrid programming model and it is necessary to support future software development for heterogeneous many-core processors. Based on workload characteristics, it is possible to design parallel software and benchmarks to evaluate new architectures in order to achieve high-performance exascale computing. Moreover, it is possible to disseminate parallelism to software engineers in a research field that emerges based on multidisciplinary concepts, since several computer components are inside the processor chip. In order words, we need to prepare (to teach) students for a new world, where parallel system is on chip and system-on-chip is different of system-off-chip. Therefore, the main contribution of this work is the teaching method based on research projects (Table I and Figure 2) as complement of traditional curricula based on disciplines.

This paper is organized into the following sections: Section II presents related work, Section III describes the proposed method, Section IV shows evaluation results, and Section V presents conclusions.

II. Related Work

The community focuses on NoC (Network-on-Chip) to design and understand the future generation of heterogeneous many-core processors. Interconnection is the basis to achieve scalability and performance. Since the first edition of NOCS (International Symposium on Networks-on-Chip) in 2007 [10], the community discusses the importance of NoC benchmarks [11], programming models [12], and concurrent applications [13].

Grecu, et al. [10] propose two types of benchmarks. The first one is called program benchmarks to exercise the entire communication architecture. The second one is called micro-benchmarks (synthetic programs) to exercise few aspects of communication. Also, Mandal, et al. [11] propose benchmarking platform for NoCs. They use NoCSim simulator and a set of synthetic and real applications benchmark. The proposal is not different from other projects that present a simulator based on set of programs to test NoC design.

The literature presents some papers related to application modeling and mapping onto NoCs [13, 14, 15]. Although they are not related directly to heterogeneous many-core processors, this procedure is important to understand workload behavior. Characteristics extracted from this type of experiment can bring new findings about workload for future software and architecture designs.

Fernandez-Alonso, et al. [16] and Paulin, et al. [17] present discussions related to programming models for networks-on-chip. Both papers show several programming models present in state-of-the-art as alternatives. The first one describes a survey of NoC design and programming models, and an open opportunity to research. The second one shows programming environment called MultiFlex for multi-processor system-on-chip based on IPv4 packet traffic management application.

In terms of method for teaching parallelism, Brown and Shoop [18] present online communities of educators and contributors. Flexible modules exploit programming exercises and supplementary materials. The modules can be used for introducing parallelism in several disciplines. This work adds information related to parallelism but the central idea is not based on heterogeneous many-core processors.

Our proposal is different from related research, since our goals focus on research projects and education [9, 19, 20, 21, 22]. Our intention is not to design new simulators, or online materials, but to propose a method based on research projects (Table I and Figure 2) that integrate experimentation and simulation to teach parallelism. The proposal is based on real parallel workloads characterization (e.g. message-passing and shared-variable models) supported by parallel infrastructure, such as clusters, multi-core machines, and well-known simulators for many-core processors.

III. PROPOSED METHOD

Projects by different agencies were planned to understand and evaluate many-core processors and workload characterization. The proposed method is supported by convergence in order to teach parallelism on heterogeneous many-core processors. Table I and Figure 2 show the projects convergence.

Table II shows three phases divided into seven activities. The method is based on workload design and characterization. The reason is explained by knowledge frontier: currently, heterogeneous 1000-core processors are not ready, so there are no known parallel applications for them.

- Phase 1 (Activities 1, 2 and 3) is related to infrastructure configuration and programs execution. Trace files are important for analysis and most simulators use them to reproduce workload behavior. So, Activity 3 generates program traces from real machines or computer clusters for next phase.
- Phase 2 (Activities 4 and 5) is responsible for analyzing traces under simulation and characterizing workload categories. Simulation is necessary since real many-core processors are not ready. Each workload can be divided into several categories. A category represents a behavior or a property, for instance, collective communication type or message size. Consequently, each category can be divided into several workload characteristics, such as communication periodicity, idle interval, etc.
- Phase 3 works on Activity 5 results. This phase is responsible for designing and evaluating parallel workload model and synthetic programs to achieve high performance. During this phase, the model is evaluated (Activity 6) as configuration data for many-core processors simulation. Activity 7 comprehends programming based on hybrid approach (message-passing and shared-variable models). Synthetic programs for benchmarking are developed, including adapted programs for simulators that do not support well-known parallel implementations (e.g. MPI and OpenMP).

Phases	Activities	Months (Cyclic – Figure 2)											
		1	2	3	4	5	6	7	8	9	10	11	12
1	1. Preparing benchmarks for execution and simulation.	X	X										
	2. Preparing simulators and infrastructure.	X	X										
	3. Executing benchmarks to generate execution traces.		X	X									
2	4. Analyzing traces/programs under simulation.			X	X	X							
	5. Characterizing workload categories.				X	X	X						
3	6. Designing and evaluating parallel workload model.					X	X	X					
	7. Designing and evaluating parallel synthetic programs.							X	X	X	X	X	X

Fig. 2 illustrates the projects correlation. Project number 1 is responsible for creating the basis related to computer cluster experimentation and networks-on-chip simulation. This project prepares the environment for extracting workload traces. Several algorithms are studied in order to understand process mapping and its impact on networks-on-chip. Project number 2 generates results related to workload characterization for Wireless Networks-on-Chip (WiNoCs). WiNoCs are alternative to improve performance and scalability for future heterogeneous many-core processors. Project number 3 is responsible for architecture exploitation. This project creates basis to study several parallel architectures including memory organization, on-chip interconnections, instruction and thread level parallelism. Besides, this project introduces GPU-based heterogeneity. Finally, project number 4 specifies GPU cores as important feature to be analyzed in order to understand how the impact on intra-chip communication is.

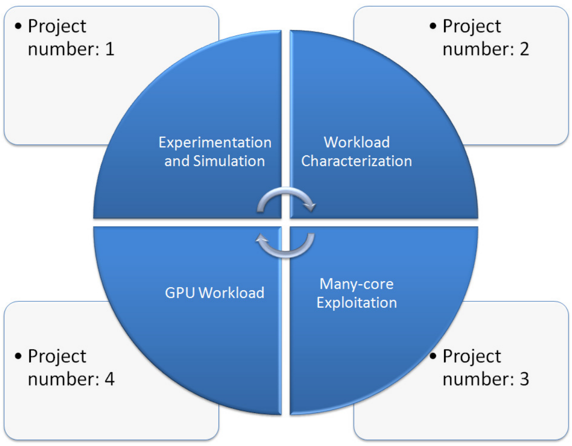

Figure 2. Projects correlation

All projects converge to create basis for teaching parallelism on heterogeneous many-core processors. The three phases highlighted by Table 2 cover all aspects discussed in projects. Consequently, we can return to project number 1 (Fig. 2) to apply the method and to teach parallelism continuously for different students.

As discussed in Introduction, it is not easy to include all aspects related to parallelism and heterogeneous many-core processor in a traditional curriculum. For this reason, the proposed method is supported by research projects based on convergence. All projects have to be planned in order to create conditions to keep students in research. For instance, Fig. 3 illustrates three targets that are important to achieve. First one is related to selection of interested students. To keep these students, the second target (scholarship) is priority. At last, the third target is parallel infrastructure. Without parallel infrastructure is not possible to execute the proposed method.

In order to select students, it is important to show that education is related to teaching and learning, but mainly, it is related to how to prepare human resources. For this reason, Fig. 4 shows the research titles organization from CArT (Computer Architecture and Parallel Processing Team). The idea is to show that, e.g. memory hierarchy (Multi/Many-core Architectures) can be related to shared-memory programming (Parallel Applications). Both can be evaluated in terms of performance, scalability and efficiency, but mainly, both can be learned together in a method that focuses on research and education.

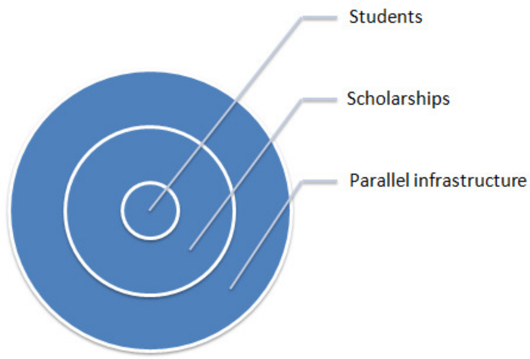

Figure 3. Method targets

IV. Evaluation Results

This section presents all results obtained from last three years based on projects execution.

Fig. 5 shows the number of students involved on projects and Fig. 6 illustrates the number of students with scholarships. There is an effort to get scholarships for all students, but it is important to take into account that some students are volunteers. This number is 7, which represents 31.8% of students. In general terms, each project has two undergraduate scholarships. The number of students per year presented in Fig. 5 represents different students. Therefore, three students from CE in 2011 are different students in comparison to 2012. For the first semester of 2013, the number of students for IS is the same and for other courses one new student is added. It is important to highlight the expressive number of students that work together as class laboratory. This class laboratory is heterogeneous based on students from different courses and levels (undergraduate and graduate) in order to exchange experiences and points of view.

Table III shows the production from 2010 to 2013. Numbers in parentheses are in execution to be concluded in 2013. For instance, there are three master's theses and two undergraduate's theses. The production is related to each project in order to emphasize the importance of each one to prepare human resources. During three years (2010 to 2012) 10 scientific papers were published related to projects. Two papers from total and one tutorial are related to education. All projects contribute to papers, but the distribution in Table III is related to student scholarships in order to eliminate replications. According to Table IV, from the total of 10 scientific papers, 8 papers (80%) have student participation. From other 20%, two papers are related to education (written by professors) without student participation from CArT.

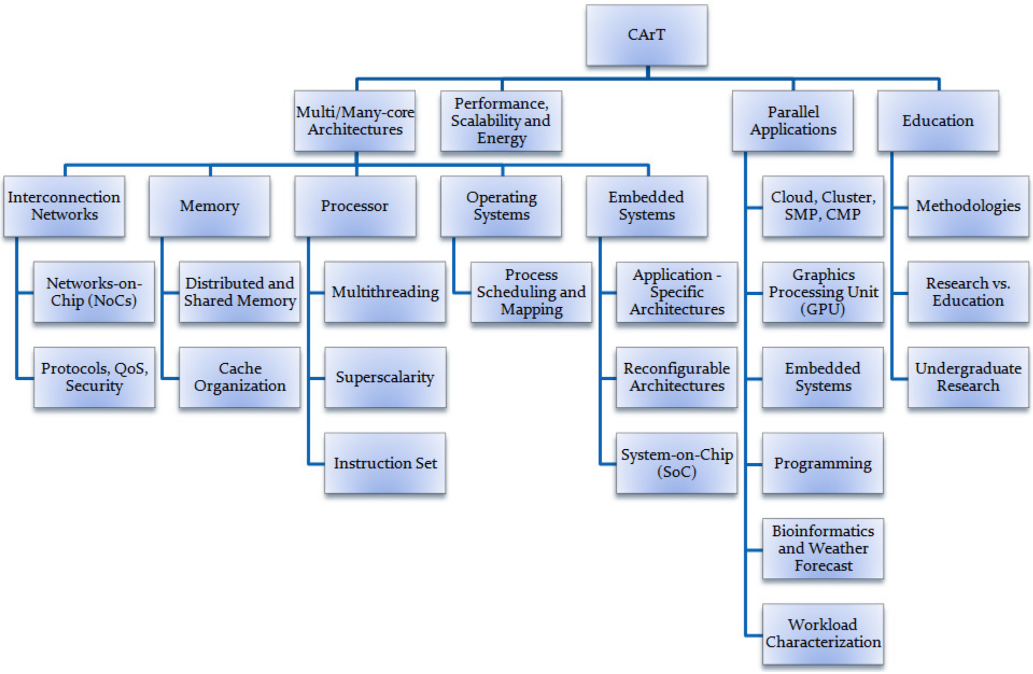

Figure 4. Research titles organization

	2010	2011	2012	2013	Total

TABLE III. PRODUCTION FROM 2010 TO 2013

Results	Projects (Table I)			
	FIP 1	FAPEMIG	CNPq	FIP 2
Master's theses	0	1(2)	1	(1)
Undergraduate's theses	2	2	2	(2)
Total number of scientific papers	1	5	4	0
Student papers	1	4	3	0
Papers related to education	0	2	0	0
Tutorial related to education	0	1	0	0

TABLE IV. STUDENT PAPERS FROM 2010 TO 2013

Courses	2010	2011	2012
Computer Engineering (CE)	0	1	0
Computer Science (CS)	0	1	1
Information Systems (IS)	1	0	0
Graduate in Informatics (GI)	0	3	1

In practice, students create an expectation related to results to publish them. Graduate students are more mature, as consequence, their accepted papers are examples to other students. Results for 2013 are not ready yet, but several undergraduate students are preparing papers for submission. Student feedbacks describe the importance to work together to their formation. The main suggestion is to create small teams based on two or three students to solve the same issue. The best type of team is one graduate student and one undergraduate student, although students at the same level can also bring good results.

V. CONCLUSIONS

Research works point out to many-core processors. A unique chip contains thousands heterogeneous processing cores in order to achieve high-performance with low energy consumption. However, there are several issues related to this new processor generation that are different. For instance, Networks-on-Chip increase scalability but increase complexity. How to program many-core processors based on NoCs? It is not easy to teach parallelism on many-core processors in a typical curriculum, since it is necessary to introduce parallelism based on multi-core processors and computer clusters. How to prepare human resources for this changing (from multi to many)?

The proposed method described in this paper is based on research projects in order to add new concepts related to many-core processors. The idea is to teach to students that we will have a new challenge in few years. Human resources are necessary not to only programming but to design new architectures. Parallelism concepts are necessary to exploit correctly all characteristics of many-core infrastructure composed of computer clusters based on heterogeneous many-core-processors.

Results indicate that students are involved and they want more knowledge about parallelism. Several papers were published and we are working in a new project that focuses on parallel workload model. Because of this, we can describe a list of benefits to students, including continuous and cooperative work along more years (future works), as follows:

- Architectural characteristics (target) that determine software programming;
- Parallel benchmarks for many-core processors supported by NoCs available to download;
- Semester-based classroom education syllabus focused on parallel programming and next generation of many-core processors;

ACKNOWLEDGMENT

This work was supported by FAPEMIG, CNPq, and FIP PUC Minas. Thanks to all students of CArT.

***Abstract*—Engineering students are increasingly being exposed to entrepreneurship education and activities as a part of their academic programs in order to equip them with the knowledge and skills increasingly valued in today's economy. Data collected from a large sample of senior-year engineering students as part of an NSF-funded study titled "Entrepreneurship Education and its Impact on Engineering Student Outcomes: The Role of Program Characteristics and Faculty Beliefs," suggested that these experiences increased students' perceived self-efficacy for entrepreneurship and their intention to pursue entrepreneurial careers. This study expands on the results of previous research by conducting post-graduation interviews with recent engineering alumni who were exposed to entrepreneurship education and/or related activities. Telephone interviews were conducted with alumni who had graduated within the past 2-5 years. The study finds that engineering graduates place high value on their entrepreneurship education and the benefits that it has brought to their careers.**

Keywords—career; engineering education; entrepreneurship; professional development

I. INTRODUCTION

Economic conditions in the past few decades have led to a rise in the delivery of entrepreneurship education to engineering students [1]. Despite this growth, relatively little research has reported on the specific benefits of entrepreneurial training to engineering students. An NSF-funded study titled "Entrepreneurship Education and its Impact on Engineering Student Outcomes: The Role of Program Characteristics and Faculty Beliefs" sought to more clearly understand the level of student exposure to entrepreneurship education and articulate its impact [2]. Data collected from over 500 senior-year engineering students as part of this research found that students who had taken one or more entrepreneurship courses showed significantly higher levels of entrepreneurial self-efficacy on a number of measures and that those students felt that entrepreneurship education could broaden their career choices. This paper seeks to examine the perceived benefits of entrepreneurship education to engineering students in more depth by reporting on interviews conducted with recent engineering alumni.

II. PURPOSE AND RESEARCH QUESTIONS

The purpose this study is to identify the areas in which engineering graduates perceive value from entrepreneurship education and the degree to which it provides them with opportunities in the workplace that they might not have otherwise. It does so by answering the following research questions: (1) What are the professions that recent engineering and entrepreneurship graduates have chosen and what are their responsibilities in these roles?; (2) What are their perceptions of the relative value of specific engineering skills and knowledge to their jobs/careers?; (3) What are their perceptions of the value of entrepreneurship skills and knowledge to their current jobs/careers?; and (4) How does entrepreneurship factor into their future career goals?

III. METHODS

Telephone interviews were conducted with engineering alumni who have graduated in the past 2-5 years. The sample was comprised of 18 former students who were involved in entrepreneurship programs at two universities. The majority of participants in this study were engineering graduates who participated in a campus-wide multidisciplinary entrepreneurship certificate program. Others participated in entrepreneurship programs embedded within their engineering programs. Qualitative analysis of interview transcripts identified common themes and trends.

IV. RESULTS AND DISCUSSION

Common themes that emerged from the interview transcripts provided insight to the four research questions listed above. During the course of the interviews, other themes emerged which are also reported.

A. What are the professions that recent engineering and entrepreneurship graduates have chosen and what are their responsibilities in these roles?

The graduates' experiences in their professions varied greatly. Most of the graduates worked in engineering-related positions, but others had gone into other fields such as education, finance, or law. Some had multiple roles within their organizations, and most reported having a breadth of responsibilities. Although participants in this study had all graduated in the last 5 years, many had already held multiple positions and worked in multiple firms. Table 1 shows the participants' job titles, current company size, and the number of jobs they had held since graduation.

Results show the breadth of professions that engineering students enter. They confirm findings of other researchers that show that engineering students are increasingly employed in positions outside of traditional engineering industries [3]. The fact that a large number of participants had changed employment in their short careers is also indicative of changes in modern work patterns identified in previous research [4].

TABLE I. RECENT GRADUATES' PROFESSIONAL CHOICES

Job Title	Company Size (# of Employees)	# of Jobs Since Graduation
Engineer	200,000+	1
Mechanical Engineer	500	1
Process Engineer	10,000	1
Engineering Specialist	86,000	1
Application Engineer	150	2
Electro-Acoustical Engineer/Scientist	~5,000	2
Development Engineer	20,000	1
Patent Agent	50	2
Regulatory Affairs Leader	300,000	1
Center Director/Owner	5	3
Project Engineer	75	2
Project Engineer	250	2
CEO	35	2
Product Support Engineer/ Marketing Specialist	30	1
Entrepreneur[a]	2	2
Field Engineer	25	2
Software Engineer	65	1
Computer Programmer/ Analyst	100,000	1

B. *What are their perceptions of the relative value of specific engineering skills and knowledge to their jobs/careers?*

Engineering programs expose graduates to a wide range of content areas. As part of this study, researchers sought to understand what knowledge and skills, specific to the engineering (not entrepreneurship) curriculum, were most relevant to their current job responsibilities. Participants were asked to describe how well their engineering programs prepared them for their current positions. While not all graduates appraised their engineering training equally, a common theme emerged as they described how their engineering training affects their current work.

In almost all of the responses, participants emphasized that learning how to think was more important than content. Many of the participants expressed that engineering training taught them how to think and approach problems that they needed to solve. They often mentioned that the content they learned (equations, properties of physics, calculus, thermodynamics, etc.) has had much less application in their current work than the ability to reason through problems and solve them in a systematic way.

> *"I learned a lot of … how to problem-solve, how to think through processes, how to quantify things that aren't quantifiable. So, the more general skills I really enjoyed. Maybe not as much the specific … technical pieces"*

> *"It prepared me to learn some of the more advanced skill sets that are required of electrical engineers, and the few basic electrical engineering classes I took obviously helped, but it was more of a good foundation of the fundamentals that I got while I was in school and have been able to carry with me that have helped me the most as opposed to some of the more, I guess, advanced theory than we learn while we are in school."*

> *"It's intangibles that the engineering program helped teach me – how to prioritize tasks that I needed to take care of, and it taught me how to manage my time and get things done. As far as content, very little of the content I learned as an engineer do I utilize right now."*

> *"I mean, you can learn formulas, and it lets you go into a company where you're actually going to design a gear or design a heating system. You may not be using formulas, but it gave me the fundamentals and the principles to do strategic planning, to work with a group, problem-solve, really look outside of the box for answers, and research. I mean, it gave me a lot of the fundamentals, even though I don't use the actual formulas I learned anymore."*

Some participants had more negative reactions to the engineering content they were exposed to. When asked how well his engineering program prepared him for his current position, on a scale of 1 to 10, one graduate said:

> *"I would say four. … I feel like most things engineering-related were just hard enough work to prove that you had to learn how to work. It's like – in engineering classes – I feel like I learned more just how I study and how I operate than I did actually absorb the stuff I'm going to use in real life. So, that's the four, because the other six is just garbage that I haven't actually used since then. Like MATLAB and all – it's basically like I use computers, I use Excel, email, and then this* [redacted] *program, which we create, and then beyond that it's just personal skills and general computer skills, which I feel like I would have learned anyway or already knew."*

Another student was fairly negative about the content taught while still praising his engineering training:

"I would say that in my current position, the really important things are project management skills, interpersonal skills, general problem-solving skills, like Lean Six Sigma project management methodology, and general technical common sense. So, it's almost as if a lot of my engineering classes were overkill. Like, I tell people I actually don't think I've used calculus once in the past two-and-a-half years. I've done some statistics, some fluid mechanics. So, in terms of was my engineering education lacking in any way? No – … but was it particularly relevant? Maybe not necessarily."

These responses indicate that some recent engineering graduates did not associate much value with a large part of the technical content they had acquired in engineering programs. However, it is difficult to determine to what degree they used this technical training without recognizing it. For example, the quote above mentions "general technical common sense," which could include technical knowledge gained in engineering courses that is not common to non-engineers. It is possible that engineering graduates are unaware of how much more technical knowledge they have than the average person. This hypothesis has been supported in prior research that shows that engineers often participate in mathematical thinking, even when they do not consider themselves to be using mathematical content knowledge [5].

Another participant indicated that he only uses 50% of what he learned in his engineering courses, but when describing the knowledge he does use, he said, "*I feel like the engineering program helped me a lot just in problem-solving and just giving me the technical background I needed.*" In many cases, it seems, engineers do not actively use much of the content they learned in engineering programs, but the "technical background" they gain from engineering coursework is still a prerequisite for them to do their work.

Regardless of the utility of the specific content in engineering programs, engineering graduates in this study highly valued the problem-solving and analytical tools they gained. Learning how to analyze data, prioritize tasks, optimize processes, and approach problems in a systematic way is of great value to engineering graduates whether or not they remain in engineering careers.

C. *What are their perceptions of the value of entrepreneurship skills and knowledge to their current jobs/careers?*

This study focused on engineering graduates who participated in an entrepreneurship programs as part of their undergraduate studies. Participants were asked to describe the knowledge and skills they gained in their entrepreneurship program that they use in their current work. They identified 5 skills and content areas that have been beneficial.

1) Communication Skills: Many of the participants said that entrepreneurship education contributed to their ability to communicate in a professional setting:

"It was the first introduction I had to anything business related, and so, whether that's how to value your own services, how to talk to clients, how to go out and ask the right questions when you're trying to get feedback… that I do on a day-to-day basis still. So, I think – I give it credit, and I say it helped out because it was the first experience I had with any of that."

"I see too many smart people who can't communicate what they've done, and too often it winds up being that the smart people never get promoted or get put into good positions because they can't tell you what they've done."

"I think in the entrepreneurship classes … they had a lot of presentations… I think anytime you have the opportunity to build and give a good presentation and get feedback from that process, that's always going to make you better."

They often cited learning to make pitches and communicate the value of their project as being useful in their current engineering work:

"It's just a way to get organized … going through that business development plan and say, OK, what's your value proposition? What's your target market? What's your budget? How do you expect to get funding? And really being able to answer these in a concise, organized sort of way."

"Trying to sell to companies to get sponsorship money has really given me foundations and formats and different ideas to pitch my ideas to companies…[It] *tells them that I understand the business principles that they're trying to address for advertising and marketing and setting themselves apart."*

"They [entrepreneurship courses] *helped my ability to think about things from a business perspective and also how to communicate effectively. In the entrepreneurship classes they talk a lot about developing your business plan and creating an elevator pitch … So, I think having those types of skills to communicate effectively and without a lot of extra words and to just be straight to the point, I think that was very beneficial."*

Based on the responses from participants in this study, students gained the most when they were given many opportunities to present with feedback from others. They also learned from having strict time constraints that forced them to be clear, concise, and persuasive.

2) Seeing the Big Picture: Many participants in this study said that entrepreneurship courses helped them to have a broader vision than their regular engineering classes. They described how the rigor and technicality of engineering coursework sometimes led to a type of "tunnel vision" in which engineers focused on narrow aspects of design or functionality. Entrepreneurship courses, on the other hand, helped them to step outside of their narrow focus and see how it fit within a larger system:

"Provided balance with the extremely technical coursework of engineering, opportunities to engage in more social interactions in the classroom discussions, be exposed to a wide variety of ideas, and then in addition to all that, learning the fundamentals of small business creation."

"Putting that business plan together, it makes you think outside of the one thing that you're focused on, and in engineering, that's the technical aspect of a business. …but it gets you to think outside of that and then try to at least understand what the other things that you need to consider are, and that's … the most valuable part. It just got you to think outside – gave you the ability to think big picture instead of having tunnel vision."

"I think a lot of the things that a typical engineering student does while they're in college is very one-dimensional. I think a lot of it is theory-based and is problem-solving, but there isn't a lot of … practical application. So, there isn't a lot of hands-on experience necessarily. There isn't a lot of looking at the big picture how some of the things we're learning can be applied to things in the real world. I kind of wish there was more of that. [Entrepreneurship] *helps me sort of look at things from more than just an engineering standpoint. It helps me realize there's more to a business than product constraints."*

This big picture view was described by many of the participants, but it was not always clear what part of entrepreneurship education had fostered it. Some, like the participant in the last quote, thought that working through creating a business plan was responsible for helping her see the big picture. This is supported by prior research on the use of business plans in entrepreneurship education [6], [7].

3) Working With Others: Another common theme was that entrepreneurship courses help engineering students learn how collaborate and work with others, especially with non-engineers. This theme was often, but not exclusively, mentioned in conjuction with seeing the big picture:

"I think one of the primary ways I think it enriched my education was just being able to work together in groups. I mean, in engineering – there's stuff you've got to work on. … You've got to figure out or solve a particular problem, but I think that's a lot different than sitting down with an organized group, getting to work with different, multiple personalities and being able to solve numerous problems, from procedure problems to really identifying goals and tasks. That's actually another thing I found about the program was that it really forced you to sit down and meet with other people and be able to bounce ideas off of each other. You really had a chance to sit down, talk, strategize, meet, plan, and so forth, and I think that's something I carry with me even until today."

"Being able to wear a lot of hats simply because I've seen other people that have those hats has been nice. … The business world's made up of all kinds. So, having been with them in class and know what makes them tick helps when I meet other people that have had the same majors and think the same way, because marketing and sales and other majors have just different views on things. So, it's nice to have seen it before."

"I think entrepreneurship, because it's multidisciplinary, offers a good foundation, because engineers, we don't necessarily have the business or the communication/ marketing side to us. I think by working with them we can figure out different traits that would help compliment whatever career we choose but not necessarily having to go into those programs but maybe having a good understanding of traits that those programs offer."

Some combined the need to see the bigger picture and work with others and described them, together, as a necessary "real world" skill:

"I think for me it's not enough being just able to do the engineering work without having to know the other elements to go after you make the product. In the [entrepreneurship] *program we would study the marketing side, the law side … the copyright stuff, and how to really work in the team, because in the team, not only* [do] *we have people from the engineering school, we also have people from the business school, and in the real world, it really does work that way. You can't really just focus on your engineering stuff and not work with people from … the other perspective. So, being in the program, it kind of helped me in how I see it in the real world now. Mostly dealing with the people, because we have – all of us have different perspectives on how to approach things."*

"It gave me a more well-rounded understanding of what I was going to be getting into after I finished school and went into the real world."

One participant described how the entrepreneurship program helped him to be more creative in group settings:

"Everyone sees the same situation differently, and primarily it's because of how they think and how they're taught to think, and someone that comes from a psychology background as compared to an engineering background as compared to a finance background, we're all going to challenge each other on our ideas. So, we're all going to look at it differently, and if someone comes up with one way of doing something, I'm going to maybe challenge it

and say maybe we should do it this way. …you either come up with very creative ways of doing things that meet others' needs, or you're able to at least understand the perspective that someone in a different background's coming from."

All participants in the study who had participated on multidisciplinary teams said that they appreciated it. Many said that working with students from other disciplines prepared them to work with different stakeholders in their professional work. Entrepreneurship education is not the only way to expose engineering students to students from other disciplines, but it appears to be an effective way to help engineering students collaborate with others in a meaningful way.

4) Help with Obtaining a Job: Many of the participants in this study described how entrepreneurship training helped them to find employment when they finished their schooling. Students who participated in entrepreneurship programs tended to list it on their résumés. They said that their involvement in the entrepreneurship programs became an important topic of discussion with prospective employers.

"When I was first interviewing out of college – I started at [redacted]*, and they really enjoyed – they really liked the fact that I was somebody who was willing to not just take the typical coursework and then just you don't really know what they know. So, I was able to present myself as a – see, look, I'm entrepreneurial-minded. I loved the classes, got the certificate – I didn't just take blow-off electives, because I was actually interested in these kinds of things."*

"So, in my interviews my senior year … I was able to speak a lot to my experience within the entrepreneurship program, and I do think that that kind of set me apart and the fact that one of the summers I was able to intern at a very small start-up company. I think at the time the company was only maybe 30 or 35 people total. So, being involved in this entrepreneurship program really helped me get that unique opportunity to work at a small start-up."

"Well, it was definitely a talking point, especially for the first job. I mean, one of the – the impression I got – I'm not sure how accurate it was – but the impression I got from the phone interview then shortly after being hired was it was a strong interest from the business development manager there that he saw in the entrepreneurship line on my resume, and it did come up in the phone interview. … I think it definitely set me apart … to get that job."

One of the participants was hired in a dual capacity, as a member of an engineering team and a marketing team. His only exposure to marketing was his participation in the entrepreneurship program. He explained:

"I would say when I first got the interview, the one that really attracted them is that, because I put being in the entrepreneurship certificate – I mean, I majored in the mechanical with this certificate – and that's one of the points that really kind of got me the job I would say.… it really helps, because not only I'm doing the engineering work but also the marketing for the company."

In addition to the students who used entrepreneurship as a talking point in interviews, some of the participants made important connections through their entrepreneurship experience:

"You meet a lot of people through these types of programs. I mean, of course you get all the VC and angel investors and stuff that are always snooping around, but you end up meeting – I mean, my last two business partners are people that I met from that class."

"I actually met with [redacted] *when he came and spoke at one of the entrepreneurship classes there at the program, and so – he told me to get in contact with the president of the company, and then just over several months, we developed a relationship, and when this Field Engineering position opened up, I guess I was one of the first candidates for that position."*

5) Entrepreneurial Mindset: Participants in the study often mentioned that entrepreneurship training gave them a new mindset. One way that the engineers described entrepreneurial mindset was tied to the previously mentioned theme of having a big picture mindset:

"I think … as an entrepreneur … you're owning whatever you're doing, you need to have the whole picture in mind. So, I think it's helped me to maintain a big picture view on projects where I don't just get pigeonholed into focusing – tunnel vision – only on what I do, but I can see how pieces fit together with other people that might be working on it or what … their viewpoints might be as well as not being afraid to try and start something new like trying to start a new group or a new process. Instead of just complaining about it, you can go out and start something up to fix it."

Included with this participant's big picture mindset, is the idea that an entrepreneur takes ownership of things and has the power to effect a change if needed. The belief that one has the power to create change has been tied to entrepreneurial mindset in previous research [8].

Other engineers said that described entrepreneurial mindset in different ways:

"I think it's really changed my mindset in a positive way. I think it's allowed me to become a little bit more open-minded both personally and professionally."

"I would say it was perspective, and it was just an introduction to a lot of stuff that I had no clue even existed before. … it was just a whole different way of thinking about things, it really was, …in addition to building a good product, you still have business fundamentals that you

need to operate, and you still have employee psychology that you need to worry about. So, there's a perspective that there's so much more out there than just building and shipping a good product."

Some participants described increased confidence in becoming entrepreneurs as a result of the entrepreneurship courses. They describe how entrepreneurship courses helped them to see entrepreneurship as a viable career option:

"I'd say it was pretty invaluable for education, yes, but motivation probably even more so than anything … the entrepreneurship program showed me that there was another path … we met with a lot of other entrepreneurs in that class, and they got to share their stories about how they did things."

"I would say it makes me a harder worker, because I know I want to hone the skills for when I'm out on my own. So, I think there was always a generic passion in me to try do well in things, but entrepreneurship program made it closer – made it seem like the work will pay off more than … big corporate business life – because I don't think I would ever want to be CEO of a 500+ employee company. So, working up through the project management roles at a big company for the future ability to get to there doesn't hold water with me. I would rather be understanding what a small company needs to survive, and the entrepreneurship program made that seem possible."

"I think it added a lot of the education that I was really looking for and really made me realize that if I did want to open up my own business that I have the tools and the education that I could actually try something – I'll just use the phrase: pursue your dreams."

These statements seem to describe increased self-efficacy as a result of involvement in entrepreneurship courses. Participants described that they would be much more comfortable with forming or working in a startup because of the skills and knowledge they gained in their entrepreneurship courses.

D. How does entrepreneurship factor into their future career goals?

Participants were fairly divided in terms of their future entrepreneurial intentions. A few of the participants had already formed companies and experienced significant success. Some expressed a great desire to start their own companies, while some had little intention to do so. Many of the participants expressed interest in starting their own company, but said they had not found an idea that they wanted to pursue.

Each participant was asked to describe how likely they were to start their own business in the future. Participants rated the likelihood on a scale of 1 to 10. 9 of the 18 participants gave themselves a 10, saying that they were either sure that they would start a business in the future, or they had already started a business at the time of the interview. The mean score for all participants was 7.8, with a standard deviation of 2.5. These responses show that most of the participants have strong interest in starting a business in the future.

E. Other Themes

During the course of the interviews, other themes and ideas emerged that may be of interest to engineering and entrepreneurship educators.

1) Desire for Increased Entrepreneurship Training: All participants in this study expressed a desire to have more entrepreneurship training for engineering students. Participants often stated that they would have liked more depth and wished that they had been exposed to entrepreneurship earlier in their undergraduate studies.

Although they agreed that engineering students should receive more entrepreneurship training, they differed in how it should be administered. Some suggested embedding more entrepreneurship in engineering design courses and projects. Others suggested that all engineering students be required to participate in entrepreneurship minors or certificate programs. One of the participants wanted entrepreneurship to be introduced to engineering students in conjunction with leadership and management training. Among the suggestions most participants thought that engineering students should spend more time in multidisciplinary groups, but one participant felt that multidisciplinary groups make it difficult to focus and suggested having engineering-only entrepreneurship projects and teams. There is a need for more research to be done on the different entrepreneurship program models and their particular benefits.

2) Instructors were Important: Participants in the study tended to credit much of their learning to their instructors. Many described that it was important to hear the experiences of entrepreneurs who had successfully started their own companies. Some felt that association with entrepreneurs was more useful than the content of the courses. Administators of entrepreneurship programs should be aware that students place high value on having experienced entrepreneurs as instructors.

3) Real Experiences were Critical: Although participants in the study reported that they enjoyed the real-world applicability of entrepreneurship skills and knowledge, some of the engineers wished that activities could have been more experiential. They said that they would prefer to actually form startups rather than participate in practice assignments.

"I think I learned a lot going through some of the exercises and projects that we worked on as part of the entrepreneurship program. I sort of wish they made it a little bit more practical. So, rather than doing these theoretical projects where we put together projections… and then said, yes, we think this could be a successful business. I wish we would have done something more practical like being told to start a Kickstarter project, and if it gets funded, then you get an A or something. … It sort of introduced you to the beginning of the entrepreneurial

process, but you didn't get a lot of experience actually executing some of the things that were taught, but, I mean, from an educational standpoint, I would say it was helpful."

This is also an important consideration for entrepreneurship educators. Even though students see value in the program and feel that they learn a lot from it, they still want more authentic experiences and more opportunities to apply what they learn.

V. CONCLUSION

In an increasingly turbulent job market, engineering students are seeking ways to differentiate themselves and gain skills that will make them valuable to companies and society at large. In many cases, students are involved in entrepreneurship programs and activities. Prior research has studied the link between entrepreneurial training and entrepreneurial self-efficacy and intentions. This study adds to that research by using a qualitative approach to understand engineering alumni perceptions of the value of entrepreneurship courses and programs.

Engineers believe that their engineering training has been valuable to their careers whether or not they are currently in an engineering field. They reported that learning how to think and solve problems has been more valuable than the specific content they learned in school.

Participants in this study highly valued the entrepreneurship training they received as well. They credited the entrepreneurship training with helping them develop the abilities to communicate, see the big picture, work with people from other disciplines, find employment, and have an entrepreneurial mindset.

This study also showed that participants in these programs have strong desires to start their own companies in the future. The participants highly value entrepreneurship, and want more engineering students to have more exposure to it. These engineers value instructors with real entrepreneurial experience and want to have more entrepreneurial experiences of their own.

Inculcating an Entrepreneurial Mindset in Engineering Education: Project Approach

Firas Hassan Heath LeBlanc Khalid Al-Olimat

Department of Electrical & Computer Engineering and Computer Science
Ohio Northern University
Ada, Ohio, USA

Abstract— **In a competitive global economy, it is important for engineering students to develop entrepreneurial skills that include effective collaboration and communication, persisting and learning from failure, management, and solving ambiguous problems. This paper summarizes a project that aims to instill these skills as part of an entrepreneurial mindset in engineering students. The project was implemented in an introductory electric circuits class with a mixed representation of students majoring in electrical, computer, civil, and mechanical engineering. Students were organized into groups of two or three to design a temperature sensor using a negative temperature coefficient thermistor. Students groups were provided with customer specifications and were given a month to research the problem and obtain a viable solution. The groups were required to provide evidence compiled into a written product proposal that included a bill of materials, cost analysis, circuit design and simulation, testing plan, layout of the printed circuit board and packaging schematic, delivery time, and the voltage-temperature relationship of the designed circuit. After submitting the written proposal, each group was given five minutes to pitch their proposal using a poster in an effort to convince the customer (in this case, the instructor) that their design was the best and most cost-effective solution.**

Keywords—entrepreneurship; electric circuits; customer appropriate value proposition

I. Introduction

In order for engineering graduates to contribute and compete in the modern global economy, strong technical knowledge by itself is not enough. Graduates are challenged with the choice of how best to enrich the economic return from their knowledge. So, they should have an ability to communicate effectively, manage time, sell ideas, recognize and properly evaluate opportunities, and incur the risk involved with acting to seize those opportunities. The aforementioned qualities lead us to the importance of developing an entrepreneurial mindset. An entrepreneurially minded engineer places product benefits before design features, and leverages technology to fill unmet customer needs [1].

As the world's dependence on technology increases, there is no doubt that the demand for engineers is increasing. This fact puts a demand on engineering institutions to produce well rounded engineers who possess qualities that are relevant to entrepreneurship such as creativity, original thinking, self-control, confidence, comprehensive awareness of market trends, prediction of future demand, conceptual ability, leadership, and initiative.

Entrepreneurship programs add value to students, the degree programs in which they are housed, and the institutions that host them [2]. Curricula that emphasize problem solving, technical writing, teamwork, entrepreneurship, and business management skills can help students overcome the barriers associated with relevance, obtain higher GPAs, and achieve higher retention rates. Specifically, it can improve the retention for women and underrepresented minorities [3]. Engineering Entrepreneurship also supports ABET program outcomes (currently defined as student outcomes) such as the ability to function on a team and communicate effectively in an interdisciplinary environment [4].

Different institutions have used different models to introduce the entrepreneurial mindset into their curricula. For example, Brown University's Division of Engineering has created a two-semester course sequence designed to introduce students to entrepreneurship through a unique merger of classroom learning and industry participation. Deliverables at the end of the two-semester sequence include a business plan and product prototype [5]. A study conducted at George Mason University shows that introducing entrepreneurial concepts in a first-year engineering course can improve students overall perceptions of the engineering profession [6]. The University of Nevada at Reno has developed a special capstone course for senior electrical and mechanical engineering students teamed with MBA students from the College of Business Administration. The course covers all phases of new product development including innovation, patent law, product liability, business, sales, marketing and venture capital [7]. Finally, Pennsylvania State University has introduced an Engineering Entrepreneurship minor that consists of five classes. The first class, Entrepreneurial Leadership, is taught during the junior year and the other four classes Entrepreneurship Business Basics, Introduction to Engineering Design, Technical Entrepreneur, and Product Development are taught in the senior year. The purpose of this minor is to build students' life skills so they can succeed within innovative, product-focused, cross-disciplinary teams [8]. At the authors' institution, the entrepreneurial mindset is also tightly integrated in the curricula through a two-course introduction to engineering sequence at the freshman level, a

This work was supported by the Kern Family Foundation as part of the KEEN (Kern Entrepreneurship Education Network) program.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

two-course capstone design sequence at the senior level, and a business elective covering the principles of entrepreneurship.

It is clear from the literature that most of the work related to entrepreneurship in engineering education has been done either at the freshman or senior level. Courses at the sophomore and junior levels typically contain the bulk of the fundamental engineering science in the curriculum. Hence, it is difficult to develop the entrepreneurial mindset in these courses without sacrificing technical content.

In this paper, we argue it is possible to add extra credit projects that concentrate on entrepreneurial concepts in courses at these levels. Such projects can help students link the gap between the concepts generally learned at the freshman level and only applied in the capstone projects at the senior level. One example of a sophomore-level technical course is electric circuits, which is a required class for most engineering majors.

The paper is organized as follows. Section two summarizes the contents of the electric circuits class. Section three describes the extra credit project that was implemented. The project is an example of a simple addition to a technical course that emphasizes entrepreneurial thinking. Section four explains the outcomes of the project and the assessment data. Section five concludes by giving some ideas on how to adapt the concepts described in this paper to other classes.

II. ELECTRIC CIRCUITS

Engineering students must acquire many skills, one of which is the knowledge of electric circuit analysis. Many branches of electrical engineering, such as power, electric machines, control, electronics, communications, and instrumentation, require knowledge of electric circuit theory. Circuit theory is also valuable to students specializing in other branches of engineering because all engineers use and operate electrical equipment and systems in practice. Mechanical engineers use motors to drive machines. Chemical engineers apply heat and drive pumps. Civil engineers oversee construction sites and use electronic surveying devices. In all of these examples, the instrumentation and control equipment is primarily electrical.

Engineering students learn electric circuit concepts and analysis skills in the Electric Circuits course, which is consolidated into a single course at most universities. That course combines both direct current and alternating current circuits, and covers various topics. Typical topics include resistive networks, nodal analysis, loop analysis, superposition theorem, Thevenin's and Norton's theorems, operational amplifiers, capacitance and inductance, first-order circuits, ac steady-state analysis, steady-state power analysis, ideal transformers, and three-phase circuits.

Despite all of this technical content, we managed to integrate an extra credit project that exposes students to entrepreneurial thinking. The next section describes the implemented project in detail.

III. PROJECT DESCRIPTION

The project was implemented as an extra credit assignment in several sections of the Electric Circuits course. Students interested in participating were asked to organize themselves into groups consisting of two to three individuals to design a temperature sensor. Each group had to pitch a proposal in an effort to convince the customer (in this case, the instructor) that their design was the best and most cost effective solution. To do so, each group had to provide supporting evidence that their design was in fact the best. The evidence was required to be compiled into a three to five page *product proposal* that included:

- a bill of materials
- cost analysis (including the profit and the team members' salaries)
- circuit design and simulation (using specific, physical components)
- testing plan
- layout of the PCB and packaging schematic
- delivery time
- voltage-temperature relationship

Each group had to develop their bill of materials, cost analysis, and testing plan based on an initial customer order of 100 sensors. Each temperature sensor was required to operate in the range of 25˚C to 100˚C. The temperature sensing element had to be a thermistor, which is a variable resistor whose resistance value varies significantly with temperature. To provide a minimal amount of structure and consistency between the groups, each group was required to use the same Negative Temperature Coefficient (NTC) thermistor produced by Murata Manufacturing Company. The specific model used was the NCP03XM102J05RL (the data sheet was provided separately).

The students were also given some of the basic operating principles of NTC thermistors. For instance, the temperature dependence of an NTC thermistor is given by the equation:

$$B = \frac{\ln\left(\frac{R}{R_0}\right)}{\frac{1}{T} - \frac{1}{T_0}} \tag{1}$$

where T_0 is the reference temperature in Kelvin [K], R_0 is the resistance of the thermistor at the reference temperature in ohms [Ω], T is the temperature under consideration (in Kelvin), R is the resistance of the thermistor at temperature T, and B is a constant called the B-constant (measured in Kelvin), which is used for a given temperature range to approximate the temperature-resistance dependence. For the NCP03XM102J05RL model, T_0 = 298.15[K] (or 25˚C), R_0 = 1[kΩ], and B = 3560[K] for the range of 25˚ to 100˚C (i.e., the operating range for the temperature sensor). The error tolerance for this model is ±5% (in resistance at a given temperature), the permissive operating current at 25˚C is 1[mA], the rated electric power at 25˚C is 100[mW], and the dissipation constant at 25˚C is 1mW/˚C. These parameters specify that as long as the current is kept below 1[mA] and power dissipation below 100[mW], then the thermistor will operate as expected (i.e., negligible self-heating). These specifications were given to help simplify the circuit analysis for the students. If they chose to operate their thermistor above this range of current or power, then they had to account for self-heating, which significantly complicates the analysis.

The students were told that the customer plans to use their temperature sensor circuit with a microcontroller that accepts a voltage in the range of 0 to 5[V] in order to close the loop and turn on some fans to dissipate heat based on the temperature. In order to design the control law to be implemented in the microcontroller, the customer needs the voltage-temperature characteristic of the temperature sensor circuit. The only specified guidelines were to make sure that the output voltage was 0[V] at a temperature of 25˚C, and 5[V] at a temperature of 100˚C.

The directions for the project were intentionally ambiguous. This was meant to encourage creativity. Moreover, we provided a vague customer specification to expose the students to realistic customer behavior. The students were given approximately four weeks to design their temperature sensors and produce the written proposal. A few days after submitting the written proposals, the students were asked to give a five minute pitch presentation where each group attempted to sell their product. The presentation was accompanied by a poster made in PowerPoint to help them make their case.

Hands On Electronics
402 W College Ave, Unit: 1799

December 5, 2012
Dear Mr. ,

Our company was thrilled when you sent us your problem involving the temperature varying circuit, the solution to which yielded a very useful piece of equipment that can be utilized for many different applications. The development of such a circuit eliminates the need for a digital sensor and utilizes analog componentry, allowing units to easily be repaired.

The attached proposal outlines the development process for the creation of the Temperature Sensing Circuit. Also included is a cost analysis, explanation of the functionality, and an analysis of the labor and production including projections for future production.

If you have any questions feel free to contact Daniel Meeks at (567) 674-0030 any time.

Regards,

Daniel Meeks,
Communications Officer

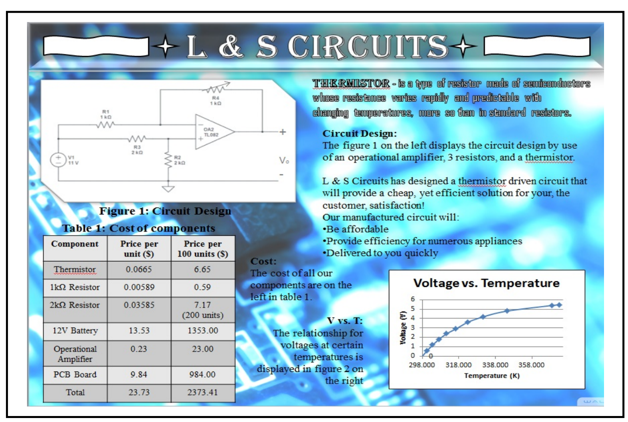

Fig. 6. Sample of a poster

Samples from different students' projects are shown above in the following manner. Figure 1 shows a sample of a cover letter. Figure 2 shows a sample of a bill of materials. Figure 3 shows an example of a designed circuit schematic. The temperature-voltage characteristic of this circuit is shown in Figure 4. Using a curve fitting algorithm, students also found the equation that relates temperature to voltage. Figure 5 shows a sample of a PCB layout. The layout has an allocated area for batteries. Finally, figure 6 shows a sample of a poster that was used as a visual aid in pitching their design.

IV. OUTCOMES AND ASSESSMENT

The project was designed to cover the following three outcomes:

- Effectively communicate a customer appropriate value proposition
- Apply critical thinking to ambiguous design problems
- Effectively collaborate in a team setting

All three outcomes are related to the entrepreneurial mindset of an engineer. The outcomes were assessed based on the students' grades along with a separate student survey.

The students were graded based not only on the quality of the design, but also on the cost of the product, and the ability to effectively communicate and sell their product. The project was worth five extra credit points, and the grading policy is summarized in Figure 7. As shown in the figure, the written proposal was given the highest weight, 50% of the score, because although the pitch may pique the interest of the customer, the substance behind the pitch is contained in the proposal, which summarizes most of the project deliverables. The pitch was given 30% of the score because the pitch is the means by which the idea is conveyed to the customer. Also, the poster is important as a visual aid to help sell the idea and weighs 20% of the grade. Finally, to model real-life competitiveness between different companies, a 20% bonus – i.e., an additional bonus point – was given only to the group that convinced the instructor that their idea was the best, while taking into account that the pitch was backed by substance.

The assessment of the elements of the total grade for the project was carried out largely through the use of rubrics that focus on the project outcomes. The written proposal rubric includes assessment of the overall organization, paragraph development, written language mechanics, and format and style. In addition to these items in the rubric, each of the required deliverables listed in Section III were assessed first based on whether it was reasonable and sound, and second whether it added value to the proposal in a way that differentiated that aspect of the proposal from the competition. The poster rubric includes assessment of the organization of the content, facilitation of communication of content and purpose, connection with the audience, and aesthetic aspects. The pitch rubric focuses on the connection with the audience and verbal and nonverbal delivery.

In any project that involves a group of students, it is usually difficult to assess the work of an individual student in the group. The deliverables are often submitted in written form so that it is impossible to determine the breakdown of contributions among the individuals in the group. However, with a pitch presentation, it is much clearer which students have contributed the most and are most passionate about their work.

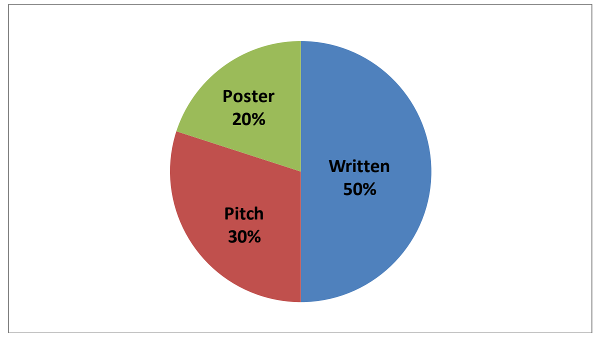

Fig 7. Grading policy

TABLE I. DISTRIBUTION OF STUDENTS' GRADES

Written Proposal			
Points	50	40	30
Number of Students	5	6	5

Poster		
Points	20	10
Number of Students	10	6

Pitch			
Points	30	20	10
Number of Students	3	10	3

A total of sixteen out of forty-eight students decided to take this project. Students who participated in the project were a good representative of all different majors in the circuits class including electrical, computer, civil and mechanical engineering. Also, their overall class grades were spread between A and F. Students who were doing well in the class material were interested in the project to improve their entrepreneurial mindset. On the other hand, students who were barely passing were interested in the project because of the extra credit. As mentioned before, the participating students were asked to organize themselves in groups of two or three. All groups assumed access to all of the equipment in the laboratory, which includes PCB prototyping and soldering stations. They were allowed to consult with the laboratory technician about the cost of operating those machines, as long as an estimated consultation fee was included in their project cost estimate.

Table 1 shows the distribution of the students' grades for the three different grading categories given in Figure 7. As shown in the Table, only two groups--a total of five students--received the full percentage on the written proposal. The remaining groups were penalized because of missing deliverables or non-convincing proposal material. Most groups did good work in their poster design and obtained all points in this category. Only three students were passionate enough to get a full grade on the pitch. Finally, the winning group that consisted of three students was the only group to receive one extra bonus point.

At the end of the project, a survey was given to the students to assess the outcomes of the project from the perspective of the students. The following statements were used in the survey:

S1. The project enhanced my understanding of the course.

S2. The project enhanced my oral, written, and visual communication skills.

S3. The project taught me how to effectively work in a group setting.

S4. The project exposed me in practical issues in an engineering design problem.

S5. The project improved my understanding of economic and fiscal issues of writing a customer-appropriate proposal.

Students were asked to rank these statements using a five-level Likert scale with one being 'strongly disagree' and five being 'strongly agree'.

Out of the sixteen students who participated in the extra credit project, fifteen completed the survey. Table 2 shows the results of this survey. The two most important statements that are closely related to entrepreneurial outcomes are statements 3 and 5. It is encouraging that most students either agreed or strongly agreed that the project taught them how to write a customer-appropriate proposal. While the results for statement 3 were also generally positive, it is interesting that one student disagreed that the project improved the student's ability to effectively work in a group. Perhaps this indicates there was a conflict within that group. Since this project had a significant design component, students strongly agreed that the project improved their problem solving skills. Students also agreed that the project enhanced their communication skills. We believe this is because the project required them to pitch their proposal orally with the aid of a poster. Finally, the results from statement 1 indicate that the project was a successful augmentation to the course. This statement is backed by the fact that the project did not hinder the overall performance of the participating students in the class. On the contrary, one student was able to pass the class because of the extra credit that he was able to receive from the project. A summary of the average scores of the five given statement in the survey is shown in Figure 8.

TABLE II. SURVEY RESULTS

	S1	S2	S3	S4	S5
Strongly Disagree	0	0	0	0	0
Disagree	0	0	1	0	0
Neutral	2	2	3	0	1
Agree	11	12	7	6	8
Strongly Agree	2	1	4	9	6

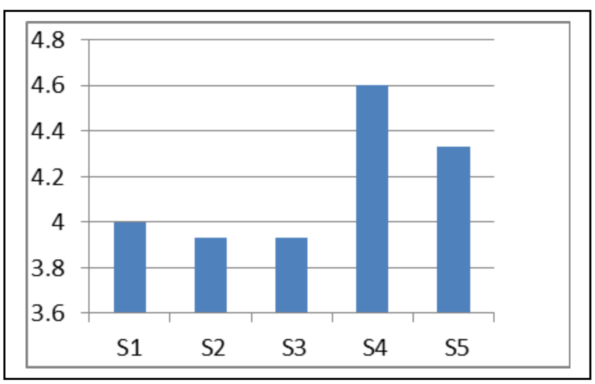

Fig. 8. Average scores of given statements in survey

V. CONCLUSION

This paper summarizes an extra credit project that was given in the electric circuits class to expose engineering students to an entrepreneurial mindset. The Electric Circuits course belongs to a group of classes that are usually given at the sophomore level and considered to be rich in technical content. While there is a lot of evidence in the literature of integrating entrepreneurial mindset at the freshman and senior level, little work has been done at the sophomore and junior levels. The focus of this paper is to cover this gap by using simple projects that can cover entrepreneurial concepts without hindering the technical content of the sophomore/junior level classes. The nature of the project can be adapted to fit in any technical class. First, the project material is related to the topics covered in the class. Second, students were given enough time to work on the project. Hence, the effort they put into the project did not hinder their performance in the class. Third, the project was given as extra credit, so students could choose not to do it. Fourth, delivering the project material only took a small portion of class time. Fifth, the project successfully covers several entrepreneurial outcomes. Overall, it is the authors' opinion that any project with the above characteristics can be easily integrated in any technical course and will instill valuable entrepreneurial skills in the engineering students. Such skills are invaluable in the workplace.

An Agile Embedded Systems Capstone Course

Overview, Experiences, and Lessons Learned

Antonio F Mondragon-Torres
Electrical, Computer and Telecommunications Engineering Technology
Rochester Institute of Technology
Rochester, NY USA
afmiee@rit.edu

***Abstract*— The objective of this paper is to present the outcomes of an embedded systems senior design capstone course offered for Computer Engineering Technology students. This course has being taught five times using the presented format. At every offering, slight modifications have been done in an attempt to improve the student's experience and engagement. The most important intended learning outcomes for this course are: to enable team collaboration, to learn project management techniques, to develop a product from idea to implementation, and to make a professional presentation of their work to an audience. The innovative practices included in this course are: use of Agile Project Management methodologies, no paper trail all information is in electronic form, emulation of an entrepreneurial experience.**

Keywords — Capstone; Senior Design; Embedded Systems Design; Project Management; Agile.

I. INTRODUCTION

You are a senior undergraduate Computer Engineering Technology (CpET) student. As part of your senior design capstone course you are given the task to come up with an innovative product that will be targeted to a particular market segment. You just have ten weeks to come up with an idea and implement it. How would you choose the product? What techniques would you use to document and track it? How can you present this information to show family and prospective investors and employers that you have the capability to come up with a complete solution to solve a particular need? These are interesting problems presented to students. This paper demonstrates the approach taken to manage an Embedded Systems Design (ESD) capstone course by using Agile methodologies.

A senior design capstone is a fundamental experience for the graduates of the CpET program at the Rochester Institute of Technology. This course represents a unique opportunity for students to make use of the entire inventory of skills acquired throughout their program. What are some of the qualities of a comprehensive senior design capstone course? A short list can include the generation and reinforcement of the following skills: team collaboration, ideation and innovation techniques, generation of product specifications and documentation, project management skills, product design and development, and communications through formal presentations.

As the students go through this course, they imprint their stories on a wiki blog; they create, prioritize, self-assign, execute and close tasks; they follow a project management methodology; and they behave like an entrepreneurial start-up company that wants to launch an innovative product.

In addition, all project documentation and source code is available in a code repository for future use. In order to disseminate their work, students create and download to the web videos of their final product. There have been several variations to the course to accommodate industry collaboration opportunities, as well as feedback from students. These modifications will be presented together with an analysis of the outcomes of the course.

In this paper we introduce on how Agile Project Management (APM) methodologies have been incorporated to a CpET senior design capstone course on ESD product ideation, prototyping, demonstration and final presentation.

In Section II an overview of the target course is given. Section III highlights the importance of project management applied to senior capstone design courses. In Section IV specific implementation details of the course are given. Project categories and examples are discussed in Section V. While in Section VI a discussion of the lessons learned is reviewed. In Section VII the paper is concluded and some recommendations for future offerings are given.

II. BACKGROUND

At the end of their program, engineering students traditionally are required to take a senior design capstone course. This is an invaluable experience where students get an opportunity to apply most of the skills acquired through their program in an open ended practical project design experience. Many employers when conducting job interviews are interested in knowing details on the student's "Senior Design Project." Their objective is to get more information on how they perform when: working under pressure; collaborating as part of a team; coming with innovative solutions; setting and following a development plan; and finally their level of engagement in their project.

An embedded system is the combination of hardware (HW) and software (SW) to tailor a product to perform a specific function. Embedded systems are everywhere, from e.g. medical devices, toothbrushes, smart-phones and cars. ESD traditionally requires multidisciplinary teams.

Our CpET students have already taken a strong sequence on ESD and are proficient in both HW and SW as described

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

in [1]. Until this course, their experience has been based more on weekly laboratory exercises where the expected outcomes are defined by the instructor, rather than the student being allowed to come up with an independent solution based on their already acquired set of skills.

In a senior design capstone course, students could be presented with an open-ended problem to come up with a solution using the skills and knowledge acquired through their program. In this particular course, students have to come with a realistic implementable solution within ten weeks from idea to implementation, including a working prototype and accompanying documentation.

In the presented course, students apply Agile project management techniques as a tool to develop their product. Once the project is finished, the development process is compared against traditional project management techniques. This particular course attempts to give students a comparable experience to that of a small startup company with limited resources, time to market (TTM) constraints, and facing global competition.

The most valuable aspects of the concepts presented in this course are the experiences the students go through to take a project from idea to conception. The initial ideas and format of this innovative course have been reported in a previous work in progress [2] and later in an industrial success story [3].

While the goals of this particular course were accomplished in previous offerings in a more traditional project management framework, the innovations included in this new course offering are: product specifications definition based on a target market; team self-organization; creation of a product backlog task list; task prioritization and execution during a finite period; self-assignment of tasks; work on incremental releases of the final product; creation of competitive but at the same time collaborative teams; HW/SW reutilization by the use of version control software; product differentiation; creation of intellectual property (IP); evaluation of TTM requirements; work with an open source hardware (OSH) and software (OSS) mentality.

III. PROJECT MANAGEMENT AND RELATION TO SENIOR CAPSTONE DESIGN COURSES.

A. Traditional Project Management

Traditional project management techniques such as those proposed by the Project Management Institute (PMI) are based on a waterfall approach where there is a sequence of stages and handoff procedures at each stage. This approach is excellent when the complete project has already been done at least once and subsequent implementations are just variations of the original project. Once a project has been successfully implemented, Lean Six Sigma quality improvement techniques could be applied to streamline the process.

To be able to come up with a creative an innovative product the question is: What project management techniques could be applied when:

- A project is being realized for the first time?
- There is no previous expertise?
- It is challenging to create a work breakdown structure?
- It is difficult to estimate resources at the different stages?
- It is hard to estimate the time to complete each task?

B. Agile Project Management

One of the possible answers is to use Agile Project Management (APM). One of the strengths of APM is that at every stage, a workable product is generated with a specific number of desired features. It is like compressing a waterfall process with very well prioritized objectives at every stage. Another interesting feature is that the teams are self-organized and self-managed.

In APM, product features are divided into a series of high level tasks or "user stories" and entered into a list denominated the product backlog. These tasks are then prioritized. A subset is selected for implementation during a finite amount of time called "Sprint" thus creating a "Sprint Backlog". The team members self-assign tasks from the sprint backlog and start working. Whenever a task is completed it is marked as closed and the team member selects a new one for execution. Ideally a team must be multidisciplinary and composed of 5 to 7 members. A sprint allocated time can range from couple weeks to couple months. This is done in order to make the best use of resources.

Agile methodologies are ideal for new product development since it is executed as a series of iterations. At the end of each sprint, a working version of the product is delivered. At the beginning of each sprint, a series of product features are prioritized for implementation. At the end of each Sprint, a retrospective is held to analyze the results, and a new set of features is prioritized for execution in the next sprint. This is a very important step to take since product owners or the development team can realize if the product is what they conceived at the beginning or not. Appropriate decisions can be taken at this time gateway.

In APM there are three main actors: the product owner, the scrum master, and the development team. The product owner has the vision and is the one that sets the direction of the project. The scrum master is a project manager who is in charge of providing resources and tracks the project; their vision is very broad and they do not have to have expertise in the particular implementation aspects. The developer team is specialized and their vision is very specialized or narrow, that is why a cross-disciplinary team is the best. In APM there is no team leader and all members collaborate to accomplish the tasks scheduled for that particular Sprint.

While APM techniques have been used for software design for more than a decade, just recently PMI has recognized APM as an alternative to the traditional waterfall approach. Several companies such as e.g. IBM and HP have recognized its usefulness and have available products and services based on APM [4-8].

IV. Course Development

A. Team Collaboration

As simple as it can be thought, collaboration is not an easy task. For most of their program, students have worked individually in homework assignments, laboratory exercises and have taken exams and quizzes. Team collaboration can be a natural social process or it can be very disruptive. Students are free to choose their teams but in some cases there are students that do not know other people in the course and have to be assigned to a team without prior knowledge of the team members. There are four cases with their respective advantages and disadvantages.

1) Advantages

a. A particular student may have already a very well established relationship with other students and may have collaborated in other courses and they will be proactive and have an excellent collaboration.

b. Even students that do not know each other beforehand can take a very proactive approach and have an excellent collaboration.

2) Disadvantages

a. A particular student may have already a very well established relationship with other students and may have collaborated in other courses but some of these students may not be equally proactive and there will not be a fair work distribution.

b. Even students that do not know each other beforehand may not take a professional approach and have problems collaborating.

In this course we have observed all cases being the majority 1a, 1b. Case 2a is not desirable since it depicts an unfair but real life situation. Even in these cases there have been great projects where few students have hold the project together. A few 2b cases have ranged from teams that have not been able to agree on meeting times to disruptive teams where students work independently and do not communicate.

B. Product Specification Documentation

Generating product specifications can become a daunting task. To come up with a new product innovative idea is not a straight forward task for all students. A very important part of the design process is to think thoroughly and systematically to come up with a good set of high level and functional level specifications.

Unless students have experienced this process while working in a company, most likely they have not been exposed on how to create specification documents. Furthermore, during the specification gathering phase they most likely overlook some of the product's critical features.

Students are asked to generate two types of basic documents: high level specification (HLS) and a functional level specification (FLS). The HLS has the information required in plain English for any person to understand the objectives of the project and the product features; this is the document that could be delivered to a potential investor. The FLS are a series of documents that will allow an engineer to reproduce or maintain the design and has all the technical information required.

C. Entrepreneurship

In the present course, the target is to give a good capstone experience to students, and have taken some steps to make this course as close as possible to a limited entrepreneurial experience. One of the project's restrictions is that they need to choose a target market where their product could be sold. The number of products to be sold is not relevant but a niche market need or a need has to be identified.

Students work as a small startup company that needs to come up with a market specific product. In addition, the students are required to create a working prototype that is demonstrated before an audience, create an upload a video of their product and give a formal presentation. Furthermore the project should be based on open hardware and software to promote reusability and collaboration. Incoming students have access to a repository of previous projects and could start right from where a former group ended to add more functionality or extra features. Students are asked to develop a company name, motto, logo and a product name and description as seen in Fig. 1.

D. Project Management

What makes this course to stand out is the adaptation of Agile project management methodologies to a senior capstone course on product ideation, prototyping, demonstration and final presentation. We have identified that innovation requires a new set of tools and shorter life cycles in order to match TTM constraints. Students go from concept to prototyping and demonstration in just ten weeks. These are some of the reasons why more versatile project management techniques that will allow the students to

Focus is on using a large number and variety of low cost, low power sensors to create an overall intelligent network through the use of cloud based data aggregation and cloud hosted applications.

Fig. 1. Company information worksheet

execute, evaluate, and make corrections in an iterative efficient way are needed.

One of the intended goals of this work is to encourage other departments at RIT to integrate the proposed techniques and extend disciplines collaboration. In order to accomplish thesea Provost Learning Innovation Grant (PLIG) has been assigned to continue, expanding and disseminating this methodology to other senior capstone design courses within RIT. A more formal approach to senior design example is already offered in the engineering school's Multidisciplinary Senior Design (MSD) (our students are in engineering technology). In this MSD course traditional PM waterfall methods are used instead of APM.

E. Project Execution

The objective of the project is to be open-ended. After the students identify the product vision and features, they start working on implementing those features selected in the sprint backlog for development in a fixed amount of time.

Being the project open-ended, there is no penalty for not implementing all the expected features like in some other courses. The difference is that in this course, there are no recipes or guidelines. Students are free to choose any hardware/software platform to implement the product's vision. Some students rely on just the acquired skills e.g. C/C++, VHDL, Altera FPGAs, and TI MSP430. Some other students embark on the task to learn complete new platforms, operating systems and programming languages such as e.g. ARM, Web Servers, Linux, Perl, Python, Java, Javascript, JSON, C#, SQL, and PHP. This is a very interesting result since students have not been limited to what was taught in courses and they have chosen to learn alternative vehicles to implement their ideas.

The results have been extremely positive in terms of student engagement; all projects have worked to an acceptable level. What is meant is that the original vision of the project has been accomplished. To observe how students research what will be the best and less time consuming way to accomplish a particular task has been very impressive. This is really important skill in these times when TTM and global competition are part of the equation.

1) Blogging

Students are asked to imprint their experience in a blog. This is where they document all the phases of their design. The course blog site is shown in Fig. 2 and a particular team's blog site is shown in Fig. 3. As mentioned previously, in this course there is no paper trail all documentation and source code are available at the different course web sites as well as in a version control repository. HLS and FLS documents are available at both the blog site as well as the version control repository. A project overview is shown in Fig. 4 as available in the blog site. As part of the blog information, students are asked to generate a story of their project. In Fig. 5 it is shown the original Microsoft Project waterfall project plan as well as project update photographs of their accomplishments.

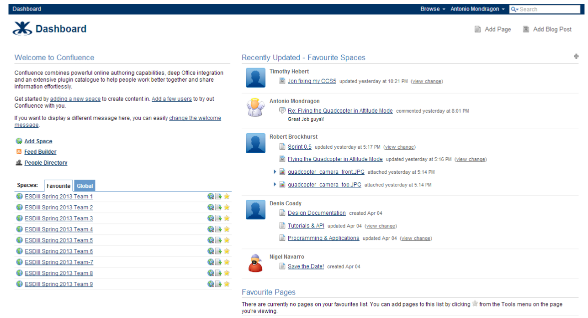

Fig. 2. Course Blog page.

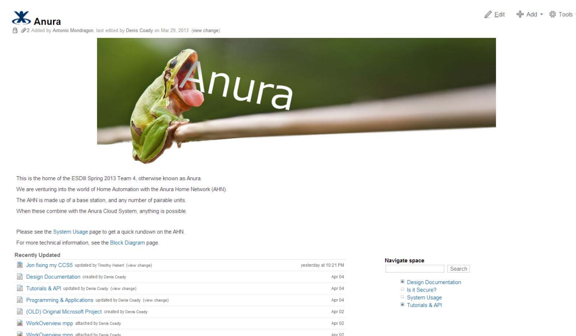

Fig. 3.Team blog site

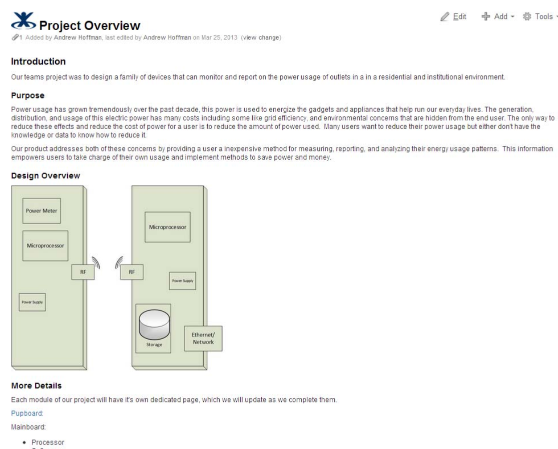

Fig. 4. High level specification document.

2) Project Tracking

In Fig. 6 it can be observed a quick view of the status for several projects. The plot on the left denotes the level of activity for a particular Sprint. The plot in the middle is a representation of tasks created against tasks completed. The right plot is a distribution of the tasks among team members. For the scrum-master this is a project progress snapshot. In Fig. 8 the "Planning Board" it is shown where all tasks for a particular sprint are organized. In Fig. 7 the "Task Board" is shown where the actual task tracking process is performed. The tasks can be in one of three states: "To Do", "In Progress" and "Done".

V. PROJECTS

There have been a total of twenty six different projects using the presented format. All projects are available at: http://antoniofmondragont.wordpress.com/

A. *Major Classifications*

- Audio (MP3 player, social network audio player)
- Energy (Power meter, smart plugs)
- Sensing (Weather meter, strain gauge measurement, vehicle surveillance, elderly care monitor, fruit ripeness sensor, internet of things)
- Video (Camera interfaces)
- Robotics (Roomba robot, line follower, quadcopter)
- Human Interface (Interactive office scheduler, wireless painter)
- Consumer (Auto diagnostics, notification system for deaf and hard of hearing, smart cane for deaf/blind, drink mixer, equalizer coffee table)

B. *Different offerings*

The first quarter the course was offered, the students had been exposed to just two different hardware platforms, one microcontroller in the second year and an FPGA that was used for four consecutive courses. As the course offerings have progressed different alternatives have been proposed in an attempt to leave students with the freedom to choose the project and then find the best hardware platforms, operating systems and languages to accomplish their goals. This is a summary of the different combinations of hardware platforms and communication used:

- FPGA only
- FPGA + Microcontroller
- FPGA + Microcontroller + Wireless
- FPGA + Microcontroller + Internet Connectivity
- Microcontroller + Wireless + Internet Connectivity

In Fig. 9, four projects are shown with different implementations of the above mentioned combinations. The “Micro Strain Gauge Wireless Real Time Measurement” was based on the Texas Instruments (TI) MAVRK platform and integrated wireless connectivity with a PC running a graphical QT interface (top left), the product owner was a joint effort between the MMET department and TI. The “aIRbrush” was a remote infrared (IR) drawing device using a Raspberry Pi, a Wiimote and a custom made IR marker (top right), the team was the product owner. The “Interactive Scheduler” came out the need to have a more systematic way to schedule appointments with faculty, the students proposed to build such a device (bottom left). The project was based on an Altera DE-2 115 FPGA board with a 7” resistive touch screen and a camera, the faculty was the product owner. The “eWaft” came out as an idea to build a device to measure the levels of methane in rotten food and over the time transformed to be a peach ripeness sensor (bottom right), the product owner was the department of Packaging Science.

Each project has been unique and all projects have worked to different levels. We have found that the individual level of student engagement has been the most important factor in project success. There have been great projects developed by complete teams and other also great where just one or two students were really engaged. Engaged students had earned better grades since weekly work is counted towards the final grade. Students have been sincere and have acknowledged who worked more and deserve a better grade.

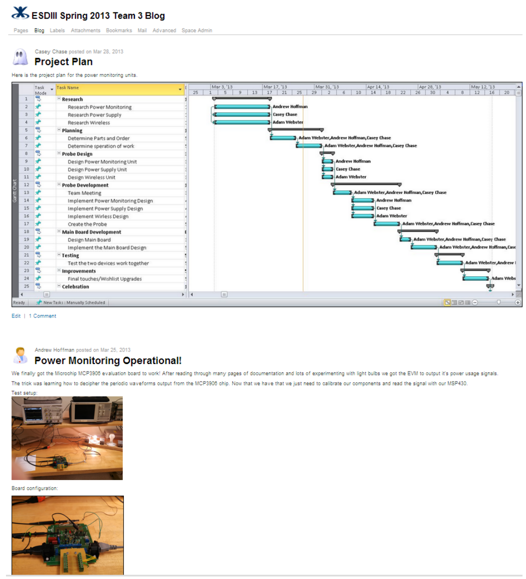

Fig. 5 Original project plan developed in Microsoft Project and project update blog and photographs.

Fig. 6. Projects dashboard.

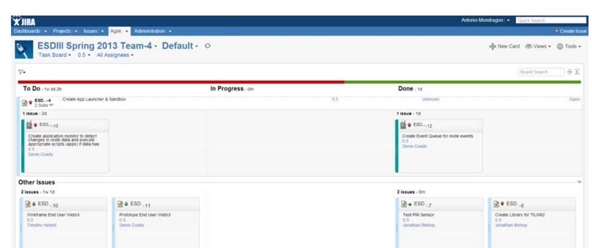

Fig. 7. Task Board

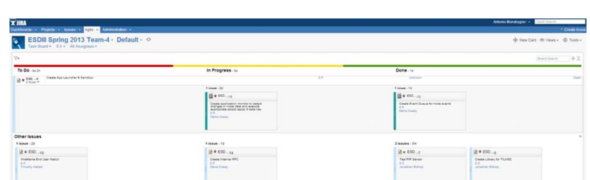

Fig. 8. Planning board

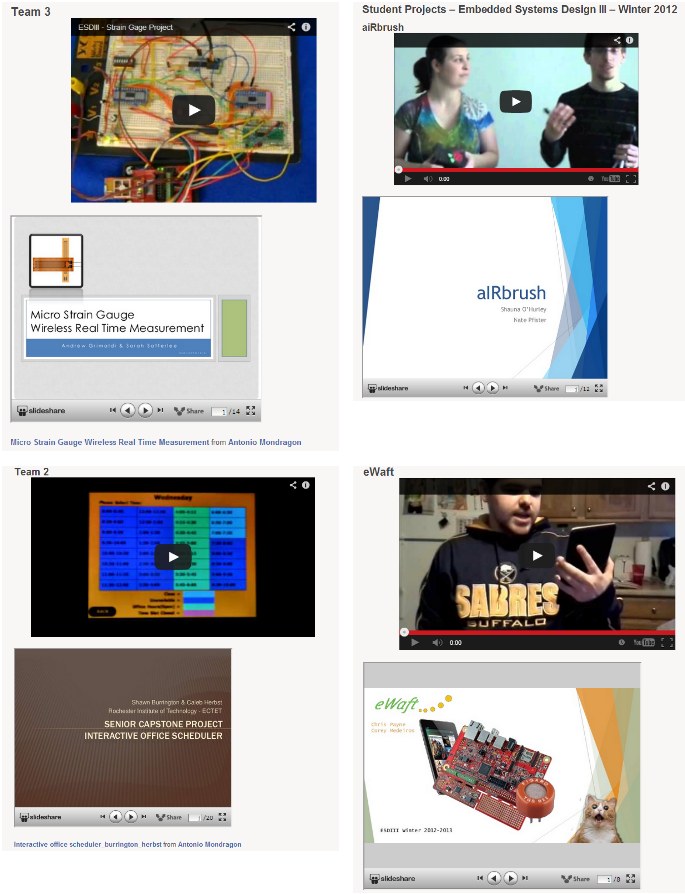

Fig. 9. Project information available for each project. Youtube video with product demonstration and slide show final presentation.

C. *Collaboration with Industry and Faculty*

There have been several interesting engagements with product owners from industry as well as faculty and even entrepreneurs looking to have somebody implement their ideas. A collaboration with TI has been published in [3] and another with Mathworks was showcased during "Imagine RIT." A large number of companies have supported this course by HW/SW gifts in kind. Many of the project ideas have been possible using the platforms introduced at the "ARM Developer Day™"[9] workshops. During the different course offerings, there have been lectures on RTOS from QNX as well as several invited lecturers which have given students another perspective from the software engineering and sustainability points of view.

D. *Course Deliverables*

As part of the grade, students are asked to deliver the following items during their final presentation and project hand-off.

- YouTube video
- Elevator's pitch
- High-Level and Functional Specifications
- Contributions & Differentiation
- Retrospective and Lessons Learned

	Historical Department Previous Winter 20122	Winter 20102	Spring 20103	Spring 20113	Winter 20122	Spring 20123
How much you learned	4.04	4.14	4.34	4.34	4.60	
Motivation	3.78	4.42	4.56	4.78	4.40	
Overal Rating of the course	3.95	4.15	4.23	4.44	4.40	

Fig. 10. Student evaluation responses for learning motivation and overall perception of the course.

E. *Course Results and Statistics*

In Fig. 10, a selected set of the university's student evaluation questions was chosen to evaluate student's perception on the course. These questions were: 1) How much you learned? 2) Motivation and 3) Overall Rating of the course. It can be appreciated that there is an increasing trend with respect to the initial values prior to the course was taught in the present format. The previous offering was modified from a traditional lab based course with a big project to a set of individual projects with different team sizes. It seems that "How much you learned?" and the "Overall rating of the course" are consistent with a fit value R^2 close to 1. It can also be observed that there is an improvement per quarter of around 12% to 16% which is encouraging. The "Motivation" shows a drastic decline in the last offering "Winter 20122" (but still 4.4/5.0 which is good). This result was very surprising since most of the students were apparently motivated to work on the project.

The motivation question results during the last offering were a very interesting result since there were actually two factors to be taken into account: first was that this was the first quarter in which the FPGA platform they used in four courses was not mandatory; and second 80% of the students already had a job secured while taking the course. On the other hand, all teams selected platforms that they have never worked with and even the developing languages for all teams were new (e.g. Python, Pearl, Squirrel, bash script). It is interesting that they were able to design their projects using totally new platforms and picked up programming and script languages in just ten weeks. Overall results seem consistent with a good senior design capstone experience and many great projects have resulted.

VI. LESSONS LEARNED

One of the most representative projects was done during the first offering of the course where two teams worked competitively to create an MP3 player. One project had two processor cores, one dedicated to audio and the other for LCD touchscreen and control. This was technically a very successful project which was showcased at Imagine RIT. The other team had organization problems and there was basically one or two members holding the project. One of these students worked on a very attractive screen display. Technically the project was not as good as the other but the user interface (UI) was really nice.

Every quarter this example is shown to students and a brief story is given, then we vote for which design they will buy. The majority chooses the second project that had limited performance but a very nice UI, while the first project was fully operational but with a simple UI. The lesson that is conveyed to students is that both parts are equally important. A product has to have all the required technical features as well as a nice external design and an engaging UI that should appeal to customers.

Another lesson learned was the following: While the DE-2 FPGA platform used in previous courses comes with examples on how to use different communication devices such as Ethernet and USB, these examples were tested using older generations of the software. When students attempted to use these, they spent a considerable amount of time trying to bring-up these interfaces without success. At that moment, decisions had to be taken in the middle of the course where some of the features had to be revised, moved to another platform or just discarded. This experience for students is very important since they are used to work in laboratory exercises where everything is tested and they know they will be able to produce the expected results. Students learned how to take decisions that completely changed the essence of the product, but not the vision.

Communication protocols was recognized as a skill that was deficient in the first course offerings. Several projects that required platform communications either between embedded devices or with a personal computer, probe to be above the level of skills students had. Students spent a large amount of time trying to create a communications protocol. This skill has been incorporated into a prerequisite course to make the students fluent in this process.

VII. CONCLUSIONS

Students are presented with an open ended problem to be solved using the knowledge acquired through their CpET program. They have to come with a realistic solution within ten weeks including a working prototype and accompanying documentation. Students apply Agile project management techniques to develop their product, and at the end of the term these are contrasted against their initial vision using traditional project management techniques for planning.

Students have been given a similar experience to that of a small startup company with limited resources, time to market constraints, and facing global competition. Students had the opportunity to give a live demonstration of their product, create a promotional video and to give a formal presentation of their work; this closes a very important aspect of their education at the same time that gives the lifelong learning skills. All projects worked as initially envisioned with limited or added functionality which again depended on student engagement and good decisions taken along the course of the project.

The student's experience seems to be consistent even several modifications have been done. Students recognize that they were able to develop a product from idea to implementation by performing extensive research, by applying project management techniques and by self-learning. They have gone through all of the facets required to have a successful product.

It is recommended to allow the students to come up with their own solutions to problems. What would be ideal is to have multidisciplinary teams collaborating towards a complete innovative product. Also it would be very beneficial to have a seminar prior to this course to go over all the material required and to start the course with a project already defined and just work towards its implementation.

This course will be offered in a semester version which will allow more time to develop their skills and get a more refined product. The objective of this work is also to look for collaboration with other engineering technology disciplines as well as other colleges. There is hope that out of these experiences students will become motivated to create innovative products and startup companies may emerge. One of the goals of this course is to plant the ideation seed to get back to the levels of innovation required to come up with practical solutions to solve every day challenges.

Abstract – **As a result of economic and workforce trends, there is a strong interest among policy makers and educational stakeholders in graduating more engineers with entrepreneurship skills and an entrepreneurial mindset. Given the role that ABET accreditation takes in shaping undergraduate engineering curriculum, wide adoption of entrepreneurship education could be driven by demonstrating the manner in which its outcomes align with accreditation mandates. This work in progress describes research taking place that is designed to develop a robust rationale for aligning entrepreneurship education with ABET Criterion 3 a-k, and to provide examples of the manner in which entrepreneurship-related outcomes can meet these criteria.**

Index Terms – Entrepreneurship, ABET, Accreditation; Engineering Education

INTRODUCTION

As a result of global economic and workforce trends, there is a strong interest among policy makers and educational stakeholders in graduating more engineers with entrepreneurship skills and an entrepreneurial mindset in order to better prepare them for a fast-changing professional environment. Consequently, over the past decade, engineering students have had increased access to entrepreneurship education and related experiential learning activities than ever before due to growing demand for engineers who possess a broader range of professional skills that allow them to lead and advocate for product and process innovation activities and venture development initiatives.

Despite heightened awareness of the relevance of entrepreneurship education to the discipline of engineering, studies have found that delivery to undergraduates is not yet widespread or institutionalized and that few students were exposed to it even at institutions with formal programs available to engineers [1, 2]. At many institutions, entrepreneurship education is often provided through elective programs, such as minors, which do not reach all engineering students. There are several major barriers, related to curriculum, that limit delivery of entrepreneurship education to engineering students. First, there is limited space in many engineering academic programs, which allow students to participate in electives that teach entrepreneurial thinking and skills [3]. Further, trends such as the increasing pressure at many institutions to improve four-year graduation rates and affordability for students, can further hamper students' ability to enroll in elective courses and participate in extra-curricular programs.

Embedding entrepreneurship-related knowledge and skills into the core of the engineering curriculum could be an effective manner to reach a wider population of students. More recently, changes in standards have emphasized a wider range of skills pertinent to engineers in order to better prepare them for "real world" engineering, broader career options, as well as management and leadership positions within organizations [4], many of which are in alignment with the entrepreneurial mindset and skills [5, 6]. From an engineering faculty and program administrator perspective, ABET accreditation is often viewed as driving the outcomes and content of core engineering courses. Better communication of the manner in which entrepreneurship education objectives meet ABET criteria could be a catalyst for programs to adopt more entrepreneurship-related objectives. It may also drive faculty to embed more entrepreneurship-related curriculum and activities into foundational or required courses.

PURPOSE OF THE STUDY

The purpose of the study is to: (a) identify and validate entrepreneurship-related outcomes that are pertinent to engineers; (b) map these to ABET Criterion a-k; and (c) develop a matrix illustrating this alignment and overlap. This work is intended to serve as the foundation for the development of an easy-to search online resource of entrepreneurship learning modules and assessment tools designed to meet ABET guidelines while infusing entrepreneurial skills into courses and programs

WORK COMPLETED TO DATE

A list of entrepreneurship education competencies pertinent to engineers was generated from a small group brainstorming session at the Stanford Epicenter Retreat in

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

2012. After the retreat, a subset of researchers agreed to transform the work into a research study that would achieve the objectives above. The first step involved examining the entrepreneurship education literature to develop and expand the list of relevant competencies. Via multiple iterations, entrepreneurship-related learning outcomes were refined and organized into four content areas: (1) creativity, (2) innovation, (3) entrepreneurship and intrapreneurship, and (4) management and leadership competencies. Figure 1 shows their interrelation and the relevance of management and leadership, which are pertinent at many points along the continuum.

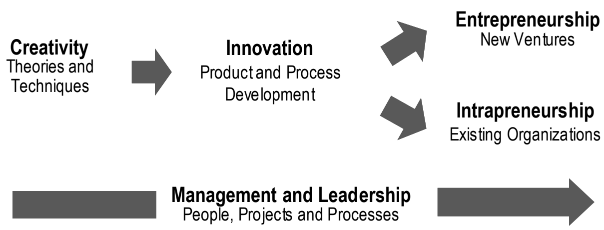

FIGURE 1
CONTENT AREAS FOR ENTREPRENEURSHIP COMPETENCIES ADAPTED FROM [7]

Individual competencies are presented in Table 1. Key words from Bloom's Taxonomy were used to incorporate the cognitive, affective and psychomotor learning domains. A preliminary mapping to ABET a-k was also explored, but not included in this summary. The next phase of the research will involve validating the competencies and their mapping to ABET a-k, by seeking input from a larger group of thought leaders within the areas of entrepreneurship and engineering education.

TABLE 1.
ENTREPRENEURSHIP-RELATED COMPETENCIES PERTINENT TO ENGINEERING STUDENTS BY CONTENT AREA

CREATIVITY - THEORIES AND TECHNIQUES

Design iteration
- Employ frequent iteration to improve a design
- Understand that failure is learning
- Extract learning from design iteration failures and successes

Opportunity recognition -- Environment
- Understand how changes in science industry and economic forces create opportunities
- Evaluate current and future trends and their impact on new venture opportunities
- Compare/contrast the different opportunities and how they create value

Opportunity recognition -- Customer focus
- Identify methods used to capture customer needs
- Detect latent or explicit unmet needs among customers
- Formulate needs into engineering problem statements

Creativity
- Use ideation techniques to generate ideas and opportunities
- Understand the environments, practices, and processes that foster creativity

INNOVATION - PRODUCT AND PROCESS DEVELOPMENT

Prototyping
- Develop specifications for usability and functionality testing
- Identify resources and techniques for prototype development
- Produce working, testable prototypes of the product/service

Feasibility analysis
- Evaluate the feasibility of moving from prototype to commercial product
- Perform market research to quantify market demand
- Conduct financial analysis of opportunity by developing budgets and pro-forma financial statements
- Relate industry and regulatory laws and standards to a design concept

Intellectual property
- Perform a comprehensive patent search for a design concept
- Justify the appropriate legal protection for a design concept
- Generate documentation necessary to file for a provisional patent

Resource acquisition/identification
- Identify potential partners for sourcing, manufacturing, and production
- Assess human capital needs
- Identify physical capital needs

Life cycle
- Analyze current product life cycles to anticipate future needs
- Demonstrate consideration of product life cycle in design decisions
- Demonstrate awareness of sustainability issues

ENTREPRENEURSHIP AND INTRAPRENEURSHIP

Legal
- Select most appropriate legal entity for new business venture
- Understand the use of non-disclosure agreements
- Understand the process and costs associated with IP protection

Marketing
- Identify sources of, and methods to obtain, primary and secondary market research
- Perform competitive analysis to develop a value proposition
- Use market segmentation to develop a marketing plan and budget

Funding/finance
- Determine financial requirements for a new venture at various stages of development
- Understand the process and requirements for obtaining funding from different sources
- Identify the pros and cons of various funding sources
- Understand business valuation

MANAGEMENT AND LEADERSHIP

Leadership
- Develop and clearly communicate a vision for the venture/organization
- Translate vision into goals and metrics
- Delegate tasks and organize work groups effectively

Communication
- Convey accurate and appropriate information tailored to stakeholder needs
- Create and give persuasive presentations and reports on status
- Collect and synthesize information from multiple sources

Project management
- Select and use appropriate project management tools and methods
- Give team members clear assignments and feedback
- Create a process for measure and reporting on progress and performance

Negotiation
- Understand and express the positions of various stakeholders
- Apply of the principles, strategies, and tactics of effective negotiation
- Identify and negotiate solutions that are satisfactory to all stakeholders (win-win)

Team building
- Identify talents and styles of individuals within a team
- Assemble work teams that make best use of members' skills and knowledge
- Implement guidelines for managing and evaluating team performance

CONCLUSION

The study is intended to provide a means to demonstrate and advocate for the integration of more entrepreneurship education in engineering programs by demonstrating its relevance and applicability to meeting ABET accreditation requirements. The next phases of the work will explore the relative importance placed by educators on particular entrepreneurship-related categories and specific learning outcomes. Ultimately, the goal will be to create a resource for faculty interested in embedding more entrepreneurship-related curriculum and activities into foundational or required courses.

ACKNOWLEDGEMENT

This work originated from a working group assembled at the NSF-funded Stanford Epicenter Retreat in 2012 and was made possible through a grant from the National Collegiate Inventors and Innovators Alliance.

Design Wars: Developing Student Creativity Through Competition

Preston Oihus, Andrea Surovek, and Dean Jensen
South Dakota School of Mines and Technology
Rapid City, SD

***Abstract*— Design Wars was developed as a multi-disciplinary design competition in which teams of students receive the same assignment, materials, technology tools for communication and time to complete the project. The student teams were separated into two groups – the documentation team (in the "design office") and the actualization team (on the "build floor'). They were tasked with designing, constructing, and documenting an engineered solution to a complex problem on site within eight hours, with all design decisions communicated between the two groups via mobile computing. The competition was developed to challenge the students' creativity and communication skills; judging was based on the elements of creativity including originality, flexibility, fluency, elaboration and aesthetics. Additionally, students were judged on their ability to document their team's decisions and alternative solutions. Because creativity in engineering is unsuccessful without functionality, the final projects were penalized if they failed in execution.**

Keywords—creativity self-assessment, design competition, mobile computing, team design

I. Introduction

Creativity is a core competency for engineers, fundamental to the process of innovation. The US National Academies of Engineering specifically call out creativity as a necessary attribute of future engineering school graduates [1]; despite this and the fact that creativity and innovation are ubiquitous terms in discussions of the role of engineering in today's society, the need to develop creativity as a skill has not developed a stronghold in traditional engineering curriculum. Kazerounian and Foley [2] suggested that creativity is not valued in current engineering education because it is antithetical to concepts of accuracy, certainty and risk limitation inherent in the practice of engineering. Creativity is also potentially stifled with the current engineering education practice when efforts are focused on determination of the single "right answer" that should be reached as efficiently as possible.

This focus on a single answer determination is one pedagocial approach that may be detrimental to the development of creativity and divergent thinking, requisite skills for finding the solution of open ended design problems. In considering the difference between beginning designers and informed designers, Crismond and Adams [3] note that one attribute of informed designers is fluency, or the number of ideas generated before settling on a solution. This identified component of creativity [4] is not developed in determining solutions of highly constrained problems. Modern design dictates that engineers need to be agile, be able to work in teams, and able to converge on innovative solutions to complex problems [1]. How big of a role individual versus team creativity plays in design processes is not entirely understood and may play a role in the educational development of engineers.

II. Motivation

Perhaps the most commonly known historical example of mobile computing and team based engineering occurred on April 13-17, 1970, when astronauts on the Apollo 13 mission worked simultaneously with mission command engineers to ensure the safe return of the crew. While much of the traditionally-defined "engineering" occurred on earth, implementation and validation of the design needed to occur at a distance of nearly 200,000 miles. This real-time, critical solution was an early validation of a concept articulated over 30 years later in the National Academy of Engineering (NAE) report, "The Engineer of 2020" [1], that engineers to exhibit numerous attributes and skills including (but not limited to):

- Strong analytical skills
- Practical ingenuity.
- Creativity
- Good communication
- Leadership
- Dynamism, agility, resilience, and flexibility (DARF).

Design Wars, a day-long team design competition, was initially developed to provide students with an opportunity to showcase and developed the skills of the Engineer of 2020, with an emphasis on communication, creativity and DARF. More specifically, Design Wars was a multi-disciplinary design competition in which teams of students receive the same assignment, materials, technology, tools for communication, and time to complete the project.

By assessing individual creativity prior to an open-ended design competition, it might be possible to identify any correlations that may be present between creativity and the success of the designs constructed in the event. A research question that arose from the development of the competition was how much impact individual creativity had on the overall creative output of the team. According to Razzouk and Shute [5] design thinking is generally defined as an analytic and creative process that engages a person in opportunities to

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

experiment, create and prototype models, gather feedback, and redesign. While the competition setting was designed to require some degree of adaptability by the teams, it also provided some time for reflection and incubation of ideas prior to design implementation.

Students performed an online, self-assessment of their creativity prior to the competition, the CREAX self-assessment (available at http://www.creax.com/csa/). The self-assessment was developed by the CREAX company in Belgium and breaks down creativity into eight components: abstraction, connection, perspective, curiosity, boldness, paradox, complexity, and persistence. The CREAX includes 40 question: six demographic, 25 self-description, five word-association (testing connection), three visual tests of abstraction and one verbal test of fluency. Validation studies on the CREAX self-assessment were unavailable, so results have been used for preliminary comparison without in-depth examination of statistical significance.

III. THE DESIGN WARS COMPETITON

The design problem with which student teams were taked was to move a tennis ball from a blue foam disk, to a French fry basket attached to the top of a four foot tall closet pole (see Fig. 1). The pole was placed in a five gallon bucket with sand in it for stabilization. The ball and foam were placed on one end of two-foot by eight-foot sheet of plywood, and the basket/bucket assembly was placed at the other end at a distance of six feet. Participants were then simply told "Your goal is to get the tennis ball from the piece of blue foam to the French fry basket." Virtually no limitations were set on how students were to achieve this goal, except that, for safety reasons, they were not allowed to use electricity or fire in their final design. Many teams eventually realized that this lack of limits meant that the original configuration of the basket and disk could be altered, although some did not move either element. The only other rule was that students could only touch their design once at the beginning to start the movement of the ball, similar to rules for the Rube Goldberg competition.

Fig.1. A Design Wars booth (pre-construction) including the disk and basket initial configuration and student selected materials.

The central theme of the competition was to challenge both the students' creativity and communication skills. The four-member student teams were separated into two groups. Two members were the documentation team (located in the "Design Office") and the remaining two members comprised the actualization team (on the "Build Floor'). For communication, students were allowed to use their tablet computers and whatever software they chose to employ. Wireless internet was provided and the use of any other communications hardware (e.g. cell phones) was not allowed. The actualization team was responsible for construction. The documentation team had to accurately document the design, including considered alternatives, so that it would match the constructed solution despite having no physical presence on the build floor.

The Build Floor layout consisted of 16 curtained-off booths on an arena floor, with two work tables and power outlets in each. A large central tool station was provided, and a check out system for tool usage time was implemented. A large assortment of construction materials and carefully selected "junk", primarily donations from local businesses, were distributed about the perimeter of the booths. Also, despite the abundance of variety, there was not a large enough quantity of any single item (other than fasteners), so that all teams could use the same material. One attribute of this was that teams were required to quickly adapt their designs, or demostrate agility, if a material they had chosen was gone before they were abe to obtain it from the materials area.

In order to stress the importance of the mobile computing component of the competition, build teams on the floor were not allowed to touch any materials for the first half of the event. Instead, the build team had to communicate what materials were available to the design team and, with their help, pre-design their final configuration. The intent was to prevent teams from simply throwing things together to see what would work. In the afternoon, build teams were let loose to grab what they needed and follow the plans determined by all the members of the team. This provided an opportunity (albeit a short one) for incubation, a necessary component in creative development of ideas [6]. A three hour window for building was used to provide some sense of urgency in the build process. The format provided an environment (or the fourth p of creativity, "press") with equal opportunity to succeed, while setting time and material constraints that required unique solutions.

At the end of the build phase, team members from both the design office and the build floor were brought to the floor, and the teams deployed their designs (See Fig. 2). Scoring was based on the sub-elements of creativity: originality, flexibility, fluency, elaboration and aesthetics as described by Kaufman et al [4].

The other portion of the design score was functionality. Engineering creativity may be considered to differ from creativity in other domains because of the requirement of functionality [7]. If the final design was unable to complete the required task of moving the ball, teams were given fifteen minutes to make modifications, and then allowed to retry. The final projects were penalized if they failed in execution in the two trials.

These two trials were judged by experts from varying disciplines (Psychology, Military Aviation Consulting, Mechanical/Electrical Engineering, Industrial/Human Factors Engineering). To consider the communication skills exhibited during the competition, students were judged on their ability to document their team's decisions and alternative solutions. The final criteria, which was used to prevent teams from hoarding materials, was the usage efficiency of the materials for construction of the design. If students took materials from the main pile of available materials, the team was required to use them or they received a penalty.

IV. Competition Data Collected

The Design Wars competition was held on Saturday, September 8, 2012 at the Rapid City Civic Center. Sixteen teams of four students each, self-selected from the undergraduate population of the South Dakota School of Mines & Technology participated. Data collected included pre-competition, judging scores and post-competition surveys.

Pre-competition creativity scores, based on the CREAX self-assessment, were requested prior to the competition, and obtained from all but three of the participants. One of the main goals was to determine if a team's score in the competition pointed to any correlations between individual creativity and team design output.

The spreadsheets accounting for each team's judging scores and material efficiencies were kept for correlation with the individual CREAX data for each team. After the judges finished assessing the functionality, the top three teams, as computed across all the criteria, were awarded monetary prizes.

Figure 2. *A Design Wars final design in demonstration.*

A. Post-Competition Data and Mobile Computing Survey

A post-competition survey was administered to all participants to assess a) their perceptions of their creative output during the competition and b) their use of mobile compution for communication. The mobile computing ability of teams was crucial to their success in communicating ideas, designing solutions, and formulating contingency plans. During the competition, the wireless bandwidth was limited, which impacted the manner in which student teams were able to communicate. Data were also collected relating to their design strategies and individual/team interactions.

V. Preliminary Results

Analysis indicated almost no linear correlation between team performance on the creativity criteria average and the mean of the individual CREAX scores for a team. However, by grouping the teams a counter-intutive pattern emerged: it appears that the teams comprised of members with near CREAX mean scores performed better than teams with lower than average CREAX means, and both performed better than teams comprised of higher than CREAX mean individuals. Numerous questions that arises from this is: could it be that it is not a good idea to try to form teams of highly creative individuals (at least within a discipline)? Does time constrainst affect the ability of teams with highly creative members to develop functional solutions?

Synthesis among team members and an ability to communicate changes "on-the-fly" were paramount to success in the competition, which is strongly related to perspective, connection, and persistence – all aspects rated in the CREAX test. The analysis shows that students may possess numerous creative abilities, but may not actively realize they are using them or even believe they have them. This might explain why creativity is viewed as an abstract, unrelated section of an engineers' toolbox. These creative, and riskier, designs may provide a better solution in the end or change what common opinion feels is "certain" in practice. Engineering as a whole requires many of the critical traits related to creativity, and developing those attributes in coursework could help students develop more of the traits considered desirable for the engineer of 2020 [1].

Acknowledgments

Design Wars was funded by a State of South Dakota Mobile Computing Grant. The research team would also like to thank the local businesses that donated materials and services, the judges, and student participants and volunteers.

***Abstract*— An NSF Scholarships in STEM (S-STEM) program has provided scholarships for cohorts of undergraduate engineering students since 2009, giving specific attention to the National Academy of Engineering's vision for the engineer of 2020 (E2020). Four E2020 outcomes are emphasized in Iowa State's program: leadership, global awareness and understanding, systems thinking, and innovation and entrepreneurship. These outcomes, or pillars, are being integrated into curricular and co-curricular activities. The four pillar areas are introduced in a one-semester first-year seminar and reinforced in a two-semester second-year seminar. These seminars supplement the regular program of study for engineering students. In this paper, we describe the curriculum and its planned integration beyond the scholarship program. We present student feedback about their experience in the program. We also introduce relevant core competencies associated with the outcomes as judged by faculty and industry representatives.**

Keywords—leadership, systems thinking, innovation, entrepreneurship, global awareness

I. INTRODUCTION

The E2020 Scholars Program is a National Science Foundation Scholarships in STEM (S-STEM) program. It is designed around a cohort model involving direct-from-high-school and transfer undergraduate engineering students from diverse backgrounds. It leverages and complements the college's learning community infrastructure and builds upon the aspirations and attributes of the National Academy of Engineering's (NAE) vision for the engineer of 2020. E2020 programming includes a set of student development and learning opportunities consistent with this vision and includes curricular and co-curricular activities [1], [2], [3].

The first two years include weekly seminar courses that introduce the E2020 scholars to knowledge, skills and abilities in each of the four developmental areas of the program, also called pillars. The pillars are:

- Leadership development, including teamwork, communication, and service;
- Systems thinking, including interdisciplinary engineering design;
- Innovation, including creativity and entrepreneurship; and
- Global awareness and understanding, including cultural adaptability.

Each pillar area is led by a faculty member. These faculty leaders work with other E2020 faculty to teach the seminar courses. In addition to providing learning opportunities for the scholars, the seminar courses are a means to develop learning experiences to be integrated into the first year experience or other engineering courses for all engineering students.

After completing the seminar series, and beginning in the third year of the program, scholars continue to develop a deeper understanding of the pillars through capstone-like experiences using project-based learning.

Fig. 1 illustrates a semester-based timeline for the student experience in the E2020 program over four years, or eight semesters, upon entry into engineering. The graphical icons represent the pillars of the program: star, leadership; arrow, systems thinking; exclamation, innovation; and circle, global awareness. Section III gives more details about the seminars.

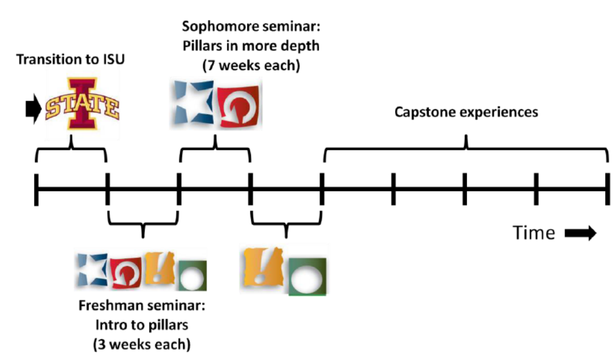

Fig. 1. The E2020 student experience.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

The E2020 program, though developed independently, is similar to a number of initiatives motivated across the U.S. in response to the NAE's report [4]. One of the earliest was the University of Wisconsin's introductory course on the engineering grand challenges [5]. Since then, Purdue University and other universities have implemented engineer of 2020 programs [6]. The Grand Challenge Scholars Program (GCSP), a collaboration of Duke University, Olin College of Engineering, and the University of Southern California, is an NAE-sponsored version of Iowa State's NSF-funded E2020 Scholars Program [7]. Several universities have established programs affiliated with GCSP.

II. Student Cohorts

The first scholarships were awarded for a cohort entering fall 2009. A total of three rounds of scholarships were awarded. The scholarship application and selection processes are described in annual reports available at the program website [2]. An online application that included essay questions pertaining to E2020 pillars was used. A selection committee reviewed and discussed every application. The entering cohorts included both direct-from-high-school (DFHS) and community college (CC) transfer students. The statistics for each cohort are summarized below.

2009 cohort:

- 22 total, 14 DFHS students, 8 CC transfer students
- 4 women and 5 minority students
- 17 of 21 entering scholars remain in or completed the program.
- 12 scholars graduated through spring 2013.
- 86% 3rd year retention in engineering; 81% 4th year retention in engineering; 90% retention at ISU.
- 2 scholars changed to non-STEM majors (economics, history).
- One scholar died in a car accident in fall 2010.

2010 cohort:

- 26 total, 12 DFHS students, 14 CC transfer students
- 12 women and 4 minority students
- 24 of 26 entering scholars remain in or completed the program.
- 10 scholars graduated through spring 2013; one scholar entered the concurrent BS/MBA program.
- 92% 2nd year retention in engineering; 81% 3rd year retention in engineering; 92% 3rd year retention in STEM; 100% retention at ISU.
- 3 scholars changed to non-engineering STEM majors (biology, industrial design); 2 scholars changed to non-STEM majors (elementary education, psychology).

2011 cohort:

- 25 total, 16 DFHS students, 9 CC transfer students
- 11 women and 3 minority students
- 24 of 25 entering scholars remain in the program.
- One scholar graduated through spring 2013.
- 96% 1st year retention in engineering; 88% 2nd year retention in engineering; 96% 2nd year retention in STEM; 100% retention at ISU.
- 2 scholars changed to non-engineering STEM majors (biology, math); one scholar changed to a non-STEM major (communication studies).

The scholarship awards have been administered through the College of Engineering student services office. Scholars who switched to non-STEM majors were no longer eligible to receive an S-STEM scholarship. Scholars who switched to non-engineering STEM majors and who remained active in the program continued to receive a scholarship. Continuing eligibility also adhered to university policies, such as satisfactory academic progress. Overall, sixty-five of seventy-two scholars remain in the program, giving an overall retention of over 90% in the program.

III. Seminar Courses

A one-credit seminar course, ENGR 110, is taken by scholars during the second semester of their first year in the program. It introduces students to each of the four pillars over twelve weeks. With three weeks per pillar, the first week introduces the students to knowledge related to the pillar; the second week focuses on developing basic skills through an active learning activity; and during the third week, students work in teams to demonstrate their ability to apply the new knowledge and skills to a real-world problem. Peer mentor sessions are interspersed with the class sessions.

Another one-credit seminar course, ENGR 210, is taken during fall and spring semesters of the second year, and provides more in-depth investigation into the pillars. The fall semester seminar is split into two seven-week periods, one for the leadership pillar and another for systems thinking. The spring semester seminar is split between the innovation and global awareness pillars. A faculty leader for each pillar has developed pillar-specific learning modules and assessment methods.

A. Leadership

"I now understand that leadership is not just about leading other people, but being able to lead myself." E2020 Scholar

The leadership seminars were designed to highlight that good leadership may be achieved differently by each leader. This concept must be understood and practiced. In the first-year seminar, we concentrated our effort on getting students to appreciate various aspects of these main topics: (1) knowing yourself, (2) teamwork, (3) communication, and (4) self-discipline. The three weeks were focused on students leading themselves. By the end of the sophomore seminar, the students were expected to achieve the following learning objectives: For any given situation, students will (1) build and foster interpersonal relationships, (2) explain why engineers must effectively communicate thoughts and ideas in writing and orally, and (3) identify ways to effectively serve as a member of a team as a leader and/or follower.

Students in the first-year seminar took the *Keirsey Temperament Sorter-II®* and received classroom instruction on personality types and temperaments [8]. Through this experience, students analyzed and described their personality and temperament preferences. Through written reflections, students performed metacognition to gain a deeper understanding of why knowing this information is important to becoming a leader. Next, students participated in a modified version of the "Stranded in the Desert" exercise from Johnson and Johnson's *Joining Together* [9]. This exercise and the following discussion helped to highlight the importance of teamwork in solving a problem. Finally, the students worked in teams to build a tower made of various common office items. Each team member was given a specific "job" and asked to perform their role. Through this experience, students were able to appreciate the complexity of solving a problem through communication, collaboration, and coordination.

The first-year seminar created the framework and opportunity for students to view themselves as leaders. During the sophomore seminar, students were introduced to new topics and exercises to emphasize the importance of interpersonal relationships, communication skills, and teamwork. Nearly every class period was delivered with students sitting in a circle or at team tables to foster the sharing of thoughts and ideas. Students were able to practice their leadership skills by working together on a service learning project. Teams were charged with finding an activity to research, plan, and accomplish together to positively impact the lives of others. Students were encouraged to find a community interest item and devote one-two hours of their time to make a difference. Students practiced their communication skills by presenting their service learning project in either poster sessions or oral presentations. Hartmann provides more background on methodology to many of these teaching methods [10].

The students were generally effective in achieving the learning objectives. After the sophomore seminar, most students were able to clearly articulate their strengths and contributions as a leader in their personal life and organizations within the university and their communities. Reflections from students indicated a greater appreciation and understanding for the importance of engineers to have strong interpersonal relationships, effective communication skills, and teamwork skills.

B. Systems Thinking

"I came to realize just how many things you have to consider when you are working on a project. Not only how something works, but also how it is going to affect the surrounding environment and those who use it." E2020 Scholar

Many definitions of systems thinking have been proposed, but several features appear in most definitions: viewing a problem broadly and holistically; identifying interdependence and feedback; synthesizing as well as analyzing individual components; and accounting for dynamic (time-varying), nonlinear behavior. In the first-year seminar, we focused on getting the students to appreciate the complexity arising from the interaction of factors from inside and outside engineering—that is, we aimed to have students explain the importance of taking a broad view of a problem and considering feedback and dynamic behavior. By the end of the sophomore seminar, the students were expected to achieve the following learning objectives involving tools of systems thinking: For complex, ill-defined, dynamic problems involving engineering, social, ethical, cultural, environmental, business, and political issues, students will (1) identify connections between subsystems with rich pictures, (2) explain relationships with causal loop diagrams, and (3) sketch the behavior over time of key variables in the system.

Students in the first-year seminar worked in teams to draw a rich picture for a topic related either to a grand challenge problem [11] or a successful team—in sports, school, music, work, etc. A rich picture uses pictures, cartoons, text, and sketches to depict connections between various elements of a systems or problem, including structures, processes, and concerns [12]. An example of a rich picture drawn by students is shown in Fig. 2. The students then presented their work either in an oral presentation or a poster session. In the sophomore seminar students chose similar problems involving at least five of the seven issues stated in the learning objective and identified the key variable measuring success or failure. Then they applied three tools of systems thinking: rich pictures; causal-loop diagrams, which show relationships between elements; and behavior-over-time graphs, in which the behavior of the key variable is sketched as a function of time. Rehmann et al. provide more details on the tools and activities [13].

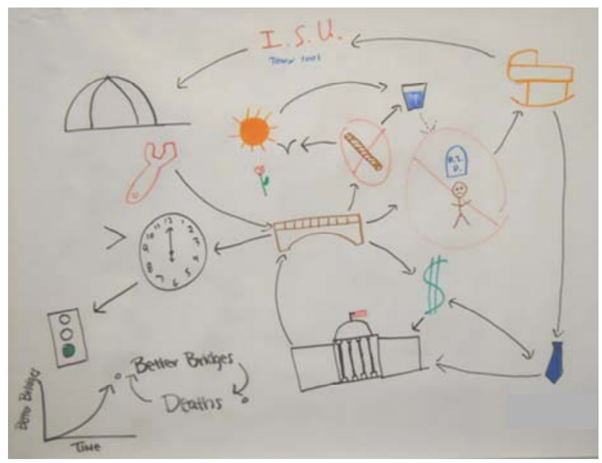

Fig. 2. Example of a rich picture drawn by a group in the FY seminar on the problem of infrastructure and safe bridges. (See [13] for a larger image.)

Based on a review of student work and written reflections, the students were mostly successful in achieving the outcomes. After the first offering of the first-year seminar, most students wrote that before the module, they did not know much about systems thinking. After the module, they knew much more and appreciated the number and diversity of issues that must be considered in a successful engineering project. In the sophomore seminar, students addressed the technical content adequately, though they struggled with identifying an appropriate key variable and sketching behavior over time. In particular, after carefully deriving a causal-loop diagram from a rich picture, many groups would mostly abandon their previous work and resort to mental models not reflected in their rich picture. Although the instructional activities can be adjusted to help students achieve the learning objectives more fully, most students demonstrated appreciation for the range of issues affecting an engineering problem and proficiency with the tools of systems thinking.

C. Innovation and Entrepreneurship

"Innovation is not just thinking of new ideas, but working together in a team, taking initiative, accepting criticism, and being creative." E2020 Scholar

Innovation and entrepreneurship involve key skills and abilities for practicing engineers. While engineering programs offer numerous design courses throughout the curriculum, these often overlook thinking like an entrepreneur. One of the primary goals of this pillar is increase students' awareness that the skills of an entrepreneur will help them to be better engineers. In the first-year seminar, students were introduced to elements of entrepreneurship and explored what it means to approach problems from an entrepreneurial viewpoint. By the end of the sophomore seminar, students developed a business plan for a proposed company to solve some aspect of a grand challenge problem [11]. The students then presented their work to a panel of judges to pitch their ideas.

The first-year seminar first introduced students to innovation by having them think about things (inventions, products, technologies, etc.) that have changed their lives. Students were then assigned to small groups, and each group selected a topic related to a grand challenge problem. The groups were asked to think more deeply about the problem and possible solutions. During the second week, students worked in their groups to refine their ideas and organize them into a presentation to the class. In the third week, groups presented their ideas, which were scored using a rubric that judges creativity of the solution as well as presentation skills. The first-year seminar concluded with feedback to the groups with an emphasis on innovation.

The sophomore seminar focused more on entrepreneurship, with the first week defining entrepreneurship and examining its relationship to engineering. The instructor again primed students on innovation, engaging them in a discussion of the greatest innovations of their time and drivers behind these innovations. These innovations were then placed in the context of grand challenge problems. Groups were formed, and each group was assigned a different grand challenge problem area. Groups were tasked to make a short "sales" pitch as to why their assigned problem area should be targeted by a company. The students then voted to select a single problem domain for their business plans the rest of the seminar. Students learned more about business plans and proceeded to work in groups to finalize their business plans. As in the first-year seminar, business plans were presented and judged. Given the same problem domain, the best plan was identified, adding an element of competition to the learning experience.

Students developed a better understanding about entrepreneurial concepts and effectively communicating their ideas. They were introduced to skills that will enhance their work as a student as well as prepare them for the workforce.

D. Global Awareness

"I never realized the importance of culture and customs in designing a product to meet a country's needs. This class has helped me to realize that there is more to engineering than just building something that works for us." E2020 Scholar

For engineers, global awareness has several possible meanings. In the E2020 project, we defined global awareness as being aware of and respectful of cultural and international differences in needs and values, understanding how regional and cultural differences affect the engineering design process and engineering business enterprise in general, and being able to work effectively with others from different cultures.

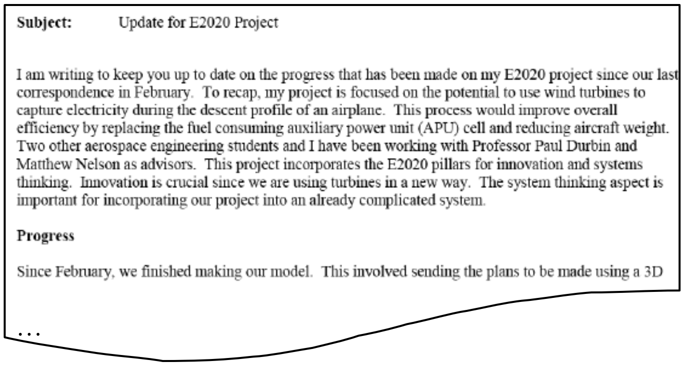
The first-year seminar introduced students to the impact of global and cultural differences on the engineering enterprise, through class discussions and brief case studies. The learning objective for the first-year seminar was that students would have a better understanding of the need for questioning and analyzing their own assumptions (about needs, values, constraints, criteria, resources, economics, etc.) when working on engineering projects.

In the sophomore seminar, the emphasis was on identifying cultural dimensions to an engineering project, with a two-pronged emphasis: one, that framing an engineering problem (and later, developing a solution) must consider the cultural and local norms and needs of the users or beneficiaries of the project, and two, that working with others from different cultures presents challenges that one can to some degree prepare for. After discussion and readings on global awareness in engineering, technology, and business, students were asked to research one of the grand challenge problems, chosen at random for each team of 4-6 students, in the context of one country, also chosen at random for each team. Drawing on the skills gained in the Systems Thinking module, in the first half of this project they were to draw a rich picture describing aspects of the grand challenge problem in their assigned country. Then through discussion and further research, each team distilled their findings to a single engineering problem statement, including constraints and criteria. Ideally, this would be aided by their work in the Entrepreneurship model to frame and communicate an engineering problem. In the second half of the project, students were introduced to Hofstede's cultural dimensions [14], a classification of major cultural norms by country; this is system widely used in international business training. The students were then asked to review their problem statement and imagine that they were paired with a team of engineers native to their assigned country, and using Hofstede's cultural dimensions, explore how each country-team might approach the problem and its solution differently, and how cross-cultural dynamics might affect their work together.

IV. Project-based Individualized Learning

After completing the ENGR 110 and 210 seminar series, and beginning in the third year of the program, scholars continue to develop a deeper understanding of the pillars through individualized, capstone-like experiences using project-based learning. Students from the 2009 and 2010 cohorts are at various stages of independent study experiences with faculty mentors. The project-based independent study assignment is described below.

As part of project management and communications skills development, scholars report their progress. A memorandum format was adopted. A memo is submitted by a student to the E2020 Blackboard site. An excerpt is shown in Fig. 3.



Subject: Update for E2020 Project

I am writing to keep you up to date on the progress that has been made on my E2020 project since our last correspondence in February. To recap, my project is focused on the potential to use wind turbines to capture electricity during the descent profile of an airplane. This process would improve overall efficiency by replacing the fuel consuming auxiliary power unit (APU) cell and reducing aircraft weight. Two other aerospace engineering students and I have been working with Professor Paul Durbin and Matthew Nelson as advisors. This project incorporates the E2020 pillars for innovation and systems thinking. Innovation is crucial since we are using turbines in a new way. The system thinking aspect is important for incorporating our project into an already complicated system.

Progress

Since February, we finished making our model. This involved sending the plans to be made using a 3D

…

Fig. 3. Memo excerpt from project-based independent study assignment.

A project-based learning (PjBL) approach was selected to facilitate independent learning and a deeper understanding of the material. Through their E2020 PjBL experience, scholars are expected to develop self-directed learning skills. As part of the assignment, scholars do the following:

- Complete a project under the guidance of a faculty mentor, selected by the scholar.
- Propose a project that meets certain criteria.
- Enroll in independent study credit to earn at least one credit per semester for the PjBL experience.
- Provide project updates, presentations, and a report to the E2020 Program.

Scholars can choose to work on projects oriented toward research, education or service. For a research project, a scholar takes an open-ended technical question, investigates it, and creates a solution. For an education project, a scholar may develop an innovation for a course that helps other students learn. For a service project, a scholar identifies a societal problem and approaches it through service learning, applying particular expertise to meet a need. A scholar is allowed to work as part of a group on a project. A scholar proposes a project in consultation with a faculty mentor and E2020 faculty. The scope and pace of a project is individualized to a particular student's situation, such as timing with respect to other activities to be leveraged (such as a design competition, study abroad, undergraduate research experience, Honors Program project, etc.). A scholar is encouraged to create a PjBL experience that complements and leverages current coursework and/or co-curricular activities.

As noted, students are encouraged to consider undergraduate research projects for their capstone experience. For example, student "Joe" transferred from an Iowa community college as an E2020 scholar in fall 2011 in mechanical engineering. He participated in the ISU BioMaP (Biological Materials and Processes) REU while a community college student during summer 2011. BioMaP consists of a variety of projects with topics such as nanovaccines, drug and gene delivery, and clinical trials with an artificial pancreas. Joe is pictured in Fig. 4, standing on the left. Joe has since participated in an industry internship while an E2020 scholar. He has benefited from early student engagement through research, first- and second-year learning experiences, and synergistic project activities. He will build on these research and experiential learning experiences to define an E2020 project that deepens his understanding and application of E2020 pillars.

Fig. 4. Project-based learning by an E2020 scholar (http://innovate.engineering.iastate.edu)

V. Student Feedback

A survey was administered to the cohorts each year to obtain feedback on their experiences in the program. Quantitative and qualitative analysis methodologies were used to analyze the survey data. Statistical evaluation of data included descriptives and frequencies of responses. Open-ended questions were coded for common themes [15] [16].

After the first year of the program, student feedback was quite positive with 89% of student respondents agreeing (indicating either Somewhat agree or Strongly agree) that their involvement in the E2020 program: was a positive experience; supported their growth as a person; enhanced their educational experience; and fit well with their courses. An E2020 scholar wrote: "I have had an extremely positive experience with being involved in E2020. E2020 has given me the opportunity to interact with students I wouldn't have otherwise met and faculty members in the college of engineering. I enjoyed coming to class once a week and I feel that I learned a lot about myself as an aspiring engineering major and of what I need to work on in order to be a successful engineer in the future." Results for the question "My involvement in E2020 has been a positive experience" are shown in Table I for the 2009 cohort.

TABLE I. Survey results, 2009 cohort: "My involvement in E2020 has been a positive experience" [16]

Response	Percent	n
Strongly agree	66.7%	12
Somewhat agree	22.2%	4
Neutral	11.1%	2
Somewhat disagree	0.0%	0
Strongly disagree	0.0%	0
Total		18

Prepared by RISE, Iowa State University

The comments by the students elicited the following themes:

- Overall: Students liked meeting other engineering students, enjoyed the discussion of the four pillars, learned a lot about being an engineer, and now think of the role of an engineer differently.
- Women: Had a very positive experience and gained greater insight into the role of an engineer.
- Transfers: The program really helped with their transition, helped them meet people, and helped them understand the four pillars.

Average transfer student responses on survey items tended to be higher (more positive) than DFHS responses, though the differences were not statistically significant. Having transfer student responses generally as positive as DFHS responses suggests that the program has provided an effective pathway for transfer students through E2020 programming.

79% of the 2009 cohort and 85% of the 2010 cohort reported that E2020 helped them feel better prepared to succeed in college. Students in their comments expressed that the pillars had expanded their perspective on the field of engineering and allowed them to see common threads across their classes. One student summarized the E2020 program experience, saying: "The ability to work with other students in different engineering disciplines on topics that are universal to all engineers will have a big impact and importance in my future endeavors as a successful engineer. Also the coordinators and my fellow scholars are amazing people!"

Results from the second survey provided a comparison between students taking ENGR 110 (2010 cohort) and ENGR 210 (2009 cohort). In the 2009 cohort, 100% percent of students agreed that the content covered in the scheduled E2020 seminars helped them to understand what the pillar concepts were all about, though students reported learning more about some of the pillars than others. In the 2010 cohort, 92% agreed. Not surprisingly, given the longer time spent with each of the pillars in ENGR 210, students in the 2009 cohort were more likely (than the 2010 cohort) to agree they had increased their knowledge, skills, and abilities in the pillar areas.

Student comments indicated that the opportunities for networking and support provided in E2020 were extremely valuable, and students commented that networking opportunities were the best aspect of the E2020 Scholars Program. Students also appreciated the learning opportunities, having a creative outlet, learning how to incorporate the four pillars into their work, enhancing their interviewing skills, having people who were willing to answer questions, learning about themselves, and learning to work in teams. The full survey reports are available from the authors.

VI. Curriculum Integration

One of the goals of the E2020 program is to identify ways to introduce the pillar topics to all engineering students, not only to E2020 scholars. The logical avenues are through the first-year experience and learning communities, using modules from ENGR 110 and 210; or via senior design, similar to the E2020 PjBL. This approach would be consistent with a recent national study that concluded:

- Engineering program chairs and faculty subscribe to most of the goals of The Engineer of 2020.
- Faculty and chairs give less attention to professional topics than to technical ones, despite the emphasis on professional skills in the NAE report and ABET criteria.
- Professional topics are typically emphasized in first-year design and capstone courses rather than integrated throughout the curriculum [17].

We have been working with the learning community program coordinators, instructors and peer mentors in the college to share instructional materials for each of the pillars. The faculty leader for the leadership pillar (Hartmann) delivered a two-part workshop during spring 2012. The faculty leader for the systems thinking pillar (Rehmann) delivered a seminar at Iowa State's Learning Communities Mid-Year Institute during spring 2013. There was interest in and outside of engineering to incorporate materials, including later in the curriculum.

Integrating E2020 pillar topics, resources and active learning experiences is an ongoing effort by E2020 faculty.

VII. Future Work

E2020 faculty have not yet formalized assessment of the pillars through well-defined student learning outcomes and instruments. Several rubrics and surveys have been used to assess aspects of the program and student learning. Previous work by E2020 faculty with the Engineering Leadership Program piloted a competency-based leadership model closely aligned with ABET student outcomes [18], [19], [20]. In the ELP model, there were eight learning outcomes that described the knowledge and skills achieved by an ELP scholar through participation in the program. Five of the outcomes were from ABET Criterion 3; three of the outcomes reflected additional skills attained through the program. These additional learning outcomes included an ability to create a vision, an ability to innovate, and an ability to value diversity and create an inclusive environment. Associated with these outcomes, ELP identified nineteen competencies and specific key actions for each competency. This competency-based approach was based on a framework developed for the College of Engineering as described by Brumm, Hanneman, and Mickelson [21].

In the college's framework, student outcomes are multi-dimensional and represent some collection of workplace competencies necessary for the practice of engineering at the professional level. Fifteen competencies are measured within this framework: Analysis and Judgment, Communication, Continuous Learning, Cultural Adaptability, Customer Focus, Engineering Knowledge, General Knowledge, Initiative, Innovation, Integrity, Planning, Professional Impact, Quality Orientation, Safety Awareness, Teamwork. Each competency is uniquely defined with a set of observable and measurable key actions that a student may take that demonstrates their development of that competency. For example, the Initiative competency has the following definition and key actions.

Initiative: Taking prompt action to accomplish objectives; taking action to achieve goals beyond what is required; being proactive.

Key Actions:

> Responds quickly. Takes immediate action when confronted with a problem or when made aware of a situation.
>
> Takes independent action. Implements new ideas or potential solutions without prompting; does not wait for others to take action or to request action.
>
> Goes above and beyond. Takes action that goes beyond job requirements in order to achieve objectives.

An assessment of the student's demonstration of competencies asks the following question for each of the key actions: "When given the opportunity, how often does the student perform the key action?" The response uses a Likert scale: 5 = always or almost always; 4 = often; 3 = usually; 2 = sometimes; and 1 = never or almost never. There is a mapping of the competencies to the ABET (a-k) student outcomes.

It would be possible to follow the ELP assessment approach for each of the E2020 pillars, resulting in a set of competencies and key actions for each pillar. This would align with and leverage the college's assessment framework. The identification of competencies appropriate for each pillar would draw from emerging engineering education research on assessment of leadership, critical thinking, entrepreneurship, and cross-cultural skills.

E2020 program evaluation is also ongoing, including annual surveys of scholars and surveying of graduated scholars.

Acknowledgment

Prof. Tom Brumm contributed to the development of the E2020 Scholars Program. Joel Johnson and Paul Castleberry assisted with program implementation in the College of Engineering.

Development, implementation and assessment of a common first year end-of-semester engineering design project in an integrated curriculum

Michael.P.Davis@maine.edu

***Abstract*— At the newly established University of Maine's Brunswick Engineering Program, an integrated curriculum is under development that covers the equivalent of the first two years of the B.Sc. in Mechanical, Electrical, Civil and Computer Engineering. Upon completion of the program, the students finish their degree following the traditional curriculum at the home campus. The program emphasizes a theory-simulation-experimentation approach that during the first semester is reflected in two core courses: IEN110 Integrated Engineering 1, and IEN120 Engineering Studio 1. These courses cover the equivalent of first semester courses in calculus and physics, introduction to engineering and engineering design, and engineering computation, and introduce CAD and a high level programming language (MATLAB).**

An end-of-semester project suitable for both courses needs to contribute to the individual course outcomes, as well as to the overall semester outcomes. The project goal is to challenge the students to, after suitably modeling the physical processes, explore the design space with the aid of the computational tools, and to then develop a design using 3D CAD that best meets the design parameters. The final design is then presented to the "client" (the faculty) both in report and presentation format (introducing the communication outcome), and subsequently is built and tested experimentally.

The project assessment is carried out in four phases (project planning, critical design review, build and test day, and post test evaluation), with separate grade components at each assessment point for each of the courses. Assessment results indicate a high level of perceived learning and satisfaction from the students, and strong alignment with the overarching project goals of understanding the engineering design process, developing the capability to represent real-world engineering problems mathematically by applying appropriate simplifications, and to communicate effectively both orally and in writing.

Keywords—first year programs; curriculum integration; problem based learning; design

I. Introduction

The Brunswick Engineering Program (BEP) is an effort initiated by the University of Maine to create an entry point into the engineering disciplines at the Maine Mid-Coast area, while at the same time introducing a program that enhances student learning and retention by delivering the academics in the form of an integrated curriculum that teaches mathematics and science in the context of engineering. The program caters to the Mechanical (MEE), Electrical and Computer Engineering (ECE), and Civil Engineering Departments at the Orono Campus, where the students finish their B.Sc. degrees after completing the first two years of study at the BEP.

The BEP welcomed its initial cohort of 9 students in the fall of 2012, and this paper documents this initial group's end-of-semester project experience. For the first year of the BEP, only first year students are enrolled in the program, where in year 2 the BEP will be fully operational with both first and second class years. As the program grows, it is expected that each cohort will be kept under 25 students to keep a low faculty-to-student ratio.

A variety of first year integration experiences have been presented in the literature, boasting a range of approaches. Examples of large scale applications include the Foundation Coalition [1]-[3], Southeastern University and College Coalition for Engineering Education (SUCCEED), and the Gateway Coalition [4]. In the context of the NSF-funded Foundation Coalition, a group of seven participating universities[1] implemented changes to their first year curriculum to enhance student exposure to the multidisciplinary aspects of the profession. The Foundation Coalition goals were adopted in respective programs at all participating institutions, however developed individually to suit the particular needs of each institution. A different approach to curricular integration, displaying the perhaps most comprehensive redesign of the entire curriculum, has been carried out at Olin college [5], where a brand new curriculum was designed from a fresh start in 2003.

[1] Arizona State University, Maricopa Community College District, Rose-Hulman Institute of Technology, Texas A&M University, Texas Women's University, and The University of Alabama-Tuscaloosa and Texas A&M University at Kingsville.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

All the integration approaches follow the same paradigm; to move the student into the center of the learning effort, and make him an active participant by engaging him through appropriate pedagogical techniques [6]. Typically employed approaches include Problem Based Learning, experiential learning [7]-[9], flipping the classroom and concept based learning [10]-[12]. These techniques are increasingly applied in the traditional classroom environment, however the application benefits the most when they are applied in a multidisciplinary context. In particular, presenting mathematics and science topics in the context of engineering, offers an immediate "aha" effect that not only enhances understanding of the concepts, but also continuously motivates aspiring engineers to continue their studies by making them feel like engineers from day one.

The design of the curriculum using these two pillars (a integrated presentation of the subject materials, and the implementation of student-centered pedagogy) defines the particular characteristics of the Integrated curriculum.

At the BEP, the presentation of the material is organized in a "theory, simulation, experimentation" sequence. This causes exposure to multiple learning modes, always presented in the context of engineering applications. This classroom approach is implemented using the pedagogical tools described above, and the content formulated by careful sequencing of the learning modules. The overall sequence is driven by the criterion that the curriculum needs to allow the students to seamlessly transition to the respective degree programs in year three. Thus the first required step is that of creating a "general" curriculum layout that satisfies all four degree-programs. This general curriculum is then transformed into an integrated curriculum by careful examination of the individual course learning outcomes, and arranging these in a form that allows the multiple learning modes described above.

A principal consideration in this curricular design process is the early introduction of engineering design tools and the engineering design process. This happens for a variety of reasons, with perhaps the most important one being the need for the students to have design knowledge and being able to use design tools so as to productively being able to apply the "theory, simulation and experimentation" process and the problem-based-learning and experiential learning context of the program. ABET's student outcomes further emphasize the design component in the curriculum, and the trend to include them into the freshman curriculum has been consolidating over the past decades [13]-[15].

The work presented here describes the development and implementation of a first semester design project developed in the context of the BEP integrated curriculum. This project is a collaborative effort between the two first semester integrated courses, and was designed to address individual course outcomes, as well as to start developing the systems vision of engineering practice.

II. Discussion

The first semester at the BEP is composed of two core integrated courses: IEN110 (Integrated Engineering 1) and IEN120 (Engineering Studio 1), with 10 and 3 ch respectively. IEN110 incorporates the specific outcomes typically found in traditional Calculus 1 and Physics 1 courses, as well as the equivalent of 2 credit hours of engineering computing. IEN120 introduces the engineering profession, and the engineering design process, including learning a parametric solid modeler. In addition to these courses, English Composition is also taught, but not integrated with the other courses due to the need to operate within the framework of the University of Maine general curriculum.

IEN110 and 120 are courses that have been designed to include all outcomes of the traditional sequence, however expanding them with outcomes that incorporate benefits resulting from the application of the theory-simulation-experimentation approach. Examples of these include ("at the end of the course, students will be able to…"):

- Use standard functions and develop custom MatLAB functions and apply them to real world problems
- Discuss the engineering design process
- Apply the engineering design process to design a simple structure
- Communicate design ideas via hand sketching
- Test predicted forces on a simple structure via experimentation
- Write a technical report to set standards
- Orally present findings of exploratory and team exercises

The above listed outcomes are only those that extend the "core" outcomes of mathematics, physics, Intro to Engineering, CAD, and computing by benefiting from the PBL and design dimensions of the integrated course environment. The common end-of-semester project that is the subject of this paper was designed to provide a multidisciplinary experiential environment in which to develop and assess these outcomes.

It is a challenge to select a project that incorporates these outcomes, while at the same time presenting a level of complexity that enables meaningful analysis at the freshman level. The project chosen here builds on previous design work carried out on a Rube Goldberg sequence. During the initial weeks of the semester, students were challenged to implement the engineering design sequence (up to conceptual level) in a teamwork environment, in the form of a conceptual Rube Goldberg (RG) design. While many more RG steps were discussed during this exercise, the capability to freely arrange stages that represent different physical processes without destroying the "meaning" and realism of the project, implies that a custom-tailored project can be composed that is maintained at the adequate level of complexity and incorporates all physical components of interest. In particular, the physical components of interest reflected applications of large portions of the material presented theoretically during the semester:

- Mathematics:
  - Derivative as the slope of a curve
  - Derivatives as time rates of change
  - Integration of equations of motion
  - Second derivatives; optimization
- Physics:

- o Units

Choosing a particular sequence of Rube Goldberg steps allows introducing all of these components, while at the same time providing a free-form design environment with a range of design variables that can be custom tailored by the faculty to force an exploration of the design space. The project chosen here consisted of the following steps:

1. A ball is launched from a projectile launcher into a cylindrical tube.
2. The ball rolls down the tube and impacts a mini-car, causing the car to start down a ramp.
3. The mini-car impacts the handle of a hammer, causing the hammer to pivot and fall, driving in a nail.

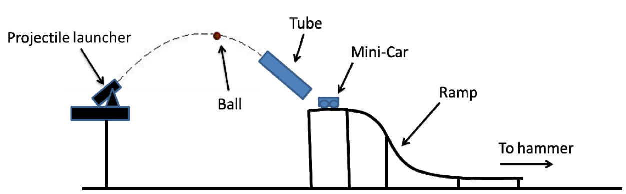

Figure 1: Rube-Goldberg Machine Schematic

The overall phases of the project are:

- Background data collection
- Project planning -> Presentation of project timeline (Gantt chart)
- Conceptual design phase -> Preliminary Design Review
- Detailed design phase -> Critical design review
- Construction -> Project build and test day
- Post test analysis

While the project is individual, the first phase, the background data collection, which includes experimentally measuring the precision and accuracy of the launcher at different angles and settings (and thus provide an assessment of the risk of the different shot configurations), was carried out in teams. Subsequent work was then done individually. The specific task at hand is to design a device that will catch the ball shot from the projectile launcher, and transfer its energy as shown above to the "receiving device", which will be a hammer that needs a certain impulse to actuate upon a nail.

The projectile launcher, tube (with its support structure), mini-car, and the hammer "receiving device" are common components that are provided and shared with the class. The launch angle of the ball and the angle the tube makes with horizontal are both adjustable from 0 to 90 degrees.

Each student then designs, models, and constructs the mini-car ramp using structural hardware available in the lab. The culmination of the project is the test of each design during the final week of classes. On test day, prior to any experimentation and in addition to the ramp geometry, each student needs to specify:

1. The launch angle of the projectile launcher.
2. The projectile launcher plunger setting ("short" or "medium" range).
3. The horizontal and vertical distances at which to place the mouth of the tube.
4. The angle of the tube axis with respect to horizontal.

The physics and mathematics needed to analyze the ball's path can be modeled with the tools that the students have learned during the course of the first semester. The projectile motion of the ball requires 2D kinematics (some students even went to the extent to include air resistance in the computation), the alignment of the tube requires a derivative; then the energy and momentum are transferred by means of a collision, and finally the kinetic energy is given by the height of the ramp. In addition to these requirements, the following "performance equation" was given[2]:

$$\text{score} = 100 - 10\cdot\left(\frac{\Delta x}{\Delta x_{avg}}\right)^2 - 10\cdot\left(\frac{2\cdot I}{I_{max}}\right)^2 - 10\cdot\left(\frac{l_{min} - l}{l_{min}}\right) - 10\cdot\left(\frac{KE_{max} - KE_f}{KE_{max}}\right)$$

Figure 2. Design equation.

This equation was developed empirically by the instructors, to reward (by means of achieving a higher "score"):

- Accurate predictions of the ball's trajectory (by penalizing the overall score for changes in the predicted location delta X)
- Accurate prediction of the required tube angle (this was measured by measuring the sound intensity f of the ball as it "rattles" in the tube),

[2] Δx: Horizontal shift of tube location from predicted location
Δx_{avg}: Distance for an "average" shift from predicted tube location (5 cm)
I: Sound intensity measured by microphone attached to tube (average of 10 shots)
I_{max}: Worst case sound intensity
l: Length of horizontal flat section of track at top of ramp
l_{min}: Minimum required horizontal flat at top of ramp (20 cm)
KE_{max}: Maximum possible kinetic energy (car + mass) just prior to impact with hammer
KE_f: Measured kinetic energy (car + mass) just prior to impact with hammer.

- Optimum energy and momentum transfer from the ball to the cart (steeper angles will transfer less momentum, resulting in a shorter (l) flat section at the tip of the ramp)
- Appropriate design of the ramp to maximize the kinetic energy of the cart at the foot of the ramp (including appropriate selection of cart weight)

These parameters are weighted so that there is no optimal solution; feasible solutions range from very steep shots using a tall ramp but a lower shot velocity, to very flat, high velocity shots that can only accommodate a short ramp (fig. 3 a and b).

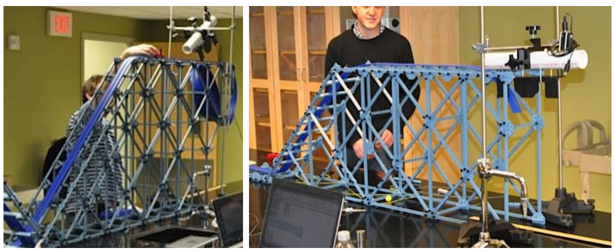

Figure 3a and 3b: Steep shot, short flat and tall ramp, vs Flat shot, long flat and short ramp

Based on the previously listed topics to be included into the final project, a set of specific project objectives was formulated, which would then serve as the basis for elaborating a set of measurable student learning outcomes. The project objectives are:

1. Apply mathematics and physics to an engineering problem
2. Apply professional engineering software tools
3. Understand that simplifying assumptions of physical systems need to be made to allow mathematical modeling of the system, and assess the validity of these assumptions
4. Experience the contradictory nature of design requirements and the iterative nature of the design process. Recognize the need for a structured approach.
5. Recognize the importance of testing assumptions with prototypes of subassemblies[3]
6. Develop the ability to bound and explore the design space to better understand system behavior
7. Recognize the need for and be able to develop appropriate simulation tools using the computational tools studied
8. Practice professional communication

These objectives then map to measurable outcomes as follows:

Learning outcomes	Project Objectives 1	2	3	4	5	6	7	8
ability to create CREO parts and assemblies		x		x				
ability to write MatLAB scripts		x					x	
ability to apply programming structures to physical problems	x					x	x	
ability to write technical reports to set standards								x
ability to elaborate and follow GANTT charts				x				
ability to follow the design process				x				
ability to model a system using mathematics and physics	x		x					
ability to orally present the results of their work								x
ability to design and conduct an experiment	x				x			

Figure 4. Project Objectives – learning outcomes mapping

These specific learning outcomes were then quantitatively assessed and constituted the graded components of the project portion of both participating courses. In addition, a qualitative summative assessment of the objectives was carried out in the form of a student survey.

III. Results

The deliverables for the project and their assigned weighting for the project grades in the IEN110 and IEN120 courses were:

1. Gantt Chart/Preliminary Design Review (PDR)
2. Detailed design report
3. 3D-CAD model of the ramp design
4. Critical Design Review (CDR) presentation
5. Demonstration day - design equation score
6. Post-test appendix

The total duration of the project from kick-off to when the final post-test analysis appendix was due was 4.5 weeks.

Based on these deliverables, the project was divided into the following phases:

A. Kick-off/background Data Collection (1 day)

For the project kick-off, both classes (IEN110 and 120) met concurrently for a joint integrated session, which consisted of two activities: a joint brainstorming session and a full experimental characterization of the projectile launcher that would initiate the apparatus.

After initially describing the project and its major deliverables, the instructors led a team brainstorming session with the students discussing questions such as:

- What design variables are important, and how do they depend on one another?
- How would you subdivide the complete Rube-Goldberg sequence into substeps that can be modeled with math and physics?
- What physical principles need to be accounted for, and can you assign specific principles to specific steps of the Rube-Goldberg machine?

[3] While the students were allowed to test specific subassemblies (such as the precision and accuracy of the launcher's different settings, and the energy and momentum transfer of the ball to the cart), they were not allowed to test the assembly.

- How do you interpret the design equation, and is there an optimum solution that maximizes its score value?
- What information do you need before you can begin designing? Is there a way to measure it?

This brainstorming session was immediately followed by a joint lab to collect data on the muzzle velocities and range of the projectile launcher for different settings. All of the raw data was collected and summarized by the instructors, and given back to the students to use in their individual designs.

B. Project Planning/Conceptual Design Phase -> PDR (1 week)

A week following the project kick-off, each student was required to submit a Gantt chart outlining their project plan and interdependencies of major project components. The culmination of this phase was a Preliminary Design Review, where each student met individually with faculty to describe their plan and initial thoughts on their design

C. Detailed Design Phase -> CDR (2.5 weeks)

During this phase, students were actively working the details of their design. The bulk of student's time in this phase was involved in creating their simulation tool in MATLAB and in the detailed CAD modeling.

Since the depth to which collision phenomena was presented in lecture was insufficient to model the ball/cart interaction, a test bench setup was made available during the detail design phase. The test bench setup isolated the subassembly where the ball rolled down the tube and collided with the cart on a flat track (the launcher and ramp were omitted). No specific guidance was provided to the students on what to do with this setup; the students were instructed to identify what (if any) useful data they could obtain, and then design a simple experiment to capture it. All students chose to use the setup in some way, with wide variation in the methodology of how. Most students used the setup in a very ad-hoc, qualitative manner, making few (if any measurements). The stronger academic students approached the setup with a very systematic plan and performed true quantitative assessments, varying the tube angle and cart position relative to the tube exit and measuring the resulting energy transfer from the collision.

The detailed design phase ended with the delivery of the design report, CAD model, and CDR presentations.

D. Construction Phase - > Project Test Day (3 days)

After the CDR, students had 2-3 days to build their designs (no construction was allowed until the CDR was completed) and then test them on the designated project test day. This phase ended with the testing of each student's design. A worksheet was provided where they indicated their choices for the major design variables (angle and setting of launcher, angle and location of the mouth of the receiving tube) which could not be changed once testing began. Each student was allowed ten shots, and the necessary data was collected to obtain the "score" from the design equation.

E. Post-test Analysis -> Appendix (1 week)

After their test-day experience and data collection, students were required to submit a post-test appendix comparing their actual results with what they had predicted in their design reports. This included an error analysis and a discussion of lessons-learned from the testing, detailing how (if at all) they would change their design.

IV. ASSESSMENT

A. Qualitative Formative Observations

Several formative assessment checkpoints were built in the project to help guide the design process. First year college students have very little experience managing a project of this scope with an (intentionally) open ended, non-concrete solution.

The initial faculty-led brainstorming session was an important observation point to understand initial student attitudes. While it was evident that many students were motivated and excited to be given such an assignment, it was also clear that to some this was a daunting assignment compared to their usual coursework. Nearly all students struggled with exactly where to begin. An open discussion of the design equation proved especially necessary, as few students initially understood what it represented or how it would influence their design. In later assessing project objectives 3- 7 this initial discussion was valuable to compare initial student reaction with how they executed the design process.

The first formal deliverable, the Gantt Chart and PDR outlining the student's overall plan, focused on project objective 4 and allowed assessment of learning outcome 5. Meeting individually with students one-on-one (rather than making this a presentation to the class) was meant to ensure it would be a forum for open two-way communication. While the activity was assigned a portion of the overall project grade, it was kept minimal to encourage students to see it as an opportunity to get feedback. At the conclusion of the project all students reported deviating significantly from their plan outlined at the PDR and in their Gantt chart; however, there was a clear correlation between student's scores at this assessment point and overall performance on the project as a whole. Those students who invested more time and effort up front devising a solid plan were rewarded with much stronger overall project outcomes.

During the detail design phase (the bulk of the overall project duration), dedicated in-class project time was used by faculty for ongoing formative assessment. This included both free time as well as faculty-led discussions on how the students felt the design process was unfolding. These sessions were critical for the faculty in assessing project objectives 3-7, which focus on the uncertain nature of design problems that are unfamiliar to typical first year students. A couple of observations follow.

As students were working on their solution, it was apparent that a major source of difficulty for students was the concept of a "design freeze". With little experience working an open-ended design problem with firm time deadlines, students were reluctant to declare their design complete and start the documentation process (i.e., writing their report and preparing their presentation). Several students tried to do both simultaneously, changing design variables and decisions right up until the CDR, resulting in poorly written reports and/or presentations.

Another observation of interest focused on project objective 7. The computing curriculum in the IEN110 course had been designed specifically with the end of semester project in mind; previous MATLAB assignments had allowed the students to build a library of subroutines and functions that were directly applicable to the project. Most students were able to recognize that these previous assignments could be assembled together to create a simulation tool that allowed them to explore the project design space systematically, which increased the number of different design options they considered. This approach greatly enhanced student's ability to meet project objective 7. Those students who created their simulation tool from scratch spent far more time building their code than running it, resulting in consideration of far fewer design options.

B. Summative Assessment

While the formative assessment was kept primarily qualitative, the quantitative assessment of the learning outcomes concentrates on the project deliverables: the design report, the presentation and the CAD model.

The design report was the primary assessment tool for project objectives 4, 6, and 7, the MATLAB Code was designed to assess outcomes 2, 3, and 7, the CAD model outcome 1, the CDR presentations outcome 8, and the post-test analysis outcomes 4 and 9. Technical writing of this scope is not common for first year students, and the results reflected that with wide-ranging quality. Compounding the problem was the situation discussed above where several students left little time for documenting their design. A major lesson learned from this experience is that first year students need assistance with their time management. A "design freeze" event, with an appropriate associated deliverable preventing students from continued design iteration and dedicating them full time to documenting the results would have resulted in improved outcomes for the report and presentation.

While the performance equation presented above was also used as an assessment tool, its primary purpose was to ensure that the design space admitted several potential solutions. It was intentionally crafted to avoid any single obvious optimum design so that students would explore the entire set of solutions and come up with different answers from one another. The results of the scores measured from the testing day indicated this to be a success; student's proposed solutions varied wildly, while the scores output from the performance equation were mostly uniform. Differences in scores between students were primarily attributed to execution (how successfully they modeled and simulated the physics) rather than which point in the design space they chose as their solution.

C. Summative Assessment – Student Survey

To assess the project objectives focusing on the student's design experience (objectives 3, 4, 6, and 7) a survey was administered at the conclusion of the project. The survey was comprised of 19 questions written to assess the project objectives. Questions were categorized by objective and the results of individual questions pooled. Student responses were measured with the following scale: 1 = strongly disagree, 2 = somewhat disagree, 3 = somewhat agree, 4 = strongly agree. With such a small cohort size (n = 9 students) the results presented are not meant to imply any statistical significance; rather, the results are useful simply as a guide to identify trends and student satisfaction with the project.

The results of the survey are presented by project objective in Figure 5. Higher question score values indicate stronger agreement by the student and are considered indicative of success in achieving the particular objective. As an example, one survey question grouped under objective number four asked for student's agreement on the statement: "I had to iterate a number of times to arrive at my final design". An average score of 3.5 for this question suggests that the project was successful in giving the students an experience reinforcing that design problems are often iterative. This question was then pooled with similar (but different) questions relating to objective four and then averaged to arrive at the aggregate score for Objective 4. The plan is to repeat the project and survey with additional cohorts in following years to increase the size of the data set to draw more meaningful quantitative conclusions.

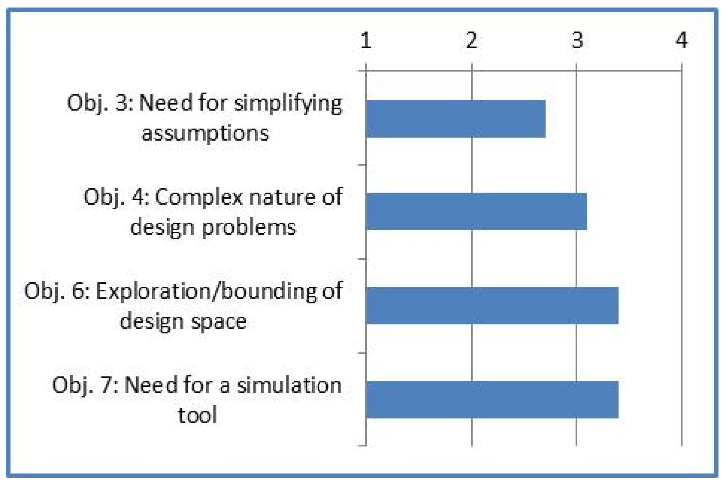

Figure 5: Student Survey Results (1 - Strongly Disagree, 4 - Strongly Agree)

Greatest student agreement was observed for Objectives 6 and 7. Students were quick to appreciate the need for a simulation tool to evaluate a large number of design options within the time constraints of the project. Weaker agreement (but still generally positive) was found for Objective 4, assessing students' appreciation for the complex, unstructured nature of design problems. Lastly, the weakest student agreement was found for Objective 3, asking about the need for simplifying assumptions. One of the requirements in selecting this particular project was to keep the level of physical phenomena in reach for a first year student. Consequently, the physical principles were fairly well defined, perhaps leading to the students' failure to appreciate how important simplifying assumptions can be to a design problem.

V. Conclusion

Overall, the project objectives described above were assessed as successful. Survey responses indicated that students were exposed to and gained an appreciation for challenges unique to design problems. In addition to the survey results presented above, additional questions, not linked to specific project objectives, were asked to gauge the level of student satisfaction with the project. These project satisfaction questions scored the highest for student of all the survey questions asked. More significantly, write-in comments on the survey from the students were consistent in pointing out how motivating and interesting the project was. The major lesson learned, that first year students' project and time management skills need extra attention, will be addressed in future cohorts.

The design-related outcomes associated with the project are thought to be a critical component to the mission of the BEP. An end of semester design experience proved to be an excellent activity for instilling and measuring these outcomes, with high student satisfaction and motivation in the project. The experience in developing this project can be generalized to other courses within the BEP curriculum. The extra focus needed to be spent in the first semester on soft skills such as time management, structuring a solution approach, making simplifying assumptions, etc. suggests a longitudinal approach to the end of semester projects within the BEP curriculum. The level of faculty support with time management and oral and written presentation skills can be pared back as students gain more experience and the technical level of the subject matter rises.

Center for Excellence in Engineering Education
University of Texas at San Antonio
San Antonio, TX 78249
mehdi.shadaram@utsa.edu

***Abstract* - We have created Just in Time Math (JITM) course for freshmen engineering students who show deficiency in math. The result has shifted the traditional emphasis on math prerequisite requirements for engineering classes to an emphasis on *engineering motivation* for math, with a "just-in-time" structuring of the new math sequence. Students still have to follow the traditional math sequences, however, the pre-requisites for some of the core engineering courses have changed from Calculus I to the newly developed Math classes. We have also incorporated engineering examples into the traditional and engineering mathematics courses. Since 2009, we have been offering cohorts of about 25 engineering freshmen every fall on a voluntary basis. The preliminary results indicate moderate improvements in the retention rate and GPA of participating students.**

Keywords—engineering math; retention and graduation rates

I. Introduction

There are a variety of bases that influence student retention and graduation rates in engineering [1-3]. Most academicians believe that lack of preparation in high school, especially in the areas of mathematics and physics, along with lack of motivation contribute to low retention and graduation rates. Additionally, the retention problem is more severe among underrepresented groups. Early intervention programs such as summer immersion camps, learning communities and math boot camps have moderately alleviated this problem [3-4]. In addition, to raise the level of motivation for pursuing engineering degrees, in recent years the engineering educators have infused engineering applications early in the curriculum. In numerous institutions, including UTSA, this has led to the creation of the freshman engineering courses (such as EE1323 Introduction to Electrical Engineering Profession at UTSA) that expose students to the applications of math and physics in designing and constructing the digital devices, such as DVD players and video cameras, that most freshmen are familiar with. Although the freshman engineering course plays an important role in motivating students and exposing them to the engineering profession early on, it is not considered a core engineering class. Typically, engineering students must pass Calculus II in order to enroll in a core engineering class such as Statics and Electric Circuits.

One issue that has been overlooked for many years is the math sequence that engineering students must finish before taking any core engineering class. For most students it takes three to four semesters to reach to a level that enables them to take engineering classes. During this period, students have no significant interaction with the engineering faculty, and it is also during this period that we suffer the most egregious retention problems in engineering. The purpose of this project is to revamp the engineering curriculum in order to shorten the time that it takes students to prepare for engineering core courses. As a result, students will be engaged in their field of study from the beginning. We strongly believe this will encourage students to continue their study in the college of engineering.

We have incorporated the ideas from the newly developed course, known as EGR 101 "Introductory Mathematics for Engineering Applications" at the Wright State University by Professor Klingbeil to create a Just in Time Math (JITM) for freshmen engineering students who show deficiency in math [4]. The WSU model concludes with the development of a revised engineering math sequence, to be taught by the math department later in the curriculum, in concert with College and ABET requirements. The result has shifted the traditional emphasis on math prerequisite requirements to an emphasis on *engineering motivation* for math, with a "just-in-time" structuring of the new math sequence. At the University of Texas at San Antonio (UTSA), the changes in the engineering courses are not as drastic as WSU. Students at UTSA still have to follow the traditional math sequences (Calculus I, Calculus II, etc.). However, the pre-requisites for some of the core engineering courses have changed from Calculus I to the newly developed Math classes. We have established the laboratory and developed the course materials and revamped the engineering curriculum. Thus, we have also incorporated engineering applications into the traditional Calculus and

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Engineering Mathematics courses in order to maximize the students' exposure to the applications of mathematics in engineering problems. Since 2009, we have been offering the newly developed curriculum to cohorts of about 25 engineering freshmen every fall on a voluntary basis.

II. STRATEGY

Incoming engineering freshmen at UTSA begin their study with calculus I as the first required math course. Although the majority of them pass calculus while in high school, unfortunately, about 60% of them fail the placement test and are not qualified to register in the Calculus I course. Typically, students are required to take Calculus I followed by Calculus II and Physics classes in order to satisfy the pre-requisite requirements for the core engineering classes. Considering mathematics and science deficiencies among our students, it usually takes several semesters for the majority of them to register in the basic engineering classes. Through our previous funded projects, which provided opportunities for undergraduates to participate in research laboratories, we have learned that when students interact with engineering faculty and peers at the early stages of their studies, they have a better chance of graduating within 4-6 years.

Our new revamped engineering curriculum based on the implementation of JITM course increases the interaction between new comers and engineering faculty and peers during the initial semesters. As a result, we expect to perceive more enthusiasm about engineering among students, better retention and graduation rates. In addition, since students graduate at a faster pace, the implementation of the new curriculum will reduce the overall cost of college education for both the institution and students. Table 1 shows the traditional engineering curriculum versus the revamped curriculum. The underlined courses are the deficiency classes and the courses shown in bold are the basic engineering courses that are required before taking higher level engineering courses. The courses shown in italic are either new or redesigned courses. The courses indicated as "Core" are the required general core courses for the entire university population. As shown, following the proposed curriculum, students can register for basic engineering courses such as statics and network theory in their second semester. Taking and passing these gateway courses early provides opportunity for students to get involved in their engineering curriculum and interact with engineering faculty and peers sooner.

TABLE I. TRADITIONAL VS. REVAMPED CURRICULA

Term	Traditional Curriculum	Proposed Curriculum
1	Pre-Calculus, Core Courses	*Just in Time Math*, Core Courses
2	Calculus, Core Courses	**Statics,** *Calculus for Engineers*, Physics I, Computer Programming, Core Courses
3	Calculus II, Physics I, Computer Programming, Core Courses	*Calculus II*, **Circuits**, **Dynamics,** Physics II, Core Courses
4	**Statics**, **Applied Engineering Analysis I,** Physics II, Core Courses	***Applied Engineering Analysis I,*** Required Engineering Courses, Core Courses
5	**Dynamics**, **Circuits**, **Engineering Analysis II,** Core Courses	***Applied Engineering Analysis II***, Required Engineering Courses
6	Required Engineering Courses	Required Engineering Courses
7	Required Engineering Courses	Elective Engineering Courses
8	Elective Engineering Courses	Elective Engineering Courses
9	Elective Engineering Courses	

III. SETTING AND PARTICIPANTS

The objectives of our longitudinal study are:

1) To create a new mathematics sequence, with the engineering applications, in order to prepare students for the basic engineering classes during their freshman and sophomore years.
2) To revamp the engineering curriculum based on the changes in the mathematics sequence.
3) To develop a continuous quality improvement (CQI) model to monitor, track, control, and feedback performance outcomes on our program.

A. Just In Time Math

As taught at UTSA, Freshman Seminar/JITM is a combination of topics offered to help a Freshman engineering student to make the adjustment from high school to university life, and to review and learn the mathematics employed in first and second year engineering courses such as statics, dynamics, electrical circuits, and mechanics of solids. The course is taught under the auspices of UTSA Learning Communities (LC), and includes student success topics such as preparing for class meetings, note taking, how to study, learning one another's names, advantages of group study, meetings with faculty during office hours, time management, and the importance of not falling behind during the semester. LC requires that students attend classes regularly, write two or more papers on themes suggested by LC and by the instructor, make an oral group presentation to the class, attend an orientation on library resources, and attend/participate in a minimum of 3 university life functions. These topics, as well as an introduction to engineering as a profession, are all addressed in Landis' Studying Engineering textbook[5].

The JITM features lectures and exercises on topics such as linear equations and quadratic equations, trigonometry (including applications of law of sines and cosines), matrix operations, complex numbers, harmonic functions, differentiation, integration, and first and second order linear ordinary differential equations. Homework problem sets are assigned for each topic, and a series of eight laboratory experiments or demonstrations are used to illustrate concepts. The book by Rattan and Klingbeil is used as a class text book [6].

Several of the laboratory experiments/demonstrations require students to plot their results in graph form. MATLAB is introduced for this purpose to manipulate and graph experimental data and to perform a variety of mathematical operations and numerical solutions. At UTSA, MATLAB is available for student use in computer labs, and online from UTSA Apps outside of class. MATLAB tutorials using the textbook by Gilat are incorporated into the schedule [7].

The laboratory experiments/demonstrations illustrate concepts and introduce the student to experimental error. Lab #5, Freefall Application of the Derivative is a good example. The laboratory apparatus was purchased from PASCO and consists of a paper tape and a counter which stamps (marks) the tape every 1/40 second by tapping a piece of carbon paper against the tape. A weight (about 0.3 kg) is attached to the end of the tape, and is allowed to fall about 1 m distance to the floor. As the weight falls, the tape is pulled through the counter and marks are stamped onto the tape. It takes about 0.4 seconds to perform the experiment. The tape is recovered, placed on a table, and student measures the distance of each mark from the start (the first set of marks) using a meter stick. The data for distance as a function of time is recorded by students in a spreadsheet. The instantaneous average velocity is approximated by the first difference function, $v(t) = [y(t) - y(t - 0.025)]/\Delta t$, and the instantaneous acceleration is approximated by the second difference function, $a(t) = [v(t) - v(t - 0.025]/\Delta t$.

Students are then asked to plot their data for distance, velocity and acceleration using MATLAB. When plotting the data for distance, they also use the MATLAB basic fitting function to calculate a least square error curve fit for a quadratic function to their data. Typical graphs for position, and acceleration as a function of time are shown in Figs. 1 and 2.

The position curve in Fig. 1 appears to be smooth, but the acceleration data is erratic. As students plot the data, a discussion of why the acceleration data is so variable is held. Also of interest is the quadratic curve fit to the position data which suggests that the acceleration was about 9.0 m/s^2 and not 9.8 m/s^2 as expected. Free body diagrams were discussed earlier in the course, and a free body diagram is used again together with Newton's second law to account for the lower than expected value of acceleration. The possibility that friction caused by the striker bar pushing the paper tape against the sheet of carbon paper is responsible for some of the error is discussed.

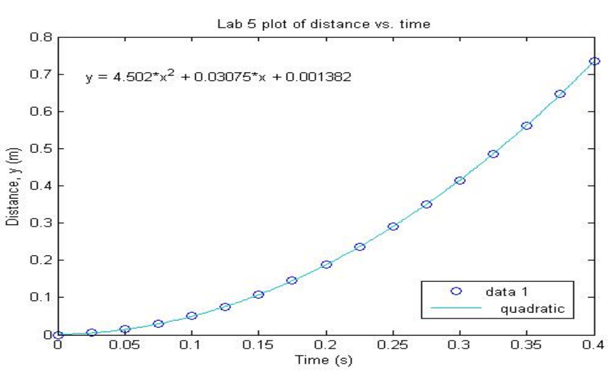

Fig. 1. Plot of lab 5 data for position vs time

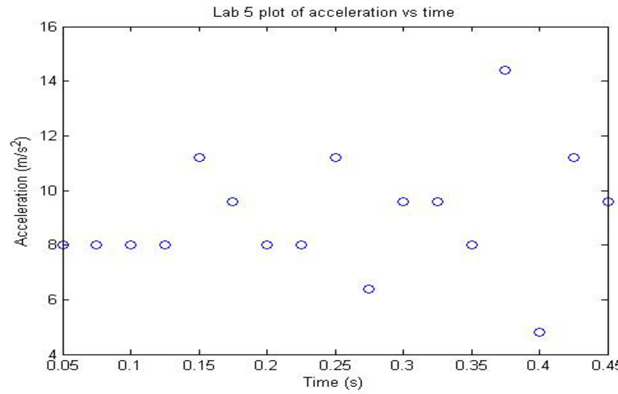

Fig. 2. Plot of Lab 5 data for acceleration vs. time

B. Calculus for Engineers

The Calculus for Engineers, which replaces Calculus I, is a new Calculus course with engineering applications. The Department of Mathematics and College of Engineering have established a fruitful collaborative relationship. At the request of the College of Engineering, the Department of Mathematics has begun a reconstruction of the Calculus sequence generally with particular emphasis on the development of calculus sections focused on students pursuing degrees in Engineering. There is much more to be done, but to this point Mathematics has set aside special sections for engineering students in which there have been some curricular changes (e.g., increasing the focus on applications), re-sequencing of some topics and the engagement of instructors with an understanding of the engineering perspective. The College of Engineering and Mathematics Department have conducted a series of workshops for the math instructors to discuss the infusion of engineering applications in calculus. Examples of the discussion topics include: application of fractional calculus in dynamical systems, and application of integrals to characterize non-uniform media. Since the fall of 2011 the College of Engineering has also provided tutoring sessions, conducted by engineering Teaching Assistants, for the calculus courses. with engineering Teaching Assistants. Overall, tutoring has improved the math grades for engineering students substantially.

C. Engineering Analysis

In the JITM and Calculus for Engineers, students are guided to get familiar with contemporary issues in engineering, use of computer-based tools, and presentation skills. The freshman curriculum should prepare students for the sophomore level Engineering Mathematics course, known as Engineering Analysis I, EA1. By the time students are registered for the EA1, they should be familiar with the basic engineering terminologies and direct experience/observation in the engineering applications. To further improve their readiness for more advanced engineering classes, we will also incorporate application of math in engineering topics by adding physical measurements to the content of the EA1. The

EA1 focuses on the application of mathematical principles to the analysis of engineering problems using linear algebra and ordinary differential equations. It also emphasizes the usage of software tools to facilitate the learning process. Topics covered in this course include: mathematical modeling of engineering problems; separable ordinary differential equations (ODE's); first, second, and higher-order linear constant coefficient ODE's; characteristics equation of an ODE; systems of coupled first-order ODE's; matrix addition and multiplication; solution of a linear system of equations via Gauss elimination and Cramer's rule; rank, determinant, and inverse of a matrix; eigenvalues and eigenvectors; solution of an ODE via Laplace transform; and numerical solution of ODE's. We have utilized the Matlab tools to incorporate engineering applications in this course by creating several simulation modules that can be used throughout the semester. Examples of such modules include time and frequency analysis of electric circuits (first, second and higher order ODE's); stability analysis of control systems (matrix algebra); and deformation of solids by forces (eigenvectors).

For the EA1, the knowledge points we o emphasize in the redesigned course include: matrix multiplications, eigenvalue decomposition, and solutions of partial differential equations. In order to fulfill the aforementioned three aspects, we have established 6 experiments for EA1. We have utilized MATLAB toolboxes to open several graphical user interface (GUI) boxes to implement these experiments. The following six experiments exhibit the assignments for the electrical engineering students in EA1. Similarly, we plan to establish new sets of experiments established for other engineering majors.

- Laboratory 1: *"Complex Numbers"* – An application on complex numbers, provides the possibility to enter numbers and visualize them in a complex plane

- Laboratory 2: *"Sinusoids"* – An application on studying and visualizing sinusoids. User can select different sinusoid parameters.

- Laboratory 3: *"RLC Circuit"* – An application simulating second order RLC Circuit where student can change R, L, and C parameters and display different results.

- Laboratory 4: *"Spectra Estimation"* – An application which demonstrates the use of matrix multiplication for spectra estimation using Discrete Fourier Transform (DFT) matrix. One can choose different type of signals, perform DFT and display the results.

- Laboratory 5: *"Compression"*– An application on using matrix multiplication and inversion for compression of images. It also demonstrates the use of Eigen value decomposition. The following matrices (1) Discrete Cosine Transform (DCT) matrix; (2) matrix composed of eigenvectors are used for the compression of images similar to JPEG format. Inverse transforms are used to reconstruct original signals with slight degradation in quality.

- Laboratory 6: *"Equalization"*– An application on using matrix multiplication, transposition and inversion for signal equalization used in communication systems to improve the reception quality.

Fig. 3 depicts the result from one experiment. The GUI shows how matrix algebra is used in solving engineering problems. It demonstrates matrix multiplication concept on the example of spectra estimation used in wireless communications, and eigen decomposition used in image compression applications.

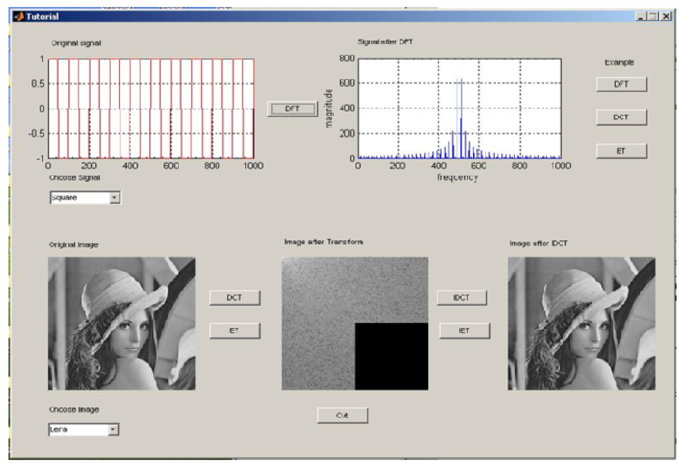

Fig. 3. Application of matrix multiplication in spectrum estimation and image compression.

IV. DATA COLLECTION

The assessment includes one factor (Program) with 2 levels (Pilot and Traditional) with 3 dependent variables that measure quality (Grade), system reliability (Retention - RET), and time (Progress Toward Degree - PTD), along with Nuisance factors (NF). The general function is shown in Equation 1.

$$(GPA, RET, PTD) = f(Program, NF) \quad 1$$

Retention is defined as the ratio of those cohorts in engineering versus the total number that began. PTD is especially important given the impetus placed on 6 year graduation rates by the State. Loosely defined, it is quantified as the ratio of number of degree catalog hours earned to the targeted number of degree hours at any point in time. As depicted in Fig. 4, would measure, at calendar time t, the ratio of completed (x) versus targeted (y) degree hours based on an N-yr graduation rate. It can be seen that when t = the actual t (ta) the student is just on track to finish in N years.

Fig. 4. Progress Toward Degree metric variables.

Several nuisance variables are accounted for as well. These are factors, shown below, that can influence the value of the dependent variables other than the treatment of interest and are not of direct interest in this assessment: college GPA (if exists); gender; ethnicity; rank of high school; math placement test score; SAT/ACT math and overall scores; engineering major; math entry level - MEL (traditional program cohorts have 2 MEL levels – Calculus II and Calculus I ready; the Pilot program cohorts have 1 MEL level – pre-calculus ready. Since the sample size is small for Calculus II ready cohorts, these students will not be included in this study. Therefore, Traditional program cohorts are those that enter UTSA Calculus I ready).

V. Data Analysis

The data collected at the end of each semester indicate that the retention rate and cumulative GPA for cohort students who participate in this study are superior compared to those of the traditional cohort. Table 2 exhibits the results for the last 3 years. In addition, Fig. 5 demonstrates the grade distribution for the Calculus I course for tutored vs. non tutored students. Based on the retention rates, we predict 4^{th}, 5^{th}, and 6^{th} year graduation rates of 30%, 45% and 60%, respectively, for the project cohorts. Meanwhile, the same graduation rates for our traditional cohorts are about 18%, 30% and 40%, respectively.

TABLE II. Retention Rates For the Project Cohorts vs. Traditional Students

	Project Cohort		**Traditional Cohort**	
	Retention	**GPA**	**Retention**	**GPA**
1^{st} year	92%	2.90	71%	1.87
2^{nd} year	82%	3.10	63%	2.79
3^{rd} year	72%	3.02	48%	2.75
4^{th} year	64%	2.96	40%	2.60

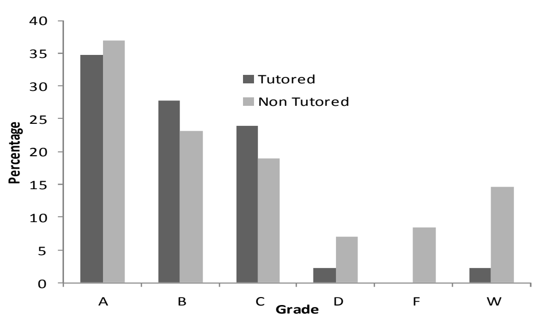

Fig. 5. Grade distribution in Engineering Calculus

VI. Summary

We have discussed the implementation of the newly developed JITM course along with the revamping of the traditional calculus and engineering mathematics courses in order to improve retention and graduation rates of engineering students at UTSA. In addition, a revamped version of the engineering curriculum has been discussed. Cohorts of students have been selected on a volunteer basis to follow the modified version of the curriculum. The primary objective for this project is to help prepare students for the basic engineering courses during their freshman year. Our initial assessment indicates a substantial improvement in the retention rates among the cohorts in comparison to the traditional cohorts. This study was initiated with 12 pre-freshman students in the summer of 2008 at UTSA. Since then, the JITM course has been taught regularly at least twice per year, either during fall and spring or fall and summer semesters. The average enrollment per semester has been about 20 students. The average grade distribution for the JITM class is A (29%), B (37%), C (25%), and D, F, and W (9%). The overall average GPA for the course is 2.83/4.0.

Acknowledgment

The support for these projects has been provided by the following agencies for the past couple of years: University of Texas System, US Department of Education (project number P120A090003) and a sub-agreement with the Wright State University, under NSF prime agreement DUE-0817332. We are also grateful to Professors Thomas Morrow and David Akopian for developing experiments for JITM and EA1 courses.

A Web-Based Interactive Intelligent Tutoring System for Undergraduate Engineering Dynamics

Ning Fang and Yongqing Guo
Department of Engineering Education
Utah State University
Logan, Utah, USA
ning.fang@usu.edu

***Abstract*—A web-based interactive intelligent tutoring system was developed and assessed in an engineering dynamics course. The system consists of two learning modules to help students learn how to apply the Principle of Work and Energy to solve particle and rigid-body dynamics problems. Student learning gains were compared using a quasi-experimental research design that involved pretests and posttests in both a control semester (n = 62) and a treatment semester (n = 44). It is shown that the ITS modules increased student learning gains by 37-43%.**

Keywords: Intelligent tutoring system; quasi-experimental design; student learning gains; engineering dynamics

I. INTRODUCTION

Nearly all mechanical, civil, aerospace, and biomedical engineering students are required to take engineering dynamics, a core undergraduate engineering course [1]. This sophomore-level course is a fundamental building block for many advanced studies in subsequent courses; e.g., vibration, system dynamics and control, and machine and structural designs. However, many students fail dynamics. On the standard Fundamentals of Engineering examination in 2009, the national average score on the dynamics exam was only 53%.

An intelligent tutoring system (ITS) is an interactive learning tool that allows students to solve technical problems with the guidance of a virtual tutor [2]. During problem solving, students can ask the virtual tutor questions or request hints on what to do next, just as may occur in a real classroom environment where students can ask a human tutor questions or request hints. A properly-designed ITS is particularly helpful for large classes where instructor-student interaction and one-on-one tutoring time are limited.

In our recent efforts to improve student learning in an engineering dynamics course, a web-based interactive ITS consisting of two learning modules was developed. These ITS modules help students learn how to apply the Principle of Work and Energy to solve particle and rigid-body dynamics problems. Literature review, such as [2, 3], showed that the existing ITSs were developed for courses such as computer-aided modeling and design, circuit analysis, and physics. With the exception of the authors' own work, no other ITS has been developed for any engineering dynamics courses.

In this work-in-progress study, the effect of the two ITS modules on student learning in an engineering dynamics course was investigated. The research question is: To what extent did the developed ITS modules improve student learning in engineering dynamics? To answer this question, a quasi-experimental research method that involved pretests and posttests in both a control semester (n = 62) and a treatment semester (n = 44) was employed. Student learning gains in the two semesters are compared. Conclusions are made at the end of the paper. Beyond this work-in-progress study, future research will be focused on a mixed-methods study of how the ITS improves student learning in engineering dynamics.

II. AN ITS FOR ENGINEERING DYNAMICS

Using the Cognitive Tutor Authoring Tools [4], we have developed two web-based interactive ITS modules for students to learn the Principle of Work and Energy in particle dynamics and rigid body dynamics. Both modules contain a carefully-designed set of hints to provide students with step-by-step guidance for problem solving.

As an example, Figure 1 shows a computer graphical user interface of the second ITS module. In this problem, an external moment is applied to a rotating disk that is linked with a spring. Students must identify a correct free-body diagram, calculate the work done by all forces and moments, calculate the initial and final kinetic energy of the disk, and finally apply the Principle of Work and Energy to determine the angular velocity of the disk after it moves a given distance.

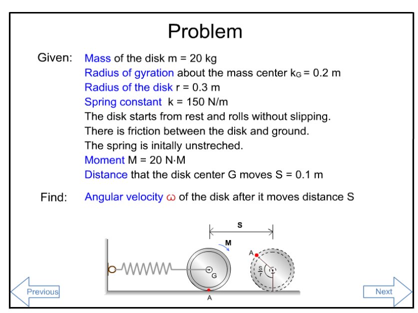

Figure 1. A rigid-body dynamics problem.

Based on students' common misunderstandings, we have developed a set of hints and incorporated them into the ITS module for use in problem solving. As an example, Figure 2 shows a hint explaining why the normal force (that is applied to the disk) does not do work.

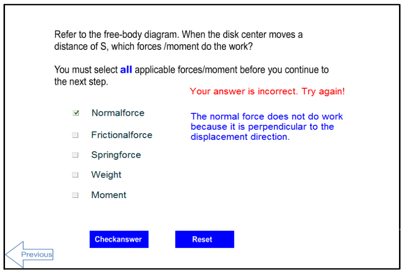

Figure 2. An example hint.

III. RESEARCH METHOD AND STUDENT PARTICIPANTS

Employed was a quasi-experimental research method that involved two cohorts of sophomore engineering student participants in a control semester and a treatment semester. The same instructor taught in both semesters. Table I shows the number of students in each semester for each ITS module. The results of t-tests showed that there were no statistically significant differences in pretest scores of two cohorts of students in the two semesters.

TABLE I. STUDENT PARTICIPANTS

	ITS module 1	ITS module 2
Control semester	n = 62	n = 55
Treatment semester	n = 44	n = 36

We have also designed a set of multiple-choice, technical assessment questions for use in pretests and posttests in both semesters. For ITS module 1, there were six assessment questions; for ITS module 2, seven assessment questions. These questions had a variety of levels of difficulty. The student learning gain was calculated for each student as

$$\text{Learning gain} = \frac{\text{Post-test score (\%) - Pre-test score (\%)}}{\text{100 (\%) - Pre-test score (\%)}} \quad (1)$$

IV. RESULTS

Based on the learning gain of each student, the class-average learning gain was calculated in both semesters, and the results are shown in Table II.

TABLE II. CLASS-AVERAGE STUDENT LEARNING GAINS

	ITS module 1	ITS module 2
Control semester	12.9%	7.0%
Treatment semester	49.7%	50.0%

As seen from Table II, the class-average learning gains in the control semester were only 12.9% (for ITS module 1) and 7.0% (for ITS module 2). The class-average learning gains in the treatment semester increased to 49.7% (for ITS module 1) and 50.0% (for ITS module 2). Therefore, it is concluded that the ITS modules increased student learning gains by 37-43%.

As two examples, Figures 3 and 4 show the percentages of students who chose correct answers to seven assessment questions used in pretests and posttests of ITS module 2 in the control and treatment semesters. Student learning was improved in all assessment questions except question 7. Question 7 requires students to *synthesize* both conceptual and procedural understanding to finally solve the problem. How to improve students' skills for knowledge synthesis still remains a great challenge for the ITS.

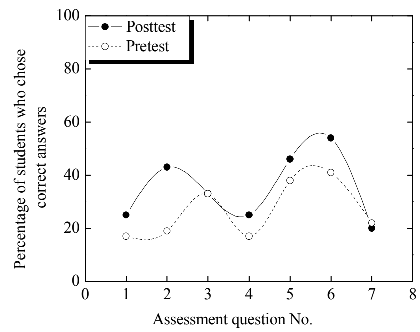

Figure 3. The control semester: students did not use ITS module 2.

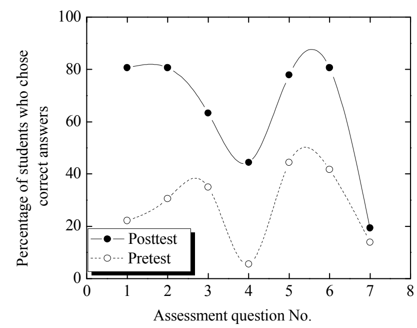

Figure 4. The treatment semester: students used ITS module 2.

V. CONCLUSIONS

In this WIP study, a web-based interactive intelligent tutoring system has been developed and assessed in an engineering dynamics course. The comparison of student learning gains in a control semester and a treatment semester shows that the intelligent tutoring system that we developed increased student learning gains by 37-43%. In the future, we plan to conduct a mixed-methods study to investigate how students use the ITS to learn engineering dynamics.

Testing the Flipped Classroom with Model-Eliciting Activities and Video Lectures in a Mid-Level Undergraduate Engineering Course

Jacob Bishop
Utah State University
Logan, Utah

Matthew Verleger
Embry-Riddle Aeronautical University
Daytona Beach, Florida

***Abstract*—This paper outlines an ongoing study of the flipped classroom with second and third-year undergraduate engineering students in a numerical methods course. The flipped classroom is a new pedagogical method, which employs asynchronous video lectures and practice problems as homework, and active, group-based problem-solving activities in the classroom. It represents the combination of learning theories once thought to be incompatible—active, problem-based learning activities founded upon constructivist ideals and instructional lectures derived from direct instruction methods founded upon behaviorist principles. Using a controlled quasi-experimental research design, we conduct a study with a full 15-week numerical methods course at Utah State University during the spring semester of 2013. Students in the experimental section completed model-eliciting activities inside the classroom and video lectures and homework outside the classroom. Students in the control section completed homework outside the classroom and group lectures inside the classroom. The two groups will be compared using scores from homework, examinations, and a sixteen-question numerical methods conceptual pre- post- test pair. The three main features that distinguish this study from previous research are: 1) This is a controlled study; 2) This study examines student performance on objective measures; 3) This study uses model-eliciting activities in the experimental classroom.**

I. Introduction

Many engineering graduates lack the ability to solve the type of real-world problems that will be encountered when they enter the workforce; however, these same students are well trained in solving textbook problems that require little more than the ability to determine which formula to apply based on which section of the textbook it appears in [1, pp. 39]. This represents a major shortcoming of the education currently offered in our institutions. The Accreditation Board for Engineering and Technology (ABET) has introduced outcomes a-k in part to formalize these concerns, and to charge university programs with addressing them [2].

Pedagogical approaches such as Problem Based Learning, Active Learning, and Peer Assisted Learning have been introduced for teaching these skills. More recently, Model-Eliciting Activities (MEAs) have been/are being developed and implemented based on many of these same theories [3], [4] to help engineering students develop real-world teamwork [5], [6], problem solving [7], and communication skills [8].

Despite these advances, even where active learning methods such as MEAs have been implemented, this implementation is typically limited. As an example, MEAs have been introduced at Purdue University only with first-year engineering students. At the other end of the curriculum, senior-level students at most universities typically participate in a capstone design project. However, for the majority of their undergraduate carreer, students still deal exclusively with "textbook problems." There is significant institutional resistance to comprehensive change. This may be due to anxiety over changing core courses, or to the perceived impossibility of cramming more into an already full curriculum. The situation seems to be at a stalemate with innovative educators recommending a more holistic approach, and institutions reluctant to give up traditional lectures and homework.

The flipped classroom teaching model may allow both sides to get what they want. In the flipped classroom model, lectures are pre-recorded, and played back by students on their own time[1]. Individual homework is also completed outside of class. In essence, the entire educational experience currently being provided in the classroom can now be obtained online. Despite the fears and over-reactions of some, this does not mean that institutions will be out of business. Rather, lectures and homework can be completed outside of class, while active learning activities take place within the classroom. Thus, it may no longer be an either-or proposition, with lectures and homework on the one hand and active learning on the other.

While the flipped classroom model seems to be a promising method for improving student learning and conceptual understanding, there is unfortunately limited evidence of its effectiveness. A recent survey of the flipped classroom research [9] found that while a number of papers have been published about the flipped classroom, almost none of the studies described in these publications used controlled research designs or reported outcomes of the flipped classroom on objective test measures. This provides the primary motivation for the current study.

II. Research Questions

The main purpose of this research is to begin the process of objectively evaluating the effectiveness of the flipped classroom. It is reasonable to assume that in order for the flipped

[1]While there is not universal consensus on what the flipped classroom is, our definition here captures much of what is currently being called the "flipped classroom."

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

classroom to be successfully adopted in universities, students from classrooms using this model must attain at least the same level of performance as students in current classrooms on traditional performance evaluations (e.g., homework assignments and unit examinations). Failure to meet this criteria would represent a significant barrier to adoption. This forms the basis of the first research question: Will students in a numerical methods course taught using the video lecture/MEA format attain equal or higher learning performance than students in a traditional lecture-based course, as measured by student homework and exam scores?

The second fact that must be faced is that unless students in the flipped classroom gain something over students in current classrooms, there is little need to adopt this model. To this end, we examine student performance on another construct: conceptual understanding. The effort to measure conceptual understanding as a dimension distinct from what typical teacher-constructed tests evaluate is epitomized in the development of the Force Concept Inventory (FCI) [10]. Adams and Wieman [11] describe the appropriate process of creating and validating this type of test. No well-researched and rigorously established concept test for numerical methods is available; however, the development of such a test is underway [12]. We use a preliminary 16-item version of this conceptual numerical methods test to evaluate the second research question: Will students in a numerical methods course taught using the video lecture/MEA format attain equal or higher conceptual understanding than students in a traditional lecture-based course, as measured by a concept test?

III. Research Design

A. Course & Participants

ENGR 2450, Numerical Methods for Engineers, is a three-credit sophomore-level engineering course at Utah State University in Logan, Utah, which is usually offered each spring semester. It is required for engineering students in five majors: Biological Engineering, Environmental Engineering, Civil Engineering, Environmental Engineering, Computer Engineering, and Electrical Engineering. Enrollment totals for the Spring 2013 academic semester, and information regarding gender and declared major for students is shown in Table I. Ethnicity data for students enrolled in the course was not directly available. However, 83% of students at Utah State University are white non-Hispanic. Three courses are required as pre-requisites to ENGR 2450: Linear Algebra and Differential Equations, Introductory Programming, and Calculus II. However, ENGR 2450 and Linear Algebra and Differential Equations may be taken concurrently. ENGR 2450 meets three times a week for 50 minutes. There are a total of 45 class periods over the course of the 15-week semester. One of these is a 110-minute period reserved for the final exam. Seven general topics mirroring those presented in the required text [13] are introduced in this course. These include number representation and error analysis; root-finding and non-linear equations; numerical linear algebra; interpolation, polynomial, approximation and curve fitting; integration and differentiation; ordinary differential equations; and partial differential equations.

Table I
Demographics for Students in ENGR 2450 Spring 2013

		Section			
		C	T	Total	Percent
Gender	Female	17	10	27	16.46
	Male	68	67	135	82.32
	Not Available	2	0	2	1.22
Major	Biological Engineering	23	6	29	17.68
	Civil Engineering	29	32	61	37.20
	Computer Engineering	10	8	18	10.98
	Electrical Engineering	15	21	36	21.95
	Environmental Engineering	2	4	6	3.66
	General Engineering	4	4	8	4.88
	Mechanical Engineering	3	1	4	2.44
	Other	1	1	2	0.61

Note. Section: C = Comparison Group; T = Treatment Group.

B. Treatment Section

The treatment section of the course was redesigned to integrate web-based video lectures and model-eliciting activities. The same topics were presented in the same order, except that all in-class lectures were supplanted by web lectures. Among the recommendations for best practice noted in the literature, a quiz or pre-class activity is said to provide motivation to watch the video lectures, and establish continuity between web lectures in-class activities [14], [15]. Consequently, a short quiz on the corresponding lecture material was required before class starts. Classroom attendance is required. The first topic of discussion in every class will be on the questions from this quiz.

Two MEAs are being conducted throughout the semester, with each MEA spanning approximately six weeks. Working in groups of 3-4, students were required to complete a total of three drafts of their work for each MEA. Each group both provided and received peer feedback between the first and second drafts of the MEA memo. Between the second and third drafts, students receive feedback from a graduate teaching assistant.

C. Comparison Section

The comparison section of ENGR 2450 is being taught in the usual manner. Specifically, thirty-four class periods will be used for in-class lectures and review. Ten class periods will be used for administering the concept test and examinations. Only minor changes will be made to ensure equivalence between the experimental and comparison section. For example, students in both sections will have access to similar written materials, and students in the comparison section will complete programming assignments in order to offset the time spent on MEAs by the students in the treatment section.

IV. Results

Results are forthcoming, and will be presented at the conference.

***Abstract*— Open-ended questions are an important means to support analysis and assessment of students; they can be of extraordinary effectiveness for the assessment of higher cognitive levels of the Bloom's Taxonomy. On the other hand, assessing open answers (textual, freely shaped, answers to a question) is a hard task. In this paper we describe an approach to open answers evaluation based on the use of peer-assessment: in a social-collaborative e-learning setting implemented by the OpenAnswer web system, the students answer questions and rate others' (and may be own) answers, while the teacher marks a subset of the answers so to allow the system inferring the rest of the marks. The aim of our system is to ease the teacher's marking burden and allow for a more extensive use of open ended questionnaires in her/his teaching activity.**

Keywords—assessment, peer-assessment, social collaborative e-learning

I. INTRODUCTION

Open ended questionnaires (where questions can be answered through free text writing) can play a crucial role in the activity of evaluation and analysis of a learner's knowledge.; from a pedagogical point of view, they can be of extraordinary effectiveness for the assessment of skills [1,2].

On the other hand, assessing open answers is a hard task. A good deal of research activity has been performed in this regard, applying a variety of Computer Science techniques (see Sec. II).

In this paper we describe an approach to open answers evaluation based on the use of peer-assessment in a social-collaborative e-learning setting; we implemented it in the OpenAnswer web system, where a student answers questions, rates others' (and may be her/his own) answers, while the teacher marks a subset of the answers so to allow the system inferring the rest of the marks. The aim of our system is to ease the teacher's marking burden and allow for a more extensive use of open ended questionnaires in her/his teaching activity.

OpenAnswer allows to: 1) deliver open ended questions to groups of students; collect the open-answers; 3) collect each student's peer assessment of some of the answers given by others (and possibly by her/himself); 4) managing a student model representing learner's competence and her/his ability to assess/self-assess; 5) support the teacher's analysis and grading of the answers, by iteratively suggesting the next answer to assess so to reach a configuration in which all the remaining answers can be graded basing on the peer evaluations and the implicit endorsement derived by the teacher's marks. The student model is managed through a simple Bayesian-networks based approach, grounding on the student's given peer assessments and their correspondence to final grading of the answers related to those assessments. The next-question-to-grade mentioned at point 5 above, is selected by taking into consideration the grades actually given by the teacher, the students models computed basing on such grades, and the peer assessments available on the remaining answers. This process brings the system to eventually assigning grades on a part of the answers still not graded by the teacher. This is done by exploiting the possible trust on the students' peer assessments, as pointed out by the underlying Bayesian networks model.

So a complete grading of the starting set of answers can be reached, saving for the teacher a part of the direct grading work, and making the use of open ended questions more feasible in a didactic setting. We think that a good side effect of the use of OpenAnswer is in the students being exposed to assessment and self-assessment, which are high cognitive level activities in the Bloom's Taxonomy [2].

In previous work we have dealt with the definition of the formal models deemed to support the marking process, with a Constraint Logic Programming based approach and with a Bayesian Networks based model [3,4,5]. We hadn't yet implemented a system able to let teachers use either models, nor we performed real experimentations (limiting to simulated experimentations). Here we show the OpenAnswer web-based system, the implementation of Bayesian networks propagation and analysis, some basics of the underlying formal system, and an experimentation involving real students data.

II. RELATED WORK

Data mining with natural language processing and concept mapping have been used to summarizing questionnaires, extracting customers opinions and defining products reputation [6,7]. Mainly, in these cases, marketing and commercial applications were pursued. An overview of educational applications of the Data Mining Technology is in [8].

In [9] concept mapping is used to define and apply so-called "coding schemes" for answers: answers are labeled by such schemes to be analyzed and classified. Classification is supported by *semantic annotations*, labeling answers' parts; labels are by human "coders" applying the coding-schemes. In [10] an implementation of a (partially semi-)automatic assessment of open-answers is shown, based on the use of ontologies and semantic web technologies. The ontology formally defines the domain of knowledge related to the questions. Then the ontological labels that have to characterize the answers are expressed as "Semantic annotations". When also the answers have been labeled in terms of the ontology, they can be analyzed, by evaluating the similarity of their ontological labels against the question's ones. Such evaluation is followed by grading.

In [11] open answers are represented by set of algebraic transformations; they are analyzed to determine the implicit conceptions (and mis-conceptions) of the students, and to treat them with the ways of an intelligent tutoring system. An evaluation of this system has proven worthy when applied to answers constituted by purely algebraic expressions, without intermixed text in natural language. The work exploits admirably the fact that the derivation and evaluation of expressions of a formal language is highly automatable [12] and a possible expansion of the work points at integrating the comments intermixed in the answer in the grading process.

III. THE OPENANSWER SYSTEM

OpenAnswer is a module integrated in a preexisting PHP-based Leaning Management System (named sLMS). In it, each course can be upgraded so as to use OpenAnswer services. A teacher in OpenAnswer can

a) define a questionnaire associated to a course;

b) define a questionnaire session, that is an occasion for administering the questionnaire to a group of students;

c) open/close the "answer time" for a session;

d) open/close the "peer-assessment time" for a session;

e) examine a session that has been peer-evaluated: here the teacher can assess and mark (some of) the given answers;

f) publish the session grading for students.

In phase a) the teacher specifies some information on the questionnaire, namely 1) the number of open ended questions, 2) how many answers will be peer-assessed by each peer, 3) cardinality of each group of students (they have to be partitioned in groups of 10-25 students, otherwise the computation burden of the system would make unfeasible its response time), 4) whether the student could be presented with her/his own answer to be assessed (and with what probability: always, never, 33% or 66%), 5) whether the answer should be anonymous or bear the author's username. Moreover the question(s) used in the questionnaire are selected from a repository (presently associated to the course, with no tag related to the topic). When a question was defined and added to the repository: a set of criteria was associated to it. Criteria are defined in a special repository. The association between a question and some criteria is important as it will help providing some directions to students during their peer-reviewing activity. When a question is selected for the questionnaire, the associated criteria are shown and some or all of them can be checked for the purposes of the specific questionnaire. In phase b) the teachers defines a session, basically by specifying what questionnaire will be used and how the groups of students are composed. In phase c) the questionnaire is submitted to the students, and the answers are entered. Then the answer period is closed the peer-assessment can take place. Consider that these time-spans can last as long as the teacher wish (from minutes to days; the only constraint is in the answer phase being closed before the peer-assessment starts.

In phase e) the teacher start the analysis of a session. The present implementation of the system the main goal is support to experimentation, so two specific services are provided (which will probably not be part of the final release): 1) it is possible to "clone" a session that has been already peer-evaluated, and 2) it is possible to select the method (strategy) that will be used by the system during the marking phase for the session (cfr. next section for the different strategies that can be used to support the teacher and suggest the "best next answer to mark"). Having clones of the same (peer-evaluated) session allows to apply and compare different strategies. One of the selectable strategies is the "manual" one: the teacher will assess all the answers (and this also is a relevant option in the present experimental phase). In this phase the teacher can select a session to grade (and select the strategy to apply) and start marking. The teacher is presented with the list of answers for the session/group (Fig.1).

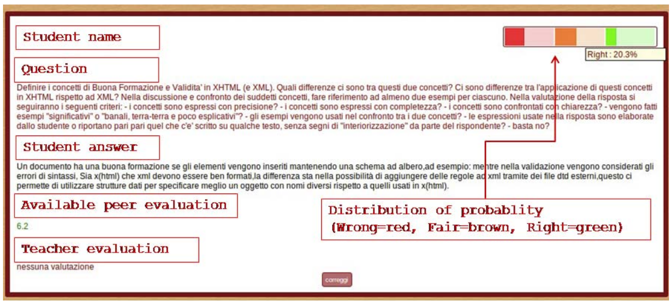

Fig. 1. Guided correction: For each answer in the list, the distribution of probability of being Wrong/Fair/Right (cfr next section) is shown. E.g. the answer in figure is more likely to be wrong/fair, than right, according to what the system can infer so far during the grading phase).

The first question is the one suggested for grading (at any stage of grading, it is supposed to be the one that helps better the system to converge towards the possibility to grade automatically the answers not yet graded by the teacher, according to the strategy in use).

In OpenAnswer a Student Model (SM) is managed: the competence of the student on the subject matter at hand, and her/his ability to assess others' and own answers are stored as the distribution of probability for her/his K and J variables over the values Good/Fair/Bad (cfr next Section). Each session grading starts using the present values in the students SMs; these values evolve, in a protected computing environment, according to the propagation mechanism occurring during teacher's work on the session. So, after a session has been graded, temporary new values for the students SMs are stored: they are not directly used to update the global values of students SMs, rather they can be used to do that, if the teacher activates the updating process. This is because, in the present implementation of OpenAnswer we can have clones of a same session, to be graded by different strategies, and we would not like the modifications of the SM due to a grading done by a given strategy affecting the results of the same-session grading performed through another strategy; so, if there are several sessions graded, when the temporary SMs produced by one of them is used to update the global students SMs, then this possibility is lost by all the other graded sessions.

IV. The Bayesian network module

In OpenAnswer a Yap Prolog ([13,14]) module supports the management of the Bayesian network. The module

- reads the run parameters from the DB;
- builds the Bayesian network corresponding to the peers' assessment network;
- introduces as evidence the currently available teacher's corrections;
- propagates the evidence through the Bayesian network to compute the probability distributions of the answers' correctness;
- selects the next answer to be corrected depending on the given strategy and the computed probabilities;
- writes back to the DB both the chosen student and the computed probabilities.

A. A simple Bayesian network model

The Bayesian network modeling the peer-assessment (defined through the CLP(BN) library available in Yap Prolog) is made of 3 finite-domain variables for each student:

K: Knowledge (good, fair, bad)

J: Judgment (good, fair, bad)

C: Correctness (right, fair, wrong)

The Knowledge variable is independent and based on the following probability distribution:

	good	fair	bad
P(K)	0.5	0.2	0.01

Notice that the above and the following probability distributions tables are "synthetic", that is they have not been (yet) extracted from actual experimental data. This is presently acceptable, we think, because our aim, for the moment, is to test if the methodology works sufficiently well with the Bayesian approach. An important property of Bayesian networks is that such probability distributions can be learned from experimental data. Thus, later, we will obtain these distributions from the student's interaction with the system.

The 3 variables of our model are related through two Conditional Probability Tables (CPTs), that (for the moment, according to what specified above) are as follows: the first table relates the student's knowledge about the questionnaire topic and the correctness of her/his answer

P(C|K)		K		
		good	fair	bad
C	right	0.5	0.2	0.01
	fair	0.4	0.5	0.3
	wrong	0.1	0.3	0.69

The rationale for this assumption is that the answer is open, therefore the student could not guess its content (for the moment we are ignoring plagiarism issues).

Similarly, we model the Judgment variable as probabilistically dependent on Knowledge. The rationale being that judging the answers of peers is a higher cognitive activity respect to both *knowing* and *using* the knowledge useful to answer. In this we take inspiration from the Bloom's taxonomy of cognitive abilities.

P(J|K)		K		
		good	fair	bad
J	good	0.5	0.2	0.01
	fair	0.4	0.5	0.3
	bad	0.1	0.3	0.69

The variables modeling a student are connected to the other students whenever a peer-assessment takes place. The student is presented with some (e.g. 3) peer answers and should choose the best (more correct) one.

We model the choice by defining 3 cases respect to J:

J = good: the student can discriminate among peers' answers, i.e. (s)he can tell apart the different values of Correctness for the answers presented:	right != fair != wrong
J = fair: the student is able to discern only among wrong and right answers	right = fair != wrong
J = wrong: the student is not able to distinguish and chooses at random	right = fair = wrong

The above rules are implemented in the Bayesian network through a CPT defining the probability of choosing answer q1, q2 or q3 depending on the student Judgment (J) and on the correctness (C1, C2, C3) of the proposed answers

P(Choice | J, C1, C2, C3)

A corresponding CPT can be easily obtained by generating all possible combinations of J, C1, C2, C3 and by assigning a uniform probability distribution only for the q1, q2, q3 answers that satisfy the above choice cases. Some examples follow:

J	C1	C2	C3	P(q1)	P(q2)	P(q3)
good	right	wrong	right	0.5	0	0.5
fair	right	fair	wrong	0.5	0.5	0
wrong	right	wrong	fair	0.33	0.33	0.33
good	wrong	wrong	wrong	0.33	0.33	0.33

Similar CPTs can be computed for peer-assessments with less or more than 3 answers to assess.

The resulting Bayesian network interconnects all student models through the Choice variable, and propagates evidence coming from the teacher's correction both:

- towards the corrected student's Knowledge (and thus to his Judgment),
- and through the Choices where the corrected answer was proposed, to the Judgment of the peers (and thus to their Knowledge and Correctness).

B. Selection strategies

Four selection strategies are available to suggest the next answer to be corrected:

- min_diff: the answer with the minimum difference among its maximum and minimum correctness probabilities is chosen. Rationale: the more the probability distribution of C is flat, the more the answer's correctness is ambiguous.
- max_entropy: the entropy of the answer's correctness probability distribution is maximum. Rationale: the answer's correctness is the most ambiguous one.
- max_wrong: the probability to be a wrong answer is highest. Rationale: students would not deem acceptable to fail "just because the Bayesian model said so", without the teacher actually checking their answer. Thus the teacher is forced to correct/check at least all the answers deduced "wrong". By grading these answers first we hope to collect enough information to deduce the rest without further work.

V. INITIAL EXPERIMENTATION

Some initial experimentation has been done by collecting data at the end of the "Web programming languages" course, part of the Computer Engineering Bachelor curriculum of Sapienza University of Roma, Italy. The first data-set (named 'marco' in the rest of the paper) is made of:

- 1 proposed question,
- 10 students answers,
- 1-3 peer assessments were made by each student,
- marks were given in the 0 – 10 range,
- the teacher graded all answers.

A second data-set (named 'carlo' in the rest of the paper) has been made available by the colleague Carlo Giovannella of Tor Vergata University, Rome, Italy. The data has been collected in a Physics course, part of the Computer Engineering Master curriculum and has been used for a different study on peer-assessment:

- 3 different topics have been used,
- 6 related questions for each topic were proposed (of which the first 4 were mandatory and the last 2 optional),
- 8-40 students answered,
- 1-3 peer assessment were made by each student,
- marks were given in the 0 - 2.5 range,
- the teacher graded all answers.

Both data-sets actually belong to other peer-assessment experiments, and collect the numeric marks awarded by the students to their peers' answers, and thus some adaptation was required 1) to transform the teacher's marks to the Correctness domain used in OpenAnswer, 2) to compute the students' choices and 3) to map back the probability distributions to the Correctness domain.

The student's choice is obtained by selecting the highest mark among those given. The Teacher's votes are discretized by using the following mark ranges:

data-set	**wrong**	**fair**	**right**
marco	0.0 – 5.5	5.5 – 7.0	7.0 – 10.0
carlo	0.0 – 1.0	1.0 – 2.0	2.0 – 2.5

The above ranges are also used to map probability distributions to Correctness values, which is a required step to evaluate the percentage of False Positives and False Negatives in our simulations.

VI. METHODOLOGY

The collected data-sets allows us to compare the different correction strategies and termination criteria with respect to:

- *Length*: percentage of answers graded.
- *OK*: percentage of the remaining answers deduced with a mark equivalent to the teacher's mark. Positive marks ("fair" and "right") are considered equivalent.
- *False Positives*: percentage of the remaining answers deduced with a mark better than the teacher's mark (e.g. "fair" or "right" instead than "wrong").
- *False Negatives*: percentage of the remaining answers deduced with a mark worse than the teacher's mark (e.g. "wrong" instead than "fair" or "right").

A. Mapping probability distributions to marks

To compute False Positives and False Negatives we first need the grades we would assign to the remaining answers, given the computed probability distributions. To map the probabilities to grades we first map each correctness label to its corresponding numeric range then we compute the linear weighted combination:

$$\begin{aligned} M = \ & P(C{=}wrong) * (MinWrong + MaxWrong)/2 + \\ & P(C{=}fair) * (MinFair + MaxFair)/2 + \\ & P(C{=}right) * (MinRight + MaxRight)/2 \end{aligned}$$

and then we map back the numeric mark obtained to the corresponding discrete value.

E.g. if we use the 'marco' data-set ranges, and

- *P(C=wrong)=0.4,*
- *P(C=fair)=0.1, and*
- *P(C=right)=0.5*

M comes out as *M = (1.1 + 0.625 + 4.25 = 5.975)* i.e. *C=fair.*

B. Simulating the correction to evaluate the strategies

The correction is simulated by repeating the following steps:

- read the peer-assessment and current marks and suggest the next best answer;
- introduce as evidence the teacher's mark for the suggested answer;
- test if the correction can be stopped, else repeat.

C. Termination strategies

As we aim to obtain a good but short correction, we need a stopping criterion, describing when the deduced marks for the remaining unmarked answers are good enough to stop.

Two termination strategies have been defined (by mapping first the probability distributions to marks in the Correctness domain as explained above):

- no_wrong: there are no more remaining answers deduced "wrong".

  Rationale: see the max_wrong selection strategy.

- no_flip(N): the current marks are the same than in the previous N simulation steps (default N=1).

  Rationale: the grades deduced are stable.

VII. INITIAL RESULTS

Table I shows the results of simulations done on the 'marco' data-set, listing for each <Strategy, Termination> pair the percentage of: answers corrected (Length), False Positives (FP), False Negatives (FN) and correct grades (OK, I.e. the percentage of marks inferred by the system in accord with the teacher's). From the table we notice that:

- The no_wrong termination criterion produces the longest correction (90%) on this data-set, obtaining 0% False Negatives (by design).
- No False Positives are present in this data-set.
- The highest percentage of OK is on the max_entropy, max_wrong and min_diff selection strategy.
- The lowest percentage of False Negatives is obtained with the no_flip(3) criterion, yet the percentage is high.

Basing on that we could come to the conclusion that even if this data-set is too limited to give us strong evidence, yet OpenAnswer is able to help the teacher by reducing the correction length of about 30% (the OK value).

Table 2, instead, shows the simulations conducted on the, bigger, 'carlo' data-set.

TABLE I. SIMULATIONS BASED ON THE FIRST DATASET

marco data-set		Termination criteria			
Strategy		**no_flip(1)**	**no_flip(2)**	**no_flip(3)**	**no_wrong**
max_entropy	Length	10%	20%	30%	90%
	FP	0%	0%	0%	0%
	FN	60%	50%	40%	0%
	OK	30%	30%	30%	10%
max_wrong	Length	20%	30%	40%	70%
	FP	0%	0%	0%	0%
	FN	40%	40%	30%	0%
	OK	40%	30%	30%	30%
min_diff	Length	10%	20%	30%	90%
	FP	0%	0%	0%	0%
	FN	60%	50%	40%	0%
	OK	30%	30%	30%	10%
min_max	Length	10%	20%	30%	90%
	FP	0%	0%	0%	0%
	FN	70%	60%	50%	0%
	OK	20%	20%	20%	10%

TABLE II. SIMULATIONS BASED ON THE SECOND DATASET

carlo dataset		Termination criteria			
Strategy		**no_flip(1)**	**no_flip(2)**	**no_flip(3)**	**no_wrong**
max_entropy	Length	6%	16%	22%	89%
	FP	45%	40%	37%	7%
	FN	7%	7%	7%	0%
	OK	41%	38%	34%	4%
max_wrong	Length	10%	14%	20%	18%
	FP	50%	49%	46%	51%
	FN	3%	2%	1%	0%
	OK	38%	35%	33%	31%
min_diff	Length	6%	15%	22%	89%
	FP	46%	40%	37%	7%
	FN	7%	7%	7%	0%
	OK	41%	38%	34%	4%
min_max	Length	6%	13%	25%	89%
	FP	46%	41%	33%	7%
	FN	8%	8%	7%	0%
	OK	40%	39%	35%	4%

From Table II we may observe that

- the best correction quality (OK) ranges from 30% to 40% for a rather good number of combinations.
- The no_wrong termination criterion produces very short corrections (Avg. Length=18%) but only when paired with the max_wrong selection strategy. The quality of the correction in this case is around Avg. OK=30%. Yet, the Avg. FP is 51%.
- The lowest percentage of Avg. FP + Avg. FN = 7% is (obviously) obtained at the expense of longer corrections (Avg. Length = 89%), when the no_wrong termination criterion is used.
- The number of False Negatives (negative marks deduced for good answers) is very low in all cases: max of Avg. FN = 8%.
- Even with the very short corrections (Avg. Length = 6-10%, corresponding to the no_flip(1) termination criterion), where just 1 or 2 corrections are made, OpenAnswer is able to correctly deduce a good percentage (Avg. OK = 40%) of grades.

- The number of False Positives of the no_flip(1, 2, 3) corrections decreases when the correction size increases and more information is collected.

Conclusions regarding the second table are manifold. First the <max_wrong, no_wrong> pair seems to be the best choice, as it gives short corrections (Avg. Length=18%) with no FP (by design) and good number of right deductions (Avg. OK=31%), but with a slightly higher number of good marks given to bad answers (Avg. FP = 51%) than the others combinations. A second conclusion is in that even with the *synthetic* probability distributions (cfr. beginning of Sec.IV.*A*) OpenAnswer is able to help the teacher by reducing the correction load of at least 30%. A final conclusion stemming from these simulation is that surprisingly short corrections are able to produce a good picture of the class' knowledge.

VIII. CONCLUSIONS AND FUTURE WORK

Assessment of skills and knowledge is a crucial factor in systems supporting e-learning in general, and personalized e-learning [15,16,17] and social-collaborative e-learning [18,19,20] in particular. The use of open-ended questions and questionnaires is deemed important in the area, while this is one of the assessing methods more work-intensive for the teacher.

We have presented the OpenAnswer web-based system, built to help the teacher marking open-answer questions through a simple Bayesian network model of the student's peer-assessment choices.

The initial experimentation and simulation shows that, even with a very simple model of grades and peer-assessment, the teacher can be helped in the correction of a set of open answers, by iteratively suggesting the most informative answers to correct first and spread the information acquired through the marking onto the network made by the students models, the peer evaluations of the answers and the teacher’s grading.

Our future lines of research can be summarized as follows.

A. Using OpenAnswer as a group diagnostic tool

Teachers need to quickly assess how much the students know the topic, either to plan further explanations or to move on to other topics. As we have seen that even short corrections, in OpenAnswer, can give some sufficient understanding of the distribution of skills among the class mates, we plan to use it as a group diagnostic tool.

B. Learning the parameters of the model

The Bayesian network modeling the peer-assessment depends on:

- the CPTs describing the probabilistic dependencies of C and J respect to K.
- the probability distribution of K

Therefore, the next required step in this research is to collect enough data to learn the above CPTs and probability distribution (for a total of 6+6+2 = 14 parameters) through machine learning of Bayesian networks parameters.

C. Using a more detailed Correctness domain

The CPT modeling the student's choice is easily computable for any domain size of the Correctness variable. Thus it is not difficult to extend OpenAnswer to use standard grades (such as the one ranging through A-F of an Anglo-Saxon grading model, or the one ranging between 5 and 10, more familiar to the authors). Yet, the domain size does impact on the K-C CPTs size, which will in turn require us to collect more data to learn the CPTs.

D. Modeling more informative peer-assessment choices

Here we mean that the amount of information coming for the peers activity can be increased (presently we just ask to select the best out of several answers). Independetly of the possible modifications of the number of answers proposed to the peer for evaluation, the planned improvements are:

- asking the peer to point out both the best and the worst answers, out of the sample;;
- asking to sort the answers, in an order related to thei correctness (such as from the worst to the best);
- asking the peer to grade individually each one of the proposed answers (according to a stated grading mechanism and to the defined evaluation criteria).

E. student model and personalization

The Knowledge variable is a description of how much the student knows about the topic. Thus it can be used a (yet very simple) student model. In our simulation we have used a “uniform” student model, without a specific representation for each involved student. As the teacher's marks entered as evidence propagate through the Bayesian network and update the Knowledge probability distributions of each student, we can update the initial student model by storing the final Knowledge distributions for each student. Even better, if enough data is available we can compute, by machine learning, the correct Knowledge distributions for each student and topic, that would allow to finely personalize the grading process, by taking into account the specific strengths of an individual.

F. Modeling plagiarism and anonymity

For the moment, we are ignoring two common student behaviors: plagiarism of answers (from peers or from external sources) and lack of anonymity during peer-assessment. We intend to model these behaviors by:

- enhancing the Bayesian student model by introducing a “Cheater” and a “PeerKnown” variables, addressing the two aspects;
- enhancing the peer-assessment CPTs to model the different cases arising from blind/disclosed peer-assessment. In this the ability of the system to learn the CPTs after the experiments will be useful.

Acknowledgment

We would like to thank the colleague Carlo Giovannella, who made available to us the main data-set used for our simulations.

***Abstract*—There is a considerable number of engineering courses that suffer with failure rates and high withdrawal of students in their first year, especially in fundamental discipline areas like mathematics and science. In order to detect the educational quality indicators, a study was conducted to validate the application of Students' Evaluation of Educational Quality (SEEQ) instrument in an engineering course, using Factor Analysis (FA). The choice of FA to validate the instrument is that this method has been used to validate the SEEQ instrument from the students' point of view but using this structure does not allowed us analyze the disciplines in focus, then we need to validate this same instrument into our research context according to a latent structure performed by the disciplines. We validate the application of the factor analysis by the Kaiser-Meyer-Olkin (KMO) and Bartletts' tests that investigate the sample adequacy. After the validation of the sample adequacy, the factor analysis validate the structure of the questionnaire, and we can state that the SEEQ instrument is valid for application in a teleinformatics engineering context to analyze the disciplines. As a final result of this procedure, we guarantee the consistency of the instrument for the application to analyze different disciplines under different criterions that can possibility a deeper analysis of the curriculum structure.**

***Index Terms*—SEEQ instrument, Factor Analysis, Curriculum , Higher Education.**

I. Introduction

Many studies have attempted to identify important factors and features that influence the evasion and failure rates in the first year of an engineering course, especially in fundamental discipline areas like mathematics and science [1][2].

Recent studies presents the use of mathematical techniques, widely used in the areas like pattern recognition and signal processing, in the evaluation contexts, however these fields are related to engineering applications, this techniques has been applied in order to processing the information and reveal other possibilities to analyze the dataset collected. The Educametrics [3][8] becomes a key area of knowledge to explore concepts related to subjective aspects of education, taking into account mathematical approaches.

Relevant contribution has been achieved by researches in the curriculum design field in an engineering course [8][7], but an important step of methodological procedure has not been done: the instrument validation. In this sense, we point out the necessity of an instrument that has the ability to capture this information with a solid and reliable structure for analysis. It is necessary that all formal instrument must be validate and only after this the inferences can be made.

In order to detect possible indicators in the quality of education as well as explaining the factors such as evasion, failure rates and to promote possible suggestions for restructuring the Teleinformatics Engineering (TIE) course's curriculum, a study was conducted in order to validate the application of Students' Evaluation of Educational Quality (SEEQ) instrument in an engineering course, using factor analysis. Factor Analysis (FA) is a psychometrics procedure that can do this validation, this method can be viewed as a mathematical approach that reveal the latent structure clustering the information that are intrinsically close to others [15]-[19].

The choice of FA to validate the instrument is that this method has been used to validate the SEEQ instrument from the students' point of view using only information related to the students and this structure does not allowed us analyze the disciplines in focus, then we need to validate this same instrument into our research context according to a latent structure performed by the disciplines.

II. Teaching Evaluation using Students' Opinion

The evaluation, in its widest sense, can be defined as a process that aims the collection and use of this information that

This work has been partially supported by CAPES, CNPq and BNB.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

allow decision making on an educational program, therefore, should be understood as a diversified activity that requires taking many kinds of decisions and the use of a great number of different information.

The use of formal instruments to measure students' evaluations of their teachers and students' perceptions of the quality of their programmes has been a good way to support the decision making from managers and students point of view [4]. In general, these instruments can provide important evidence for assessing the quality of teaching, for supporting attempts to improve the quality of teaching and for informing prospective students about the quality of course units and programmes [5].

Certain student rating forms provide important feedback that can be used to improve teaching performance [10][6]. The feedback in question usually takes the form of students' ratings of their level of satisfaction or their self-reports of other attitudes towards their teachers or their course units.

An instrument was created in order to obtain the students feedback. This instrument is called Students' Evaluation of Educational Quality (SEEQ) that appears to measure the most broadly representative set of scales and has the strongest factor analytic support of these instruments [10]

The factor structure of the SEEQ has been confirmed in several studies. In particular, Marsh and Hocevar [12][13] showed that it was invariant across teachers of different status and across course units in different disciplines and at different levels.

Marsh [9]-[13] conclude that Students' Evaluation of Educational Quality (SEEQ) is:multidimensional, reliable and stable, primarily a function of the instructor who teaches a course rather than the course that is taught,valid in relation to a variety of indicators of effective teaching, relatively unaffected by a variety of variables hypothesized as potential biases and is considered to be useful to students to use in course selection, to administrators to use in decisions about staff and to teachers as feedback on teaching.

In this research, we consider these factors from the measured statistical data that comes from the application of the SEEQ instrument applied to students in the first year of the TIE course, under the organizational and operational approach of linear algebra (Factor Analysis).

III. Factor Analysis

Factor Analysis is a statistical method commonly used during instrument development to cluster items into common factors, interpret each factor according to the items having a high loading on it, and summarize the items into a small number of factors. Loading refers to the measure of association between an item and a factor. A factor is a list of items that belong together. Related items define the part of the construct that can be grouped together. Unrelated items, those that do not belong together, do not define the construct and should be deleted. Computationally, this method is equivalent to low rank approximation concept. This technique was originated in psychometrics, and it is wide used in behavioral sciences, social sciences, marketing, product management, operations research, and other applied sciences that deal with large quantities of data [15]-[19].

Exploratory Factor Analysis (EFA) is a particular factor analysis method used in this research to examine the relationships among variables without determining a particular hypothetical model[].

The Confirmatory Factor Analysis (CFA) help us to validate the application of the SEEQ instrument into the Federal University of Ceará - UFC context [15]-[19]. However this instrument was widely validate, an important step in our research is validate the application of this instrument since we use a brazilian portuguese translation version and we can lose some information about the instrument when the translate was made.

A. Validating the Factor Analysis

We can assess sampling adequacy by examining the Kaiser-Meyer-Olkin (KMO) output provided in the factor analysis. A KMO correlation above 0.60 - 0.70 is considered adequate for analyzing the EFA output [14]. In addition to examining KMO for sampling adequacy, it is important to evaluate the correlation matrix of all survey items to determine if the matrix can be analyzed using factor analysis. If the correlation matrix is an identity matrix, ie there is no relationship among the items, it cannot be analyzed. Bartletts test of sphericity provides a chi-square output that must be significant, which indicates the matrix is not an identity matrix. If the KMO correlation indicates sample adequacy and Bartlett's test of sphericity indicates the item correlation matrix is not an identity matrix, researchers can move forward with the factor analysis.

IV. Methodology

A. Subjects and Course

1) TIE Course: The Teleinformatics Engineering (TIE) course was created in 2003 under the responsibility of the Department of Teleinformatics Engineering that put together two important areas, Computation and Telecommunications, with the perspective of forming professionals with skills and competencies that dealing with both areas in an integrated way with a great impact to the contemporary society.

2) Characteristics of the Sampling: The research was administered with students in the 3rd and 4th years of the TIE course. The SEEQ instrument was performed in 4 classes of students. Students were invited to participate voluntarily in this research, ensuring their anonymity as well as teachers. Students were selected, because all of these had already attended the all basic disciplines of the TIE first year and we also had a prior authorization of the teachers to apply the SEEQ. During the application of the questionnaire, some characteristics of the instrument were clarified to the participants like the importance to identify current problems into the course's curriculum, and also a awareness process was done, highlighting the importance and necessity of the questionnaires to be answered in the most faithful and true to the reality of events during classes taught in the disciplines investigated

TABLE I
FACTOR ANALYSIS RESULTS WITH THE EQUAMAX ROTATION WITH KAISER NORMALIZATION.

SEEQ Factors	Questions	10 Latent Factors									
Learning	Q1									$\|0, 77\|$	
	Q2	$\|0, 632\|$

Student and Discipline Characteristics	Q32										$\|0, 775\|$
	Q33										$\|0, 84\|$
	Q34										$\|0, 529\|$
	Q35										$\|0, 947\|$

in the first year. Of the total of 120 students, 100 students completed the questionnaire, yielding a participation rate of 83.3%.

B. Data Collected

The data obtained has a three dimensional structured since we have the information related to students, disciplines and SEEQ questions.The original SEEQ instrument has 40 questions, distributed into nine factors. In this research, an adaptation of the questionnaire was made using only 35 issues and the number of factors was increased to 11 in order to analyze more aspects of the questionnaire.

Although we have a tri-dimensional data structure, an average was performed into the discipline mode in order to reduce the dimensionality of our dataset. For reasons of space, the questionnaire used in this study is not given here, but is available upon request.

Just for the knowledge, the disciplines that have been analyzed: Fundamental Physics (FP), Experimental Physics (EP), General Chemistry (GQ), Engineering Design (ED), Fundamental Calculus (FC), Linear Algebra (LA), Programming Techniques (PT) and Digital Logic Project (DLP) .

V. RESULTS AND DISCUSSION

A. Reliability of the Dataset

The Cronbach's α was calculated to estimate the reliability of the dataset, and the results revealed high internal consistency. The α-coefficient of the dataset was high at 0,9536. The reliability analysis showed the scales to be highly reliable.

B. Validating the SEEQ instrument

The Table II shows the Kaiser-Meyer-Olkin (KMO) and Bartlett's tests that indicate the suitability of our data for structure detection. It is important to notice that this is an important step into Factor Analysis context, since we need to prove that our dataset is useful for this kind of analysis.

The KMO test is a statistic that indicates the proportion of the data variance that can be considered common to all variables, namely that can be assigned to a common factor, then: the closer to 1 (unity) the result is better, ie, the sample is better suited to the application of factor analysis.

The sphericity Bartlett test verify whether the correlation matrix is a identity matrix, which would indicate that there is no correlation among the variables. In this way, we looking for a significance level (Sig.) of 5% to reject the null hypothesis of the identity correlation matrix.

TABLE II
KMO AND BARTLETT'S TESTS.

Kaiser-Meyer-Olkin Measure of Sampling Adequacy		0.886
Bartlett's Test of Sphericity	Approx. χ^2	2919.637
	Sig.	0.000

These tests validate the Factor Analysis application into our dataset, since we have value higher than 0.5 in KMO and the

Sig. less than 0.05 in the Bartlett's test, the last one means that the correlation matrix of the dataset is not the identity matrix [17]. The chi-square coefficient is a value of dispersion for two nominal scale variables, used in some statistical tests. It tells us to what extent the observed values deviate from the value expected if the two variables were not correlated. According to [19], the chi-square test testify that our variables are correlated.

A Confirmatory Factor Analysis (CFA) was conducted to verify if the domain configuration theoretically of the SEEQ instrument, defined by Marsh and Bailey previously [10], could be confirmed empirically. This procedure was chosen because it has been applied by the developer of the instrument in order to validate their ability to assess its application context.

As we can see in Table I, only the items Q1 and Q11 are nonstandard, these two items does not influence into the validation of the SEEQ instrument, since we have a total of 35 items and a average has been performed into SEEQ factors. In the final analysis, these items were removed when the average matrix of the students' responses was calculated. Nevertheless, this does not mean a lot of change, because the item's average not change too much.

Although factor analysis has provided 10 clusters, the cluster 9 will be unbundled in two more factors (Overall Discipline and Overall Instructor), as a matter of the importance of these two factors in the overall analysis of the factors for their relevance in relation to the other factors. This situation was discuss in [10].

This study presents limitations. We used a small number of disciplines belonging to the curricular unit of TIE course and a panel composed of 100 students, a number that is not representative of the population but this not invalidate the factorial structure obtained.

VI. Conclusion and Perspectives

To validate the data collection instrument, the confirmatory factor analysis has been applied on the data collected by the SEEQ instrument in order to validate its application in the context of the TIE course. As a final result of this procedure, we guarantee the consistency of the instrument for the application in the TIE course's context. This is an important step to ensure the correct analysis of the data collected. This instrument allow us to analyze the curriculum structure, in an engineering course, as we can see in [8][7]. This analysis can contribute to potential changes in the curriculum and requirements among the disciplines of the course.

An important topic for future research is the application of high order factor analysis in order to validate the tri-dimensional structure of the dataset collected. This procedure can reveal another kind of relathionships among the factors obtained in a bi-dimensional model [20].

***Abstract*—Processes and evaluation methods are gaining prominence in the social and educational contexts. In this context, it is proposed to contribute to the improvement of the higher education quality, through the analysis of information obtained in six engineering courses offered by the Federal University of Ceará. The study seeks to strengthen the interface among data analysis methods typically used of engineering contexts in order to allow the analysis of the relationship between academic management processes of engineering courses and outcomes from external evaluations. This discussion aims to propose a mathematical model to support the academic management, based on multivariate analysis (MVA) and data processing, such as Principal Component Analysis (PCA). The instrument created aims to identify professors' point of view about the management practices developed in their academic courses where they work. The application of the reliability tests revealed the suitability of the sample for the application of PCA. In the PCA application, we observed the formation of three responses' clusters, that has been well characterized by the similarity of their factor loadings that are related to students' academic education, academic formation processes and institutional environment. It should stand out even that the application of MVA showed strong evidence for a relationship among the methods of management in higher education, through the manifestation of latent variables in order to define a mathematical model based on MVA academic management support.**

***Index Terms*—Courses' management, Factor analysis, Principal component analysis, engineering education.**

I. Introduction

Nowadays, in Brazil we experienced an increase in the vacancies in courses in higher education. This demand has been followed by the need to develop processes and evaluation methods [1][2]. This interest gains strength in the Brazilian context of the current moment expansion of Higher Education Institutions in the country. Thus, the necessity of a more effective evaluation of these institutions has been growing [7][8].

The assessment is used in order to provide input for the analysis and improvement of classes, projects, programs, and institutional processes even more complex systems, such as the education systems at various levels. Currently, we highlight some experiences of assessment in the context of engineering courses [1][3][13][14][15]. In this scenario, stocks and faculty members of educational administration should position themselves against these processes, remodeling ideas, techniques and criteria, to promote changes that characterize a new way to lead to the desired quality of education at all levels [9].

The Brazilian education is under a process of expansion within in Higher Education, and must find mechanisms that enable the "control" of teaching quality in order to verify that the goals set are being achieved and consequently to observe critically the training provided to professionals from several areas. In this study, we will investigate the process of formation of an engineer in the context of the Federal University of Ceará-UFC, located in northeastern Brazil.

The search for data/facts your organization in the form of structured information allows the identification of patterns and a qualitative/quantitative analysis that can generate proposals for intervention and produce positive results to the management in higher education. This view is gaining prominence both in relation to aspects of a quantitative but also qualitative. Thus, it is proposed, during the research, contribute to the analysis of information obtained in six university courses in engineering offered by the UFC that have undergone external evaluations in recent years. Aiming to this study to identify management practices and their consequent contributions in

This work has been partially supported by CAPES, CNPq and BNB.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

quality indicators, especially in external indicators applied periodically by the government agencies.

In this research, we will investigate the potential for applying a mathematical tool of multivariate statistics, called Principal Component Analysis, in the assessment of undergraduate engineering on the teachers' perspective. It is expected to recognize patterns and determine significant clusters in the processing of information collected, enabling the identification of previously unknown relationships and contribute to the evaluation of undergraduate courses in general and also its possible application to the institutional evaluation and its consequent improvement of management methods.

II. Educational Management in Higher Education

Institutions in a general way have been going through a process of renewal in their ways of acting in recent years, aiming to better meet this target audience. Educational institutions are not out of this process of renewal, and required changes in its management practices[4].

The educational management has a ratio of the areas of administration and education. However, there is a complexity arising from the need to manage processes related to teaching and learning in its several instances. There is a need for a multi-mode educational quality [10]. This research can contribute to address the existence of the relationship between quality and their indicators or indices, and this is supported by the analysis of the factors added to the process [11]. The educational management should add other knowledge to strengthening the interdisciplinary characteristics in the process of students' education.

Assessment in higher education can be used to verify other aspects beyond the institutional process of teaching and learning, such as: mission, institutional development plan, policy research, extension, graduate, social responsibility, human resources policies, physical and pedagogical infrastructure [4].

According to Ralph Tyler [5], evaluation and educational measure are distinct processes. The educational measure is important in the evaluation process, however we can not limit the assessment to only those aspects. Thus, we can gauge that the assessment now covers programs, curricula and educational systems and not just the assessment of student using the learning criteria. Featuring the model Tyler, the importance of goals in the evaluation process that guide and direct the assessment enabling decision making, from the reality/context of the program/course and their respective institutional function.

The assessment/evaluation from the Tyler's perspective [5][6], provides grants for a critical analysis of the institution, since from the assessment the institution may investigate the causes of ineffective elements, reorganize and readjust positive aspects of its operation. We also highlight important aspects of its assessment model, such as: interaction teacher/student, education as a process of creating standards of conduct, diversity of instruments in the evaluation process, among others.

Based on the assumptions presented, the evaluation of undergraduate courses on the UFC provide subsidies that contribute to the improvement and constant pursuit of educational excellence desired by the educational institution as well as providing a better service to the society.

III. Multivariate Analysis Method

In this research, the Principal Component Analysis (PCA) is used to analyze the relationships among the variables analyzed. The PCA is a multivariate statistics technique that aims to achieve a rank reduction of a dataset with $X_{m \times k}$ dimension into a new dataset with $X_{m \times p}$ dimension, where $p < k$. This new dataset has some important algebraic features such as orthogonality of column vectors, which characterizes the non-overlapping of information [16][17].

The decomposition of the original database into a new database with orthogonal properties, is given by the fact that the PCA be treated as a case of reduction of rank of a matrix using eigenvalue decomposition [17]. This decomposition brings with the possibility of extracting the most important factors of the original database in order that we can relate the relevance of information with the eigenvalue associated with it , called Principal Component - PC, ie, the larger the eigenvalue greater the importance of that information due to the original database. In this sense, there is a compression of information, called latent variables, without loss of relevant information, since the arising analysis should enable a connection with the original data in the process.

It is necessary to let two concepts very clear, the latent variable and manifest variable. The first one is widely used in social and behavioral sciences, concepts they are constructed with the purpose of a particular area of interest, on which there is no method to measure operational. Furthermore, the observed variables can be viewed as observable manifestations of latent variables, by which they are characterized [12].

IV. Scenario and Methodology

This research was conducted in the Technology Center and the Center for Agricultural Sciences at Federal University of Ceaá - UFC. We had a total of 6 courses that participated in this research, they are: Civil Engineering, Fisheries Engineering, Mechanical Production Engineering, Teleinformatics Engineering, Electrical Engineering and Chemical Engineering. The research seeks to identify the perspective presented by professors of engineering courses about procedures/methods/ management actions in higher education in each of the courses. A total of 23 professors answered the research, which proved to be satisfactory for the results analysis. We seek to establish a relationship of the procedures/methods/actions and their respective concepts/grades/indicators achieved by courses in external evaluations.

A. *Measurement Instrument*

A formal instrument for obtaining the information from professors was developed in brazilian portuguese language (see Table I). This instrument consists of 15 statements and has as response, the level of agreement of the respondent's

TABLE I
INSTRUMENT FOR THE DATA COLLECTED.

1	The course's coordination contributes to the students academic formation, monitoring their performance and help them when needed.
2	The course's coordination contributes to students and teachers performed the Course Educational Policy Project on their part.
3	The course's coordination encourages students to participate in academic events (scientific conferences, meetings technology, sports activities, extension and/or artistic, etc).
4	The course's coordination explains the students about the importance of participating in the Brazil National Survey of Student Performance (ENADE).
5	The course's coordination discusses the results of ENADE with the internal community.
6	The course's coordination promotes, systematically, moments of dialogue about formation, curriculum and labor market.
7	The course's coordination encourages students to evaluate teachers.
8	The course's coordination encourages students to assess the disciplines (or modules) of the course.
9	The course's coordination contributes to providing a climate academic conducive to a meaningful and sustainable learning for the students.
10	The course's coordination takes reasonable actions steps to ensure the maintenance of support specific equipment (computational, laboratory, etc).
11	The course's coordination seeks to maintain bibliographic updated and able to the full use by teachers and students.
12	The course's coordination contributes to the development of curricular internships.
13	The course's coordination adopts reasonable actions steps to ensure the maintenance of the physical structure of the course.
14	The course's coordination has recognized academic competence.
15	The course's coordination have recognized competence in managing academic and administrative support.

using a six-point Likert scale (1-Totaly disagree ... 6-Totaly agree).

The availability of the instrument was made through an electronic address where teachers accessed and sent their responses by the website. For reasons of space, the questionnaire used in this study is not given here, but is available upon request.

B. Mathematical Modeling

The PCA was applied to analyze the interrelationships of management methods as a major factor in the performance of the courses on the results obtained on the external evaluations conducted primarily by the federal government.

C. Computational Tools

For the data treatment, we have used two computational tools: the MAtrix LABoratory - MATLAB® and the Statistical Package for Social Sciences - SPSS®. The decision to use both tools is due to the fact that the research has a hybrid character, seeking an interface between the methods of engineering, mathematics, statistics and education through the study of methods of educational management, especially with regard to the higher education.

V. RESULTS AND DISCUSSION

A. Validating the Results

1) Cronbach's alpha: In order to guarantee the reliability and internal consistency of the data, we applied the Cronbach's alpha index [15]. For the data set collected, the Cronbach's alpha was high at 0.9391, ensuring uniformity of data and validating the analysis.

2) Kaiser-Meyer-Olkin and Bartlett's test: The first step for the application of PCA is the verification of the sampling adequacy to use this technique. The tests of sample adequacy is the Kaiser-Meyer-Olkin (KMO) and Bartlett's Sphericity tests that check whether the data variables are correlated with each other, generating a hypothesis that the correlation matrix of the variables is the identity matrix, in this case we have uncorrelated variables [16]. The application of the tests validated the applicability of PCA in the dataset at a value of 0.684 for the KMO test and rejection of the hypothesis that the correlation matrix is the identity matrix was obtained by Bartlett's test [17].

B. Selecting the number of Principal Components

The Scree plot was used as a resource for obtaining the number of principal components to be used in this research, which presents a graphical view of the descending order of the eigenvalues in terms of the principal components [18].

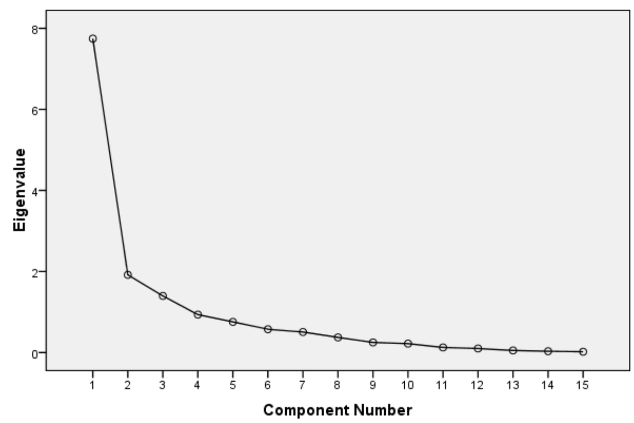

Fig. 1. Scree Plot.

Observing the behavior of Fig. 1, we realize that there is a decay curve of the graph line to its stabilization. This decay occurs abruptly until the second component, tending to stabilize on the following components. In this sense the graph suggest the extraction of the first two components and relating the eigenvalues observed we highlight that the first two components have a cumulative variance of the 64.411% over the representation of the original data. Percentage considered satisfactory for researchers.

C. Clustering Analysis through PCA

From the two principal components selected, we can see the relationships among the variables (questions) observed. Is worth noting that all questions are uncorrelated then the analysis will be done through the intrinsic information related to the original database.

Analyzing the Fig. 2, we can observe the formation of three clusters, well characterized by the responses' intrinsic correlations, however, we note the existence of two outliers (questions 10 and 13). The explanation for the occurrence of these outliers, may be linked to the fact that these issues have been understood as actions outside the jurisdiction of the course coordination.

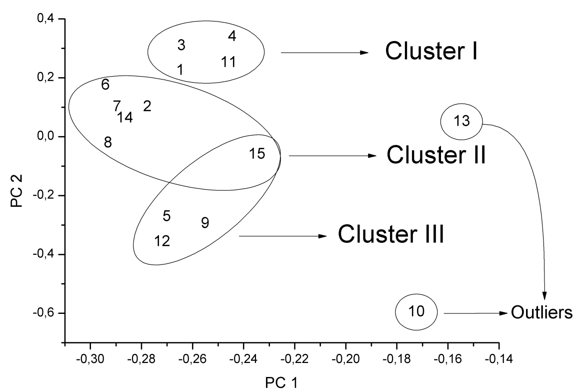

Fig. 2. Components Biplot.

Starting to the analysis of the clusters identified, it can be seen that in Cluster I, formed by the questions 1, 3, 4 and 11, which have in common the fact that they refer to the students' academic training. The Cluster II, formed by the questions 2, 6, 7, 8 and 14, point to the definition of a latency-related leadership the course coordination with regard to the assessment and management processes of academic training in higher education. Then, Cluster III (questions 5, 9 and 12) presents characteristics related to institutional environment facing the higher level training, ie describes the ambience of learning in the course's context.

We highlighted that the question 15 belongs to the Clusters II and III, this is due to the fact that it has an meaning hybrid, bringing leadership characteristics related to the the coordination regarding the academic and physical structure.

It is intended that these results can serve as support for educational planning and strategic decision-making in this field, seeking to contribute to the consolidation of the use of mathematical tools and its analysis applied to the educational context - the Educametrics [15][13], a term that still has been uncommon in the literature.

VI. Conclusions and Future Works

The purpose of this research was the application of a technique for interrelationships analysis based on multivariate statistics on a dataset related to management engineering courses at the Federal University of Cear- Brazil.

The main results show the viability of using the PCA to analyze data of an educational nature, being the relevant information brought to the application of this technique. From the observed latent variables, we highlight the creation three clusters of responses that are related to the students' academic training, the leadership on the of the courses' coordination assessment and management processes of formation and the characteristics related to the institutional environment in the formation level.

As seen, we have evidence that there is a relationship among the methods of management in higher education, through the manifestation of significant latent variables. Showing that there is the possibility of making inferences about the actions and methods of management and thus enable the delineation of interventions that may contribute to the improvement of teaching and learning in engineering courses.

This study has limitations regarding the small number of professors' respondents, which despite being small the whole dataset is adequate for analysis by PCA. As a future perspective, we emphasize the analysis of a higher number of courses that enable the analysis of the relationship of management processes with the index calculated by external evaluations.

***Abstract*—This study is to evaluate whether peer evaluation increases student participation and thus improves learning achievement in an e-learning 2.0 environment. We first implemented an e-learning 2.0 platform and then collected data from student participants, including RSS, blogs, Wiki, and other online forums. A quasi-experimental design was used in the study. The student participants were divided into an experimental group (N=52) and a control group (N=60). The results indicated that the e-learning 2.0 platform had a positive effect on student learning process. When comparing the academic performances of the control group and the experimental group after using e-learning 2.0 for a period of time, students in the experimental group had significantly better academic results than those in the control group.**

Keywords—peer evaluation; e-learning 2.0; quasi-experimental design

I. INTRODUCTION

E-learning has become a trend in higher education. Learners in such an environment can learn anytime and anywhere [1]. Recent e-learning research studies indicated that collaboration and interaction are important learning factors, particularly when incorporating Web 2.0 technologies into e-learning courseware design [2-4].

Among many e-learning studies, exploring students' motivation in the e-learning 2.0 environment has become an important issue [5-7]. Our study is to evaluate whether peer evaluation increases student participation and, as a result, improves their learning achievement. To evaluate the effectiveness of peer evaluation in the e-learning 2.0 environment, we first implemented an e-learning 2.0 platform and then collected data from student participants to investigate the research purpose. Data sources include RSS, blogs, Wiki, and other online forums.

Four major research questions were investigated. First, students' satisfaction toward e-learning 2.0 was identified. Second, the relationship between student participation and peer evaluation in e-learning 2.0 was examined. Third, we studied the effect of student participation in peer evaluation process on their learning achievement. Finally, we examined the relationship between student participation and their satisfaction.

II. SYSTEM IMPLEMENTATION

An e-learning 2.0 system was implemented in the study to function as an evaluation platform (hereafter referred to as TeachSys). The implementation of the system was based primarily on the concepts of knowledge sharing, peer evaluation, and the characteristics of collaborative learning. It provided keyword links to Wikipedia and other external resources such as Yahoo+ by way of text mining technology. In addition, TeachSys allowed users to publish articles, responses, and discussions in the framework of knowledge sharing.

III. SYSTEM EVALUATION

To evaluate the effectiveness of peer evaluation in the TeachSys, a quasi-experimental study was designed to achieve the research purpose. We divided participants into an experimental group (N=52) and a control group (N=60). The control group was taught using a traditional face-to-face teaching method, while the experimental group followed the same course outline but was additionally assisted by the TeachSys e-learning 2.0 platform that incorporated peer evaluation mechanism.

The experiment lasted 18 weeks. All students, regardless of which group they were assugned, had similar work during the semester. The control group using the traditional bulletin board e-learning system, which received information from teacher without interacting with classmates online.

In the experimental group, students' participation rate in peer evaluation process was recorded through the TeachSys system. The procedure of the experiment was introduced in the first class. The assigned work for the term was then posted in the TeachSys system. The participants were asked to discuss their work in the e-learning platform before the next lecture. The students could express their concerns and discuss with their classmates through the platform.

A. Subjects

The participants in this study included two separate classes of undergraduate students who were enrolled in the same academic course taught by the same instructor during two different semesters. The ratio of males to females was nearly

1:1. The ages of the participants ranged from 18 to 20 years. There were 52 students who participated in the experimental group; another group of 60 students in the same department who were not using the e-learning platform was used as a control group for comparison.

B. Instructional Context

Both groups of students enrolled in an undergraduate Database Management course that focused on fundamental database management skills covering ER data model, SQL, database design, functional dependencies, normalization, query processing, transaction processing, concurrency control techniques, and distributed architectures.

C. Independent variables:

One independent variable was examined in this study: TeachSys platform usage. A group of students who did not use this platform was used as a control group in the experimental design.

D. Dependent variables:

The measurement instruments in this experiment included a five-point Likert scale questionnaire for evaluating student satisfaction toward system usage and student learning achievement from post-tests.

IV. Results

A. Academic achievement post-test

The academic achievement of the control and the experimental groups was determined by a U test. The results of the first midterm examination (control = 81.67, experimental = 73.58; $p < 0.01$) indicated that the mean score of the control group was significantly higher than that of the experimental group. In contrast, in the second midterm examination (control = 65.28, experimental = 75.30, $p < 0.01$) and in the final exam (control = 75.44, experiment = 81.92, $p < 0.01$), the mean achievement of experimental group was significantly higher than that of the control group.

B. Correlation between participation and learning satisfaction

In academic achievement, compared to the different levels of participation, there were no significant differences found between the “RSS”, “Blog”, “Wiki”, or “Recommend” categories. However, online discussions ($F = 5.013$, $p = 0.013 < 0.05$), personal collection ($F = 9.248$, $p = 0.012 < 0.05$), peer evaluation ($F = 3.346$, $p = 0.049 < 0.05$) and TeachSys overall function ($F = 5.505$, $p = 0.009 < 0.05$) demonstrated significant differences. It seemed that students had different preferences in Web 2.0 technologies for e-learning 2.0. Moreover, a possible explanation was that greater participation in peer evaluations and online discussions was required before these technologies would have an effect on their performance.

V. Conclusion

According to the results in this study, the e-learning 2.0 platform seems to have a positive effect on learning as the majority of the students indicated that the e-learning 2.0 and the Web 2.0-related application tools provided significant assistance as they engaged in the learning process. When comparing the academic achievements between the control group and the experimental group after using e-learning 2.0 for a period of time, the academic performance of the experimental group was significantly better than the control group.

The results showed that there was a direct relationship between participating in e-learning 2.0 and student satisfaction. The more the students engaged in and used the Web 2.0 features, the higher the students’ satisfaction with e-learning 2.0. Although most of the students’ learning needs were satisfactorily addressed, part of the design features still had room for improvement. Providing more usable tools would enhance user participation in and satisfaction with e-learning 2.0. When students spent more time discussing and interacting with peers in the e-learning 2.0 environment, their learning achievement was significantly improved.

A longitudinal study of the effects of a high school robotics and computational thinking class on academic achievement (WIP)

Pat Ko
STEM Education
University of Texas at Austin
Austin, TX, USA
contactpatko@gmail.com

Abstract—**While there has been a rising interest in computational thinking (CT) and a push to include it into the K-12 curriculum, there is little empirical evidence that a class that teaches CT will have any measurable long-term effects on student performance. Using robotics as an example of CT instruction, I propose to examine a high school that has had a large number of robotics students over the past six years to find evidence for the long-term benefits of CT. I will analyze school records (e.g. STEM class enrollment, STEM test scores, SAT scores) for differences between robotics and non-robotics students and compare interviews with selected students.**

Keywords—robotics, computational thinking, longitudinal

I. Introduction

In 2006, Wing [1] wrote an influential opinion piece that described "computational thinking" (CT) as the way that computer scientists think about problems, design systems, and understand behavior. She asserted that CT is applicable to a wide variety of other fields and that it should be considered a foundational skill to be taught to all students. Since then, CT has been the subject of many papers and panels, e.g. [2]-[5]. Proponents have advocated for CT instruction in public K-12 education and have hypothesized how students with CT skills, such as problem decomposition and abstraction could apply them to medicine, law, and other disciplines [6]. While enthusiasm for the subject is high, the connection between CT skills, and long-term benefits is still theoretical. There is little direct evidence that actual CT students are able to apply the skills to other disciplines to perform better than students who do not have CT experience.

II. Background

As an emerging field, the exact definition and boundaries of CT are still forming [6]. To move the field forward, the Computer Science Teachers Association and International Society for Technology in Education have published an operational definition that states:

> CT is a problem-solving process that includes (but is not limited to) the following characteristics:
>
> - Formulating problems in a way that enables us to use a computer and other tools to help solve them
> - Logically organizing and analyzing data
> - Representing data through abstractions, such as models and simulations
> - Automating solutions through algorithmic thinking (a series of ordered steps)
> - Identifying, analyzing, and implementing possible solutions with the goal of achieving the most efficient and effective combination of steps and resources
> - Generalizing and transferring this problem-solving process to a wide variety of problems [7, p7]

While there have been disagreements on the precise definition of CT, one principle that is commonly held is that CT is not the same as programming. "CT is an approach to solving a problem that empowers the integration of technologies with human ideas" [7]. Some researchers believe that CT is a prerequisite skill for programming [8]. Thus separated from programming, it is argued that parts of CT can be taught outside of a traditional programming class.

One non-traditional field where CT skills may be learned is through educational robotics, such as LEGO MINDSTORMS or VEX. Through robotics, students are exposed to open-ended problem-solving tasks that require design, implementation, and debugging. In addition, students are required to program the microcontroller to accept input from the sensors and drive the motors. Though there is some programming, they do not learn a general purpose programming language as in a traditional programming class. Depending on the age of the students and the scope of the curriculum, a full year class in robotics has the potential to address most or all of the CT characteristics listed above.

While there have been some studies on the effects of robotics education, they have typically had strong limitations. Barker and Ansorge [9] tested the domain knowledge gained by students, but had a very small number of students and only tested information about robotics instead of transfer to other subjects. Lindh and Holgersson [10] and Hussain, Lindh, and Shukur [11] tested a large number of students in math and problem solving skills, but they did not follow the students for multiple years to find if the gains were maintained over time. Similarly, Iturrizaga [12] had examined several hundred students on a diverse set of subjects, such as math, technology and reading, and triangulated his data with interviews, but did not follow up with his participants over multiple years. Gibbons [13] measured the effect of a robotics intervention on convergent and divergent thinking, but the intervention time was only a few hours long and the post-tests occurred shortly after the intervention. While not strictly a study on robotics, Wolfgang, Stannard, and Jones [14] followed students from pre-school through high school. They compared students who were proficient in constructing with LEGO when they were young against ones who were not, using standardized test scores and enrollment in advanced STEM classes. While certainly taking a long-term perspective with transfer to other subjects, the study has less than 20 subjects. None of these studies were able to study a large number of students who have had a long, consistent intervention and examine the effects on other academic subjects over multiple years.

III. Study Proposal

I have identified a public high school in the southern United States that offers a full year educational robotics elective class for academic credit. Over the past six years, between 400 and 600 students have taken the class. The curriculum incorporates topics identified by [7] as CT skills, such as algorithmic thinking, and identifying and implementing possible solutions. My project will use existing school records to compare the robotics students to control groups of students who are enrolled in the same school, but did not enroll in robotics. The research hypothesis is that students who complete a robotics course will outperform students who do not take robotics on:

1. Math/science standardized grade-level test scores
2. Grades in math/science classes
3. Enrollment and grades in elective math/science classes, including AP scores
4. SAT/ACT scores

Since I am particularly interested in long-term effects, I will be emphasizing the scores, grades, and elective enrollment that occur several years after the robotics instruction.

Where appropriate, I will use matched data sets by selecting control group students so that each robotics student will have a corresponding non-robotics student that has one or more similar demographic or previous achievement measure (e.g. gender, ethnicity, or previous math standardized scores). This will allow the matching variables to be used as covariates in an ANCOVA statistical analysis.

In additional to the quantitative data, I will also conduct semi-structured interviews with a number of students who have recently completed the robotics classes. The questions they will be asked include:

1. What did you learn in robotics class?
2. What did you expect to learn in robotics when you enrolled in the class?
3. What did you not learn in robotics that you wish you did?
4. What factors influenced your decision to enroll in the class?
5. Are you more likely to take more STEM classes than before you took robotics?
6. What did you learn in robotics that you believe will be useful in your other classes or in your life?

A number of students who completed the robotics class in previous years will also be interviewed. In addition to some of the questions above, they will also be asked:

7. What skills did you learn in robotics class that you still use?
8. Did your robotics experience cause you to enroll in classes they would not have enrolled in otherwise?
9. Did robotics change the way you approach challenges?
10. Did robotics make you more enthusiastic about STEM classes or a career in a STEM field?

The quantitative data and the interviews will be analyzed separately, but also compared to each other. While it is likely that the results of the data sources will reinforce each other to provide a consistent conclusion, it is also possible that they will contradict. Robotics may leave a strong impression on the students, but have non-significant effects on test scores and class enrollment. Robotics may also have more subtle effects, nudging the students in a particular direction, but outside of their perception. In former case, we must stop and revisit whether our chosen quantitative instruments are the appropriate ones to measure effects of the curriculum.

IV. Summary

In the past few years, there has been a tremendous push to incorporate CT into an already crowded K-12 curriculum. The rationale for this movement is the theoretical hypothesis that students who study CT will be able to apply this knowledge to a wide variety of fields that they will encounter in future. While the arguments are persuasive and the benefits tantalizing, there has been relatively little empirical evidence that learning CT skills results in higher academic performance or the transfer of skills into other domains. Robotics has a high overlap with CT skills and is already being taught in some schools. However, previous studies on robotics classes have frequently suffered from small sample size, limited intervention time, inconsistent instruction, or a lack of a long-term study.

This proposed study focuses on a high school where over the last six years, a relatively large number of students have completed a full year academic robotics class. There are a significant number of samples, extended intervention time, relatively consistent instruction, and student data for multiple years after the class. Using a combination of high school transcripts and semi-structured interviews, I will statistically analyze the quantitative data and triangulate with the interviews. When completed, this longitudinal study will provide some empirical research to support or refute the assertion about the usefulness of robotics (and by extension, CT) education.

Web-based Collaboration System to Improve the Interactivity for Mobile Education through Smart Devices

Tao Zhang, Shiyu Lu, Zhenyu Zhang, Jun Li
Information Service & Platform Laboratory
Hitachi (China) Research & Development Corporation
Beijing, China

***Abstract*—Mobile education is a term that describes a relatively new way of education. Generally speaking, mobile education is aimed to facilitate teachers, students, and parents to interact with each other through mobile devices. This term gains much popularity especially in recent years with the smart devices coming into vogue. With the development of broadband networks as well as the evolution of smart devices, more and more people have come to realize that smart devices can become an effective medium for mobile education. This paper proposes an innovative approach to implement a mobile education system through web technology, which is regarded as an effective mean of overcoming cross-platform obstacles caused by the diversity of smart devices. Considering the constraints of web technology, research and development are undertaken to enhance the stability of the connection as well as the instantaneity of communication. Also, an awareness component is designed for detecting the user's environment such as location, network condition, and hardware specification in order to provide appropriate services. Our research and development lead to significant improvement in the interactivity and the usability of a web-based system.**

Keywords—interaction; smart device; mobile education; mobile learning; remote education; web-based system

I. Introduction

A. Concept and Background of Mobile Education

Mobile education is a term that describes a relatively new way of education. One definition of mobile education that is commonly accepted by the public is that educational activities can happen anywhere, at any time, by taking advantage of mobile technologies. The concept has gained much popularity in China in recent years.

When this technology was just beginning to develop, a number of apparatuses were exclusively designed for mobile education, one such example being a series of digital learning devices produced by the Noah Corporation, which undertook a case study on the implementation of mobile learning in basic education [1]. However, this type of apparatuses faced several challenges such as the low performance on its hardware, difficulty to upgrade software, and the high cost for maintenance. Later, people began to try implementing mobile education through mobile phones [2]. Nevertheless, these types of systems were only able to provide teachers and students with limited functions owing to limitations of network bandwidth and hardware performance at that time. With the development of broadband networks as well as the evolution of smart devices, more and more people have come to realize that smart devices could become an effective medium for mobile education and some researches have already been undertaken in recent years [3] [4].

B. Necessity of Mobile Education

It is anticipated that mobile education makes flexible and ubiquitous leaning possible. Meanwhile, another "side-effect" of mobile education is that it can greatly enhance the interactivity between students and teachers by using the smart devices. It is widely acknowledged that students' learning efficiency can be greatly improved through interactive pedagogical activities. Based on this point, many educators are seeking new approaches for education with the principle of enhancing interactivity. In this paper, an innovative mobile education system for classroom scenario by taking advantage of smart devices is introduced, which also takes the special need of China market into consideration.

C. Prerequisite for Mobile Education

In order to fulfill the functionalities of mobile education, which is to make flexible and ubiquitous learning possible, several prerequisites should be considered.

- Network condition: In this paper, a survey on the 3G network services provided by several major providers in China in terms of the accessibility and expense is conducted. A report from China Telecom, which is one of the major telecommunication carriers in China, indicates that on average 97% of the urban area and 92% of the rural area have been covered with 3G networks by the end of 2012. In addition, the proportion of the users who have subscribed the telecommunication plan with the bandwidth of no less than 4 Mbps to all has reached to 70% by 2012. Besides, the expense varies from 80 RMB per month to 300 RMB per month based on the available utility time and data volume, which is affordable for the majority of the families in China. Therefore, the network infrastructure in China has provided a ready-to-use environment for mobile education.

- Mobile devices: With the advent of smart devices, it is widely accepted that these inventions can become a useful tool for mobile education. An earlier study [5] shows that students are more willing to use mobile devices for learning because such devices can provide them a flexible way of assimilating knowledge. In the meantime, the physical design of the most recent smart devices such as accessibility of wireless network, large screen size, and user-friendly interfaces makes them easier to be utilized for mobile education.

Therefore, the development of wireless and mobile technologies makes it feasible to implement the mobile education in China right now.

D. The Obstacle for the Implementation of Mobile Education from the Perspective of Technology

An earlier study [6] points out that one of the core issues for mobile education is how to facilitate users to utilize different devices to participate in educational activities. Currently, the most commonly used operating system for smart devices are iOS, Android, BlackBerry, and Symbian. As a result of that, the biggest headache for the developers of mobile education is to implement the interconnection among all kinds of smart devices. Thus, this paper also presents an effective way for solving this problem by taking advantage of web technologies.

E. The Outline of the Paper

This paper consists of four parts, among which the first one introduces the concept of the mobile education. It also gives analysis of the necessity, the prerequisite, and the difficulty of mobile education. The second part illustrates a mobile education system from the perspectives of functionalities, architecture design and workflow, followed by the third part, which evaluates the characteristics of the proposed mobile education system. Finally, the market promotion information related to this system is presented and certain future works are proposed in the fourth part.

II. System Design

A. Functionalities

After analyzing the most frequently used teaching methods, it is found that in the majority of situations, the teacher employs pedagogical techniques, while the students passively follow the teacher's instructions and explanations. Therefore, the following functions are designed for teachers and students based on the principle derived from the above phenomena.

1) Teacher:

a) Lesson preparation: The proposed system provides teachers an interface to prepare a lesson easily. A survey conducted by Hitachi researchers shows that most of the Chinese teachers prefer making courseware such as PPT, PDF, and short videos in advance. Consequently, the designers for the mobile education system consider the habits of the teachers and provide them a flexible approach to utilize their existing courseware. The proposed system allows the teacher to upload the prepared courseware beforehand.

b) Courseware distribution: As stated earlier in this paper, teachers get used to taking advantage of the courseware which is prepared in advance for efficient teaching. The proposed system provides them a convenient way to distribute their courseware which is uploaded during the "lesson preparation" phase. The courseware can be mainly classified into two categories, one of which is the document such as Word, PDF, and PPT, the other is the multimedia such as short videos and audios. After a teacher starts a lesson, the server of the proposed system will send related courseware to the teacher's and the student's clients according to their operations.

c) Teaching and demonstration: The proposed system provides teachers the functionality to demonstrate the courseware. These functions can be classified as two categories, one of which is for demonstrating documents such as Word, PDF, and PPT, the other is for demonstrating multimedia such as videos and audios. For instance, if the teacher chooses to show a PPT, he or she can directly flip to the slide which is required to demonstrate to the students. Besides, the client of the teacher provides basic tools for the teacher to make annotations directly on the document which can be kept even after the end of the lesson for the students to review later. These tools, such as straight-line pen, rectangle pen, and ellipse pen, can greatly facilitate teacher's teaching process. In addition, the system provides the teacher unlimited white boards for drawing and writing. In this way, all these valuable and useful notes can be conserved completely, which solves the problem caused by limited space of one white board in the traditional classrooms. For another instance, if the teacher chooses to play a video, he or she can click down and drag the playback progress bar to adjust the playback progress.

d) Camera and microphone control, question collection: The proposed system allows the teacher to open the student's local camera to transmit video image back to the teacher. Besides, the teacher can also open his or her local camera for the students to look at the teacher. This function is necessary and essential especially when there is a strong demand for demonstrating the experiment process during the class such as chemistry, physics, and biology. Besides, the teacher's client will automatically display the questions which are collected from the students' clients. This can greatly help the teacher to understand the difficulties that the students encounter during the course of learning, and then adjust the teaching process appropriately and timely.

e) Controlling transfer: During the teaching process, the teacher may often need to appoint one student to temporally act as the teacher to give a presentation. In this case, the proposed system allows the teacher to transfer the controlling right to a specific student, which enables the student to carry out all the operations just like the teacher.

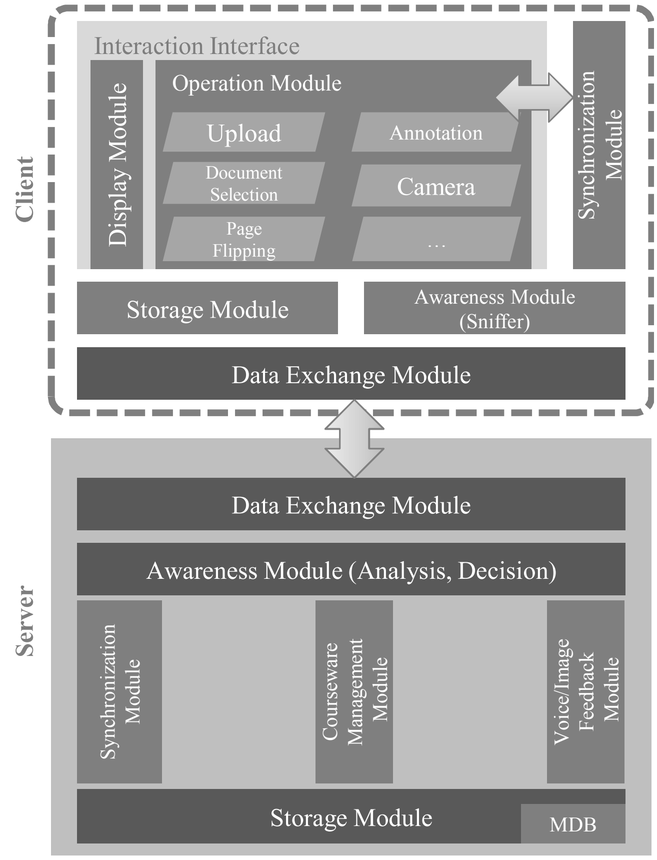

Fig. 1 Architecture of the mobile education system

However, the teacher can retrieve the controlling right at any time.

2) *Student:* The system provides students two modes to use, which are the passive mode and the active (self-study) mode. The student can decide to switch over between the two modes according to his or her own choice. If a student chooses the passive mode, the student no longer need to do any operations and his or her client will duplicate the main client's operations (main client is the teacher's client, otherwise it is the student's client to which the teacher transfers the controlling right) without the student's triggering. For example, once the teacher flips a document, the documents on the student's client will be flipped automatically. Once the teacher broadcasts a video, the video will be played on the student's clients simultaneously. Besides, all of the annotations made by the teacher will be synchronized to the student's client in real time. However, students can type their questions into a text area and then send to the teacher anytime during the class. In contrast, if a student chooses the active mode, then the student can operate to view all the courseware separately.

B. Architecture

The design of the architecture for the proposed system is aimed to eliminate the technical obstacles raised in the first part, which are the instability and the delay over ordinary network environment between various smart devices as well as the cross platform issue.

Browser-Server structure (BS) is chosen as a basic framework to implement the system. Since the HTML5 progresses greatly in the recent years, it has greatly increased the capability of web browser by supporting the latest multimedia. Besides, some of its new features make it possible to complete complex and smooth interactive operations through a web browser. Furthermore, almost all kinds of the operating systems for smart devices integrate the web browsers, so BS structure can help eliminate the cross platform issue easily.

Fig. 1 shows the architecture of the proposed system. In order to explicitly illuminate the architecture, this section explains the client and the server separately.

1) The architecture of the client consists of the following parts:

a) Interaction Interface: Interaction interface contains two modules, which aim at bridging the system and the users. In other words, it provides the functions directly related to users. One of the modules in it is the display module that renders certain contents on the client's screen. The other one is the operation module that processes the commands received from the user or the synchronization module.

b) Synchronization Module: This module helps implement the function related to synchronization by managing a status record of its own client. The format of the status record is shown in TABLE 1. Each courseware, such as the document or the multimedia (video and audio), is assigned a unique ID after the teacher uploads it to the server. And each client keeps the record of the "Document ID" and the "Video/Audio (V/A) ID" of which are being demonstrated. Meanwhile, the "Page Number" of the demonstrated document and the "Playback Time" of the demonstrated video or audio are kept. Besides, the status of the local camera and the microphone is also kept in the record.

If a client is a main client, for example, the teacher's client, it will send the status of its own to the server automatically for other's synchronization. If a client is a subordinate client, it will retrieve the status of the main client and compares it with its own. After that, certain functions of the operation module in the interaction interface will be invoked automatically for synchronization if it finds differences.

c) *Storage Module:* It mainly stores two kinds of content, one of which is the courseware downloaded from the server, and the other one is the client's status information which is used by the synchronization module.

d) Awareness Module (Sniffer): This awareness module

TABLE 1. STATUS RECORD

Courseware				Camera and Microphone
Document		Video and Audio		
Document ID=0	*Page Number=0*	*V/A ID*	*Playback Time*	*no/off*

collaborates with its counterpart on the server side to acquire appropriate services for the client according to its environment. The client's awareness module collects the environment parameters such as the network bandwidth, the available memory, the screen size and resolution, then sends them to the server.

e) Data Exchange Module: It is designed for establishing and maintaining the connection between itself and the server.

2) Corresponding to the client architecture, the architecture of the server consists of the following parts:

a) Data Exchange Module: It collaborates with the client's data exchange module to implement the communication between the server and the client.

b) Awareness Module (Analysis, Decision): It receives and saves the information which is collected by the client's awareness module (sniffer). Then, this information is analyzed by the server for better understanding each client's environment. Finally, the decision is made on what kind of services should be provided to each client.

c) Synchronization Module: This module maintains a copy of the status record for the main client. It modifies the record as long as the record of the main client changes in order to keep them unified. Subordinate clients then keep synchronization with the main client by comparing the record of their own with the record of the server.

d) Courseware Management Module: This module manages the courseware, including compressing, storing, and acquiring documents and multimedia uploaded by the teacher.

e) Voice/Image Feedback Module: This module controls each client's camera and microphone for retrieving image and voice.

f) Storage Module: This module abstracts database accessing from the upper level. The upper level modules send the requests with the unified format to this module for the requirement of storing and acquiring information. In order to provide rapid synchronization among all devices, frequently used data and public information such as the main client's status record is kept in the memory database (MDB).

C. Workflow

This section explains how each module cooperates with each other to complete the interaction between the teacher and the students. It is supposed that all the courseware has been uploaded to the server through the teacher's client before the class. When the class begins, all clients, including the teacher's and the students', connect with the server and each of their display modules shows a courseware list.

The Fig. 2 illustrates the workflow of the function that a teacher selects a document and then a student synchronizes with the teacher's operation. The part rounded by the dashed line is the main procedure that implements the synchronization, which is introduced below in detail.

First, the teacher selects a document through the operation module. Then the synchronization module modifies the status

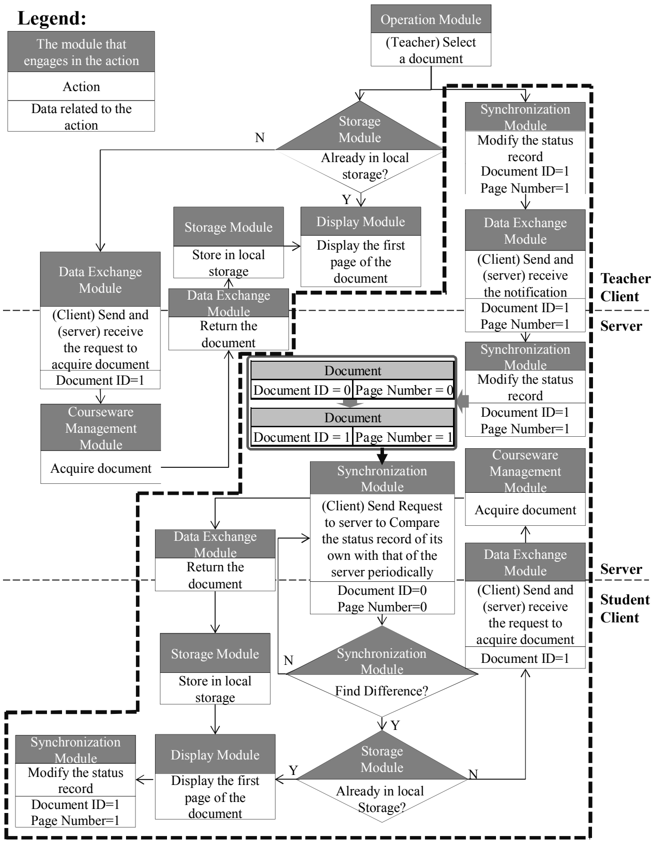

Fig. 2 Workflow

record from the initial state (Document ID = 0, Page Number = 0) to a new state (Document ID = 1, Page Number = 1), and the data exchange module sends a notification to notify the server in the next step. After receiving the notification, the synchronization module of the server also modifies the status record from the initial state (Document ID = 0, Page Number = 0) to the new state with "Document ID = 1" and "Page Number = 1" in order to keep the same with the teacher's client.

The synchronization module of the student's client sends requests to the server to compare the status record of its own with that of the server periodically. As soon as a difference is found, it will invoke certain process to synchronize with the server.

After the server modifies the status record, the student's synchronization module finds that its own status record (Document ID = 0, Page Number = 0) differs from the server's. Then the storage module checks whether the document with the "Document ID = 1" has already been stored in its local storage. If so, the display module will display the first page of the document and the synchronization module will modify its own records with the "Document ID = 1" and "Page Number = 1" to keep the same with the server's. If not, the student's client will send the request to the server for acquiring the document with "Document ID = 1" then store it in its local storage for displaying. After that, it will modify the status record to be identical with the server's.

TABLE 2. WIRELESS ROUTER SPECIFICATION

Cisco CVR100W	
Wireless transmission rate	300Mbps
Transmission standard	IEEE 802.11b/g/n

TABLE 3. SERVER AND CLIENT SPECIFICATION

		Server	Client (iPad)	Client (Sumsung P5110)
Hardware	CPU	Intel G645	A6X	NVIDIA Tegra 3
	Memory	4GB DDR3	1GB	1GB
	Storage	250GB	32GB	16GB
Software	OS	Windows 7 ulimate	iOS 6	Android 4.1
	Browser	Chrome v21.0.1180	Safari	Chrome Android

D. *Awareness*

The proposed system also contains an awareness function, which can take the environmental information into consideration for providing teachers and students with appropriate services. There is an awareness module in both the client and the server but they are different in functionality. The awareness module on the client side is responsible for collecting client's environmental information such as the network condition, the available memory, the screen size and resolution, which will be sent to the server periodically. The awareness module on the server side is responsible for saving the environmental information for each client. Furthermore, it analyzes the information in order to better understand the users' circumstances so that it can adjust the services provided to the teacher and students accordingly. For instance, a student's client reports its network bandwidth every five minutes to the server through its awareness module. The server notices that this client's bandwidth is decreasing for certain reasons. As a result of that, the server makes the decision that documents with the lower resolution should be provided to the client for avoiding the transmission delay. After that, the server sends the client the documents with a lower resolution each time the client sends a document acquisition request.

The awareness module on the server side can work independently. It keeps records of the decisions made for each client. As long as there is a request to provide certain service to a client, the server can refer to these decisions and take action reasonably.

III. EVALUATION

A. *Evaluation Purpose and Approach*

The purpose of this section is to verify the stability and the instantaneity of the system. The system is built in a real classroom environment, and the monitoring software WireShark 1.6.3 records the data transmission time and the data size.

First, a wireless local area network is established through the router "Cisco CVR100W". Then one server and ten clients, including five iPad and five Samsung P5110, are connected to the network so that they are interconnected with each other. The technical specification for the router, the server, and the clients are listed in the TABLE 2 and the TABLE 3.

B. *Test Results*

The main functions that have been tested are document selection, page flipping, and annotation creation. The synchronization time for each operation begins at the moment that the main client makes an operation and ends at the moment that the last subordinate client completes the same operation. The transmission data size for each operation is the total size of the data that is required to be transmitted between the server and a client for synchronization. Each operation listed in the Fig. 3 and the Fig. 4 is repeated for one hundred times. The synchronization time and the transmission data size for each operation are recorded and the average values are calculated accordingly. The Fig. 3 shows the result that in the various operations, the average synchronization time of the system is 886 milliseconds, which is less than 1000

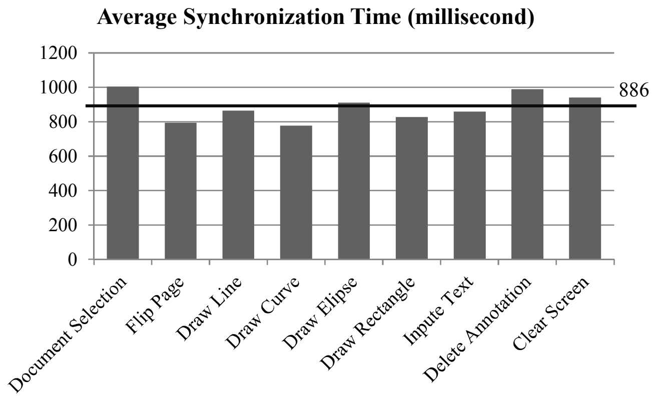

Fig. 3 Average Synchronization Time

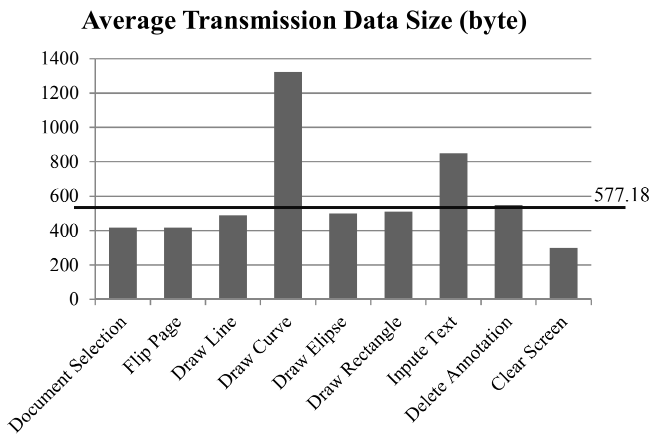

Fig. 4 Average transmission data size

milliseconds. The data proves that it can support smooth education process with tolerable delay in the real classroom environment. The Fig. 4 shows the result that in the various operations, the maximum transmission data size is 1300 byte, and the average data size is 577.18 byte. The regular 3G networks should be able to carry this kind of data amount with full capability to achieve the stable and real-time data communication for educational purpose.

IV. CONCLUSION

This paper proposes a relatively new way to implement a mobile education system. Through introducing the latest web technology, the system has many advantages such as zero cost deployment, cross-platform, and high interactivity. These features are always the key factors that determine whether a mobile education system can be successful.

So far, this system has been proposed to many Chinese local education bureaus and showcased at a number of exhibitions. The fact that numerous feedbacks have been received indicates that it has huge potential to become a dominant product in education industry in China. Many teachers comment that this system truly incorporates their teaching demands and habits, which makes it easier for them to accept and use. On the other hand, this system takes good advantage of children's interests in smart devices, a fact that can potentially trigger their desire for learning.

There is still a long way to go to improve the mobile education system. As mentioned at the beginning of this paper, the system considers only the teaching phase currently as the first attempt. It also has the potential to be adopted as a tool for remote education. In order to build a complete education system that covers the whole education process, further investigation and research must be carried out.

***Abstract*—In this paper, we present a functional prototype of an interactive multi-touch book with drawing capabilities, intended to enhance the understanding of engineering graphics concepts and improve visualization skills. Our multi-touch book combines textual elements with rich media content and interactive exercises to allow students to practice technical sketching in an environment that simulates traditional paper-based drawings and tools. Additionally, finished drawings can be submitted to the instructor via email directly from the digital book, which facilitates management tasks. A comparative study of traditional and digital sketching using our prototype was conducted with a small group of participants to evaluate the effectiveness of the tool. Preliminary results show positive reactions and acceptance.**

Keywords— multi-touch book; virtual sketching; interactive book; mobile learning

I. Introduction

Freehand drawing and sketching have been traditionally considered fundamental building blocks of the engineering design process and important activities in the development of spatial skills. In engineering education, the Accreditation Board for Engineering and Technology (ABET) lists the “ability to communicate effectively” as one of the eleven student outcomes required for accrediting engineering programs [1]. This outcome is typically interpreted as a broad term that comprises written, verbal, and graphical communication [2].

In 2004, the Engineering Design Graphics Division of the American Society for Engineering Education piloted a study to categorize the most important outcomes for engineering students in terms of graphical communication [3]. In this study, the “ability to create 3-D solid computer models” and the “ability to sketch engineering objects freehand” appeared at the top of the list. Despite major adoptions of Computer Aided Design (CAD) software, many engineering schools still require students to be able to sketch and communicate their ideas graphically without the aid of computer tools as part of their curricula.

According to the taxonomy proposed by [4], sketches can be classified as thinking sketches, aimed at guiding non-verbal thinking; talking sketches, used to support the design discussion with colleagues; and prescriptive sketches, which provide instructions to the draftsman/designers in charge of developing the final drawings. Sketching is considered a powerful design instrument, which can greatly boost creativity and innovation. It is among the best forms of documentation in the early stages of the engineering design process and an effective tool to communicate preliminary design ideas to others [5].

In educational settings, sketching is usually practiced using paper-based exercises and traditional tools such as pencils and erasers. Drafting books and engineering graphics teaching materials typically include design problems and drawing activities that must be completed freehand. Although electronic books are being well-received in many areas, paper-based activities are still dominant in sketching and technical graphics courses. This is due, in part, to a lack of appropriate digital alternatives.

Although both traditional books and sketching have transitioned to digital forms, they have done it separately, creating a disconnection between them. On one hand, current electronic books are designed to read and visualize content, but users cannot draw or sketch directly on the pages. On the other hand, digital sketching software and tools allow users to create freehand drawings in the computer, but these tools are not fully integrated within electronic books. Digital sketching tools are becoming commonplace in engineering and product development, particularly during conceptual design stages, but in educational contexts, a closer integration with existing teaching materials is desirable.

In this paper, we present a prototype of an interactive electronic book with built-in digital sketching capabilities targeted at engineering graphics and visualization courses. Our system takes advantage of the multimedia elements offered by modern eBooks and the interactive multi-touch features available in tablets. The result is an integrated digital resource with enriched interactive learning materials and “digital worksheets” that students can complete either by touching the tablet screen with one finger or, preferably, with a stylus pen. Additionally, these "worksheets" can be submitted electronically to the instructor using the email functionality also implemented in the digital book.

II. Electronic Books

Electronic books, or eBooks, are considered to have started with Project Gutenberg in 1971 [6, 7]. It was that year when the idea of digital books for personal computers was originally conceived. Project Gutenberg pioneered the concept of digital library and since then, multiple events, especially after the introduction of the World Wide Web in 1990, have contributed to the growth and popularity of eBooks.

In 1995, Amazon opened the first online bookstore. Two years later, in 1997, electronic ink (E-ink), a popular technology used by modern e-readers, was developed. Best-selling author Stephen King released his book "Riding the Bullet" exclusively in digital format in the year 2000; and in 2004, Internet giant Google launched Google Print, a service that made thousands of books and magazines available online.

The first commercial eBook readers, or e-readers, with black and white electronic paper displays appeared in 2006. Most devices included Internet access to online digital bookstores, which along with the development of popular file formats for digital books such as epub, contributed to increased eBook sales worldwide [8].

In early 2010, Apple introduces the iPad, the first commercial tablet with a multi-touch screen that allows users to interact with all multimedia elements associated to a personal computer (images, video, interactive graphics, 3D models, etc). Since then, other companies have released their multi-touch tablets, making electronic books more popular than ever before [6, 7]. Finally, in 2012, Apple releases *iBooks Author*, an authoring tool to create multimedia books for iPad. The tool was released free of charge and represents another step forward in the evolution of electronic books.

A. Standards for Electronic Books

Standardization of digital formats is a fundamental requirement for proper compatibility and interoperability between applications. Standards establish consistent and reliable protocols that ensure that information is clearly communicated and universally understood.

There are currently multiple formats for electronic books at different stages of standardization [9]. EPUB, for example, the main open standard for eBooks, is in its version 3 at the time of this writing. The popular PDF file format has been the de facto standard for printable documents for many years. In 2008, it was released as ISO standard 32000.

Because of the wide variety of formats, not all electronic books are supported by all devices. Furthermore, support for multimedia components within eBooks is currently not standardized, which means that different eBook formats may support different types of multimedia content. After selecting a representative group of eBook formats and comparing their relevant features and multimedia support, Apple's iBook format was selected for our prototype and tests.

Fig. 1. Prototype eBook in Digital Tablet

The availability and affordability of mobile devices, particularly tablets, as well as the ability to incorporate multimedia content make multi-touch books a very attractive tool for educational applications, particularly in technical and scientific areas with significant visual content (medicine, biology, etc). In the area of engineering design graphics, for example, three-dimensional models can be very effective when used to illustrate the concept of orthographic projection. 3D visualizations can also help students understand certain architectural and civil engineering structures.

Visual content in educational materials was traditionally created by graphic professionals and technical illustrators and was limited almost exclusively to static images [10]. The use of multimedia content in tablets and eBooks represents a major improvement over classic educational resources [11].

A view of the prototype eBook described in this work can be seen in Fig. 1.

III. Digital Tablets

The development of digital tablet devices started few decades ago. In 1972, Alan Kay designed the Dynabook [12], a portable educational device for children. Multiple uses and applications for this design were described, but the Dynabook was never produced despite reaching the prototype stage.

In the early 1990's, portable computer devices such as NCR system 3125, IBM's 2125, and the Apple Message Pad, also known as Newton, were released commercially [13]. For about a decade, the Personal Digital Assistant (PDA) dominated the world of tactile portable devices, where Palm positioned itself as the market leader. In 2001, Microsoft introduced the Microsoft Tablet PC, a pen-enabled computer running Windows XP Tablet PC Edition. During the following years, other notebooks and portable devices with reduced price and size were also launched. In 2010, Apple announced the release of its revolutionary digital tablet, the iPad, which takes advantage of the company's previous experience with multi-touch mobile devices already in the market (iPhone and iPhone Touch). The popularity of these devices is partly due to a successful combination of hardware, built around the device's multi-touch display, and Apple's operating system iOS, and to the creation of a virtual store (App Store) for applications. This store provides a digital software distribution platform with applications for Apple devices that can be directly downloaded from the Internet. Since 2011, other brands and manufacturers of digital tablets have created their own application stores, such as Google Play for Android devices.

The popularity and rapid expansion of portable electronic devices, particularly smart phones and tablets, are gradually transforming learning styles and opening new possibilities for distributing educational content to students. Some authors use the term "tablet-learning" to actively encourage the development of new educational materials for tablets, which take advantage of the technology and adjust to the digital and mobile nature of modern students' habits and lifestyles [14].

Previous studies have been done to determine the factors that influence the students' acceptance of digital tablets in educational settings [15]. In 2010, a six-month research study with 40 faculty members at the University of San Francisco experimented with and shared potential uses of the iPad in higher education [16]. The study concluded that educational iPad apps could be used to support teaching and learning, and evaluated the usability of the device in terms of reading, writing, communication, and creation of content.

Not surprisingly, many educational applications are already available for digital tablets. These applications benefit greatly from the mobility, multi-touch capabilities, and 3D interaction offered by the tablet technology. These features are particularly helpful in drawing apps, providing an interesting way to interact with graphic content. An extensive compilation built by [17] in 2011 illustrates the potential of "tablet-learning" for teaching drawing, design and graphic arts.

With the advent of *iBooks Author* (Apple' free authoring tool for *iBooks*) in early 2012, many multimedia educational books are being developed. There are some examples in the area of engineering design graphics, but more work needs to be done to fully exploit the multimedia capabilities.

IV. Design of a Multi-Touch Digital Book for Technical Sketching

As part of this work, we developed a functional prototype of a multi-touch digital book aimed at providing an integrated environment for digital sketching (see Fig. 1, Fig. 2, and Fig. 3). The ability to visualize and interact with three-dimensional models included within the electronic book is a desirable feature, as is the completion of traditional sketching exercises without having to print out any drawing templates.

For this prototype, we selected a representative learning unit present in most engineering design graphics curricula: orthographic projection and multi-view drawing. All exercises included in the eBook simulate traditional freehand sketching activities. The prototype was developed as an iBook (version 3 or higher) for iPad using Apple's *iBooks Authoring* tool.

Fig. 2. 3D widgets in Prototype eBook

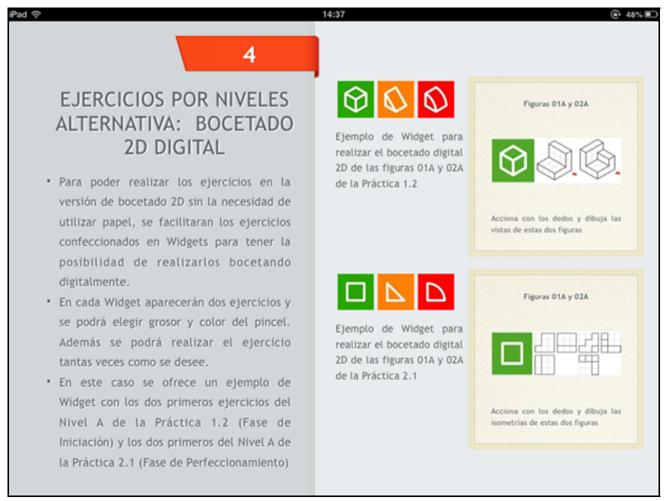

Fig. 3. Interface of Prototype eBook

By default, Apple's *iBooks Author* allows the inclusion of a variety of multimedia elements, such as graphics and video, within the iBook. In addition, custom widgets can be developed to provide extra functionality. Widgets are relatively small pieces of software that provide a specific service within a bigger application. Desktop widgets in personal computers, for example, are used to show the latest news headlines or the current weather. In interactive eBooks, widgets can be used to customize utilities, tools, and other features.

For our prototype, we developed a custom widget to provide a digital sketching environment, where students can "draw" directly on the pages of the electronic book and submit the exercises electronically to the instructor. The following elements were included in the prototype:

- Photo Gallery.
- Custom widgets, designed to simulate a traditional sketching environment.
- 3D models, with solutions to the exercises.

- Videos, with learning materials covering orthographic projection and Multi-View Drawings.
- Email capability, to send exercises and assignments.

V. Preliminary Pilot Study

In order to evaluate the usefulness and effectiveness of our interactive sketching eBook, we conducted a preliminary study with a small group of seven graduate students enrolled in a Master's degree program in Teaching with a concentration in Drawing, Design, and Graphic Arts. Because of their artistic backgrounds, all participants had previous experience with traditional sketching.

For this pilot study, we compared traditional sketching activities, using grid paper and a pencil, versus digital sketching, using our eBook prototype. The digital sketching activities were performed on an iPad tablet with iBooks version 3.1. The study was conducted as part of the workshop "Representation and Analysis of 3D Shapes" available as a multimedia book at http://www.anfore3d.com. The new prototype sketching eBook was provided as supplementary material and made available free of charge in Apple's iBook Store: http://goo.gl/m5obv. The sketching iBook "Maqueta ejercicios 2D" can be viewed with iBooks version 3.0 or higher with iOS 5.1 or higher.

A. Methodology

For the first part of the study, participants were given a traditional drawing template with several exercises and a pencil (see Fig. 4). First, they were asked to sketch the orthographic views of different objects given their isometric views. Next, a second page was distributed where participants were asked to sketch the isometric views of different objects given their orthographic views. In both cases, grids (orthographic and isometric) were available in the template as visual aids.

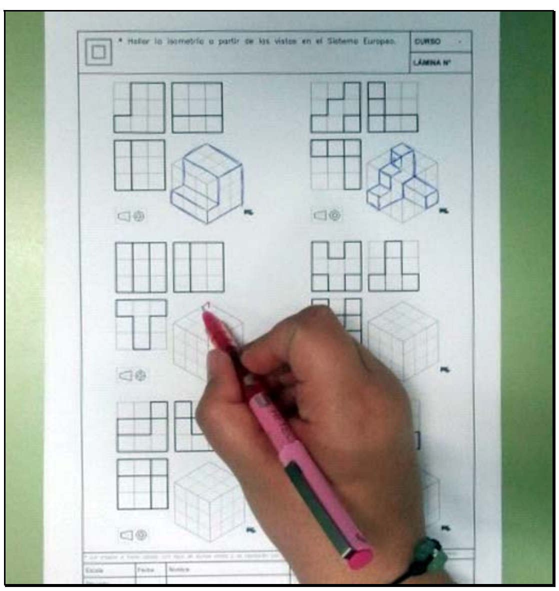

Fig. 4. Drawing Template for Traditional Sketching

In order to test the effectiveness of our prototype, a second series of similar exercises was completed by the participants using an iPad with the interactive sketching book we developed (see Fig. 5). Participants created the drawings freehand either by touching the screen with one finger or with a stylus pen. This was implemented using the Sketchpad widget available at bookry.com. Drawing submission via email was also tested, which participants acknowledged as a valuable feature in terms of saving time and paper when completing the exercises.

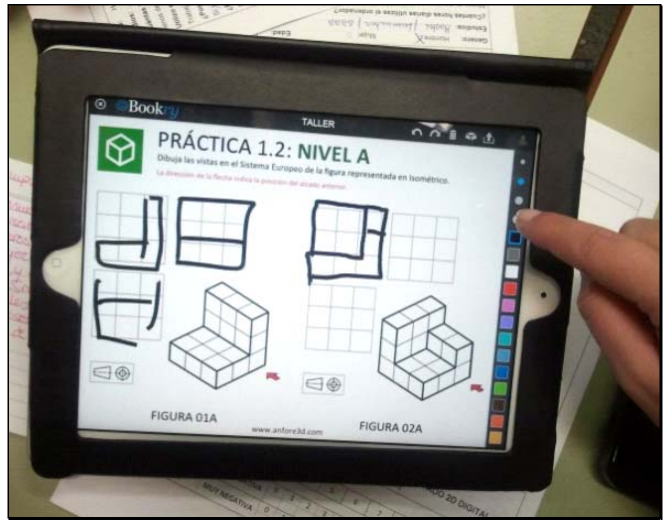

Fig. 5. Custom Widget for Digital Sketching

VI. Results

To estimate the educational value and the level of user satisfaction, we compared our digital sketching prototype with the traditional sketching approach using a simple questionnaire that was distributed to participants at the end of the exercise. Participants were asked to score both sketching experiences (traditional and digital) from 1 (lowest) to 5 (highest) based on a series of questions. The seven questions presented in the questionnaire as well as the mean scores for both sketching experiences are shown in Table I and illustrated in Fig. 6.

TABLE I. Traditional Sketching vs. Digital Sketching

Question	Mean Scores	
	Traditional Sketching	Digital Sketching
Q1. Improves visualization skills	3.43	4.43
Q2. Useful	3.14	4.29
Q3. Intuitive; easy to use	3.14	4.14
Q4. I would like to complete more exercises (Motivation)	2.43	3.71
Q5. Helps with the understanding of technical graphics concepts	2.86	3.86
Q6. Easy to learn	2.57	4.43
Q7. Overall Experience	3.9	4.16

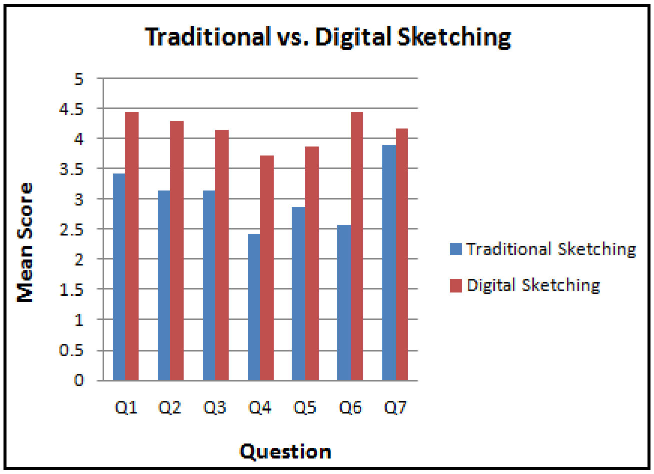

Fig. 6. Comparative results of sketching experiences

Due to the small sample size used in this pilot study, the results regarding user experience with our interactive sketching prototype cannot be considered conclusive. It is interesting to see, however, that this preliminary data show a slight tendency of the participants toward the digital sketching experience.

VII. Conclusions and Future Work

Our work has shown that the use of multimedia elements in electronic books has the potential to enhance traditional teaching materials and learning activities. Interactive three-dimensional visualizations can be easily incorporated to eBooks, providing additional value to plain text and static two-dimensional graphics. This can be particularly useful in technical and scientific areas that are rich in visual information, such as engineering design graphics.

The multi-touch displays in modern tablets provide a natural interface for activities that must simulate traditional paper-based exercises, such as sketching. Additionally, internet connectivity features allow the integration of network services into the electronic book. In our prototype, students use the built-in email client to send their work to the instructors, which reduces de amount of paper in the classroom, reduces time, and facilitates grading and management tasks.

In the future, we plan on expanding our interactive book for engineering design graphics by increasing the number of chapters, exercises, and interactive multimedia content. Although positive preliminary results were obtained in our first pilot study, we would like to conduct a more extensive analysis with larger groups of participants to evaluate the effects of our prototype in the students' performance. We believe interactive books are attractive, engaging, and provide new ways to complement existing learning materials.

***Abstract*—Dimensioning plays an important role in the product development process. It is usually learned through sketching exercises where students add the corresponding dimensions to different parts of an engineering drawing. Nevertheless, being able to self-learn proper dimensioning methods is challenging, as a geometric figure requires a specific number of dimensions to be correctly defined. This paper presents an educational software application for multi-touch tablet devices to support dimensioning activities. Our application uses a multi-touch interface where students can create 2D parametric drawings with dimensions using freehand sketches and receive feedback from the system about the quality of their dimensioning exercises. When a student finishes a sketch, the system reports back the correct and incorrect dimensions. Multi-touch gestures are also used for basic sketch manipulation (panning, zooming, and rotating), similar to the standard functionality found in modern smart phones and tablets. Preliminary experiences show that multi-touch interfaces provide an effective way to capture students' attention. Students found the system very natural, and the time required to learn how to use the application is short. They enjoyed the simplicity of the interface and valued the powerful control of the geometry.**

Keywords—Innovation and technology; multi-touch displays; sketch-based interfaces

I. INTRODUCTION

Sketching and dimensioning are considered important learning outcomes in the engineering curriculum. The Accreditation Board for Engineering and Technology (ABET) recommends a list of eleven outcomes for assessing engineering students, one of which, criterion 3, states that students must possess the ability to communicate effectively [1]. Many engineering programs interpret this ability as encompassing written, oral, and graphical forms. In 2004, a survey [2] conducted by the Engineering Design Graphics Division of the American Society for Engineering Education (ASEE) identified "the ability to sketch engineering objects in the freehand mode" as the second most important graphics skill to be learned by engineering students, while the "ability to create dimensions" was put in the fourth place.

In a classroom environment, students typically practice dimensioning through exercises, where they create the orthographic views of an object and add the corresponding dimensions, or just add the missing dimensions to a given drawing. Dimensioning is a common subject in introductory engineering graphics courses. However, self-learning is difficult as dimensioning exercises are open-ended problems. While a geometric figure requires a specific number of dimensions to be properly defined, there are different sets of correct combinations. In this paper, we present an educational software application for multi-touch tablet devices to support dimensioning activities in engineering graphics courses. Our application uses a multi-touch interface where students can create 2D parametric drawings with dimensions using freehand sketches and receive feedback from the system about the quality of their exercises.

II. RELATED WORK

Different approaches have been taken to teach dimensioning effectively. Some methods are purely methodological. For example, the "Simple Geometry Method (SGM)" developed by [3] involves breaking down a drawing by a process of simplification. A drawing can be understood as complex geometry that is comprised of multiple simple geometric entities such as lines and circles. Students learn to identify these simple geometric forms and provide dimensions for them.

Other methods include the integration of dimensioning and tolerancing topics within CAD modeling courses. As reported by [4], some contents that were traditionally offered as stand-alone courses (e.g. geometric dimensioning, tolerances, and descriptive geometry) can be partially covered in a parametric modeling course, using CAD tools to apply geometric dimensioning and tolerances to 3D models, and drafting and analysis tools to solve descriptive geometry problems.

In previous work by [5], educational modules were designed to illustrate geometric dimensioning and tolerancing examples employing a portable Coordinate Measuring Machine (CMM), which interfaced with a parametric solid modeling software package allowing students to visualize tolerance zones.

McInnis et al. [6] developed an online working drawing review video and online assessment tool. This tool paid particular attention to dimensioning and ASME ANSI Y14

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

standards with the objective of improving the quality of the working drawings required in final design project reports.

There is practically no computer software specifically designed to support students with dimensioning activities. Martinez and Félez [7] developed a methodology based on a computer application that uses variational geometry, which allows students to draw a simple shape and obtain the different alternative dimensions, according to the ISO-129 standard. Their system consists of a sketching module that supports the creation of shapes. These shapes are created by combining lines, circles, and arcs. A calculation module outputs a complete set of dimensions for the sketch that are consistent with the rules established by the ISO-129 standard. Although the most suitable set of dimensions is provided, the application is flexible. If the student wants to replace a specific dimension, the algorithm automatically reconfigures the complete dimensioning set and proposes a different one.

III. Dimensioning Technical Drawings

Before an object can be built, complete information about both size and shape must be provided. The process of adding size information to a drawing is known as dimensioning. Dimensioning technical drawings is used to provide a complete description of an object so it can be built and defined. If a part is dimensioned properly, then the intent of the designer is clear to both the person making the part and the inspector checking it.

Additionally, proper dimensioning improves the quality of the 3D models created with parametric CAD packages, since students can also learn to use geometric and dimensional constraints efficiently. If students know how to add dimensions properly, they also understand the concept of degrees of freedom and the fully-constrained sketch paradigm (a fully-constrained sketch is a sketch with zero degrees of freedom, i.e. a sketch in which all degrees of freedom of each geometric element are defined using geometric and dimensional constraints).

The main challenges for students when adding dimensions to a drawing are the following:

- How many dimensions are needed to define an accurate and complete object? In general, dimensions should not be duplicated. Also, only the minimum number of dimensions required to produce or inspect the part should be provided. Over- and under-dimensioned sketches are common errors in students' work. Therefore, many exercises need to be done in order to learn how to fully-dimension a drawing.

- What set of dimensions should be used? There are different sets of dimensions that define a part, but not all of them are correct. A typical selection criterion involves analyzing what information is necessary to manufacture the object. For example, to drill a hole, the manufacturer needs to know the diameter of the hole, the location of the center of the hole, and the depth to which the hole needs to be drilled. These three dimensions describe the hole in complete detail for the feature to be made [8].

Selecting a correct set of dimensions for a drawing requires the correct control and use of the following items:

- Size dimensions (indicate the overall sizes of the object and the sizes of the features).
- Location dimensions (locate features of an object from a specified datum, surface or other feature).
- Dimensions of chamfers, fillets, and rounds.
- Dimensioning of symmetrical parts.
- Dimensions of arcs.
- Dimensions of revolved solids.
- Inclined surfaces.
- Dimensions of standard features and shapes (prism, cylinder, hole, etc).

With the educational objective of assisting engineering students in learning proper dimensioning practices and standards, a computer aided sketching application called eParSketch has been designed. It is described in detail in the next section.

IV. Methodology

A. Software Application for Learning Dimensioning

Our application for learning dimensioning, called eParSketch, is a version of a research application for managing 2D parametric freehand sketches [9] adapted for educational purposes.

The application eParSketch uses a multi-touch tablet where students can create 2D parametric drawings by using freehand sketches to define the geometric elements (line, arc, circle and ellipse). Combined shapes, which are automatically broken down into basic elements, are also supported. These sketches are automatically recognized by the software and converted to parametric entities, such as those usually employed in modern 3D CAD systems. The drawn shapes can be controlled using a set of gestures (symbolic codes) representing geometric constraints (parallel, perpendicular, tangent, vertical, horizontal or concentric), dimensional constraints (linear, diameters or radii) and delete command.

Fig. 1. Inking mode operation: drawing a dimensional constraint.

The application eParSketch uses a single-touch and multi-touch gesture alphabet to distinguish between the two basic modes of operation: inking and visualization. Inking allows the creation of drawing entities, supporting both thick and thin lines. This mode follows technical drawing conventions where thick lines are related to edges and object contours, and thin lines are used for dimensions and other types of annotations. In the context of our application, drawing with a finger on the screen means thin (Fig. 1) and putting two or more fingers together means thick. The whole hand is used to delete elements.

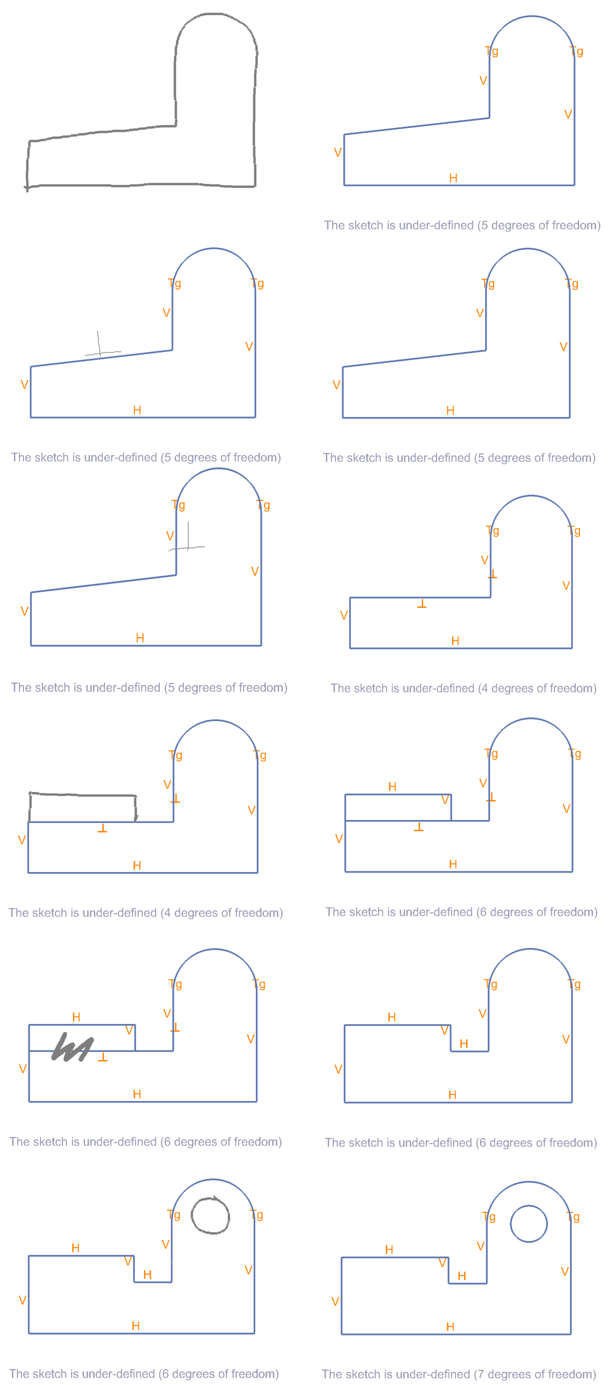

Fig. 2. Sketching sequence in exercise to learn how many dimensions are needed (I): students define, constrain and edit a shape.

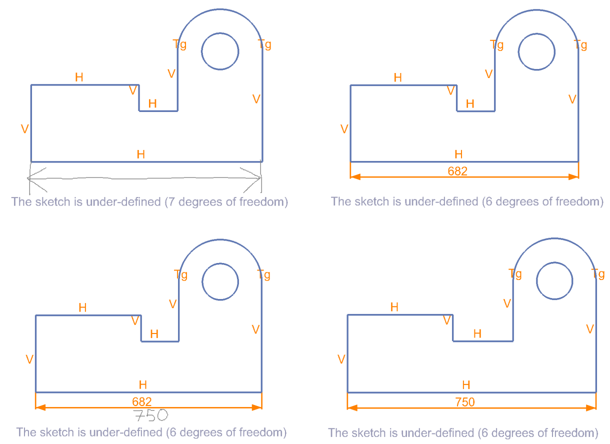

Fig. 3. Sketching sequence in exercise to learn how many dimensions are needed (II): students dimension a given shape (dimensional control).

Visualization mode is controlled by a set of multi-touch gestures where several fingers (pan function) can be used, or two hands at the same time (zoom and rotation). This is similar to the functionality found in modern multi-touch smartphones and tablets. The sketching methodology that is supported by the application follows the typical steps employed by engineers for creating technical sketches. This is an important point, as students do not need to learn any special sketching tools or program commands. They can apply the rules they have learnt previously.

We conducted a pilot study of our application with freshman engineering students to test the usability of the software. We used two types of exercises in this study. The first group of exercises was defined to assist students in finding how many dimensions are needed to fully-define a drawing, and a second group was used to select what set of dimensions is appropriate.

B. Exercises to learn how many dimensions are needed

The first type of exercise is based on drawing creation and dimensioning. As the user is editing, constraining and dimensioning the corresponding sketch, the system reports the current number of degrees of freedom, which is indicative of the number of missing dimensions. The sketching sequences presented in Fig. 2, Fig. 3 and Fig. 4 illustrate the process.

In this type of exercise, the student defines the geometry of the 2D shape (the strokes made by the user are interpreted as geometric entities) which is automatically corrected, adjusted, and connected to other existing elements in the drawing (Fig. 2). Once the user has entered the complete sketch outline, the shape can be edited, dimensioned, and constrained. The user can manage the geometric entities and the geometric constraints using a set of gestures (where the strokes are interpreted as commands). Therefore, if the user wants to generate design alternatives, or adjust some sketch features to reach a specific dimensional condition, the system provides parametric capabilities and handwritten dimensional control to the two-dimensional freehand sections (Fig. 3). The majority of gestures are inspired by the conventional symbols used in technical drafting. During the sketching process, the system provides feedback with the remaining number of degrees of freedom that need to be constrained. This is used to inform the student if the sketch is over- or under-defined (Fig. 4).

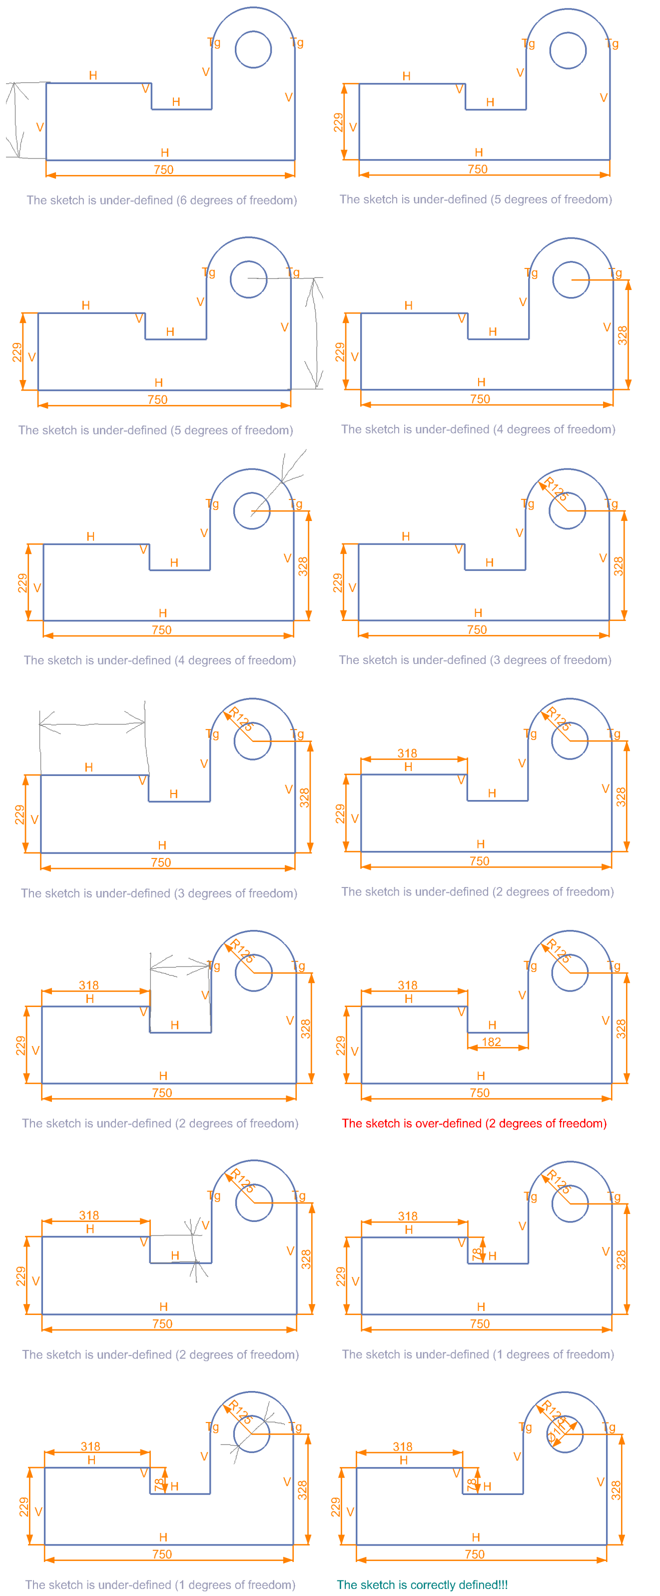

Fig. 4. Sketching sequence in exercise to learn how many dimensions are needed (III): students dimension a given shape.

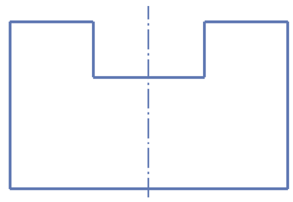
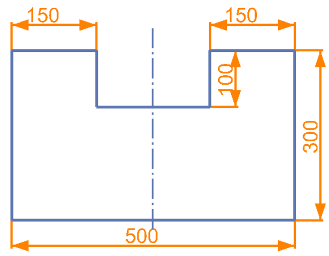
C. *Exercises to learn what set of dimensions to use*

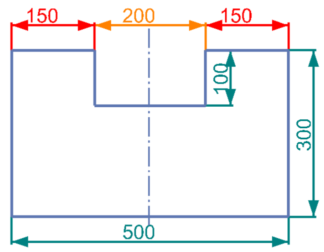
In this type of exercises, a drawing without dimensions is presented to the student (Fig. 5 and Fig. 6). The student is asked to add dimensions. When the student finishes the sketch, the system reports the correct dimensions (in green color), the incorrect dimensions (in red color), and adds the dimensions that were missed by the student (in orange). The application has successfully solved all proposed exercises, and the dimensions drawn by the user are compared with the correct set dimensions of the solution.



a) Sketch presented to the student



b) Dimensions created by the student



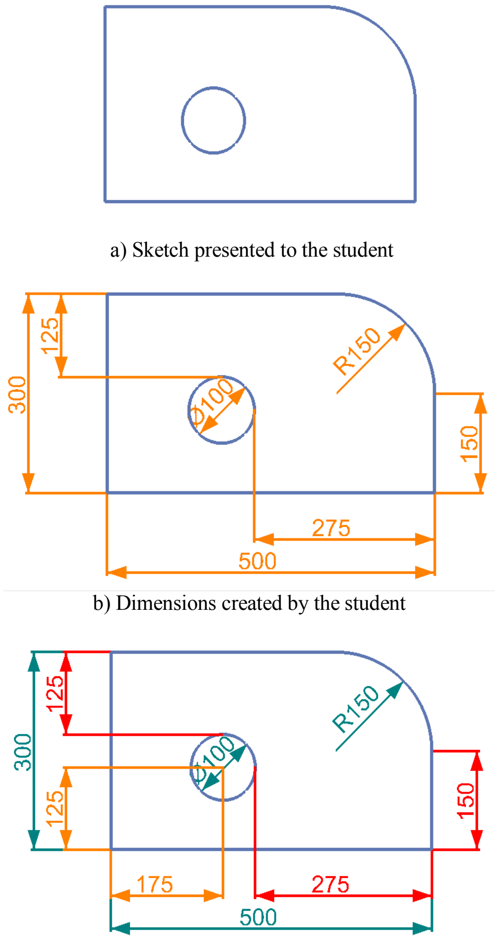
c) eParsketch correction

Fig. 5. Sketching sequence in exercise to select the correct set of dimensions to use (I): dimensioning symmetrical parts.

D. *Preliminary studies*

Our preliminary experience with students shows that multi-touch interfaces are a powerful tool to capture students' attention. They stimulate and build positive attitudes in students toward dimensioning tasks. Initial tests have revealed encouraging results. Students with an engineering background find the system very natural and the learning process very effective. They enjoy the simplicity of the interface and value the powerful control of the sketched geometry.

We have tested our application in multiple Tablet-PC's running Microsoft Windows 7, supporting pen-input using a stylus. The parametric engine used to power the system, Siemens 2DCM, is only available for the Windows platform, which is a limitation in terms of portability to Android and iOS tablets.



a) Sketch presented to the student

b) Dimensions created by the student

c) eParsketch correction

Fig. 6. Sketching sequence in exercise to select the correct set of dimensions to use (II): rounds and location dimensions.

From a usability standpoint, preliminary tests show that a pure tactile management system is not as effective as the combination of pen-input (for sketching) and multi-touch gestures (for visualization tasks, such as zoom, pan and rotate). The screen size is a limiting factor for using a pure multi-touch operation, as users feel less precise in the drawing tasks.

V. Conclusions

In this paper, an educational software application for dimensioning is presented. It was designed for multi-touch tablet devices to assist engineering students in learning proper dimensioning practices and standards. Our application allows students to create freehand sketches, apply dimensions, and receive immediate feedback about the completeness and correctness of their work. The interface was intentionally designed to simulate a traditional sketching environment, and it offers a promising alternative for self-learning complex topics such as dimensioning.

Preliminary results from our tests show that multi-touch interfaces are an effective way to stimulate students, capture their attention, and build a positive attitude toward dimensioning tasks. Participants found the application intuitive and very easy to learn.

Although some manufacturers have decided to exclude pen input from their current models of tablet devices, our experience in the context of this work suggests that, for sketching and technical work, users can greatly benefit from the precision offered by a stylus instead of a pure touch-based drawing.

Abstract — **Mobile embedded system is an excellent candidate to provides depth, breadth, and rigorousness for meeting the emerging workforce and education needs in science, technology, and engineering. However, the high requirements of investment in resources and instructors make the mobile embedded system education impractical for universities and colleges that lack the resources and build-ups. This work-in-progress paper presents a novel low-cost and portable labware for hands-on labs and projects using Android smartphones and scalable sensory platform. It is easy-to-adopt, promotes students with authentic and creative learning, and supports wide dissemination.**

Index Terms – Mobile embedded labware, low-cost and portable, modular design, authentic and creative learning.

I. MOTIVATION

The evolution of embedded hardware and software technologies has rendered the embedded systems more and more important roles in all aspects of our society [1]. This importance has been reinforced with the explosive growth of smart mobile device. The mobile embedded systems have expanded the connectivity and functionality of embedded systems to a new era. In addition, there is an emerging trend of enhancing the connection between mobile embedded systems and the physical world via various sensors so that these systems can be more capable to learn, think, and understand the surrounding world [2]. All of these imply great demands for well-trained workforce in mobile embedded system to meet the technology trends and the industry needs.

On the other hand, due to the wide involvement of hardware and software components that interface to various communication and networking processes with real-time requirement, embedded system has been recognized as an excellent candidate to provides depth, breadth, and rigorousness for meeting the emerging workforce and education needs in science, technology, and engineering. Many universities have offered courses related to embedded systems design [3, 4].

A key component in embedded system education is laboratory, which is required in most embedded systems courses [5]. However, existing laboratory models rely on significant investment in resources (e.g., embedded system labs) and high requirement for instructors (e.g., faculty whose expertise is in this area). These prerequisites make the mobile embedded system education impractical for universities and colleges that lack the resources and build-ups. Furthermore, the hands-on lab resources for the emerging mobile embedded system education are even more limited.

II. LOW-COST AND PORTABLE LABWARE WITH SCALABLE MOBILE SENSORY PLATFORM

To overcome the above difficulties and broaden new generation computing education to universities and colleges that have limited resources, this work-in-progress paper presents a new labware to enhance the effectiveness of teaching mobile embedded system and significantly improve the learning outcomes. Taking into account that most students currently have their own smartphones, we developed a novel low-cost and portable labware based on our past successes and experiences on mobile learning environment [6, 7] for hands-on labs and projects using Android smartphones and scalable sensory platform. The labware will be extended to support iOS based smartphones after the completion of the design of the Android based labware. According to the latest statistics [8], the Android based smartphones have 52% market share, while the iOS based smartphones have more than 39% market share. Therefore, the developed labware will support more than 92% smartphones.

In the labware, the sensors are used to collect raw data from physical world. The developed Android apps then convert the raw data to useful digital data, so that the data can be analyzed and used for device control. Currently, most smartphones have built in sensors, such as motion sensors, gravity sensors, gyroscopes, rotational vector sensors, orientation sensors, magnetometers, temperature and pressure sensors, etc. The sensory platform can be extended by integrating external off-the-shelf sensors that are usually only cost a few dollars with mobile devices via microcontroller, USB, Wi-Fi or Bluetooth modules. Figure 1 shows an example of Android-external gas sensory embedded system with Bluetooth that we provided to

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

students in the preliminary evaluation. This system can measure the concentration of CO, CH_4, and CO_2 from surrounding environment. The data were acquired by the TI-MSP 430 microcontroller [9] and processed by the embedded program. The microcontroller communicates with Android phone through Bluetooth wireless connection. The total cost for this prototype is $120 (gas sensor: $10, microcontroller: $15, Bluetooth module: $30, Android based smartphone: $50, and miscellaneous items: $15). It is lower than the cost of a typical textbook in science, technology, and engineering areas. If the students use their own Android based smartphone as the learning tool, the total cost can be dramatically reduced to $70.

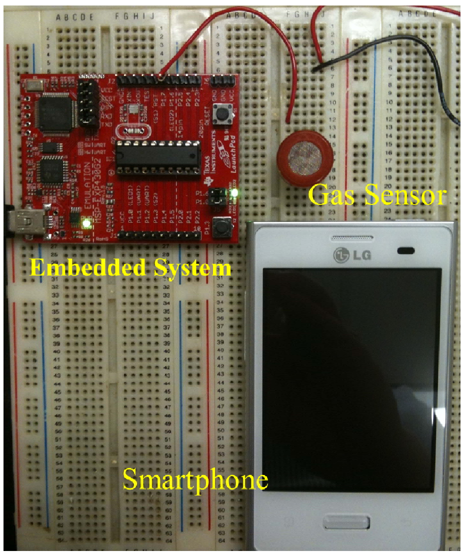

Figure 1. Android external gas sensory embedded system with Bluetooth

The affordable and easy-to-adopt labware is designed to promote students with authentic and creative learning. Through collecting, processing, and analyzing authentic data using the android smartphones and sensors, the hands-on exercises tie the learning process with real-world applications. The open-ended problems in the labware provide a creative learning environment. Consequently, after using the labware, students' skills with hardware and software, comprehensive ability, hands-on and innovation abilities can be better cultivated. Also, students' capacities for employment competitiveness can be strengthened.

The labware is developed using modular approach and has multiple learning levels in each module. This gives instructors the flexibility to adopt the full labware or to integrate selected modules based on their specific needs. Currently, we are developing the following six modules:

- Module 1: Getting started with Android application development.
- Module 2: Getting started with Android sensor management API
- Module 3: Getting started with hardware-software co-design of android-based embedded systems.
- Module 4: Microcontroller (MCU) interface to Android mobile device.
- Module 5: Android apps with built-in internal sensors.
- Module 6: Android apps with external environmental sensors.

Each module in the labware contains three major components, the pre-lab that introduce concepts, theoretical background, and lab preparation; the lab activities that require students to work on internal and/or external sensors for data collection, conversion, processing, and analysis; and the post-lab activities that include student add-on labs and open-end projects.

The labware will support wide dissemination. We will deliver the developed labware as an integrated package and deploy it on a Google site to provide a "ready-to-adopt" model. The Google site is a free service powered by Google Cloud technique. It not only makes anytime anywhere access to the labware possible, but also provides a place for educators to share learning materials, such as sensing related apps, lab manuals, and information for low-cost external sensing devices. Figure 2 shows the main page of this mobile friendly user interface for low-cost and portable labware.

Figure 2. Mobile friendly user interface for low-cost and portable labware

III. CURRICULUM UPDATE

The proposed labware covers basic and advanced computing topics such as programming, networking, hardware software co-design, real-time operating systems, and I/O interface. It can be used as laboratory in a single embedded system course or as selected teaching modules in a sequence of courses in the computing curriculum.

According to the 2004 IEEE/ACM computer engineering model curriculum [10], we are currently revising the curriculum in electrical engineering, computer engineering, and computer science programs by integrating the developed labware to existing courses offered by the authors' departments.

In the revised curriculum, the students will be exposed to mobile embedded system concepts from their freshmen fundamental course by using the developed module 1 and 2 in Introduction to Engineering/CS, Engineering Programming, and Introduction to programming. Then progressing through a sequence of courses, students will build their knowledge and skills to culminate in a senior-level capstone design experience. Module 3 will be integrated to Introduction to Microprocessor. Module 4 and 5 will be integrated to Linear System and Communication Systems. Module 6 will be integrated to Control Systems.

The related concepts and skills among the impacted courses will be emphasized by utilizing previous designs as components in subsequent courses. This vertical integration of concepts and skills of mobile embedded system among courses are expected to significantly increase students' proficiency in mobile embedded system design.

IV. PRELIMINARY EVALUATION

The prototypes of the first five modules have been presented to students for preliminary evaluation. The feedback is very positive and encouraging. Most students enjoy what they learned from the new labware and are excited with the hands-on experience of solving real-world problem with the android-based sensory platform. They feel that experiences with this labware give them confidence and motivation to explore more advanced topics in computing related areas. All of them encouraged us to finish the development earlier.

Significant Predictors of Learning from Student Interactions with Online Learning Objects

L. Dee Miller, Leen-Kiat Soh

University of Nebraska, Lincoln
{lmille, lksoh}@cse.unl.edu

***Abstract*—Learning objects (LOs) are self-contained, reusable units of learning. Previous research has shown that using LOs to supplement traditional lecture increases achievement and promotes success for college students in the disciplines of engineering and computer science. The computer-based nature for LOs allows for sophisticated tracking that can collect metadata about the individual learners. This tends to result in a tremendous amount of metadata collected on LOs. The challenge becomes identifying the predictors of learning. Previous research tends to be focused on a single area of metadata such as the learning strategies or demographic variables. Here we report on a comprehensive regression analysis conducted on variables in four widely different areas including LO interaction data, MSLQ survey responses (that measure learning strategies), demographic information, and LO evaluation survey data. Our analysis found that a subset of the variables in each area were actually significant predictors of learning. We also found that several static variables that appeared to be significant predictors in their own right were simply reflecting the results from student motivation. These results provide valuable insights into which variables are significant predictors. Further, they also help improve LO tracking systems allowing for the design of better online learning technologies.**

Keywords—Learning Objects, Predictors of Learning, Regression Analysis

I. Introduction

The last 20 years has seen the rapid proliferation of online instructional materials to support distance education and to supplement the traditional classroom environment. One such type of instructional material is learning objects (LOs). LOs are most often described are independent and self-standing units of learning content that are predisposed to reuse in multiple instructional contexts [1]. An example of a LO is a self-contained lesson on a computer science topic (e.g., recursion) with a tutorial, interactive exercises, and assessment questions. LOs have been used to supplement traditional lectures in college-level engineering and computer science courses [2][3]. LOs have two features that can increase achievement and promote success in students:

First, the reusable nature of LOs and the availability of searchable LO repositories mean that the quantity of available LOs is growing, not only in terms of their numbers and content, but also in their usage [4]. This results in a multiplicity of LOs on the same topic but with different content, design strategies, etc. This diversity offers a tremendous potential for providing instructional support for college students with differing attitudes, diverse backgrounds, and prior knowledge on the subject matter.

Second, the computer-based nature of LOs facilitates sophisticated data tracking, which can collect and combine information about the learners, their interactions with the LOs, and their learning efficiency into LO metadata. Tracking is typically based on learner attributes and the content and pedagogical characteristics that are expected to be associated with or predicting learning, but the capability exists for literally every interaction with the LO (i.e. mouse click) to be tracked and time stamped.

However, there is a problem with the data tracking feature for LOs. LO designers have no way of knowing a priori what variables derived from the metadata collected are going to be significant predictors of student learning. Since there is no practical way of redeploying the LOs to collect additional metadata from the same set of students, LO designers tend to err on the side of collecting too much metadata [5]. What results is a tremendous amount of metadata on individual usage of LOs as well as data aggregated across courses, learning strategies such as motivation and demographic characteristics such as gender. This resulting "mountain of metadata" makes it extremely difficult for anyone to benefit from the LO results; for example, instructors will have no idea what metadata to look for when selecting appropriate LOs for their students.

The most common solution to the data tracking problem is an a posteriori analysis of the metadata to determine which of the variables collected are actually significant predictors of student learning. After this analysis is done, the subset of significant predictors is made available and interested groups can take appropriate actions. LO content developers, for example, could improve the tracking system for current and similar LOs to focus on the significant predictors. Previous approaches on analysis of significant predictors tend to focus only on the metadata in a similar area. For instance, Chyung et al. [6] focus on MSLQ survey while Kay & Knaack [7] focused on evaluation survey. These approaches tend to assume that the significant predictors are found in a single area when, in fact, the most significant predictors may be dispersed across multiple areas. Further, they do not consider interactions between variables such as a variable dependent on another variable in a different area and, as such, not truly a significant predictor.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

We report on a regression analysis that involves comprehensive metadata from multiple areas including LO interaction data, MSLQ survey results, demographic information, and evaluation survey results. The metadata analyzed was based on 1335 distinct sessions of student interactions with LOs. These sessions involved 16 different LOs and 134 different students from three different undergraduate computer science courses at two different universities. We used a least-squares regression analysis to identify the variables that are significant predictors of learning based on the LO assessment score from that session. We provide an extensive discussion of the variables found in each area that were significant predictors and also discuss possible interactions between variables.

The rest of this paper is organized as follows. Section 2 describes the learning objects and metadata in more detail. Section 3 discusses the regression analysis. Section 4 discusses the analysis results on the LO metadata including significant predictors of learning while Section 5 provides the conclusions and future work.

II. Learning Objects

Here we provide background on the LOs used in our regression analysis. We start by describing the overall design of the LO. We then discuss, in more detail, the metadata collected during the LO deployment.

A. Learning Object Design

The LOs used in the regression analysis are part of the intelligent learning object guide (iLOG) framework [8]. The iLOG LOs follow the Sharable Content Object Reference Model (SCORM) standard for web-based e-learning. These LOs are designed as self-contained lessons on introductory CS concepts (e.g., searching and sorting). Each of these LOs consists of the same three basic components. First, the LO contains a tutorial with the learning objectives and a set of pages explaining the concept using text and figures (analogous to a traditional textbook). Second, it contains a set of interactive exercises that further explain the concept and provide immediate feedback for students (analogous to homework problems). Third, it contains a set of assessment questions designed to measure whether students have learned the CS concept (analogous to a quiz or test). Students are allowed to freely navigate back and forth between the tutorial and exercises, to allow for review, but once they start the assessment they are locked out of the rest of the LO.

The regression analysis below uses the student score on the LO assessment questions as the measure of whether a student has learned the CS concept. Previous work has shown that assessment scores have a strong connection with actual student learning outcomes [9][10].

B. Metadata Collected

The iLOG framework provides automatic, comprehensive metadata collection for the LOs [8]. Each LO contains software that automatically tracks user interactions with the LO. Examples of the user interactions tracked in LO components are given in Fig. 1. The LOs are also bundled together with surveys designed to collect additional data from the students. There are three different types of surveys: student demographic, motivated strategies for learning questionnaire (MSLQ), and LO evaluation. Students fill out these surveys as part of taking the LOs. After deployment, the iLOG framework automatically "crunches the numbers" and provides statistical metadata based on the data collected; for example, the average time spent on each page. The metadata is provided in a flat file, suitable for further analysis, with a single row for each session between a student and LO.

There are four diverse sets of metadata used in the analysis below: (1) student interaction metadata such as average time spent on a page, (2) demographic metadata such as gender and GPA, (3) MSLQ metadata such as student motivation and self-efficacy, and (4) evaluation metadata such as LO ease of use. Now, we "cast our net" and examine this wide range of diverse metadata for two main reasons. First, we expect variables that are significant predictors of learning to be dispersed across multiple areas. In this event, focusing on a single area of metadata may actually provide an incomplete picture on how the LOs impact student learning. Actions taken based on this incomplete picture are likely to result in unexpected or even unwanted results; for example, actions taken to improve LO content could negatively impact undiscovered predictors resulting in reduced student learning. Second, we expect there to be dependencies between the variable in different areas. In this event, dependent variables appear as significant predictors when only a single area is considered. Actions taken based on dependent variables are, again, likely to have unexpected results.

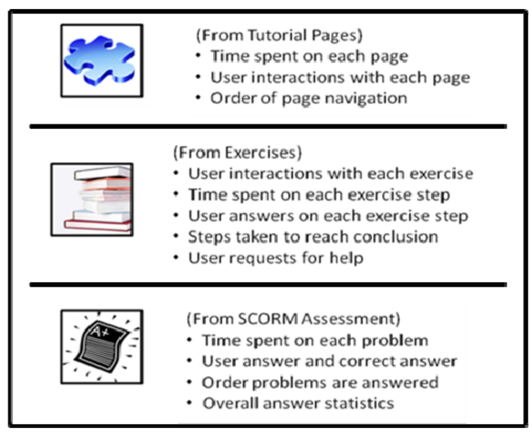

Fig. 1. Examples of user interactions tracked in iLOG LOs.

III. Regression Analysis

Here we provide details on the regression analysis used in our results and discuss previous work using regression to find significant predictors of learning.

A. Methodology

We use a least-squares regression analysis to determine whether a given variable is a significant predictor of learning. This process consists of two separate steps. First, we compute the slope for the least-squares estimate that best "fits" the data:

$$slope = \frac{\sum xy - (\sum x)(\sum y)/n}{\sum x^2 - (\sum x)^2/n} \quad (1)$$

where x contains the session values for the variable in question and y contains the assessment scores on same sessions and n is the number of sessions. The y-intercept is trivial to compute with the slope. Next, we plug the results of the least-squares estimate into an F-test and compute the p-value based on the distribution. If the p-value is less than or equal to 0.05, the variable is deemed a significant predictor of learning.

B. Previous Work

Regression analysis has previously used to find significant predictors of learning for related areas of metadata. First, regression analysis was used in a study by Kruck & Lending [11] to find the significant predictors of learning in an introductory college-level information systems course. This study considered student demographics including gender, major, SAT scores, etc. and student motivation. The authors reported that, based on a regression analysis, GPA and motivation were significance predictors of learning whereas SAT was not. One important detail is that student motivation was measured using homework grades as opposed to the more widely accepted MSLQ used in this study.

Second, regression analysis was used in a study by Chyung et al. [6] to find significant predictors of learning for nine LOs on material science and engineering concepts (e.g., mechanical properties of metals). This study gave students a MSLQ survey to measure motivation, goal orientation, and self-efficacy as well as a pre- and post-test survey to measure student learning of the concepts. Based on regression analysis, student intrinsic goal orientation and e-learning practice were significant predictors of learning but self-efficacy was not. One important detail is that authors were unable to analyze student interactions directly (as we do) since the LOs lacked tracking capability. Instead, the authors relied exclusively on self-reported student knowledge from the pre- and post-test surveys.

Third, regression analysis was used in a study by Kay & Knaack [7], to predict the validity of a wide range of LOs. This study gave students an evaluation survey asking about how much the LOs helped student learning and the quality of the LOs. The authors reported that, based on a regression factor analysis, student responses to the learning questions were significant predictors of learning. One important detail is that the factor analysis was based on a wide range of LOs from different developers. These LOs covered widely different concepts as opposed to the iLOG framework LOs on similar, CS concepts considered in this study.

To summarize, regression analysis has been previously used to find significant predictors of learning for demographic, MSLQ, and evaluation areas. However, to the best of our knowledge, no study exists that *provides a compressive analysis on metadata in all these areas*. Further, analysis to find significant predictors of learning based on actual student interactions with LOs in much more limited.

IV. Results

Here we discuss the results for the comprehensive regression analysis broken down by metadata area.

A. Student Interaction Metadata

Table I shows that nine student interaction variables are significant predictors of learning.

First, assessmentTotalClicks is a significant predictor of learning based on the coefficient and p-value in Table I. In the assessment, students were not allowed to go back to the tutorial but they could go back and change answers to previous assessment questions. We observed that numerous times for each LO, the number of assessmentTotalClicks was greater than the minimum number of clicks required to complete the assessment test. This means that students reviewing and revisiting the test pages had higher assessment scores.

Second, we look at metadata related to student interactions with the LO tutorials. The results for tutorialTotalSeconds and tutorialAverageSecondsOnAPage indicate that a higher assessment score is associated with more time invested by students on each page of the tutorial and the overall tutorial section of the LO. Students need to spend substantial amounts of time to fully understand and comprehend the underlying notion of the LOs provided by these tutorial pages. The more time they spend studying the content on the tutorial pages the better prepared they are for the assessment test, resulting in higher assessment scores. This makes sense given that the assessment questions are designed to evaluate student understanding on the tutorial content. The results for tutorialMinClicksOnAPage show that students who interacted more each page of the LO tutorial received higher assessment scores. The more minimum number of clicks students had on tutorial pages, the higher their test scores. This makes sense because each tutorial page contains a significant amount of information requiring students to click the scroll button a few times to look at all the information provided on the page.

Third, we look at metadata related to student interactions with the interactive LO exercises. The positive results for two variables, namely exerciseAverageSecondsOnAPage and exerciseMinSecondsOnAPage show that students who had visited and spent some time on the exercises did well in the assessment test. Additionally, the results for exerciseAverageEntries, show that students who tried the exercise pages received higher test scores. On the surface, these results make sense given that each exercise is fairly complicated requiring time for students to go through completely. The benefit of the exercises is that they provide active feedback on the LOs which has been shown to improve student learning [10]. However, the other results cast doubt on the effectiveness of the LO exercises. We found that exerciseTotalInterval is a negatively associated significant predictor of learning. The exerciseTotalInterval is the time students spent reading the provided feedback after answering the questions contained in the exercise about the LO topic on an exercise page and clicking the submit button. Further, the exerciseTotalEntries, which is the total number of entries students made in the exercise pages, is also a negative predictor of student learning. Taken together, these two negative predictors seem to indicate that students who struggle with the exercises, as measured by the time spent reading the feedback and making additional entries, also struggle to do well on the assessment questions. In a sense, the exercise questions failed to prepare these students properly for the assessments questions. These results could also result in student frustration from struggling with difficult LOs—we will return to this in Evaluation section. Based on these results, one action to improve the LOs would be to revise the exercises to provide more effective feedback.

TABLE I. SIGNIFICANT PREDICTORS OF LEARNING IN STUDENT INTERACTION METADATA WITH REGRESSION COEFFICIENTS AND P-VALUES.

Student Interaction Var.	Coefficient	p-value
assessmentTotalClicks	**0.1255**	**0.0031**
tutorialTotalSeconds	**0.0028**	**0.0009**
tutorialAverageSecondsOnAPage	**0.0434**	**0.0001**
tutorialMinSecondsOnAPage	**0.2654**	**0.0002**
tutorialMinClicksOnAPage	**7.5953**	**0.0000**
exerciseAverageSecondsOnAPage	**0.0130**	**0.0081**
exerciseMinSecondsOnAPage	**0.0172**	**0.0010**
exerciseAverageEntries	**0.1410**	**0.0336**
exerciseTotalEntries	-0.615	0.446
exerciseTotalInterval	**-0.0001**	**0.0001**

B. *MSLQ Metadata*

Table II shows that eight MSLQ variables are significant predictors of learning.

First, we observe that Extrinsic Goal Orientation (EGO) is a negatively associated significant predictor of learning based on the negative coefficient and p-value in Table 2. Note that EGO refers to student motivation to do well in class for better grades, rewards, evaluation by others, and competition. To further investigate the negative association, we divide the data by courses. We observe that EGO is positively associated predictor with all but one course. On this course, the students were able to take the learning object again and again, with only their last assessment score being used for course grade calculation. As a result, it is possible that those students randomly answered all the questions the first time they took the test, only performing well the second time after they knew the test content. To confirm our suspicious, we found that the time spent was *significantly lower* the last time students took the assessment test compared to the first time they took the test while assessment scores are *significantly higher*.

We think that, after their introduction to the assessment test, these students realized that they could score better when they repeated the test if they learned the test content the first time. That these students were "gaming the system" to achieve higher assessment scores also helps explain the lack of significant results for Intrinsic Goal Orientation (IGO) which has previously been reported to be a significant predictor of learning [6]. Again, if we leave out students in that course, the IGO becomes a significant predictor of learning. Based on these results, one action to improve student learning with the LOs is not allowing students to retake the LO assessment multiple times. Alternatively, if instructors still want this capability, the LOs should be equipped with a larger battery of questions that are randomly presented to students making "gaming the system" less practical for students.

TABLE II. SIGNIFICANT PREDICTORS OF LEARNING IN MSLQ METADATA WITH REGRESSION COEFFICIENTS AND P-VALUES.

MSLQ Variables	Coefficient	p-value
Intrinsic Goal Orientation	0.2717	0.0912
Extrinsic Goal Orientation	**-1.0693**	**0.0000**
Control of Learning Beliefs	**1.2354**	**0.0000**
Self-Efficacy for Learning	**0.9340**	**0.0000**
Task Value	**0.8795**	**0.0000**
Elaboration	0.1245	0.5164
Organization	0.0965	0.4748
Self-Regulation - planning	**1.3040**	**0.0000**
Self-Regulation - monitoring	**0.6859**	**0.0000**
Self-Regulation - checking and correcting	**1.4880**	**0.0000**
Effort Regulation	0.1180	0.6004
Help seeking	-0.0754	0.5382
Problem-Solving	**0.6230**	**0.0006**

Second, we found that Self-Regulation - checking and correcting is a positively associated significant predictor of learning. Self-Regulation - checking and correcting refers to student checking and correcting behavior as they progress through a task. Those students who rated high in this category are more likely to change the way they study to fit course needs and the teaching styles of professors. They are also more likely to attend to feedback and make changes to improve their understanding of the course material.

Lastly, the results for the remaining four variables are expected and consistent with previous work that MSLQ variable are, in general good predictors of learning [12]. Control of Learning Beliefs means that the students control their own learning and their learning outcomes are proportional to their hard work [13]. They believe that results are not affected by the other factors such as teacher or luck. Students who put a high rate in this category strongly believe that the good assessment score they received is because of the hard work they put in. These students are likely to study the material more diligently leading to higher assessment scores. Self-Efficacy for learning is how the students judge themselves on their capability of learning the material [14]. Students who put a high rate in this category are more confident that they can learn the material. These students are likely to work harder at learning the material leading to higher assessment scores [15]. Task Value refers to the student determination about the value of the assessment [16]. The students work on the assessment if they think that the assessment is important to their score in the course. The higher the students rate on Task Value, the more attention they will pay to the assessment and thus they receive better assessment scores. Problem-Solving is a mental process that involves determining, examining, and solving problems [17]. With a high rating in Problem-Solving, it is to say that the students are able to understand the question and are capable of solving the question in the assessment.

C. Demographic Metadata

Table III shows the results for the eight demographic metadata variables. Four of these variables have categorical rather than numeric values so we use the F-test, rather than regression, to determine the p-values. Overall, seven demographic variables were found to be significant predictors of learning.

First, student's ACT score, the student's grade point average, and the student's highest math course taken (i.e., math background) are all positively associated significant predictors of learning based on the regression coefficients and p-values in Table III. These results are expected and consistent with previous work which found that ACT and GPA [18][19][20] and math background [21] are all significant predictors of student learning.

Second, student gender is not a significant predictor of learning. These results are *consistent* with previous research which has shown that gender is not a significant predictor of learning [22][23][24]. To further convince readers, since the influence of gender is still contested [25], we summarize previous work on the iLOG LOs. In the past, female students had more difficulty with these LO assessment questions than did male students [26]. This difficulty led to a systematic revision of the LOs using assessment validation tools from educational research [27]. After this revision, gender was no longer a significant predictor of learning [3].

Third, student's grade level, major, and required course all appear to be significant predictors of learning. These results are undesirable since the LOs are intended to allow students with a wide variety of backgrounds to all learn the CS topics [27].

- To explain grade level, we compared the average assessment scores for each grade level of students against all the other grade levels (e.g., freshmen vs. non-freshmen). We found that the freshmen students achieved significantly higher average assessment scores than all the other years (82.02% vs. 69.34%) based on a Welch's t-test ($p <= 0.05$) contributing to the significance of grade level as a predictor of learning. Looking further, we realized the majority of freshmen were in the CS honors course and, as such, were highly motivated to get good grades (i.e., high EGO motivation). When these honors students were removed, the significant difference between freshmen and non-freshmen students disappeared (71.35% vs. 69.34%). These results seem to indicate a dependency between grade level and EGO motivation in some students.
- To explain major and required course, we looked at the assessment scores broken down by CS students required to take the course and students taking the course as an elective. Surprisingly, non-majors taking the course as an elective achieved significantly higher average assessment scores than majors (84.58% vs. 76.57) based on a Welch's t-test. These results can be explained in terms of IGO motivation. Non-majors taking it as an elective have significantly higher average IGO than non-majors required to take the course (4.81 vs. 4.54 on the 7-point Likert scale). Further, majors with high IGO motivation (>4) achieved significantly higher average assessment scores than majors with low motivation (81.02% vs. 61.85%). These results seem to indicate a dependency between these variables and IGO motivation.

Overall, based on these results, the differences in assessment scores for the students have more to do with motivation than the grade level, major, or required course. In a sense, these dependent variables are simply reflecting the differences between students with high and low motivation. Thus, these variables should not be considered significant predictors of learning. As a result, actions taken to engage lower motivation students are likely to be more effective at improving the LOs than customizing LOs for specific grade levels or majors.

TABLE III. SIGNIFICANT PREDICTORS OF LEARNING IN DEMOGRAPHIC METADATA WITH REGRESSION COEFFICIENTS AND P-VALUES. THE (*) INDICATES CATEGORICAL VARIABLES WHERE F-TESTS WERE USED.

Demo. Variables	Coefficient	p-value
Gender*	N/A	0.0669
Grade Level*	N/A	**0.0000**
College Major*	N/A	**0.0006**
Required Course*	N/A	**0.0000**
ACT	**2.6645**	**0.0000**
GPA	**11.0135**	**0.0000**
Highest Math Course	**4.7810**	**0.0000**
Programming Courses	**-4.2619**	**0.0000**

D. Evaluation Metadata

Table IV summarizes gives the results for the ten evaluation metadata variables. Six evaluation survey variables are significant predictors of learning. The negative regression coefficients for Q8 and Q9 can be explained by the negative wording. On these two questions, students who agreed with these questions (higher survey values) struggled with learning the content more than other students providing the negative coefficients. In general, these results are consistent with previous work which found these questions to be significant predictors of student learning [28]. Based on these results, actions to improve the LOs should focus on improving LO user friendliness. One prime section for such improvements is in the exercises that, as discussed in Section IV.A, are troublesome for the students.

We looked further at the remaining four survey variables. We repeated the regression analysis broken down by course and found that the results were still not significant. To dig deeper, we broke these variables into two natural groups. Group 1 contains Q2 and Q7 that have similar wording and compare the LOs and the professor using traditional lecture. Group 2 contains Q4 and Q6 which ask students about future preferences. For Group 1, we found a significant negative correlation (dependency) between these variables and the MSLQ Self-Regulation – checking and correcting (-0.09 for Q2 and -0.08 for Q7 with DF = 400). Students with high checking and correcting seemed to prefer lectures where they could ask for immediate feedback. For Group 2, we found that non-majors were less likely to use the LOs in the future than majors (3.23 vs. 3.38, p-value 0.12). Based on these results, we have increased confidence that these questions are, indeed, not significant predictors of learning. Therefore, no actions need to be taken to address these questions.

TABLE IV. SIGNIFICANT PREDICTORS OF LEARNING IN EVALUATION METADATA WITH REGRESSION COEFFICIENTS AND P-VALUES.

Evaluation Survey Variables	Coeff.	p-value
Q1- LO was easy to use	**6.2157**	**0.0000**
Q2-LO maintained interest more than professor	1.7167	0.0606
Q3- LO was valuable addition to course	**2.7967**	**0.0014**
Q4-More course material via the web	-0.3622	0.6546
Q5- LO helped me understand this topic	**3.7838**	**0.0000**
Q6-I will use the same LO again in the future	1.1039	0.1580
Q7-Learned more from LO than professor	0.1279	0.8908
Q8-LO material was difficult to understand	**-6.5382**	**0.0000**
Q9-LO needed to go into greater detail	**-4.9595**	**0.0000**
Q10-Overall how would you rate this LO	**4.1535**	**0.0000**

V. CONCLUSIONS AND FUTURE WORK

Learning objects (LOs) are reusable instruction material that support distance education and supplement the traditional classroom environment. The computer-based nature of LOs allows for sophisticated data tracking such as recording user interactions with the LOs. However, such data tracking results in a "mountain of metadata" only some of which are actually significant predictors of learning. This makes it difficult for anyone to utilize the LO results. Previous studies have focused on a posteriori analysis to identify the metadata variables that are actually significant predictors of learning. Unfortunately, these studies tend to focus on metadata in a specific area (e.g., MSLQ or demographic) and, thus, fail to identity variables dispersed across multiple areas. Further, these studies do not take into account variables that are dependent on those in different areas and, as such, not truly significant predictors.

In this work, we found a number of significant predictors of learning based on student interactions with the LOs. Students who spent more time on the LOs and reviewed their answers on the assessment questions received significantly higher scores. Further, students with higher motivation, self-efficacy, and self-regulation also tended to receive higher scores—consistent with previous work. Lastly, student gender was not among the demographic variables found to be significant predictors of learning.

This work has two further general contributions. First, we provide a regression analysis that involves metadata from multiple areas: interactions, MSLQ, demographic, and evaluation. This regression analysis shows that, indeed, significant predictors of learning are dispersed across multiple areas. Second, we further investigate the dependencies between variables that appear (initially) to be significant predictors of learning. This investigation shows that several of variables in the demographic and evaluation areas are, in fact, dependent on variables in other areas such as student motivation.

The above contributions establish the need for more comprehensive analysis on metadata collected for LOs. We see three main avenues for continuing this work in the future.

- First, we intend to make use of the findings (predictors) to improve the LOs. Based on the findings, engaging the students with the LOs may be more effective than customizing the LO content for, say, a given major. One possible way to *further engage* students is to tap into creative thinking. The LO content could be redesigned to engage multiple senses and require imaginative thought as opposed to the current LO content that may be too dry and pedantic—like reading a text book.
- Second, we intend to continue our investigation on the previously collected metadata. This metadata shows clear signs of dependencies between variables in different areas. However, we have likely not found all the interdependencies between these variables. In particular, we still question whether several of the variables in the evaluation and demographic areas are truly significant predictors or simply reflecting other variables.
- Third, we are extremely interested as to whether the significant predictors for these LOs, which are taken individually by the students, are still applicable for students in collaborative learning environments. In particular, we intend to investigate whether motivation and other MSLQ variables remain significant predictors for teams of students working together to write online wikis or essays.

ACKNOWLEDGMENT

This material is based upon work supported by the National Science Foundation under grant no. 1122956 and IIS-0632642. The authors would also like to thank Sing Hwa Lee for his help on the initial regression analysis.

New National Science Foundation Opportunities for Improving Undergraduate Engineering Education

Chan Hilton, A.[1] and Finger, S.[2]
Division of Undergraduate Education
National Science Foundation (NSF)
Arlington, VA, USA
[1]achanhil@nsf.gov; [2]sfinger@nsf.gov

***Abstract*—The goal of this mini-workshop is to increase the participants' knowledge of current opportunities at the National Science Foundation (NSF) to support excellence in undergraduate science, technology, engineering, and mathematics (STEM) education. In particular, the discussion focuses on new and current opportunities in the Division of Undergraduate Education as well as highlight examples of project activities that support these opportunities. The mini-workshop uses a highly interactive format, using team-based games and discussion, to engage the participants and to foster the sharing of ideas, to clarify misconceptions, and to potentially initiate new ideas in engineering education innovations and research. This mini-workshop closely encourages the sharing of ideas and interaction amongst peers, and also informs participants about current NSF funding opportunities in STEM education.**

Keywords—funding opportunities; engineering education; National Science Foundation; student learning; curriculum development; faculty development; institutionalization

I. Goals

The goal of this mini-workshop is to increase the participants' knowledge of current opportunities at the National Science Foundation (NSF) to support excellence in undergraduate science, technology, engineering, and mathematics (STEM) education. In particular, the discussion focuses on new and current opportunities in the Division of Undergraduate Education (DUE) as well as highlight examples of project activities that support these opportunities. The mini-workshop uses a highly interactive format, using team-based games and discussion, to engage the participants and to foster the sharing of ideas, to clarify misconceptions, and to potentially initiate new ideas in engineering education innovations and research. The goal of this mini-workshop closely aligns with the goals of FIE because it encourages the sharing of ideas, interaction amongst peers, and inform participants about current NSF funding opportunities in STEM education.

II. Mini-Workshop Topics

In this interactive mini-workshop, participants explore new emphases and opportunities for funding high-impact projects in STEM education. Participants actively engage in learning about new and current opportunities, discussing project activities and elements, initiating the design of potential projects and interventions, and identifying fit with available funding programs.

Recently, several NSF funding programs have used and developed creative new mechanisms to greatly advance knowledge building in engineering education, impact educational practice on a broad scale, and significantly increase the number and quality of graduating engineers. For example, the program Widening Implementation and Demonstration of Evidence-Based Reforms (WIDER) was announced in April 2013. The goal of the WIDER program is to scale up the application of highly effective methods of STEM teaching and learning within and across the higher education sector to achieve improved student learning, increased numbers of students choosing STEM major, and improved retention to graduation of all STEM majors.

A new program Catalyzing Advances in Undergraduate STEM Education (CAUSE) has been proposed and is anticipated to include the goals of past DUE programs (Transforming Undergraduate Education in STEM (TUES), WIDER, and STEM Talent Expansion Program (STEP)), among other goals. Additional undergraduate STEM education programs are highlighted to allow participants to identify potential programs that might match their ideas and goals. Moreover, participants will become familiar with NSF and its goals to put these opportunities into context. Participants also will become aware of the recent revisions in the NSF Proposal & Award Policies & Procedures Guide (PAPPG), which affect proposal preparation, merit review, and reporting.

III. Qualifications of Presenters

All the presenters in this mini-workshop are program directors in the Division of Undergraduate Education at the National Science Foundation. Each presenter has extensive experience in leading and engaging in engineering education and research projects as well as engaging with students in and out of the classroom. The presenters work very closely in developing the STEM education funding programs at NSF. In particular, they are directly involved in writing the program solicitations, reviewing proposals, making funding decisions, communicating expectations to principal investigators, and interacting with potential principal investigators.

IV. WORKSHOP AGENDA

The mini-workshop includes the following topics:

- Introduction and overview of mini-workshop and format
- NSF organization structure and its goals
- Interactive activity on NSF opportunities to improve undergraduate STEM education, using a team-based game and follow-up discussion to highlight key elements of each program
- Summary of STEM undergraduate education opportunities at NSF and follow-up questions and discussion, lead by presenters
- Interactive discussion on project activities
    - This focuses on the types of activities within a potential project and key elements of a successful project.
    - Participants have opportunities to think about and discuss their project ideas
- Revised NSF Proposal & Award Policies & Procedures Guide (PAPPG)
    - Highlights on changes in proposal preparation and reporting
    - Clarification in the merit review criteria
    - Questions and discussion

V. INTENDED AUDIENCE

The anticipated audience of this mini-workshop includes STEM educators who are interested in developing high-impact projects in STEM undergraduate education. This includes instructors, faculty members, and administrators at U.S. college and universities in the engineering, computing, and engineering education disciplines. The content of this mini-workshop would be of interest to the broad FIE audience.

VI. KNOWLEDGE ATTENDEES WILL ACQUIRE

At the end of the mini-workshop, participants will have extended their knowledge about opportunities at NSF for undergraduate STEM education. In particular, the participants should be able to:

- Describe the goals, objectives, and scopes of the programs discussed;
- Identify the program(s) that fit their needs and interests;
- Discuss high-impact project activities that support the goals of the opportunities; and
- Summarize revisions to the proposal preparation guidelines, review process, and project reporting requirements.

Through the highly interactive and engaging activities, participants will have opportunities to increase their knowledge about NSF programs in STEM education, initiate new ideas in engineering education innovations and research, clarify questions and misconceptions related to the opportunities discussed, and share ideas.

Model Collaboration for Advancing Student-Centered Engineering Education

Deyna C. Aragon, Peter Golding, Roger V. Gonzalez, Gilbert Moreno Jr., Daniela Natera, Richard F. O'Brien, Richard T. Schoephoerster, Scott A. Starks, Elsa Q. Villa, William S. Walker, Isaiah N. Webb
College of Engineering, University of Texas at El Paso
El Paso, Texas 79902 USA

Vincent P. Manno, Richard K. Miller, Robert Martello, Mark Somerville, Lynn A. Stein, Jonathan D. Stolk, Jessica Townsend
Franklin W. Olin College of Engineering
Needham, MA 02492 USA

***Abstract*— The University of Texas at El Paso (UTEP) and the Franklin W. Olin College of Engineering (Olin) are establishing a student-centered hands-on interactive approach to engineering education (similar to Olin's) at UTEP, where it will reside in UTEP's innovative B.S. in Leadership Engineering (LE) program. The goal of the proposed collaboration is to catalyze UTEP's educational innovation through a cross-campus collaboration between the two institutions by incorporating the Olin educational process, both design and features, into the first offerings of the Bachelor of Science in Leadership Engineering (BSLE) program. Specifically, the collaboration includes faculty exchanges between the two institutions; a series of retreats for planning and assessment; curriculum development; and student recruitment practices. The 21st century workplace demands a new engineer — one who effectively contributes to solving problems using innovation, creativity, and strategic foresight. Graduates of the Olin-UTEP developed Bachelor of Science in Leadership Engineering (LE) program will possess these attributes through the program's rigorous yet flexible major in engineering, and in-depth study of leadership and its effect upon technology and society. In this panel we will share the context for our innovative approach, key features of the partnership to date, and acclaim the value of inter-institutional sharing.**

Keywords—student-centered, collaboration, partner, Olin, UTEP, frameworks, engineering education, Leadership Engineering

I. Introduction

A. Motivation for the Project

The need for educating more and diverse engineers is well documented, and the reform of engineering education has been slow and occurring in a piecemeal fashion. Moreover, the National Academy of Engineering issued a report calling for engineers of the 21st century who are broadly educated and see themselves as global citizens [1]. The emphasis in this NAE report was not on whether engineering education should continue to change, but on how, to what degree, and how soon this change should happen. Thus, successful implementation of this proposed BSLE program has significant implications for national reform of engineering education, as it will address NAE concerns. UTEP is a public, urban four-year university serving a majority underserved population of Hispanic students, and Olin College is a small, private and highly selective university. These two institutions are diametrically diverse, and successful adaptation of some of Olin's innovative approaches to curriculum design and implementation at UTEP could pave the way for a broader set of institutions across the U.S. to consider adapting a similar approach.

B. Together Supporting Student-Centered Innovations

The UTEP Leadership Engineering (LE) Program is developing with support from Bob and Diane Malone, and the Halliburton Foundation, under the umbrella of the Center for Research in Engineering and Technology Education (CREaTE) in the College of Engineering at UTEP [2] and the Franklin W. Olin College of Engineering [3].

The Franklin W. Olin College solicits applications from engineering educators and their institutions to participate in the Argosy Collaborative Faculty Exchange program, developed with support from the Argosy Foundation [4]. Olin's Argosy program is designed to catalyze educational innovation through cross-campus collaboration. The exchange creates partnerships — such as the Olin-UTEP partnership — with departments or programs — such as UTEP's College of Engineering — committed to educational change.

Olin evaluates proposals based on the potential impact of change that the projects will have in their home institutions, the level of commitment that the participating institutions make towards actually implementing change, and the participants' professional background, interest and personal commitment to change in engineering education; and the fit with existing Olin activities and resources. Olin and UTEP are embarking on an exciting partnership, and it is an open forum discussion of the partnership in process that is the subject of this Frontiers in Engineering (FIE) 2013 conference panel.

II. Olin-UTEP Partnership

A. Olin-UTEP Partnership Creating Leadership Engineering

UTEP is partnering with the Franklin W. Olin College in the Argosy Collaborative Faculty Exchange program [4]. It is

Sponsored by the Argosy Foundation, Bob & Diane Malone, and the Halliburton Foundation.

this program that has led to the Olin-UTEP model for student-centered engineering education.

The partnership includes collaboration between Olin and UTEP over at least a two-year period, with opportunity to extend the partnership as needed or desired. Our joint approach (as partners) and the work completed to date will be shared at the FIE workshop. The types of engagement include Olin-run workshops for UTEP faculty, visits to the Olin and UTEP campuses ranging from short trips to semester and year long faculty exchanges, and joint assessments of both the partnership and of the outcomes of the BSLE degree.

The goals of the Olin-UTEP partnership are very well aligned with the Argosy Faculty Exchange program, and the engagements described above are the types of activities outlined in the Argosy Program guidelines [3].

The Olin program, funded by the Argosy Foundation, is designed to catalyze educational innovation through cross-campus collaboration. The exchange creates partnerships — such as the Olin-UTEP partnership — with departments or programs committed to educational change, embedding faculty from partner schools for year-long residencies at Olin College, and providing participants with time, space and support for planning transformative activities at their home campuses. Partnerships are typically expected to include two consecutive years of residencies at Olin, with varying faculty participants. The multi-year program includes a comprehensive assessment of the exchange's impact on the partner schools as well as Olin.

Participating institutions, such as UTEP, are invited to nominate pairs of senior and junior faculty who will work on the proposed projects. The pairing of senior and junior faculty is designed to provide a coalition for change in engineering education at the partner institution. Senior faculty members have deep understanding of their institution's culture, students and facilities. Junior faculty will drive the innovation as they advance their careers and serve as future leaders of change.

During the residency period, partner faculty work with Olin faculty and engage in collaborative curricular creation and innovation. Teaching opportunities – such as co-teaching in some of Olin's distinctive courses – are strongly encouraged and may also include piloting of courses developed during the residency for the home institution. Olin faculty and students will benefit from the fresh perspectives that visiting faculty will offer. As a part of the program, Olin faculty also spend time on the UTEP partner campus, to help focus, guide, and positively influence faculty and staff teams at UTEP in implementing the planned Leadership Engineering curricular innovations.

B. *Maintaining the Integrity of the Olin Approach at UTEP*

The characteristics of Olin's approach to curriculum design most relevant to the UTEP LE Program are:

- Frameworks and approaches for student-centered curriculum design
- Development of intrinsic motivation, self-direction, and autonomy through authentic project and leadership experiences.
- Culturally and socially responsive curricula, where students creatively investigate and solve social problems through innovative technological design.

The first class of BSLE students begins in the fall of 2014, and the goal is to incorporate this model for curriculum development and innovation into the first offerings as part of this new program.

III. Leadership Engineering Education

Integration of engineering and liberal arts education is central to developing the engineer of the conceptual age. The art and science of engineering is key to providing engineers with the technical and system thinking capacity needed to achieve leadership in our complex modern society. The US is at a tipping point regarding global competitiveness in technological innovation, and to a very large extent, humanity is critically dependent on the duopoly of technological innovation and liberal thinking for improvement of quality of lifestyle.

Leadership Engineering (LE) is defined as an emerging engineering sub-field that integrates disciplinary knowledge and practice with communication, business, and leadership skills. This innovative approach to engineering has emerged as a direct result of industry's immediate and long-term need for a new kind of engineer: one with a new skill set to work in complex 21st century contexts. LE is about creating engineers, who have the technical competence and leadership acumen to play vital roles in the future wellbeing and success of the US and all it stands for, and the citizens of the US, and thereby the future of the world.

The Olin-UTEP development of the LE program seeks to visualize and actuate a new paradigm for engineering education by responding to the call from students, alumni, businesses, and civic organizations. To address these needs, the new program features problem-based, student-focused learning across disciplines and situated learning through professional practice experiences.

A. *Details of Planning*

Details of planning for the new undergraduate program in Leadership Engineering at UTEP will be shared at the FIE panel. We will overview inputs from key stakeholders. Included is the contextual development of the program, the parameters considered as key, and the finalized degree plan. The program features are explained including engineering accreditation, and tracks and stems that provide flexibility for students. Balancing the competing demands within the curriculum, proved challenging but attainable given the strong administrative support and leadership for this program, and UTEP's desire to provide innovative undergraduate engineering education that leads toward increased retention and advancing opportunities for serving underrepresented populations.

Sponsored by the Argosy Foundation, Bob & Diane Malone, and the Halliburton Foundation.

B. Olin-UTEP Sharing of Lessons Learned

At the FIE panel faculty from Olin and UTEP will share lessons learned in development of this program, which revolve around curriculum determinations, development, and accreditation. A delicate balance is achieved with balancing the number of credit hours in the program, the general education core mandated as a public institution, and providing the needed LE coursework, internships, professional practice experiences, and flexible tracks in business, education, and technical specialization. Of paramount importance is that all LE courses provide student-oriented, practice-/problem-/project- based learning with intrinsic motivation, self-direction, and autonomy achieved through authentic project and leadership experiences. The result is a challenging, engaging, and exciting new program that promises to push the boundaries what it is to undertake engineering education at UTEP.

C. Final Comments – Our Panel Process

The sharing of the Olin-UTEP partnership FIE 2013 is appropriate since the forum provides an opportunity for discussion at a major international conference about educational innovations and research in engineering and computing. The Olin-UTEP panel being presented at FIE 2013 continues a long tradition of disseminating results in innovative areas of engineering education. It is an ideal forum for sharing ideas; learning about new partnerships, and developments in engineering and technology education, and interacting with colleagues in these fields.

Given the unique individual Olin and UTEP history and culture, panel discussion and focus areas will include:

- Innovation in approach and implementation of engineering education, across regions, and institutions.
- Diversity initiatives, and matters of regional development through community engagement.
- Interdisciplinary programs, at the interface between engineering, technology and society.

The panel make-up includes input from Oliin and UTEP faculty, including clinical professors (or professors of practice), and stakeholders. It is noteworthy that the Olin-UTEP LE program creation includes inputs from students, who as key stakeholders are participating as integral partners in the programmatic development. This initiative follows that process used at Olin in establishment of the first cohort curriculum.

The panel seeks to serve participants at FIE 2013 who are themselves involved in innovations in engineering education, and to provide mentoring and support for their efforts.

Assessment of a Sustainability Program in Graduate Civil and Environmental Engineering Education

Judith A. Perlinger, Kurt G. Paterson, Alex S. Mayer, Veronica W. Griffis, Kirsten L. Holles
Civil & Environmental Engineering Department
Michigan Technological University, Houghton, USA

***Abstract*—The engineering professions are becoming increasingly international and oriented towards a sustainability mindset. To enable graduate students in the Civil and Environmental Engineering (CEE) Department at Michigan Technological University to prepare to meet these demands, the National Science Foundation awarded the University a "Scholarships in Science, Technology, Engineering, and Mathematics (S-STEM)" grant that enabled 45 students in six CEE degree programs to receive $5,000-$10,000 scholarships in 2008-12. The Michigan Tech S-STEM Program was designed to advance a global outlook of economic and social prosperity that protects the environment through various means. A complementary goal was to advance intercultural competency. The S-STEM scholars' knowledge of and attitudes toward sustainability and intercultural competency was assessed during the grant period. Pre-/post-intercultural competence assessment results were similar, however, through coursework, one sub-group of scholars displayed increased intercultural competence in pre/post assessment. Emergent content analysis of scholar written materials suggests that maturation in scholar perspectives, balancing engineering with community, economic, and environmental realities, occurred during the scholarship periods.**

Keywords—STEM education; engineering; sustainability; intercultural competency

I. Introduction

The engineering professions are becoming increasingly international and oriented towards a sustainability mindset. While sustainability conceptualizations in other fields incorporate the necessary "human" element as the governing factor in subjective design decisions, sustainability in engineering is rarely perceived in this light. Furthermore, the social and cultural dimensions of sustainability are not present in the majority of sustainable engineering courses in higher education institutions [1]. To enable graduate students in six degree programs in the Civil and Environmental Engineering (CEE) Department at Michigan Technological University to prepare to meet these demands, the National Science Foundation awarded the University a "Scholarships in Science, Technology, Engineering, and Mathematics (S-STEM)" grant.

The Michigan Tech S-STEM Program was designed to advance a global outlook of economic and social prosperity that protects the environment. A complementary goal was to advance intercultural competency. A key means to advance this outlook was the creation of a novel mentoring scheme that engaged scholars, faculty in CEE and eight additional units of Michigan Tech, as well as off-campus experts from academic, government, non-government, and tribal organizations (inter)nationally.

The grant enabled 45 students in six degree programs (MS Civil Engineering, MS Environmental Engineering, MS Environmental Engineering Science, Peace Corps Master's International MS, PhD Civil Engineering, PhD Environmental Engineering) to receive $5,000-$10,000 in annual scholarships during the 2008-12 grant. Scholars gained experience in conduct of research in a two-semester reciprocal mentoring project on a sustainability topic in groups composed of at least one MS and one PhD scholar, and one faculty member. Scholar education activities included required enrollment in a course on life cycle assessment, in which the scholars conducted a life cycle assessment project. Scholars were also required to enroll and participate in the Environmental Engineering graduate seminar. Their participation involved facilitating colloquia discussions on the topic of their reciprocal mentoring projects (described below) with faculty and graduate students in the CEE Department (and others who attended the colloquia), and in-so-doing informing and engaging the skills of those who attended who were not directly involved in reciprocal mentoring projects. The colloquia provided means to extend reciprocal mentoring to those attending.

Scholar research activities included reciprocal mentoring projects. Scholars participated in reciprocal mentoring projects for the duration of their scholarship. The reciprocal mentoring model was created through the S-STEM Project as a way to improve the traditional model in which there is one-way flow of knowledge and information from a faculty member to a student. According to the model, research development is based upon two-way knowledge transfer among all participant pairs: groups of faculty participate with scholar researchers to share a broader perspective of science, engineering and sustainability expertise. Doctoral scholars integrate sustainability knowledge at new research interfaces, then share with the faculty, and transfer research methods to masters scholars; masters scholars share the subtleties of implementing research with doctoral scholars and applications in practice with faculty. Using this novel reciprocal mentoring model, the program facilitated increased mentoring relationships among students as well as faculty within and outside CEE and off-campus.

Programmatic activities included regular program meetings in which scholars provided updates on reciprocal mentoring projects, discussed papers and documentaries covering a range of sustainability science and engineering topics, and encounters with professionals in sustainability science and engineering from outside the University. These encounters included listening to formal presentations, discussion in informal groups or individually on topics related to sustainability science and engineering, and career path mentoring. In addition, doctoral scholars had the opportunity to apply for funding to travel to conferences or to work with MS scholars in developing countries on sustainability projects. While knowledge, skills, attitudes, and identity may evolve through participation in any sustained learning environment, two attributes were of main interest to this program: cultural and sustainability competencies. Two research questions posed were: Did individual CEE graduate student scholars or certain groups of scholars demonstrate advancement in intercultural competence during the program? Did these scholars/groups demonstrate progress in understanding of environmental, economic, and social aspects of sustainability? Methodologies used to assess cultural and sustainability competency and key findings are discussed, followed by presentation of the results of the research.

II. Methods

A. Assessment of Intercultural Competence

Cultural competency is a relative measure of one's ability to interact with people from different cultures [2, 3]. The value of cultural competency in engineering is grounded in enhancing the effectiveness in working on teams with engineers, scientists, etc. from diverse races and cultural backgrounds. Its value is also evident in understanding the needs of worldwide clients who will use the engineered product or project, define problems differently, and work across cultural boundaries. Many learning through service experiences, especially those related to international efforts (such as Michigan Tech's Peace Corps Master's International (PCMI) Program), require students to work in a culture entirely different from their own. The impact of such efforts on how students work in a different cultural norm is of value to understand their learning. There were two critical motivations for attempting to assess intercultural competency in our S-STEM scholars:

1. our program design required reciprocal mentoring research teams; each were inherently multi-cultural regardless of their makeup; and
2. our program focused on sustainability; past evidence [4] suggests that engineers tend to give least attention to the social domain of sustainability in their project work as compared to environmental or economic concerns.

The Intercultural Development Inventory (IDI) is a cross-culturally valid and reliable method to assess intercultural competence development [5]. The IDI is suggestive of a student's proficiency at working with others who view the world differently. The IDI is available as an online 50-question tool but requires a qualified administrator for use. While the IDI provides quantitative data, its results are difficult to interpret without further awareness of the test subject (e.g., from observation, examination of project documentation, and assessment of peer-mentoring feedback). Due to its cost ($11/test) and time for completion (30-60 minutes), the IDI was administered in a pre/post S-STEM program involvement. The IDI yields quantitative results, placing the student along a spectrum of intercultural sensitivity from ethnocentrism to ethnorelativism in stages of denial, defense, reversal, minimization, acceptance, and adaptation [6]. The IDI produces two scores, a perceived orientation (PO, i.e., where the student thinks they are on the spectrum) and a developmental orientation (DO, i.e., where the student actually lies on the spectrum). Our evaluation plan focused primarily on the DO, although the gap between PO and DO was also examined as a measure of progress.

B. Assessment of Advancement in Understanding of Sustainability

Although sustainability initiatives have infiltrated engineering curricula and research over the past decade, many engineering faculty are not certain of the meaning of sustainability in the context of engineering, or how educational experiences should be designed (let alone assessed) to address the issues [7]. While sustainability conceptualizations in other fields incorporate the necessary "human" element as the governing factor in subjective design decisions, sustainability in engineering is rarely perceived in this light. Furthermore, the cultural and social dimensions of sustainability are not present in the majority of sustainable engineering courses in higher education institutions [1]. The S-STEM Program introduced a project-based learning experience and multi-level mentoring network to address some of these concerns.

To assess understanding of sustainability among S-STEM scholar participants, we took advantage of an instrument currently under development [8]. This tool, Sustainable Engineering through Service Learning (SESL), is being developed through NSF sponsored research and assesses three dimensions of sustainability mastery: self-efficacy (e.g., choices, efforts, and persistence), value (e.g., beliefs and interests), and affect (e.g., attention, character, conscience). SESL is available as a two-part evaluation, a forty-question online survey and an open-ended essay to a sustainable engineering design challenge scenario. For our program, due to a limited number of trained scenario essay evaluators and assessment time and resources, only the online survey portion of SESL was used in our evaluation strategy in a pre/post approach.

To further assess potential connections between learning experiences and outcomes, an emergent content analysis was performed on all final reports submitted by scholars on their reciprocal mentoring project research (n=25; reports were written by project teams). The nearly 80,000 words contained in the reports were examined for frequency. Those words used

This research is supported through a grant from the National Science Foundation, Grant No. DUE-0806569.

more than ten times were included in the analysis. These (132 resulting) keywords were thereafter binned into one of three sustainability categories: environment, economics, or society. The total frequencies of words in those bins were summed and normalized to the category with the maximum frequency.

III. RESULTS

A. Demographics

Fractions of female scholars were 33%, 43%, 52%, and 50% in Years 1-4, respectively, for an average of 48%. Over the entire project minorities represented 13% of all scholars, with one scholar of Asian race and five scholars who were of Hispanic or Latino ethnicity. The fraction of scholars who were Hispanic/Latino (8%) was half the fraction of the U.S. population that was Hispanic in 2010 (16%), the year a spike in college enrollment of Hispanics of 24% occurred [9]. The program exhibited higher diversity over the grant period than the Michigan Tech CEE Department. Department percentages for race and ethnicity were relatively constant over the grant period, whereas for gender there was an increase in the fraction of female graduate students from ca. 30% to ca. 40%, for a 4-year average over this period of 32% in comparison with the 48% of all scholars who were female in this period. The fraction of S-STEM female faculty mentors was lower at 20%. The fractions of scholars that were Asian or Black/African American was lower than those of the Department (2% as compared to 5% and 0% as compared to 1%, respectively); however, the fraction of Hispanic/Latino scholars was 8%, four times higher than that of graduate students in CEE (2%) and faculty mentors (0%). The greater gender and ethnic diversity of the scholars as compared to their faculty mentors provided opportunities for faculty mentors to interact with scholar mentors with a broadened scope in world views and experiences in the reciprocal mentoring experiences.

B. Intercultural Diversity Inventory

While sample pools were too small to draw statistically significant conclusions, information can be gathered about sub-cohorts for semi-quantitative comparisons. The findings for intercultural competency, as expressed by the IDI, are given in Table 1 for scholars who completed the pre- and post-program evaluations. Changes in intercultural competency are computed as the difference in post- and pre-program evaluations divided by the average of the two scores. While percent changes were small (for all scholars, an average increase of 1.8%), past work suggests changes in the > ±5% range are difficult to manifest without a significant experience (either planned major intervention, or unplanned culturally disruptive event). In general, women increased in intercultural competency, whereas men decreased; PCMI scholars increased, whereas MS/PhD scholar counterparts decreased; civil engineering scholars increased more, with environmental engineering scholars having higher competency. The 11.6%

Table 1. Intercultural competency as determined by the Intercultural Development Inventory, developmental orientation (DO) scores. Only scholars with pre and post scores were included (n=29).

Sub-cohorts	IDI (pre)	IDI (post)	Change (%)
Female (n=17)	92.4	96.8	4.4
Male (n=12)	92.4	90.5	-1.9
PhD (n=3)	96.3	84.7	-11.6
MS (n=2)	93.7	92.2	-1.5
PCMI (n=24)	89.8	96.0	6.2
Civil Eng. (n=7)	86.6	90.1	3.5
Env. Eng. (n=22)	94.2	95.5	1.3

decrease in pre/post IDI for the small group of PhD scholars may be meaningless. For example, the result could be explained by one scholar making an error on the post test. The most recent PCMI cohort had more information/knowledge in the form of a required curriculum including a new course on Cultural Dimensions of International Immersion and Research. (A separate, unpublished examination of the 22 (of the 24 in Table 1) PCMI scholars in that course showed a 9% increase in IDI over the one-semester course intervention.)

Using Hammer's IDI scale [5; Figure 1], plotted as a group, most scholars in this S-STEM cohort were found to have a minimization cultural view; effectively, they see the commonalities among cultures as their main feature. (The three PhD scholars that completed pre/post evaluation would be categorized as possessing a defense mindset, a view that one cultural perspective is better than others). Through their involvement in the S-STEM Program, most scholars moved somewhat to the right in the spectrum, inching toward an acceptance framework (a cultural view towards accepting that various cultural perspectives are present and relevant; Table 1). These results suggest that this group of engineers progressed in intercultural competence during the scholarship period.

C. Sustainable Engineering through Service Learning

Changes observed in pre- and post-program scores for the three independent SESL sub-scales (sustainable engineering self-efficacy, value, and affect) provide some clues to program impacts: self-efficacy changed little, value decreased, and affect increased dramatically (Table 2).

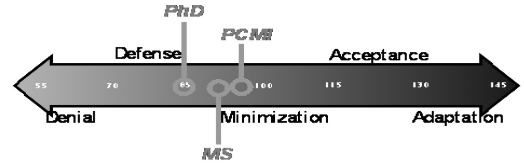

Figure 1. Intercultural Development Inventory score spectrum mapped to Bennett's [6] developmental model of intercultural sensitivities and the scale of Hammer et al. [5]. Approximate positions of S-STEM degree objective sub-cohorts are presented.

Table 2. Normalized sustainable engineering index sub-scores (sub-scores sum to unity). Only scholars having pre and post scores were included (n=26).

	Self-Efficacy	Value	Affect
Pre	0.346	0.434	0.228
Post	0.358	0.391	0.251
Change	3.41%	-10.4%	9.60%

In other words, on a group average basis, these students claim to have little change to their sustainable engineering abilities (self-efficacy), care less about sustainability (value), but are more attuned to sustainability. The change in value sub-scores may seem contradictory, but an explanation may be found in the high initial score (pre) and in a common observation of more experienced students that "nothing is sustainable". This view may simply indicate maturation of perspective, balancing engineering with community, economic, and environmental realities. It may also indicate an increased pessimism of the scholars in regards to the potential for the public to make lifestyle changes that promote sustainability.

Stepping away from group averages, Figure 2 displays the pre- and post-program positioning of each scholar (n=26) in a three-dimensional space representing the SESL sub-scales. As hinted at by the table above, the general movement is to the right, indicating a dominant shift in the affect sub-scale, and a decrease in value.

Comparisons of SESL assessment results by gender, program (PCMI, MS, PhD) and degree (civil/environmental engineering) cohorts did not yield significant results due to small sample sizes. Self-reported self-efficacy results (not shown) were for the most part stable. Male scholar self-efficacy was generally lower pre but similar to female self-efficacy post (9.8% increase overall in males). Lower (than MS and PhD scholars) and similar pre/post scores were reported by PCMI scholars. Comparisons among the sub-cohorts for sustainable engineering value indicated that women finished with bigger decreases (-9.2%, but still higher scores) than their male counterparts. PCMI scholars decreased more than other majors (-9.9%), whereas civil engineering majors decreased the most among all sub-cohorts examined (-14.4%). Women and PCMI scholar groups started with the highest scores, and may simply be "re-calibrating" their perspectives on sustainability after an academic year of wrestling with real projects, interacting in group discussions, and better appreciating multiple disciplinary perspectives through mentoring. Civil engineering, women, and PCMI scholar groups made large gains in affect (35.5%, 21.1%, and 20.0%, respectively), suggesting these students became more attuned to sustainability during the scholarship period. While the S-STEM participants are certainly influenced by other academic forces, by the end of the S-STEM Program, these groups all reported dramatic gains in their abilities to be aware of and act on sustainability issues within their work and lives.

D. Emergent Content Analysis

Scholars explored mostly environmental, then economic, and lastly, societal aspects of sustainability in their research projects (Figure 3). Terms related to economics were used at 77% the frequency of terms related to environment, whereas societal terminology was used less than half as frequently, 45%. This data is aligned with the assessment findings above and with curricular coverage for many graduate scholars in civil and environmental engineering. However, further research is needed to determine whether the lack of societal focus found in the scholars, as expressed by these research communications, is a result of lower cultural/awareness competencies, or of limited exposure to these domains in college education. It is likely even more challenging for the general engineering populace to base engineering practices on social, economic, and environmental aspects of sustainability. These scholars are pre-disposed to be interested in sustainability, and in the case of PCMI scholars, in community development as well.

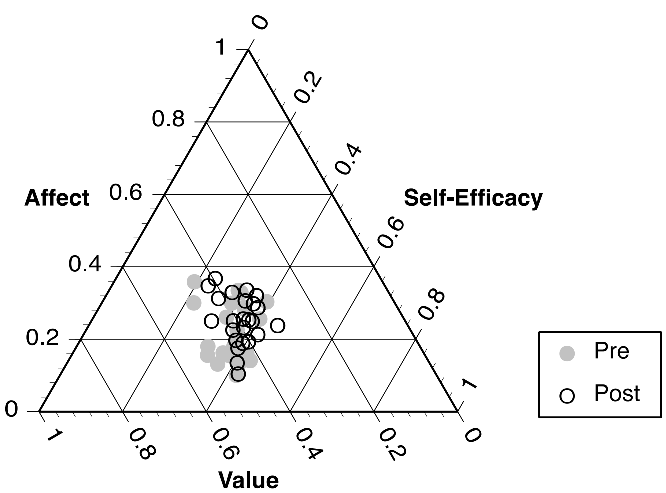

Figure 2. Representation of sustainable engineering index by its three sub-scales (self-efficacy, value, and affect). Only scholars having pre and post scores are displayed (n=26).

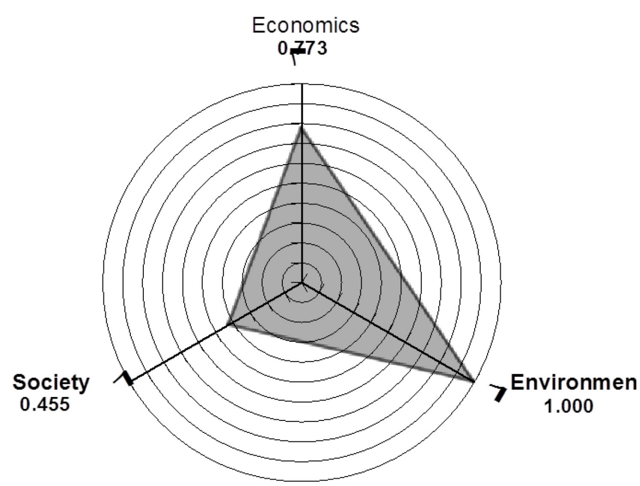

Figure 3. Sustainability content frequency analysis of final research project reports submitted over all years of the S-STEM Project (n=25; 79,769 words). Frequency numbers are normalized to frequency over maximum sector (Environment).

IV. Conclusion

Comparison of the results presented here and CEE Department-wide results would be of value in order to assess how these cohorts view cultures and consider the dimensions of sustainability differently. Such a comparison might lead to the finding that, during the project, the S-STEM cohort progressed in these areas relative to all CEE students. If we are to promote development of engineers having balanced worldviews of cultures and a sustainability mindset as the world demands [10-13], assessment of intercultural and sustainability competency in education programs is essential.

Abstract *— Knowledge in Basic Sciences, Basic Sciences of Engineering and Specifics of Engineering are fundamental for the education of an engineer. However the insertion in labor market demands sometimes some practice or experience that should also be provided by the engineering schools. Taking this into account, the Engineering Education Research Team of COPEC – Science and Education Research Council has designed a program for an engineering school which main goal is to prepare engineers for the future work market, the engineer for the future. It is an interdisciplinary environmental engineering program that intends to offer students an exciting opportunity to focus their technical capabilities on evolving science that affects human quality of life in an international scale and can simultaneously help preserve and restore areas in which they work. Emerging issues challenge environmental engineers in public health, conservation and restoration of natural systems, water and wastewater treatment, pollution prevention, and more.*

Keywords *— global education perspective; PhD program; technical skills; regional environmental issues; growing economies*

I. Introduction

It is currently common to watch the innumerous achievements of so many engineers all around the world in TV shows, who have diligently built and transformed the environment to make men's life better. The number of prominent professionals who have been referenced by their accomplishments is uncountable. Based on this, it is possible to say that the education of engineers is fundamental to keep the level of development of humanity in order to achieve social development similar to technological development. However the present challenges of engineering education institutions are not limited to the education of a professional for an international work market, but also to defeat the crises of education in which they are inserted.

It is accurate to state that engineers are responsible for the development of science and technology once they design tools, systems and instruments that make the acquisition of knowledge in a vast amount of fields possible. Engineering is responsible for the deep transformation of human relations in the first decade of 21st century, changing both education as well as business paradigms. A new era in working environment has started, which characteristics are peculiar due to new communications, mobility and globalization. These aspects lead to the fact that now it is also important to provide engineers with tools that enable them to act in a working environment that demands a very flexible and innovative mind in order for them to be fully inserted and to keep up with the work market [1].

The expanding global population has brought with it a growing concern about the environment and the impact of technological development on it. The goal of this work is to show the engineering program developed with the objective of training engineers to enter and remain in the future labor market. The choice of a PhD program is due to the investments that are being done in the region and the future possibilities for civil engineers. It is a region where petrol has been found in a great amount and also where the enlargement of the seaport for 2020 is being planned, two big endeavors that require many constructions.

The present program is an interdisciplinary environmental engineering program that intends to offer students an exciting opportunity to focus their technical capabilities on evolving science that affects human quality of life in an international scale and can simultaneously help preserve and restore areas in which they work. Emerging issues challenge environmental engineers in public health, conservation and restoration of natural systems, water and wastewater treatment, pollution prevention, and more. Students in this program acquire the professional skills to manage these complex issues and help their planet. This is also the opportunity for young people who are seeking for a career and a job.

II. Some Discussions About Engineering Education

The globalization phenomenon is here to stay and scientists, educators and politicians worldwide have been searching for sustainable development with social promotion of individuals and society. Despite the efforts of so many sectors of society, the present status of Education plays an important role in the development of peoples worldwide. It is the key factor to fight ignorance and consequently poverty. The growth investment in education is fundamental for all. Education in every level in western world is not yet as good as it should be. However many efforts are taking place at governmental level, because it is not enough to invest in the development of science and technology, it is necessary to have good researchers and good professionals applying the achievements of technology.

Technological power is an asset pursued by nations worldwide. Fortunately the achievements will spread and bring some balance in terms of political play in global economy. It will also contribute for the adoption of free market, highly trained workforce and innovation in the use of natural resources, and University is still the cradle of science and technology development.

The innumerous achievements of so many engineers all around the world who have diligently built and transformed the environment to make men's life better are also visible. The number of prominent professionals who have been referenced by their accomplishments is uncountable. Based on this, it is possible to say that the education of engineers is fundamental to keep the level of development of humanity in order to achieve a social development level similar to the technological development.

However the present challenges of engineering education institutions are not only limited to the education of a professional for a new global work market, but also to defeat the crises of education in which they are inserted. It is crucial to rethink the kind of education that has fragmented knowledge which drives people to not being able to articulate its several parts. Education must promote the natural ability of the mind to set and to solve problems and by inter-relation to stimulate the full usage of general intelligence [2].

The role of teachers at the higher level is drastically being changed and challenged to move from the holder of knowledge to the Master who will illuminate the path, as a backlight, so that the student can find and construct his/her knowledge and acquire the capability of applying the knowledge and build a career. The future teacher will be more of an adviser than a professional who just delivers some knowledge. It is imperative to prepare the future educators to take on this new role in order to make education advance.

o *II.1 The education for the Future*

The present work market in general is extremely complex and demanding for both professionals and enterprises, and mainly to the educational institutions - the universities - that prepare the high-qualified professionals. In the engineering field, the challenges are enormous. It became more and more necessary to prepare the engineer for a much more changing world full of complex issues of global and regional dimensions.

For engineering colleges the task is huge, once above all it is imperative to deliver a professional capable to enter and keep up with the work market, working in companies, in governmental organizations, as entrepreneur or consultant.

The actions towards the quality of a program have to be taken by the engineering college members responsible for the creation and development of an engineering program that fits the new demands [3]. It is necessary to:

- create a balanced program that integrates technical skills and professional practices;
- provide professional development and opportunities that enable faculty to teach effectively in an integrated curriculum;
- implement an integrated curriculum that meets diverse student populations;
- develop a rigorous assessment program that balances indirect and direct measures;
- establish and maintain an active research community with a research agenda that completes a feedback loop to strengthen engineering.

It is generally agreed that the engineers that universities train gain tremendous professional advantages if they write and speak well, work in teams and manage projects effectively, and listen carefully. Their communication needs to be technically complete and accurate, logically organized for the audience, visually appealing, and interesting; it also needs to be mechanically and grammatically conventional, and it must say something worthwhile. This is the recipe for success in any field and so any engineering program should include courses to enhance these skills.

III. Environmental Engineering Program developed by COPEC Engineering Team

Environmental engineers are a hybrid of an engineer and a scientist, thus making them the best profession to deal with environmental issues and problems; it is a branch of engineering that is more broadly defined and multi-disciplinary by nature, as it encompasses issues from other branches of study ranging from science, arts, mathematics and engineering. The broadness explains why there is such a wide variation between the courses of study.

Environmental engineering basically involves assessing, managing, preventing and controlling the impact of human activities on the environment. The environment can be defined as the nature surroundings, air, land, water, humans, and all non-living and living things. It entails the planning and designing of systems, equipment and technology for the management and protection of the environment, meaning that the environment is top priority in every decision-making processes [4].

The necessity of sustainable development regionally and the opportunity brought by political and geological aspects have started a new era. It has led to the need of creating a program in environmental engineering. The Engineering Education Research Team of COPEC – Science and Education Research Council has designed a program for an engineering school which main goal is to prepare engineers for the future work market, the engineer for the future. The program has been designed in detail in accordance to the present labor market of engineers, with its particular characteristics and considering a growing need for engineers. The success of the program depends on the ability to inspire the students by showing engineering as an exciting career, a personal upward path, and a way to affect local social and economic well being. The implementation of the program is meant for 2014.

The possibilities are increasing for environmental engineers. They have been employed by universities and research enterprises, government agencies, and also by major corporations.

Environmental Engineers can work in a wide variety of industries, including chemical, pharmaceutical, water/wastewater treatment, mining and manufacturing, and can be involved in hazardous waste remediation, air pollution control, facilities planning, and environmental consulting.

IV. Aspects of the Program

It is an interdisciplinary environmental engineering program that intends to offer students an exciting opportunity to focus their technical capabilities on evolving science that affects human quality of life in a global scale and can simultaneously help preserve and restore areas in which they work. Emerging issues challenge environmental engineers in public health, conservation and restoration of natural systems, water and wastewater treatment, pollution prevention, and more. Students in this program acquire the professional skills to manage these complex issues and help their planet [5].

It is a PhD level program with topics for research ranging from power storage to water quality preservation, and opportunities to work in outdoor settings and communities as well as in laboratories. Following the world trend educational model of theory and practice, student projects provide unique, hands-on opportunities to explore the multifaceted considerations surrounding environmental engineering problems at local and global levels, and to improve living conditions in the subject areas.

It offers a unique depth in this specialization, with educational options that supply the comprehensive understanding swiftly transforming field demands. It is a full-time PhD program that lasts two years, offering classes conducted on an undergraduate-type schedule.

It has a curriculum that addresses the time-crunch problem by integrating professional practices into the technical curriculum — that is, professional practices are contextualized in engineering in ways that reinforce and strengthen students' understanding and their ability to apply that understanding to address engineering problems. Throughout their graduate program, students work to master the engineering body of knowledge and simultaneously become skillful communicators, ethical decision makers, team leaders, creative thinkers and problem solvers.

It is has been designed for an engineering School of a private university in Santos, Brazil. There is no other program of environmental engineering in the region at present time. Taking this fact into account and also the fact that it is a need for this kind of engineers, this particular university is investing a great deal in this program.

This is a new kind of program because the students have out of class lecturers and meetings with project developers groups of enterprises that have agreements with the school. The students will also have classes in environment research centers located in the region.

Today, engineers must keep up with emerging technologies and understand the financial and strategic impact of their decisions. The program strongly focuses in career development fostering the accumulation and cultivation of skills and knowledge that enable a professional to advance or grow in the field of his or her choice [6].

The two-year program (120 ECTS) consists of courses amounting to 90 ECTS, followed by a Degree project (30 ECTS). The system is compatible with ECTS credits, the European credit system. Although the system of the country is in credit hours, the choice of having the European credit system is due to the fact that it is a trend for the future. It makes no difference as in terms of credit hours the amount is in accordance with the demands of the Ministry of Education.

At the end of the program the students receive a diploma registered and recognized by the Ministry of Education of the country.

V. The Courses

The choice of courses is based on the global and regional demand for engineers capable to work in projects taking into account the environmental issues and to enhance the practice of engineering for the betterment of whole community, nature and human groups impacted by projects.

The courses are dimensioned to explore the content pertinent for the development of a mind focused on research.

The courses are as follows:

ENVIRONMENTAL STUDIES: The study of environmental problems and their solutions requires an interdisciplinary approach. This course examines current environmental issues from the intersection of several key disciplines including: environmental philosophy and history, environmental policy, and science. The course develops these different approaches for analyzing environmental problems, explore the tensions between them, and present a framework for integrating them. Topics such as environmental justice, developing nations, globalization, and climate change policy are explored.

GEOGRAPHIC INFORMATION SYSTEMS: This course introduces Geographic Information Systems (GIS) as a powerful mapping and analytical tool. Topics include GIS data structure, map projections, and fundamental GIS techniques for spatial analysis. Laboratory exercises concentrate on applying concepts presented in lectures and focuses on developing practical skills. These exercises include examples of GIS applications in environmental modeling, socio-demographic change and site suitability analyses. Although the course is computer-intensive, no programming background is required.

ENVIRONMENTAL POLICY AND ETHICS: In this course, we will examine some of the important moral, legal, and public policy concerns which are raised by the interaction of human beings with the natural environment. How are policy frameworks, the beliefs and actions of environmental activists, and your views guided by deep seated notions of who has standing in the moral community? The course considers a range of moral perspectives including: anthropocentrism, biocentrism, egocentrism, animal rights and others, and examines them in the context of various contemporary public policy case studies [7].

GOVERNANCE, TECHNOLOGY, AND INNOVATION: This course examines how public policy models have the capacity to shape technological change and social innovation in a time of ecological crisis. With global attention dominated by environmental catastrophe and despair, it spotlights new work that has brought together scientists, environmentalists, engineers, and artists to tackle the most serious problems facing communities. It explores the political ecology implications of control over essential resources and the positive consequences of rethinking and democratizing basic social needs for a more sustainable future [8]. Recent exciting case studies feature examples of simple solutions that inspire elegant, transferrable, and inexpensive applications of technological design. It examines the role and obligation that scientists have to collaborate with interdisciplinary and public policy efforts that benefit people with sustainable approaches to architecture, food, energy, transportation, and infrastructure.

HUMAN BEHAVIOR AND ENVIRONMENTAL PROBLEMS: This course examines how people think about and behave toward the environment. Environmental problems can ultimately be attributed to the environmental decisions and actions of human beings. These behaviors can in turn be understood as resulting from the nature and limitations of the human mind and the social context in which behavior takes place. Knowledge of the root causes of environmentally harmful behavior is essential for designing effective solutions to environmental problems. The goals of the course are:

- to provide students with the basic social science knowledge needed to understand and evaluate the behavioral aspects of such important environmental problems as air and water pollution, global warming, ozone depletion, preserving biological diversity, and hazardous waste and
- to help students identify and improve shortcomings in their knowledge and decisions related to the environment.

Topics include, but are not limited to:

- environmental problems as tragedies of the commons;
- public understanding of global warming and global climate modeling;
- folk biology;
- risk perception;
- intelligent criticism of environmental claims;
- making effective environmental choices;
- strategies for promoting pro-environmental behavior;
- human ability to model and manage the global environmental future.

ENVIRONMENTAL PROBLEMS IN GROWING ECONOMIES: Environment and development are often seen as incompatible, in part because many poor people in the developing world depend directly on natural resources for their livelihoods. At the same time, poor people are often seen as responsible for causing environmental degradation because they lack the knowledge, skills and resources to manage the environment effectively. The vicious circle is completed as environmental degradation exacerbates poverty. However, optimists argue that poor people can and do contribute positively to environmental outcomes, that states and organizations can facilitate their efforts and that environmental interventions can coincide with development [9]. This course examines these different perspectives on environmental problems in the developing world through the insights and critiques of social science. Subjects covered include sustainable development, population, environmental risks, gender, urbanization, environmental decision-making and non-governmental organizations (NGOs). The goals of this course are to think critically about the various links between environment and development and the role of governmental and non-governmental organizations in promoting sustainable development in the developing world.

ENVIRONMENT & RISK COMMUNICATION: Environmental risks consist of incidents or trends, either man-made or natural in cause, that have potential to inflict harm to human health and/or ecosystems and could include physical assets or the economy (i.e., business and social disruption). Communication of environmental risks can be divided into two distinct categories, according to the time-sensitivity of the need for sharing information:

- events that might occur in the future where prevention is the focus, and
- emergency scenarios where an event has occurred, and there is a need for immediate notification and deployment of mitigation actions.

Moreover, the consequences of these events can produce either acute or chronic effects. The communication process is at the heart of effective environmental risk communication because it establishes the policies and procedures under which individuals and organizations will operate. Another requirement for effective communication is the ability to disseminate risk information in a timely, reliable and targeted manner. Reaching the proper audience through the proper means at the proper time is a prerequisite to effective environmental risk communication [10]. This course examines the needs of an effective communication in case of environmental risks. It provides a series of case studies in order to allow students to acquire knowledge on effective ways of communications in case of environmental risks to the wide environmental risk stakeholders.

ORIENTED CAREER DEVELOPMENT: Reflect, plan and chart a future career becomes vital condition for professional success in a globalized world. Plan a career is not just choosing a profession or an undergraduate course to follow, but also an industry segment and a performance for which the young or trader should prepare by preparing himself/herself with all the necessary tools that will bring competitive desired expertise and differential [11]. The goal of this course is to foster students with the search for career development in terms of niche choice and entrepreneurial initiatives.

ENVIRONMENTAL STUDIES SEMINAR: The course is designed to integrate each student's educational experience (e.g., core environmental courses, environmental electives, and environmental projects) in a capstone seminar in Environmental Studies. Through seminar discussions and writing assignments students will critically reflect on what they learned in their previous courses and project experiences. In teams, students will prepare a final paper and presentation that critically engages their educational experience in environmental studies and anticipates how their courses and experiences will translate into their future personal and professional environmental experiences.

The content delivery of each course is up to the teacher who can sense the development of the students and make adjustments in order to cover the topics. The choice for this more liberal approach aims to provide the students with comprehension and application of the learnt concepts in practical works [12].

VI. PROGRAM GOALS

The goals of the program are to position graduates to:

- use their knowledge and understanding of engineering sciences and design to advance their professional career;
- think critically when solving and managing tasks;
- communicate effectively in multidisciplinary, professional environments;
- exercise professional responsibility and sensitivity in the context of the social, economic, ethical and environmental implications of their engineering work;
- function effectively and efficiently as an individual and as a part of a team; and
- pursue life-long learning to earn relevant professional credentials.

VII. FINAL CONSIDERATIONS

Environmental engineering has become an important area and will be in the future, as environmental problems are worsening and cannot be eliminated, only controlled. Considering this reality, there will be a higher demand for more environmental engineers as they become more scientifically and technically prepared to find solutions to environmental problems. There is a demand for more environmental engineering programs which have the character that a proper education and training demand, as well as a well-structured and well-designed curriculum. There is no doubt that education is the key to solving global problems, contributing to global sustainability and achieving better policies for environmental issues.

If environmental engineers have all the skills and knowledge needed, they can perform their best in order to find solutions to control environmental problems and thus promote a better future for generations to come. The proposed program has the possibility to provide the students hands-on work and case studies due to the current regional scenario and the geographical location in the country besides belonging to a historical moment of a growing economy country. It is a PhD program of high quality in order to fulfill the work market's demand.

ACKNOWLEDGMENT

This work was partly funded by FEDER funds through the Operational Competitiveness Program (COMPETE) and by FCT with the projects PEst-C/CTM/UI0264/2011 and FCOMP-01-0124-FEDER-022674.

This work explores the use of interactions between teachers and students as a basis to infer the students' learning status and generate suitable feedback for them. We propose a system that lets teachers and students register the interactions face to face, so they can be capitalized for improving traditional teaching/learning. The recorded interactions will be exploited in a similar way to how teachers infer the knowledge status of their students from their interventions. In order to discover the teachers' strategies and, specially, their necessities regarding the interactions with their students, we have run a questionnaire and verified some previously stated hypotheses. The design of the PresenceClick system is a first result. It has a double aim: to show teachers the knowledge status of their students, so that they can adapt their teaching; and to show students their progresses and the one of the overall class so they can compare them. PresenceClick incorporates an Attendance module, which automatically collects the list of students attending the class with no effort from the teacher. This paper presents the results of this study, the PresenceClick architecture and the Attendance module, as an essential component to help and complete traditional F2F, blended or e-learning scenarios.

Student centered learning, F2F interactions, presence monitoring, attendance control, student model

I. Introduction

Current educational trends consider students as principal actors of their learning processes instead of being passive knowledge receivers. Thus, learner centered methodologies must involve continuous evaluations and control of the student's activities, which significantly increases teachers' workload during the whole course presence sessions. Therefore, new educational methods and supporting student-centered tools [1] are required.

Concerning students' competencies and learning achievements, many studies in the adaptive education field have been conducted about student modeling [2]. Most of them present different approaches for modeling the student: his or her acquired knowledge, and even interests, goals and tasks [3]. Recent works point out the relevance of enriching the student model to improve personalization and adaptation to the learner. They propose to consider new aspects such as learning styles [4] or cognitive styles [5]. Other works try to go further and investigate the modeling of the learning context: user platform [6], user location [7], environment and human dimension [8] or affective states of the students [9]. So far the study of interactions has been mainly focused on the student-system learning flow, despite the fact that the most successful and used way of tutoring is the traditional face-to-face interaction (F2F), as stated in the Interaction Hypothesis [10]. This hypothesis predicts also that the effectiveness of tutoring increases monotonically with the degree of interactivity: the more interactive the tutoring is, the more the student learning [11]. Chi et al. proved also that the one-to-one tutoring is the best way to learn [12]. However, currently this is practically impossible to be carried out in the schools, institutes or at university level. Nevertheless, tutorial sessions could be used to support attendance classes, but they are not used as often as they should.

Taking these aspects into account, a clear question arises to us: *How can we exploit to the maximum the interactions between teachers and students to take advantage from them and improve learning*? The answer is not that simple. Therefore, starting from modeling traditional interactions on the basis of didactic communication according to [13][14], our final aim is to create a tool that helps both teachers and students to manage their interactions, moving a step further towards the student-centered learning. Accordingly, we propose to monitor the F2F interactions. From the teacher's point of view, the main goal is to build an in-situ interactions acquisition system that provides them with valuable information about students' presence characteristics. This will be useful for improving the overall learning process, and for making lighter the teachers' workload. From the students' point of view, the system will allow them to incorporate their perceptions of these interactions, for example misunderstood concepts, problems with exercises, or the correct progress in the subject.

On the one hand and as a founding base, we are exploring how teachers obtain, use and exploit their knowledge about the student's learning process from F2F interactions. As a first step, we have carried out an empirical inquiry process to obtain information about teachers' expertise and necessities concerning direct interactions with students. In a similar way, a survey was conducted to discover the teachers' needs [15]; however, this study focused on tracking the interactions arisen between students and computer systems, instead of those between teachers and students. A questionnaire was passed out at the Computer Science and Engineering centers of the University of the Basque Country. In next future, we will carry out a parallel study with students to squeeze the

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

interactions from both points of view.

On the other hand, we have started to develop the PresenceClick system by considering the results of the questionnaire. The system aims to provide with agile and intuitive means for teachers and students to record information about F2F interactions. These interactions are related to presence learning activities, e.g. exercises assignment, evaluations, annotations of questions and answers, etc. The PresenceClick architecture assumes some meta-knowledge structures from classical Intelligent Tutoring Systems such as the Domain and the Student models. In addition, it incorporates an Attendance module that automatically collects the list of students that attend class. Data from students' interactions are used to enrich the attending students' models, what will allow teachers to provide students with more adapted feedback. In summary, the system should be: (1) *intuitive*, to make an understandable tool with just a glimpse, no matter the user's background; (2) *simple*, to motivate teachers and students to use it, and (3) *agile*, to avoid waste of time in class to register the interactions and to decrease workload outside class.

The paper is structured as follows. Section 2 summarizes the questionnaire, the previously stated hypotheses and its results, which highlight the interest of the majority of the teachers to be helped by an educational tool. Section 3 describes the PresenceClick tool which allows teachers to register and manage just-in-time information about students' presence interactions in a flexible and easy way. Finally, Section 4 draws the conclusion and future work.

II. OBTAINING TEACHING EXPERTISE

A first step to spread student-centered learning in traditional environments is to discover the current and desired mechanisms that run the interactions among teachers and students. We believe these mechanisms will allow to derive new learning tools capable of providing both teachers and students with more adapted and contextualized help. Thus, we have conjectured that there exist different aspects of presence classes and their actors that determine the set of possible teaching strategies, material and technological tools to be applied. Besides, we presume teachers infer interesting feedback from the spontaneous class behavior.

Therefore, in order to discover these aspects, their inter-relationships and the actual teachers' perspective, we run a questionnaire about classroom teaching activities. This questionnaire promoted an introspection process oriented to reflect on the students' learning conditions in order to help teachers to specify, articulate and identify that deal of information.

We designed the questionnaire by means of an iterative process. First, we identified a meaningful question set that was gradually tested, corrected and improved. A pilot test was carried out with thirteen teachers. After analyzing their responses and interviewing all of them, we finally obtained an understandable and agile inquiry process. The resulting questionnaire is composed of 26 questions categorized in four item blocks: (1) *Teaching context* –e.g. teacher's age, number of students in class; (2) *Planning of learning sessions* –e.g. type of session, week or course plan made, and different aspects included in the plan; (3) *Interactions with students* –i.e. attendance classes, tutorial sessions and evaluation; and (4) *Teachers collaboration* –e.g. about the student workload and progress in other subjects.

The questionnaire is mostly composed of two types of question: scaled and multiple-choice. The latter facilitates answering while maintains the motivation, whereas the former aims at discover the interest of teachers about some proposals. In addition, two open-ended questions were included for teachers to deeply explain their behavior. Besides, every block includes an open entry question to freely record teachers' opinions or suggestions. TABLE I. shows an excerpt of the questionnaire entailed by two scaled questions and a multiple-choice question, the three of them concerning to block 3 (*Interactions with students*).

Once finished the refining process, the questionnaire was presented at some centers of the University of the Basque Country, where 69 Computer Science and Engineering teachers took part voluntarily. The statistical and inferential study of the teachers' answers allows us to corroborate some of our conjectures and beliefs. We have analyzed four hypotheses whose statements and results follow.

***Hypothesis H1**: The number of students in class influences the teaching strategies, i.e. material and tools used, information registered, etc.*

Teachers were divided into three groups depending on the number of students in their classes: Gsmall (less than 25 students), Gmedium (from 25 to 59 students) and Glarge (more than 59 students). Groups were balanced, so Gsmall group included 24 teachers, 22 teachers were in Gmedium, and 23 in Glarge. We found significant differences on the behavior of the groups in the following cases:

TABLE I. FRAGMENT OF THE QUESTIONNAIRE

16. Regarding the activities and the interactions in class, identify the types of information you register, you would like or you consider irrelevant.

	I register	**I'd like**	**Irrelevant**
Given concepts	○	○	○
Solved exercised	○	○	○
Proposed exercises	○	○	○
…	○	○	○

17. Choose the communication types you employ to interact with your students outside the classroom.

A. *E-mail*	B. *Individual tutorials*	C. *Collective tutorials*
D. *Forum*	E. *Chat*	F. *Others*

25. Regarding the students' behavior in non-specific , identify the types of information you register, you would like or you consider irrelevant.

	I register	**I'd like**	**Irrelevant**
Particpation in class	○	○	○
Activities performance	○	○	○
…	○	○	○

- *Teaching context –Functionalities on teaching tools (e.g. Moodle)*. Teachers in Glarge group significantly seek more supporting functionalities than teachers with less than 25 students ($p=1.2e^{-07}$), especially for *evaluating exercises*: p=0.02 between Glarge and Gsmall, and p=0.01 between Gmedium and Gsmall.

- *Interactions with students –Recording of information, e.g. assessment of presentations*. Teachers in Gsmall record information significantly more than teachers in Gmedium (p=0.03) or Glarge (p=0.001). Obviously, as the number of students increases it is more difficult to assess presentations because of time demands.

- *Interactions with students –Tutoring communications types, e.g. collective tutorials or forum*. Students in large groups require more *collective tutorials* or communication outside class than those in small ones (p=0.002). We also found a positive correlation between the use of *forum* and the number of students. TABLE II. shows usual communication types between teachers and students, and the percent of teachers that normally employ them. This information has been inferred from the answers to the 17th question of the questionnaire (see TABLE I. TABLE III. shows p-values when comparing the distributions of the communication types employed by teachers and considering the number of students in their classes.

- *Interactions with students –Content of tutorial session and its implication*. Demands of theoretical knowledge and exercises during tutorials correlate with the number of students enrolled in the class. As it was expected, students in small groups tend to ask more doubts about practice tasks or laboratories during class time. But teachers in Glarge take advantage of tutorial sessions in different ways, like *individual or class monitoring*. So, they especially *generalize* in the class those *questions* that students ask in tutorial sessions (there is a difference between Gsmall and Glarge p=0.02).

TABLE II. STATISTICS ON THE USE OF COMMUNICATION TYPES

Group	n	Communication Types				
		Email	*Individual Tutorials*	*Collective Tutorials*	*Forum*	*Chats*
Gsmall (<25)	24	96%	96%	29%	38%	4%
Gmedium (25 to 59)	22	100%	96%	55%	45%	5%
Glarge (>59)	23	96%	96%	79%	52%	0%

[a] Group=group by number of student; n=number of students in each group

TABLE III. P-VALUES COMPARING THE USE OF COMMUNICATION TYPES

p-value comparing the employment of communication types		
distribution x	*distribution y*	*p-value*
Gsmall (<25)	Gmedium (25 to 59)	0.51
Gsmall (<25)	Glarge (>59)	0.001
Gmedium (25 to 59)	Glarge (>59)	0.38

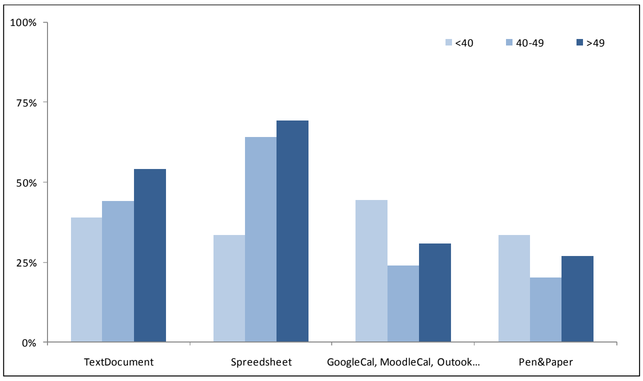

Fig. 1. Use of planning tools depending on the teachers' age

Hypothesis H2*: Non-digital natives are more reluctant to use technology in learning, so they need some kind of motivation to lose this fear.*

For this hypothesis, teachers were divided into three groups depending on their age: G40- (less than 40), G49- (from 40 to 49) and G49+ (more than 49). We found significant difference on the behavior of these three groups in the following cases:

- *Planning of learning sessions –Planning tools*. Teachers in G49+ tend to use text documents or spreadsheets to plan, while teachers in the G40- start to use other kind of tools like MoodleCalendar, GoogleCalendar, Outlook, etc. (p=0.004 between G40- and G49+, and p=0.01 between G40- and G49-). Almost the half of the youngest teachers uses this kind of tools, while teachers older than 40 use much more spreadsheets or text document (Fig. 1). This leads us to think that young people are more open minded to new tools that the older ones, who could need some kind of motivation or extra help to start using them until they feel comfortable.

- *Interactions with students –Registration of interactions*. We have found significant differences in some aspects like students' mistakes, where the youngest teachers (G40-) try to record them while the oldest ones (G49+) just express their possible interest in doing it (p=0.002). This could be related to the fear of technology in the non-digital native people, who being used to well-established tools don't like to try new applications, even being computer scientists. The teacher's experience seems to be important in other aspects: older teachers pay attention to some factors like *students' answers to questions* made in class. The youngest teachers think these aspects are not relevant (p=0.03), despite the fact that they could be hints about the individual or general knowledge level of the class.

Hypothesis H3*: Teachers are interested in registering some interactions aspects of the class in order to receive feedback.*

- *Interactions with students –Registering spontaneous aspects in class*. Fig. 2 shows the results of the 16th question (see TABLE I. They establish that the majority of the teachers (>75%) already register concerns related to planning, such as given concepts, exercises solved in class and exercises proposed for the next learning session. However, less than 50% of teachers register the non-planned aspects related to the interactions, such as students' mistakes, spontaneous questions and answers, evolution of the work, etc. Nevertheless, they show big interest in doing it.

- *Interactions with students –Registering students' behavior in class.* Fig. 3 shows that the majority of the teachers already register a set of defined and evaluable aspects of the student behavior, like the tasks they do individually or in groups, the work they develop in laboratories or the resolution of exercises. In all these cases, more than 60% of teachers record this kind of information. However, less than 25% register more abstract aspects of the students' behavior, such as participation in class, performance of activities, suitability of questions posed in class, perseverance in daily work or personality features (learning style, leadership skill, etc.), although an important percent of teachers show their willingness to do that. We consider this interest from teachers really motivating for improving our tool with this kind of interactions.

***Hypothesis H4**: Teachers are interested in coordination aspects with other teachers in order to obtain valuable information about their students.*

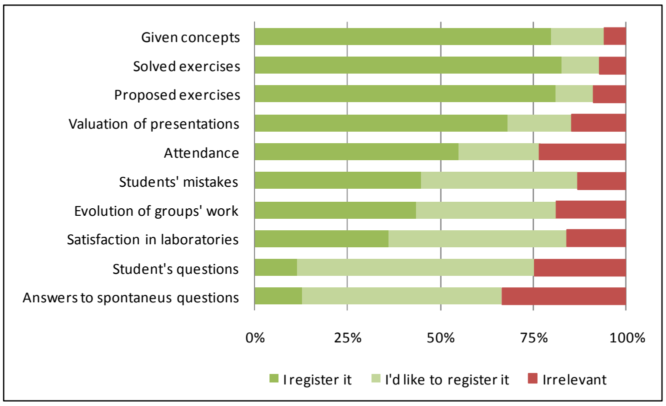

Fig. 2. Teachers' interest in registering class interactions

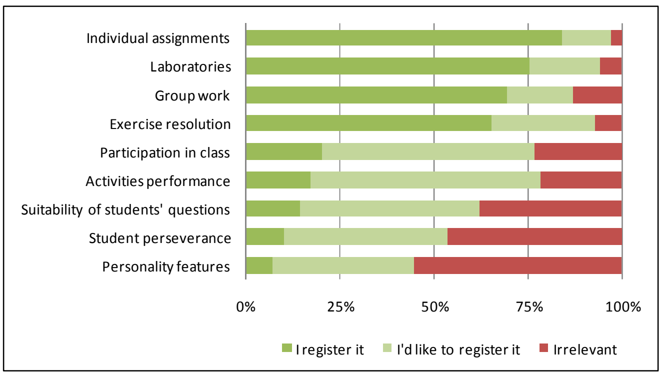

Fig. 3. Teachers' interest in registering students' behavior in class

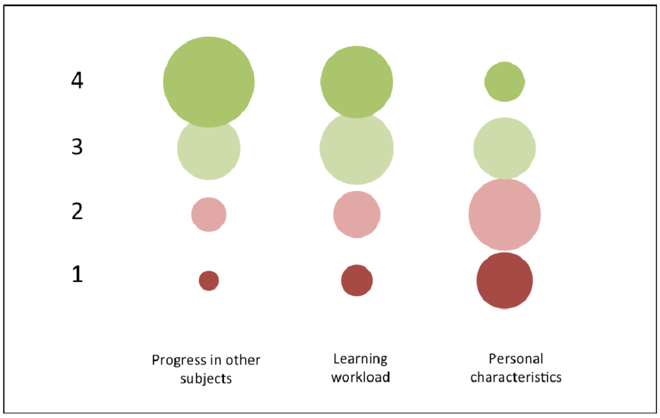

Fig. 4. Teachers' interest in coordination between colleagues

The questions about "coordination among teachers" aim for examining teachers' willingness to share information about their students with their colleagues. The issues were: learning workload, progress in the subject and personal characteristics. Fig. 4 shows the teachers willingness to coordinate with peers. The circles represents the number of teachers who valued from 1 to 4 depending on their interest, from low to high. Thus, teachers show big interest in knowing the students' workload and progress in other subjects. This positive response could open future collaboration mechanisms through exchange of non-private information.

This questionnaire has let us know how teachers interact with their students: the strategies and tools they use, how they register the information, etc. Therefore, we can derive some conclusions from these hypotheses and their results that are relevant for designing our system. First, ***H1*** results indicate that big groups of students provoke that their teachers seek more support in learning tools, and also restrict their registering of some kinds of interactions. This confirms that teachers of big groups need extra help in order to follow the students' evolution in the subject, which reinforces our purpose. In addition, it brings the prerequisite of *agility* for not increasing teachers' workload. Second, ***H2*** leads to build an *intuitive* and *easy to use* system; that is, a motivating and engaging tool for all teachers, no matter the age, that helps more experienced teachers to lose the fear of technology and lets them share their teaching strategies. Third, ***H3*** confirms that teachers are interested in registering the interactions with their students for getting feedback, which supports our system objective. This enlightens *simplicity* as the most important system requisite in order to fully explote teachers' interest in registering all interactions (see Fig. 2 and Fig. 3). A too complex system will cause teachers give up using it. Finally, if ***H4*** is taken into account, teachers could collaborate at subject level by accessing an open student model, what would increase the knowledge at course level, and would improve the skills to detect students' problems.

Taking all this into account, we are designing a system, named PresenceClick, to support registering of the teacher-student interaction information flow. Currently it is devoted to give feedback to teachers, and the obtained results have defined the teachers' necessities to fit with.

III. A PROPOSAL: PRESENCECLICK

This section thoroughly presents the main ideas underlying PresenceClick. Its main functionalities are to record the interactions in F2F sessions, to explicitly visualize them and to provide useful feedback for improving the learning process. The overall environment is devoted to two types of user, i.e. teachers and students, and so it collects the most relevant interactions that arise between them in the typical F2F learning sessions. Then, these interactions are exploited by extracting and showing valuable information for them. The teachers' goal is to know "*what happens*", i.e. the events and evolution of each student in the learning sessions. Thus, PresenceClick helps teachers to monitor their students through different aspects, such as students' (or groups') interest or participation, problems derived from exercises, theory comprehension, probable giving up of the subject, etc. The students' goal is to know *"how does my learning go"*, i.e. his/her learning progress and its comparison to the one of the overall class. PresenceClick helps students to be aware of their own subject knowledge regarding peers, and also to increase their motivation.

In summary, three main user requirements can be derived from the survey results: intuitive handling, simplicity and agility. For this purpose, the system has been designed by following an agile and user-centred interactive software development methodology [16].

A. General PresenceClick behavior

As mentioned, the tool must gather the greatest deal of information in the fewest clicks, and must collect just-in-time interactions in the shortest possible time. In addition, getting technology close to the non-digital natives in an easy to use way will increase motivation of older teachers (see ***Hypothesis H2)*** and then their willingness to use the system. Fig. 5 shows graphically the PresenceClick proposal. Teachers and students introduce different kinds of F2F information in the system (*arrow 1 and 2*). Then, the system provides them with feedback, such as global statistical attendance information, progress of group or each student, interest on topics, problem detection, etc. (a*rrows 3 and 4*).

On the one hand, teachers record any kind of incidence or student participation that can be considered relevant (see ***Hypothesis H3***), e.g. assigned tasks, given grades, questions or other spontaneous aspects arising in class (*arrow 1*). On the other hand, students may give their opinion about theory and exercises, express their satisfaction about different aspects, respond just in time any question of the teacher, or even make new questions.

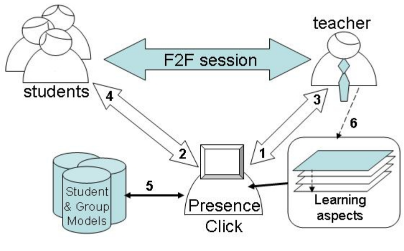

Fig. 5. PresenceClick approach

The students' procedure will be similar to that of Audience Response Systems, where they show their knowledge during presence sessions by using 'clickers devices' to answer teacher's questions just in time. These systems have proved to be a big advantage for improving the learning process [17] by increasing some students' aspects, such as attendance, motivation, attention or interaction.

This way, students make teachers aware of the class knowledge status by indicating which exercises they have done (in class or outside), and so on (*arrow 2*). Thus, the tool accesses to actual information about students' current status, which allows updating their student models, and so infering the group model of the attending students. That is, PresenceClick will feed the Student and Group Models (*arrow 5*) with the interactions' information that teachers and students include. And these models, in turn, will provide PresenceClick with updated information that will allow it to generate suitable feedback for the teachers' and students' issues (*arrow 3 and 4*). Also other functionality is needed by teachers, i.e. the authoring characteristics that allow them to specify those learning aspects they consider worth to monitor (*arrow 6).* In order to record all the relevant class interactions just in time, while doing other teaching activities, teachers need the list of attending students in an agile way. For this purpose, we have built the Attendance Module.

B. PresenceClick architecture

The PresenceClick architecture (Fig. 6) assumes some meta-knowledge structures from classical Intelligent Tutoring Systems, such as the Domain and the Student models. The Domain meta-knowledge enables teachers to plan the learning sessions and to define the relevant learning aspects of interactions to be record. In the same way, the Student Model meta-knowledge defines the significant student learning aspects to be noted. In addition, PresenceClick includes an Attendance Module that automatically collects the list of students that attend to class. Other functionalities allow teacher and students to provide the system with the interactions occurred in the F2F sessions, which feeds the databases hosting the Student and Group Models. Besides, users can visualize both kinds of models. This tool is aimed to be a helping component for the traditional F2F teaching method, or even as a complement for blended-learning scenarios in which the F2F communication line is usually under-represented (e.g. Magadi [18]) or e-learning (e.g. moodle[1] or blackboard[2]).

A plan for a F2F learning session includes aspects such as *subject*, *lesson*, *concept*, *example*, *exercise*, etc. All these meta-knowledge terms are used to define the subject domain, i.e. the activities and the concepts to be worked in a specific learning session. They enable teachers to express learning aspects of the interaction to be recorded. In addition, although plans are not compulsory, if a session plan has been provided by the teacher to the system (*arrow 6 in Fig. 5*), a more agile process of recording interactions is offered in the F2F session, i.e. *the more planning the less clicks*.

[1] https://moodle.org/
[2] http://blackboard.com/

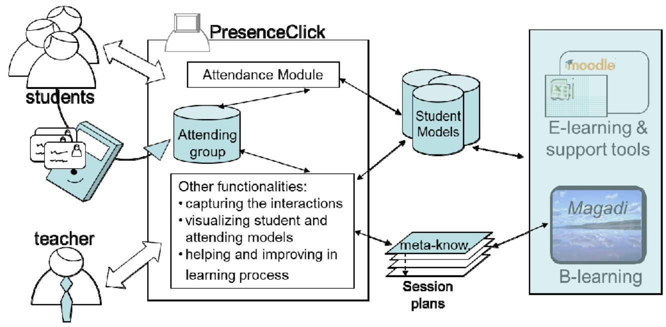

Fig. 6. PresenceClick architecture

For example, if the teacher has previously defined a plan for a specific day −e.g. *lesson 2* and *exercises 4* and *5*, this information will be automatically included in the model of each student attending the class, just when the teacher confirms it with one click. If no previous plan exists, the teacher can add the planning aspects once finished the class session. In any case, although PresenceClick is thought to be used in presence sessions, teachers always can visit the sessions to edit or add new information. This functionality may be merged or integrated within the planning characteristics of blended or e-learning platforms, in such a way that their authoring/edition interfaces be re-used for this purpose. The system is being developed incrementally and, currently, planning aspects are not being considered. The focus is on visualizing attendance information without previous planning effort from teacher.

C. Attendance Module

PresenceClick provides teachers with an agile and just-in-time snapshot of the students attending class so that teachers can personalize their activities. This Attendance Module provides teachers with this list without any effort, forgetting the piece of paper where they usually note these aspects and avoiding the waste of time it generally involves (as much as in class as later when they have to transfer it to their own documents). According to the ***Hypothesis H3*** this module can reduce teachers' workload and help teachers of large groups (see ***Hypothesis H1***). The main functionality is to record the students' arrivals to class. This module uses a presence control device together with the students' identification cards provided by the university (Fig. 6 left part)—the University of the Basque Country provides teachers and students with an identification card that is valid for various services, such as access to buildings, library loans, parking lot, etc. This device is connected to the university network through TCP/IP or WIFI, while a server is waiting to receive the calls. Each time a student passes his/her card, the device stores the marking time. The server asks for new stored markings every time slot. Then, PresenceClick's database is filled with the metadata related to the marking: student's card code, device code, marking time, IP of the connecting device, etc.

In order to just-in-time visualize the attendance information of one specific class, its starting and finishing time and device code must be provided to the system. Then, PresenceClick generates and shows the list of the students in class together with other statistically enriched information (Fig. 7 left). In case that a student has forgotten the card or the system fails, teacher may add students manually to the attendance list. Teachers may also view general information about the group (Fig. 7 right): (1) student attendance to each session and percent of attendance; statistical information about (2) the medium attendance of the group (global view and by type of session) through pie charts, and (3) detailed percent of attendance by session through bar diagrams.

The information attendance streamlines the capturing of valuable information during the F2F learning sessions. Similarly, students in [19] indicate their position in class and have the possibility to include their affective state, respond to questions or make new ones. However, our main idea is to include also all this information in the Student Model in real time, so they can get feedback from these interactions. The attendance registration will also let teachers and students know the student daily attendance as reflecting the evolution of the interest of the class during the whole course. In addition, both teachers and students will be able to configure the advice management by means of an advice module [20]; depending on the number of unjustified absences or the allowed minimum attendance percent, the advice mechanism will allow teachers to identify those students at risk for losing whatever chance related to attendance, for instance a continuous evaluation. Students will be also aware of that loss and will be able to mend it.

So far we have evaluated incrementally this module with two registering devices, which were tested with different teachers, groups of students and locations (buildings and classrooms). The aim of these evaluations was to register different parameters, such as: time to start-up the device and connect with the computer, cards marking process and database update, unforeseen events, etc. The tests were well received by the participants, with curiosity and enthusiasm. The obtained and updated database is 100% reliable.

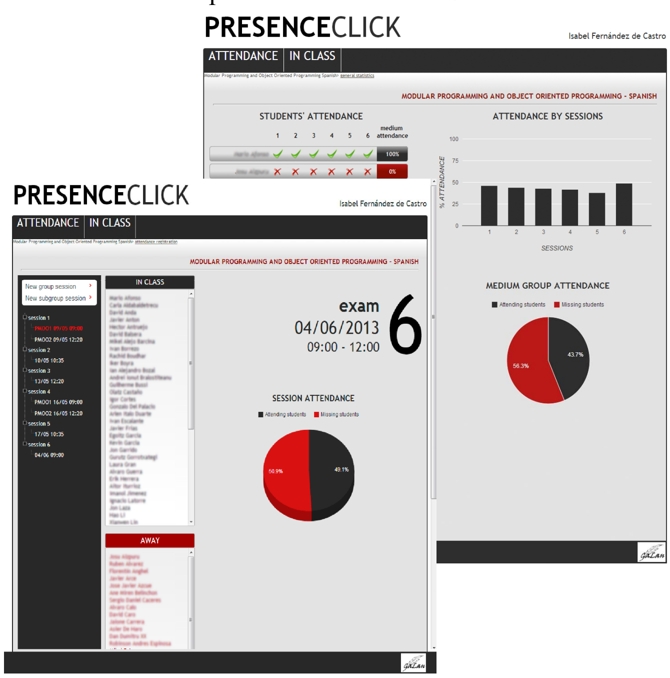

Fig. 7. Session and group interfaces for the Attendance module

The next objective is to incorporate this system in the daily routine for the first year students of the Computer Science Faculty at the University of the Basque Country. The experiment will be developed during the 2013-2014 academic year, with a device assigned to each classroom (6 to 8 devices will be needed). As the schedule will be already defined for each classroom (subject, teacher, students), the system will include automatically the students' attendance in the corresponding models, with no teacher participation. Although this tool is thought to be used just in time during presence sessions, it is also possible to use it offline to visualize or edit its information.

IV. Conclusion and Future Work

The final purpose of the work here presented is to build a tool that provide teachers with relevant information about each one of their students regarding their learning processes and knowledge status, with no workload increment. Concerning students, the tool will give them feedback about their learning progresses and the possibility of comparing their results with those of the class. This information will be obtained by exploiting different kinds of face to face interactions that arise in presence class, in a similar way to teachers use to do. These interactions will be recorded by teachers and students in a just-in-time manner. The designed tool is endowed with simple and agile authoring and recording means that allow defining and registering the learning aspects to be considered.

Up to now, we have designed a questionnaire for teachers to identify main functionalities of a software learning tool by means of an introspection process. A total of 69 Computer Science and Engineering teachers of three centres of the University of the Basque Country carried out this questionnaire. They expressed different needs related to the traditional learning method, i.e. face-to-face classes. The results of this survey have given us the basis for designing and implementing PresenceClick, a tool aimed to support teachers and students in F2F learning tasks. Currently, PresenceClick collects just-in-time the attendance information with no teacher effort, which is the first step in order to gather interactions arisen in class in an agile way. The agility of the system is a big premise aimed to decrease teachers' workload and get technology closer to non-digital natives.

The next evolution of PresenceClick will include advice module and the possibility for teachers to record just-in-time the students' interactions. We propose to give them the possibility to include valuable information in their Student Model about the tasks they do, and to express the learning aspects of the interactions to be recorded in F2F sessions. Planning and coordination will be also considered.

The Appalachian Cohort for Engineering: An Evaluation of S-STEM Strategies for Success

Valerie Young, David Juedes, Holly Raffle
Ohio University
Athens, OH, U.S.A.
youngv@ohio.edu

***Abstract*—The Appalachian Cohort for Engineering (ACE) at Ohio University is an NSF S-STEM funded scholarship program for students in Engineering and Computer Science that combines intensive early intervention approaches (i.e., learning communities, peer-led team learning, midterm progress reports, and purposeful selection of academic advisors) with peer advising and cohort building activities. The intent of this program is to help academically capable but financially insecure students from the economically disadvantaged Appalachian counties of Ohio and surrounding states to complete important early milestones in their academic careers. The ultimate goal of this project is to build evidence-based approaches for encouraging retention and early academic milestone completion for a broad range of undergraduate students in the STEM disciplines. The research component of this project seeks to determine which services are most effective at encouraging and supporting these students to reach early academic milestones to promote long-term retention and degree completion. This component involves substantial data collection that includes observational field notes and one-on-one contact records, along with the required NSF data elements. Much of the data collection is provided by trained peer advisors; capturing the following dimensions of academic wellness: personal/transitional, social, academic, financial, health and stress-coping, study sessions and tutoring, goal setting, follow up data, and academic reviews by course. In addition, field notes are collected that describe the setting, attendees, acts, and reflections on specific events that happen throughout the year. This project is in its first year of implementation. In this work-in-progress paper, we report on the design of the project, early successes and challenges, the data collection strategy, and the preliminary results of this project. In this first year, early observational results indicated that this body of students needed both social and academic support; with both being equal emphasis. Furthermore, this body of students indicated that one-on-one support and goal setting were important components of their early success.**

Category

Keywords—retention strategies; cohort building; peer advising

I. Introduction

Retention in the STEM disciplines is viewed as a significant problem nationwide. According to a recent report by the President's Council of Advisors on Science and Technology [1], "Fewer than 40% of students who enter college intending to major in a STEM field complete a STEM degree." Since nationwide production of STEM graduates is seen by many as crucial to continued economic growth in the U.S., improving retention rates among students who are initially interested in the STEM disciplines has become a national priority. With that being said, the factors involved in retention issues in the STEM disciplines are complex and multi-faceted, and local influences likely play an important role. At Ohio University, we face similar STEM related retention challenges and are in the beginning stages of project that aims to provide an understanding of these issues among our unique blend of students. Many of our strategies follow recommendations laid out in a recent STEM related retention study [2]. Our project is called the Appalachian Cohort for Engineering (ACE).

The ACE program is a collaborative effort including three Ohio University entities: the Russ College of Engineering and Technology (Russ College), the Voinovich School of Leadership and Public Affairs (Voinovich School) and the Office of Multicultural Student Access and Retention (OMSAR). Faculty from the Russ College serve as project leadership providing and coordinating recruitment, retention, and academic cohort building activities. Faculty from the Voinovich School provide technical assistance related to educational research and evaluation as well as cultural competence. Administrators and staff from OMSAR provide the backbone of the student support services.

This work-in-progress paper describes the design of the project, early successes and challenges, the data collection strategy, and preliminary results from this project.

II. Project Design

ACE is an NSF S-STEM funded scholarship program for students with demonstrated financial need who reside in the Appalachia and have chosen majors in Engineering or Computer Science. It is important to note that ACE is more than a scholarship, it is a *program.* Each student in the program receives a scholarship that covers roughly 80% of the yearly tuition at Ohio University. These scholarships are then renewable for up to four years under the condition that students achieve satisfactory academic progress, maintain a 3.0 GPA, and remain in a STEM major in the Russ College of Engineering and Technology.

Faculty and staff associated with the project provide a variety academic support programming for the students. The first component of the program is the *first year student learning*

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

community. In order to make sure that students are connected with their majors and the Russ College of Engineering and Technology, ACE students are required to enroll in a one-credit semester Learning Community course. These courses provide students with academic guidance regarding their specific major and provide students with an engaging atmosphere in which to meet and connect with other students in their academic major.

A second component of the program is the *All ACE Meetings*. To foster cohort building, ACE students were required to meet once a week as a group. The All ACE Meetings evolved over the first year. The first semester, the goal of the meetings was primarily cohort building and the activities were structured by the program staff. Beginning second semester, responsibility for planning the All ACE Meetings became a shared venture; the project staff planned half of the sessions and the ACE scholars planned half of the sessions. Throughout the year, the All ACE Meetings covered a variety of topics, including: co-op and internship opportunities, resources for academic success, curricular and career paths, entrepreneurship, and leadership opportunities within their majors. These discussions helped supplement and reinforce topics that were also covered during the Learning Community courses.

A third component of the program was *academic support*. ACE scholars were strongly encouraged to attend Supplemental Instruction (SI) and Peer-Led Team Learning (PLTL) sections of specific mathematics and science courses, when available. Furthermore, ACE scholars are paired with selected well-qualified academic advisors (faculty) who work with them on academic and career related issues throughout their academic careers. ACE students are evaluated by the instructors in their courses at the mid-point of each semester, and their academic advisors are provided with Academic Progress e-reports. Finally, ACE scholars had access to free tutoring from through OMSAR.

The final component of the program was *peer mentoring*. ACE students are required to meet once a week with a peer mentor who works with that student on academic, social, and other adjustment related issues. Student peer mentors associated with the ACE Scholars program received training through the OMSAR. The usual peer mentor training consists of a seven week program, where mentors receive two hours of training each week on a range of topics that explain the role of the peer mentor. (Our first peer mentors received a compressed version of this training, due to the late start of the project.) The topics covered include understanding diversity, supporting academic success, providing personal support, working as an advocate and ally for the student, providing social support, and the best practices for peer mentoring. The peer mentors are also provided with a 25 page training manual that covers many of the procedural aspects of the peer mentor program. Peer mentors also meet bi-monthly with OMSAR staff to debrief about the ACE scholars that they peer mentoring. In addition, the peer mentors meet monthly with Russ College and Voinovich School faculty to discuss any concerns or successes the ACE scholars may have as well as provide input on program planning.

III. Data Collection, AnALYSIS, and Relevant Research Questions

The initial cohort of ACE scholars consisted of 8 students from Appalachian counties in Ohio. The STEM disciplines chosen were as follows: Electrical Engineering (N = 1), Computer Science (N = 1), Industrial and Systems Engineering (N = 1), Mechanical Engineering (N = 1), Chemical Engineering (N = 2), and Civil Engineering (N = 2).

This project was approved by the Ohio University IRB, Protocol 12X147. ACE scholars were provided with an informed consent process prior to entering the program. All ACE scholars who were minors at the start of the program were required to have parental consent to participate in the program.

The evaluation design includes both formative and summative assessment, using a mixed-methods approach to describe and measure the progress of the ACE scholars as well as the ACE program. Quantitative measures include demographic profiles, student achievement data, and student questionnaires. Qualitative methodologies include observations, interviews, focus groups, and document review. The evaluation design facilitates interaction between qualitative and quantitative components and permits the close examination of both the processes associated with and the impact of the ACE program.

For this work in progress paper, the following data were utilized: data collected from a facilitated session with the ACE scholars and a document review of the first semester one-on-one meeting reports.

Artifacts from the facilitated session (i.e., chart paper activities and meeting notes) and one-on-one interviews were coded using MAX-QDA, a software package for qualitative data analysis [3]. Content analysis was used to analyze the information collected; Patton [4] describes content analysis as "searching for recurring words or themes." Text was analyzed to see what phrases, concepts, and words were prevalent throughout the data. During this stage of the analysis, coding categories were identified. Through the coding process, data were sorted and defined into categories that were applicable to the evaluation questions at hand. Codes were defined and redefined throughout the analysis process as themes emerged. At the end of the analysis, major codes were identified as central ideas or concepts, as explained in Glesne [5]. These central ideas were assembled by pattern analysis for the development of major themes. From the major themes, we drew conclusions. To ensure credibility of both the procedures and the conclusions, we used analyst triangulation. Patton [4] defines analyst triangulation as "having two or more persons independently analyze the same qualitative data and compare their findings." Teamwork, as opposed to individual work, is likely to increase the credibility of findings, as noted by Lincoln & Guba [6].

For the purposes of an early assessment, we examined the following evaluation questions:

1. What did students actually receive in terms of the ACE program? What were their primary activities? What did they experience? To what extent were those services culturally

competent? What was the evidence of cultural competence? How was the ACE program tailored to meet the needs of individual students?

2. What did the students like and dislike about the ACE program? Did they "buy into" the program's goals and intended outcomes?

IV. Early Challenges and Successes

Formative evaluation is essential with any new project. By utilizing qualitative data techniques, we were able to acquire and analyze data in real time to make course adjustments and corrections. With a strong focus on the evaluation questions, throughout the academic year, we were able to develop the program with feedback from the project team, faculty advisors, OMSAR staff, peer advisors, and the ACE scholars themselves.

As can be expected with any new project, we experienced a few initial challenges. For example, we experienced some early challenges related to *academic support*. Through the formative evaluation process, we realized that there was some disconnect between the college-wide advising provided to all incoming freshmen and the specific course expectations (e.g., PLTL sections of Chemistry) for the ACE students and their specific majors. This will be corrected in Year 2.

During the facilitated session with the ACE scholars we learned that the *peer advising* component was perceived to be very important to the scholars. They like to have a weekly meeting scheduled with their peer advisor as they found the reflection time helpful. That said, the scholars felt as if the meeting could be shortened to 30 minutes from an hour. We made that change for the second semester.

Having the peer advisors meet with the Russ College faculty advisors monthly was also a modification made using formative evaluation data. During the first semester, many of the faculty advisors had weekly contact with their ACE Scholars through the first year student learning community. It was realized early second semester that many of the faculty advisors would have little or no contact with their ACE scholars. As such, the faculty requested they meet with the peer advisors monthly to get updates on the "pulse" of the program. This strategy has proven to be very successful at keeping the faculty members engaged with the program.

The increased responsibility the ACE scholars took during second semester for the *All ACE meetings* was also a result of the formative evaluation process. After the facilitated meeting, it was evident that the ACE scholars had coalesced as a group. The project staff was also faced with the question: What would be the role of the Cohort 1 ACE scholars when the Cohort 2 ACE scholars came to campus in the fall? At the facilitated meeting, two main themes were uncovered: the ACE Scholars were (1) very interested in shaping the program and being connected with the future ACE scholars and (2) craving more "engineering specific" information. To meet both of those needs, the project staff decided to share the responsibility of preparing for the All ACE meetings with the ACE scholars. During second semester, project staff designed seven sessions to promote a greater understanding of the engineering opportunities available during college and beyond. For the remaining 7 sessions, the ACE scholars worked with the current peer advisors to develop 7 sessions that they would facilitate with the Cohort 2 ACE next academic year. This was well received by project staff, faculty advisors, and ACE scholars alike.

V. Conclusions

Overall, we believe that the experience provided for the first cohort of ACE scholars was a success. By the second semester, we succeeded in helping these students form a cohesive group who were able to talk and laugh with each other. Overall, retention of these students was good for the first year, with 75% (6) students achieving important academic milestones and remaining in their selected STEM programs. However, we did not retain one electrical engineering and one mechanical engineering student. The electrical engineering student chose to leave the university in order to pursue other career opportunities, whereas the mechanical engineering student decided to leave engineering and to pursue another major. We have collected the appropriate exit data to try to learn from these students who were not retained in STEM-related majors.

While only in the first year of a multi-year project, we are beginning to collect enough data through field observations and other means to create a picture of the diverse issues involving retention among the unique STEM-related student mix at Ohio University. Early results suggest potential retention strategies that we will discuss further in later works.

The Nature of Learning in a Guided Inquiry Classroom

Elliot P. Douglas, Jack Vargas, Claudia Sotomayor
Department of Materials Science and Engineering
University of Florida
Gainesville, FL
edoug@mse.ufl.edu

***Abstract*— Active learning approaches are becoming of increasing importance within engineering education, and it has been established that an active learning environment leads to improved student outcomes. What is less known is the ways in which these classes support student learning. Our study takes place in the context of a Process Oriented Guided Inquiry Learning (POGIL) classroom. We use grounded theory to answer the research question: How do students construct knowledge in a POGIL classroom? Constructivist grounded theory was used to code student interview data and develop a theory of how student learning occurs. The resulting theory shows that the use of POGIL results in a concept-focused class, as opposed to focusing on discrete aspects of knowledge (facts). This concept-focused class provides for both conceptual understanding and improved retention of information. The findings illustrate one way to design a class for deep conceptual understanding and suggest broader implications for curriculum design.**

***Keywords*— active learning, guided inquiry, grounded theory**

I. Introduction

Recently there has been an increasing awareness of the effectiveness of various types of active learning approaches. Within engineering, a number of active learning approaches have been developed, including cooperative and collaborative learning, problem-based classes [1-6], and guided design [5]. Prince & Felder have provided a comprehensive review of the effectiveness of various types of active learning methods, both within engineering and in education more generally [7]. Their review shows that, while there may be differences depending on the type of method chosen, the experience of the instructor, and the characteristics of the students, in general active learning techniques result in improved student outcomes, particularly when deep learning is the goal.

Various models of learning also support the use of active learning methods, including constructivism [8-10], social construction of knowledge [9,11], cognitive models of learning [7,12], and the learning cycle [13,14]. One particular approach that applies the learning cycle model is Process Oriented Guided Inquiry Learning (POGIL). Despite several studies that show the effectiveness of POGIL [15,16], there is little known about how student learning occurs in a POGIL classroom. The purpose of this study is to examine the ways individual students learn within this collaborative environment. Therefore, this study was undertaken to answer the following research question: How do students construct knowledge in a POGIL classroom? The focus was on the specific aspects of the class that they used for learning. This study does not address issues of the course design or implementation; these issues have been discussed in other papers [15,16].

II. POGIL Classroom

The POGIL approach was originally developed for the chemistry curriculum, and is now used in a variety of STEM disciplines including biochemistry, math, computer science, and materials engineering. In a POGIL class, the instructor does not lecture. Rather the goal of the class is to have the students develop their own understanding of the material through a set of guided questions. During class students work in groups to complete activities containing the following elements: 1) Data or information as background material; 2) Critical thinking questions, which are designed to lead the students to understanding the fundamental concepts represented by the data, and 3) Application exercises, which provide the students with practice in solving problems using the concepts they have derived. The instructor's role is to guide the students, walking around the room and probing them with questions to check their understanding.

III. Methods

This study was conducted at a small liberal arts college in the Rocky Mountain region of the US. All students (17 total) in a second semester general chemistry class were invited to participate. A total of 11 students agreed. Students were interviewed using a semi-structured interview format which focused on identifying aspects of the class that helped or hindered their learning. Students were compensated with US$20 in cash. Each interview lasted 20-30 minutes and was recorded. Students are identified with pseudonyms.

All interviews were transcribed verbatim. Analysis was conducted using the approach of constructivist grounded theory [17,18]. Analysis was conducted by coding each significant statement in the transcript with a brief descriptive tag. A typical transcript thus resulted in 50-70 individual codes. Initial codes were grouped into focused codes by identifying those codes which addressed similar issues, with reference to the original data as necessary. Focused codes were then examined to identify the theoretical codes that they represented, as well as the connections between focused codes. Again, the original data was consulted throughout this process. The resulting

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

connections were illustrated with a diagram that shows the grounded theory developed by the analysis. The trustworthiness of the analysis was ensured through the involvement of multiple researchers who worked together until a consensus was reached on the codes and their relationships.

IV. FINDINGS

Figure 1 shows the grounded theory resulting from the data analysis. The major finding is that the POGIL class is a concept-focused class which results in both improved retention of knowledge and a conceptual understanding of the material. Improved retention and conceptual knowledge are mutually reinforcing, with each benefiting the other. Additional aspects of the class provide the support needed to realize these goals.

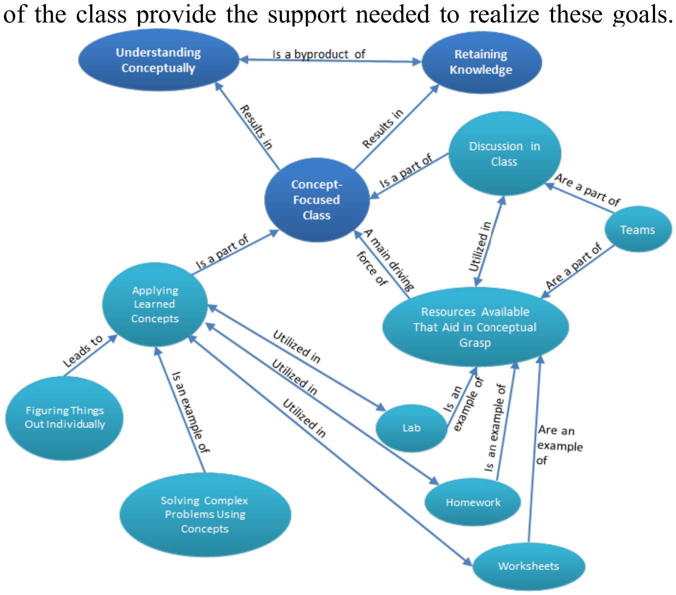

Fig. 1. Grounded theory of student learning in a POGIL classroom.

A. *Concept-Focused Class*

Fundamentally, students see the POGIL class as focused on concepts rather than facts. This approach to knowledge results in the other two theoretical codes, Understanding Conceptually and Retaining Knowledge. Students describe the class as heavily focusing on concepts and derivation of knowledge rather than on memorization and recitation. Tom contrasted the two types of learning: "It gets you thinking, thinking you know, the why, how. In my Linear Algebra class right now it's, you know, I just read the textbook and then kind of plug things in where they need to go and I don't always understand why and so it's kind of hard to ask more questions about a concept you don't, you know, understand why 100%. So with a greater understanding of the concept you can see how it relates to you know, anything else or in the real world."

B. *Understanding Conceptually*

"Understanding Conceptually" is a direct result of a concept-focused class, since students are exposed more to concepts than to memorization and recital. Cheri cited this as one of the key elements of this class, stating that an important element is "making sure you understand where the formulas come from before you use them and then being able to apply those." In this view, understanding conceptually is correlated to the ability to derive equations, and understanding behavior of certain interactions as opposed to simply memorizing them. Tom provides one specific example of this where he learned about equilibrium constants for acids and bases: "…like to come up with K_A for example, like first we found, we knew the equation for K_W and then we knew the equation for K_C and then we combined those to find like K_A and K_B for example, like to derive those equations."

C. *Retaining Knowledge*

"Retaining Knowledge" is also a direct result of a concept-focused classed, since the class takes a different approach to the retention of content. Instead of having students directly memorize certain concepts and be able to recite them, a concept driven class results in not only a deeper conceptual understanding of the subject, but also a more permanent retention of the knowledge acquired mainly because the students can, at any point, derive that knowledge themselves if needed. As pointed out by Brett, "Because it makes us think more about it and you know, and then I feel like when I figure it out for myself I understand it better and I don't just forget it when I walk out of the classroom." Patty added that "retention" goes beyond just remembering, it includes an active understanding of the material: "Because, I think if you just watch it or read it there's a lot more chance that you're going to zone out and you're not going to actually, you might think you know what's going on but when it comes down to actually doing it yourself when you get to the homework, you probably didn't." Retaining knowledge is therefore a by-product of conceptual understanding itself.

V. DISCUSSION AND CONCLUSIONS

The findings point to the power of the constructivist model of learning. In this setting, the learners recognized the benefits of social construction of knowledge. When Susan said "Like each one of us kind of throws out a brainstorming idea and like okay, yeah, that makes sense and then from there we'll try to approach it this way," she was talking about the initial social interaction. This social interaction led ultimately to what Vygotsky called inner speech [11], or as Anna put it "Because if we think of it ourselves then it's, I feel like it's more permanent." Through this inner speech students were able to achieve deep understanding of the material beyond simple memorization of disconnected bits of knowledge. Instead, they were able to create their own conceptual understandings. The findings also point to the power of the learning cycle in developing the deeper understanding required for "learning", and provide guidance as to what students see as needed to support that learning. The learning cycle is not the only approach to develop effective learning, but the findings here show that when it is applied it can result in deeper learning than a lecture class. In addition, while the findings were obtained in a POGIL classroom, they point to broader implications for pedagogical design. There are a number of similar approaches based on constructivist models of learning, including collaborative and cooperative learning, problem-based learning, and guided design. For any of these approaches, ensuring that the classroom is "turned", so that responsibility for teaching by the instructor becomes responsibility for learning by the student, is likely to lead to the same kind of deep learning observed here.

Development of a Reliable, Valid, Multi-Dimensional Measure of Student Engagement in Group Projects

Irena Bojanova
University of Maryland University College, Adelphi, USA, ibojanova@umuc.edu

***Abstract*—Student engagement is widely explored, but there is no specific measure of student engagement in group projects. This paper presents a Student Group Project Engagement Questionnaire (SGPEQ) instrument and discussed its reliability analysis, validity exploration, and further validity verification. Explanatory factor analysis revealed four dimensions of student engagement in group projects that were distinct and reliable: effort, teamwork, motivation, and organization. Relationships were found between these factors and self-reported engagement and endorsement of self-theories.**

Keywords—student engagement; group projects; measures' reliability and validity.

I. Introduction and Background

A. Measuring Student Engagement

"Student engagement is generally considered to be among the better predictors of learning" [3] and research on this construct date to the mid-1980s [16]. Search on student engagement research revealed there are higher education studies that assess student engagement at institutional and program level, such as: the Higher Education Research Institute (HERI) [6]; the National Survey of Student Engagement (NSSE) [15]; the Community College Survey of Student Engagement (CCSSE) [5]. There are also studies at course level and particularly for online courses. For example, Handelsman at al. developed a measure of in class college student engagement [9]; Molinari & Huonker studied student engagement in business school classes [14]; Robinson & Hullinger, studied student engagement in online classes [17]. However, no reliable and valid measure of student engagement in group projects was identified.

B. Student Engagement in Group Projects

Group projects are essential for graduate level programs and the question is not: Should we have graduate level group projects? The question is rather: How should we optimize students' learning experiences from group projects, as well as the projects' outcomes? Student experiences in immersive vs. traditional group projects were examined during two consecutive semesters in 2011 at University of Maryland University College (UMUC), and "student engagement in group projects" was identified as a distinguishable construct, worth to be studied further [1].

C. Developing a New Measure

Research on constructs that are relative to attitudes, emotions, and opinions involve the use of Likert-type scales [12]. To quantify a not directly measurable construct such as "engagement", a summated ratings scale was developed [1]. The scale has multiple items – each related to a quantitative measurement continuum, having no right answer, and being a statement that can be rated [18]. To capture the many potential dimensions of "student engagement in group projects", an inductive approach was applied. Focusing on student engagement definitions, students and faculty were asked to describe what engaged in group projects students *do*, *feel*, and *think*. The responses were used to develop a preliminary scale for a new Student Group Project Engagement Questionnaire (SGPEQ) instrument, which was further discussed and refined by a focus group. The preliminary SGPEQ is shown in Table I.

TABLE I. PRELIMINARY SGPEQ SCALE

To what extent do the following behaviors, thought, and feelings described you in this group project? Please rate each of them on the following scale: 1=Very little; 2=Some; 3=Quite a bit'; 4=Very much
Q1 Worked on project on regular basis
Q2 Put forth effort
Q3 Preferred to work on my own
Q4 Took detailed notes during discussion meetings
Q5 Wished my teammates were working harder than me
Q6 Completed all assigned tasks on time
Q7 Rehearsed for project presentation
Q8 Was motivated and enthusiastic
Q9 Found project activities relevant to my life
Q10 Thought about project activities between meetings
Q11 Found ways to make project interesting to me
Q12 Was inspired to learn and contribute
Q13 Felt presence of team members during meetings/ presentations (as if in person)
Q14 Found project academically challenging
Q15 Would like to have similar projects in other classes
Q16 Fulfilled the assigned role
Q17 Contributed to discussions with ideas and opinions
Q18 Got to know teammates' strengths
Q19 Had fun during team activities
Q20 Incorporated teammates ideas and opinions
Q21 Helped/ tutored teammates during project activities
Q22 Preferred team-work than working on my own
Q23 Experienced sense of discovery and accomplishment
Q24 Trusted teammates will do well on their project parts
Q25 Found ways to involve non-participating team members
Q26 Stepped in when a teammate was not performing (+ N/A option if everybody participated)
Q27 Was organized and prepared
Q28 Communicated clearly and effectively
Q29 Attended all group meetings
Q30 Applied critical thinking and problem solving
Q31 Did good work on my part
Q32 Was creative and productive
Q33 Developed leadership skills
Q34 Presented final research product clearly and effectively
Q35 Was confident we can learn and do well on the project

The presented in this paper research was conducted in 2012 and focused on the theoretical development of SGPEQ as a reliable, valid, multi-dimensional measure [10] of student engagement in group projects. A study on the SGPEQ initial data reliability and validity was conducted in accordance with established psychometric principles for use in survey research. Initial item reduction and factor identification [13] on SGPEQ was performed through exploratory factor analysis and examination of reliability estimates. The validity of the measure was further verified through a study on relationships between the SGPEQ factors and students' self-reported engagement and endorsement of self-theories [8].

II. The Study

A. Purpose

The purpose of the study was to assess SGPEQ reliability and internal consistency and establish criterion-related and construct validity for the measure to be usable with confidence for quantitative analysis.

B. Data

Students from 40 sections of Information and Technology Systems (ITS) courses were invited to participate. Data was gathered from 260 students (gender: 25% female, 75% male; age: 16% in 20-30, 35% in 31-40, 36% in 41-50, 10% in 51-60, 3% over 60 years old), which reflects the composition of the ITS UMUC student body. The overall response rate was 82%.

C. Method

First, a study on SGPEQ initial data reliability and validity was conducted. Then, initial item reduction and factors identification through exploratory factor analysis was performed. Finally, verification of validity through a study on relationships between the factors and students' self-reported engagement and endorsement of self-theories was obtained.

III. Initial Data Reliability and Internal Consistency

Reliability refers to the ability of a measurement instrument to give similar results for similar inputs. The IBM SPSS guide [9] elaborates that "Ideally, to obtain a good estimate of reliability, a survey should be administered twice to same group of people and then correlate the two sets of results." However, as some bias may be introduced the second time or students may not be willing or able to take the survey twice, often other solutions are needed. The IBM SPSS guide suggests "to compute Cronbach's alpha" or "to split the instrument into two and then to compare the results as if they were separate administrations of the same survey" [9].

Following these suggestions, the reliability analysis for SGPEQ was conducted based on two models: Cronbach's Alpha ("model of internal consistency, based on the average inter-item correlation") and Split-Half ("model that splits the scale and examines the correlation between the two parts") [9].

The Cronbach's alpha (0.940) and Split Half (0.894 | 0.884) values for SGPEQ confirms high level of reliability – Table II.

The presented research was completed in Spring and Summer 2012, under the sponsorship of the UMUC's Faculty Research Grant Program.

TABLE II. SGPEQ Reliability

Cronbach's Alpha	Cronbach's Alpha Based on Standardized Items	N of Items
.941	.945	35

Cronbach's Alpha			
	Split Half - Part 1	Value	.894
		N of Items	18
	Split Half - Part 2	Value	.884
		N of Items	17
	Total N of Items		35

The inter-item correlations also confirm suitability of the data for factor analysis, as 64% (783 from all 1225) inter-item correlations are larger than the recommended level of 0.30.

TABLE III. SGPEQ Inter-Item Correlation Matrix
(Note: Not al values are shown due to space constraints.)

…	…	…	…	…	…	…	…	…

a. Q3 is with inverted meaning.

IV. Explanatory Factor Analysis and Reliability Estimates

The SGPEQ factor structure was tested through explanatory factor analysis and construction of reliability estimates.

A. Item Reduction and Factors Identification

Principal axis factoring with Varimax rotation was performed on the 35 SGPEQ items. The questions were: "How many components (factors) are needed to represent the variables?" and "What do these components represent?"

Six-factor and four-factor extractions were performed via a principal components analysis with Kaiser's criterion, retaining only factors with eigenvalues of 1.0 or more; and Scree test plot of eigenvalues, retaining all factors above the "elbow".

The communalities extracted via Principal Axis Factoring are shown in Table IV. Initial communalities are "proportions of variance accounted for in each variable by the rest of the variables" [9]. "Extraction communalities are estimates of variance in each variable accounted for by the factors in the factor solution – small values indicate variables that do not fit well with the factor solution, and should be dropped from the analysis" [9].

The SGPEQ extraction communalities are acceptable, except the low value of Q26 shows it should be dropped; the lower values of Q20 and Q29 (in both factor solutions) show they do not fit as well as the others. Note that mean responses for Q26 – 10.6%, 19.3%, 12.9%, 25.0%, 32.2% – show the "N/A" option is not defining for the low communalities.

TABLE IV. SGPEQ COMMUNALITIES

Question	Six-Factor Solution		Four-Factor Solution

Q35	.569	.488	.569	.451

Low values in both factor solutions are shown in bold

The total variances explained are shown in Table V. For the six-factor solution, 12 iterations were required. The first part shows "the variance explained by the initial solution" [9]. There are only six factors in with eigenvalues greater than 1; altogether they account for 65% of the variability in the original variables. This suggests that six latent influences are associated with student engagement in group projects, but there remains room for a lot of unexplained variation. The second part shows "the variance explained by the extracted factors before rotation" [9]. The cumulative variability explained by these six factors in the extracted solution is 58%. This is a difference of 7% from the initial solution, which means that 7% "of the variation explained by the initial solution is lost due to latent factors unique to the original variables and variability that simply cannot be explained by the factor model" [9]. The last part shows "the variance explained by the extracted factors after rotation" [9]. The rotated factor model makes adjustments to factors 1, 2 and 3; some small adjustments to factors 4 and 5, but factor 6 is left virtually unchanged – the changes between the unrotated and rotated factor % of variance show how the rotation affects the interpretation of the 1 to 5 factors. The picture is better with the four-factors solution, for which 5 iterations were required.

The six- and four-factor matrices, extracted by Principal Axis Factoring, are shown in Table VI. The relationships in the unrotated six-factor matrix, show that only some questions are associated to only one factor – for example, Q8 has only factor 1 greater than 0.2. However, there are a lot of questions that have correlations greater than 0.2 with multiple factors, which muddies the picture. A rotation is used to clear it up – "a rotation method gets factors that are as different from each other as possible, and helps interpret the factors by putting each variable primarily on one of the factors" [9].

Q3 is with inverted meaning

The rotated six-factor matrix is computed from the original (unrotated) factor matrix using Principal Axis Factoring as extraction method and Varimax with Kaiser Normalization rotation method, where rotation converged in 7 iterations. However, the relationships in the unrotated four-factor matrix and the rotated four-factor matrix, where rotation converged in 7 iterations, shows clearer and better interpretable picture.

Based on the analysis of the six- and four-factor solutions and the inspection of a scree plot (please refer Fig. 1), four factors were retained. After four factors, interpretability of factors was difficult, confirmed by the scree plot slope decreasing by only a small amount after four factors. The four factors accounted for 59.15% of the variance. The first factor consisted of 12 items that were labeled “Effort” (19.69% of the variance) – "Did good work on my part", "Communicated clearly and effectively", "Was creative and productive", etc. The second factor consisted of 10 items that were labeled “Teamwork” (14.04% of the variance) – "Had fun during team activities",

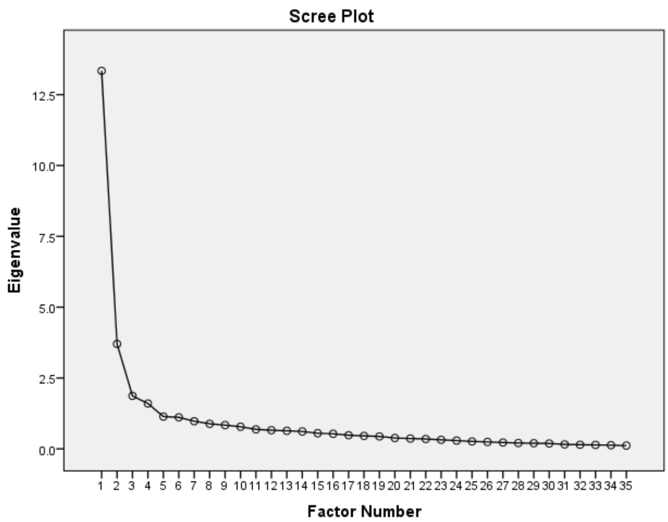

Fig. 1. Scree Plot

"Trusted teammates will do well on their project parts", "Felt presence of team members during meetings/ presentations (as if in person)", etc. The third factor consisted of six items that were labeled “Motivation” (11.69% of the variance) – "Thought about project activities between meetings", "Was inspired to learn and contribute", "Found ways to make project interesting to me", etc. The fourth factor consisted of six items that were labeled “Organization” (8.23% of the variance) – "Helped/ tutored teammates during project activities", "Found ways to involve non-participating team members", "Took detailed notes during discussion meetings", etc. Table VII shows the factor solution and the items (questions) for each factor. Only one question, “Q26 Stepped in when a teammate was not performing”, was dropped due to low communality and low loading on all factors.

B. Factors Reliability and Preliminary Validity

The four SGPEQ factors show reasonable reliability (Cronbach's alphas are .926, .838, .889, .766) and the inter-factor correlations (the highest is .088) support the discriminant validity of the measure – Table VIII.

TABLE VIII. SGPEQ FACTORS CORRELATIONS

	Factor 1	Factor 2	Factor 3	Factor 4
Factor 1	1.000	.004	.039	.072
Factor 2	.004	1.000	.088	.035
Factor 3	.039	.088	1.000	.064
Factor 4	.072	.035	.064	1.000

V. FURTHER VERIFICATION OF VALIDITY

SGPEQ validity was further verified through a study on the relationship between the identified factors and students’ self-reported engagement and endorsement of self-theories. The questions were added to the same SGPEQ instrument.

A. Self-Reported Engagement

Factors predicting absolute engagement (engagement in this group project) and relative engagement (engagement compared with other group projects) were determined. For that two analyses that regressed each of the two dependent variables on the four factors of SGPEQ were performed.

- *Absolute engagement*

Dependent variable: “How engaged were you in this group project? (1=not at all, 6=extremely).”

Regression of relative engagement on the four factors shows that the factors account for 63.1% (R Square in Table IX) of the variance in absolute engagement; 70% of absolute engagement was explained by the model: $F(4, 166) = 70.81$, $p < .001$ (F and Sig. from ANOVA table). Factor 1 “effort” (β = .611); Factor 2 “teamwork” (β = .174); Factor 3 “motivation” (β = .325); Factor 4 “organization” (β = .236) are all positive predictors of absolute engagement. ANOVA tests the acceptability of the model from a statistical perspective – a significant F statistic, indicates that using the model is better than guessing the mean.

TABLE IX. MODEL SUMMARY, ANOVA, COEFFICIENTS (ABSOLUTE ENGAGEMENT)

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.794	.631	.622	.66386

ANOVA: Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	124.841	4	31.210	70.817	.000
	Residual	73.159	166	.441		
	Total	198.000	170			

Model		Unstandardized Coefficients		Standardized Coefficients
		B	Std. Error	Beta
1	(Constant)	4.988	.051	
	REGR factor score 1	.686	.053	.611
	REGR factor score 2	.206	.056	.174
	REGR factor score 3	.395	.058	.325
	REGR factor score 4	.290	.058	.236

Relative engagement

Dependent variable: "How engaged were you in this group project compared to other group projects you worked on during the same semester? (1=less engaged, 6=more engaged)".

Regression of relative engagement on the four factors shows that the factors account for 44% of the variance in relative engagement (R Square in Table X); 33% of relative engagement was explained by the model: $F(4, 166) = 32.54$, $p < .05$. Factor 1 "effort" ($\beta = .387$); Factor 2 "teamwork" ($\beta = .259$), Factor 3 "motivation" ($\beta = .326$), Factor 4 "organization" ($\beta = .233$) are all positive predictors of relative engagement.

TABLE X. MODEL SUMMARY, ANOVA, COEFFICIENTS (RLATIVE ENGAGEMENT)

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.663	.440	.426	1.00489

ANOVA: Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	131.614	4	32.903	32.584	.000
	Residual	167.626	166	1.010		
	Total	299.240	170			

Model		Unstandardized Coefficients		Standardized Coefficients
		B	Std. Error	Beta
1	(Constant)	4.624	.077	
	REGR factor score 1	.534	.080	.387
	REGR factor score 2	.377	.085	.259
	REGR factor score 3	.487	.088	.326
	REGR factor score 4	.352	.088	.233

B. *Incremental and Entity Self-Theories*

Dependent variable: "You have a certain amount of intelligence and you cannot do much to change it. (1=do not agree, 6=strongly agree)"

Regression of belief in incremental theory on the four factors shows that the factors account for 59% (R Square in Table XI) of the variance in absolute engagement; 3% of the variance in incremental theory beliefs was explained by the factors: $F(4, 166) = 2.6$, $p < .001$. Factor 2 "teamwork" ($\beta = .141$) and Factor 4 "organization" ($\beta = .171$) are positive predictors of belief in incremental theory. Factor 1 "effort" ($\beta = .024$) is probably too small to be considered a predictor. Factor 3 ($\beta = -.112$) shows "motivation" is not a predictor of belief in incremental theory.

The results indicate that effort, teamwork, motivation, and organization are all related to self-reported global ratings of absolute and relative engagement. However, while teamwork and organization are related to incremental self-theories, effort is almost not related to it and motivation is surely not related to it.

TABLE XI. MODEL SUMMARY, ANOVA, COEFFICIENTS (INCREMENTAL AND ENTITY SELF-THEORIES)

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.244	.059	.037	1.52935

ANOVA: Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	24.476	4	6.119	2.616	.037
	Residual	388.260	166	2.339		
	Total	412.737	170			

Model		Unstandardized Coefficients		Standardized Coefficients
		B	Std. Error	Beta
1	(Constant)	2.160	.117	
	REGR factor score 1	.038	.122	.024
	REGR factor score 2	.241	.130	.141
	REGR factor score 3	-.196	.134	-.112
	REGR factor score 4	.302	.134	.171

VI. CONCLUSION

The conducted research resulted in creation of a reliable, valid, multi-dimensional measure of student engagement in group projects (SGPEQ) – Table XII. Evidence was found of four interpretable and internally consistent factors: effort, teamwork, motivation, and organization. The low correlations between variables suggested initial evidence for discriminant validity of the measure. Evidence of convergent and discriminant validity was obtained by relating SGPEQ scores with students' self-reported engagement and self-theories – it was confirmed that students who are engaged in learning, presumably believe this engagement will increase their capacity for learning. Evidence was obtained also for the reliability of the measure – all factors have reliabilities above recommended level. As a result, empirical evidence of the usefulness of SGPEQ was obtained, so it can be easily administrated while providing a comprehensive snapshot of students' engagement in group projects.

The SGPEQ instrument can be utilized as a diagnostic tool. Group project results from one course section can be benchmarked against those of other course sections. Benchmarking can be done against sections taught by the same faculty, by other faculty, by all faculty teaching the same course, or by all faculty teaching in the department. Then benchmarking can be further detailed for each of the four SGPEQ factors, and for each of the items comprising each factor, to get additional insight into student engagement and take actions to improve performance in next group projects. The SGPEQ instrument can be utilized and comparisons can be done on class, department, school, university, and even country level.

TABLE XII. VALIDATED SGPEQ SCALE

To what extent do the following behaviors, thought, and feelings described you in this group project? Please rate each of them on the following scale: 1 = Very little; 2 = Some; 3 = Quite a bit'; 4 = Very much
Effort
Did good work on my part
Communicated clearly and effectively
Was creative and productive
Was organized and prepared
Fulfilled the assigned role
Presented the final research product clearly and effectively
Contributed to discussions with ideas and opinions
Applied critical thinking and problem solving
Completed all assigned tasks on time
Attended all group meetings
Put forth effort
Developed leadership skills
Teamwork
Had fun during team activities
Trusted teammates will do well on their project parts
Felt presence of team members during meetings/ presentations (as if in person)
Got to know teammates' strengths
Preferred team-work than working on my own
Would like to have similar projects in other classes
Experienced sense of discovery and accomplishment
Was confident that we can learn and do well on the project
Incorporated teammates ideas and opinions
Preferred to work on my own
Motivation
Thought about project activities between meetings
Was inspired to learn and contribute
Found ways to make project interesting to me
Found project activities relevant to my life
Found project academically challenging
Was motivated and enthusiastic
Organization
Helped/ tutored teammates during project activities
Found ways to involve non-participating team members
Took detailed notes during discussion meetings
Rehearsed for project presentation
Wished my teammates were working harder than me
Worked on project on regular basis

Kyle, USA

***Abstract*—Three educational institutions in South Dakota are collaborating to develop pre-engineering courses to increase the enrollment and success of students transferring from Oglala Lakota College (OLC) to 4-year bachelor degree programs in science and engineering at South Dakota School of Mines and Technology (SDSMT) and South Dakota State University through a grant from the National Science Foundation Tribal Colleges and Universities Program (TCUP). Activities of this grant have led to a partnership with the native-led Thunder Valley Community Development Corporation (TVCDC) and have provided significant opportunities for students at OLC and SDSMT in the areas of civil engineering and sustainability. The most recent opportunity includes incorporating TVCDC's plans for an 800-person net-zero regenerative community on the Pine Ridge Indian Reservation into the Capstone Design course at SDSMT. The project includes sustainable design objectives in wastewater treatment, rainwater harvesting, and the use of straw bale and compressed earth walls as renewable building materials for phase I of the planned community. Four teams of students working on the regenerative community and four teams of students working on a more traditional capstone design project completed proposals and their first progress reports during the Fall 2012 semester. The Comprehensive Assessment of Team-Member Effectiveness (CATME) instrument was administered twice during the semester to evaluate team functioning. A comparison of the data for the two capstone projects is presented. Results from these surveys indicate students working on the regenerative community project were more positive and consistent with the behavioral and satisfaction categories within the peer evaluation survey.**

Keywords-Capstone Design; regenerative community, CATME peer evaluation

I. Introduction

The Pre-Engineering Education Collaborative is an effort by Oglala Lakota College (OLC), South Dakota State University (SDSU), and the South Dakota School of Mines and Technology (SDSMT) to develop a pre-engineering curriculum that will enable students graduating from OLC with associate degrees to transfer to 4-year engineering programs at the junior level. Summer research and service learning projects are incorporated into the program to provide a hands-on introduction to science and engineering topics, promote community service, and to stimulate student interest and motivation to pursue engineering. One of the specific project goals is to transform classical engineering program curricula to follow the constructivist philosophy of learning through vertical integration of the first two years of introductory engineering topics.

University-level curricular materials have typically been designed to improve understanding of topics in a linear but not interrelated or integrated fashion. The linear cognitive development model [1] has become a very popular and well used model within STEM disciplines, while Bloom's Taxonomy [2] has provided the active-voice language for developing, assessing, and evaluating the success of STEM programs of study in the linear cognitive development model [3]. STEM curriculum design has also typically followed the linear development pattern of a Piagetian [1] theoretical framework [4]. That is, material designed to specifically improve understanding in one area typically is not assessed for its impact on other areas.

In contrast to the Piagetian learning model, other researchers [5] focused on the structure of the field explaining that the "grasping of the structure of a field" is understanding it in a way to permit many other meaningful relationships to be established. Student learning experiences need to be facilitated in a manner that allows them to construct complex interrelated understandings of STEM fields. The development of knowledge is a complex process including stimulation, reflection, abstraction, and experimentation [4] [6]. In general, constructivist pedagogy emphasizes the importance of knowledge gained through experience [7]. Also, it has been stressed that one of the most important ideas is that students must construct their own knowledge structures and that basically correct preconceptions can be used to help the student learn [8]. Thus, the integration of learning activities is important because mastery of the fundamental ideas of a field involves both the grasping of general principles and the development of an attitude toward learning and inquiry, guessing and hunches, and the possibility of solving problems on one's own [5].

A partnership between the OLC/SDSU/SDSMT Pre-Engineering Education Collaborative (OSSPEEC) and the Thunder Valley Community Development Corporation (TVCDC) has provided an opportunity to vertically integrate the Civil and Environmental Engineering design process through a proposed 800-person regenerative community. Phase 1 of the development was used to provide real-world civil engineering design problems set in a sustainability framework at SDSMT during the Fall 2012 semester. An effective and unique integration will be achieved as the service learning and research projects continue through OSSPEEC and the regenerative community is introduced in engineering and sustainability courses taught at OLC and SDSMT. We describe the successes observed through completion of the Fall 2012 semester Capstone Engineering I course at SDSMT as

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

measured by the Comprehensive Assessment of Team-Member Effectiveness (CATME) instrument [9] and discuss the results.

II. Capstone Design Projects

Students were given two project statements created during the Fall 2012 semester for Capstone Design to choose from: Phase 1 at Thunder Valley, and a proposed Research Building on SDSMT's campus. Introductory descriptions of the projects as presented to students from which they based their preferences in August of 2012 are included below.

A. Thunder Valley Regenerative Community (TVRC)

The Thunder Valley Community Development Corporation is developing an 800-person community ¼- mile north of Sharps Corner, SD (~70 miles SE of Rapid City). Objectives of the development include creating a net-zero community through maximizing water reclamation and energy efficiencies. An architectural rendering of the development is shown in Figure 1. Phase I of the development includes construction of five single-family houses, a Youth Empowerment Center, and two apartment buildings. The initial development phase will accommodate 70-100 people. All design concepts must be scalable to meet the needs of the final 800-person community. Design tasks must consider principles of sustainability, life cycle costs, and environmental impacts and include a cost estimate for construction. Design aspects of the project include:

- Design treatment systems for waste and greywater. Various innovative and sustainable methods will be compared between different design teams.
- Design rainwater harvesting and greywater recycling systems and identify applications for the recycled water (e.g., greenhouses, greenway).
- Design of a water distribution system
- Design of storm water and erosion control systems
- Site layout and roadway design. Concrete, pervious concrete, and asphalt pavements will be considered.
- Structural design of the Youth Empowerment Center. Steel and wood structures will be compared between different teams.
- Foundation design of the Youth Empower Center. Deep and shallow foundations will be compared between different teams.
- Employment of LEED design principles.

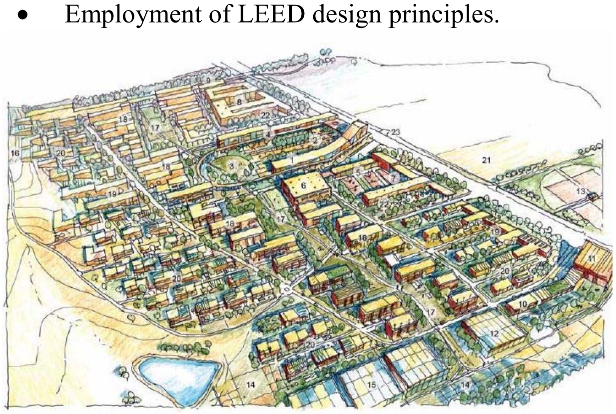

Figure 1. Thunder Valley Regenerative Community

B. SDSMT Research Building (SRB)

The South Dakota School of Mines & Technology is developing plans for a \$40-60 million, 120,000 ft^2 3-story research facility in support of the university's growing research efforts. The building will be located somewhere on campus (Figure 2. . Key features of the research facility design are: a central area with a meeting location; a central auditorium with a 600 person capacity; separate institute areas with clusters of specific institute-associated research laboratories; and a single cluster of institute directors' offices with joint administrative staff areas.

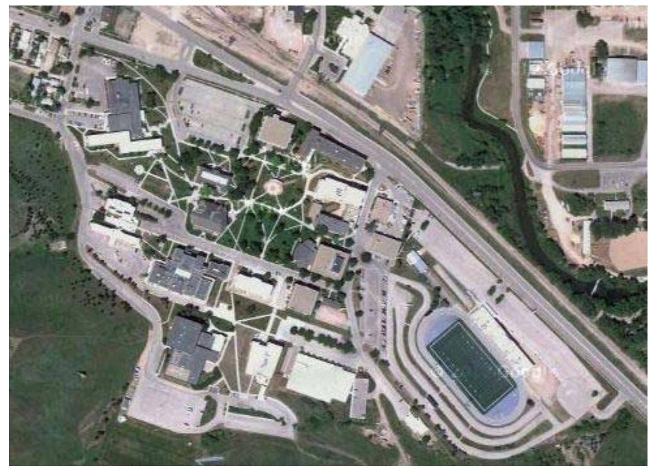

Figure 2. SDSMT Campus

Designs must consider principles of sustainability, life cycle costs, and environmental impacts and include a cost estimate for construction. Aspects of the project include:

- Site selection considering the recently published campus master plan and other factors.
- Design of rainwater harvesting and greywater recycling systems and identification of applications for the recycled water.
- Design the water piping system
- Design storm water and erosion control systems
- Site layout and parking area design. Concrete, pervious concrete, and asphalt pavements will be considered.
- Structural design of the research building. Steel and concrete structures will be compared between different teams.
- Foundation design of the research building. Deep and shallow foundations will be compared between different teams.
- Apply LEED design principles.

C. Team Assignments

The instructor assigned teams based on student's heterogeneous GPA which was obtained from transcripts and homogeneous interest in the project based on their initial preferences. This method of assigning groups resulted in better attitudes at the end of similar courses [10]. The instructor applied a third criterion distributing student contributions to a multi-disciplinary teaming component across the four teams.

Four teams for each project were assigned and are shown in TABLE I. The number of declared disciplines shown represents all areas of Civil Engineering students were interested in and therefore can exceed the number of team members.

TABLE I. CAPSTONE DESIGN TEAM ASSIGNMENTS

Team	Team Members	Average GPA	Number of Declared Civil Engineering Disciplines: Environmental	Water Resources	Geotechnical	Structural	Project Preference: SRB	TVRC
SRB-1	4	3.00	1	1	1	4	3/4	
SRB-2	5	2.88			2	2	4/5	
SRB-3	5	2.93		1	2	3	5/5	
SRB-4	5	3.05		1	2	2	3/5	
TVRC-1	4	3.45	1	2	1	1	2/4	2/4
TVRC-2	4	3.27	2	2		2	1/4	3/4
TVRC-3	4	3.43	2	2		1	1/4	3/4
TVRC-4	4	3.18	1	3	1	1	1/4	3/4

The GPA disparity for the two teams was greater (53% vs. 12% higher) for women than the class as a whole. Five of the 35 students enrolled in the Capstone Design course were women, three of which selected the TVRC project as their preference. Female student average GPA was 53% higher than the students preferring the SRB project. The average GPA for students preferring the Thunder Valley project was 12% higher than those for the SRB teams. All SRB team members received their preferred project or indicated no preference, while five students were assigned to TVRC teams had a preference for the SRB project.

III. DATA

Independent and pair-wise comparisons of student responses to the CATME behavioral categories [12] and the team satisfaction [13] results were performed using SPSS software [11]. Levene's test was used to test the assumption of equal variance before performing the t-tests. Pre-test TVRC student behavior (M = 4.3, SD = 0.33) was significantly different from the SRB group behavior (M = 3.9, SD = 0.47) at the 99% confidence interval, $t(33) = 2.9$, $p = 0.006$. Pre-test TVRC student satisfaction (M = 13.7, SD = 1.74) was not significantly different from SRB group satisfaction (M = 12.2, SD = 2.45) at the 99% confidence interval, $t(31) = 2.0$, $p = 0.051$. Post-test TVRC student behavior (M = 4.5, SD = 0.24) was significantly different from the SRB group behavior (M = 3.9, SD = 0.39) at the 99% confidence interval, $t(33) = 4.9$, $p < 0.000$. TVRC student satisfaction (M = 13.9, SD = 1.95) was significantly different from the SRB group satisfaction (M = 11.2, SD = 2.91) at the 99% confidence interval, $t(31) = 3.1$, $p = 0.004$. Pairwise comparisons between pre and post-tests for the TVRC and SRB groups were not significant at the 99% confidence interval, $t(15) = 0.59$, $p = 0.56$, $t(15) = -1.565$, $p = 0.138$. These data are summarized in TABLE II.

IV. ASSESSMENT RESULTS

The CATME Smarter Teamwork is a web-based instrument that allows instructors to effectively manage and assess student teams [9]. The standard peer evaluation method was used with five questions related to the following behavioral characteristics: 1) Contributing to the Teams Work, 2) Interacting with Teammates, 3) Keeping the Team on Track, 4) Expecting Quality, and 5) Having Related Knowledge, Skills, and Abilities [12]. Students were asked to rate themselves and their teammates based on a description of behaviors provided. An example with fictitious names is shown in Figure 3.

TABLE II. CATME RESPONSE COMPARISON SUMMARY

	Pre-survey		Post-Survey	
Student Behavior	M	SD	M	SD
TVRC	4.3	0.33	4.5	0.24
SRB	3.9	0.47	3.9	0.39
Student Satisfaction				
TVRC	13.7	1.74	13.9	1.95
SRB	12.2	2.45	11.2	2.91

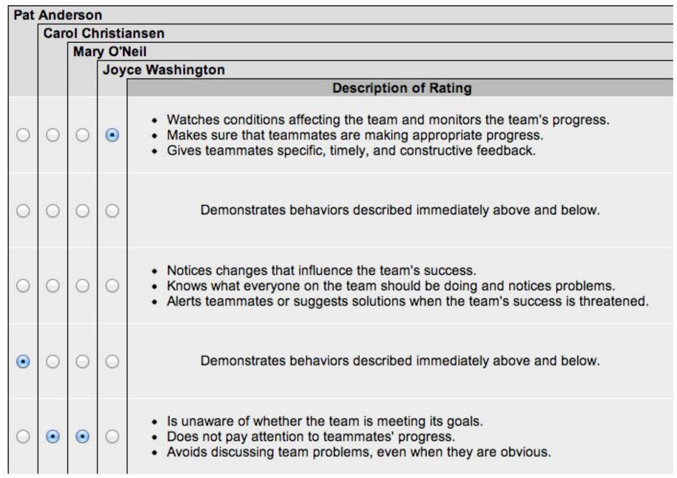

Figure 3. CATME Behavior Description Example

We administered two Peer Evaluation surveys during the semester. We assigned the first evaluation after the proposal (pre-survey) during week seven of the semester. The second evaluation was assigned after the progress report writing assignment (post-survey) during week 14 of the semester. Response rates were 91% (34/37) for each survey.

Three team satisfaction questions were included in the teaming assessment in addition to the behavioral questions described above: 1) I am satisfied with my present teammates, 2) I am pleased with the way my teammates and I work together, and 3) I am very satisfied with working in this team [13]. Responses were measured using a five-point Likert scale.

A. Behavioral Characteristics

Averages team ratings on a scale of 1-5 for the 5 behavioral categories for all students in a group were used to evaluate the differences between SRB and TVRC teams for the two peer evaluations. Error bars are reported with plus/minus two standard errors. Results for peer evaluations 1 and 2 are shown in Figure 4. and Figure 5.

The results indicate the TVRC group was more committed to teaming in both the pre- and post-tests. However, this difference only became significant in the post-test as students as a whole scored themselves slightly higher on average and as the variance decreased.

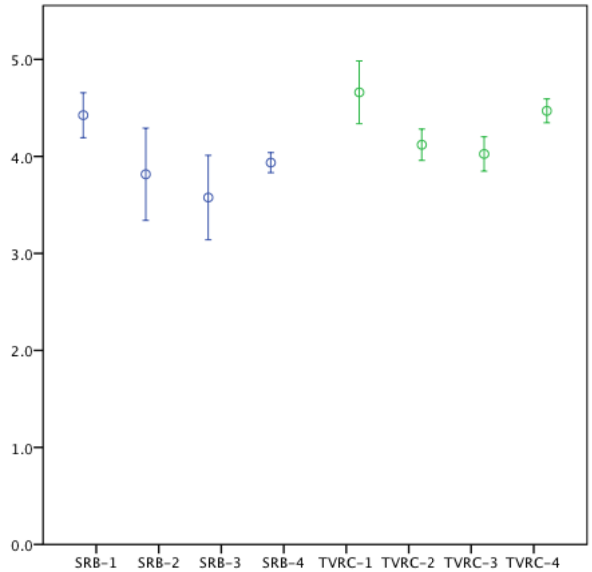

Figure 4. Average Behavioral Characteristics – Pre-Survey

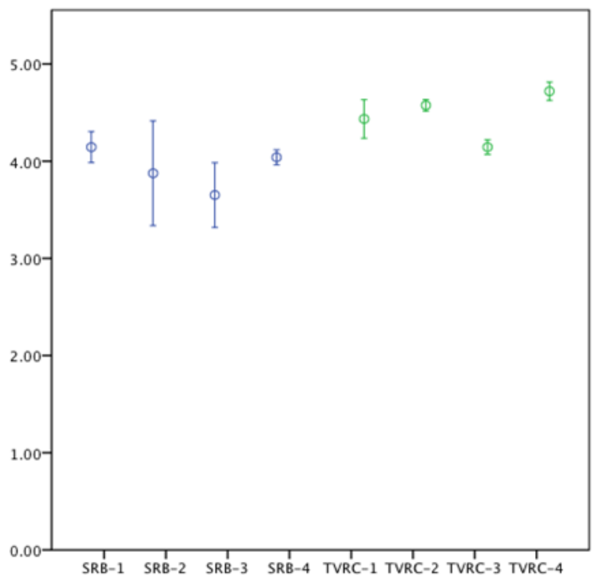

Figure 5. Average Behavioral Characteristics – Post-Survey

B. *Team Satisfaction*

The average scores for each of the three questions were added together for the team satisfaction evaluation, resulting in a maximum score of 15 (1-5 points for each question). Results for pre- and post-surveys are shown in Figure 6. and Figure 7.

TVRC group average scores were higher in the pre-test, but the difference was not statistically significant. TVRC group average scores were statistically higher in the post-test. The overall SRB group became less satisfied by the post-test, while the TVRC group became slightly more satisfied on average. The differences among groups at the post-test were significant.

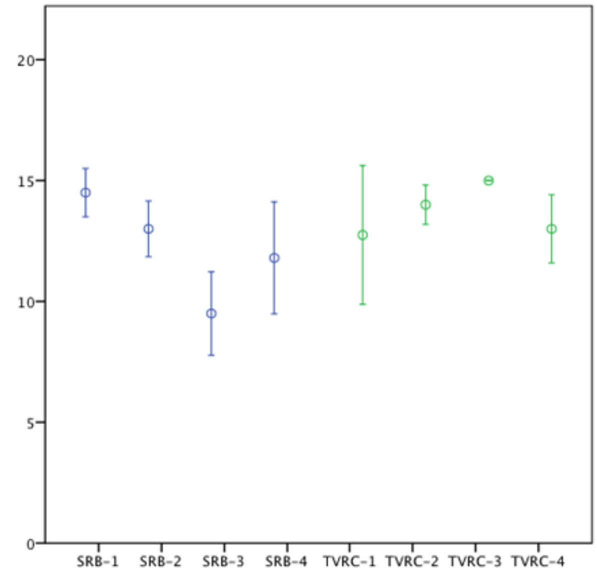

Figure 6. Average Team Satisfaction – Pre-Survey

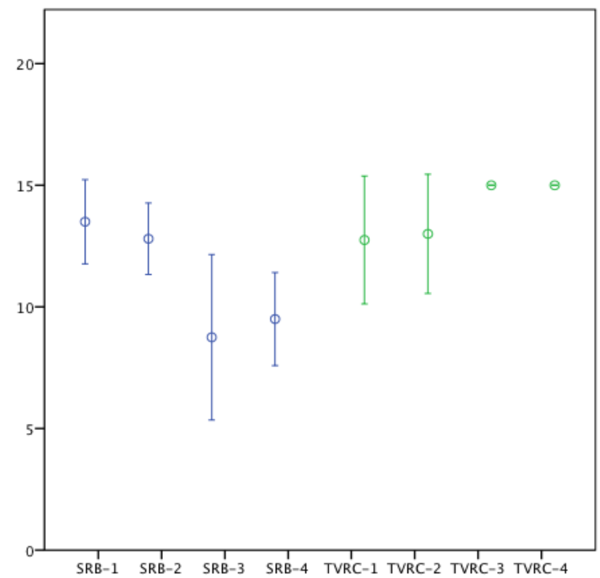

Figure 7. Average Team Satisfaction – Post-Survey

V. DISCUSSION

Engineering has been defined as the application of science for the benefit of humanity [14]. The results of the CATME behavioral and satisfaction surveys demonstrate that factors exist beyond the integration of learning activities in the construction of knowledge structures. Both the Thunder Valley Regenerative Community (TVRC) and the School of Mines Research Building (SRB) design projects contain constructivist elements. However, the TVRC project has an additional element of a clearly defined community that will benefit from the design. Students who worked on the TVRC project demonstrated responses consistent with altruistic behavior such as: increased satisfaction, a greater sense of accomplishment, and a more positive view of others. These behavioral and perceptual differences became more pronounced throughout the year-long project. The results may demonstrate the importance of providing students engaged in service learning with a clearly defined community that receives the service may be an important factor in student engagement in constructivist-based service projects.

These challenges required students to apply design principles on a larger scale and broader context than what they had experienced during their junior-level coursework. A small-group instructional diagnosis performed by a faculty member not associated with either Capstone Design Project revealed students were not comfortable extending this knowledge and suggested more technical feedback and focus would assist them in their learning. It is unclear how these challenges influenced the CATME Peer Evaluations.

Although both capstone design projects had similar design components and problem statements, it should be noted, different challenges for each project developed during the semester. Design tasks that fell outside of junior-level coursework for the Thunder Valley Regenerative Community included the use of a wetlands treatment option for wastewater and rammed earth and straw bale construction materials for the design of one of the residential structures. Additionally, laying out transportation and water infrastructure for a scalable community with up to 800 residents was challenging for students. Architectural drawings were available for the residential structure; however engineering coordination had not taken place and inconsistencies and incorrect information existed in the drawings. For the SDSMT Research Building, the largest challenge included laying out the building and research spaces that were only generally described in the University Master Plan. Architectural drawings were not available for the proposed building and information was only provided by a guest speaker with a career of industrial experience related to the subject. A second challenge was the land-space needed to meet parking requirements for the 600 person auditorium.

VI. SUMMARY

The OSSPEEC program is a collaborative effort between OLC, SDSU, and SDSMT to develop pre-engineering courses at OLC and to advise students in service-learning and research projects on the Pine Ridge Indian Reservation. One of the objectives of this program is to vertically integrate the design process beginning in the entry-level engineering courses, continuing through service-learning and research projects, and culminating in the Capstone Design course. A partnership established with the Thunder Valley Community Development Corporation has enabled the inclusion of an 800-person sustainable community development as one of two projects used for the Civil and Environmental Engineering Capstone Design course during the Fall 2012 semester. Results from two CATME Peer Evaluation Surveys indicate students working on the regenerative community project were more positive and consistent with their peer ratings and overall satisfaction.

Student Beliefs about Learning Communication Skills

Kelly Cross, Marie Paretti and Holly Matusovich
Virginia Tech
Blacksburg, VA

***Abstract*—Communication remains an essential skill for engineering graduates in both academic and industry settings, and ABET considers it a key student learning outcome for accreditation. Despite numerous studies of effective approaches to integrating communication into disciplinary courses, few engineering courses apply those approaches. To address this gap, we have undertaken a multi-year mixed methods study to explore faculty and student beliefs about communication. Faculty beliefs have been reported elsewhere; this paper focuses on student beliefs. We analyzed five focus groups conducted with engineering students at partner schools. The focus groups sought to uncover students' beliefs about where and how they learned communication skills within their engineering education. Focus groups were recorded and transcribed verbatim, then coded using standard open-coding procedures. The findings indicate that while students do have opportunities to practice communication in engineering courses, they may not always have optimal opportunities to learn communication in those courses. Most notably, students desired more examples and direct instruction for communication skills, including not only samples of "good" documents but also explanations about why they were good. Identifying pedagogical gaps between faculty practice and student experiences can help us develop targeted strategies to help creatively integrate these critical skills into an already packed engineering curriculum.**

Keywords—communication; situated learning; student beliefs

I. INTRODUCTION

Communication remains an essential skill for engineering graduates in both academic and industry settings, and ABET considers it a key student learning outcomes for accreditation. Despite recognition of the importance of this skill, however, gaps in teaching persist. Despite numerous studies of effective teaching approaches, few engineering courses apply those approaches [1]. To close the critical gaps between belief and practice, we are engaged in a multi-year year mixed methods study that explores faculty and student beliefs about both communication and teamwork (another central professional skill). The overall project goals are to: 1) understand faculty and student beliefs about effective practice and learning outcomes related to communication and teamwork; 2) articulate how well student and faculty beliefs align and how well beliefs and practices align; and 3) identify and test interventions to enhance the teaching and learning of communication and teamwork skills in engineering courses.

This paper focuses on the first goal, and attends specifically to the student perspective to identify student beliefs about the teaching and learning of communication skills. Specifically, we analyzed five focus groups conducted with engineering students at partner schools. The purpose of the focus groups was to uncover student beliefs about where and how they learned teamwork and communication within their engineering education. The exploratory focus group protocol was developed to mirror the questions being asked separately of faculty about teaching and learning communication skills. Asking parallel questions of students and faculty, allows us to address the second goal of the study which is exploring the areas of alignment and divergence between the two groups. The results from the faculty perspective are reported elsewhere [2]. The purpose of this paper is to articulate the beliefs of a sample of engineering students to highlight their concerns and challenges with learning communication skills and to better aid in improving student learning of these objectives

II. THEORY AND METHODS

A. *Theoretical Framework*

Situated learning, which is vital to language development of engineering students, provides a basis to characterize how students learn to communicate [1, 3] and was used as a lens to examine the five focus groups. As articulated by Lave and Wenger, situated learning theory describes the relationship between the situation and the context of the concept being learned [4, 5]. Situated learning highlights the social and contextual nature of student development and, in Lave and Wenger's work, includes participation in a community of practice [5]. This participation, referred to as "legitimate peripheral participation" [4], occurs when students undertake tasks that are reflective of and aligned with the kind of work they will engage in after graduation. Legitimate peripheral participation is particularly salient in the current study in that it refers to the ways in which novices learn by taking on small tasks that begin "at the edges" of the authentic practice, under the guidance of experts, and gradually assume more responsibility as they move from the periphery to the center of the task. According to Lave and Wenger, *participation* is the process through which novices start on the edges of the community and work towards the inner circle of experienced members. Working towards the inner circle is indicated by an increase in responsibility and authority in the community activity (e.g. the writing activity) [4]. During a community sanctioned activity, such as oral or written presentation of technical information, the experienced members should model community behavior and explicitly provide examples for novices (learners) in the authentic environment. Because our focus was on advanced students (juniors and seniors), we argue that the classroom is an approximation of an authentic environment, particularly since many of the focus group discussions centered on design or project-oriented classes. Since classrooms and engineering practice have two entirely different functions (i.e., learning how to do engineering vs. doing engineering) the classroom may not be an exact match from what students will face in professional practice. In the case of communication, the engineering faculty mentors who are considered experts at communicating their technical knowledge can act as role models of effective professional behavior (e.g. gathering information about stakeholders or audience) and create sites for students to learn authentic engineering communication practices [3]. Therefore, the community behaviors around communication that students observe faculty mentors model in an authentic learning environment are an important component of this current study. Situated learning provides a means to consider how engineering students learn community sanctioned communication skills and how these skills relate to professional development [3]. The current study points to the ways in which faculty's ability to both exemplify and situate professional engineering communication may effectively support student learning.

A. Participants

As noted above, data for this paper is drawn from a larger multi-university study. The study includes five universities geographically distributed across the U.S.; the study sites include public and private institutions as well as technically focused and comprehensive institutions. The study focuses on mechanical, civil, and industrial/systems engineering programs to provide a large sample population with diverse perspectives on the role of communication in the discipline [2]. Sites were intentionally selected to provide broad representation of differing types of programs. In this analysis, we included one focus group from each of the five sites, for a total of 25 students. Focus group participants were identified through coordinators at each site, involving a combination of snowball and convenience sampling to provide a rich source of information designed to address the research question [6, 7]. In other words, the sampling combination (different sizes and types of schools in different geographic locations with different curricular focus and practices for teaching communication and students from three different majors) provided a broad representation of communication learning experiences and contexts to explore a range of student beliefs about where and how they learn to communicate as an engineer. Prospective participants (e.g. students in technical writing or senior design courses) were recruited via the site coordinators and through solicitation emails that indicated the time and location of the focus group. The students were offered pizza and soft drinks as a modest compensation for participation in the study. Students self-selected to participate, and their participation was not disclosed to either the coordinators or the engineering faculty at the site. All names used in this paper are pseudonyms.

B. Data Collection and Analysis

The central question for study, what are student beliefs about communication, is intentionally broad, exploratory in nature and requires a qualitative inquiry strategy to effectively answer.[7] With limited studies investigating student beliefs about how and where they learn to communicate, the intent of this paper is to begin developing thick, rich descriptions [8] of the complex set of factors relevant to students perceptions about communication. Since the factors were previously unidentified, a qualitative research methodology provided a means to gain a deeper, more sophisticated understanding [9] of student beliefs about the role communication plays in their engineering education. Therefore, this paper highlights a portion of qualitative data collected during the study and specifically synthesizes the student focus groups as one inquiry strategy in the context of the larger study.

The focus group protocol was developed to elicit student's beliefs about both effective communication and the process of learning to communicate; questions asked students to define "good communication" and to describe specific opportunities or experiences that helped them learn to communicate effectively. Prompts were drawn from the existing literature on learning to communicate (see [1] for an overview of this literature). The focus group discussions, typically lasting 30-70 minutes, were audio recorded and transcribed verbatim. Typically, two researchers conducted the focus groups, where one managed the focus group discussion and the other took notes and tracked speakers. After each focus group, field notes about the focus group were compiled and combined across researchers when appropriate.

To analyze the data, we used an open coding approach with MAXQDA software to code the focus group transcriptions. Multiple rounds of open coding were performed to identify emergent themes and a detailed codebook was developed to avoid code definitions drifting throughout the analysis process [10]. For example, modeling was defined as novices beginning to participate by taking on small portions of a project or a task of lower complexity under the supervision of an experienced member of the community such as a faculty mentor. The code was only applied to statements from focus group members about mimicking faculty behaviors on a writing project or sections of a paper distributed throughout the course of a semester. The code definitions were developed based on widely accepted literature on situated learning and pertinent literature review for this project. The primary code definitions can be found in Table 1.

Table 1: Code name and definitions

Code Name	*Code Definition*
Examples	Descriptions of sample texts or templates provided by faculty and is available to all students
Lack of examples	Statements explicitly noting a lack of examples
Example Source	Statements about the source of the example (e.g. Faculty mentor, project manager, or client who gives the students an example of a deliverable)

Code Name	*Code Definition*
Legitimate Participation	Statements in which students connect classroom work to engineering practices.
Lack of Legitimate Participation	Statements in which students explicitly note the lack of connection between classroom and workplace experiences or expectations.
Participation Source	Statements about who provided connections between classroom and workplace communication or modeled professional practices

III. RESULTS

Three primary themes emerged during data analysis that indicate that students desire more direct instruction for communication skills and greater articulation as to how these skills relate to professional engineering work –issues that are, in fact, critical in situated learning. The three themes are 1) a desire for explicit examples, 2) a clear distinction between engineering writing and other writing, and 3) a need faculty mentors to provide clear links between school assignments and workplace practices, and to model professional practice. Each theme is illustrated with corresponding quotes and a brief discussion on its relationship to situated learning. When applicable, counterexamples for each theme are included in the analysis to demonstrate the variety in students' beliefs about the emergent themes.

Note that although we asked about communication in general, focus group participants tended to focus on written communication. We recognize that there are many other forms of communication, including formal oral reports, informal conversations, etc. Our analysis is not intentionally excluding such formats of communication; rather, we represent the focus of the students which is heavily grounded in writing as communication.

Theme 1: Students desire "examples," where an example is a tangible product, such as a template, provided by faculty and available to all students

Students across sites believe that tangible examples or templates can enhance their ability to learn various communications skills. Several students stated they wished they had an example or template to follow to initially learn how to effectively construct a technical report. For example, a student at Site 3 is not confident in his or her ability to write an abstract due to the minimal exposure to technical writing in high school:

> "Or like, here's how to write an abstract or this is what an abstract is, because the work, you know, you look up papers and its like this is an abstract and I remember the first time coming out of high school I didn't really do anything with engineering coming here and it's like I'm looking for a paper and found the abstract, and was like, um, abstract, that's a weird concept like what is this (A: right) and no one had ever explained it to me (A: right, right) so I had to figure it out on my own."**_Site 3**

One interpretation of the quote is that the student not only desires an example of what engineering writing "is," but also wants to know how his previously learned skills prepare him to learn how to communicate as a professional engineer. The student has not learned the importance and function of an abstract from class experience, but clearly wants to understand. Another student at Site 3 expressed a similar lack of resources such as a class discussion about specific writing issues to explain how to communicate as an engineering professional:

> "There's never really been a class that's like, this, this is how you're supposed to sit down and write an introduction to a technical document." **_Site 3**

Both quotes suggest that students desire explicit examples and direct instruction on how to "write like an engineer," to borrow Dorothy Winsor's phrase [11]. While Site 3 did not have a required technical writing course at the time of the focus group, students at other partner sites with such courses expressed similar desires for explicit instructions about how to generate a technical report:

> "I always liked when teachers hand you an example that you can use as a blueprint initially, and just, for your first, like, two or three, almost copy it verbatim in terms of formatting, and then as your group develops you start to move in a different direction. 'Cause it's always really awkward, at least for me, when your teacher goes, 'Okay, I want a report on how you're doing' -what kind of report? A technical report, uh, informal report, an update, you know, a memo? What do you want?"**_Site 2**

Here, the student describes the value of explicit example and direct instruction. What is also notable here is that the student recognizes the example as a starting point that must then be adapted to the needs of a particular project.

In addition to multiple comments expressing students' desire for more explicit examples of engineering writing, some students described examples or resources they considered inadequate. Students at Site 3, for example, describe a resource not effectively articulating communication skills that applied to engineering:

> [Student 1; S1]: "You know, coming into [course] they tell you to get this thing called a guide to writing as an engineering." [Student 2] "It's largely worthless. [S1]: Well I've never read it because most of what I've seen when it's been references is ok, that's common sense, I haven't seen it actually have anything earth shattering or ground breaking or wow this is a way better way to write (Interviewer: hmmm) and there's never really been a class that's like, this, this is how you're supposed to sit down and write an introduction to a technical document." **_Site 3**

These students consider communication skills important, but do not see the relationship between the resource provided and its useful application to engineering writing. These students desire a clear connection between the resource and their own communication of engineering information. In this case, an explicit example that applies the information in the resource could demonstrate to this student the role of the communication resource within the field of engineering and how it pertains to professional development.

Examples and templates are a critical component of situated learning because they provide students with tangible examples of the practices associated with the professional. And while faculty may raise concerns about students "copying" examples, the comments from the student at Site 4, in particular, demonstrate that students have the capacity to learn from and then *adapt* effective examples. Fostering adaptation, however, requires some time on the part of faculty to provide not only exemplary texts (e.g. a "good" report), but also commentary to explain why the exemplars are "good" and how they might be adapted. This process is, in fact, one of the bases of the Calibrated Peer Review system that facilitates electronic peer review among students [12-14]. For faculty uncertain about how best to articulate the features students can or should emulate, dialogue with experts in writing can prove quite helpful [15]. Once the examples themselves are selected and documented, minimal class time can be used to introduce and situate those examples. Providing students with examples or templates helps communicate expectations regarding the style and quality of the written work.

Theme 2: Students believe that technical (engineering) writing is different from other (i.e. "English") writing.

The quotations noted above, as well as comments throughout the focus group discussions all illustrate the ways in which students draw clear distinctions between the kind of writing used to present and interpret the outcomes of engineering work and the "other" style of writing – a style students often link to English courses. For example students at Sites 5 and 3 had this to say;

> "Like, my English class, and what not. What I was taught is that engineering writing is real cut and dry… It's, 'These are the facts, these are the calculations I did to get these facts, uh, this is the outcome." Where if I went and took another writing intensive course, say with say, Greek mythology, [A: Right] or with other electives like that, they wanted to build up a characters…."**_Site 5**

> "…how to write an engineering document, you know it's, It's not what you wrote in IB English in high school that was you know spat out 2 pages about whatever. I'm writing my first paper for that and it was like a little sample paper and [professor] just scratched out the first paragraph and said like, extraneous" **_Site 3**

Both quotes show how students perceive engineering writing as different from past educational writing. More importantly, the students view engineering writing as highly direct and factual – a place where the kind of "extraneous" information they found helpful in reaching page limits on essays is dismissed out of hand by engineering faculty. One danger in students' perceptions, however, is that in treating engineering as "dry and factual," students may not understand their role as interpreters of data and the need to argue for engineering decisions [1], a possibility more fully explored in the work of Leydens [16] and Winsor [11]. Because they may perceive attempts to persuade an audience as "biased" or "made-up," they may not understand how to construct an argument within engineering communication. Thus students may not be aware of how to present or develop an argument within a technical report, for example, in order to demonstrate that the design they have completed is feasible, desirable, and meets the project requirements. The situated nature of writing and learning to write [1] implies that all writing has a function; in engineering, that function is often to persuade others of the value and significance of the data. Without sufficient context in which to communicate engineering knowledge, students may not learn to understand the more complex reasons for writing, or see the connection between arguments made in English courses and arguments made in laboratory or design courses.

The focus group findings also hint at the ways faculty may be complicit in promoting certain student beliefs. For example, a student at Site 5 described a faculty member telling the class that engineering writing was boring; the student had adopted that position and thus was limited in their ability to understand the "why" of technical reports.

Theme 3: *Peripheral Participation* is the process by which novices take on small portions of a project or tasks of lower complexity under the supervision of an experienced member of the community such as a faculty mentor.

The misconceptions about engineering writing noted above directly lead to the last theme – that of peripheral participation. Just as examples can provide students with clear statements of expectation, they can also help students understand how such documents are used in engineering practice. Example texts can provide faculty opportunities to discuss the connection between the information that engineers generate and how that information is communicated to a variety of audiences. In other words, the example or template can foster a discussion about why communication is important in engineering practice, and faculty can then share disciplinary expertise with students explicitly in ways that model effective skills.

What practices or behaviors are engineering faculty modeling to students in regards to communication styles/skills and its role within the engineering profession? Similar to tangible examples, students expressed a desire for more transparency and intentionality in understanding how faculty members connect communication skills to the curriculum and, perhaps more importantly, to engineering practice. Specifically, students want to understand the situated nature of communication as it fits into engineering work. Engineering faculty previously interviewed for this study expressed high levels of communication competence [2] but the students in the focus groups did not. Therefore, the confidence in communication skills expressed by engineering faculty is not being transferred to students. Based on the student focus group data, it seems the value of communication can be lost if students do not see the value in a class activity to develop communication skills purposefully linked to engineering practice. For example, students at Sites 2 and 4 had this to say:

> "Every single class has a presentation that you have to do once and it's five minutes long and, it's just a whole lot of anxiety and doesn't really serve any practical purpose. Nobody's gonna learn how to be a better presenter by doing one presen-, or five presentations at the very end of the semester when they're already crammed with everything else."**_Site 2**

> "I feel like there's not enough writing in Engineering. Well, I recently, well, last summer, got an internship-type

thing. And I could not believe how much writing there is in Engineering. Like, it's insane. I feel like I am not prepared for that at all. And like communicating with clients and being able to tell them, they have no Engineering background, and you have to tell them, like, you can't show them your calculations, and be like, "Doesn't that make sense to you?" [A: (laughs)] I just feel like just presenting, we don't have any presentation skills, I am horrible at presenting."_**Site 4**

In different ways, both students are identifying a gap between classroom experiences and expected practice. Both quotes speak to the low competence and confidence of students in regard to their communication skills, which contrast the highly competent faculty members teaching them. Implicit in the comments from the student at Site 2 is the sense that course presentations are a missed learning opportunity and that they lack any kind of workplace value – they are merely more course assignments to be done as quickly as possible. A class discussion about the purpose and goal of the presentations, along with expectations or guidelines for acceptable presentation skills for engineering professionals, and time for meaningful feedback could alleviate the student's concerns. The quote from the student at Site 4, in addition to pointing to the gap between classroom and workplace practice, highlights the misconception noted in the previous section regarding the "dry" nature of engineering writing. The student's workplace experience has demonstrated the ways in which engineering calculations do not speak for themselves but instead require skillful communicators to situate and interpret them appropriately. Such behaviors, the student notes, are not modeled in engineering curricula.

In other cases, students did find faculty who could help them make connections by modeling professional practice. For example, a student at Site 3 stated:

> "It's definitely individual like if you put the work in and try and learn how to effectively communicate there are tools here and there are professors here that will help you learn to communicate better but if you just come over here to get a degree and walk out of here with a piece of paper and hopefully a job 4 years later, (M2: you're not), you're not really gonna go anywhere with that." _**Site 3**

This participant describes an academic culture that clearly provides the resources, including faculty mentors/models, needed to develop the necessary communication skills. Notably, this participant is one of the few student comments who reflected on their own accountability regarding their learning of communication skills.

IV. Conclusions

Situated learning emphasizes the ways in which students learn by engaging in authentic activities situated in meaningful professional contexts. This study highlights students' desire for search learning when it comes to communication – a desire reflected in the need for more explicit instruction and more modeling around communication in engineering and its role in professional practice. The study used situated learning as a theoretical framework to make meaning of the student focus group comments. The three themes that emerged from the data analysis suggest a series of pedagogical adjustments that may help students understand the importance and value of good communication skills as they relate to professional engineering practice. Such adjustments can, in practice, be integrated seamlessly into technical courses with well designed examples and brief discussions, though engineering faculty may find discussions with technical writing experts helpful in the process. These pedagogical adjustments may result in the legitimate peripheral participation of students, as defined by situated learning theory, being applied in engineering courses. In other words, as faculty model behaviors and support the notion that communication skills are critical to engineering professional practice, the novices (students) can observe and adopt the community behavior and perspective.

V. Limitations and Future work

As with any research endeavor, our study has some limitations. One limitation is the small number of focus groups. Our results reflect the beliefs of an intentionally chosen (with regard to research site and major) sample of self-selected students. Our results may not reflect all beliefs within the major or schools we studied. Moreover, students with dissenting opinions may have chosen to not participate in the focus groups. Another limitation was the limited background available on each focus group participant. For example, we were unable to consider the academic level of participants and/or the academic performance of participants to contextualize responses. However, our findings are still meaningful with regard to representing the experiences and needs of some students. Future work could address these limitations such as a mixed methods study to relate student performance (e.g. GPA) to the places where students believe they learn the skills to communicate technical information. Also, future work could consider dimensions of academic culture that student believe impact the ability to learn communication skills.

Acknowledgment

This work was part of a larger project sponsored by the National Science Foundation, funded under EEC 1025189. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

Professional communication skills for engineering professionals

Aletta Nylén Arnold Pears
Dept. of Information Technology
Uppsala University
Uppsala, Sweden
aletta.nylen@it.uu.se arnold.pears@it.uu.se

***Abstract*— Oral and written communication proficiency is an important professional skill for engineering graduates. However, developing these skills is often poorly integrated into the engineering curriculum. We present a three year integrated approach to developing professional competence in oral and written communication, which has been implemented in the IT engineering program at a Swedish research university. In the paper we describe the educational approach, the nature of assessment items and measures taken to ensure progressive skills development in order to ensure that graduates emerge with fully fledged communications skills. The goal of the paper is to describe a successful model for professional skills development, and to encourage a continuing dialogue on how to best equip students with communication skills for professional practice. (*Abstract*)**

Keywords—engineering education; communication skills; professional competencies; (key words)

I. INTRODUCTION

Professional engineers use communication for many different purposes, e.g., pitching ideas, describing solutions, reporting results, discussing work with collaborators, customers, etc. Graduating students need to acquire the necessary communication skills and become familiar with a broad selection of styles during their education. The American Computing and Accreditation Commission (ABET) acknowledges this, e.g., in their general criteria for accrediting engineering technology programs [1] where "*an ability to apply written, oral, and graphical communication in both technical and non-technical environments; and an ability to identify and use appropriate technical literature;*" is listed as a required student outcome.

Many teachers regard teaching the main course subject their only task and do neither teach nor comment on how well students communicate within the subject. IT faculty are hesitant to grade communication skills due to a perceived lack of language expertise or because they find the task tedious [2]. At Uppsala University, a Swedish research university, a student survey shows that isolated efforts, often in the form of writing assignments or oral presentations, have been made to improve the situation, but more often than not, students do not get the feedback they need to be able to develop their communication skills.

In this paper we present an approach to developing professional communication skills in engineering students. When this work was started, we focused primarily on written communication. The work has then gradually expanded towards including oral communication, but some of the work presented here has a focus on writing. Oral and written communication skills have a lot in common. For example, explaining a concept requires being able to adjust the amount of context that need to be presented in order for a specific audience to be able to understand, no matter whether it is done orally or in writing. Hence development in written communication will also be beneficial for oral communication and vice versa. The differences between the two forms of communication are, however, significant enough to motivate that they both need to be practiced in the education.

In the literature, there are two main approaches to teaching professional communication skills – those where communication is taught in dedicated courses [3] [4] and those based on writing across the curriculum (WAC) [5], where teaching is done in several courses throughout the education. Furthermore, communication can be taught in general language courses or in core subject courses, within the discipline, where it can serve both to enhance learning and to practice professional activities [6].

The approach presented here is an across the curriculum, within the discipline approach to developing both oral and written communication skills. The approach has been implemented in the first three years of the IT engineering program at Uppsala University. Our approach has been developed to address problems that were discovered through a student survey in 2012. We describe the ideas behind our approach, what has been done to achieve progressive development, how we work with assessment, and challenges that we have addressed in our design. The ideas presented constitute a framework that can be used to develop other competencies such as group working skills and information literacy and they are also valid for other branches of engineering education.

II. BACKGROUND

The IT engineering program at Uppsala University, in likeness with other engineering programs, aim at educating students to become competent professionals. This means that the students do not only have to learn their core subject, they

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

also have to develop a number of competencies that are essential to professionals. We refer to OECD [7] for a definition of a competency:

"*A competency is more than just knowledge and skills. It involves the ability to meet complex demands, by drawing on and mobilising psychosocial resources (including skills and attitudes) in a particular context.*"

In this work, we focus on communication ability for IT engineers, which OECD describes by

"*the ability to communicate effectively is a competency that may draw on an individual's knowledge of language, practical IT skills and attitudes towards those with whom he or she is communicating*".

To graduate from engineering programs at Uppsala University, the students must

"*demonstrate ability in both national and international contexts, to, orally and in writing, in dialogue with different groups, clearly present and discuss their conclusions and the knowledge and arguments that form the basis for these.*"[1] [8]

This requires students to be skilled at communication within their subject, and to be able to adjust their communication to different situations and different audiences that they may encounter professionally.

Study programs at Uppsala University, typically consist of a collection of courses, most of which are in the program's core subject. In the IT engineering program, isolated efforts of including professional skills development have been done, but there has been no previous attempt to structure this development across the education.

In 2012, we explored the students' view on the current writing training situation in the IT engineering program at Uppsala University by conducting a survey. Although the survey focuses on writing, the results have been used as a basis for developing both oral and written communication education.

In the survey, we asked the students

- if they have had writing training previously during their education,
- if they think that writing training is relevant to their education, and
- how good writers they perceive themselves to be.

Free text answers and comments have been analyzed with the aim of finding a variation in how students experience the use of written communication in IT and in how useful they perceive the writing training they have had to be for their skills development.

Students from one course in year 2 and two parallel courses in year 3 were asked to participate. Out of the total 65 students that were asked, 27 participated which gives an answer ratio of 42%.

Slightly less than half of the students answered the survey. We cannot be sure of how representative this group is for the total student body. However, opinions expressed by a large number of students (>80%) in this sample would be strongly represented even if all other students were of a different opinion. It is also clear, both from statistics and from free text answers, that both students who are interested in and/or strong in writing and students who are not are represented.

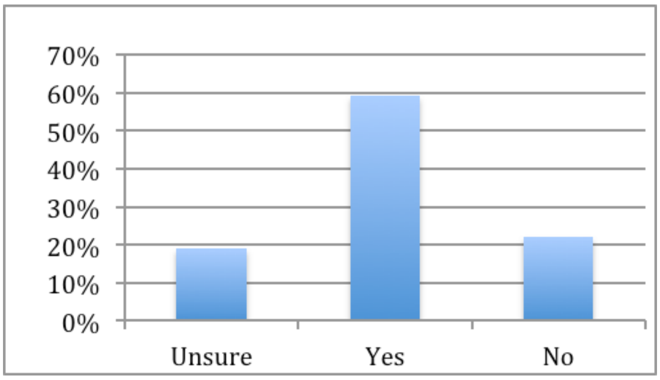

Figure 1: Previous writing training.

A. Writing training

As shown in Figure 1, the survey showed that 60% of the participating students say that they have had previous writing training in their education, 20% that they have not had writing training and 20% are not sure.

Students that reported having had writing training in their education were asked to explain in what courses and how that had affected their writing skills.

Half of those students (8 out of 16) reported having writing training in 1-2 courses, 2 wrote that writing training occurred only in project courses, and 6 reported that they had writing training in many courses. Of the 9 students who commented on how these courses has contributed to development of their writing skills, 5 reported that they could not see any development. 3 of these students also mentioned that they had not gotten any feedback on their writing. 2 students mentioned that they had learned the general framework for writing reports, and another 2 students claimed that they had learned to write reports by the practice they got from these courses.

We conclude that writing practice is useful and that we need to make sure that the students get more of it. We also see that not all students can learn from practice alone, and for that reason, feedback is very important. This result agrees with what is written about the need for feedback in [9]. In our survey, one student expressed that

[1] Translation from Swedish.

"Many of the courses within the IT program has given opportunity to practice writing, but never given specific feedback on the writing. It didn't develop much, but rather gave the opportunity to keep my previous standard up."[2]

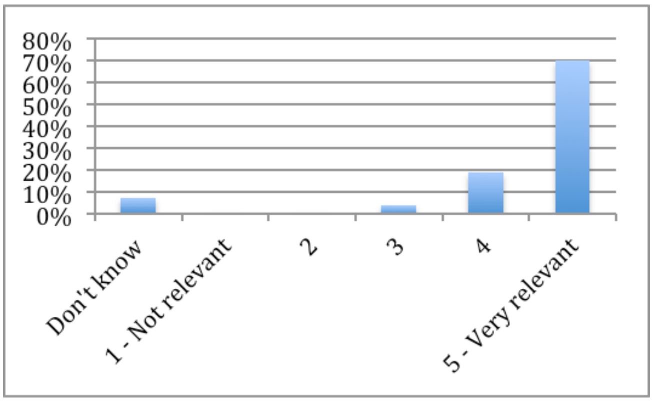

Figure 2: Relevance of writing training.

B. Relevance

On the question how relevant writing training is to their education (see Figure 2), 70% thinks that it is a 5 on a scale 1-5. Another 19% thinks it is a 4, 4% thinks it is a 3 and 7% do not know. Apparently, students think that writing is important for an IT engineer but this raises the question of why students think that it is relevant and how they expect to be using writing in their profession. In 11 free text comments to this question, we find that

- 5 students think that is it generally important to be able to express one self correctly but that it has no particular importance for their profession
- 5 students think that it is important to be able to present ones work by writing reports
- 2 students think that writing is important for making their work (products and solutions) and research available to others

It is also mentioned that writing will be used for work applications, communicating with coworkers and that good writing makes it easier to get through with opinions.

Our conclusion is that students have a general feeling that writing is important but their image of how it will be used in their future profession is not clear. In order to get through to students with the communication education that is provided, we need to provide examples of different kinds of professional communication.

C. Assessment of writing skills

The students were asked to assess their own writing skills on a scale 1-5, where 5 is "good enough for writing a thesis", 3 is "good enough for my current level of studies" and 1 is "I definitely need more training". 4% of the students chose not to rate themselves. 7% rated themselves 2, 85% rated themselves 3 or 4 and only one student was rated 5. The results are presented in Figure 3.

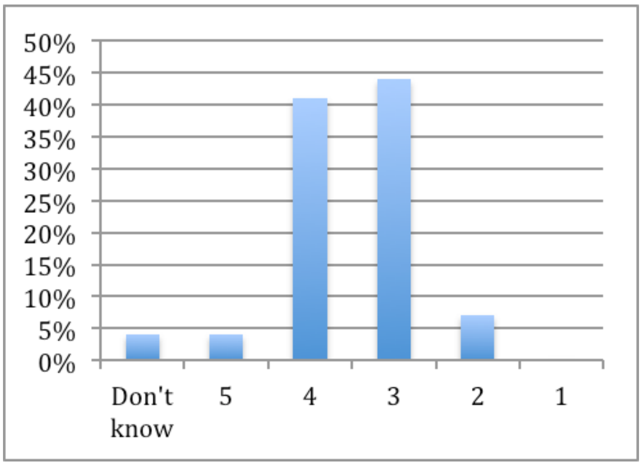

Figure 3: Self-assessed writing skills.

These figures suggest that 92% of these students need future writing training and at least 7% would have been better of with more writing training earlier in the program according to their own estimate. However, if we look at the 13 free text comments on this question, all but 3 students either express that they need more writing training or that they are unsure about the level of writing that is required. The other 3 students express that their general writing skills are good, but that they are unsure about their academic writing skills or about writing within their discipline.

We expect the students to learn good general writing skills in high school and to develop academic and discipline specific writing skills at the university. Our interpretation is therefore that the students lack of understanding of what writing in their subject is, leads them to rate their own writing higher than an IT teacher would and that improved communication education throughout the program is needed.

III. PROPOSED APPROACH

We will present the ideas and theory behind our approach before describing how it has been implemented at Uppsala University and explaining why this approach has been chosen.

A. Frequent practice.

Students need reoccurring opportunities to work on improving their communication skills. Students that are exposed to different writing assignments throughout their studies perceive improvement in writing skills [10]. Presentation skills are also improved by practice [11].

B. Practice within the subject.

Skills achieved in dedicated courses are not necessarily transferred to other contexts [12]. This means that general language courses may not have the desired impact on the students' development in professional communication, which is in their core subject. In addition to being ways of communicating, writing, explaining and discussing are also

[2] Translation from Swedish.

ways of learning [13] and help to form the professional identity [14]. If the practice is not performed within the discipline, these advantages will be lost.

C. Instructions, feedback and reflection.

Moore concludes that without proper instructions, guidance and feedback, the only effect of writing assignments is to reinforce bad writing [9]. He also argues that with proper guidance, students show significant improvements both in writing skills and in content knowledge. For oral presentations, [11] report getting good skill development when using a combination of practice, reflection and peer review. In [15], the authors report that letting students reflect on their own work, in addition to formal assessment, advances the development of professional competencies.

D. Progression.

We believe that it is not only important that students practice communication regularly and that they get feedback. In order for the students to continue progressing over time, it is important that the level of communication required in assignments increases as the students mature. The feedback should also meet students at their current level and promote further development.

IV. Teaching methods

To ensure that IT engineering students at Uppsala University are subject to reoccurring communication practice, communication proficiency is a prioritized learning outcome for at least two core subject courses each of the first three years of studies. This also makes it clear, for the students, when communication is practiced and assessed and stresses that development of communication skills is an important part of the education.

Factors like restricted time, limited access to information and the stressful situation makes assessing professional skills through traditional exams difficult [16]. In our approach, communication is therefore practiced and assessed in different kinds of assignments, where students can prepare for oral assessments and have time to work on written material.

From the survey presented in Section II, we learned that students agree that writing is important for IT professionals but when asked how it is used, they seem to lack an answer. This also means that the character of communication in IT, how it differs from general academic communication, is unclear. By providing students with a variety of different kinds of well-chosen communication assignments, we hope to acquaint the students with professional style communication and highlight the communication skills that are specific to IT.

In [2], Garvey presents a categorization of student writing with particular examples of assignments in each category. The communication assignments that our students encounter during the first three years are best described by Garvey's categories "Summarizing assignments", "Programs as writing", "Reviews/critiques of the writing of others" and "More creative kinds of writing" although, in our case, the work is sometimes presented orally. "Team-based writing" also occurs. Examples of assignments that our students encounter are paper reviews (summarizing), project proposals (creative), lab and project reports (programs), literature discussions (summarizing, reviews) and project presentations (programs). Sometimes our students present and critique each other's work resulting in assignments that span three of the categories, summarizing, programs and reviews.

Another important component in making students familiar with communication in their discipline is to provide examples. We are collaborating with the university's writing center to form a database of examples of student and professional writing. Reading and presenting research papers is also an activity that contributes.

In oral communication, students need to become skilled in presentation techniques, but it is equally important that they become skilled in discussing their subject. In addition to being able to present ideas and solutions, they need to be able to relate to and ask and answer questions about material that is being presented and they need to be able to communicate efficiently about their work when cooperating with others in teams.

Most approaches to oral communication education described in literature address presentation skills [4] [11]. We find that there is also a great need for practicing discussing the subject of studies. Students struggle with describing issues related to IT, concepts, solutions, etc. both orally and in writing. In discussions, this is even harder since a good description has to be provided without having as much time to think about how to explain what they want to say as when given a written assignment or preparing a presentation. This is obvious even when students are to describe and discuss what they have previously written about. The need for oral communication training that goes beyond presentation skills is supported by the work of Ruff and Carter [17], where professional communication goals were identified through focus groups and interviews with software engineers and managers.

To practice and assess discussion skills, we work with oral assessment of both theoretical content and practical work. With the help of follow up questions, the teacher can create a situation where the student can no longer rely on previously prepared answers but has to create explanations and solutions on the fly. Course evaluations show that students experience that they need to have a thorough understanding of course material to pass this kind of oral assessment. Teachers experience that oral assessments make students aware of what it means to understand contents and thus seem to encourage deep learning. In addition, they find that need for communication practice is exposed and that student performance is drastically improved with practice.

Teaching the main course content is the primary concern for many teachers and they do neither teach nor comment on how the students communicate in their work. Previous literature [2] [18] report that IT faculty hesitate to grade

Beginners, first course
Students should be able to
1. identify different types of text in the field and describe their structure.
2. write a text that reproduces information from other sources.
3. write a text that is suitable[1] for the intended reader.
4. write a text that has a clear theme and is appealing[1] to the intended reader.
5. write text that is linguistically correct for spelling, paragraphing, punctuation, etc.
6. use references and citations correctly.
7. discuss what information is necessary and what information is sufficient for a text.

First and second year
Students should be able to
1. provide constructive feedback on the work of others with the help of checklists.
2. write summaries of simple scientific articles.
3. describe and evaluate their own work in writing, e.g., lab report. The report should have a good structure.
4. apply principles of necessary and sufficient information in your own texts.

Second and third year
Students should be able to
1. give constructive feedback on the work of others.
2. describe and evaluate larger projects in writing. A special focus is on selection of appropriate levels of abstraction in different parts of the text.
3. use figures and diagrams in a proper manner.
4. produce "well-prepared" text in Swedish.
5. write original text in English.

Figure 4: Progression goals for writing.

writing since they do not have language expertise and since they consider evaluating writing to be a tedious task.

We collaborate with the university's writing center to offer support for teachers when it comes to making instructions for writing assignments and material on how to write. The writing center also supports the students by giving instruction lectures and writing aid, e.g., in the form of comments on student work before the final submission.

Providing feedback, especially to written work, is a time consuming task for teaching staff. We sometimes let senior students help with grading to reduce the teacher's workload and thus the teacher's task shifts from grading large numbers of assignments to supervising a group of students and making sure that their grading is at an appropriate level for the course. Peer reviewing, students giving feedback to each other, is also sometimes regarded as being a time saving alternative which has the additional advantage that students learn from reviewing as well as from doing the assignment. Investigations in [19] support our impression that students need training and education, both in giving and responding to feedback. Since peer reviewing is used frequently, students get to practice giving feedback. For written assignments, students must sometimes respond to feedback by improving their work.

For oral presentation, [11] report student development when using a combination of practice, reflection and peer review. When it comes to writing, our investigations support the results of [19], that students do not find feedback from peers as trustworthy and beneficial as feedback from teachers. In our approach, we use peer review both for oral and written work but for written work, we make sure that students also get feedback from teachers or teaching assistants. We also make it part of the assignment for students to reflect on their own performance. We share the experiences presented in [15], that students lack experience in reflecting on their work. Since reflection does not only advance development of skills, but is also an important tool for achieving lifelong learning if incorporated in professional practice, we make reflection a mandatory part of selected assignments spread throughout the education.

To encourage progressive development, we have defined learning outcomes for written communication, presented in Figure 4. The learning outcomes are linked to different course levels. The learning outcomes are designed for students that are native in Swedish, not in English. At Uppsala University, there are four course levels during the first three years of study. At each level, students should fulfill the outcomes from previous levels as well as the ones from their current level. The fourth level, which does not occur in Figure 4, is the level of Bachelor thesis work and does not contain any new learning outcomes. A more detailed description and an analysis of the learning outcomes in relation to competencies that are needed to fulfill them is presented in [20].

At the first level, for beginner students, the focus is on high school level writing skills and general academic writing skills such as proper academic style language and correct use of references. At later levels, other aspects, e.g., being able to explain and describe solutions at appropriate levels of abstraction, are added. A typical example from IT is that to explain an algorithm or a program, you need to provide a high level description, a figure or a natural language description. Just presenting excerpts from code is not sufficient at the second and third levels.

The learning outcomes serve as a structure, both for teachers and for students, for achieving progression in the level of assignments, the quality of student work and the grading criteria for assignments. Because of the many similarities between written and oral communication, it is easy to adjust the learning outcomes to suit both kinds of communication. To help students appreciate their own development, assignment solutions, feedback and reflections can be used to compile a student portfolio.

V. IMPLEMENTATION

The communication training starts at the beginners level, in the very first course in the IT program and is continued in five more courses spread over the first three years. By the end of the third year, the students show that they fulfill all communication goals discussed above in an independent project corresponding to a bachelor thesis.

In the first course, the writing education focuses on the difference between academic texts and general texts with a special emphasis on the style used in different types of IT related texts. For example, the students learn the structure of academic reports and they start to practice explaining IT concepts in a precise and unambiguous manner. Since the students do not yet have deep subject knowledge, typical assignments consist of presenting IT concepts and discussing them in relation to society and everyday life. The texts are directed towards audiences that are at the same level as the students themselves, audiences that do not have deep understanding of IT. An important goal at this level is that the students learn to use text sources in a proper manner.

To practice oral communication, the students are required to do most of the course work in groups. In addition to being an arena for practicing discussion skills, the groups can serve as a motivator for students to perform better and learn more and thus the group can have a positive influence on students' study habits [21].

The rest of the first year is dedicated to practicing describing and evaluating the students' own work. The students present their own solutions to programming assignments, both orally and in writing. They evaluate their solutions and draw conclusions e.g., about performance of algorithms. They start working on presentation skills by presenting small projects to the class. An important task for students during this period is to provide feedback on the work of other students. By doing this, the students get to see both good and bad examples and how they affect the general quality of texts and presentations. At this level, peer reviewing is guided by checklists that help students focus on relevant properties of texts and presentations rather than getting stuck in commenting on details, such as spelling errors.

In the second and third years, this work continues but as student projects get larger, the demand for descriptions at different levels of abstraction increases. Although the students have used illustrations earlier, the emphasis on proper selection and use of illustrations is increased. At this level, we also require that students relate their work to other work in the field properly.

Peer reviewing is still used, but with less aid from checklists as we expect students at this level to have a general knowledge of what to look for. Group work and oral examination is also used, but as the students' subject knowledge increases, so does the required level of correctness in descriptions and of how students can draw conclusions from course contents.

In the later years, students are required to present their work to different audiences ranging from novice students to professionals depending on the purpose of the different assignments. An example from the third year is a writing assignment where students are required to explain database concepts and give illustrative examples directed towards audiences not knowing anything about databases. Another example, from a concurrent programming course in the second year, is a project proposal where the students have to sell an idea while giving enough technical background to convince a professional that their idea is realistic and should be accepted.

VI. DISCUSSION

We have described a model for professional skills development and how it has been implemented to develop communication skills in IT engineering students at Uppsala University. Through a student survey, we have found that the isolated efforts that have previously been implemented in the program, students have encountered communication practice, but that feedback and progression have been sparse. It is also clear that students have a vague and incomplete picture of how communication will be used in their future profession. We argue that an across the curriculum approach is needed to ensure that students encounter a broad variety of professional communication activities and thus develops a knowledge of what communication in their discipline is and how it is used. Such an approach also makes it possible to progress the level of communication activities the students are to engage in and how they are graded.

Our approach has been successful in that it has engaged faculty in participating in developing students' communication skills to a much larger extent than previously. The model have not been used to a full extent long enough to present definitive results on how student performance is improved, but the preliminary impression is that students are adopting study habits more directed towards deep learning and that students' oral communication skills are developing.

Groups are natural training grounds for communication. Hence, an interesting future extension of this work is to include group and project working skills. A well functioning group can have a positive impact on learning that would be interesting to take advantage of in professional skills development.

ACKNOWLEDGMENT

Thanks to Sofia Cassel for collaboration in development of the writing skill education. Thanks also to Karl Marklund for fruitful discussions concerning oral assessment.

Correlation of Learning Styles with Team Performance and Perception in a Chemical Engineering Unit Operations Course

Elif Eda Miskioğlu, David W. Wood
Chemical and Biomolecular Engineering

miskioglu.1@osu.edu, wood.750@osu.edu

Abstract—**Teamwork is emphasized in high-level engineering courses to help prepare students for their chosen career. When left to self-select, students often form homogenous groups with respect to several indicators, including learning style. While homogeneous groups may occasionally be preferred for specific tasks, heterogeneous groups have shown better performance over a wider range of tasks. Qualitative data (interviews) suggest that students grasp the value of heterogeneous groups and are able to recognize the gains of such diversity. We are interested in the relationship between learning styles and team dynamics in advanced chemical engineering students taking the team-based unit operations course. We are looking to correlate team composition with respect to learning styles preferences with team performance and student perceptions of team efficacy. Students are given a learning styles questionnaire to determine preferences in the course's lecture portion. These are used to identify potential correlations between team make-up, team performance and student perceptions during the subsequent laboratory portion. Understanding variability in performance based on team composition can help elucidate the complex nature of team dynamics. Armed with such information, instructors can create the most educationally efficient teams, and students will have a better understanding of teams as they enter the workforce.**

Keywords—team dynamics, learning styles, student performance, student perception

I. INTRODUCTION

Engineering is a highly team-oriented discipline. Undergraduate engineering curriculum emphasizes teamwork in upper-level courses in an effort to prepare students for the demands of their future careers. There is a general understanding that diversity in team members is of high value, but when left to decide for themselves students will self-aggregate into teams that are homogenous based on several indicators. We are interested in exploring the correlation between team make-up with respect to student learning styles and the perceived team dynamics and team performance in the context of a senior-level chemical engineering unit operations course.

This material is based upon work supported by the National Science Foundation Graduate Research Fellowship under Grant No. DGE-0822215

II. LEARNING STYLES PREFERENCES

While the validity of learning styles has been disputed since their establishment, many models exist to describe how individual's best receive new information. We are specifically interested in learning styles in the context of engineering.

A. Felder-Silverman Learning Styles Dimensions

Published in 1988, the Felder-Silverman model of learning styles for engineering identifies five dimensions: active/reflective, sensing/intuitive, visual/auditory (verbal), sequential/global, and inductive/deductive [1]. While the names of several dimensions give an intuitive understanding to the dimensions, they are also previously described in detail [1]. The inductive/deductive dimension was later removed from the Felder-Silverman model, as described by Felder in a 2012 preface to the work. Because of its specificity to engineering, we will be using the updated Felder-Silverman model of learning styles dimensions.

B. Felder-Soloman Index of Learning Styles

The Felder-Soloman index of Learning Styles (ILS) is a 44 item questionnaire designed to identify student learning preferences in the four dimensions of the Felder-Silverman model [2]. There are 11 questions for each dimension, each of which has two possible answers representing the opposing preferences within the dimension [2]. Each dimension is scored on a scale from -11 to +11, with individual answers being either a +1 or -1 [2]. For example, when considering the active/reflective dimension, answers showing an active preference are +1 and answers showing a reflective preference are -1. The absolute value of the final score reveals the "strength" of a preference, ranging from "balanced" (score of 1 or 3) to "strong" (score of 9 or 11) [2]. Reliability and validity studies of the ILS have shown student agreement with results [2][3]. While the Felder-Silverman model is considered specific to engineering, the ILS instrument has been used in not only engineering, but also other fields such as computer sciences and internal medicine [2][4][5].

III. TEAM DYNAMICS

Teamwork is emphasized in high-level engineering courses to help prepare students for the highly team-oriented career their degree entails. When left to themselves, students will form groups that are homogenous with respect to several indicators, including personality and learning style [4][6]. While homogeneous groups may occasionally be preferred for specific tasks, heterogeneous groups have been shown to have better performance over a more broad range of tasks [4]. Qualitative data from interviews suggests that students also grasp the value of heterogeneous groups, and that despite some difficulties because of clashing styles are able to recognize the gains of such diversity [7]. Quantitative data on the matter regarding teamwork and learning styles consists of student surveys conducted on a numerical scale corresponding to agreement (*e.g.* Likert scale) [7]. This does not provide concrete data regarding group success at tasks, but rather gauges the student perceptions of team efficacy.

IV. UNIT OPERATIONS IN CHEMICAL ENGINEERING

Unit operations is a team-based laboratory course in chemical engineering. At most institutions it is taken as part of the senior year curriculum. At The Ohio State University (OSU) the course is divided into a spring semester lecture, taken by most students at the end of their third year, and a one-month laboratory course taken immediately following.

A. *Chemical and Biomolecular Engineering 3630*

Chemical and Biomolecular Engineering (ChBE) 3630 is the semester-long lecture based prerequisite for the unit operations laboratory course. This course offers the foundation material for completing the month long laboratory. Topics covered range from teamwork and six sigma leadership to how to read a temperature indicator or review of heat exchanger systems.

B. *Chemical and Biomolecular Engineering 4630*

ChBE 4630 is a four-week, team-based laboratory course. Students complete week long laboratory assignments in teams of four in one of three tracks: classical, biological, and environmental. Team members take on specific roles (team leader, design engineer, operating engineer, development engineer) that reflect the common components of industrial process teams. Roles rotate among the students so that each student may serve in each role once during the course. Students report to Teaching Assistants (TAs), who serve as supervisors, during their experiments. Requirements of each laboratory exercise include a daily summary report, data submission, design extension problem, and formal written laboratory report. Students are evaluated on the group laboratory reports and individual quizzes throughout the term, as well as a final examination at the end. A peer evaluation is also submitted by each group member for every laboratory.

V. STUDY DESIGN

We are interested in the correlation between team composition with respect to learning styles, perceived team dynamics, and team performance in the context of ChBE 4630. Approximately 150-200 students are enrolled in the course annually, providing a large potential sample size.

The study will be correlational, using surveys as a means of data acquisition. It will have qualitative and quantitative components, as we will be examining student performance as reflected by assignment grades and student feedback on both a Likert scale and as open response. The primary variable of interest is team composition with respect to student learning styles. We are interested in determining whether team composition has a significant effect on performance and perception, as measured by team performance on each assignment as well as post-assignment attitude surveys.

We aim to investigate the team dynamics of the students in ChBE 4630 without otherwise influencing the course content or design. The study will consist of the following:

1) Administration of ILS early in the spring 2013 ChBE 3630 course, as well as collection of informed consent responses.
2) Compilation of ILS data to determine make-up of student population enrolled in course with respect to learning styles dimensions.
3) Assignment of students into groups, done as usual by the faculty member teaching the course. Group assignments do not consider learning styles, offering a variety of team compositions with respect to learning styles.
4) Progression of course in month long “Maymester” term, as usual, with administration of additional survey for all students (disseminated by TAs to each team they are supervising) at the end of each laboratory to evaluate students’ perspective on their work as a team. Also, collection of informed consent and ILS from any students who may not have taken ChBE 3630 the preceding spring semester.
5) Collection and compilation of team grades, and analysis (of data from students who have consented to participate) to determine whether a correlation with team composition exists.
6) Comparison of performance of teams in the course as suggested by grades and students’ survey results.

VI. SURVEY DESIGN

The survey consists of a combination of statements evaluated on a one to five Likert scale and short answer questions. Statements are designed to evaluate student perceptions of their group dynamics. We are interested in whether the group communicated well, considered each other’s input, and whether the student believes that both the laboratory protocol and report benefitted from working in a team. Furthermore, we are interested in whether the student believes the final report is of high quality and if they would have preferred to work alone. The short answer questions are directed toward identifying the student’s personal contributions to the group, as well as understanding what specific benefits they received from the group. There is also room for further comments.

VII. Inherent Challenges

Successful implementation of this study requires clear communication between the investigators, the faculty instructor, and TAs (of which there were nine during 2013). Throughout the term, teams meet among themselves and with their respective TAs, but the entire class does not often gather in an organized manner. Students and teams come and go as needed in order to get their laboratory exercises completed. Thus, we are relying on the TAs to consistently provide the students with the perception surveys and accompanying instructions for completion and submission.

As with any study that relies upon survey results for data, another inherent challenge is obtaining responses and ensuring those responses are valid. Survey completion is incentivized by awarding ½ point to the student's final grade for each survey completed (regardless of consent or declination of participation in the study). To ensure the validity of all survey responses analyzed, the survey includes repeated questions restated for both affirmative and negative responses. Thus, a student who answers affirmative or negative to both conflicting questions (*i.e.*, "group members communicated clearly" and "group members did not listen to each other's contributions") is likely guilty of completing the survey without paying proper attention to the questions. These responses will be omitted from the data used in analysis.

VIII. First Trial Improvements

After conducting the study in 2013 (results not yet available at the time of this submission), several areas of improvement have been identified for a more robust study. First, logistically, we need to ensure that all TAs understand the study intent, consent process, and the intended administration dates for the four surveys (one with each laboratory assignment). In Maymester 2013 there were three graduate and six undergraduate TAs. Communication of the study details to these TAs is crucial, and may require greater involvement from the investigators.

There are several potential improvements in regards to survey design. While we opted for a five point Likert scale to simplify responses for the students, the commonly used ten point scale appears preferable to further differentiate perceptions. The administered survey only had two short answer questions asking students for their perceived specific contribution to the group and the aspect of working with their team that they found most beneficial. This offers room for expansion to additional short answer questions. While we strive to keep the survey short and manageable, it would be worthwhile to ask students to expand upon any responses that indicate a negative perception of their team/teamwork.

These improvements will be outlined in a revised IRB application for exemption and implemented with the next trial in Maymester 2014.

IX. Desired Outcomes

Understanding the relationship between team learning style make-up and team dynamics and performance will establish a foundation for improved curriculum with respect to teaching teamwork. A greater emphasis on incorporating an understanding of learning styles and their role in team dynamics may prove to be a valuable component to undergraduate engineering education as we prepare students to enter the ever-shrinking and changing global workforce.

Acknowledgment

We would like to thank Dr. Carlo Scaccia, instructor of ChBE 3630 and 4630, for his cooperation in allowing us access to his courses.

Abstract— **In computing courses, the teaching and learning approach normally emphasizes theoretical knowledge at the expense of practical knowledge. The major disadvantages of this approach are learners´ lack of motivation during class and their quickly forgetting the knowledge they have acquired. With a view to overcoming these difficulties, Problem Based Learning (PBL), an institutional method of teaching, has been applied to teaching computing disciplines. Despite the growth of the practice of PBL in various disciplines of Computing, there is little evidence of its specific characteristics in this area, the effectiveness of different PBL methodological approaches, or of benefits and challenges encountered. In this context, this paper presents a systematic mapping study in order to identify studies which involve best practices when using the PBL method in Computing between 1997 and 2011, answering five research questions: "What are the main characteristics of PBL that support teaching in Computing?"; "What are the criteria for applying PBL effectively in this area?"; "How is the PBL methodology applied?", "What are the advantages and benefits of applying PBL in Computing? "and, finally, " What are the main challenges about learning in PBL in Computing?".**

Keywords-component; Problem Based Learning; Education; Computing.

I. INTRODUCTION

In the evolution of the Information Technology and Communication (ICT) industry, professionals in the field of Computer face constant changes which leads to there being a need to adapt concepts, methods and techniques for specific situations that may arise in the labor market. These issues affect not only businesses, but also software engineers, who besides having as a prerequisite vast knowledge of software development tools, should also have a broad view of the problem to be solved, ie, an understanding of business, entrepreneurialism and interpersonal skills [1].

To succeed in the field of Computer Science, one needs to have knowledge of and to master a variety of skills such as: being at ease with mathematics, logic, problem solving, algorithmic thinking and programming. Unfortunately, many students struggle to develop these skills, especially when the subject is related to object-oriented programming, discrete mathematics, data structures and analysis of algorithms [2]. This happens because of the way in which teaching is approached in undergraduate courses, since what can be seen is a lack of practice after being given the theory [3]. Practice along with theory enables students to make connections, and thus to link prior knowledge to new knowledge learned during the new learning process [4, 5].

As a consequence of this factor, what also needs to be mentioned is that teachers get greatly frustrated and students abandon their courses, as many give up working in the area due to such difficulties [2]. When students do not give up, there is poor professional training, as they do not have enough practice for the labor market. [6]

With a view to finding solutions for these problems, the instructional method of teaching, Problem Based Learning (PBL), has been applied to the teaching of computing, aiming to promote collaborative and motivating learning, based on problem solving. According to Peterson [7], PBL meets three important criteria that promote ideal learning: first, it provides an environment where students are immersed in a practical activity, secondly, they can receive guidance and support both from other students and a responsible teacher/ tutor; and, finally, learning is based on solving a real problem.

Despite the growth of the practice of PBL in various disciplines of Computing, there is little evidence of its specific characteristics in this area, of the effectiveness of different methodological PBL approaches, or of the benefits and challenges encountered. It was out of this context, the problem tackled by this research arose which sought to understand the studies that highlight best practices for using the PBL method in disciplines related to the field of computing. To this end, the method of systematic mapping was used and focused on constructing a broad overview of how the PBL method was applied in the everyday routines of these courses from 1997 to 2011.

II. PROBLEM BASED LEARNING IN TEACHING COMPUTING SCIENCE

Problem Based Learning (PBL) is an instructional method of teaching that differs from the traditional model by virtue of its using real-life practical problems to start the learning process in order to encourage the development of problem-solving skills. These problems based on reality are worked on in groups, in order to initiate, direct, motivate and focus learning, unlike traditional methods that put the problem at the end of the presentation of content [8, 9].

This approach began in the medical field, in the 1970s, at McMaster University's Medical School [10], the precursor

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

being the physician and educator Howard Barrows who developed methods to instruct doctors to develop their own capacities for reflection when not in medical school [11]. The goal of this method is not only the solution of the problem, but rather learning from the problem presented, ie reporting solutions based on the problem and the process used to obtain them. Barrows [12] describes six key characteristics of PBL:

- Learning is student centered;
- Learning takes place in small groups of students;
- There is the presence of a tutor who is seen as a facilitator or guide;
- The problems are presented at the start of the process.
- The problems encountered are used as instruments to attain the knowledge and skills to solve problems;
- New information is acquired through self-directed learning.

In the process of teaching, teachers must understand correctly the problem as being the basis in the learning method, which differs from the traditional model of education, which is teacher-centered. PBL directs the role of learning to the students and the teacher's role changes to a single form of teaching: that of guiding, as well as that of teaching. [6]

In Computing Science, the difficulty lies in having good professionals in the area of information technology, viz., software engineers. PBL tries to overcome this difficulty by offering students a way to acquire knowledge and develop the skills and attitudes expected of a professional.

Software engineers face many problems of adapting concepts, methods and techniques to the specific situations of problems in the market, in general influenced by the variation in scope, cost and deadlines of software projects. For the professional training of software engineers, PBL approaches can help by fostering the ability to work in teams, to solve problems and also to encourage the development of one’s skills and attitudes, such as self-directed learning skills, cooperation, ethics and respect for people’s other points of view. [3]

Authors like Peng [6] discuss problems with reference to textbooks on programming, and state that part of the books are written with the main focus on the logical structure of knowledge, starting with the introduction of an abstract and unclear concept, for example, the concepts of "object", "property", "event" or "method", and thus do not respect the students’ cognitive rules.

Bearing in mind the benefits of the PBL method, in different areas of knowledge, it is appropriate to make a more in-depth study with the aim of supplying a broad overview of research studies that that have been undertaken in the area of Computing Science and of analyzing gaps that may yet need to be explored in research on PBL

III. SYSTEMATIC MAPPING

The study of Systematic Mapping (SM) is a method designed to provide a broad overview of a particular area of research that enables the results to be identified, quantified and analyzed, thereby establishing evidence on a particular topic [13, 14].

The Systematic Mapping conducted in this study was divided into three stages, based on the guide by Kitchenham [13], namely:

1. *Planning Systematic Mapping*: drawing up a protocol containing all the information of the study;

2. *Driving the Systematic Mapping*: carrying out searches and collecting data;

3. *Presenting Systematic Mapping:* analysis of results and writing a report from the information stored.

The initial research studies were conducted using digital libraries: IEEExplore Digital Library, ACM Digital Library, Elsevier Scopus, Elsevier ScienceDirect. The selection of these sources was based on the relevance and credibility of articles indexed in the area of Computer Science.

Starting out from the objective of answering the central question of the study: "How is learning based on PBL characterized and what is its contribution and challenges for teaching Computing Science?", five secondary issues were put forward for answer:

1.What are the main characteristics of PBL that were found and supporting education in Computer Science?

2. What are the criteria for the *effective application* of PBL in Computer Science?

3. How is the PBL methodology applied in the teaching of Computer Science?

4. What are the *advantages and benefits* of applying PBL in Computer Science?

5. What are the main *challenges* about learning in PBL in Computer Science?

For the construction of the key terms of the research, the key-words of the central question were used. In addition to the key-words, their synonyms were identified based on the area of research, which facilitated the search: Learning (learner, education, educational program, constructivism, constructivist, instruction); Problem Based Learning (PBL, problem-based learned); Contribution (advantages); Challenges (outcome, results); Computer (software, computer engineering, information technology, computer science).

The search string was constructed by combining key-words and synonyms. Two operators were, OR (or) between the synonyms and AND (e) between the key-words, as shown in Table I

TABLE I. SEARCH STRING.

Search String
(learning OR learner OR education OR methodology OR approaches OR "educational program" OR constructivism OR constructivist OR instruction) AND "problem based learning" OR PBL OR "problem based learned") AND (contribution OR advantages) AND (challenges OR outcome OR results) AND (computer OR software OR "computer engineering" OR "information technology" OR "computer science")

Initially, using the search string resulted in 2,464 studies being located. From that number, the process of selecting primary studiesbbeagan and was conducted first of all on the title and abstract. As a result, 2,412 studies wwere discarded from this total.

For the classification of the studies, inclusion and exclusion criteria wer designed, which are:

- Inclusion: the relevance that the study has in relation to the proposed research question: Studies that describe research related to the topic of the PBL teaching methodology and Computer Science; studies that relate experiences of the teaching methodology being favourable for teaching on Computer Science courses.
- Exclusion: Studies published in editorials, prefaces, summary articles, interviews, news and reviews; Studies with experimental results that are inconsistent or with incomplete content; Studies that are not part of the research area.

Based on reading the introduction and conclusion of the Relevant Studies and the criteria for inclusion and exclusion, a total of 52 Primary Studies was obtained. Of the 133 ostensibly Relevant Studies, 80 of them were considered "Not Relevant" and 12 were unavailable for download, as shown in Table II.

TABLE II. RESULTS OF THE SEARCH.

Primary Studies					
		1st Phase: Title and Abstract	2nd Phase: Introduction and Conclusion – Excluded		2nd Phase: Introduction and Conclusion – Included
Sources	Returned Studies	Relevant studies	Irrelevant	Unavailable	Primary Studies
IEEE	1,242	69	33	0	36
SCOPUS	681	38	30	12	8
SCIENCE DIRECT	327	3	3	0	0
ACM	214	23	15	0	8
TOTAL	2,464	133	80	12	52

During the process of analyzing the studies, they were classified according to their year of ublication year. Thus a count could be made of studies on PBL over the last 15 years. Figure 1 shows a graph of the the evolution of the PBL approach over the years.

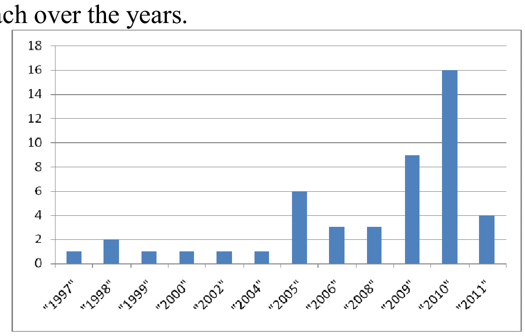

Figure 1. Distribution of results published over the years shown above.

As can be seen, it is clear that PBL approaches in the area of Computer Science have been growing since 2009, with a high incidence in 2010.

IV. MAIN RESULTS

The studies found were associated with categories corresponding to the secondary research questions outlined in Section III. To prove each association, evidence was collected from each "Primary Study", represented in the following subsections by the notation "EP". The following subsections present and comment the results for each category. Due to size limitations of this article, only some evidence of the complete work will be mentioned.

A. *Characteristics of PBL*

The purpose of this question was to map the characteristics of the PBL method in the teaching of Computing Science. The topics were defined as per the characteristics of PBL defined by Woods [15] and Barrows [16]. Figure 2 shows the primary studies qualified for each of these topics.

Topic	Primary Study	Qty -%
Change in the role of student	EP_08	1 – 5%
Change in the role of teacher	EP_01, EP_16, EP_18, EP_37, EP_43	5 – 25%
Problem starts the process	EP_35, EP_46	2 – 10%
Focus on solving problems	EP_09, EP_11, EP_14, EP_27, EP_31, EP_39	6 – 30%
Self-directed learning	EP_22, EP_23	2 – 10%
Collaboration among participants	EP_03, EP_07	2 – 10%
Learning in a group	EP_21, EP_24	2 – 10%

Figure 2. Results on Characterístics of PBL

In general, the authors are clear when they affirm the need for a problem that starts the process, and that all knowledge should be acquired through solving problems, thus enabling the student to have greater contact with real-world problems, as the evidence makes clear:

EP_11: "The problem-based learning method dictates that the students' projects must aim at solving a problem.

EP_03: "In PBL students learn by addressing ill-defined and open-ended problems and reflecting on their experiences, thus developing problem-solving strategies and building domain knowledge in a self-directed manner."

Another important feature is the need for a change in attitude and role of teachers and students, in the latter, thereby stimulating the capacity for self-initiative:

EP_08: "...teaching based on problem solving (in which students have an active role in their learning) allow students to understand difficult concepts better and retain the knowledge acquired for a long period of time."

EP_14: "The educator should use a problem to prompt students' experiences and interests, and then help them to be actively involved with further learning."

EP_27: "the author takes the method of problem-based learning and suitably arranges the course design, which with a good result not only improves the quality of teaching, but also trains students' capacity for self-learning, active exploration and mutual cooperation."

Finally, the studies highlight the characteristic of collaborative learning activities with emphasis on group learning as a key point of PBL:

EP_08: "The design project is structured around a formalized base group which exists for the duration of the subject. The base groups are selected at random from the different degree programs and, in general, consist of three members with no two members from the same degree program."

EP_11: "It is clearly an advantage of the PBL curriculum that students have ample opportunities to practice teamwork skills."

B. *Effectiveness*

The purpose of this question was to research in primary studies which of them showed their effectiveness, ie good results as to applying the PBL method. The studies were divided into eleven (11) topics that diversify the effectiveness of the PBL process, as given in Figure 3.

Topic	Primary Study	Qty -%
Interactions	EP_36	1 – 3,57%
E-Learning support tools	EP_08, EP_17, EP_48	3 – 7,14%
Critical vision	EP_18	1 – 3,57%
Better environment for the lessons	EP_13	1 – 3,57%
Homework	EP_28	1 – 3,57%
Developing games	EP_29, EP_46	2 – 7,14%
Use of real problems	EP_01, EP_43, EP_44, EP_45	4 – 14,29%
Group work	EP_01, EP_34, EP_43	3 – 10, 71%
Use of other approaches	EP_01, EP_03, EP_24, EP_26, EP_29, EP_31, EP_38, EP_40, EP_46, EP_47, EP_48	10 – 35,7%
Construction of applications	EP_13, EP_36, EP_37, EP_44	4 – 14, 29%
Competitions	EP_42	1 – 3,57%

Figure 3. Results on the Effectiveness in PBL.

Most studies (35.7%) are summarized into one topic, where the authors state that PBL is more effective when combined with collaboration strategies, such as collaborative learning, and constructing motivating applications, such as developing games, competitions or applications related to market problems, as highlighted in the evidence:

EP_01: *"This article described o PBL mode under the guidance of instruction system design, constructivism learning theory, Brunner's discovery method and PBL pedagogy."*

EP_03: "Combining PBL with cooperative learning provides a mechanism for students to maximize their own and other group members' learning by working in teams to accomplish a common task or goal."

EP_29: *"In a game development project, students can develop their own requirements for a domain in which they are experts."*

EP_42: *"... develop a National RoboCode Competition both authors saw potential benefits to enhance their PBL initiative and to add an interesting challenge for their students.*

EP_43: *"The cases are written in close consultation with industry practitioners to ensure that they resemble, as realistically as possible, real-world business problems."*

EP_44: *"I examined how student self-efficacy, as it relates to being software development professionals, changed while involved in PBL environment."*

Other criteria were also mentioned, such as the formation of teams of group work, e-learning support tools, development of critical vision by the students and activities outside the classroom:

EP_34: *"The team includes a group of people (about 5-6 people) that work together to learn or work on a subject or project. They have different backgrounds, such as academic disciplines, skills and expertise, and working experiences."*

EP_n:"... in an internet-based learning environment, it is considerably more efficient for students to exchange information and opinions in comparison to the traditional classroom-oriented learning environment, which indirectly encourages communication among students."

EP_18: *"MALESAbrain encourages learners to judge or critically evaluate the solutions posted by others before exploring further knowledge-content."*

EP_28: *"it is also necessary to leave homework, especially experimental projects to students so as to consolidate their knowledge learned in the classroom."*

C. *PBL Methodology*

The purpose of this question was to point how the PBL methodology is applied in the teaching of Computer Science. To answer this question, five elements considered essential in a PBL methodology applied to the teaching of computing were used, which, according to the authors Santos et al. [3] and [17], are problem, environment, content, people and processes. Figure 4 shows the topics and the number of primary studies associated with these elements

Topic	Primary Study	Qty-%
Problem	EP_04, EP_06, EP_45, EP_46	4 – 8,5%
Environment	EP_05, EP_08, EP_09, EP_10, EP_14, EP_18, EP_31, EP_32, EP_36, EP_39	10 – 21,3%
Role of the student/teacher	EP_24	1 – 2,13%
Content	EP_01, EP_02, EP_03, EP_04, EP_06, EP_07, EP_08, EP_10, EP_13, EP_14, EP_15, EP_16, EP_25, EP_28, EP_40, EP_45	16 – 34, 4%
Process	EP_03, EP_09, EP_10, EP_11, EP_14, EP_25, EP_28, EP_29, EP_38, EP_39, EP_40, EP_42, EP_43	13 – 27,66%

Figure 4. Results on the PBL Methodology.

Among the criteria cited, the part of content was the most discussed, 34.4% of the primary studies doing so, in which the disciplines that adopted PBL methodology were cited: software engineering, robotics, embedded systems, information systems management, operating systems, digital systems, and the development and quality of software. Some pieces of evidence comment on the proposals of these disciplines:

EP_01:"The Software engineering course was taken as the example to illustrate the implementation of the PBL model."

EP_02:"Topics are introduced in a way such that students are confident with what computer studies imply despite the use of the robot. Robotics is only the "toy" for motivating beginner students on the subject."

EP_16: "In order to verify the effect of PBL in online teaching, we have made an experiment on the course of "Object-Oriented Programming With Java" over the last 3 years: we recorded students' performance, their feelings and the outcome of study; by making comparison, we analyzed and summarized the strategy for guidance, improved the strategies and teachers' ability in guiding students."

The criteria associated with the processes of the PBL method, for example, the steps of teaching and assessment methods used were also highlighted in 27.66% of the primary studies:

EP_03: *"Student feedback is used extensively to evaluate the performance of both the teaching staff and the subject. These student evaluations consist of both formalized university-wide evaluations (JCET) and informal evaluations conducted solely for this subject by teaching staff associated with the subject.*

Another important element was the environment, mentioned in 21.3% of the studies, in which the most diverse environments that support teaching based on PBL were discussed:

EP_08: *providing a richer learning environment, offering students alternative ways of gaining knowledge and information, enabling more accurate assessment, and individualizing practice, feedback and reflection."*

D. *Advantages and benefits of PBL*

This question aimed to investigate the advantages and benefits of using PBL methodology in Computer Science. Various benefits were listed, divided into eight (8) different topics. The most discussed topic, with 38.24%, was that of the students' improvement in developing their skills. Also from the perspective of the students, other topics were highlighted such as the ease in solving problems, a better critical view on various subjects, motivated students mmotivated by the lesson and more participatory, self-directed learning, planning study time, being better prepared for the work environment work. From the perspective of the teacher, what stands out is the improvement in the practice of teaching. Fig.5 summarizes all the topics, as well as primary studies associated with them.

Topic	Primary Study	Qty-%
Improvement in the development of the the practice of teaching	EP_28, EP_29, EP_37, EP_40, EP_42, EP_45	6 – 17,65%
Improvement in the development of skills	EP_02, EP_03, EP_04, EP_06, EP_07, EP_09, EP_10, EP_18, EP_24, EP_25, EP_39, EP_42, EP_44	13 – 38,24%
Facilty in identifying and solving problems	EP_01, EP_22, EP_33, EP_38, EP_41	5 – 14,71%
Better preparation for the jobs market	EP_43, EP_44	2 – 5,88%
Application in other courses	EP_08, EP_12	2 – 5,88%
Positive feedback from the students	EP_19, EP_24, EP_35, EP_37	4 – 11, 75%
Better management of study time	EP_31	1 – 2,94%
Better/ greater particicipation in class	EP_16	1 – 2,94%

Figure 5. Results on the Advantages and Benefits of PBL.

Among the pieces of evidence found, are those that stand out which reinforce these advantages and benefits:

EP_40: *"... the application of this methodology have enabled students to receive all the theoretical concepts and, also, the students have developed transversal skills such as writing, learning and oral expressions in the same course, thereby developing a project consisting of a semi-complex digital system."*

EP_07: *"PBL skill is very important in learning. Students are encouraged to use their present knowledge and skills to find the answer in PBL. Assessment is ongoing and regular so as to provide feedback that assists, extends and improves learning. The tutor is an essential part of providing appropriate and constructive feedback that is meaningful to students, supports and empowers their learning, and contributes to their development."*

EP_44: *"Twenty-seven students indicated that because of the course they were ready to deal with the demands of actual software development projects, even though some seemed surprised about their new-found confidence."*

EP_24: *"Student feedback indicated that the project was preferred as a learning experience over traditional, lecture-based methods. The product-based method maintained student engagement and encouraged intentional learning tendencies."*

EP_16*:"Class participation rate has increased by 73%, and the rate of on-time handing in assignment by 36%, and the percentage of significant questions increased prominently too."*

E. *Challenges Identified*

This question aimed to list the main challenges and problems encountered during the process of teaching / learning with PBL in Computer Science. Twelve (12) different topics that address challenges and problems were identified. Figure 6 shows the 12 topics and the number of primary studies associated with them.

Topic	Primary Study	Qty-%
Application of the methodology	EP_09, EP_10, EP_28	3 – 13,04%
Difficulties in disciplines	EP_28, EP_37, EP_39	3 – 13,04%
Knowledge of methodology	EP_09, EP_35, EP_39	3 – 13,04%
Time	EP_25, EP_28, EP_40	3 – 13,04%
Few goood problems	EP_42, EP_43	2 – 8,70%
Resrictions on the methodology	EP_29	1 – 4,35%
Variety of knowledge of the students	EP_14	1 – 4,35%
Dissemination of knowledge	EP_12, EP_28	2 – 8,70%
Use of other technologies	EP_36	1 – 4,35%
Interest of the students in Computer Science	EP_46	1 – 4,35%
Difficulty in the objectives reached and good results	EP_03, EP_07, EP_11	3 – 13,04%

Figure 6. Results on Challenges found in PBL.

According to the studies, the main challenges of using the methodology are the lack of belief in and knowledge of the methodology, deficiencies in the formation of basic foundations of Computer Science and difficulty in applying the methodology as highlighted by some of the evidence found:

EP_28: *"It is difficult for a teacher to organize and control the learning process when the number of students is large."*

EP_28: *"Before taking this course, students generally have learned object-oriented programming language(s) such as C, Java, unfortunately they usually only know the language syntax but don't have practical project experiences."*

EP_35: *"... in o PBL environment, these students have to climb a stiff learning curve and overcome much resistance that might pose challenges to students in the initial stage, and limit the potential effects of PBL."*

EP_25: *"... the traditional teaching method is more efficient in knowledge of teaching and learning; in contrast, PBL may require teachers and students to expend more time and effort. Under the limited class hours, the teaching timetable may not be completed in*

PBL. In this regard, we believe that some appropriate additions and adjustments be made according to the actualnumber of class hours."

EP_43: *"Unfortunately, the adoption of a real-world project is not always a feasible option. This is mostly due to difficulty in gaining access to suitable real-world organizations and resource constraints in managing the projects."*

EP_29: *"What challenges educators the most is often not the lack of teaching materials, but the constraints imposed upon a course. These include (1) type of audience, (2) the limited amount of time available for a prearranged set of course objectives, (3) a rigid curriculum, and (4) the choice of teaching methods."*

EP_14: *"The variety of student backgrounds had the potential to cause problems when teaching the module."*

Another important point refers to the learning process, since not all students learn equally. Also, some students take on different responsibilities, thus making teachers' evaluation of this difficult. As a result, teachers very often do not know how to assess students and hence the effectiveness of the methodology, by ensuring that students have achieved the desired goals, as the evidence stresses:

EP_28: *"When students are organized as groups, their capabilities may not be developed equally. Some play a dominant role in the group, while others are there just to make up the number."*

EP_11: *"Besides the fundamental challenge of creating a good problem, educators are faced with the task of deciding how to evaluate the technique's effectiveness and how to assess whether students have met the overall learning objectives for the course.*

V. FINAL REMARKS

This paper has presented and discussed the results of a systematic mapping, and has identified the main characteristics of having used PBL in the field of Computer Science from 1997 to 2011. After the initial assessment of 2,464 articles, 52 primary studies were selected tthat were relevant for the research. From five research questions, it was possible to find evidence in a satisfactory way which showed that most applications of the PBL methodology are geared towards its applicability in the disciplines of Software Engineering and Programming.

From all the evidence reviewed, it was moreover possible to conclude that the PBL methodology has been applied in Computer Science, and been widely accepted by teachers and students and facilitated improving the education and training of professionals by providing a broader view of the real problems in the area. However, there is still a need to overcome several challenges and, above all, to provide good results from the application of the methodology with a view to disseminating positive points of this method and to increase belief in it by both educators as well as the students who have no knowledge or understanding about PBL.

Historically, very limited studies have focused on information technology (IT) programs in community colleges, let alone of women's participation in them. In light of the growing national debate on the need to increase female participation in Science, Technology, Engineering, and Mathematics (STEM), this study closely examines women's involvement in IT in higher education. This study builds on Belenky et al's study of women's five ways of knowing (silent knowing, subjective knowing, received knowing, procedural knowing, and constructed knowing) in the social sciences and humanities. Through analysis of women's IT pursuits at a community college, this study provides evidence not only for the five existing ways of knowing found in Belenky et al's study but also for a new way of knowing exclusive to IT: logistical knowing.

Keywords—Gender, STEM, Women's ways of knowing

I. INTRODUCTION

Over the last three decades, numerous studies have focused on addressing the concerns of women's representation in science, technology, engineering, and mathematics (STEM) programs in higher education [1]-[10]. In particular, since the birth of the computer, the field of information technology (IT) has seemed male dominated. Joint efforts of more than 1,200 American colleges and universities and STEM programs to promote, attract, and retain women, as well as seek female representation, have increased in the last few years [10][11]. This trend is reflected in a study done by Snyder, Tan, and Hoffman [12], in which women made significant progress in STEM programs, particularly in engineering, physics, and chemistry. However, the number of IT-related bachelor's degrees awarded to women dropped nearly a third during the same period, while degrees in other sciences increased progressively [9][13][14] (see Fig. 1).

According to statistics from U.S. Department of Education [15], from 1991 to 1997, there was nearly no significant difference between the numbers of associate degrees awarded in IT-related subjects to men and those to women. However, between 1997-1998 and 2002-2003, the number of degrees awarded peaked, and the growth rate of male students receiving associate degrees in IT-related subjects almost doubled, growing faster than the rate for female students [15] (see Fig. 2). Although the growth rate began to decline, the total number of men receiving associate degrees in IT-related subjects was still three times higher than the total number of women doing so.

universities. As Tsapogas [16] stated, the National Science Foundation (NSF) documented the positive impact of community colleges on undergraduates' and graduates' career and educational paths in science and engineering. Based on data from NSF's 2001 National Survey of Recent College Graduates, Tsapogas finds that 42% of computer and mathematical science bachelor's and master's degree graduates attended community colleges some time during their study. Of these, about 38% earned associate degrees in computer and mathematical science.

In Tsapogas' [17] second report, as of April 2003, there were more than four million individuals (less than 25% of whom were female) with at least a high school education working in science and engineering professions in the United States. Within that group, about 17% of responses indicated that their highest levels of educational achievement was an associate degree. However, in the computer and math occupations, less than 7% of four million individuals were females.

A variety of reasons has been suggested to explain this phenomenon, including a lack of female mentors and instructors [9][18][19], and parental support [18][19]. As technology plays an increasing role in people's lives and usage of computer applications, women's low representation and decreasing participation are receiving more attention [9]. There is no simple explanation for the imbalanced gender representation in IT-related subjects. This study approaches this gender imbalance by investigating women's ways of knowing in six specialties of IT-related subjects rather than in a traditional approach of treating computer science subject as a whole. The six specialties used in this study are: (1) computer programming, (2) Office application development, (3) Web application development, (4) database application development, (5) networking, communication, and security, and (6) non-IT.

II. METHOLODOLOGY

The focus in this study is women. Mertens argues that the qualitative methods, from feminists' perspectives, are the only truly "feminist" choice because they include the use of open-ended interviewing and ethnographic data collection to focus on interpretation, allow the immersion of the researcher in the social setting, and facilitate intersubjective understanding between the researcher and the participants [20].

Thus, the rationale for choosing the qualitative method, as Fine [21] argues, is to avoid a separation between the investigators and the persons under study. Such separation is considered a result of quantitative methods, which some feminists believe is a representation of patriarchal thinking.

A. Participants

Three departments of a local community college from one of the Midwest metropolitan areas in the United States participated in this study. This community college serves an average of 31,000 students a year. It offers more than 90 certificate programs, 59 occupation degrees, and 45 transfer prebaccalaureate programs. It is the largest single-campus community college in the nation outside of California. The departments involved in the study belong to the technology subdivision which offers computer-related courses to the community college district. On average, over 100 sessions of classes are offered and over 3,000 students are served every term by this technology subdivision.

Participants were students who took IT-related subjects at this college. In order to recruit these participants, the researcher contacted faculty members in three departments via e-mail to explain the nature of this study and request a list of women student's e-mail information. From the list, over 60 potential candidates were contacted by e-mail. Only 51 of them confirmed participation in the study. Ultimately, 41 participants successfully completed the questionnaires: two women preferred not to participate after reviewing the questions; six women did not return the questionnaires; and two returned questionnaires which were not included in the analysis due to insufficient data. For the five participants who were students taking courses with the researcher during the study, they were notified that their final course grade regardless would not be impacted in any way regardless of their participation or results in the study. Students who took basic classes such as introduction to computers were not chosen due to insufficient IT knowledge or skills to identify themselves as students in one of the IT specialties.

Demographic information of participants is grouped by the specialty rather than by IT as a whole, which is a typical and traditional way to analyze data. The racial composition of the sample included: 31 Caucasians; 1 Hispanic, 6 Asians, 2 African-Americans, and 1 American Indian. The ages of the participants ranged from 22 to 60 years.

B. Data Collection

Students' contact information was removed if they declined to participate in the study or if they did not respond to the questionnaires via e-mail. After receiving questionnaires via e-mail from 41 participants, each of the participants was assigned to a unique ID code. In the final analysis, an alias was assigned to each participant to further maintain anonymity. They were informed of how the study would be conducted under the guidelines established by the Office of Research Compliance and approved by the Institutional Review Board (IRB).

C. Instrumentation

A set of questionnaires (see Appendix) was incorporated with open-ended questions retrieved from the study conducted by Belenky et al. [22]. Permission to use the questions from Gilligan and Belenky et al.'s study was received via e-mail. These questionnaires were designed using the following eight categories:

Section I Profile: This category contains 10 multiple-choice questions to gather participants' demographic information, such as race (African American, Asian American, American Indian, Caucasian/White, or Hispanic American), highest level of education before taking courses at the college, IT specialty pursued, full- or part-time student, employment status, age (filled in), computer ownership, Internet accessibility, and parents' highest education level (none, high school, college degree, graduate degree, or professional degree).

Section II Background [22]: This category contains two open-ended questions to solicit participants' reflections on their lives over the years, what is important to them, and their present life.

Section III Self-descriptions [23]: Three open-ended questions are in this category to determine how participants see themselves, how they present themselves in their own words, what has changed in their lives from the past, and how they see themselves in the future.

Section IV Gender [22]: One open-ended question is in this category to ask participants how it feels to be a woman, and prompt self-examination of gender issues at work and home.

Section V Education: There are 14 open-ended questions (5 questions from Belenky et al.'s study) in this category to ask participants how they feel about the learning environment in terms of meeting learning needs for job or personal enrichment, why they chose this specific field/specialty, what influences they received to encourage or discourage to work/study in this specific IT specialty, the faculty/student relationship, a description of their learning style, their confidence level before and after entering the study, and what was the powerful learning experience they had.

Section VI Ways of knowing [22]: There are 10 open-ended questions in this category. It is designed to provide insight into their intuitions on how they judge an expert, how they determine the truth, how they deal with contradictions between answers between authorities (that is professors), how they assess some books, movies, or ideas to be better than others, and how they view opinion.

Section VII Comments [22]: It contains three scenarios to ask them for comments, such as, "Sometimes when someone has written something that really impresses me, I say to myself that I'll never have an idea as good as that," "People from different countries believe something is different in terms of right and wrong," and "Sometimes I really get bored with school because it is sitting around listening to people talk about unimportant things." There are no standard comments here. The purpose was to see how participants approached the scenarios and how they analyzed, expressed, and built their responses by identifying the words participants used in the responses to support what way of knowing they possess.

Section VIII Conclusion [22]: Two open-ended questions are in this category to ask them how they view themselves 15 years from now, and give an opportunity for a free response to any concerns not covered by the above questions.

This interview was designed to allow participants to review their responses on each question before sending in. Authentic answers for each question would be anticipated from these participants since they sat in their own comfort zone at home or in an office with ample time to think their responses.

D. Data Analysis Strategies

A paper copy of each answered questionnaire was prepared and grouped into a folder according to the IT specialty claimed. Making sense out of text, as Creswell [24] notes, is involved in the process of data analysis. Ryan and Bernard [25] say that the qualitative data is text. Therefore, the method to analyze texts found in questionnaires is called key-words-in-context (KWIC) [25]. KWIC uses particular words or phrases as units of analysis.

After questionnaires were checked for completion, analysis proceeded from one specialty to the next. This means that participants within the same specialty would have all of their responses reviewed and marked using the KWIC method before the researcher analyzed the responses of participants in another specialty. The particular words, phrases, or implications used in the KWIC analysis method were cited from the study conducted by Belenky et al. [22] except the logistical knowing, which was found by this study. They are grouped by each way of knowing as follows:

- Silence: follow, take order, just do it, whatever, feel deaf, feel helpless, do not care, etc.
- Received knowing: professor says, I believe my instructor, either yes or no, assume there is only one right answer, believing that truth comes from others, they still their own voices to hear the voices of others, I have to rely on the experts, no way to determine "truth" without the aid of authority, etc.
- Subjective knowing: I want, I think, my experience, stubborn, generous, opinionated, no longer agree with what some people thought was a simple matter of right and wrong, intuition, instinct, just knowing, I have a right to my opinion, it's just my opinion, women become their own authorities, I think and feel all at the same time and I know what is right, my gut is my best friend etc.
- Procedural knowing (separate knowing): step by step; follow the instruction; objective; feel; reasons; "ways of looking" is central to this position; you have to see things for what they are, not for what you want to see them; applying procedure for obtaining and communicating knowledge.; world becomes more manageable; knowing requires careful observation and analysis; engaging in conscious, deliberate, systematic analysis; truth lies hidden beneath the surface, not immediately accessible; think before they speak, they speak in measurable tones. Often, they do not speak at all. But, this is not a passive silence, it is on the other side of silence; reason is stirring; law, not men, govern the world; authority is nonarbitrary; it rests on reason rather than power or status; experts are only as good as their arguments, etc.
- Procedural knowing (connected knowing): trustworthy knowledge comes from personal experience, rather than the pronouncements of authorities (builds on the subjective conviction);

develop procedure for gaining access to other people's knowledge; share experience; believing game; not engage in metaphysical debate; no one tried to prove anything or to convert anyone; do not judge but to understand people's words by some impersonal standard, etc.

- Constructed knowing: reclaim the self by attempting to integrate knowledge learned from others, all knowledge is constructed, circumstances change our ways of looking at thing change, good expert whose answers reflect the complexity, passionate knowers, true expert must reveal an appreciation for complexity and a sense of humility about their knowledge, aspire to work that contributes to the empowerment and improvement in the quality of life of others; using my mind to help people, caring for others, a room of their own, commitment and action, cradling the environment, humanizing cities, etc.

- Logistical knowing: needs a degree to prove to employer, needs a degree/education in order to find employment, update skills, strengthen ability, working experience related to education, try to connect what they now have to what they want to have, having a career, to be independent, to be self-supportive. This logistical knowing was identified by this study and was not found in Belenky et al.'s study [22].

Following the analysis, a table of all participants' ways of knowing was created by listing their responses that were most representative of the characteristics found in Belenky et al.'s model [22]. The purpose of this table of knowing is to highlight the ways of knowing each participant possesses.

III. FINDINGS

This section shows the most common ways of knowing among women from each IT specialty. The most common ways of knowing are shaded in colors according to the table of knowing found in each specialty.

Figure 3 shows three common ways of knowing (constructed knowing, procedural knowing, and logistical knowing) exhibited among participants in the programming specialty.

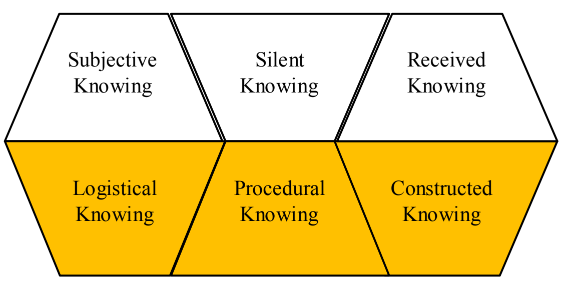

Fig. 3 Ways of Knowing for Programming Specialty

Figure 4 shows two common ways of knowing (subjective knowing and procedural knowing) found among participants in the Web application development specialty.

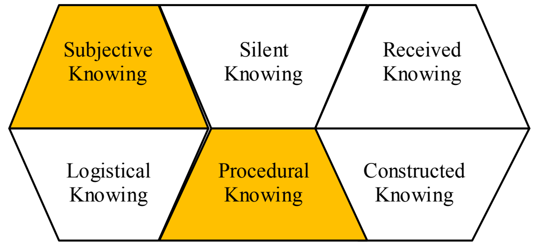

Fig. 4 Ways of Knowing for Web Application Development Specialty

Figure 5 shows three common ways of knowing (constructed knowing, procedural knowing, and logistical knowing), identical to that of the programming specialty, found among participants in the Office application development specialty.

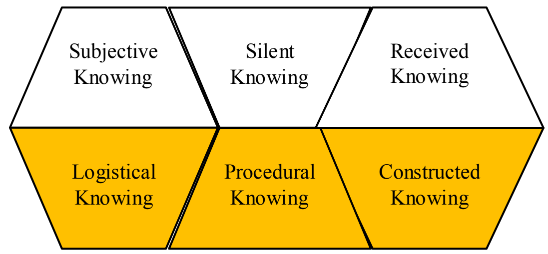

Fig. 5 Ways of Knowing for Office Application Development Specialty

Figure 6 shows two common ways of knowing (constructed knowing, and logistical knowing) found among participants in the networking, communication and security specialty.

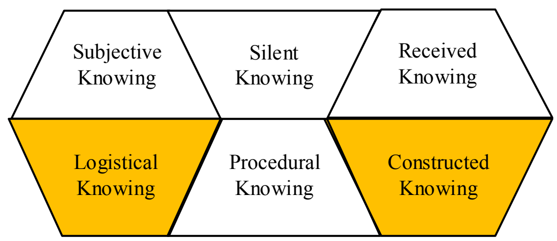

Fig. 6 Ways of Knowing for Networking, Communication and Security Specialty

Figure 7 shows only one common way of knowing, which was found in participants from the database application development specialty.

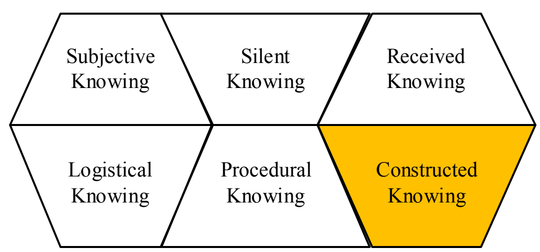

Fig. 7 Ways of Knowing for Database Application Development Specialty

Figure 8 shows two common ways of knowing constructed knowing and logistical knowing) found among participants in the non-IT specialty.

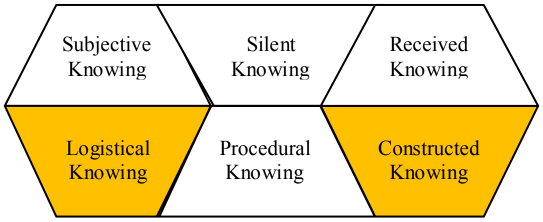

Fig. 8 Ways of Knowing for the NonIT Specialty

IV CONCLUSION

The ways of knowing, Belenky et al. found [22], do not always exist or stay the same; they are a snapshot which should not be used to represent the whole picture of women's thoughts and lives due to their complexities and uniqueness. Similar ways of knowing can be identified in men's thoughts and lives as well, and different researchers might approach this subject differently. This study did not intend to replicate Belenky et al.'s study [22]. Instead, it used their findings as a foundation to interpret the ways of knowing among women studying in six IT specialties.

The findings for women from the same IT specialty showed that they did not possess all six ways of knowing. During different stages in life, these women exhibited different ways of knowing. In different IT specialties, these women might not possess the same ways of knowing either. Thus, this study echoes Belenky et al.'s findings that women do not keep the same way of knowing all the time and it is only a snapshot of the whole picture in these women's thoughts and lives which are not only complex and unique, but also inspiring. The sequence of the ways of knowing (silent knowing, receiving knowing, subjective knowing, etc.) in this study does not imply that one way of knowing is superior to another. Further research is necessary to determine the causes of such different ways of knowing, such as childhood, socioeconomic background, heritage, and life experiences.

This study has two implications for practices and two implications for research. For practices, the first is to show female students what ways of knowing they possess and how each fits into the IT specialty they want to pursue. Doing so allows them to take advantage of their ways of knowing and to reach their potential. The second is to show IT instructors that women possess many ways of knowing that are shared among men as well. Harding [26] points out that "women can do good science just as well as men; [therefore] they should be given the same opportunities to demonstrate their abilities" (p. 61). However, equal opportunity does not mean teaching everyone in the same way. Instead, based on individual ways of knowing, instructors should consider applying different pedagogy to different women, but uphold the same requirements. In terms of implications for research, the first is that women using certain ways of knowing are suited for one or more of the IT specialties. Web application development, for instance, is well-suited for women possessing a subjective way of knowing with a talent in design. Identifying ways of knowing aids selection of an IT specialty to study. The second implication for research is that women's ways of knowing exist not only in the field of social science and liberal arts [22], but also in the field of IT in higher education. Due to the growing reliance on IT in business and everyday life, women in this study also show use of the logistical way of knowing, which did not exist in Belenky et al.'s study.

Furthermore, there is no need to overemphasize how valuable women's participation in technology was in the past, such as in the creation of typewriters [27][28][29], the microwave oven [30][31], automotive design, and the computer keyboard [31]. The value of women's participation should not be discounted and absent from present and future IT development. Thus, the significance of this study is identification of not only a new way of knowing - logistical knowing - but also provision of direction for educators to assist women in selecting IT specialties in higher education. Continued research can harness this knowledge to establish an inventory of ways to best support women in their exploration of IT.

Appendix

I. <u>Profile</u>

A. Which one can best describe your race/ethnic group?

(1)African American (2) Asian American (3) American Indian (4) Caucasian/White (5) Hispanic American

B. Your highest level of education before taking courses at this institution.

(1)High school or less (2) Some university or college (3) University or college degree (4) Graduate degree (master, doctoral or equivalent) (5) Professional degree

C. What is your major/concentration/emphasis? (select **<u>one</u>** that most closely matches your study/learning/job):

1) Programming (all programming languages, C++, Java, VB, C#, .Net etc.)
2) Web application development (HTML, CSS, ASP, Perl, XML, Dreamweaver etc.)
3) Office application development (Word, Excel, Access, PowerPoint, Publisher, Keyboarding, etc.)
4) Networking, communication & security (CISCO, Unix, security, Windows etc.)
5) Database application development (Oracle, SQL Server, DB2, MySQL etc.)
6) Game application development
7) Management of information systems
8) Other (please specify)_______

D. Are you a? 1. full-time student 2. part-time student

E. Current employment status 1. full-time 2. part-time 3. N/A

F. Your age____.

G. Do you own a computer at home? 1. Yes. 2. No.

H. Do you have Internet access at home? 1. Yes. 2. No.

I. What is your mother's highest level of education?

(1)None (2) High School Diploma (3) College Degree (4) Graduate Degree (5) Professional Degree

J. What is your father's highest level of education?

(1)None (2) High School Diploma (3) College Degree (4) Graduate Degree (5) Professional Degree

II. Background

A. What stands out for you in your life over the past few years? What kinds of things have been important? What stays with you?

B. Tell me something about what your life is like right now. What do you care about, think about?

III. Self-Descriptions

A. How would you describe yourself to yourself? If you were to tell yourself who you really are, how would you do that?

B. Is the way you see yourself now different from the way you saw yourself in the past? What led to the changes? Have there been any other turning points?

C. How do you see yourself changing in the future?

IV. Gender What does being a woman mean to you? Do you think there are any important differences between women and men? How has your sense of yourself as a woman been changing?

V. Education

A. What do you think will stay with you about your experiences here in this school, in this program?

B. Did you meet anyone during the study who had the same experience as yours?

C. Has being here [being in this program] changed the way you think about yourself or the world?

D. In your learning here, have you come across an idea that made you see things differently or think about things differently?

E. What has been most helpful to you about this place?

F. Are there things this [school, program, environment] doesn't provide that are important to you? Are there things you would like to learn that you don't think you can learn here?

G. Looking back over your whole life, can you tell me about a really powerful learning experience that you've had, in or out of school?

H. Why did you choose this specialty/concentration/profession you are studying?

I. How did your family members influence the above choice?

J. How did your professors and peers influence your choice of specialty?

K. How confident did you feel before and after entering to your program of study?

L. Describe your learning style (visual, group, individual etc.)? Give some examples.

M. If you could change three things about your program, what would they be?

N. What are student/faculty relationships like in your program? Are you happy with the student/faculty relationships as they are? In your opinion, what would the ideal student/faculty relationships be like (i.e. role model, mentor, facilitator etc)?

VI. Ways of knowing

A. Please comment on: "In areas where the right answers are known, I think the experts should tell us what is right. But in areas where there is no right answer, I think anybody's opinion is as good as another."

B. In learning about something you really want to know, can you rely on experts, why or why not?

C. How do you know someone is an expert?

D. What will you do if the answer from two professors contradicted each other?

E. If experts disagree on something today, do you think that someday they will come to some agreement? Why or why not?

F. How do you know what is right/true?

G. Do you agree with this person who says that where there are no right answers anybody's opinion is as good as another's?

H. Can you think of an opinion that you think is wrong?

I. Are some movies (books, ideas) better than others? (If yes) What makes them better?

J. Sometimes people talk about "searching for truth." What do you think people mean when they say that? Is that what scientist are doing, do you think? Searching for truth? Will they find it? How about artists (painters, writers, and so on)? Are they searching for truth?

VII. Comment on followings:

A. "Sometimes I read something that someone has written or I hear somebody say something, and it really impresses me. I say to myself, 'I'll never have an idea as good as that.' I just don't know how people ever get to the point where they have something so important to say."

B. "If the people in one country say,' We believe such and such is the right way to think about something,' and people in another country say just the opposite, and the opposite is so or the right way to think, then time will usually tell which country is right."

C. "Sometimes I really get bored with school, because it is just so much sitting around listening to other people or the teacher talk about things that aren't important."

VIII. Conclusion

A. What will you and your life be like fifteen years from now?

B. Are there any other questions that I should have asked you, that would have thrown some light on these issues we are interested in: women's lives and women's learning?

The Good, the Bad and the Ugly: Using Videos to Reverse Systems Analysis and Design Instruction

Imelda Smit & Roelien Goede
Information Technology Department
North-West University (Vaal Triangle Campus)
Vanderbijlpark, SOUTH AFRICA
imelda.smit@nwu.ac.za | roelien.goede@nwu.ac.za

***Abstract*—Systems Analysis and Design (SAD) is a second-year subject offered within the Information Technology (IT) course at the Vaal Triangle Campus of the North-West University in South Africa. The diverse environment of this campus includes students representing most ethnic groups in South Africa, adding to the complexity of classroom interaction. This is further complicated by the fact that students find the subject difficult, mostly because it includes many new concepts used in different contexts. SAD students also grapple with fuzzy issues such as fact-finding from system users and representing information obtained from models that are designed for feedback. SAD is therefore far removed from the more exact subjects like programming and mathematics that many IT students excel in.**

Videos explaining difficult SAD concepts were produced and made available to students on a Learning Management System (LMS). The students were motivated to come to classes prepared. During the first semester concepts were explained during formal class times. Formal explanations were not given during the second semester because students were expected to build on the knowledge that they had gained during the first semester. The students were also required to make use of all the resources available to them to come to class prepared. Group work was done in class during both semesters.

The success of implementing reverse instruction in the second semester is evaluated through an interpretive lens. The fifteen modal aspects developed by the philosopher Herman Dooyeweerd were used to ensure a clearer picture of the researched situation was painted with a view on diversity and unexpected usage.

Keywords—reverse instruction; Dooyeweerdian modal aspects; Systems Analysis and Design; video usage

I. Introduction

In an environment where resources are limited and where students come from diverse and predominantly deprived backgrounds, instructors are expected to find ways to enable students to enhance their learning. In the information technology (IT), the situation is even worse, especially when some students have access to their own computers while others do not. In a subject like Systems Analysis and Design (SAD), certain module outcomes overwhelm the students. Some of these outcomes include addressing an overload of new material in combination with a practical group system implementation, acquiring new skills and building solid relationships with both business users and technical staff. This is due mostly to the fact that many students prefer the rigor of writing a program to the fuzziness of determining the needs of business people.

In this context, it was decided to produce videos that explain the difficult concepts students come across when studying SAD. Videos were uploaded onto eFundi, the university Learning Management System (LMS). All registered students have access to eFundi and computer laboratories are available to students on a 24/7 time-table. Students who have access to their own computers and the Internet can access eFundi from home. It is also possible to download the videos to watch offline.

Several reasons motivated the decision to use videos: they are easy to make; they can be used in subsequent offerings of SAD; they can be used in other subjects to do revision on concepts previously discussed; they do not take up any class time (a limited commodity at university level) and; students can watch videos an endless number of times.

As a starting point it was decided to focus on difficult concepts and to keep the video lengths as close as possible to ten minutes.

This paper aims to investigate the use of the modal aspects as developed by Dooyeweerd to achieve a greater understanding of this intervention, while providing the grounding necessary for further research.

II. Literature Review

A. *Utilizing Videos*

Videos are a very good way to encourage learning. YouTube, for example, allows one to learn about a topic of your choice. A more sophisticated example of this is the Khan Academy (www.khanacademy.org) developed by Salman Khan, which uses videos to tackle more than 4000 topics and concepts which are covered in school as well as at tertiary level. Students of today, the millennials, are accustomed to using videos as learning tools. According to Thompson (2011), Khan-videos are seven to fourteen minutes in duration and are used in structured and unstructured ways by teachers and pupils all over the world. Prensky (2011) states that the most valuable feature of these videos is that they, or parts of them, can be replayed numerous times. This happens in an environment where a student does not have to reveal his or her ignorance or slow down the class.

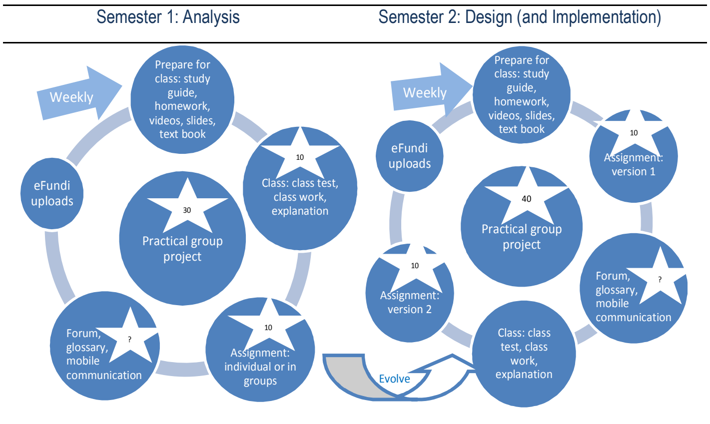
A study conducted by Laine, Myllymäki and Hakala (2010) found that in the context of technology subjects, video-teaching offers a different learning environment to that of face-to-face teaching. They also found that one of the advantages of using videos is that a student can control the progress of his or her own learning. Keenan (2008) found videos to be a cost effective way to train people. This finding is significant in an environment where budgets are tight – something that is true in many educational settings.

B. Reversed Classes

One of the purposes of Khan-videos is the flipping of classes, or reversing instruction. This happens when lectures are made available to students in the form of videos. The videos are assigned to students as homework. In this context class time is viewed as too valuable to be used for formal lectures and is reserved for guided homework, one-to-one tutoring and hands-on project work (Khan & Noschese, 2011). According to Crouch and Mazur (2001), Eric Mazure, who does not make use of videos but who does make use of reverse instruction, reported that students learn very little through traditional lectures. According to him, students need to be actively engaged with study material and this can only happen when they come to class prepared.

C. Context of the Research

The course offering relied on conventional classes, supported by an LMS – an open source Sakai development used by the university. Students were expected to come to classes prepared. Classes commenced with baseline assessment, followed by class discussions and the completion of assignments which were facilitated by the instructor. A practical project spanned the full year and students applied the concepts covered each week in order to develop a practical system. Individual as well as group assignments formed part of the course structure. The focus of assignments was to encourage students to participate actively in the learning process. The group project and some of the assignments (towards the end of the semester) allowed students to learn collaboratively. This is similar to peer instruction which is advocated by Crouch and Mazur (2001). During class various strategies and forms of media were used to accommodate different learning styles. A bonus mark scheme was implemented to encourage students to read beyond the prescribed course material.



Notes:

- Bubbles with stars indicate assessments contributing to the participation mark.
- Semester Tests (not shown in the depiction) are written every few weeks (3 per semester) and make up the remaining marks (50% in semester 1 and 40% in semester 2).
- Strict guidelines were established regarding the allocation of questions according to Bloom's taxonomy.
- During semester 1 forum and glossary contributions were evaluated to improve low scores for assignments/class tests.
- Examinations take the format of a first opportunity followed by a second opportunity if the first is failed. Both the participation mark and the examination mark have a weight of 50% in the calculation of the final mark.
- Examination questions are drawn from semester tests, class tests, assignments/class work, homework and videos.

Fig. 1. Instructional design of systems analysis and design modules.

The following learning outcomes on National Qualifications Framework (NQF) level 5 were covered in the modules and the students should have mastered these upon completion of these modules:

- Knowledge: Upon completion, students will demonstrate that they possess the necessary knowledge of and insight into the phases and techniques of the Systems Development Life Cycle to apply this to the planning, analysis and design of a system.
- Skills: Students will be able to apply the phases and techniques of systems analysis, design and techniques of systems development in a project. They will be able to manage a project. Students will be able to apply creative skills when they develop a computerized system. Teamwork forms an integral part of their skills. The student will be able to solve problems creatively and develop a computerized system. Group work will be completed successfully.
- Attitude: Awareness of the following is important:
  - Systems are developed for consumers and their preferences and requirements have to be addressed during the analysis, design and development process;
  - Systems must be completed accurately and according to the agreed upon manner;
  - Client information must be treated with the necessary confidentiality; and
  - Computer resources must be used ethically and responsibly.

The framework for the application of system thinking forms the backbone of the course. This is the hypothetical methodology used throughout the course to demonstrate a representative systems development process. Students were also introduced to alternative routes and strategies, like the waterfall development approach, the iterative development approach, model-driven development and the rapid development strategy. These are all covered in the prescribed textbook *Systems Analysis and Design for the Global Enterprise, 7th Ed* by Bentley and Whitten.

The second semester focused on self-directed learning and reversed instruction (or flipped instruction). A depiction of the instructional strategy is shown in Figure 1.

D. Issues to be Addressed

From the discussion on background general issues influencing the research were identified. These two issues are: (1) problems resulting from the diversity of students and within the learning environment, and (2) the unexpected uses of the technology.

1) Diversity

Several issues related to diversity played a role in this research. As stated earlier, the students in this course came from several diverse backgrounds. This impacted on the interaction in class. A further issue related to the fact that not all students had access to their own computers. This resulted in them using a diverse number of computers from the university, family members and friends to gain access to the material – which was in this case a minor challenge. In addition, a diverse group of people was involved in this study, each of whom played an important role and offered up different perspectives. The lecturer guided the students, the students made use of technology to learn about technology, and their peers supported and interacted with them. Each of these role-players needed to be managed in a diverse setting.

2) Unexpected Uses

The intention of this research is to get students to use videos to assist in class preparation, but is that all that they will gain from the intervention? What other possibly uses could be found when you use videos to teach students? Will they start using videos for other purposes? Since students are known to love technology, it is hoped that many unexpected uses will evolve through the use of the videos for class preparation.

III. PHILOSOPHICAL FRAMEWORK

The work of Herman Dooyeweerd, a Dutch philosopher who developed fifteen modal aspects, stands central to this study. It provides a framework for theoretical thinking and understanding reality and guides the understanding of how reverse instruction through the use of videos can enhance learning within the South African context.

An important part of Dooyeweerd's philosophy is his theory of modal aspects in which he discusses fifteen aspects of reality. Dooyeweerd (1969:4) argues that it is possible to describe all aspects of reality in terms of these fifteen aspects. Table 1 list the fifteen aspects and illustrates each with examples of the types of things qualified by the aspect. Each aspect has a kernel of meaning along with retrocipation and anticipation of other aspects.

Through the retrocipation and anticipation of other aspects, each aspect inherently relates to others. Retrocipation is when an aspect reaches back to an earlier aspect, while anticipation is when an aspect reaches forward to a later aspect. For example, a video can be watched with peers, making it a social activity, but that interaction creates interest and fun (aesthetic aspect) for the users. In this way meaning of an aspect is built in the sense that we have a kernel of meaning with retrocipation and anticipation of other aspects.

Another important part of Dooyeweerdian thinking is the theory of individuality structures. An individuality structure refers to a concrete entity or event which has special qualities distinguishing it from all other individuality structures (Kalsbeek, 1975: 42-43). When we work with individuality structures we always ask the question "What?". With aspects the question is "How?" since aspects are concerned with the manner of being (a mode). That is why Dooyeweerd refers to them as modal aspects.

TABLE 1. Dooyeweerd's fifteen modal aspects of reality listed as types of things by qualifying aspect along with using videos to learn difficult SAD concepts (as discussed by Basden 2008: 25).

Aspect	Example things	Using of videos to learn difficult SAD concepts
Quantitative	Amount, Proportion	Number of participants, number video's
Spatial	Shape, Distance, Angle, Direction	Shape of computer (desktop, laptop), space you are in when watching a video, size of video
Kinematic	Path or route, Flow	Movement while using the device (watching, listening)
Physical	Solids, Fluids, Gases;, Energy, Waves, Particles, Materials, Fields, Forces	Capacity of computer, capacity of network in streaming the video
Biotic	Plants; Organism, Organ, Tissue, Cell; Animals	Interruptions hinders study progress, interruptions motivate much needed break from watching/studies
Psychic	Sound, Colour, Feeling, Emotion, Excitation	Users feel good about using video's for learning
Analytic	Concepts; Distinctions, Deductions, Awareness	Get answers to question – "how do I do this?"
Formative	Goal, Achievement, Forming, Will, Tool, Skill	Structuring of sentences and diagrams
Lingual	Word, Sentence, Book, Writing, Utterance, Diagram, Index	Communicate with student by lecturer, formulating questions and explanations, student's lingual capacity
Social	Friendship, Institution, Status, Respect	A "fun" way to learn, can it be done with peers?
Economic	Resource, Limit, Production & consumption, Money, Management	Using technology resources (only at campus or at home with own resources as well); clarity of video's
Aesthetic	Music, Sculpture, Cuisine, Humour, Fun, Sport, Nuance	Style of video
Juridical	Responsibility & rights, Reward & punishment, Laws	Addressing actual student study needs (which will improve their ability to understand and scaffold)
Ethical	Act of generosity, Sacrifice	Give pupils the motivation they need to understand the subject
Pistic	Religions, Ideologies; Faith, Trust, Loyalty, Worship, Commitment, Ritual	A shared goal to ensure improved systems analysis and design skills among students

Therefore, when an individuality structure is analyzed theoretically, it is crucial to start with the modal aspects. Only then can the investigator understand the entity as a whole. This summary of Dooyeweerd's philosophy provides the conceptual basis for addressing the issues identified above.

IV. EMPIRICAL STUDY

A. Research Design

According to Myers (2011), there are various ways to classify research methodology. Two of the most common are quantitative and qualitative research. Quantitative research was developed to study natural phenomena mostly in the natural sciences environment. Quantitative methods used in the social sciences include survey methods and numerical methods. Qualitative research, on the other hand, was developed to study social and cultural phenomena in the social sciences. Qualitative methods include grounded theory and action research. The reason for conducting qualitative research, as opposed to quantitative research, stems from the fact that there is one aspect that distinguishes humans from the natural world – our ability to talk. The goal of this type of methodology is to build a reality from the multiple realities of participants and qualitative research methods are specifically designed to assist researchers in understanding people, as well as the social and cultural contexts in which they live (Creswell, 1998). Although researchers will in most cases use either quantitative or qualitative research, some researchers often combine these research methods in one study, allowing for the corroboration of findings and the enhancement of validity. The current study makes use of such a combined approach. Quantitative data are obtained from the university LMS, while the qualitative data are collected by applying the Dooyeweerd model aspects in order to understand video use as a form of reverse instruction when studying SAD.

B. Data Collection and Analysis

The LMS used in this study is eFundi and it allows for the collection of statistical data in the form of number of reads (watches) of videos per student. It should, however, be noted that this data does not distinguish between a read that was started, but not actually watched by the student. In addition it does not keep track of how many students watched a video with a friend. Furthermore, it also does not count video watches done by students who download offline versions of the videos. Although the statistical data do not give a perfect count of video watches, they do give an indication of a video's usefulness.

Table 2 demonstrates that students were slightly more reliant on videos during the first semester (1.82 watches per student per video) when compared to the second semester (1.81 watches per student per video). More students chose not to watch videos during the second semester – with 63 out of 69 students watching videos in the second semester as compared to 81 out of 82 during the first semester. In general the pass rate was good during both semesters, with total of 62 of a possible 82 students successfully completing the modules.

From the lecturer's own observation, more work is covered during the first semester than in the second semester. First semester work is also newer to students and covers more theory. In addition, the lecture observed that students evolved from being unsure in the first semester to bold and full of confidence at the end of the second semester. Bearing this in mind, it is encouraging to see that 9 students revisited the first semester videos during the second semester (75 watches).

It is also interesting to note that the highest number of video views per student for both semesters was 12, with one student revisiting a first semester video 4 times during the second semester. This supports the literature (Prensky, 2011).

The lecturer also noted that in previous years some concepts required repeated explanations, however, the introduction of the videos reduced this as students preferred to watch the videos.

TABLE 2. Student watches per video, pass rate.

<table>
<tr><th colspan="4">Watches per video</th></tr>

<tr><td>MAXIMUM WATCHES</td><td>12 (4)</td><td>MAXIMUM WATCHES</td><td>12</td></tr>
<tr><td>PASS RATE (81 (82) --> 68)</td><td>83%</td><td>PASS RATE (68 (69) --> 62)</td><td>90%</td></tr>
<tr><td>OVERALL PASS RATE</td><td colspan="3">76%</td></tr>
</table>

When students were asked about the value of the videos at the end of their course 45 of the 69 students completed questionnaires. Almost half of them (21) found the videos extremely useful, everybody who used it, found some value in it, while only 3 did not use it – mainly because of time constraints. The numbers are represented on a bar chart below (figure 2):

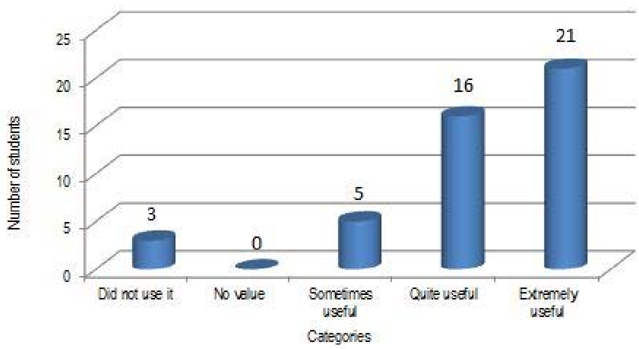

Fig. 2. The value of videos.

In an open question students indicated that it gave them "a good idea of how things are done", it "emphasizes main points", it "clears confusion", it "helps understand practical work" and it is "visually stimulating". Some students asked for more videos. One indicated that a problem experienced was that "I can't ask a video questions"!

C. Dooyeweerd Provides a Useful Framework

This section motivates why Dooyeweerd's philosophy provides a useful framework for this study. This is done by looking at how Dooyeweerd addresses issues relevant to the research.

1) *Dealing with Diversity*

In this study, videos were developed to enhance the learning of SAD and to reverse instruction. It is hoped that the introduction of these videos will encourage students to become life-long learners, who are actively involved in their own learning. Technology keeps on changing and as a result SAD students will need to constantly learn new things. Group work was used to assist with active learning. This also included the completion of a practical project which was worked on outside of class. The diverse approach of giving students assignments to force them to gain knowledge about a topic before coming to class was used. Students were encouraged to voluntarily form diverse groups for their project development. During class groups were formed by the lecturer. The groups comprised male and female students, and black and white students. Although students complained about these groupings, they learnt to work with peers from diverse backgrounds, in terms of culture, skills and capacity. This situation imitates the working environment.

Table 1 shows how Dooyeweerd can help address the complexity or diversity of the use of videos in helping to prepare students for reverse instruction, by allowing us to unpack a complex situation where diversity is prominent.

Using these aspects makes it possible to recognize the distinct importance of each and every phenomenon or factor the researcher might be presented with. Dooyeweerd's aspects therefore address the issue of diversity.

2) *Dealing with Unexpected Uses*

Expected and unexpected uses may lead to unexpected results. As mentioned previously, students had access to computers in a laboratory at the university or they could access the videos through their own computer at home or on campus. Videos could be watched individually or in groups. The computer's capacity was not a huge issue. Although videos were intended to be used to prepare students for class, they were also used to gain knowledge on how to complete an assignment. Videos were watched in class when group work was discussed, and students revisited the videos to prepare for tests and examinations. First semester videos were also used during the second semester to revise related concepts. It is hoped that students will revisit the videos in subsequent modules because the videos on database modeling may be helpful when students start a course on databases.

The modal aspects of particular interest in this study include the lingual, social and juridical aspects. However, it is important to acknowledge that teaching students SAD through the use of videos is not something that can be restricted to a limited number of modal aspects. According to Basden (2008) most aspects will be prevalent to a certain extent. In addition, it is also important to realize that "many things are of multiple aspects", for example a computer is used by most people to create documents. It will also, in an IT course, be used to develop systems using a language such as C# – which is embedded in a particular technology (formative aspect). Dooyeweerd called this a retrocipation – when an aspect reaches back to an earlier aspect. Anticipations occur when an aspect reaches forward to a later aspect, and can help us to understand, for example, when a video may be a tool for social interaction. This interaction also creates interest and fun (aesthetic aspect) for the user. Dooyeweerd's retrocipations and anticipations can therefore address the issue of wider or unexpected usage.

V. CONCLUDING REMARKS

As stated in the title, the implementation of videos to assist in reversing instruction has a good, a bad and an ugly side. Prensky (2011) is of the opinion that the flip-side to videos are that they are "a new way to do an old thing (blackboard teaching)" – a true deduction and a possible negative aspect. This research supports Prensky's (2011) view by stating that students watch videos repeatedly. Unfortunately, some students do that and still perform badly. Although videos allow students to study at their own pace, their use will not guarantee good performance. The implementation of some form of group or peer learning to encourage students to become active learners is crucial to ensure success.

The fact that the lecturer for these modules was not asked by the students to explain difficult concepts numerous times, and in some cases no explanation was requested, is encouraging. Shy students, who would most probably not ask the lecturer a question, are able to watch a video and receive an explanation without any interaction with the lecturer. The existence of videos could also help students who have a legitimate excuse for absence, like illness, to catch up easily. Unfortunately it may also bring about laziness in students and create the impression that it is easy to do the subject by just watching the videos. This could result mean that there is no active involvement of a student with the subject material and could defeat the actual purpose for introducing the videos.

Reversing instruction occurred at the end of the first semester without too many growing pains. Various reasons may be cited for this: students grew during the first semester; their background knowledge was well developed (partly because of the introduction of the videos); they were able to do revision using videos; the second semester built on the first semester's knowledge; students knew the lecturer. This resulted in students being able to focus on a broader range of aspects in the subject, instead of only tests – like they would do at the beginning of a module.

There is also room for improvement and in this study it was felt that students should get more from videos. It was decided to provide an accompanying document for each video. This document provides background information, helping students to know what to look out for in the video. Questions are also listed to assist in the student's focus. Some follow-up questions are provided to help students to build on the knowledge they gained by watching the video. In future the possibility of using software to build these questions and guidance into the video itself, will be investigated.

Commercial Competency and Computing Students

Using the Skills Framework for the Information Age in Higher Education

Tom McEwan
Institute for Informatics and Digital Innovation
Edinburgh Napier University
Edinburgh, UK
t.mcewan@napier.ac.uk

***Abstract*—Commercial acumen has emerged recently as a third aspect of employability which employers expect from computing graduates, in addition to technical capability and "soft skills" (or similar terms like transferable skills). Our experience has been that viewing commercial acumen (or even commercial awareness) as simply one of the soft skills, has failed to meet the needs of local employers, who tell us they seek innovation skills and entrepreneurship. A case study illustrates a structured approach to adding commercial awareness to the computing curriculum, and, more generally, tying the learning experience more closely to the achievement of standardized competency statements. Changes to future provision are discussed following workshop discussion of a draft of this case study.**

This paper will be of interest to computing and engineering academics who seek to increase the commercial awareness of their students, and to those who seek to align their courses with commercial definitions of competency

Keywords—competency frameworks; commercial awareness in computing degrees; innovation

I. Introduction

It has become increasingly desirable for computing graduates to be able demonstrate commercial acumen. Governments and employers state this need in different ways, but our experience is that it is emerging as a third key factor in defining employability, beyond the existing desire for the optimal combination of domain-specific skills (programming, design, etc) and "soft skills" (time and project management, communication). In earlier work [1] we discussed the derivation of a current working set of generic graduate attributes and it was noticeable that only one of the eight components [2] referred to employability. Discussions with local employers suggest that these generic attributes are indeed desirable but more salient are areas such as customer-centeredness, innovation, entrepreneurship, business-awareness, market analysis and customer awareness. However, in an already overcrowded curriculum, how can this additional expectation be effectively integrated?

The growing use of national and global competency frameworks (such as SFIA: the Skills Framework for the Information Age [3]), both in term of job specification and skills gap analysis for individuals and organisations, and the increasing integration of these with the accreditation requirements of professional bodies, provides a potential focus for a solution.

This paper builds on other previous work, first in engagement with the maintenance and enhancement of competency frameworks [4], in arguing for more socially-responsible forms of innovation [5], and an earlier version of this work [6] presented in a workshop organized by an special interest group of BCS, The Chartered Institute for IT.

After discussion of BCS activity in the relevant area, this paper discusses a case study which illustrates generic challenges in embedding SFIA competency statements in higher education learning outcomes, in particular where learners' intended job roles are in a fast-emerging area of computing and thus lack, as yet, formal codification. The case study describes the process of gaining university quality acceptance for a masters-level module (IMD11108 Digital Markets) based on SFIA competency statements, and reviews the first deliveries of the module. The approval process for this module provides a mapping of SFIA levels to higher taxonomies of learning, and illustrates how both students and course leaders construct degree courses. These experiences are contrasted with the experience in other countries, with reference to the BCS workshop [17] and the position statements from other workshop participants (drawn from three continents), each of whom reported on related activity using SFIA. A parallel process, led by BCS Interaction Specialist Group, used this module to define both competency and courses for the relatively new skill of User Experience (UX).

Contrasting experiences with academics from other universities and countries provides evaluation of the module and the approach to create it. It also feeds back into subsequent delivery of the above module, this time to a small but more international cohort of students (from Asia, Middle East, Spain and the UK, drawn from a number of different MSc programs). Here the requirements become more complex, as the learners from different countries start with very different understanding of, and attitudes towards, commercial issues.

The module requires each learner to develop a concept for the digital marketplace, and to identify the nature of the opportunity, commercial viability, and "freedom-to-operate" (for example, whether patents exist in certain jurisdictions). The learners then peer-review each other's proposals, and indicate their preferences for future development, before

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

forming into two groups to develop the proposals for an end-of-trimester pitch to established entrepreneurs, who provide feedback as if this was a commercial situation. To conclude, learners must provide a reflective commentary on the project experience as part of their assessment.

This paper discusses approaches to "level up" each learner to the same starting point for the group activity, reflects on the management of the groups and identifies patterns of learner activity and reactions, which can be used to improve subsequent delivery.

II. Background: UX and BCS

The author views the domain of User Experience (**UX**) as encapsulating much if not all of the commercial acumen agenda. UX, as a discipline, arguably has grown out of the **Usability** sub-specialism of Human-Computer Interaction (**HCI**), itself part of a longer tradition of **Human Factors** within **Computing**. UX also grows out of ergonomics, psychology, and marketing. It looks at people's engagement with technology and services, and seeks to ensure that their experience of using the technology is not only problem-free, but also exceeds expectations, delights the user and thus becomes valued by that user. As more transactions are completed online, good UX is fundamental to fitness for purpose. There is a global shortage of these skills, and senior salaries are amongst the highest in any field of computing.

The global professional body, UXPA, has fifty chapters around the world, coordinates the annual World Usability Day in forty countries, and seeks to create a global professional community [7]. The author is a member of IEEE, BCS, ACM and UXPA, and informal contact with other members of UXPA suggests a considerable overlap in memberships across these and other professional bodies, including ergonomics, engineering, psychology, design and marketing. It is difficult to pigeonhole UX into the work of a specific sector skills council (the collective term used in the UK for bodies which define job competency), although UX is an important part of the future of Computing, and thus a key opportunity area for BCS and other professional bodies for the field of computing.

A. BCS and HCI

In 1984, BCS calved one of the world's first specialist groups in HCI, variously known through the years as BCS-HCI, British HCI Group and, now, Interaction Specialist Group (which the author chaired 2009-2011). After a special edition of BCS's Computer Bulletin, this group launched one of the first HCI academic journals [8], which, despite periodic changes in publisher, retains a leading impact-factor (5-year impact factor: 1.455 [9]. The group's annual conference [10] and UsabilityNews.bcs.org web portal also have global impact.

The group worked with the UK government to produce Usability Now (1990), an initiative to embed usability in UK software. Many would argue that the industry is yet to fulfil these values. By the turn of the century, the group worked with the UK government's E-Envoy to ensure accessibility in public websites [11]. Members of the group executive committee and contributed to iterations of SFIA and the BCS's extended version SFIAplus [12], resulting in an increased number of usability roles being recognised from SFIA v3 onwards [4]. Most recently SFIA v5 [3] is the first version to include UX in its skill definitions, shifting the focus from "non-functional requirements" (particularly a misnomer, from a cognitive ergonomics point of view) towards a more holistic understanding of the needs and the experience of the user, in definitions for skills such as:

- User experience analysis (UNAN);
- Ergonomic design (HCEV);
- User experience evaluation (USEV);
- Human factors integration (HFIN).

For example, the latter is defined as: "Achievement of optimum levels of product or service usability, by ensuring that project and enterprise activities take account of the **user experience**."

B. UX Competency Workshops

On behalf of the group, the author led two national workshops, UXCF2010 in London, UK, and UXCF2011 in Newcastle, UK. UXCF2010 attracted around 40, mainly industry, participants, and sought to understand roles and organisational processes in the fast-developing field of UX. While some of these roles are already recognisably part of SFIA (for example Business Analyst, Programmer), others are not, nor are they adequately defined in the national occupation standards (NOS) such as those published by UK sector skills councils such as e-skills, Skillset or CCDesign.

UXCF2011 extended the materials produced in the first workshop in a smaller event involving three academics who design relevant BSc/MSc courses, and three senior UX professionals, supported by other interested parties. Most had contributed to and/or reviewed the recent SFIA revisions. We reviewed an example set of modules against typical UX roles to identify gaps, and to evaluate how well the new module discussed here, IMD11108 Digital Markets, fills any gaps. Elsewhere [6], the author summarises the UXCF activity in more detail. The work with SFIA and UXCF is linked, maintains close coupling between academia and industry and and used to define and evaluate the module described below

III. Case Study: Digital Markets

This section describes the first experiences of running a masters-level module, IMD11108 Digital Markets [13], which was written explicitly to use learning outcomes based on SFIA competency statements. This module lasts a semester, carries 10 ECTS (European Credit Transfer System) credits (one-sixth of a full academic year), with 36 hours of classes and 164 hours of student centred activity including group-work. It addresses UX in the sense that it focuses on entrepreneurship and innovation from a Human-Centred Design (HCD) perspective [5], contrasting different approaches to innovation, in particular what the OECD term "non-R&D innovation" [14,15], which focuses on user-driven innovation, ie demand-led rather than "marketing-push".

A. Quality Approval

The first challenge was to gain university quality acceptance for a module based on SFIA statements. University quality procedures, at least in the UK, reflect a complex set of stakeholders as previously discussed [1]. The module itself was not created for the sake of delivering competency – at best this would be seen as *necessary* but not *sufficient*. Meeting the emerging needs of employers, while providing an opportunity for critical evaluation of different approaches to applying innovation theories, more fully addresses all agendas. The module descriptor runs to several pages [13], but the key points discussed here are the Learning Outcomes (LOs). These are the basis of our quality system: all assessment plans are moderated against the LOs, and all teaching events and directed study are designed to be necessary and sufficient for students to achieve, and demonstrate through assessment, the learning outcomes.

B. Matching Levels and Breadth

The first consideration of the module was in March 2009. The first task was to contrast the language of the different skills levels within SFIA with the required vocabulary of module accreditation at levels 10 (Honours (final year) undergraduate) and 11 (Masters-level) of the Scottish Credit and Qualifications Framework (SCQF) [16]

10	Accurately assess; adapt; analyse; anticipate; appraise; argue; arrange; assemble, attribute; calculate; categorise; classify; combine; compare; compose; conclude; connect; construct; contrast; create; critically reflect; criticise; defend; derive; design; devise; develop; differentiate; discriminate; distil; distinguish; examine; experiment; extract core issues; formulate; generalise; hypothesise; infer; integrate; invent; make effective use of; manage; modify; organise; précis; prioritise; propose; reconstruct; separate; substitute; synthesise; test; validate
11	Analyse; appraise; argue; challenge; conceptualise; conclude; convince; critically appraise; critically assess; critically engage with; critically explore; critically reflect; critique; debate; defend; discriminate; drawn conclusions; engage in critical dialogue; estimate; evaluate; examine the impact; examine the elements of; exercise appropriate judgment; generate ideas; hypothesise; judge; justify; plan; predict; produce; rate; rationalise the use; recommend; resolve; review; test

Figure 1: "Acceptable" verbs to meet SCQF10 and SCQF11 learning outcomes (Edinburgh Napier University internal memo)

Our experience has been that the language in SCQF 10 is found between SFIA levels 4 and 5, and that of SCQF 11 at SFIA levels 5 or 6. Although the question has been asked at open forums for SFIA, there appears to be no definitive mapping between SFIA levels and university learning taxonomies. A typical response is that higher level roles within SFIA require not only knowledge and understanding (as delivered in a degree), but practical experience (seen as not delivered in a degree). One might infer that universities educate at a level well above initial graduate jobs, and that employers are investing in the proven potential of these graduates to progress over 3-5 years to professional roles.

The terminology of SFIA and, more generally, of human resources can be inconsistent, or change over time. Sometimes, words like job, role, skill, occupation, task, activity, competency, knowledge, expertise, and so on, overlap in their usage. For the purpose of this paper, a job involves one or more roles, each of which might be needed at different levels of skill (based on expertise, knowledge and understanding). Our experience was that a single SFIA skill appears to be too narrow a focus for a 200 hour learning experience, and thus two related SFIA skills Emergent Technology Monitoring (EMRG) and Innovation (INOV) were mined to provide sufficient breadth for IMD11108. The language of academic learning outcomes (LOs) is traditionally more concise than that of competency. The relevant statements for SFIA levels 4- 6 in EMRG are (with key wording **highlighted** and commentary in *italics*):

"Maintains awareness of opportunities provided by new technology to address challenges or to enable new ways of working. Within own sphere of influence, works to further organisational goals, by the use of emerging technologies and products. Contributes to briefings and presentations about their relevance and potential value to the organisation". (EMRG4)	*In any case level 4 statements appear to require less synthesis than expected at Masters or even Honours year level. Thus the following LOs were mapped onto* ***EMRG5****, although LO5 goes slightly beyond (as highlighted).*
"Monitors the market to gain knowledge and understanding of currently emerging technologies. Identifies new and emerging hardware and software technologies and products based on own area of expertise, assesses their relevance and potential value to the organisation, **contributes to briefings** of staff and management".(EMRG5)	LO4 Monitor technology markets to gain knowledge and understanding of currently emerging technologies (EMRG5). LO5: Identify new and emerging hardware and software technologies and products, assess their relevance and potential organisational value **and brief** staff, management and investors (EMRG5).
"Co-ordinates the identification and assessment of new and emerging hardware, software and communication technologies, products, methods and techniques. Evaluates likely relevance of these for the organisation. ***Provides regular briefings*** *to staff and management".(EMRG6)*	*Limited possibility for students to "co-ordinate"*

Innovation (INOV) provided the basis for the other learning outcomes. Only two levels currently exist for this:

"Actively monitors for, and seeks, opportunities, new methods and trends in IT capabilities and products to the advancement of the organisation. Clearly articulates, and formally reports their benefits." (INOV5)	*"Monitoring" and "reporting" alone, were judged insufficient to meet SCQF level 11, being more typical of the investigation that an Honours Project student might carry out (SCQF level 10). Thus INOV6 was the basis for the three other Learning Outcomes, although the taxonomy falls midway between levels 5 and 6*
"Recognises potential strategic application of IT, and initiates investigation and development of innovative methods of exploiting IT assets, to the benefit of organisations and the community. Plays an active role in improving the interface between the business and IT." (INOV6)	LO1: Recommend potential strategic application of IT in the digital marketplace (INOV6). LO2: Work in a group to exploit IT assets in an innovative way, to the benefit of organisations and/or the community. (INOV6). LO3: Conceptualise ways to improve the interface between the business (or organisation) and IT. (INOV6).

The UX dimension is notably missing from both LOs, and other SFIA roles were considered including Human Factors Integration (HFIN). While these did not add value to the LOs, the "Overview" section of the HFIN skill is more relevant and thus provides a backdrop to the module:

Human Factors Integration – Overview	"Achievement of optimum levels of product or service usability, by ensuring that project and enterprise activities take account of the user

	experience."

The module was accepted at the second submission to the Faculty Quality process, subject to amendments. One such amendment was to clarify the variety of job roles to which the learning outcomes would lead. This information is fairly vague, even in SFIAplus, and the following was proposed to gain acceptance:

"This module helps prepare learners for the following roles in the Skills Framework for the Information Age (SFIA): INOV6, EMRG5, HFIN5. These roles are found in digital media innovation and new product development teams in larger organisations and relevant job titles include: Digital Media Developer/Designer within an Innovation Team or New Product Development team, User Experience Developer/Designer/ Manager, Imagineer (a Disney Corp. term), Human-centred Designer. This module will also support a potential digital media entrepreneur to develop their concept."

Once accepted, the module then also had to be made attractive to students – the first mandatory running for the integrated masters (MEng) programmes was not until 2011-12. In the meantime it was available as an option for other postgraduates, but there was insufficient demand until the Fall trimester, 2011.

C. *Structure*

The module simulates a commercial innovation cycle. For the mid-term assessment, individual students build up their own proposals for a viable product or service for the digital marketplace. After submission, they peer-review each other's work and select the best of these ideas to develop in groups of 3-4 to the point where they can pitch to local entrepreneurs, as if for around $250k in seed-corn investment (several such programs do exist locally for university spin-out ideas). Their presentations are formally assessed as a group, and their final assignment is to reflect on the group and their own performance. The teaching is front-end loaded to prepare students for working in groups to accomplish the main objectives of the module. At the end of the module students must reflect individually on the experience, which is the opportunity to display their Masters-level capabilities.

Table 1: Time Management advice given to students

Week	Work	Description
2-3	Heavy (20hrs per week)	You have 12 hours of classes and a great deal of directed study to do, meaning you will likely work more on this module than other modules.
4-9	Moderate (12hpw)	No classes - 5 short tutorial meetings: you will be focused on your individual coursework (due week 8) and starting to develop your group for the second coursework. Your only classes will be some individual supervision meetings and then short group meetings with the module leader to discuss group formation and objectives.
10-12	Heavy (20 hpw)	18 hours of classes: you will prepare in a group for, and give, a 15 minute Dragon's Den type pitch for your concept
13-15	Light (10 hpw)	Completion of final 1500-word paper reflecting on the group experience

Table 1 explains the unusual contact time pattern – double the normal contact hours for the first few weeks, brief weekly group supervision meetings in the middle six weeks, and double the normal contact. The expectation was that students would be highly self-motivated and self-organizing, having already gained experience in managing their solo project in fourth year, and in participating in formal group projects in previous years.

D. *Experience of Delivery*

For a variety of reasons, the cohort of undergraduate integrated-Masters students (a five-year degree) who took the module lacked both the highest and lowest performing quartiles of the previous year. The "less average" students had elected to graduate with the more typical BSc (Hons) or BEng (Hons) at the end of their fourth year. Thus the first cohort for this module contained "average students", and so there was little variation in their attainment. We routinely contrast the performance of all students in any module, compared to their collective performance in their other modules. The resulting performance for this module in 2011 was only slightly above average for that cohort. This analysis could not be completed in 2012, as only a single student remained for the fifth year, as a favourable local job market absorbed the rest of the cohort.

In contrast, several one-year MSc students from overseas considered the module in 2011, but elected to take "more technical" subjects instead, expressing worry about the discursive, group and presentation-based assessment regime. In the 2012 delivery, proactive steps allayed such fears, and the resulting cohort, though small, was globally diverse: students from Saudi Arabia, Spain, Egypt, three regions of China, and one local student.

This 2011 instance involved only seven students, four from the MEng Software Engineering and three from the MSci Interactive Media Design. The overall response in student feedback was highly positive and the advice one student gave to future students was interesting:

"Try and create a new idea, as my idea wasn't new or a good business plan, I did not take it further after the module. But with the support of the module, by the end of it, you have a lot of useful information if you decided to create a start up company."

Largely, the module met ambitions. The students did a very good job of each researching a digital market idea and writing a short paper (3000 words) on it, submitting in week 8. Example topics included an on-demand BluRay burning kiosk (an interim solution to slow local broadband rollout), an app for stag and hen parties (in the USA, "bachelor(ette) parties"), and an app that used live geodata and public data about granted collection licenses to detect and avoid "chuggers" – aggressive on-street charity collectors. For the second half of the module, they split amiably into two groups, each adopted one of the latter two ideas, and further developed it, until they were ready to pitch, in week 12, to an audience of six industrialists, entrepreneurial advisers and lecturers:

- The CEO of a successful spin out company now in its second year of trading

- An experienced entrepreneur, business "Angel" and senior advisor to government
- An entrepreneur and advisor for Proof of Concept (PoC) commercialisation spin-out project funding from a local government agency (Scottish Enterprise).
- The director of the university's Moffat Centre, which advises around fifty students each year on how to start their own companies
- An academic who had recently run a PoC
- A professor with responsibility for coordinating faculty-wide research and commercialization

The panel rated each group's pitch in a number of dimensions (although final grading decisions were taken by the module leader). Both pitches, though trenchantly criticised on the day by the expert audience (in a way that the students reported, in the post-presentation discussion session, as "brutal" and "a wake-up call") were also (in the formal feedback sheets) well-received by the experts. No-one rated any aspect less than "adequate", most were rated "good" and some were rated "very good". Since the experts had been asked to judge these on a commercial basis, this alone was a remarkable achievement, and one which suggests that the use of SFIA statements in the LOs was effective in leading to competency, in particular LO5: ("Identify new and emerging hardware and software technologies and products, assess their relevance and potential organisational value and brief staff, management and investors").

E. 2012- second delivery

Only minor changes were made to the timetabling, but these, combined with a delayed start by several of the students, and acclimatisation by those who had recently arrived from overseas (most of the students), meant that the first two weeks class activity did not result in the same level of familiarity with the nature of commercialisation. Additionally some of the students come from cultural backgrounds with very different approaches to investment, legislation, regulation, consumer protection and so on. While the latter was all anticipated, trying to run a crash course in liberal Western economic and business values, at a time of acclimatisation was unwise, resulting in an initial response of culture shock. The relatively poor performance in the mid-term assessment prompted a more hands-on approach during the middle period, something that is feasible with a small class, but would have been problematic with a more typical class size of 20-40.

It became clear that the students needed careful shaping into their groups for the second half of the module to work. The middle section of the module has a lot of activity that does not count for assessment but does build students' abilities to peer evaluate, as well as and providing a mechanism for the groups to coalesce around the most viable ideas.

The planned individual meetings in weeks 4-6 were augmented with two additional weekly meetings of four students at a time (Groups A and B) to develop their own and critique each other's proposals for the first assignment. Since all students had chosen quite distinct topics, there were no plagiarism risks involved in this. Some of the ideas were less well developed than the previous year and often highly derivative of examples provided in-class (travel recommenders, study guides, tourism apps), but others were of a very high standard – a brokerage for statutory recycling of medium value electronic waste, a data scraping app that supplied "key information sets" (a new form of open data about UK universities that has proven costly to collate), an organic food delivery brokerage, personalized location-based M-Commerce services.

Within these groups a strong understanding each other's proposals emerged. This, however, could have compromised the anonymous peer review of each other's papers in weeks 7-9 (which refers students to typical journal and conference reviewing guidelines).

The solution was to give three papers from group B to each student from group A to review, and vice versa. This then meant that each student received three anonymised reviews of their business idea from members of the other group (with whom they otherwise had little close contact). Students then discussed these reviews within their groups. This now meant that all students had a detailed knowledge of all eight potential projects for the group stage. Students received a summary of the positive and negative points of each paper and then were invited to send their project idea preferences for the group stage. Most review criteria were on a scale of 1-5, and reviewers were invited to supply additional free text.

Reviewer 's Expertise	Please rate your own knowledge of the Concept proposed in the paper, how much you think you know generally about Business/Digital Markets and add any comments about your knowledge
Strengths of the Proposal and Potential improvements	Try to identify up to three good aspects of the proposal in this paper, and also three possible improvements
Commercial opportunity and potential barriers to success	Try to identify the profitability and scale of the commercial opportunity described , and the barriers that the proposer would have to overcome
Investment potential	If you had £500,000, would you invest £100,000 in this idea?

The resulting preferences clearly prioritized two ideas, although, curiously, neither of the original authors voted first for their own idea! The final allocation into groups ensured that each student got their first or second choice, while maintaining a reasonable balance of ethnicity and gender, and transfer of members between groups A and B.

Subsequently, the resulting groups successfully presented to a similar audience as in the previous year. Some niggles emerged within groups – a protocol had been advised for resolving group breakdowns, but it's more effective to avert the need for this with regular and detailed group supervision meetings. The grades for both the presentations and reflective statements were slightly better than the previous year, and, again, found to be slightly higher in cohort analysis.

These two experiences, coupled with group discussions at subsequent workshops, and comparison with teaching and learning approaches elsewhere in this subject area, has prompted a rethink of the delivery for next year, in anticipation of larger class sizes. A more traditional contact pattern will be used: three hours a week of contact throughout the trimester, one of which will remain in small groups.

F. Evaluation

The experience of the 2011 delivery was presented at a recent workshop [17], in a session with presenters who had attempted related integration of competency definitions with undergraduate teaching in Chile [18], Australia [19] and England [20]. This provided an opportunity to evaluate the intervention with peers who were attempting related innovations in their own countries.

While national or state governments in Chile and Australia emerged as more developed in mandating the mapping of university courses to SFIA, a clear consensus emerged that basing curricula on competency definitions in SFIA was effective for educators, learners and employers, and a more nuanced approach than for example "Body of Knowledge" (BOK). Other participants confirmed the mismatch between the advanced level of learning that universities require, and the likely lower level of initial graduate employment. Strategies are needed to help learners and graduates understand that, while initial roles may seem menial and to make little use of their advanced learning, their employers are investing in graduates' proven ability for future, more senior, roles. While graduates have always been told that they need to gain practical experience as well as theoretical knowledge, it will be important to define that practical experience. Plainly some quite advanced practical experience can be gained during study, for example using the scaffolded PBL approaches we discussed at FIE2012 [1].

This module illustrates both the possibility and usefulness to build postgraduate teaching around SFIA competency statements. Both the university quality approval and quality enhancement processes proved to be no barrier, and the assessments produced clearly met expectations. The selection of level 5/6 for Masters-level, and 4/5 for Honours-level appear to be generalizable to other areas of computing, although basing a 20-credit module (nominally 200 hours of student work, including classes) on a single role level may be inadequate.

An additional subsequent workshop, organized in 2013 by one of the constituent parts of the BCS Academy, identified many other entrepreneurship and innovation modules in computing-related degrees at a wide range of other UK universities, for example at Queens University, Belfast [21], University of Dundee [22] and the University of Northumbria [23] and around twenty others. Local employers appear in each area to remain unaware both of such modules (notable exceptions are Durham University, where Computing students carry out group projects for external clients, and the University of Kent, which has a student-led computing contracting company). More importantly employers are clearly often unaware that the commercial acumen agenda is very much being addressed by these type of modules.

As well as providing opportunities for students to gain knowledge and understanding well in advance of their first jobs in industry, university study can provide opportunities for developing practice competency to be ready for future opportunities.

IV. Parallel and Future Work

The evolution of this module was done in parallel with the UXCF process described earlier – the author's attempts to build a coalition to call for updates to the most recent version of the skills framework, SFIA, to maintain currency with graduates' skills and emerging UX job specifications, many of which require enhanced levels of commercial acumen that IMD11108 Digital Markets assesses. Space only permits brief coverage here, but uxcf.org has been reserved for more detailed exploration of the work carried out, and for follow-up workshops.

UXCF2010 (BCS Covent Garden, Feb 2010) involved ten papers, half from industry, half from academia, and attracted a further 30 participants mainly from industry. Alternate sessions involved group discussions to identify how organizations and individuals developed competency in UX. As well as discussions, the groups created a number of affinity mappings or other diagrams intended to capture the skills needed in UX practice. By the end of the day much of the discussion was about organizational maturity, both in terms of the UX companies and also their clients. This is consistent with findings of other initiatives eg [24]. In other work we plan to analyse this in more depth.

In the first session, much of the dialogue centred on understanding to what extent definitions of job role or competency were shared across different organizations. In later discussion, groups focused on range of skills, knowledge and understanding required. For the academics present, there was much value in hearing about the different, often highly dynamic, approaches taken by employers to assemble project teams based on sets of skills. For the industrialists, there was growing appreciation of different levels of capability maturity within organizations to deliver UX consistently, and in a commercially sustainable way.

UXCF2011 (University of Northumbria, July 2011) was more focused and specific to the design of degree programs. The individual learning outcomes of existing modules were mapped [6] against the table of professional competencies articulated the previous year. This enabled both employers and academics to agree potential gaps helped identity gaps, and confirmed where IMD11108 would contribute both to meeting existing requirements, but also to giving a new commercial perspective to graduates ensuring that they are indeed ready to "energize the future".

***Abstract*— Moodle is a well-known open source system to support teaching and learning through the web. It provides Quiz, a tool for learning assessment, which is also adopted by a large community along the world. Another tool that allows automatic assessment within Moodle is the iAssign package. iAssign provides means for integrating interactive Learning Modules (iLM) to Moodle, empowering it with interactive intense activities concerning specific issues implemented in iLM. However, such tools present some limitations that prevent their users to take more benefit of the question types and iLM such as (i) authoring is not a simple task; (ii) iAssign integrates iLM to Moodle without incorporating Moodle questionnaires; (iii) Quiz database for questions and questionnaires is not integrated to a repository with search and retrieving tools; (iv) in the current version of Moodle, Quiz didn't allows the incorporation or exportation of assessment content that follows the IMS-QTI 2.1 (Question and Test Interoperability) specification. In this paper we address such limitations proposing a generic model and its implementation for the Moodle system.**

Keywords— Moodle; Quiz; iAssign, assessment; repository; IMS-QTI 2.1

I. INTRODUCTION

The use of systems to support learning through the web has gained increasing attention in the last decades [1][2][3], mostly with the use of Learning Management Systems (LMS). Among the large family of available LMS, an open source solution is Moodle [2]. Since its first version, Moodle evolved considerably and it presents several functionalities to facilitate the processes of teaching and learning, as well as to manage activities related to them. We can cite some of the more important functionalities as the ones associated with the authoring, interactivity, and automatic assessment of instructional content [4][5][6][7]. In fact, almost a decade ago we could find in the literature some research directions related to increase the types of ways of interacting and assessing multimedia instructional content, including automatic assessment resources [4].

These functionalities allow, while logged in the system, the development of instructional content and the assessment of students' performance while interacting with such content during the learning process. Nevertheless, such content can be stored in instructional repositories and reused whenever needed. Moreover, authoring and assessment are important issues for any LMS. Quiz is the Moodle module associated with authoring and assessment [8]. By using Quiz, one can build questionnaires (quizzes) with automatic assessment resources. The quizzes may adopt several types of questions, including multiple choice, true-false, and short answer. Also, Quiz questions can be stored in a "question bank" to be further reused. Although Quiz provides features to the building of new types of questions, some issues may cause limitation on using them [9]. In addition, this prevents importing or building interactive intense instructional content [7], as the ones provided by iAssign [5] and questions that follow the IMS-QTI 2.1 specification [10].

In this paper we present an integrated model to provide means of authoring, automatic assessing and storing instructional content. Such model is implemented as a Moodle plugin called *iQuiz* (*interactive Quizzes in the Internet*). In section II we describe the model, and in section III we present iQuiz. Some related work is given in section IV and, finally, section V outline our conclusions and suggests future work.

II. AN INTEGRATED MODEL FOR ASSESSMENT WITHIN LMS

Our proposal for improving the scenario described along the introduction is an integrated model that adopts a component-based structure to provide a solution for combining authoring activities with automatic assessment and storage. The model is composed of three main components: authoring, interoperability and repository (see Fig.1).

The authoring component is responsible for providing means to create instructional content to be used during the learning process mediated by the LMS. Such component must provide support for creating interactive intense instructional content with automatic assessing and exporting the created content to instructional format standards. This component is the core of the proposed model since it has its main responsibilities.

Instructional standards are provided by the interoperability component that feeds both, the authoring and the repository component. The compliance with instructional standards must

This work is partially supported by grant #2011/10926-2, São Paulo Research Foundation (FAPESP) and grant # 550449/2011, National Council of Research – CNPq, Brazil.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

be transparent to the LMS, since this component didn't communicate with it.

The repository is responsible for storing instructional content, as well as providing tools for searching and retrieving such content, that must follow instructional format standards to provide interoperability among distributed repositories along the world.

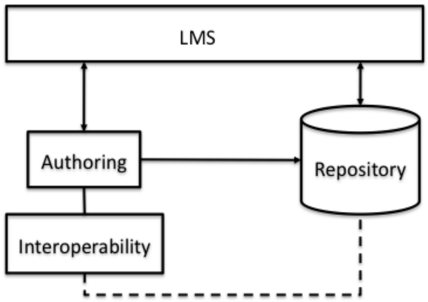

Fig. 1 The model structure

An important feature of the iRepository is its integration with LMS internal data. This means that an item in the repository could be associated with its usage by the end user, usually the students. This feature is important to support future work leading to IRT (Item Response Theory) [11] or some data mine to extract information about the item related to the student performance [12].

In order to validate the proposed model, an implementation of it to the Moodle system was designed.

III. IQUIZ: IMPLEMENTING THE PROPOSED MODEL

The model implementation adopts some Moodle packages to serve as basis for the authoring component; a question and test assessment specification (IMS-QTI 2.1) to deal with interoperability issues and a repository.

The Moodle packages considered are: Module Quiz; the iDCR repository and the iAssign Moodle package. Quiz was aforementioned in introduction and will be further explained. iDCR (Interactive Digital Content Repository) is a proof of concept of a repository that is integrated to Moodle [13]. iAssign is a Moodle free package that allows incorporating Interactive Learning Modules (iLM) [14], and it is available at http://www.matematica.br/ia. Also, iLM provides means for integrating interactive learning tools to any LMS. Usually an iLM is an applet Java.

iAssign is a Moodle package that provides means for authoring interactive intense instructional content since it integrates iLM to Moodle. Whenever an iLM allows automatic assessment, the same is true for the derived interactive intense instructional content. Therefore, iQuiz's underlying idea is to incorporate a new type of question to the Moodle Quiz using the iLM in a similar way iAssign does it.

The IMS-QTI is acronym to Question and Test Interoperability, a specification to promote interoperability between LMS when considering tests [15]. It was initiated in 1999 and is under the responsibility of the IMS Global Learning Consortium (http://www.imsglobal.org/qti.html). The IMS-QTI 2.1 specification can express interactive and parameterized assignment, meaning that any student can get a different instance of the exercise. Additionally, with IMS-QTI 2.1 it is possible to express constraints between interdependent parameters to assure that any instance of the exercise has the same level of difficulty [10].

The last component considered in iQuiz is the repository, an essential tool to easy share any educational content (or Learning Object - LO) [16]. The iQuiz repository component is iRepository, an extension of the iDCR.

Therefore, the authoring component of the model is an extension of Moodle Quiz in order to provide questions of iLM type, which means questions (ideally) with interactivity intense with automatic assessment resources, and interoperable resources. The extension also will allow other types of questions as the ones based in constraints with IMS-QTI 2.1 (e.g. advanced Math [16]). Also, a new user interface will be provided to deal with limitations described in [9]. It is represented by the iQuiz Question Type in Fig. 2.

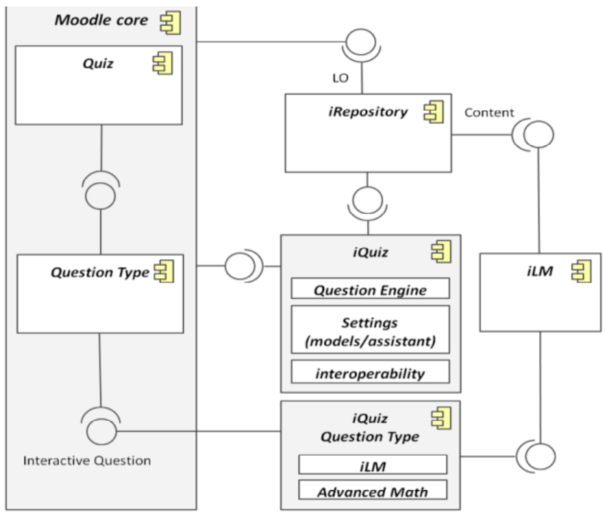

Fig. 2 iQuiz big picture

The interoperability component provides the usage of questions under the specification IMS-QTI 2.1. It feeds the authoring component with information to import and export the questions to IMS-QTI 2.1 specification, through Question Type Component of Moodle (it is represented in component iQuiz of Fig. 2). It also allows the description of questions types that follow Moodle standards, as well as new question types such as iLM and Advanced Math. In addition, it is used by the iRepository to maintain conformance with instructional content standards for content description and assessment.

Fig 2 presents the big picture of the model implementation. The iQuiz core could have several new types of question. In particular, it has the iLM type of question and one type of questions from IMS-QTI 2.1.

IV. Related Work

In [20] is reported the combined use of Moodle Quiz with the WIRIS quizzes, since they are already integrated. WIRIS quizzes (CAS) are developed to enhance the computer-based assessment in mathematics and science when integrated to an LMS. It offers: (i) formula edition at authoring time and formula visualization at presentation time; (ii) WYSIWYG input of formulas in the student answers of an open question; and (iii) formulas are input in the common mathematical notation [21]. Nevertheless, it didn´t provide interactive intense content within questions, since it is an algebraic (symbolic) system. Therefore, questions description looks like in a book and interactivity is just the immediate feedback provided by the automatic assessment resources.

STACK is another open-source system to assess elementary algebra [22], with emphasis on formative assessment. It provides a question type for Moodle Quiz and the STACK questions are the ones whose answers are mathematical expressions. It adopts a computer algebra system to evaluate whenever an answer is right. iQuiz will provide more than one Moodle question type, since each iLM [6][17][18] will define one question type. There isn't any citation about the importation or exportation of STACK question types to IMS-QTI 2.1 as will be for iQuiz.

V. Conclusion and Future Work

In this paper we presented a model for creating and integrating educational assessment content and iQuiz, its implementation as an integrated module to Moodle, one of the most known and used LMS within the world.

iQuiz extends the Moodle module Quiz by incorporating new question types, specially the one which provides interactive intense questions generated using iLM. Also, it provides interoperability resources to encourage assessment content sharing and reuse. Nevertheless, iQuiz is integrated with a repository that provides instructional content storing and retrieving in a granular fashion, meaning that questions may be searched and retrieved in isolation or in group, as a full questionnaire.

Teaching strategy focused on sensory perception, students' interest and enjoyment:

Successful application in Electrical Engineering (EE) lab for non-EE majors

Sudarshan Sivaramakrishnan and Alexander Ganago
Department of Electrical Engineering and Computer Science, ECE
University of Michigan
Ann Arbor, MI 48109-2122, USA
sivas@umich.edu; ganago@umich.edu

***Abstract*—We report the development and successful teaching of new laboratory experiments for a large introductory course in Electrical Engineering (EE) for non-EE majors. Our goal is to create the learning environment that would engage students' senses; provide hands-on experience, to which they can easily relate; stimulate intuitive understanding of EE concepts; foster enjoyment of learning, and eventually, help them succeed in their own fields. The first experiment focuses on applications of Fourier series to the spectra of sounds of music played on a Virtual Keyboard®. In the second experiment, students solder their own filter circuit to serve has low-pass/high-pass audio filters, and then they apply their filters to an excerpt of music, with the goal of understanding effects of the filter transfer function on the audio signal through listening. Both experiments expand the conventional range of application of theory and circuits in introductory courses (usually, only standard waveforms are used, e.g. sinusoidal and square). In the scheme of the entire course, all lab projects aim to introduce realistic, practical applications that pique student interest, show students the relevance of electrical engineering, and help them transfer their newly learned skills and experience to their own fields of work and future studies.**

Keywords— Laboratory instruction; motivation; non-majors; Electrical Engineering; hands-on learning; sensory perception; student interest; student feedback

I. INTRODUCTION

Recent, unprecedented progress of Electrical Engineering (EE) have made it necessary for non-EE engineering students to take at least an introductory EE course in order to be successful in their specialties. Creation and teaching service courses for non-EE majors is a challenge for instructors due to many reasons, starting with the selection of concepts to cover and the ways to present them in the ways that non-EE students can relate to their fields of major. Taking these courses and passing them with success may become a struggle for students, also for several reasons. One of the difficulties is that non-EE students see EE as very abstract and non-intuitive compared to other engineering fields. In Mechanical Engineering, things move, get hotter or colder, break under stress; in Chemical and Materials, samples undergo obvious changes due to chemical reactions, etc. By contrast, what happens in EE is mostly invisible (because electrons are so small) or abstract like a wiggle on the screen of an oscilloscope. Psychologically, the main venue of learning EE is via abstract thinking, while sensory perception remains only weakly involved. Clearly, this style of teaching can be successful only for a few learning styles [1]. As a result, students' interest in the course material and motivation in learning EE can be undermined. Eventually, the students may suffer because they miss valuable learning of EE that may help them advance in their fields of major.

Our goal is to create the learning environment in our introductory EE service course for non-EE majors (average enrollment ~190 per semester) that would engage students' senses; provide hands-on experience, to which they can easily relate; stimulate their intuitive understanding of EE concepts; foster their enjoyment of learning, and eventually, help them succeed in their own fields.

In other reports, we have already outlined the overall structure of our course and its Lab component, and described the results of our detailed surveys of student learning. Here we focus on two new Lab experiments created and introduced in 2012, which help students relate the abstract concepts of Fourier spectra and transfer functions of various filters to their favorite pastime – listening to music and engaging in Internet activities. Noteworthy, this is not mere entertainment: our students perform all "mainstream EE" measurements in the lab, solder their own filter circuits and test their characteristics, and write full-fledged lab reports with printouts of oscilloscope screenshots, etc. Our surveys conducted in Fall 2012 indicate that these experiments were very important for the development of student understanding of the course material and their appreciation of value of EE for their further learning and work.

Other authors also studied various aspects of teaching EE to EE and non-EE majors, including lab projects. For example, Sterian et al. [2] developed a project-based approach to teaching introductory circuit labs with a special focus on intuitive understanding of simple circuits. Unfortunately, their report does not provide information on the enrollment in their course, and includes only a cursory description of the surveys conducted in connection to the newly developed projects. Hajjar and Sobahi [3] described the design of an introductory EE course for non-majors. From communication with universities, professors, research groups, and industry, they identified the need to present application-focused material, multidisciplinary systems with different types of sensors, and familiarity with software used outside the classroom (e.g. LabVIEW) but do not mention the laboratory component. Malik et al. [4] examined the challenges that non-EE students encounter in an introductory EE course and emphasized the need for content that would be more engaging and relevant to students' interests. Northrup [5] reported innovative lab experiments with many interesting and circuits of practical importance including temperature and light sensors, feedback control of motor speed, and music equalizers, but the level of difficulty is seemingly too high for non-EE majors.

Our approach is unique, because it engages students in several types of activities, from learning the theory to working with modern software to soldering a filter circuit to doing measurements of waveforms, spectra, and transfer functions with the oscilloscope. Psychologically, it helps students blend their mental picture of abstract concepts with sensory perception of music and invites them to explore their favorite music using the strategies and skills learned in EE, with test/measurement instruments in the lab and the filters they built themselves.

In this report, we present the contents of experiments, comment on the teaching experience and logistics in a large class, and summarize the students' feedback (obtained through anonymous online surveys in multiple-choice and open-ended question formats). Lastly, we discuss how our lab projects address several ABET General Criteria for Student Outcomes [6].

II. Background

A. Course Overview

The course for which we have developed the lab projects is an introductory Electrical Engineering service course intended for non-EE majors. The goals of the course include:

- ✓ Help non-EE students learn the key EE concepts and skills they can use in projects across many fields of engineering
- ✓ Highlight practical applications in which EE is used
- ✓ Provide a hands-on, insightful, and enjoyable lab experience

The laboratory component of the course includes 8 lab projects, each designed to be 2 hours in length for students working in groups of 2.

B. Student Audience

We first offered these new lab experiments to 156 students in the Fall 2012 term, although we ran a pilot test of many of the innovations in the Spring 2012 term for 34 students. In Fall 2012, the student audience was comprised of 90 juniors, 64 seniors, 1 sophomore and 1 graduate student, with the primary audience coming from Mechanical, Aerospace, and Nuclear engineering departments (see Fig 1).

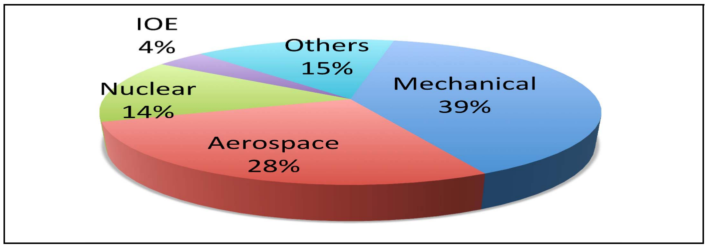

Fig. 1. Student enrollment for this course in the Fall 2012 term

III. Lab Projects

A. Spectra Lab

The Spectra Lab has been developed as 3 modules, in which students explore:

(1) Spectra of standard signals
(2) "Fourier Synthesis" of standard waveforms from their sinusoidal components
(3) More complex spectra, i.e. that of musical instruments

In the first module, students use the function generator to produce standard signals (sine, square, and ramp/sawtooth waves) and the oscilloscope to observe the waveforms and acquire their Fast-Fourier Transform (FFT) spectra. They are then asked to compare their lab data with theoretical predictions. This module follows a traditional and conventional approach to exploring frequency composition and Fourier synthesis of standard waveforms.

In the second module, students continue their studies of Fourier spectra through the use of the **Fourier Synthesizer.vi** – a LabVIEW ® program that builds standard waves as partial sums of harmonics, displays the waveform, spectrum, and analytic formula (see Fig 2). We also incorporate sensory perception by asking students to play the sounds of these signals via a speaker and appreciating the distinctions in what they hear. This aural perception of waveforms enhances students' understanding of the abstract concepts, and it serves to complement their visual observations.

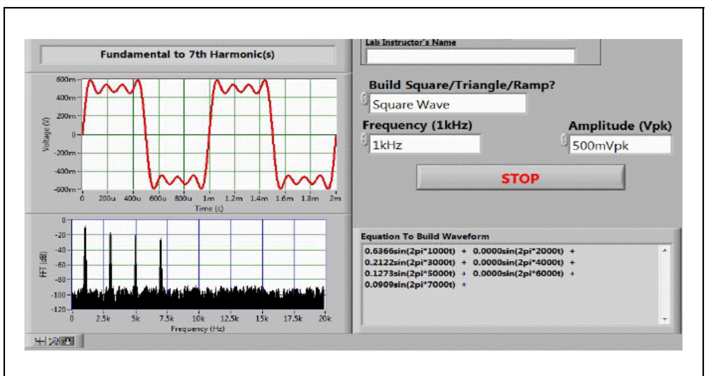

Fig. 2. The front panel of **Fourier Synthesizer.vi** includes the fields to be filled by the user (choice of waveform, frequency, and amplitude) and the windows where the computer builds the desired signal (the waveform, its FFT

spectrum, and the algebraic expression used to calculate the sum of sinusoidal spectral components).

The third module is our most recent innovation within the Spectra Lab, and it extends upon the studies of the frequency composition and Fourier synthesis of standard waveforms to sounds more familiar to students, namely those of common musical instruments. These musical instruments are simulated by a Virtual Keyboard® software program freely available on the Internet (see Fig 3). In the pre-lab, students play the Keyboard and guess how many harmonic components are involved in the sounds produced by various instruments and predict the distinctions in spectra and waveform based on what they hear, e.g. the Flute vs. Bass guitar, etc. In the lab, they play the same sounds and use an oscilloscope to measure the actual waveforms and spectra (an example of a measurement taken in the lab is shown in Fig 4). Students compare their lab data with their intuitive expectations; then they are encouraged to measure the waveforms and spectra of their favorite music, which is the fun part of the lab and provides an opportunity for additional exploration for the motivated student.

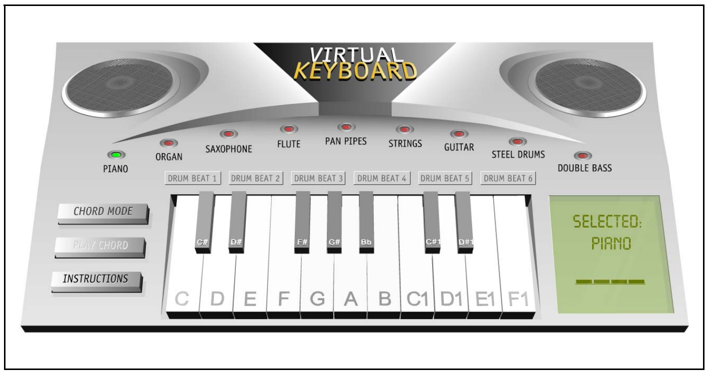

Fig. 3. A screenshot of the Virtual Keyboard software, found on the Internet at http://www.bgfl.org/custom/resources_ftp/client_ftp/ks2/music/piano/. Students have the opportunity to explore sounds produced by a variety of instruments and musical notes.

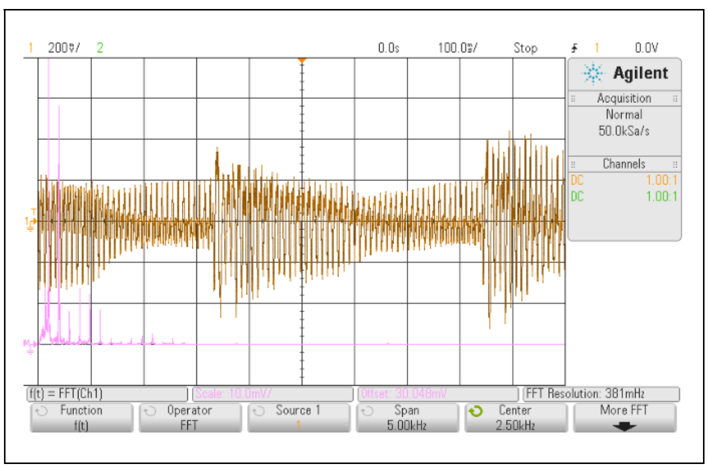

Fig. 4. A screenshot of the oscilloscope screen showing the waveform (orange trace) and FFT spectrum (purple trace) for the signal produced when the note G is played for the Virtual Keyboard's Double Bass instrument.

B. *Filters Lab*

The Filter Lab has been developed as 5 modules, in which students:

(1) Solder their own filter circuits
(2) Apply the soldered circuit as a Low-Pass filter and characterize its transfer function
(3) Apply the soldered circuit as a High-Pass filter and characterize its transfer function
(4) Use their soldered circuits to explore the resonant response in LC and RLC
(5) Apply their Low-Pass and High-Pass filters to the sounds of music

In the first module, gain experience in soldering their filter circuit, for which they are given step-by-step instructions along with numerous photographs. The specific circuit that they build is shown in Fig 5. Students are then asked to perform a few basic measurements to test the connections they have soldered, as this circuit is used in all subsequent modules. The components were carefully chosen so that the circuit can serve as RC Low-Pass and High-Pass filters in the audio range as well as LC and RLC filters that can clearly demonstrate resonant response.

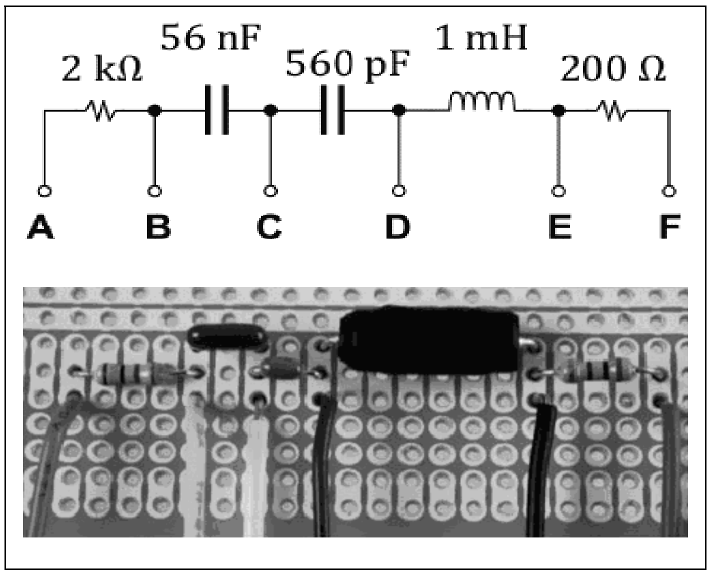

Fig. 5. The circuit diagram (top) is provided to students, and in the lab they are asked to build the circuit according to the diagram. The photograph (bottom) shows the final soldered circuit. The two left-most components, namely the 2 kΩ resistor and 56 nF capacitor, are used for modules 2, 3, and 5, while the remaining components are used for module 4.

In the second/third modules, students connect their soldered circuits as Low-Pass/High-Pass RC filters and investigate the effect of the filter transfer function and cut-off frequency. These two modules follow a more traditional approach to understanding filters, as students apply their circuit filters to sine waves and compare the output response of the filter to theoretical predictions of the frequency response. In addition, students use **Bode Plot.vi** – a LabVIEW ® program that generates plots of the transfer function magnitude vs.

frequency for the specific filter over a user-input range of frequencies (see Fig 6).

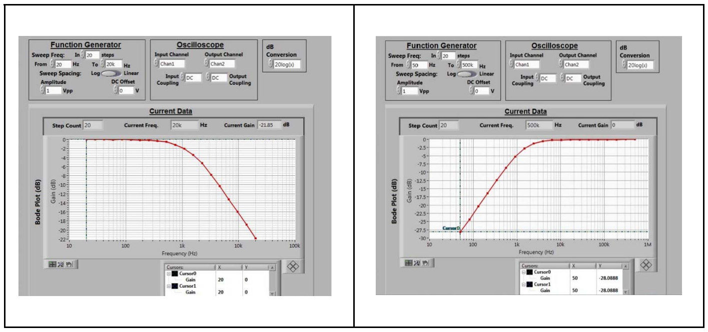

Fig. 6. Screenshots of the front panel of the **Bode Plot.vi**, showing the plotted transfer function magnitudes for the Low-Pass filter (left) and the High-Pass filter (right)

The fourth module addresses the topic of resonant response. Students use the function generator to apply a 30-period "burst" of a sine wave at the resonant frequency of an LC/RLC circuit, and they examine the buildup and decay of the resonant response, noting the distinctions between the LC and RLC circuits. Students are also asked to understand and explain how the phenomenon of resonance is consistent with conservation of energy.

The fifth module is our most recent innovation within the Filters Lab, and it extends upon the studies of the transfer function magnitude and cutoff frequency by applying it to a favorite pastime of students, namely listening to music. The audio clip used in this experiment is an excerpt from the Beatless song *Help!* It was specifically chosen because it is comprised of sounds from sources that occupy three separate spectral regions: bass guitar, vocals, and cymbals/percussion (see Fig 7).

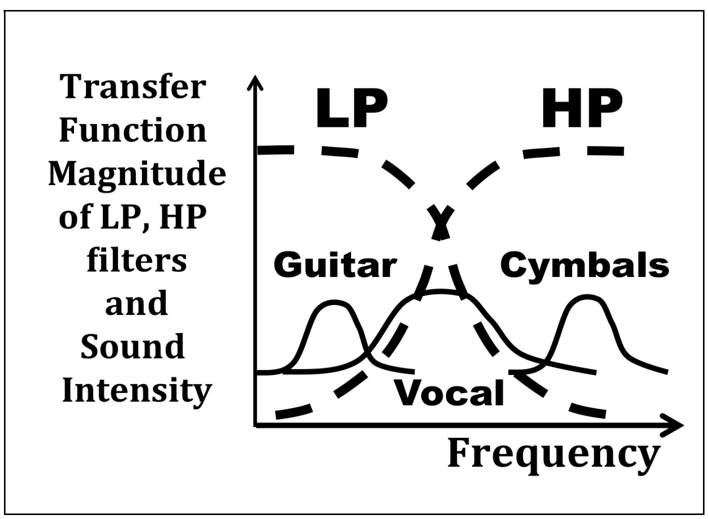

Fig. 7. A sketch that approximately indicates the three spectral regions of the music, relative to the transfer function magnitudes of the Low-Pass and High-Pass audio filters soldered in the lab.

In the Pre-Lab, students use the freeware Audacity® found on the Internet to create digital low-pass and high-pass filters with the same cutoff frequency as the in-lab filters, and listen to the clip through each filter and without filtering. In the lab, they apply their soldered filters to the provided excerpt of *Help!* and listen to the sounds produced with and without filtering. When no filter is applied to the audio, students can clearly hear all three sources of sound. Through the Low-Pass filter, students can no longer hear the high-frequency percussion, whereas through the High-Pass filter, students can no longer hear the bass guitar. Students can then compare the listening experiences with the digital filters from the Internet and with their own soldered filters. By listening to these effects, students can relate their sensory perception to the theory of transfer functions. At the same time, the experiments have been designed in a way that students find fun, relevant, and applicable to the real world.

Lastly, students are given an opportunity to apply their audio filters to their own selection of music. We encourage them to bring their mp3 players to the lab and observe the effects of filters on various types of sounds found in their favorite songs, allowing for open-ended exploration driven by student-specific interests.

IV. Student Feedback

To evaluate the success of our lab development in the context of student learning, we designed and implemented a set of comprehensive surveys for each Lab. Each set of surveys contain multiple-choice and open-ended questions, facilitating quantitative and qualitative evaluation. We used a professional version of SurveyMonkey® to collect responses from students and separately collect their personal information (so that we could provide them a small amount of extra credit for completing the survey) in a way that maintained student anonymity. Here we report a summary of students' responses to survey questions for the Spectra Lab and Filters Lab.

A. Spectra Lab

Our multiple-choice questionnaires for Spectra Lab focused on identifying whether or not students found the labs applicable, interesting, and helpful in reinforcing concepts learned in lecture. We presented the questions in the form of statements for which we asked students to evaluate their agreement (given a choice between "Strongly Agree", "Agree", Neither agree nor disagree", "Disagree", and "Strongly Disagree"). Statistics for five of the statements we asked (see Table I) are highlighted in Fig 8. Between 80-90 students participated in this survey.

TABLE I. Statements for Spectra Lab Multiple-Choice Survey

	Statements for Spectra Lab
Q1	"I feel that my learning in Lab 5 is valuable for what I do outside this course"
Q2	"I had enough time in the lab to think about what I was doing"
Q3	"I understood each step of the In-Lab work"
Q4	"I feel that my learning in previous Labs (1-4) helped me in

	Statements for Spectra Lab
	Lab 5”
Q5	“Lab 5 has been interesting”

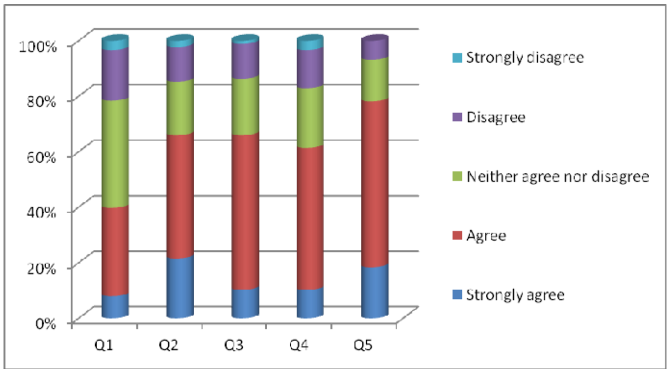

Fig. 8. Distribution of student responses to statements about the Spectra Lab. The statements Q1-Q5 are listed in Table I.

Based on the results of the surveys, we can infer a number of points:

- Nearly 40% of students indicated (via the choices “Agree” or “Strongly Agree”) that they found the Spectra Lab valuable to their work outside the course.
- Over 65% of students “Strongly Agree” or “Agree” that there was enough time to think and understand what they were doing in lab.
- Student interest is one of the major achievements of the Spectra Lab, since over 75% of students responded with “Agree” or “Strongly Agree” for statement Q5.

The open-ended questions provide further insight into students’ experiences in the Spectra Lab. We can also identify common “key words” that different students used when answering these questions. Presented below are a few select student responses that capture the overall student sentiment.

For the question, “What is the most memorable thing about Lab 5?”, more than half of the 91 respondents directly referred elements from the third module. A few representative quotes are provided below:

- “Being able to see the different frequencies and waveforms of the various instruments, it was actually quite interesting to see what we are actually hearing”
- “The most memorable thing was DEFINTELY the experiment about virtual keyboard and the music!! :)”
- “the most memorable thing about the lab was that musical instruments have very different waveforms and spectra than pure tones.”

To better understand student learning in Spectra Lab, we asked “What do you think is the most important thing that you learned in Lab 5?” We found that in general students referred to spectra decomposition and synthesis of waveforms from harmonics. Some answers that we highlight are:

- “Fourier approximations finally make sense”
- “The most important thing I learned in lab 5 was Fourier's theorem. I have seen this in other classes, and now that I have seen a practical application, the theorem is more clear. This theorem is very important for my other classes in my major.”

To see students’ evaluation of the applicability and relevance of Spectra Lab to their work outside the course, we asked “How can you apply your Lab 5 experience to your endeavors outside the course?” Many students referred the understanding of spectra, circuitry bandwidth, and Fourier analysis. However, a number of students felt the lab material, although interesting, was not directly applicable to their engineering work, but rather in musical hobbies. This calls for the need to strengthen the connection between the Spectra Lab material to non-EE engineering applications.

B. Filters Lab

The format of our multiple-choice questionnaires for Filters Lab is identical to that for Spectra Lab, although our set of questions is slightly different. Statistics for six of the statements we asked (see Table II) are highlighted in Fig 9. Roughly 90 students participated in this survey.

TABLE II. STATEMENTS FOR FILTERS LAB MULTIPLE-CHOICE SURVEY

	Statements for Filters Lab
Q1	“Listening to music helped me understand how filters work”
Q2	“I feel that my learning in Lab 6 is valuable for what I do outside this course”
Q3	“I had enough time to think about what I was doing”
Q4	“I understood each step of the In-Lab work”
Q5	“I feel that my learning in previous Labs (1-5) helped me in Lab 6”
Q6	“Lab 6 has been interesting”

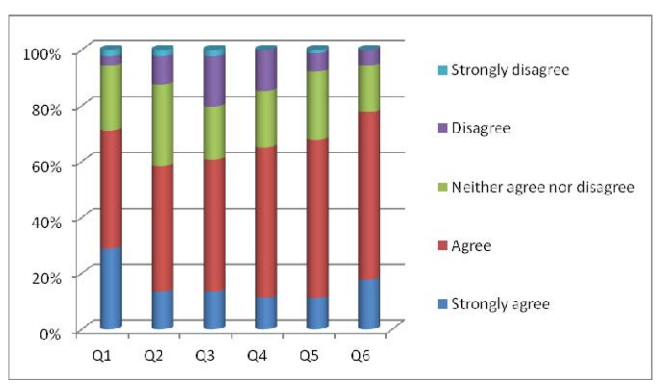

Fig. 9. Distribution of student responses to statements about the Filters Lab. The statements Q1-Q6 are listed in Table II.

Based on the results of the surveys, we can infer a number of points:

- Over 70% of respondents ("Strongly Agree" + "Agree") felt that the music component of the lab contributed to their understanding of filters.
- Nearly 60% of students found the learning experience in the Filters Lab applicable outside of the course, which is significantly higher compared to the 40% for Spectra Lab.
- Again, a major achievement of this lab is in regard to student interest, where nearly 80% of respondents "Strongly Agree" or "Agree" with statement Q6.

For the open-ended survey about Filters Lab, we asked similar questions as we did for the Spectra Lab. We provide highlights of the Filter Lab open-ended survey data below, for which we had roughly 97 respondents.

When we asked, ""What is the most memorable ... interesting ... insightful thing about Lab 6?", over two-thirds of students mentioned soldering experience and about half of the students referred to components of the fifth module, namely applying filters to music. The responses indicate that students enjoyed this lab and particularly liked the hands-on experience. Further, they indicated a sense of accomplishment for having built a complete circuit for which they could perceive its effects and evaluate its functionality in the lab. Some representative quotes from student responses are given below:

- "I really enjoyed soldering my own circuit and seeing/hearing first hand how the high/low pass filters work was great."
- "It was interesting to hear how filters work instead of just trying to understand how they work without any evidence."
- "I liked listening to the Beatles song to see how low pass and high pass filters affected the song. It was a much more memorable and interesting way to sense the frequency."

We also specifically asked students their views on the music aspect of the Filters Lab. In general, we received positive, interesting, and occasionally unexpected answers, for example:

- "This part was very interesting. This was the part that helped me understand the physical aspect of harmonics of waves and their frequencies. The sounds of music was not exactly relevant to my interests, however it did help me understand (just a bit more) the construction of wave functions that apply to quantum mechanics (Nuclear Engineering)."
- "It is VERY cool certainly! I find it amazing that I now have the knowledge to build a music filter, and it is VERY much relevant to the field of study I am interested in. It has helped me to see the effects of what we do in theory on a VERY COOL real life application :)"
- "More coursework should be like this. Engagement = learning."

To evaluate student learning in the Filters, we asked, "Has this lab strengthened your understanding of the connection between theory (both the physical concepts and mathematical formulations) and experiment (what you do, see, hear, and observe in the lab)? If yes, how? If no, then what do you think is lacking?" Nearly all responses were positive, for example:

- "Yes. Before, I only understood it through the formulations and looking at the circuits on paper. Having to build the certain filters and then hearing the sounds and lack of sounds helped put a physical result with what I had thought I knew. It helped legitimize the theory."
- "Yes, the use of the music signal was especially illustrative."
- "Yes, being able to see something happen in electrical engineering is rare, let alone being able to build something. If we could build something in every lab, this would be the best lab ever (as long as we don't have to print a lot of graphs)."

V. Discussion

From our teaching observations and survey evaluations in the course, we find success in our lab development efforts. In particular, we note positive results and experiences in the aspects of student learning, understanding, interest, and motivation. We also see that students have an improved appreciation for the applications of EE concepts to their respective non-EE fields of work.

Our lab development also addresses ABET General Criteria for Baccalaureate Level Programs. Specifically, we highlight our achievements towards 5 criteria for Student Outcomes [6].

(3a) an ability to apply knowledge of mathematics, science, and engineering
(3d) an ability to function on multidisciplinary teams
(3e) an ability to identify, formulate, and solve engineering problems
(3i) a recognition of the need for, and an ability to engage in life-long learning
(3k) an ability to use the techniques, skills, and modern engineering tools necessary for engineering practice

Our lab projects have students apply abstract concepts of spectra and transfer function magnitude to the familiar, everyday aspect of music to become comfortable with the EE concepts. They learn valuable EE skills, such as soldering and using various instruments, tools, and components to generate, alter, observe, and analyze waveforms and spectra. Eventually, students learn to connect their understanding of EE concepts to their engineering work as well, and they appreciate the benefit of this life-long learning process. This is in accordance with criteria (3a), (3i), and (3k).

In this course, and particularly in the lab, we establish an atmosphere conducive to multidisciplinary work. Given the diversity in the student audience, student interact with others different majors and backgrounds. Also, the EE lab instructor and the course material and projects are of a different major/discipline than the students. This multidisciplinary environment addresses criteria (3d).

Lastly, these lab projects expose students to engineering problems and solutions that they may encounter in the real-world, in accordance with criteria (3e). Interestingly, many students initially overlooked or at least undervalued the fact that music and other arts have rich engineering applications. These lab projects have the goal of broadening students' perspectives and inspiring them to be open-minded as they look for innovative ways to apply their engineering skills.

VI. ACKNOWLEDGMENT

This work has become possible due to ongoing attention of Khalil Najafi and Dave Neuhoff to undergraduate education, including the lab instruction. We greatly appreciate the support of the Department of Electrical Engineering and Computer Science, ECE, in many aspects, including financial support for S. S. for the course development during the summer 2012. We are grateful to the Center for Research of Learning and Teaching, especially, the Engineering section, for many opportunities to present and discuss our work. We thank Rob Giles and Mike Stander for their excellent help in the lab.

N-FUELS and SOPRANO: Educational Tools for Simulation, Analysis and Processing of Satellite Navigation Signals

Emanuela Falletti, Davide Margaria, Mario Nicola, Gabriella Povero and Micaela Troglia Gamba
Navigation Signal Analysis and Simulation (NavSAS) Group
Istituto Superiore Mario Boella (ISMB), Torino, Italy
Email: {name.surname}@ismb.it

***Abstract*—In recent years, research activities in the field of Satellite Navigation have boosted worldwide. At the same time, it has become evident that few educational opportunities in the field were available for students and there was a need to develop dedicated tools for hands-on sessions. To partially answer this need, the NavSAS Group has developed N-FUELS and SOPRANO. N-FUELS, a MATLAB®-based signal simulator, allows students to understand the physical layer of the Global Navigation Satellite Systems (GNSS) signals and to learn how to manipulate them via software. SOPRANO, a collection of ANSI C language routines, implements the whole chain of GNSS signal elaboration in post-processing and enables testing and validation of new GNSS signal processing algorithms and architectures. Both tools are used in post-graduate courses at Politecnico di Torino with a high degree of internationalization, which opens interesting points of discussion concerning the introduction of novel educational tools able to meet the demand and the learning styles of students with different educational backgrounds and cultures.**

I. Introduction

In the last decade, research activities in the field of Satellite Navigation have boosted worldwide. New Global Navigation Satellite Systems are under design and deployment, such as European Galileo or Chinese BeiDou, while already existing systems, such as US GPS or Russian GLONASS, are undergoing modernization processes. This has led not only to an enlargement of the GNSS scientific community but also to the birth of companies interested in GNSS-based products and services. As a consequence, a number of new jobs are expected to be available in coming years worldwide in the field of GNSS and its applications. On the other hand, few educational opportunities focused on this topic are presently available for students [1]. This was recognized by the European Commission, that started actions to foster and support initiatives in this field [2] so as to educate the future GNSS engineers and researchers. At the same time, there was a need to develop new dedicated tools which professors could use in courses and hands-on sessions.

This fact was particularly evident to our research group, who has been involved in educational activities on GNSS for almost a decade. One example is the Specializing Master on Navigation and Related Applications [3], a post-graduate programme offered by Politecnico di Torino since 2004, where we teach some modules on Satellite Navigation Systems and Receivers. The Specializing Master is offered in English and this opens it to the participation of international students: on average over 50% of students are from outside Europe. This makes the Specializing Master an interesting melting pot where different educational backgrounds and cultures merge. The result is an international community of people trained in GNSS who are expected to be the tomorrow technical and scientific work force in this field.

II. Two educational software tools for GNSS-oriented students

Learning from experience of many years of courses on signal and system simulation, as well as from the practice of designing and testing algorithms for the core signal processing in GNSS receivers, we felt the need of developing simple and flexible software tools to, on the one hand, simulate a wide variety of GNSS signals at their physical layer; on the other hand, to build a completely open software architecture of a GNSS receiver, modular and simple enough to be used as a training ground for the implementation of functional blocks in real-time architectures, such as those presented in [4]–[7].

The two software tools we have developed are a MATLAB®-based signal generator (N-FUELS, FUll Educational Library of Signals for Navigation), and an ANSI C complete GNSS receiver (SOPRANO, fully SOftware fully Programmable GNSS Receiver for Algorithm testiNg and validatiOn). Their basic characteristics are reviewed in the following subsections. What is worth highlighting right now, is that these two tools have allowed us to provide the students with highly reliable software tools, which overcome the initial difficulty of simulating quite complex signal architectures [8] and propagation effects, as well as realistically reflect the signal flow in a receiver and the logical sequence of the receiver's states.

A. N-FUELS: FUll Educational Library of Signals for Navigation

N-FUELS is a MATLAB®-based signal simulator designed to offer a complete and intuitive software tool which simulates the physical layer of GNSS signals, as they appear at the Analogue-to-Digital Converter (ADC) output of a receiver's front-end, either at Intermediate Frequency (IF) or at baseband [9]. From an already trained user's perspective, it allows neglecting all the issues related to the correct implementation of the signal structure (including spreading code

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

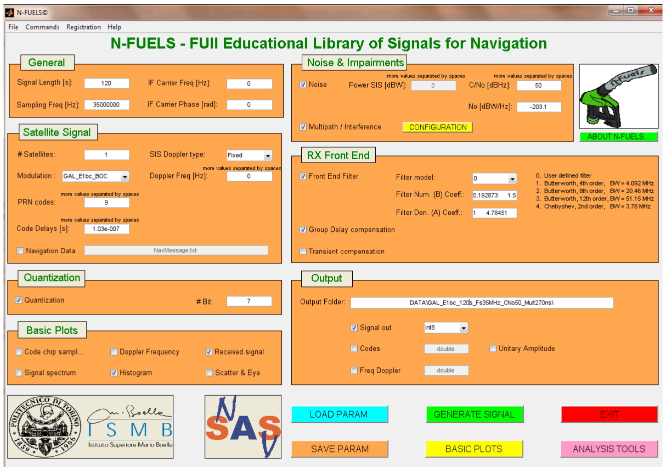

Fig. 1. A screenshot of the N-FUELS graphical user interface.

generation) and of a number of common propagation effects, such as propagation delays, Doppler shift effects, thermal noise, multipath and various models of interference. From a students' perspective, it is a tool that directly and simply puts in their hands samples of the signals introduced of during the lectures; observing such simulated signals, students can get an immediate understanding and a hands-on experience of several signal properties and propagation effects.

The goal of being an intuitive and wide-use tool is pursued without loosing flexibility and generality. Indeed, the GNSS signals supported by N-FUELS are all civil GPS services (including signals under modernization), all open Galileo signals, and the EGNOS signal. The student can control several parameters of the simulation through a very user-friendly Graphical User Interface (GUI), where he/she can act on several settings. Namely, three families of settings are provided:

- *parameters related to the Signal-In-Space (SIS),* including the length of the simulation, the number of simulated signals, the signal modulation, the PRN codes number, the code delays, the Doppler model, and the received signal power;
- *propagation channel parameters,* including Carrier to Noise density ratio (C/N_0), thermal noise spectral density, multipath (a static N-ray channel model is embedded, with selectable N), disturbance models (continuous wave, filtered noise-like interference, pulsed interference, inter/intra-system interference, emulation of a spoofing attack);
- *receiver front-end parameters,* including sampling frequency, intermediate frequency, front-end filter model, possibility to compensate the filter group delay and its transient time, number of quantization bits, format of the output binary file (double, float32 or int8 sample representation).

A screenshot of the GUI is shown in Fig. 1.

In addition, N-FUELS includes a set of simple signal analysis tools for quickly testing and monitoring several signal metrics [10]–[13]: for example, power spectral density estimation, group delay estimation associated to a certain front-end filter model, auto correlation and discriminator curves, multipath error envelope and running average curves, spectral separation coefficients, etc... Again, this set of simple tools for the signal analysis is a fast bridge for students towards the undestanding of the basic properties of the GNSS signals, allowing them to circumvent the "obstacle" of coding, at least at a very early stage.

B. SOPRANO: fully SOftware fully Programmable GNSS Receiver for Algorithm testiNg and ValidatiOn

As the acronym suggests, SOPRANO is an ANSI C-based fully software receiver, which implements the post-processing GNSS signal elaboration. It processes, i.e., acquires, tracks and uses for PVT (Position-Velocity-and-Time) estimation, both the GPS-SPS (Standard Positioning Service) and Galileo OS (Open Service) signals. It accepts as input binary files, containing the ADC output samples, either generated by N-FUELS or recorded from a GNSS front-end, such as for example [14], with up to 8 quantization bits. Thus it can be employed to process either simulated signals in a completely ideal environment or real signals. The current version of the receiver supports only real IF samples, but future releases will also include the baseband elaboration.

SOPRANO has been expressly thought as a lab instrument for signal processing, enabling developers (either trained researchers or graduate students) to describe, test and validate GNSS signal processing algorithms and architectures. It takes also advantage of the processing speed of the C language, differently from other famous software receivers [15]–[17] which employ MATLAB® as modeling language. Similarly to the GNSS Software Defined Radio (SDR) receiver in [18], it aims at being an open-source and public reference receiver, both with educational and training purposes. SOPRANO implements all stages of the whole processing chain, by means of state-of-the-art algorithms only, making it a non-patented and completely free solution. Thus, as N-FUELS, it meets the needs of both trained and student users. While a student can get a deep understanding of the GNSS processing flow, looking how the learned theory becomes practice, the trained user can easily found and modify the desired functions, thus testing his own solutions. The handiness in use of SOPRANO is one of its main features and its crucial point. First of all, its ANSI C structure does not need special libraries, which aids the fully portability among different compilers and different operative systems; furthermore, the user can openly access the entire source code, making the desired changes wherever he/she wants.

The code structure is easy to read: it is organized in a sequence of folders, each one including a list of source and header files, belonging to the same processing stage. For example, the directory entitled "acquisition" collects all functions related to the signal acquisition, while that called "tracking" contains those devoted to implement the tracking loops, and so on. All the signals/data/measurements needed to perform signal elaboration are included in structures which are accessed through the use of pointers, avoiding other less intuitive ways of data access, such as First-In-First-Out (FIFO) data structures, sockets, etc. The name itself of all data structures and functions always refers to their functionality. SOPRANO's flexibility is allowed by the intrinsic nature of its software implementation. In fact, besides working with different IF front-ends, thanks to a simple text configuration file, also several processing setups can be changed via other simple configuration files, for example the number of coherent/non-coherent sums in acquisition, Doppler and code delay resolutions, gain and bandwidth of the frequency and code discriminators, early-to-late spacing of the correlators and so on. This allows the user to quickly create his tailor-made receiver.

III. EXAMPLES OF PROPOSED EXERCISES

In the frame of the Specializing Master on Navigation [3] introduced in Section I, the *GNSS Introduction* course introduces the mathematical description of the physical structure of the GNSS signal, including all the current signals and those under modernization. It also discusses the issues of interoperability and coexistence among different GNSSs.

Another advanced course on *GPS and Galileo Receivers* gives students a knowledge about the fundamental architecture of a GNSS receiver. The course combines theoretical principles about the employed algorithms and hints about their implementation in real GNSS receivers. In order to reach this target, the course combines both theoretical lectures and practical assignments.

In this section, a couple of assignments, proposed to the students during the mentioned courses, are shown as examples of the employment of N-FUELS and SOPRANO in education. The first exercise is focused on the use of the Spectral Separation Coefficient as a tool to theoretically assess inter-system interference. The second exercise is about the algorithms to acquire the GNSS signal in a typical receiver.

A. Exercise 1: Evaluation of Spectral Separation Coefficients

The spectral separation coefficient (SSC) [12] is a theoretical method proposed to assess the level of inter-system interference among GNSS signals (and also between a GNSS signal and an interferer). The SSC is a measure of the spectral coupling between two signals, defined as a sort of inner product of the normalized power spectral densities of the two signals, evaluated over a certain front-end bandwidth. The average SSC is defined as [12]

$$\kappa_{is} = \int_{-B_{fe}/2}^{B_{fe}/2} G_i(f) G_s(f)\, \mathrm{d}f \qquad (1)$$

where $G_i(f)$ is the unit-power power spectral density of the signal i (taken as the interference) and $G_s(f)$ is the unit-power power spectral density of the reference signal s. Once evaluated the SSC κ_{is}, the effective carrier to noise density ratio can be computed, where the interference component is assimilated to an additional noise effect.

Having commented such a metric during classes, it is effective for the students to see examples obtained in simulation. With this aim, a specific assignment based on the use of N-FUELS is proposed in the course. The text of the assignment is reported in Table I.

TABLE I. TEXT OF THE EXERCISE ABOUT SPECTRAL SEPARATION COEFFICIENTS

Exercise 1
Objectives: Understanding the spectral separation coefficient.
Description: The spectral separation coefficient (SSC) is a theoretical metric that measures a normalized level of interference between two GNSS signals (or a GNSS signal and a certain interferer). It is based on the measure of the "overlapping portions" of the power spectral densities of the signals of interest. Here we want to evaluate the SSC between a CBOC modulation and the other modulation formats of the GNSS family (BPSK(1), BPSK(5), BPSK(10), BOC(10,5), BOC$_c$(15,2.5)).
Use N-FUELS to generate 100 ms of each of the above signal formats at the intermediate frequency $f_{IF} = 0$ MHz, sampled at 50 MHz, received at the power of 0 dBW without noise. Set the Doppler frequency to 0 Hz. The receiving filter is ideally flat on the digitization bandwidth and there is no quantization. Generate the estimated Power Spectral Density (PSD) of each signal (*hint:* save your simulations in different output folders, one per configuration, so that you can reuse your data sets).
Superimpose each estimated PSD to that of the CBOC signal and observe the portion of overlapping spectra. Then set the file of the parameters for the SSC analysis (`ParamSSCoefficients.txt`) to produce the SCC for each modulation with respect to the CBOC.
Questions:

1) Use N-FUELS to obtain a table of the SSC for each modulation format with respect to the CBOC one; sort in descending order of SSC value.
2) Observe that the "amount" of overlapping portions of the spectra, as seen from the PSD figures by simple inspection, is compliant with the numerical results put in the table.

TABLE II. SPECTRAL SEPARATION COEFFICIENTS BETWEEN THE CBOC MODULATION DEFINED FOR GALILEO E1 AND OTHER POSSIBLE COEXISTENT MODULATION FORMATS

i	BPSK(1)	BPSK(5)	BOC$_c$(15,2.5)	BPSK(10)	BOC(10,5)
$\kappa_{i,\text{CBOC}}$ (dB/Hz)	-61.94	-69.18	-70.28	-72.60	-73.59

1) Comments about the assignment: The students are expected to comment the result of this assignment during their oral exam. The simulation through a numerical computation of the formula (1) enables the students to fill a table with SSC values for different modulations, with respect to the CBOC one. The comparison between these results and the figures, where the corresponding PSDs are actually superimposed, should ease the understanding of the SSC concept. For example, the table of the SSC values is reported in Table II, while the estimated power spectral densities for the two "extreme" cases of maximum and minimum SSC's are shown in Fig. 2.

B. Exercise 2: SW Implementation and Test of an Acquisition Algorithm for a Galileo E1b/c Signal

In a GNSS receiver, the signal transmitted by one satellite is received using local replicas of the carrier and the spreading code employed by the transmitting satellite. The main task of the receiver is to obtain the alignment between these local replicas and the received signal: the receiver must produce a

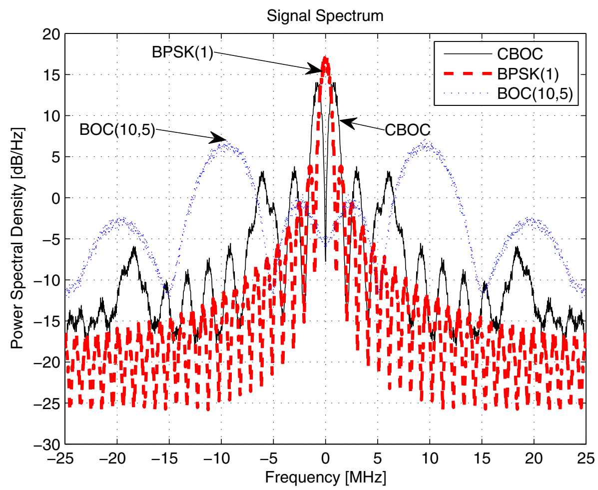

Fig. 2. Power spectral densities of the modulations analyzed in Exercise 1. The minimum separation of the spectra, as measured by the SCC, is obtained between CBOC and BPSK(1), as their main lobes partially overlap. On the contrary, the maximum spectral separation is obtained between CBOC and BOC(10,5), whose main lobes are well separated in frequency.

local replica of the spreading code with the same code rate and delay as the incoming signal, and a local replica of the carrier with the same frequency and phase of the incoming carrier. Such synchronization is the key point that allows to correctly estimate the distance between the satellite and the receiver and, consequently, to evaluate the position. The acquisition stage gives the receiver a first rough synchronization with the incoming signal, whereas the following stage, named tracking, refines and updates the alignment [10] [19].

1) The assignment: After a lecture about the theory of the GNSS signal acquisition, students are required to implement main acquisition algorithms that can be found in literature [15] both in MATLAB® and in C language. The text of the assignment is reported in the Tables III and IV.

2) Comments about the assignment: In Exercise 2a (Table III), students implement acquisition algorithms using MATLAB®. This approach allows the students to focus on the employed algorithms and almost ignore implementation details. In this way, they can acquire a deeper knowledge of the subject if compared to what can be obtained with a pure theoretical lecture. Under these conditions, the use of N-FUELS is a key point. Using signals generated by N-FUELS, students have a perfect control over the unknowns of the acquisition (carrier frequency, code rate and delay): this facilitates the debug of the implementation. Moreover, the use of N-FUELS enables an easy generation of signals at different carrier to noise ratios, making possible the part of the exercise when students verify the effects of noise on acquisition results. Fig. 3 shows a graphic obtained solving Exercise 2a.

The MATLAB® implementation of the acquisition algorithms hides some unnecessary details, but it is very far from an implementation able to elaborate samples of a signal from an antenna or from a hardware signal generator. In order to teach students the architecture of a software receiver able to elaborate real signals, Exercise 2b requires the use of SOPRANO (see Table IV). As stated in Section II-B, SOPRANO does not exhibit the performance required to elaborate the signal from an antenna in real-time, but its architecture directly derives from a real-time fully software receiver able to do it [4]. Consequently, the insertion of the new acquisition strategy in SOPRANO allows the students to understand the architecture of a software GNSS receiver able to elaborate real data. Moreover, they can experience which are the most critical parts of the receiver and why they demand an optimized implementation, in order to cope with performance requirements for the elaboration of a real signal.

TABLE III. TEXT OF THE FIRST EXERCISE ABOUT ACQUISITION

Exercise 2a
Objectives: Implementation of the Parallel Acquisition Schemes in Time and Frequency domain.
Description: Following the MATLAB® given example (SerialSearch.m) for the Serial Search Acquisition scheme, write two functions that implement the Parallel in Time and Parallel in Frequency acquisition schemes.
Use N-FUELS to generate the code and signal sequences necessary to test the behaviour of the SerialSearch function: generate a few ms of a GPS L1 signal (f_{IF} = 4.152 MHz, fixed Doppler shift at e.g. 1.5 kHz, without noise, without front-end filter, without quantization). Then generate 1 ms of the local code (same PRN as before, same sampling frequency, code delay = 0 s, Doppler = 0 Hz, without noise, without front-end filter, without quantization)
Questions:

1) Read from the corresponding data file the code and signal sequences and pass them to the SerialSearch function. Visualize the obtained search space and determine the maximum; determine and verify the corresponding estimated code delay and Doppler frequency shift (acquisition parameters). Plot the 1-D search functions along the delay axis (row of the 2-D search space corresponding to the estimated Doppler frequency) and Doppler frequency axis (column of the 2-D search space corresponding to the estimated code delay)
2) Repeat the generation of the signal sequence, with the insertion of the front-end filter. Repeat the signal acquisition and compare the obtained search spaces and estimated acquisition parameters.
3) Repeat the generation of the signal sequence at different levels of C/N$_0$ (e.g. 33 dBHz, 38 dBHz, 44 dBHz, 50 dBHz). Repeat the signal acquisition and compare the obtained search spaces and estimated acquisition parameters.
4) Repeat point 3 by using the other two acquisition schemes: Parallel in Time and Parallel in Frequency.

IV. Conclusion

The use of N-FUELS and SOPRANO in hands-on sessions of courses in the Specializing Master on Navigation have improved students' understanding of the characteristics of GNSS signals and related processing techniques. On the one hand, providing students with well-structured environments where they can “play” with parameters, such as N-FUELS, allows them to acquire the needed sensibility to deeply understand the structure of GNSS signals and receivers. On the other hand, the SOPRANO tool permits to smoothly move to an open

TABLE IV. TEXT OF THE SECOND EXERCISE ABOUT ACQUISITION

Exercise 2b
Objectives: Implementation of one acquisition scheme in a fully software receiver.
Description: Replace the Parallel in Time acquisition employed in the SOPRANO fully software receiver with a C implementation of the Parallel in Frequency strategy.
In particular, open the file "/acquisition/cafEvaluation.c" and modify the `PerformCaf` function, whose prototype is the following:

```
TCafEvaluationStatus PerformCaf
(TSopranoStruct * r, int channelIndex,
char *data1, int size1, char *data2, int
size2);
```

where:

- `TSopranoStruct * r` is the pointer to the main structure, containing all data structures needed by the receiver;
- `int channelIndex` is the index of the channel assigned to a satellite. This parameter must not be changed;
- `char *data1`, `char *data2`, `int size1` and `int size2` are related to the circular buffer which contains the ADC output samples. The first two parameters are pointers to two different chunks of data, while size1 and size2 are the number of samples available at the location data1 and data2 respectively. All these parameters must not be changed, since they involve the receiver framework.
- `TCafEvaluationStatus` is the type of the return parameter, indicating the status of the CAF evaluation. It assumes one of the following values: {`CAF_EVALUATION_IN_EXECUTION`, `CAF_EVALUATION_SUCCESSFUL`, `CAF_EVALUATION_UNSUCCESSFUL`}.

The `PerformCaf` function has access to the data structure `TCafEvaluation *caf`, needed by the acquisition and contained in `r`, as clearly appears looking at this assignment: `caf =&((r->channelArray[channelIndex]).caf)` where `channelArray` is the vector of channels, each one assigned to a different satellite. All the variables that you need to employ to implement the "Parallel in Time" strategy are contained in that structure, while the acquisition parameters are read from the file "configurationFile/acquisitionParameters.txt" and stored in `TAcquisitionParameters *acqPars` structure.

Questions:

1) Repeat simulations performed in Exercise 2a, and compare the obtained results.
2) Discuss the strategies employed in the software receiver in order to reduce the complexity of the employed algorithm.
3) Perform an execution time profiling of the code and list the most critical points that must be further optimized in order to enable a straight execution with samples from an antenna.

In order to be compliant with SOPRANO, input files described in Exercise 2a must be generated using 8 bits per sample.

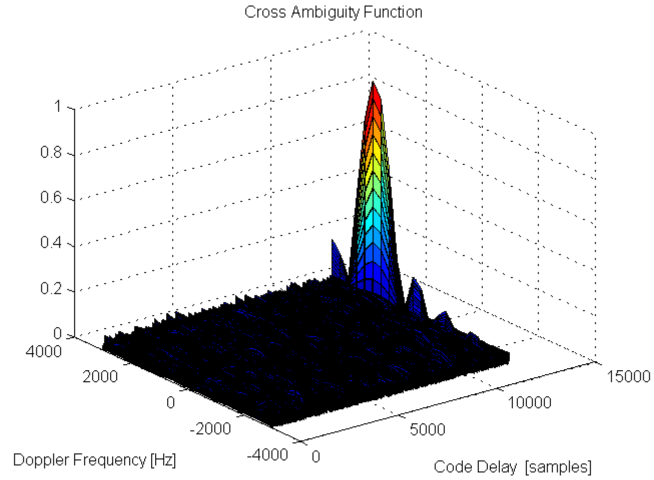

Fig. 3. Graphic representing the result of the acquisition procedure implemented in Exercise 2a. The position of the peak reflects actual values of Doppler shift and code delay.

environment, where students can start experiencing receivers implementations which are more similar to those available in real-time software receivers.

In the on-going edition of the Specializing Master on Navigation we have used for the first time both N-FUELS and SOPRANO in our classes. With respect to past years, when only N-FUELS was used together with a collection of MATLAB® routines, we have appreciated an easiest conduction of hands-on sessions, and a better understanding and acquired knowledge by students. As a matter of fact, being the geographic origin of our students quite variegated (from Africa to Australia passing by South East Asia and, of course, Europe), their background knowledge is not always homogeneous. The use of the two tools allowed us to better overcome lacks of background in programming which we sometimes verify in some of our students. In addition, the exercises discussed in previous subsections proved to be effective for increasing the motivation and the satisfaction of our students, encouraging them in improving their programming skills and providing a practical feeling about GNSS signals and receiver algorithms. At the end of the courses, we received positive and encouraging feedbacks from our students about their experience with N-FUELS and SOPRANO: in detail, we received positive comments from anonymous questionnaires and multiple expressions of interest for possible internships in our research group.

In consideration of the positive results achieved, we are planning to extend the use of these tools to other courses on GNSS in the M.Sc. in Telecommunication at Politecnico di Torino.

Teaching Electric Circuits Using a Modified Flipped Classroom Approach

Asad Azemi
Pennsylvania State University, azemi@psu.edu

***Abstract* - This paper describes our initial effort to implement a flipped classroom approach to teach an Electric Circuits course. Prior to each scheduled class meeting, students are required to watch a recorded short lecture, which covers the topics in details and includes simple worked out problems. We have used Tablet PC in combination with PowerPoint, OneNote, and Camtasia as the capturing software, to produce the short-recorded lectures. We have also produced a set of narrated dynamically worked-out problems, with different difficulty levels that students are encouraged to watch. These recorded worked-out problems will complement the recorded lectures and help students with their problem solving skills. A typical lecture consists of a quick review of the concepts followed by solving more challenging problems, related to the lecture material. A more detailed discussion of this approach and the advantages and disadvantages of such a scheme are presented. The preliminary evaluations of the proposed approach by a group of students have been encouraging.**

***Keyword* – Filliped classroom, Electric Circuits, Multimedia, Problem Solving.**

I. INTRODUCTION

"Flipping the classroom" is a pedagogical concept that replaces the standard lecture-in-class format with an opportunity to explore concepts and to review materials from outside of class. This can happen in many forms, but the underlying premise is that students review information outside of class and, instead of simply receiving information from the instructor, come prepared to discuss concepts. The "flipped classroom" approach has received considerable attention in recent years in many subject areas but not as much in engineering [1]-[3]. In this work, we describe a modified flipped classroom approach that we have started using to teach an electric circuits course. We first start with a brief background information that would explain the reason behind choosing electric circuits for the implementation process. Electric Circuits (EE 210) is a required course for all Electrical and Computer Engineering students at Penn State. Like most other institutions, EE 210 is the first course in electrical engineering and gateway for subsequent EE core courses. Our statistics indicates a direct correlation between strong performance in electric circuits (i.e. B and above) and subsequent success in the follow-up courses in the EE curriculum. Problem solving has always been the key to success in engineering, it is imperative that all students enrolled in this course obtain a strong foundation in the key theoretical circuit analysis concepts and solution techniques. In this regard, our experience with this course, and similar type courses, indicates that the major instructional problem faced by instructors is that students have difficulty knowing where and how to start a given problem as opposed to the mechanics of problem solving. In order to address these challenges, in our previous works [4]-[6] we reported the development of a set of dynamically worked-out problems, so that students could obtain a greater understanding of the subject matters and increased competency in their ability to analyze basic circuits using the appropriate tools and concepts. Since the proposed approach is not intended to eliminate the lecture portion, we have called it a "modified flipped" classroom approach. We believe the proposed approach enables the instructor to focus more on improving problem solving skills, and consider it as the natural extension of our previous works in this area.

II. PROPOSED APPROACH

The main resources for the proposed approach include (i) recorded short lectures, (ii) a set of recorded dynamically worked-out problems, and (iii) a set of challenging problems for in-class discussions. These resources are made accessible to students via ANGEL [7], our course management system. Prior to the beginning of the semester, based on our previous experiences, we prepared a detailed course schedule including weekly agendas and the other required materials, organized in different folders in ANGEL. The weekly lecture folders contain lecture material and in-class problems, in PowerPoint format. Another folder contains a set of dynamically worked-out problems [4]-[6]. The recorded lectures are produced by using Tablet-PC, Microsoft PowerPoint and OneNote, and Camtasia [8] for recording the auditory explanation and capturing the annotations. We have avoided including challenging problems in order to keep the length of each recording no more than 30 minutes and focus on explaining the concepts. The dynamically worked-out problems were developed based on step-by-step, expert, think-aloud process to model the details of the problem solving process, and thereby scaffold student problem solving. The hypothesized outcome of the narrated engineering problems is the following: Students who listen to and watch the narrated problems will better understand the steps necessary for successful completion. A typical worked-out problem contains links to similar but different complexity level problems.

III. A TYPICAL LECTURE

A typical lecture consists of a quick review of the concepts followed by solving "in-class" problems. These problems are more challenging than the ones in the pre-recorded lectures and are similar to the advanced problems in our dynamically worked-out problems. In order to encourage students to take advantage of the dynamically worked-out problems, we introduced in-class team based problem solving exercises, bonus points were awarded to the first group that would come up with the right answer during the class.

In order to achieve our main goal of enhancing students' problem solving skills, we made sure that the following points are emphasized/covered in every in-class problem:

- Recognizing/identifying the 'type' of problem that is being considered.
- Identifying the tools/laws/concepts that can be used to solve the problem.
- Identifying the most appropriate and efficient approach/tools to solve the problem.
- Setting up the problem given the problem constraints.

IV. MEASURING PROJECT SUCCESS

- We have been able to increase the number of problems that we normally cover in a typical lecture and accommodate more in-depth discussions.
- We have observed that students are more engaged in the classroom discussions and problem solving.
- We have observed a modest increase in the homework and exam grades.

Summary of these comments will be presented at the conference.

V. FUTURE WORK/REMARKS

The following items represent a few of our observations and directions for our future work:

- Watching the pre-recorded lecture should be treated as a course assignment and part of the grading system.
- A process needs to be set up to make sure that students have watched the pre-recorded lectures. Including a set of questions at the end of each lecture is recommended.
- Use of Tablet PC or touch screen devices would enhance the lecture delivery.
- Use of communication tools such as Adobe Connect [9], would enhance the lecture delivery, enables recording of the lecture, and facilitating active student participation.

ACKNOWLEDGMENT

This project has been partially funded by The Leonhard Center for the Enhancement of Engineering Education.

Embedded Systems Design Curriculum Conversion from Quarters to Semesters

An Opportunity to Improve an Already Successful Course Sequence

Antonio F Mondragon-Torres and Jeanne W Christman
Department of Electrical Computer and Telecommunications Engineering Technology
Rochester Institute of Technology
Rochester, NY, USA
afmiee@rit.edu, jxciee@rit.edu

***Abstract*— In this paper we present a vision of how a sequence of three embedded systems design courses currently being taught for computer engineering technology students will be adapted from a quarter based delivery to a semester based delivery. The conversion brings the opportunity to revise the course contents, platforms used and make changes that will prepare students with a more up-to-date skill set and a robust industrial training. In this work in progress we will present some of the new ideas that will be implemented in our semester courses. After offering these courses multiple times, feedback will be gathered from students and industry, and a future study will be presented outlining the achieved outcomes as compared to our intended outcomes for curriculum continuous improvement.**

Keywords—Embedded Systems Design; FPGA; System on a Chip; SoC; Real Time Operating Systems; RTOS

I. INTRODUCTION

While the Embedded Systems Design (ESD) course sequence that is currently being taught in the Computer Engineering Technology program [1] is in a reasonable steady state, RIT is transitioning from a quarter system to a semester system. This transition provides the opportunity to revise the complete course material, the embedded platforms being used, the contents of the laboratory exercises and the overall type of projects and skills the students will acquire. By listening to our industrial partners, and the trends of academia, this opportunity is being taken to bring more meaningful content in terms of hardware computer architectures as well as to incorporate the latest electronic design automation (EDA) software tools and methodologies.

Previously, the ESD sequence had a significant revision in fall of 2008 when an Altera field programmable gate array (FPGA) platform was adopted as the development platform for the sequence of courses. Additional courses in digital design were also modified for a total of six courses using a single hardware platform development system. The change proposed this time is not as drastic as only the ESD courses will switch platforms. Ultimately, the question that we are trying to answer in this paper is: “For ESD courses, is five years a good time gateway to look into industry practices and update the course contents, platforms, skills, and engineering practices?”

In recent years, ESD courses in our program have been centered on FPGAs and soft-core [2] processors. However, to better provide the skills our students must have to join the workforce, a switch to using FPGA and hard-core processors will be implemented and evaluated. In addition, the new curriculum will further be enhanced with the addition of a course in Real Time Operating Systems (RTOS) and additional background in Digital Signal Processing (DSP).

II. BACKGROUND: STATE OF THE CURRENT PROGRAM

The current quarter-based capstone sequence in Embedded Systems Design consists of three 10-week courses taken in the student’s fourth and fifth year [1]. The focus of these courses is to prepare strong students in both digital hardware design and embedded software design. A wide range of topics are covered in these three courses exposing the students to many facets of embedded design. In these intensive hands-on courses, students gain experience with embedded C programming in both a hard-core ARM Cortex M3 [3] and a configurable soft-core Altera NIOS-II processor [4]. Along with programming skills, students develop embedded hardware design proficiency by creating custom intellectual property (IP) cores and hardware acceleration modules for a System on Programmable Chip (SoPC).

The first course, ESD-I, focuses mainly on computer organization [5]. While the labs focus on a SoPC system, a newly introduced series of homework assignments are performed on a rapid prototyping SoC platform with an ARM processor. These programming assignments create an application platform for investigating topics such as LCD control, pulse width modulation, servo motor control, serial communications, and basic cryptography. Embedded hardware development along with hardware/software tradeoffs are the emphasis of ESD-II. In this course students create their own IP cores to be included on the SoPC. One of the advantages of using a soft-core processor in this course is the ease in which hardware can be developed and integrated into the processor for the investigation of hardware/software tradeoff concepts. The deliverable for the final course in the sequence, ESD-III [6, 7], is an innovative open-ended project targeted to a particular market segment or need. Students are given freedom in choosing their team, their project and their development platform. Some projects are developed with

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

industry partners or other academic units within RIT, while others are purely student-driven.

III. Platform Convergence: Industry & Academia

In choosing the best platform and tools to use in our embedded systems sequence, we must consider which skills will be necessary for students to be productive in industry upon graduation. Unfortunately, when it's in a high-tech field knowing what skills they will need can be a moving target. Current industry reports show a trend towards 32-bit processing. 32-bit processors can allow more performance and functionality while maintaining good code efficiency, low cost, and low power consumption. This is evident in the ARM architecture-based processors implemented by a vast number of semiconductor companies. Today, ARM is the most widely used microcontroller architecture in the world. ARM processors can be found in products ranging from smartphones to automobiles to giant neutrino detectors and are especially popular in portable communication devices. ARM powers 90% of the smartphone processing market and has 31% market share in mobile computing. Additionally, ARM has a 60% market share in embedded systems and that is expected to grow to 68% by 2016. Using an ARM based development system will keep students abreast of the most current technology as well as give them a competitive advantage when applying to the myriad of companies using an ARM based processor.

For an ESD course the ideal platform is an FPGA since it is versatile in terms of programmability and re-configurability. However, an FPGA has some drawbacks. Traditionally, FPGA platforms, including the one currently being used in the ESD sequence, have lacked native analog interfaces for communication with external analog interfaces. In recent years, some manufacturers of programmable SoC devices have taken steps to embed analog processing into the platform [8, 9]. The new generation of programmable SoCs, consist of an FPGA platform containing a high performance hard-core processor with one or multiple cores and a large number of digital peripherals. Some platforms now include analog peripherals as well. The two major manufacturers of FPGA devices have announced SoC devices in the current and next generation programmable devices [10, 11].

Given the current state of the industry, it seems logical to evaluate the most up-to-date tools and to offer our students skills on a programmable SoC with ARM architectures, analog interfacing and the capability to design accelerators and coprocessors using a hardware description language (HDL). Evaluation of such development platforms is currently ongoing.

IV. Future Plans: Semester-based Sequence

The conversion from a quarter system to a semester system has provided the catalyst to make improvements to the courses to meet the demands of today's ever-changing technological society. The first change is in the course offerings. Instead of simply converting 3 quarter classes into 2 semester courses, the sequence has been expanded to 3 semester courses. ESD-I, will still focus on computer organization but will include content on performance enhancement and IP core development in an HDL. Concurrent with ESD-I, students will take a course in RTOS. The final course in the sequence, ESD-II, will be a 15 week project-based course

In addition to changes in the curriculum structure, changes are being proposed for the development platform and course content. The soft-core processor development board that is currently being used in ESD-I and ESD-II provides many advantages but is limited in its lack of analog peripherals. Since students will be entering the sequence having already taken a digital signal processing (DSP) class, analog peripherals will broaden the possible content for laboratories and mini-projects. Background experience with analog and DSP will help to make the students more well-rounded embedded designers.

V. Course Outline Proposals

A. Embedded Systems Design 1 (Studio Format)

This course will focus on the architecture and design of embedded systems. Microprocessor, as well as system level design principles will be investigated from both hardware and software perspectives. Fig. 1 below illustrates how parallel activities will be used to comprehend, apply and analyze concepts in peripheral interfacing and industry-standard communications protocols.

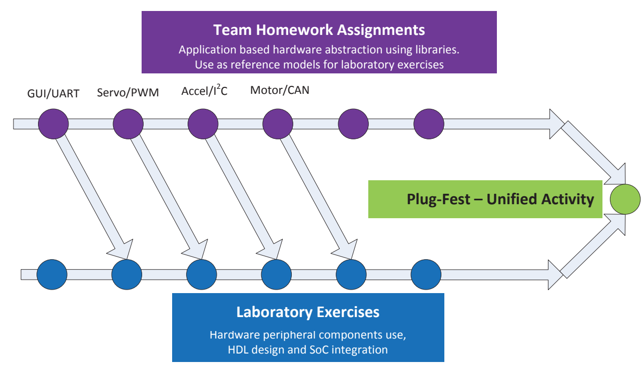

Fig. 1. Sequence of activities to comprehend, apply and analyze the concepts covered in the course.

Both an ARM based rapid prototyping system and the course's FPGA ARM-based development board will be used. Students will first comprehend the concepts by creating applications based on the hardware abstraction, using libraries in the rapid prototyping board. These will be used as a reference as the same applications will be created and analyzed using hardware peripherals; some of which will be written by the students in HDL. A "Plugfest" during which the teams will collaborate to achieve board-to-board communication will be the integrating and culminating experience.

In addition to interfacing, signal datapath algorithmic design will be studied in depth. Hardware/software co-design and partitioning will be investigated and HDL will be used to create hardware accelerators. Upon successful completion of the course, students will be able to design and debug hardware and software systems, evaluate design trade-offs and choose the best design solution, and perform functional and timing analysis of an embedded system.

B. Real Time Operating Systems (Studio Format)

According to the 2013 Embedded Market Survey, 72% of current embedded projects use an operating system, an RTOS, a kernel or a scheduler. With this in mind, we felt it was crucial to add a course in RTOS to our embedded systems curriculum. The RTOS course, currently being developed, will provide students with an introduction to operating systems (OS) theory and practical problem solving approaches to real-time systems. An embedded RTOS will be used as the foundation for a variety of programming projects. To avoid long pre-requisite chains in the curriculum, this course will not be a prerequisite for the ESD I or II courses. Students on schedule will complete the course prior to taking ESD-II and thus will have the option of including an RTOS in their capstone project.

One of the challenges in designing this course from the ground up is the plethora of available textbooks, embedded platforms, and RTOS providers. While the first half of the course will be focused on OS in general, the second half will focus on a specific RTOS and a development platform will be necessary. We are currently soliciting recommendations from our industry advisory board as well as from companies that are willing to support the course with hardware, software, and teaching material. A similar course offered in the College of Engineering will be reviewed for the purpose of leveraging on their experience, but our course must be developed as a hands-on experience as required by engineering technology standards.

C. Embedded Systems Design 2 (Capstone)

This project based course will be an enhanced version of the current quarter-based ESD-III course [1]. The fifteen-week project will represent a culmination of the Computer Engineering Technology curriculum and will include product ideation, Agile and traditional project/resource management techniques and best practices, system level specification, modeling, partition and design, team collaboration and communication, best documentation practices, industry level coding practices, hardware and software co-design methodologies, design reuse and IP creation, design verification and validation, and design sign-off. Students, will have an industry-like embedded system product design experience, starting by developing the vision for a product, including the voice of the customer, and progressing through the phases to develop a complete product prototype. In addition, the students will track and present their progress, make use of version control systems, participate in design and code reviews, demonstrate their product and highlight product differentiation. At the end of the course students will give a formal presentation, product demonstration, deliver professional documentation, review lessons learned and suggest future improvements.

Given that students will have already acquired the knowledge on embedded system design, lecture topics will include project management, team collaboration and best design practices. This course will concentrate on the capstone experience to emulate a real industrial environment and ideation of a novel product from vision through prototyping and demonstration. Students will be free to choose design platform as well as development languages.

VI. CONCLUSIONS

As an opportunity to revise and revamp the curriculum in Embedded System Design the present work in progress present some of the changes proposed to a series of three courses by identifying opportunities where the sequence can be improved and modernized. Trends in industry and technology have resulted in the need to converge to common processor architecture while at the same the main FPGA manufacturers have also come together with a unique solution to the above industry trend. These changes come as a reflection of the last major revision five years ago where a drastic modification was done to these courses and the curriculum in general. If the courses are heavily dependent on training and developing skills for students to join industry, then it is prudent to establish a framework to update highly technological reliant courses every four to five years.

While at this moment it is difficult to propose a single platform, it is intended to explore different FPGA platforms and to come with the best trade-off between the intended learning outcomes and the platform used. The RTOS course could leverage on this decision or it can be set as a standalone course covering the principles using a hard-core processor platform and an embedded RTOS.

It is planned to present the results of the decisions presented here backed up by statistical data, student and industry surveys, as well as by a retrospective of the faculty involved in this work in progress.

***Abstract*—A step-based tutoring system for linear circuit analysis is being developed with the capabilities to automatically generate circuit problems with specified characteristics, including randomly generated topologies and element values. The system further generates fully-worked, error-free solutions using the methods typically taught in such classes, and accepts a rich variety of student input such as equations, matrix equations, numerical and multiple-choice answers, re-drawn circuit diagrams, and sketches of waveforms. A randomized, controlled study was conducted using paid student volunteers to compare the effectiveness of two of our tutorials in comparison to working conventional textbook-based problems. The average learning gain was only 3/100 points for the textbook users, but 29/100 points, about 10 times higher, for the tutorial users. The effect size on the post-test scores was 1.21 pooled standard deviations (Cohen *d*-value) and was statistically significant. A motivational survey administered to these students yielded a 0.53 point higher rating for the software than for the textbook (on a 1-5 scale). The system is being used in Spring 2013 by over 340 students in EEE 202 at Arizona State and two community colleges. About 99% of these students rated the system as "very helpful" or "somewhat helpful."**

Keywords—linear circuit analysis; computer-aided instruction; step-based tutoring

I. Introduction

Linear circuit analysis is a foundational topic for electrical engineers, but is also widely studied by other engineering majors. For example, this course is taught to over 600 students a year at ASU in 11 sections, about 90% of whom are non-majors. Students frequently struggle with this material, due to such factors as delayed or inaccurate feedback on their homework, inadequate use of active and cooperative learning strategies, an insufficient (from the student's perspective) supply of worked examples of carefully graded difficulty, and failure on the part of instructors to recognize persistent misconceptions about basic electricity that students frequently bring into these classes [1-3]. Traditional lecture-based instruction offers only a single pace to all students, regardless of prior knowledge and ability, and inevitably leaves some students bored and others unable to keep up. One method to address these issues is to supplement conventional approaches with computer-aided instruction, which has been employed in a number of prior studies [4-35]. While useful, many of these studies have developed only incomplete or partial prototypes, or have not carried out rigorous evaluations to determine their effectiveness in increasing student learning. There has been little sustained, widespread usage of previously developed systems, and most have not had the ability to generate new circuit problems, which can be a tedious and error-prone task when done by hand.

Publisher-based web sites as supplements to textbooks have been more widely used in recent years. Whereas these sites provide additional resources to students and can be used to automate grading, they mainly provide algorithmic problems, in which some of the element values are varied in a given problem. They are typically answer-based tutors, which provide rapid feedback on the correctness of an answer, but do not accept a sufficient amount or variety of student input to diagnose the reason for a wrong answer (they lack sufficient "bandwidth" in the language of intelligent tutoring systems). A recent meta-analysis by VanLehn concludes that the typical effect size (Cohen's *d*-value) of answer-based tutoring systems is around 0.31, compared to 0.76 for step-based tutors and 0.79 for expert (expensive) human tutors [36]. Thus, we have undertaken to develop a potentially more effective step-based system that can do a better job of analyzing a wide variety of student inputs [37, 38]. Further, we automate the process of generating problems and solutions, eliminating both human error that can result in great frustration to students and the temptation to misuse solution manuals that are widely available on the Internet. This type of system can provide rapid, accurate feedback and an unlimited supply of problems, examples, and solutions of any desired difficulty and complexity.

II. Software design and features

A. Circuit Generation

The algorithms we use to generate circuit problems and solutions have been described elsewhere in detail [37, 38]. We generate circuit layouts rather than netlists to ensure that our circuits are planar so that mesh analysis can be applied. Briefly,

This work was supported by the National Science Foundation through the Transforming Undergraduate Education in Science, Technology, Engineering and Mathematics Program under Grant No. DUE-1044497.

the circuit generation process involves a series of three steps, to avoid the prohibitive combinatorial issues involved in trying to place circuit elements in a purely random way. We first generate a “topology” with the desired number of meshes, consisting of only shorts or opens placed on a square grid with the desired number of rows and columns. The generation algorithm ensures that it is fully connected and has no “dangling” shorts. It is checked to ensure that it is not “hinged” (i.e., it cannot be drawn so that two parts of the circuit are connected by only a single wire, and therefore constitutes effectively separate circuit problems). In the second step, the desired number of shorts are replaced by generic circuit elements, leaving the others as shorts and leaving all opens permanently as opens. In doing so we place at least two elements on every mesh including the “outer” mesh around the circuit periphery, to ensure that no element is shorted and that there are no meshes of shorts (which would reduce the true number of meshes below the desired value). We then check that this “populated topology” has not become hinged as a result of element placement (which includes shorted elements. If the result is not acceptable, the process is restarted.

In the third step, the generic elements are replaced with actual circuit elements of the desired types. To avoid insoluble (inconsistent) problems, we first find all or many trees of the populated topology. Voltage sources and inductors are placed exclusively on the twigs of a randomly selected tree, and current sources and capacitors are placed exclusively on the links of that tree, thereby avoiding insoluble problems involving loops of only voltage sources or stars consisting only of current sources (resistors can be placed anywhere). The placement algorithm also allows us to limit the number of voltage sources in series and the number of current sources in parallel, and can optionally prohibit passive elements of the same type in series or parallel with each other. Further, it optionally avoids creating problems where a given circuit element is “redundant” and has no significant impact on the rest of the circuit (such as any element in series with a current source or in parallel with a voltage source). The algorithm also has the ability to create a desired (feasible) number of floating supernodes (i.e., supernodes that do not include the reference node), through a combination of source repositioning and/or choice of specific reference nodes. Circuits can also be automatically selected having a desired number of supermeshes. The user also has the option to reject circuits whose node voltages are all controlled directly by voltage sources, or whose mesh currents are controlled directly by current sources, since such problems are relatively trivial to solve. Control variables for dependent sources are randomly selected in accordance with rules described elsewhere [37]. Element values including dependent source gains are then randomly generated within specified ranges, and the circuit is checked and modified as necessary to ensure that it is soluble.

To specify the type of circuit to be generated, the user specifies the number of squares in the grid in both x and y-directions, the number of nodes, the number of meshes, and the number of each type of circuit element to be used. However, any one of the last three quantities is determined by the other two, so that the user has the choice of which two to specify [37].

Once a circuit has been generated, the program randomly selects a user-specified number and type of “sought quantities,” or values of unknowns for which the student is asked to solve. These may be branch voltages, branch currents, non-branch voltages (i.e., voltages that do not appear directly across any one circuit element), or branch powers. We avoid specifying quantities that are trivial to determine (such as a branch current for an element in series with an independent current source). Alternatively, the student can be required to solve for all node voltages or all mesh currents.

B. Solution Generation

The system currently generates and displays complete sets of node or mesh equations and solves them using matrix methods. Equations are automatically adjusted based on a user-selected choice of reference node. There is an optional “pre-simplification” step prior to this solution, in which independent voltage sources in series and independent current sources in parallel are combined into single sources of each type, and in which any passive elements of the same type that are in series or parallel with each other are combined. The circuit diagram can be automatically re-drawn after each such simplification step to illustrate the process to the student. Work is currently in progress to implement a number of other common solution methods, such as use of voltage and current division, superposition, source transformation, and use of Thévenin or Norton equivalent circuits. We also plan to extend the system from its current coverage of DC resistive circuits to cover steady-state AC phasor analysis and transients using both differential equation and Laplace transform approaches. A sample automatically-generated circuit and its solution by mesh analysis are shown in Fig. 1.

C. User Input Modules

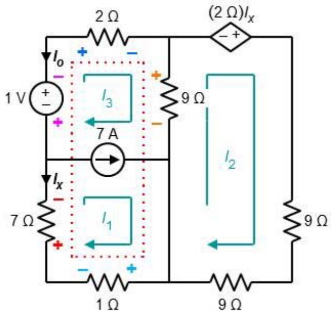
Students input node or mesh equations using a specially designed template interface as shown in Fig. 2, in which they are offered a palette of properly formed terms from which to choose [depending on the type of equation, such as a voltage constraint equation, Kirchoff’s current law (KCL) equation, dependent source control variable equation, etc.]. They can drag these terms into the equation area as needed, and easily reposition or delete them. In Fig. 2, for example, the user has dragged the various terms needed for a KVL equation for mesh 3 from the upper palette into the equation entry area below, and is about to check the equation for correctness. Once the user selects the appropriate templates, they complete each term by filling in the numerical values and subscripts. Students appear to find this interface to be highly intuitive and easily adapt to using it with little or no instruction. The program then indicates immediately if the equation is correct, and optionally displays the correct solution if it was not. In the latter case, the student then has to work an additional problem of the same type to proceed.

Simplified forms of the algebraic equations are entered on a special form designed for that purpose, as is the matrix form of the equations. They are provided with feedback at each stage, so they do not waste time and become frustrated by proceeding to the next stage when they have already made a mistake (as

Circuit Diagram with Mesh Analysis

Compute the following 2 quantities for this circuit:

V_o; I_o



Each colored +/– symbol pair corresponds to a term in KVL equation #1 of 2.

Current constraint equations:

$I_1 - I_3 = 7$ A

KVL equations for each mesh or supermesh:

$I_1(7\ \Omega) - 1\ \text{V} + I_3(2\ \Omega) + (I_3 - I_2)(9\ \Omega) + I_1(1\ \Omega) = 0$

$(I_2 - I_3)(9\ \Omega) - (2\ \Omega)I_x + I_2(9\ \Omega) + I_2(9\ \Omega) = 0$

Equations for control variables of dependent sources:

$I_x = -I_1$

Matrix form of mesh equations:

I_1	I_2	I_3	I_x			
1.000	0.000	-1.000	0.000	I_1		7.000
8.000	-9.000	11.000	0.000	I_2	=	1.000
0.000	27.000	-9.000	-2.000	I_3		0.000
1.000	0.000	0.000	1.000	I_x		0.000

Solution:

$V_o = 3.42$ V; $I_o = 3.58$ A

$V_1 = 3.42$ V; $V_2 = -9.60$ V; $V_3 = -23.9$ V; $V_4 = -22.6$ V; $V_5 = -22.9$ V; $V_6 = -15.8$ V;

$I_x = -3.42$ A

$I_1 = 3.42$ A; $I_2 = -1.45$ A; $I_3 = -3.58$ A; $I_x = -3.42$ A

Fig. 1. Example of an automatically generated problem and solution using mesh analysis.

they would do in typical answer-based tutors). Numerical answers are accepted in a tabular format, and multiple choice responses can also be processed.

Some types of circuit solution (such as superposition, or simplification by combining elements) require students to re-draw the given circuit diagram prior to writing any equations. We have therefore constructed a graphical circuit editor function in which students can modify a given circuit in any required way (or even create a new circuit from scratch). By checking if this step has been completed correctly, we will again be able to avoid letting the student waste time by writing equations for an incorrect diagram.

We are also currently constructing a web-based graphical waveform sketching tool that students can use to draw waveforms as a function of time. This module will be useful when students are given the current through a capacitor and asked to sketch its charge or voltage as a function of time, for example (or similar problems involving inductors). The tool is similar to a vector graphics drawing tool, but will include various scientific functions such as exponentials, sinusoids, piecewise linear functions, and so on. The student input will be checked automatically against a correct solution, without requiring that problems be of a multiple choice format.

Some problems of a more qualitative nature are also being developed, to help dispel typical student misconceptions. An example is one in which a circuit diagram is displayed and students are asked to input lists of which elements are in series or in parallel in the circuit (or which form wye or delta connections). Students typically have difficulty in doing this at first, particularly for the parallel case, which can lead to many other errors in quantitative analyses.

D. Pedagogical Features

We have included a number of items to help students understand and visualize the methods by which circuits can be analyzed. For example, different nodes can optionally be color coded, to help visualize the nodes. The circuit elements can even be temporarily blanked out, leaving only the wires, to help students understand the definition of nodes. We also illustrate sets of elements in series or parallel (or forming wye or delta connections) by selectively highlighting each set in red in turn. Nodes and mesh currents can be automatically labeled and numbered. There are also features to help students understand the origin of node or mesh equations. For example, the currents leaving a selected node or supernode can be automatically labeled with color-coded arrows, in which case the terms of the KCL equation are correspondingly color-coded to match. Similarly, the path around which a KVL equation is written for a supermesh can be labeled automatically, and voltage drops around any selected mesh or supermesh can be labeled with color-coded +/– signs, with corresponding color-coding of the terms in the KVL equation. In Fig. 1, for example, the first KVL equation is the one that has been selected for highlighting, so the supermesh path and +/− signs appear around meshes 1 and 3, which form a supermesh. (In this view, the unknown voltage V_o is not shown.)

E. Tutorial Modules

To date we have implemented three software tutorial sequences on the topics of identifying elements in series and

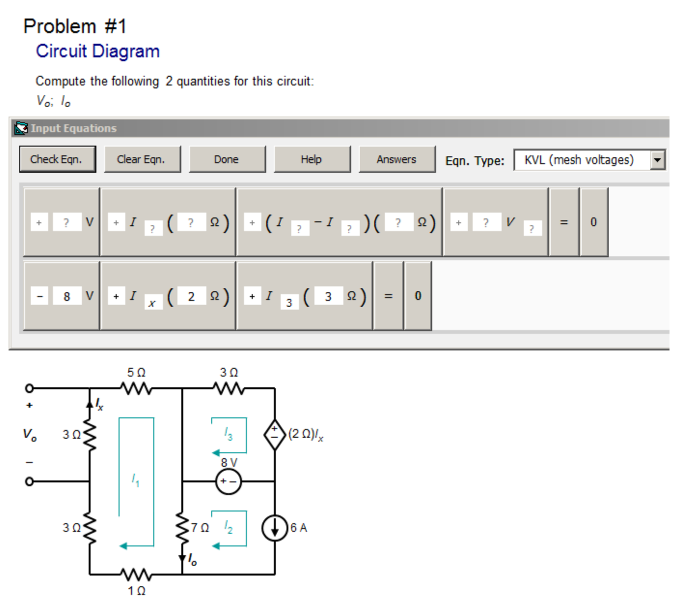


Fig. 2. Equation entry interface.

parallel and on writing node and mesh equations. The series/parallel tutorial includes a sequences of illustrations and examples with associated interactive questions, followed by the option to view examples and complete exercises at four different levels of difficulty. The node and mesh equation tutorials present a brief set of instructions, followed by the opportunity to view worked examples and do exercises at five different levels. Student activity in each tutorial is logged to a server to record their progress, allowing them to stop or re-start at any time. The results can be viewed and downloaded by the instructor. Students are required to complete the highest level of difficulty in each tutorial before receiving full credit. At the completion of each tutorial, a one-question survey is administered and the student can enter comments to provide feedback.

We are also developing scripts for future tutorial sequences, which will be implemented later in software using a planned tutorial scripting and execution interface. A total of 14 scripts have been generated to date, including 5 on node analysis, 5 on mesh analysis, and 4 on basic electrical concepts such as current, voltage, power, KCL, KVL, etc. The scripts outline sequences of instructional material together with interactive questions and exercises that will be posed to the students.

III. LABORATORY-BASED STUDY

To test the effectiveness of our software in improving student learning, a laboratory-based study was conducted in December 2012 using 33 paid student volunteers, all of whom were either enrolled in the relevant course (EEE 202) or had completed it within the last year. Students were given a pre-test and a post-test using two different test forms that were randomly assigned and similar in difficulty. The two topics were identification of series and parallel circuit elements and writing node equations for DC resistive circuits. The students were randomly assigned either to use two of the corresponding software tutorials for a total of one hour (for 25 min. and 35 min., respectively), or to work on similar textbook problems, as they would normally do in the course. All students were given a copy of the course textbook [39] and advised that they could consult any relevant material in it as needed. After completing the post-test, both groups of students were asked to complete the Instructional Materials Motivation Survey (IMMS) developed by Keller to assess the effects of the different instructional approaches on student motivation [40].

The pre-test and post-test data for both groups are summarized in Table I. Both groups had very similar pre-test scores (averages of 59% and 58%), as would be expected from the randomized experimental design. The textbook users had only a small average increase in average score up to 62%, about 3 points higher. The software users saw an approximately 10× larger improvement, to an average of 86% on the post-test. The effect size (Cohen *d*-value) of the experimental condition on the post-test scores was found to be 1.21 in units of the pooled standard deviation of those scores. The difference was statistically significant assuming independent samples (but not equal variances, as they are substantially different) at the 95% confidence interval, $t(19.7) = 3.303$, $p < 0.05$. We therefore conclude that the tutorials are much more effective than conventional homework assignments

TABLE I. LEARNING GAINS IN LABORATORY STUDY

	Exptl. Group	Pre-Test Score	Post-Test Score	Gain
Average	Textbook*	58.6	61.6	2.9
Median	Textbook	60.5	67.0	1.5
Std. Dev.	Textbook	25.3	28.0	14.1
Average	Software**	57.8	86.4	28.6
Median	Software	57.0	85.0	30.0
Std. Dev.	Software	22.1	11.5	14.9
Std. Dev.	Pooled	23.0	20.5	14.1

*16 users. **17 users.

in terms of immediate learning gains. We attribute the difference to the step-based nature of the tutoring process, the rapid feedback provided to the student, their ability to practice or view examples as many times as needed (within the available study time), and the pedagogical features that help them learn to understand the formation and structure of the equations.

The results were better for both the qualitative (series-parallel identification) and quantitative (node equation) topic, suggesting that this approach may be effective for a wide variety of course topics when fully developed. The mean post-test scores for the series-parallel identification were 68% and 91% for textbook and computer users, respectively, and were 57% and 83% for the node equation topic for the two corresponding groups. In particular, the easier node analysis problem (having only independent current sources and resistors, with four nodes) on the post-test yielded a remarkable average score of 98% for the computer users (and only 70% for textbook users), suggesting near-perfect mastery of that level of the topic after only 35 minutes of automated instruction. It is unlikely that most students were able to complete the tutorials during the allotted time, so results on more difficult problems could be even better given more time.

The results of the IMMS are shown in Table II. Overall scores were determined (where 1=least favorable and 5=most favorable response) as well as scores on four subscales corresponding to the attention-relevance-confidence-satisfaction (ARCS) factors proposed by Keller to model the effects of instructional materials on student motivation [40]. The mean score was higher for the software on every scale, though the difference was statistically significant only for the total scores and attention and satisfaction subscales. The relevance factor showed the least difference, which makes sense as both the textbook and tutorials addressed the same topics and the students seem to be making appropriate connections between the practice problems and real-world engineering applications in both cases. The degree to which the software engaged students' attention and especially their overall satisfaction were the biggest differences (the latter being nearly a full point higher for the software users, with a large effect size of 1.27 pooled standard deviations). We believe that it was the ability to repeat exercises and examples without limitation for practice, and the rapid feedback provided on student errors, that led to the higher satisfaction rating. The Cronbach alpha coefficients we measured for the total score,

TABLE II. RESULTS OF INSTRUCTIONAL MATERIALS MOTIVATION SURVEY (SCALE = 1-5, 5=BEST)

Group	Statistic	Total	Attention	Relevance	Confidence	Satisfaction
Software Users	Means	3.54	3.44	3.22	3.94	3.62
	Std. Dev.	0.40	0.49	0.60	0.52	0.66
	Medians	3.57	3.54	3.11	3.83	3.75
Textbook Users	Means	3.01	2.84	2.99	3.51	2.65
	Std. Dev.	0.77	0.80	0.83	0.99	0.91
	Medians	3.01	2.88	3.00	3.72	2.33
Comparisons	Diff. of Means	0.53*	0.60*	0.23	0.44	0.97*
	Pooled Std. Dev.	0.58	0.64	0.70	0.75	0.76
	Cohen *d*-value	0.91*	0.94*	0.33	0.58	1.27*

*Statistically significant difference with $p < 0.05$.

attention, relevance, confidence, and satisfaction scales were 0.932, 0.851, 0.756, 0.855, and 0.838, suggesting good reliability and consistency of the survey instrument, though it is marginal on the relevance scale.

IV. CLASSROOM TRIALS

Preliminary trials were conducted on a voluntary basis in Summer 2012 and Fall 2012 in our course EEE 202, but sample sizes (in either the control group or the experimental group, depending on the class section) were not large enough to make statistically significant evaluations of the effects of the software (though favorable effects were suggested by the data). A much larger trial with strongly encouraged or mandatory participation is being conducted in Spring 2013 with over 340 students in five sections with five different instructors. Assessment of the impact of the software on student learning is in progress, but of course it is challenging to isolate the effects from variations in instruction and students from semester to semester. However, student satisfaction with the tutorials appears to be quite high. At the completion of each tutorial, students were asked to rate the tutorial as "very helpful," "somewhat helpful," "not very helpful," or "a waste of time," and were given the opportunity to enter comments. About 98.5% of students gave favorable ratings of "very helpful" or "somewhat helpful," and 74% rated them as "very helpful." Some sample student comments (verbatim) are shown in Table III. Most negative comments (relatively uncommon) asked for better instructions on the user interface (which we will add), or complained about platform compatibility, as the program currently runs only on Windows with Microsoft PowerPoint installed. A future web-based version is planned to address that issue. Some students requested more detailed feedback on their errors, which could be added in a later version.

TABLE III. SAMPLE STUDENT COMMENTS ON TUTORIALS

Good job on the game! It was actually fun going through it and trying to do a good job! Thanks for making this.
Worked as intended, didn't take too long, kind of fun, and I feel like it helped!
I HAVEN'T EVEN LEARNED IT YET BUT IT WAS REALLY EASY TO GRASP USING THIS! YAY
I really thought it was awesome; it was very helpful. I understood the concepts, but this helped me develop a thought process on it.
I like how you are not marked off for getting on wrong, you just get to try again. You only really fail if you give up, and that is reassuring.
These modules honestly do help me learn circuit analysis. I feel that it is extremely helpful to have a good amount of practice problems, and a system that provides instant feedback. This helps me learn the correct techniques and master
I AM A PRO AT THIS. Major self-confidence booster. Really though, I feel like I'm talented at this node analysis!
It definitely helped me understand supernodes, I think this was more usefull than book work
This exercise helped me understand loop analysis very well. The assignment was great.
I would prefer to have a statistics page showing # of correct and incorrect attempts and possibly even a ladder [leader?] board showing how well different students did as opposed to everyone getting a congratulatory gold medal for doing thier hw
Wow is all i can say... This is the best, better than any hw I have done so far

Some limitations are that the topical coverage is not yet large enough to have a major impact on the overall class (though additional development is in progress), and retention of material from the time of the tutorial completion until the time of exams may be an issue. Refinement of the tutorial to require regular "refresher" exercises is planned to try to address retention. The DIRECT concept inventory [1] is being used as a pre- and post-test, but post-test results for Spring 2013 are not yet available. Additional analysis of the effect on student grades is planned, as is additional usage in future semesters. Ultimately we hope to assess if the students can transfer the knowledge gained using this software to work in subsequent courses and to real-world engineering applications.

V. CONCLUSIONS

Our progress in developing a system to automate the generation of problems and solutions for linear circuit analysis has been described, as well as initial incorporation of these modules into a tutorial system that can be used for homework assignments in this type of course. The rapid feedback characteristic of a step-based tutor, pedagogical features, and unlimited practice opportunities appear to be very popular with students and increase learning in laboratory-based trials compared to conventional textbook exercises by a factor of about 10. Additional work is needed to expand the scope of material covered by the system, and to refine the user interface and platform compatibility. The modular system is designed to be very flexible, so that it could be used, for example, to generate homework problems and solution manuals for a conventional textbook, to automate the generation and grading of individually customized homework assignments, to generate problems for examinations and quizzes, and to create problems for interactive in-class exercises. The overall approach of this system may be extendable to a number of other domains in engineering education as well where students must solve problems of well-defined types, such as logic circuit design, statics, and so forth.

ACKNOWLEDGMENTS

We thank Daniel Sayre of John Wiley & Sons, Inc. for providing the textbook copies used in our laboratory study and for his support. We thank Professors R. Gorur, G. Karady, B. Matar, C. Tepedelenlioglu, T. Thornton, Chao Wang, Hongbin Yu, and Hongyu Yu for using our software in their EEE 202 sections and for their interest in this project. We also thank P. Selveraj and S. Ramalingam for their assistance.

First-Year Students' Understanding of Direct User in Open-Ended Problem Solving Activities

Farshid Marbouti, Heidi A. Diefes-Dux
School of Engineering Education
Purdue University
West Lafayette, IN
{fmarbout, hdiefes}@purdue.edu

***Abstract*— This paper presents an investigation into First-Year Engineering (FYE) students' ability to identify the direct user in open-ended client-driven problem solving activities. To guide FYE students in formulating an open-ended problem, students are asked a series of questions about the stakeholders, the direct user of the solution, and its needs. The purpose of these questions is to help students think about the problem individually by listing stakeholders including the direct user and the stakeholders' relationships to the problem and its solution prior starting to solve the problem in teams. One hundred (out of ~1600) students' responses to three open-ended problem solving activities during two successive semesters were randomly selected and analyzed. Results showed improvement in students' ability to identify the direct user over time. The majority of students' responses shifted from identifying non-users instead of direct user in the first MEA, to identifying indirect-users in the second MEA, and to identifying direct user correctly in the third MEA. This shows a clear improvement in students' ability to understand these problems over time. However, even for the third MEA, only 60% of students identified the direct user correctly, raising concerns about comprehension of the problem by about 40% of the students.**

Keywords — first-year engineering; open-ended problem solving; model-eliciting activities; direct user

I. INTRODUCTION

In two required First-Year Engineering (FYE) courses at Purdue University, students are engaged in open-ended problem solving activities referred to as Model-Eliciting Activities (MEAs). MEAs were originally created for research in mathematics education [1]. MEAs are realistic problems, lead to generalizable solutions, and require students to engage in mathematical modeling, self-assessment to improve their solutions, and document generation to communicate their solutions [1]. These principles are used to design MEAs for the FYE program at Purdue University [2]. In the FYE program, MEAs are completed by student teams through an iterative solution process. The completion of MEAs requires communication, team working, critical thinking skills, and problem formulation.

Problem formulation is a primary and an essential step in solving open-ended problems such as MEAs [3] and design problems [4]. One of the goals of problem formulation is to develop effective problem solving strategies [5]. Some scholars (e.g., Voss & Post [6]) believe problem formulation can affect the success or failure of the entire problem solving process. Because of its importance, problem formulation has been studied in the context of open-ended problem solving, especially design problems.

Studying the differences between expert and novice designers using a novice-expert conceptual framework [7] reveals that experts spend significantly more time on problem formulation compared to novices [4, 8, 9]. Beginner designers tend to skip this step and try to solve the problem and generate solutions immediately [10]. Compared to beginner designers, informed designers tend to do research about the problem and the users [11] leading to a better understanding of the problem [12] and consequently a better problem formulation and higher quality solutions. Since beginner designers are used to solving problems with one best answer [10], they apply the same methods to solve a design problem. They tend to solve the design problem without any research about the problem or looking for any additional information [4, 13]. Asking students explicit questions about the users of the problem solution and their relationship to the problem and reporting their results as a preliminary step, before solving the problem, can help students gather related information and achieve a better understanding of the problem [3, 4].

In the context of MEAs, similar to design problems, doing research about the problem and its users may help students to understand and formulate the problem. In the FYE MEAs, the primary step is a careful reading and mental sorting and processing of the problem text. Identifying the user of the problem solution and obtaining additional information can help problem solvers achieve a better understanding of the problem, its relationship with stakeholders, and find a solution [4]. Research studies (e.g., [3, 4]) identify problem formulation and acquiring relevant information as an important step in solving open-ended problems such as MEAs. Solving a MEA under specific constraints, within a context, and to meet clients' needs requires understanding of problem complexity and having background knowledge about or experience relevant to the problem [3].

Similar to beginner designers, first-year engineering students tend to skip problem formulation and acquiring

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

information, and attempt to solve the problem immediately as a problem with one best solution. Some scholars (e.g., Salim & Diefes-Dux [3] and Crismond & Adams [4]) suggest asking students explicit questions about users as a teaching strategy to guide students in problem formulation and information gathering activities.

To guide FYE students to formulate the problem and acquire necessary information to solve a MEA, students are individually asked to answer a few questions before solving the problem in teams. The questions include the following:

- List stakeholders who may be impacted by your deliverable and explain the relationship between the stakeholder, the problem, and the deliverable.
- Consider list of stakeholders. Who is the direct user of the deliverable?
- What does the direct user need? (Remember to describe the deliverable, its function, the criteria for success, and constrains.)

The purpose of these questions is to help students think about the problem individually by listing stakeholders, including the direct user, and their stake in the problem or solution before starting to solve the problem in teams. The direct user is an individual or team (typically inside the client company) who will use the students' solution. By answering the first question, students should think about all related stakeholders and the impact the deliverable will have on them. This listing of stakeholders prior to answering the question of "who is the direct user?" was added to the set of problem formulation questions in Fall 2011 when in prior semesters it was found that students struggled to answer the direct user question. The aim of the second question is to identify the person(s) that would use the product. The purpose of the third question is to enable students to describe the problem in some details including the deliverable, its function, and the constraints.

Although answering all three questions is important for students' understanding of the problem, identifying the direct user is a primary and important step in solving the problem. If students are not able to identify who uses their solution (the direct user), it is less likely that they know what the direct user needs and will not be able to develop a high quality solution. Therefore, in this study we focus on students' understanding of the direct user.

II. Research Questions

This paper investigates first-year engineering students' understanding of the direct user in MEAs by answering the following research questions:

- Who do first-year engineering students identify as the direct user in open-ended problem solving activities?
- Does students' ability to identify the direct user change over time (with solving multiple MEAs)?

III. Methods

A. Participants/Settings

In Fall 2011 in a required FYE course with about 1700 students one MEA, the *Travel Mode Choice* MEA was implemented. In Spring 2012, in the consecutive required FYE course with about 1600 students, two MEAs, the *Just-in-Time Manufacturing* MEA and the *Shredded Document* MEA, were implemented. Prior to starting the *Travel Mode Choice* MEA, students received classroom instruction on how to answer these questions for a sample MEA. From students who enrolled in both courses and participated in all three MEAs, 100 students were randomly selected. The selected students' responses to the questions of "who is the direct user?" in the three MEAs were extracted and analyzed for this study. The followings are brief descriptions of each MEA.

1) Travel Mode Choice MEA

The *Travel Model Choice* (*TMC*) MEA [14] was the only MEA implemented in Fall 2011 and the first MEA that students participated in. This MEA is about student transportation to University of Central Florida's (UCF) campus. A consultant company, E3 Trans Consultants, has been hired by the Department of Physical Facilities Management of UCF (indirect user) to develop the next campus master plan. FYE students are asked to help the planners group within the consultant company (the direct user) by developing a model to predict UCF students' travel mode choice. See Appendix A for the E3 Trans Consultant executive director's (indirect user) memo to students.

2) Just-in-Time Manufacturing MEA

The *Just-in-Time Manufacturing* (*JITM*) MEA [15] was the first MEA in Spring 2012 and the second MEA for the FYE students in the 2011-12 cohorts. This MEA provides students with potential shipping companies that can be used by the client company, D. Dalton Technologies (DDT), to deliver product between two subsidiaries (Ceramica to Bowman) in a Just-in-Time fashion. Data consist of a record of the shipment delays for each shipping company. CEO of DDT (indirect user) asks students to develop a procedure to rank the shipping companies using this data. This procedure will be used by the DDT logistics manager (direct user) to rank potential shipping companies. The data sets provided to the students are not normally distributed, encouraging close examination of the distribution of data in addition to central tendency and variance to solve the problem [16]. See Appendix B for DDT company CEO memo to the students.

3) Shredded Document MEA

The *Shredded Document* (*Shred*) MEA [14] was the second MEA implemented in Spring 2012, and the third and last MEA for FYE students. In this MEA, Federal Security Services (FSS) is a freelance security consulting firm with numerous governmental contracts including high profile cases. FSS needs to develop software to recover the documents that have been shredded. The evidence document manager (indirect user) of FSS asks students to develop an algorithm to help the software development team (direct user) by developing an algorithm to be used in the software.

See Appendix C for the FSS Company evidence document manager memo to the students.

B. Data Analysis

Following a coding scheme developed by Salim and Diefes-Dux [3], students' responses to the question of "who is the direct user?" for all three MEAs were coded. The coding scheme includes the following codes:

- Direct user: who will use the deliverable.
- Indirect user(s): who may need to understand, evaluate, or use the deliverable indirectly.
- Non-user(s): who will not use the deliverable or unknown responses.
- Mix: any combination of the previous codes.

IV. RESULTS

A. Travel Mode Choice

The *TMC* MEA was the only MEA in the Fall semester and the first MEA students were exposed to. In this MEA, in answering the question of "who is the direct user?", about two-third of students identified non-users or unknown entities instead of the direct user (Table I). Less than one-third of the students correctly identified the direct user. A few of the students identified indirect users or reported more than one entity. Table I shows the number of students' responses in each code category for the *TMC* MEA and a sample response for each category.

B. Just-in-Time Manufacturing MEA

The *JITM* MEA was the first MEA in the Spring semester, and the second one that students participated in. In this MEA, more than two-third of the students identified indirect users instead of direct users (Table II). In this MEA, and similarly to the first MEA, less than one-third of the students correctly identified the direct user. A few of the students identified non-users instead of the direct user. Table II shows the number of students' responses in each code category for the *JITM* MEA and a sample response for each category.

C. Shredded Document MEA

The *Shred* MEA was the second MEA in the spring semester, and the third (and last) one that students participated in. Unlike the two previous MEAs, in answering this MEA, about two-third of the students identified the direct user correctly (Table III). However, about one-third of the students identified indirect users. A few of the students identified non-users instead of the direct user. Table III shows the number of students' responses in each code category for *Shred* MEA and a sample response for each category.

TABLE I. NUMBER OF STUDENTS' RESPONSES AND A SAMPLE RESPONSE FOR EACH CLIENT TYPE FOR *TMC* MEA.

Client Type	Description	Sample Response	Number of Responses
Direct User	Planners group at E3 Trans Consultants	"The direct user is Planners Group. They are a division of E3 Trans consultants".	27
Indirect Users	Departmenr of physical facilities and its manager, E3 Trans Consultants and its executive director	"University of Central Flori[d]a's Department of Physical Facilities they will take our predictions into account to improve the transportation services on campus".	7
Non-Users	Any entities not listed above including but not limited to students, faculty, UCF (in general), bus company, and its staff	"The direct user of the deliverable will be the students and faculty at University of Central Florida that use the bus system everyday to get around campus faster and more efficiently".	65
Mix	Any combination of direct, in-dierct and/or non users	"1.Planner Groups 2.other universities campuses 3.federal, state and local government"	1
Total			100

TABLE II. NUMBER OF STUDENTS' RESPONSES AND A SAMPLE RESPONSE FOR EACH CLIENT TYPE FOR *JITM* MEA.

Client Type	Description	Sample Response	Number of Responses
Direct User	DDT logistics manager	"The Logistics Manager of DDT will be the direct user of our procedure as it is his job to choose a shipping company using the deliverable".	24
Indirect Users	DDT company including Ceramica and Bowman, DDT CEO	"Devon Dalton, CEO of DDT (D. Dalton Technologies), is the direct user".	69
Non-Users	Any entities not listed above including but not limited to manufacturer, shipping companies, and customers of DDT	"The direct user is the manufacturer because they are the ones who will control the time it takes to produce and ship the products to the costumers."	4
Mix	Any combination of direct, in-dierct and/or non users	"DDT, cust[o]mers, shipping company"	3
Total			100

TABLE III. NUMBER OF STUDENTS' RESPONSES AND A SAMPLE RESPONSE FOR EACH CILENT TYPE FOR *SHRED* MEA.

Client Type	Description	Sample Response	Number of Responses
Direct User	FSS software development team	"The direct user is the FSS Software Development Team".	61
Indirect Users	FSS and its Evidence Documents Manager	"The FSS's Evidence Document Manager, Dorothy Belding, is the direct user".	34
Non-Users	Any entities not listed above including but not limited to prosecutors, alleged criminals, and alleged victims	"authorities who need to un shred documents"	2
Mix	Any combination of direct, in-dierct and/or non users	"The direct user is the firm, Federal Security Services, and specifically the Software Development Team".	3
Total			100

D. *Students' responses over time*

Table IV summarizes the students' responses to the question "who is the direct user?" over time for the three MEAs. In the first MEA, *TMC*, students mostly indentified non-users. In the second MEA, *JITM*, students mostly identified indirect-users. In the third and last MEA, *Shred*, students mostly identified the direct user. These results show improvement in students' responses over time with solving more MEAs. However, after participating in two MEAs, about 40% of students could not identify the correct answer in the third MEA. Overall, 33% of students never identified the correct answer in any of the three MEAs.

TABLE IV. SUMMARY OF STUDENTS' RESPONSES FOR THREE MEAS. (GRAY CELLS SHOW THE MAJORITY OF RESPONSES FOR EACH MEA).

Client Type	MEA		
	TMC	***JITM***	***Shred***
Direct user	27	24	61
Indirect user	7	69	34
Non-user	65	4	2
Mix	1	3	3
Total	100	100	100

V. DISCUSSION

Analysis of students' responses to "who is the direct user?" shows improvement in responses across the three MEAs. Students' responses to the first MEA indicate a poor understanding of the problem and its stakeholders, which most likely leads to a low quality solution. In the second MEA, while the number of correct answers (identifying the direct user) was similar to the first MEA, students' responses shifted from non-users to indirect users. This indicates an improvement in students' understanding of the problem and its stakeholders from the first to the second MEA. In the third and last MEA, students mostly identified direct users correctly, a clear indication of improvement in the comprehension of the problem.

The findings of this paper confirm previous research suggestions, such as Salim and Diefes-Dux [3] (in the MEA context) as well as Crismond and Adams [4] (in the design context). Asking students direct questions about the user of their solution encourages them to read the problem statement (including the provided memo) more carefully, think about the users, and try to understand the context of the problem in order to be able to answer the questions. This helps the students understand the problem and prevents them from starting to prepare a solution without fully understanding the problem. The improvement in students' responses over time indicates that, similar to other skills, practice is necessary for problem formulation.

While students' responses improved over time, even in the last MEA the percentage of correct responses was about 60%. In other words, after participating in the two MEAs, 40% of the students could not identify the direct user in the third MEA correctly. In addition, one third of the students never identified the correct direct user in any of the three MEAs. Thus only asking questions about the stakeholders may not be sufficient for understanding the problem. Salim and Diefes-Dux [3] suggest direct instruction and constructive feedback in addition to asking questions about the users may help students to improve in problem formulation. While teaching assistants provided feedback on students' responses, it may be advisable to review students' responses to these questions with the class during or following each MEA.

One of the limitations of this study is the content and context of the MEAs. In some MEAs, direct users may be easier for students to identify compared to the other MEAs (e.g., familiarity of students with the context, clarity of the memo, number stakeholders woven into the problem). Thus, the design and context of the MEA may have influenced the results. These issues need to be evaluated in future research.

While the results of this paper illustrate improvement in identifying the direct user over time, it also shows a lack of understanding of the problem for some of the students. Thus, future research is needed to improve problem formulation instruction to beginner (first-year) engineering students. Further analysis is required to investigate students' responses to identify direct user's needs and problem constraints. For future research, analyzing students' responses to the other individual questions including identifying stakeholders, their relation to the problem, and direct user's needs could help shed light on students' understanding of the problem. A continuation of this study also might look at the nature of the TA feedback received those students who improved over time versus those that did not. It might also look at the relationship between the stakeholder list question or the direct user's needs question to the responses to the direct user question. This would inform instructor training on MEA feedback.

Appendix A - *Travel Mode Choice* MEA

Internal Memo

To: Engineering Team
From: Ollie Fiji, Executive Director, E3 Trans Consultants
Re: Student Travel Mode Choice

Our firm has been hired by the University of Central Florida's Department of Physical Facilities Management which is working with the UCF Board of Trustees to develop the next Campus Master Plan. In general, the UCF Board of Trustees wants to improve transportation facilities and services. UCF estimates that within the next 10 years the student population will increase from approximately 40,000 to 50,000. Without planned and scheduled improvements to the transportation and transit systems, the campus and surrounding roads could become congested. In an initial survey of UCF students, the Planners Group (a unit within E3 Trans Consultants) received comments including:

"Take the bus? No way, I'd prefer to just drive and park on campus."

"I like the bus; it's so convenient."

"I need the exercise, I just walk or roller blade to my classes."

Now the Planners Group needs a model developed that they can use to predict students' travel mode choice on this and other university campuses. The Planners Group is interested primarily in trips between home and campus. Home, in this study, refers to a student's residence during the semester. About 15% of students live in residence halls and the remaining students live off-campus in the Orlando area. This study is important in planning for the growth of the UCF and the future of LYNX but may be useful to transportation and transit designs at other university campuses.

Based on research from other universities, we have identified several variables that may have an effect on travel mode choice. In a second survey of UCF students, such data was gathered regarding students chosen modes for trips from home to campus. A portion of the survey data is stored in an Excel file **travel_mode_data_partial.xls**. The travel mode options for each student are walking, driving, or taking the bus/shuttle. Each trip starts when a student leaves the door of his/her homes and ends when s/he arrives at the door of the campus destination. The data provided includes these variables and the actual travel mode used by the student. The table below describes the data.

Column	Description	Value or units	Notes
car	Car ownership	y=yes, n=no	
ttimewalk	Travel time for walking	minutes	
ttimeauto	Travel time for driving	minutes	
costauto	Cost of parking	$ per semester	
ttimebus	Travel time for bus or shuttle	minutes	Some students do not have the option of taking UCFS
costbus	Bus or shuttle fare	$ per one way ticket	UCFS is free, students pay for LYNX
freqbus	Frequency of bus, time between buses	minutes	
busstop	Distance from home to bus/shuttle stop	blocks (1 block = 1/8 mile)	
mode_used	Mode selected by the student	bus, walk, or drive	

Your team is responsible for creating and evaluating a general procedure to predict the most likely travel mode for a given student. Your model must be able to predict the travel mode choice of additional non-surveyed students for whom similar data can be obtained.

Your team's general procedure should strive to reflect the relationship between the data and actual student mode choices in the campus survey results. So, as your team develops your model, you will need to analyze the accuracy of your model. That is, your team must *quantify* how well your model predicts the actual student reported chosen travel mode. Your team should use this information to improve the level of accuracy of your model.

In a memo addressed to me, please reply with the following information:

- Your team's general procedure for predicting student's choices of transportation given similar data. Be sure to clearly state the reason for each step, heuristic (i.e. rule), or consideration in your procedure.
- **The results of applying your revised general procedure to the data provided.**
    - **Your team must report quantitative results for *all* students with the predicted mode and the actual mode.**
    - **Your team must quantitatively assess the ability of your model to predict a student's travel mode choice. You must be able to quantitatively answer the question, "how accurate is your team's model?" Further, your measure(s) of accuracy should identify weaknesses in your model (e.g. is your model good at predicting the driving mode but not the bus/shuttle mode?)**

Thank you,
Ollie Fiji

APPENDIX B - *JUST-IN-TIME-MANUFACTURING* MEA

Interoffice Memo

To: Applications Engineering Team
From: Devon Dalton, CEO
RE: Shipping Issues
Priority: [Urgent]

Our company operates a just-in-time manufacturing system. After several years of shipping with Pathways Transit (PT), it has come to my attention that PT has not been meeting our shipping needs. We are having problems with late arrival times. The fact that PT is not consistently arriving at the time they have promised is causing D. Dalton Technologies (DDT) production problems. This means that our Logistics Manager needs a method to identify a new shipping company.

I want to make use of your team's analytical expertise. DDT is small; therefore, we need your team to serve in an engineering project management function on this project. Your team's task is to design a procedure to rank potential shipping companies. My assistant has collected historical data on several potential companies for you. Eight shipping companies have been identified as able to transport materials directly from Ceramica to Bowman. As you know, arrival time of materials is a big issue for DDT. Since the piezoelectric materials are designed specifically for each custom order, it is imperative that the delivery of materials occur just-in-time for Bowman to begin the manufacturing process that uses all of the shipped materials. Because we operate with a small workforce and only one shift, minutes to a few hours can make a difference in our ability to complete devices for our custom applications by our contracted delivery date. This makes arrival time of materials of great importance. We have in excess of 250 data points for each shipping company. At this time, the data for only four companies is available. This data is stored in a file called jit_data_partial.txt. The four shipping companies are Iron Horse Expeditors (IHE), Delphi Shipping (DS), ShipCorp (SC), and United Express (UE). The data is in hours late for shipping runs from Lincoln, Nebraska to Noblesville, Indiana.

Your team should brainstorm different ways in which to analyze the shipping data. Then, your engineering team will use the sampling of data provided for the four shipping companies to develop a procedure to rank the shipping companies in order of most likely to least likely able to meet our timing needs.

In a memo to my attention, please include your team's procedure and the rank order of the shipping companies generated by applying your procedure to the sample data. Be sure to include additional quantitative results as appropriate to demonstrate the functionality of your procedure. Please be sure to include your team's reasoning for the each step, heuristic (i.e. rule), or consideration in your team's procedure.

Please send your complete memo to me by next week.

DD

APPENDIX C - *SHREDDED DOCUMENT* MEA

Memorandum

To: Engineering Team
From: Dorothy Belding, Evidence Documents Manager, Federal Security Services
Re: Shredded Document Recovery Process

Federal Security Services (FSS) is a freelance security consulting firm with numerous governmental contracts. Due to the recent increase in illegal business practices, state and federal government prosecuting teams have been contacting us to aid in their investigations. We need to develop a structured method for the recovery of shredded documents. The high profile nature of many of these cases has resulted in more intense scrutiny of how evidence of this nature is obtained and recovered. Currently, few formally documented processes exist for the recovery of shredded documents, causing key documents to be excluded as evidence due to the potential for tampering. FSS would like to develop a computer-based tool to handle document recovery.

The picture shown in Figure 1 is a digitized, grayscale image. This image happens to be a view seen in an optical microscope. Similar images are currently being created of scanned document strips. An image is stored as a data file which contains an array of numbers. Each number refers to the grayscale value for each pixel of the image. A sub-sample of the complete Figure 1 file is shown in Figure 2 and Table 1. This sub-sample shows the grayscale values for the square superimposed on Figure 1 and exploded in Figure 2.

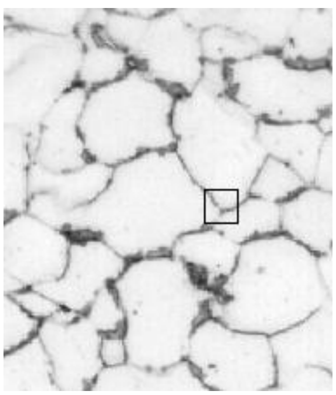

Figure 1. Micrograph of crystals with sub-sample shown.

Figure 2. Sub-sample of micrograph shown in Figure 1.

In a true black and white document, such as a text-only document, the grayscale values present will be limited to 0 (black) and 255 (white). A perfectly black and white image will contain ONLY 0's and 255's. Grayscale values range from 0 for black to 255 for white.

Table 1. Digital file for sub-sample from micrograph of crystals shown in

128	160	221	221	221	241	241	234	241	255	241	241	241	241	255

234	241	227	241	221	215	221	227	227	227	234	241	234	234	255
234	234	241	204	215	204	204	215	227	234	227	227	255	227	241

The grayscale value of each pixel is accessible information that can be used to make decisions about whether or not document strips fit together.

Last week, a government raid on a major automotive company resulted in the seizing of 8 bags of shredded documents. Though the majority of the documents are most likely legitimate confidential business memos, there is evidence to suggest that some documents were shredded to cover up indications that a high ranking vice-president was aware of poor product performance which resulted in a number of deaths.

I would like your engineering team to develop an algorithm that the FSS Software Development Team will use to reassemble documents that have been shredded into full length strips. The FSS Software Development Team will take your written description and translate it into a computer-based tool. Because the FSS Software Development Team is still evaluating several potential computer-based means of implementation, *you should avoid using any specific computer tool language to describe your procedure.*

***Abstract*— Nanotechnology as a research field presents many new opportunities and challenges for educating the next generation of engineers. In this paper, we attempt to understand the impact of this research team's initiatives to increase engineering students' awareness and understanding of nanotechnology. This is a case study of how four student teams changed their iteratively-developed design solutions for a nanotechnology-based design project. The goal is to investigate how first-year engineering (FYE) students developed their demonstrated knowledge of nanotechnology. We found that all four teams discussed nanotechnology concepts from the beginning of their solutions. Although they had difficulty relating their nanotechnology applications to science and mathematics concepts, they had consistent ideas for the nanotechnology-specific content they wanted to focus on throughout their project. The results show that all four project cases have a clear potential connection to a field of engineering. Connecting nanotechnology to potential engineering fields may present a better content focus than science and mathematics concepts.**

Keywords—first-year engineering; nanotechnology; design projects

I. INTRODUCTION

First-year engineering students know very little about nanotechnology [1,2], which is a field that is changing many aspects of our world [3] and offers many new learning and discovery opportunities [4]. Design projects offer opportunities for students to explore the topic of nanotechnology. A partnership between faculty teaching a required First-Year Engineering (FYE) course at Purdue University and the NSF-funded Network for Computational Nanotechnology (NCN) resulted in a FYE design project to address multiple course learning objectives and improve students' awareness and knowledge of nanotechnology. For this project, FYE student teams were challenged to create a simple interactive tool (using MATLAB) to enable high school students to learn about nanotechnology through relevant state-standards for science and mathematics. This study is driven by this research question: How do student teams' knowledge about nanotechnology change over the course of a nanotechnology-based design project? An investigation of student teams' solutions to the design challenge will reveal whether or not and how the design project facilitated FYE students' learning about nanotechnology. The purpose of this study is to unpack the successes and shortcomings of our initiatives and to enable others to more effectively incorporate nanotechnology concepts into their courses.

This work was made possible by a grant from the National Science Foundation (NSF EEC 1227110).

II. LITERATURE REVIEW

Nanotechnology is science, engineering, and technology conducted at the nanoscale (1 to 100 nanometers) [2]. The scale of nanotechnology is difficult for students to grasp [5, 6]. Previous research has found that students have trouble discerning the difference between micro, nano, and atomic scales [7]. Although the nanoscale is a difficult concept to grasp, it is important that education about nanotechnology not focus only on the nanoscale. It was found that students that learned about nanotechnology in an educational environment typically learned only about the nanoscale and were not educated about its potential impacts and applications [2]. This connection to potential applications is vital for student motivation and engagement in the topic. Nanotechnology is an area of research that is in high demand of professionals [8] and presents opportunities for students to learn in multidisciplinary [9] and interdisciplinary [10] environments.

In a previous qualitative analysis of 28 teams' executive summaries of their final design projects, it was found that the teams that anchored their project in a specific nanotechnology product appeared to have the greatest understanding of nanotechnology [5]. For this study, four teams, each having a different science and/or mathematics foci, were identified from the 28 teams as demonstrating a greater understanding of nanotechnology and an ability to relate their topic to a nanotechnology product [5].

III. METHODS

A case study is used to examine a phenomenon (i.e. the "case") in its real-world context [11]. The purpose of these analyses will be to investigate what led to the success of these identified teams. The success will be determined by their ability to represent their knowledge of nanotechnology through their design project solution. Although these teams were somewhat uncommon instances of greater understanding, they may help inform instructional design to encourage deeper understanding in future nanotechnology-based design projects.

A. Participants and Setting

At Purdue University, all students in the FYE Program are required to complete two sequential 2-credit hour courses that focus on learning objectives associated with problem-solving, design, computer tool skills, teamwork, and communication. In Spring 2012, 1651 students were enrolled in 15 sections (up to 120 students per section) of the FYE Program's second semester course. Of these 15 sections, four sections implemented a nanotechnology-based design project. The focus of this study is on the nanotechnology-based design project completed by student teams (with 3 or 4 students per a team).

B. Nanotechnology Graphical User Interface (GUI) Project

The nanotechnology graphical-user interface (GUI) project was introduced in Week 11 of the semester (16 week semester) with a memo from the project partner and a short presentation by the instructional team that highlighted available nanotechnology resources. Students were also given access to NCN's interactive online data and research sharing environment (nanoHUB.org) to learn about nanotechnology. The environment has 64,659 interactive users and primarily consists of online simulations for those interested in nanotechnology. NCN's mission is to support the National Nanotechnology Initiative by creating and operating a cyber-platform for expanding and supporting the formation and growth of the nanotechnology community by sharing computational simulations and educational resources. NCN served as the client and set the goal and the criteria by which the project solutions could be judged for success. The goal was for student teams to create an interactive learning module relating nanotechnology to grades 11 or 12 science and mathematics topic as listed in the state standards. The five criteria for success stated that the student teams' solutions must:

1. Clearly show how the rationale for this project will help students learn nanotechnology,
2. Clearly address one state science standard for the targeted grade level,
3. Clearly connect the science or engineering topic to math activities that are appropriate for the targeted grade level,
4. [Be] highly stimulating and interactive for targeted grade level, and
5. [Be] easy to use and operate.

To achieve these goals, students were asked to plan and create a fully developed GUI utilizing MATLAB [12]. This project was to be completed in six milestones. These milestones served to help the teams develop their solution along a predetermined timeline and use design concepts learned in the prerequisite course. The students received feedback from the instructional team or the project partner for every milestone submission. The milestones were as follows:

1. Brainstorming (Week 11): This involved brainstorming 30 potential ideas for a solution to the Nanotechnology GUI project and then going through concept reduction using a decision matrix. The deliverable was a memo to the project partner describing two design ideas the team felt were worth pursuing.
2. Project Storyboard (Week 12): The team selected one idea and used PowerPoint to create a prototype of their solution for the project partner.
3. Project Layouts and Flowcharts (Week 14): The team fully develop the GUI layout in MATLAB and flowcharted the algorithms that would need to go behind each layout to achieve desired functionality.
4. Project GUI Beta Version 1 (Week 15): Teams began to convert their flowcharts to MATLAB code. The instructional team provided students with detailed feedback during team demonstrations.
5. Project GUI Beta Version 2 (Week 16 – Class A): Teams presented a complete and improved solution to the instructional team. This version was evaluated by the project partner during a class demonstration.
6. Project Final Demo and Executive Summary (Week 16 – Class B): Teams gave a final demonstration of their solution to the instructional team and submitted their written documentation in the form of an executive summary. This GUI version was evaluated by the instructional team during a class demonstration. Project reports had to demonstrate how the feedback from the client was incorporated into the final design.

C. Data Collection and Analysis

Four teams from one section were selected for this case study based on previous research in which all 28 teams' executive summaries from one section were analyzed [5]. Based on the previous study, half of the teams incorporated a nanotechnology application into their project (including the four selected teams) and over half of the teams that did not admitted that their greatest shortcoming was Criteria 1 [5]. The analysis found that teams that incorporated some application indicated greater confidence in their projects' ability to teach others about nanotechnology. The four selected teams each included some nanotechnology application and selected a different approach to connecting nanotechnology to a science and/or mathematics concept to fulfill Criterions 2 and 3. The purpose of this study was to examine characteristics of their approaches that may have led to their greater success in exploring nanotechnology. This qualitative analysis focused on the changes that the teams made and the consistencies that the team maintained across all six milestones. The results section consists of an analysis of each team individually and the discussion section communicates the found commonalities between the changing and consistent concepts of the four teams' project solutions.

IV. Results

In the sections that follow, changes to each of the four team's solutions are discussed. The solutions submitted in Milestones 5 and 6 were very similar for all four teams, so the GUI submitted for Milestone 6 is the only one discussed. From Milestone 5 to 6 there were primarily interface improvements and reformatting without much content change.

A. Team A

The two ideas proposed by Team A for Milestone 1 were: (1) biomedical nano-sensors and (2) identifying cancer cells. Their science focus was proposed to be biology, specifically cellular structure and reproduction. In Team A's memo to NCN, they discussed "nano scale", "nano-particles", and "nano-sensors".

For Milestone 2, they settled on the idea of using biomedical sensors as the anchor for their solution. They continued to focus on biology with the addition of chemistry; their proposed topics were cellular chemistry (biology) and behavior of gases (chemistry). Their proposal became more specific at this point. They proposed challenging (high school) students to "compute various pressures within the blood stream" using "[evaluation] models of sensors on varying scales (visible, micro, and nano)" and demonstrating "improved accuracy data obtained from these nano-sensors". They dropped the discussion of "nano-particles" in this milestone and added the discussion of other scales larger than the nanoscale.

For Milestone 3, the team presented layouts of the actual GUI generated in MATLAB. They continued to add greater detail about how the interface would present nanotechnology-focused information; the team did not discuss the science and mathematics focus in this milestone. Three scales were used to describe the application. The visible scale would discuss the "blood pressure measured by stethoscope and sphygmomanometer". The microscale would focus on a specific technology called MEMS: "MEMS, micro-electro-mechaical systems, can be used to measure blood pressure more accurately… [and] can be implanted in patients who have blood pressure problems." The nanoscale would discuss information and calculations related to a "nano pressure sensor".

For Milestone 4, the team remained consistent regarding all of the biomedical measurements; however, the team changed their science and mathematics focus at this point. The team transitioned to a mathematics focus regarding linear equations and physics of motion and forces.

For the executive summary submission of Milestone 6, the team only discussed the mathematics focus of the project (i.e. linear equations); they no longer explicitly related the project to a science concept. For the GUI solution that Team A submitted for Milestone 6, the team continued their focus on the biomedical applications of nanotechnology through an organization similar to what they previously discussed in Milestone 3. First they incorporated an interactive window to input blood pressure information obtained from a "stethoscope and sphygmomanometer". The next window described MEMS with text similar to that presented in Milestone 3. The GUI also included three windows that discussed carbon nanotubes, piezoelectric effect, and construction related to nano-pressure sensors. Each topic informed the "user" through written text and images. After this nanotechnology-specific information, the GUI went to an interactive page that challenged the user to calculate the slope and y-intercept "to discover the desired trendline [of the given] test data" supplied through a "nano-wire strain test". A screenshot of this portion of the GUI is shown in Figure 1. (This figure was formatted to better fit in this paper and does not represent the actual layout of the GUI. In the original window, the "Best Fit Line" and "Experiment Data" boxes were to the right of the "Nano-Wire Experiment" box.)

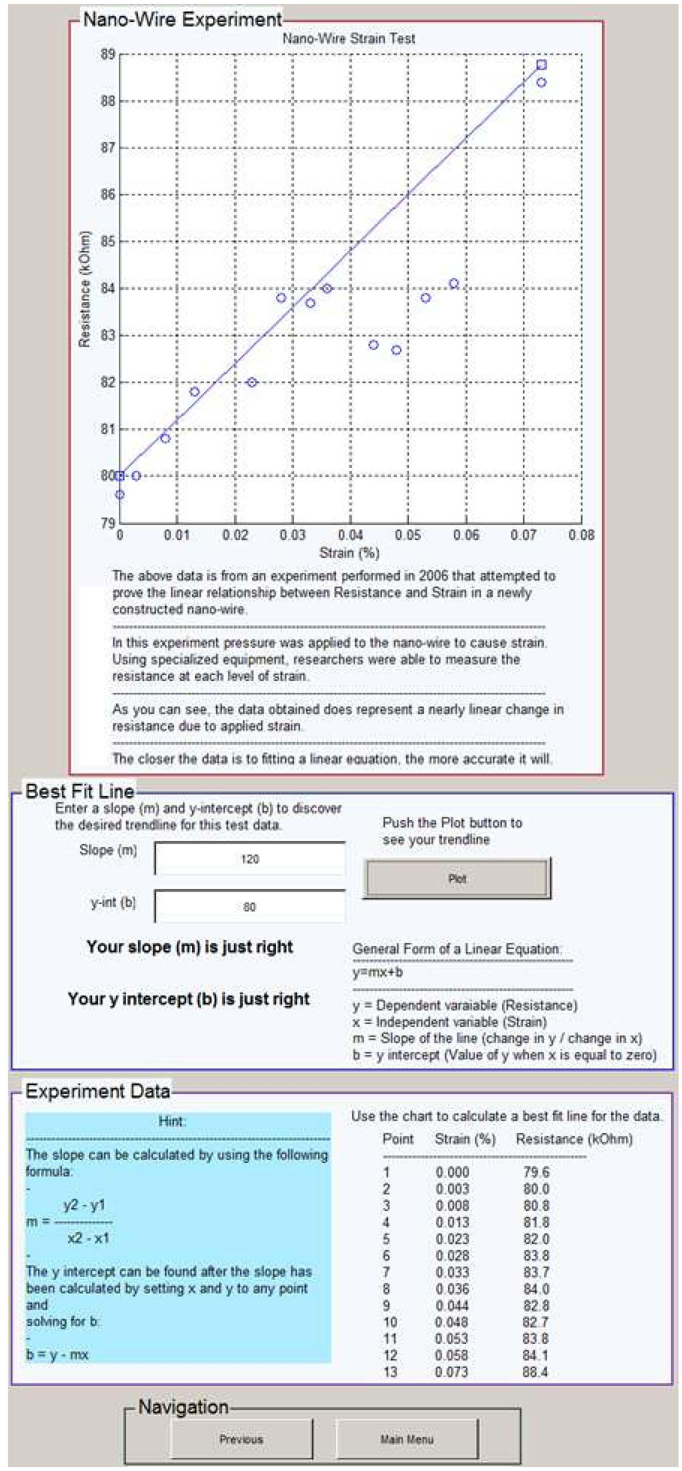

Fig. 1. Screenshot of the nanotechnology-specific, interactive portion of Team A's GUI.

B. Team B

The two ideas proposed by Team B for Milestone 1 were: (1) quantum physics/light behavior and (2) acid-base titration. The team elaborated on the first idea by stating, "Quantum physics relates to nanotechnology through a particle called quantum dots." This statement includes all of the nanotechnology vocabulary included in this milestone. The team's focus for this idea was on physics concepts "explaining the relationships among wave characteristics like frequency, amplitude, etc." and some basic mathematics skills, including unit conversions (e.g. "grams and moles") and "various formulas". In this milestone, the team discussed "quantum dots", a nanotechnology application.

For Milestone 2, the team further developed the quantum physics idea by explaining their physics and mathematics foci. The physics focus was on "electromagnetic spectrum", "electromagnetic waves", wave properties (i.e. wave speed, wavelength, frequency of period, and amplitude), and "light properties" (i.e. absorption, emission, and transmission). The mathematics focus was on "antiderivatives" (i.e. velocity and acceleration), "graphing technology to find approximate solutions for polynomial equations", and plugging values into formulas and conversions (i.e. frequency, wavelength, and amplitude). Their proposed GUI included lessons on "the concepts of light behavior and how they apply in the designing and making of engineering innovations and nanotechnology in different fields."

For Milestone 3, the team discussed the same topics as in Milestone 2 without any clear details of how the plan would be executed or communicated; this submission was actually less detailed than Milestone 2.

For Milestone 4, the team included more details regarding nanotechnology. The team stated, "Nanotechnology refers to any kind of technology or science that functions in the Nano scale. It includes the manipulation of matter and their properties at the Nano scale. Through nanotechnology we can manipulate matter, its molecules and properties at an atomic level and create new matter with unique properties." The team discussed a specific activity they planned to include in their GUI, "In one of the activities, the user learns various properties of light including wavelength, frequency and more. The user then has the chance to calculate, manipulate and experiment with different wavelengths and frequencies measured in nanometers as well as observe a visual display of how the different changes in each affect light."

For the executive summary submitted in Milestone 6, the team stated the science and mathematics foci. The science focus was still physics, specifically light properties; the mathematics focus was simplified to only address algebraic problem solving. The nanotechnology focus was still quantum dots, which was initially discussed in Milestone 1. The GUI submitted for Milestone 6 consisted of four main activities (i.e. "wave generator and properties", "electromagnetic spectrum", "photon emission", and "light and nanotechnology"). Each activity had some interactive component and definitions that defined and discussed pertinent information on the topic. The nanotechnology-specific activity consisted of primarily text discussing quantum dots. A screenshot of this activity is shown in Figure 2.

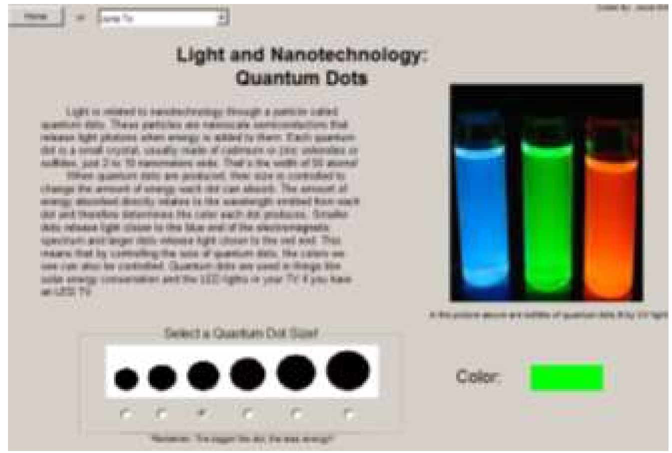

Fig. 2. Screenshot of the "light and nanotechnology" activity in Team B's GUI.

C. Team C

The two ideas proposed by Team C in Milestone 1 were: (1) carbon nanotubes and their application and (2) molecular geometry used in practical applications of nanotechnology (e.g. Rain-X rain repellant). The foci for their first idea were "organic chemistry and biochemistry" (e.g. carbon atoms bonding) and creation of graphs to visualize mathematics concepts. In this milestone, the team used the following nanotechnology vocabulary: "nanoparticles", "nanotubes", and "carbon nanotubes".

For Milestone 2, the team selected carbon nanotubes along with their strength and utility. The science focus was still chemistry; they focused on "organic chemistry and biochemistry" (i.e. properties of carbon allotropes and bonding) with the addition of atomic structure (i.e. valence electrons). The mathematics concept was changed to problem solving strategies through interpretation of Young's Modulus. The team explained this, stating: "The activity will tie together problem solving skills to mathematically show that Young's Modulus is that same for a material no matter what the stress or strain." The team proposed a GUI that focused on material properties challenging "users" to calculate stress and strain; they also incorporated atomic structures that discussed allotropes.

For Milestone 3, the team focused on the same chemistry and mathematics concepts as proposed in Milestone 2. The proposed plan for the GUI consisted of a more detailed plan on how to incorporate ideas for material weights, Young's Modulus, stress, strain, allotropes of carbon (i.e. graphite, diamonds, and carbon nanotubes), and bonding orbitals.

For Milestone 4, the team had the same content with a clear path of how they planned for the "user" to progress in their GUI. The established path consisted of physics and mathematics concepts, Young's Modulus, carbon nanotubes, engineering applications, and then structure of carbon nanotubes.

For the executive summary submitted in Milestone 6, the team focused on a physics topic (i.e. material properties), chemistry topics (i.e. hybridization and atomic properties), mathematics topics (i.e. algebraic problem solving and variable manipulation), and a nanotechnology application (i.e. carbon nanotubes). The final submitted GUI consisted of an interactive component that prompted the "user" to input required values to calculate stress, strain, and Young's Modulus. The majority of the submitted GUI consisted of text that required some minor interaction through pushing various buttons; the text incorporated some nanotechnology-specific ideas. An example of a few of these interfaces is shown in Figures 3 and 4. Figure 3 shows a window in the background with a "Carbon Nanotubes" button that navigated to the "Carbon Nanotubes" window in the forefront of the figure. Figure 4, presented in the same format, is about hybridization.

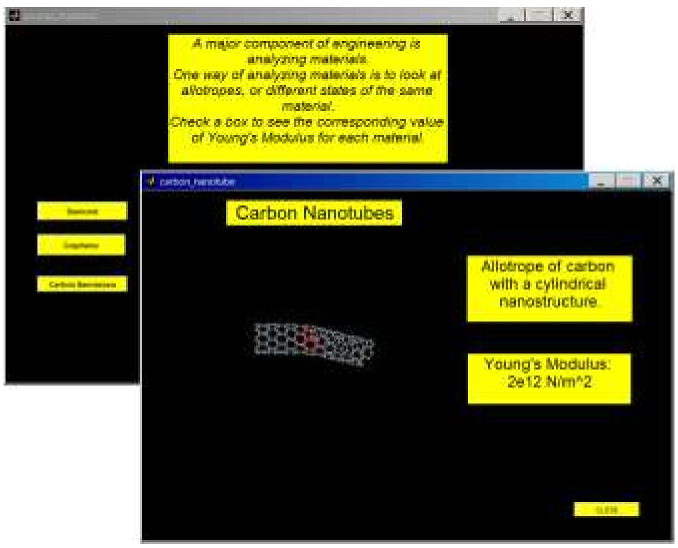

Fig. 3. Screenshot of the "Young's Modulus" screen along with the "carbon nanotubes" selection in Team C's GUI.

Fig. 4. Screenshot of the "hybridization" screen along with the "sp^2 hybridization" selection (peritinent to carbon nanotubes) in Team C's GUI.

D. Team D

In Milestone 1, Team D expressed their two ideas as: (1) "fractal silver structures are really effective in photovoltaic energy harvest" and (2) "carbon nanotubes are used as a catalyst in extraction". The first idea was related to mathematics, specifically "using recursion to describe fractals". The second potential concept was related to "catalysts in biology".

For Milestone 2, this team focused on "practical fractals", specifically harvesting photovoltaic energy through fractal silver structures. They discussed how there topic related to physics (i.e. correct units in describing common physical quantities), chemistry (i.e. how an atom can acquire an unbalanced electrical charge by gaining or losing electrons), and mathematics (i.e. recursion to describe fractals). They proposed a path for their GUI projectthat consisted of "how fractals are made", "how fractals are used in nanotechnology", and then to fractals "in photovoltaic energy cells". They proposed that the application of fractals would demonstrate that "fractals greatly increase the density of a given area".

For Milestone 3, the team maintained their fractals and photovoltaic energy idea and a similar plan for the GUI development. The mathematics concepts were converted to fractals as iterative functions. The science focus was changed to harvesting light at the molecular level. In this milestone, the team began discussing "photovoltaic energy cells". The photovoltaic energy had been discussed in previous milestones, but at this point the team began discussing "cells".

For Milestone 4, the team related their project to the same science and mathematics topics discussed in Milestone 2; the team dropped the different science concepts discussed in Milestone 3. The ideas for the GUI were the same as described in Milestones 2 and 3.

In the executive summary submitted at Milestone 6, the team related their project to biology (i.e. photosynthesis), mathematics (i.e. algebraic problem solving and geometry), and a nanotechnology application (i.e. "solar panel cells"). For the final submission of the GUI project, the team created a selection of interactive activities that taught users about fractals (i.e. graphical representations of fractals, quiz about examples of fractals, and calculating the length of a fractal) and the application of fractals in measurement. The final GUI did discuss fractals, but the team no longer identified this as the mathematics concept that they were connecting their project to. The final portion of the GUI consisted of an image and text that described how fractals related to nanotechnology; a screenshot of this is shown in Figure 5.

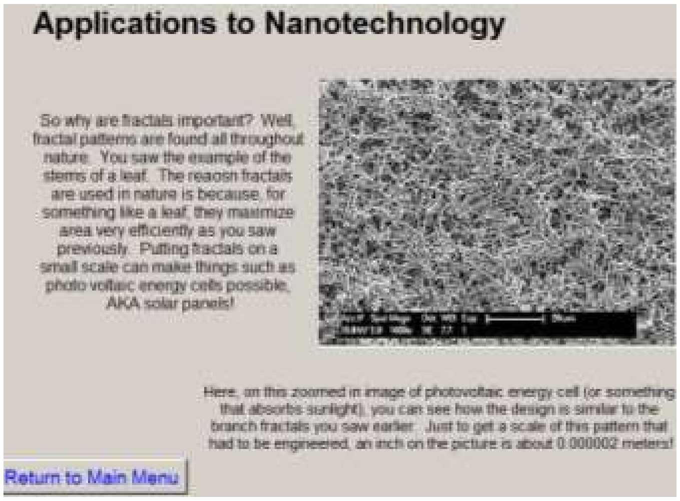

Fig. 5. Screenshot of the "Applicationss to Nanotechnology" portion of Team D's final GUI project.

V. DISCUSSION

All four of these teams consistently discussed the same nanotechnology application throughout the entire project. Table I shows each of the teams nanotechnology application discussed across each milestone. Team A and Team D changed some of their wording for how they referred to the nanotechnology application between Milestone 2 (M2) and Milestone 3 (M3), but discussed the same application.

TABLE I. NANOTECHNOLOGY APPLICATIONS IN DESIGN PROJECTS

Teams	Nanotechnology Applications across 6 Milestones (M)				
	M1	M2	M3	M4	M6
TeamA	Biomedical Nano-sensors		Biomedical Nano Pressure Sensors		
TeamB	Quantum Dots				
TeamC	Carbon Nanotubes				
TeamD	Photovoltaic Energy		Photovoltaic Energy Cells		

All four teams did not discuss the same science or mathematics concept throughout the entire project. The teams were required to have a connection to a science and mathematics concept in their project, but even with the requirement the teams did not discuss this connection in some milestones.

This variation of science concepts across the six milestones can be seen in Table II. Team A is a clear example of a team that struggled to find a science concept connection. The team stated that their project related to biology, chemistry, and/or physics at different milestones and did not connect to any science concept by Milestone 6 (M6). Team C and Team D also had some variability in their idea of how to connect their project to a science concept. Team B was the only team that seemed to have a consistent connection to a science concept throughout their project development (i.e. physics).

TABLE II. SCIENCE CONCEPTS IN DESIGN PROJECTS

Teams	Science Concepts across 6 Milestones (M)				
	M1	M2	M3	M4	M6
TeamA	Biology	Biology + Chemistry	Not discussed	Physics	No science concepts
TeamB	Physics (wave properties)	Physics (wave and light properties)			Physics (light properties)
TeamC	Chemistry (carbon bonding)	Chemistry (carbon bonding and atomic structure)		Physics (material properties)	Chemistry + Physics
TeamD	none	Physics + Chemistry	Harvesting Light	Physics + Chemistry	Biology (photo-synthesis)

The variation of mathematics concepts across the six milestones can be seen in Table III. Team B and Team C had different ideas about how to connect their project to mathematics concepts across the six milestones. Team A did not even discuss a connection to a mathematics concept for the first three milestones and only connected their project to linear equations in the final milestone (M6). Team D was the only team that had a somewhat consistent connection to a mathematics concept. Although they do not explicitly state that there project is about fractals in the final milestone, it is clear that their project is still connected to this concept.

TABLE III. MATHEMATICS CONCEPTS IN DESIGN PROJECTS

Teams	Mathematics Concepts across 6 Milestones (M)				
	M1	M2	M3	M4	M6
TeamA	No mathematics concepts			Linear Equations	
TeamB	Unit conversion	Anti-derivatives	Not discussed		Algebraic problem solving
TeamC	Creation of graphs	Problem solving strategies (Young's Modulus)			
TeamD	Fractals				

Throughout the project, it appears that the teams are connecting their project to a science and mathematics concept based on the established criteria. This idea does not seem to help give the teams' projects a clear direction. Only the two discussed examples of Team B's connection to light properties and Team D's connection to fractals show a solution development that may have been driven by a connection to science or mathematics. Although these required connections change, all four teams have a clear connection to a nanotechnology application throughout the entire project; this connection seems to provide the primary direction for the teams' projects.

Although the teams do not explicitly discuss a connection to a type of engineering, there seems to be a potential connection between each project and a type of engineering. Team A's project explicitly discusses biomedical applications of nanotechnology and clearly connects to biomedical engineering. Team B's project explicitly discusses electrical applications of quantum dots and clearly connects to electrical engineering. Team C's project explicitly discusses material properties of carbon nanotubes and clearly connects to materials engineering. Team D's project discusses photovoltaics and clearly discusses nanotechnology in alternative energy engineering applications.

VI. Conclusion

The results of this study support the findings of previous studies that state that nanotechnology should be taught through nanotechnology applications [2,-5]. A commonality between all four teams' projects is that each team had a selected nanotechnology application in the beginning of their project and discussed this same application throughout their entire project. The connection to science and mathematics concepts did not seem to give teams an effective platform to connect nanotechnology concepts to. Although the teams did not explicitly state their connection to an engineering field of study, this seems to be a potential context that appeared in all four projects. Based on these and prior findings, the Spring 2013 project description, goal, and criteria for success was updated. The criterion regarding focusing on high school science and mathematics topics was removed. A new criterion was established that required the team to connect their project to an engineering field/s of study of their choice with their peers as the target audience. Earlier in the course and before the start of this updated project, each student was also challenged to complete a context setting assignment that encouraged them to investigate how nanotechnology applies to their engineering field of interest; students' responses to this assignment were investigated in another study [13]. The effectiveness of these changes will be studied in the future after their implementation in Spring 2013. As for implications for teaching practice, a greater focus on nanotechnology applications and how the various fields of engineering are related to nanotechnology present two potential paths for enabling students to engage in discovery learning of nanotechnology to enhance their understanding and awareness.

A Community Learning Component in First Year Seminar

Lin Cheng
Department of Engineering
Trinity College
300 Summit Street
Hartford, CT 06106
lin.cheng@trincoll.edu

Abstract— **This Work in Progress paper describes current efforts to engage Liberal Art College freshman to the Engineering discipline and its impact to the broader community, through a topic-based, writing-intensive seminar course. In this particular seminar developed by the author, we aim to discuss the role of engineers in tackling challenges in the Community around the Hartford area and beyond. While students enrolled in the seminar course in this paper are mainly "undecided" students, we believe by emphasizing technologies applied to the immediate community around our students and humanitarian applications, we can inspire students' interest in Engineering and show students how the skills they will be learning can have a positive impact on the quality of life for the surrounding community. The seminar was assessed by gathering student comments concerning each major course components.**

Keywords—first year seminar, community learning, service learning

INTRODUCTION

Orienting first year students to engineering is an important topic in Engineering Education. Many new practices have been researched recently on this topic. For example, Jenkins and colleagues [1] reported a first year engineering seminar at the University of Southern California. Their topics include the engineering problem solving, the social and historical context for engineering activities, and professional ethics. Taylor and colleagues [2] discussed an integrated freshman industrial engineering seminar at Rochester Institute of Technology. The course introduces students to campus life, engineering ethics, with team building activities. [3] reported a zero credit first year seminar at the University of Pittsburgh, taught in small groups by student mentors to assist student in the academic and personal transition from high school to college. Another group of educators at University of Southampton reported a similar program that orients freshman in the week prior to their incoming semester using student mentors [4]. Three first year seminars at Purdue University are described by Montgomery, Follman, and Diefes-Dux in [5]. These seminars are offered in different formats including large lecture with faculty presenters from individual disciplines, smaller group sessions led by upper-level student mentors, as well as a faculty member on specific engineering topics.

Complementary to the related work above, this Work in Progress paper describes current efforts to engage Liberal Art College freshman to the Engineering discipline and its impact to the broader community, through a topic-based, writing-intensive seminar course. While many excellent educational ideas have been reported in Engineering freshman seminars recently, implementation of these research ideas, especially for service based learning, has not been widely tested in writing intensive seminars and in the contexts of small liberal art colleges.

Trinity College is a small liberal arts college with about 500 freshman each year. They are divided and placed into seminars taught by faculty from different disciplines. In this particular seminar developed by the author, we aim to discuss the role of engineers in tackling challenges in the Community around the Hartford area and beyond. While students enrolled in the seminar course in this paper are mainly "undecided" students, we believe by emphasizing technologies applied to the immediate community around our students and humanitarian applications, we can inspire students' interest in Engineering and show students how the skills they will be learning can have a positive impact on the quality of life for the surrounding community.

COURSE STRUCTURE

This one-credit course is divided into three modules. In the first introductory module, all students sit in circles meet together in seminar format and are introduced to the engineering discipline and the engineering design process, start with the design process of preparing a family dinner. We also blend in a 15 minute module in each class meeting. Half of these modules discuss topics including campus life, time management, and curriculum issues. Half of these modules discuss transitions from high school to college level writing. Weekly writing assignments of about five to ten pages in length are performed. These strategies help students in the following dimensions:

This work is sponsored in part by the Community Learning Initiative at Trinity College, Hartford, CT.

- Get a basic understanding of the Engineering field.
- Get familiar with the Engineering design process using everyday examples.
- Encourage students to consider the cause-and-effect of design decisions.
- Find common grounds and sharing perspectives with each other.
- Get a smooth transition to College level writing.

Module 2 features more focused Engineering topics around our everyday lives. Digital technologies are emphasized with two particular themes of digital music and digital images. These themes are taught in both hands-on sessions and discussions. Simple Matlab scripts are introduced to help students analyze digital music and images. This way we energize the seminar classroom sessions by providing a context for small and large group discussions, followed by writing intensive assignments. Students were required to reflect on and to respond in writing to encountered problem solving issues. Some responses were formulated in groups to stimulate group discussions among students.

Fig. 1. In module 3, students are working on otoscopes for diagnosis of otitis media at Connecticut Children's Medical Center.

Module 3 focuses on a few specific themes that tie together several Community learning projects in the engineering context. Example projects offered in Fall 2012 semester include:

- In collaboration with the biology department, we initiated a citizen science venture to identify wildlife visiting residential compost piles in eastern Connecticut. The goal of this experiment is to determine whether or not the addition of animal-based kitchen scraps really does affect wildlife visitation to compost piles. Through citizen science, we are challenging students to reach this goal by identifying animals from images collected from the field site.
- In collaboration with Connecticut Children's hospital, we initiated a community based learning project for the accurate diagnosis of acute otitis media, a common disease for small children around the Hartford area. With the established experimental apparatus, students are challenged to analyze images collected from ears (with IRB approval). Figure 1 shows the students students are having hands-on experience with otoscopes for diagnosis of otitis media at Connecticut Children's Medical Center.

This third module encourages students to see themselves as capable of pioneering creative problem solving for the community, rather than simply as implementers. The carefully selected themes promote the notion of problem solving that focuses on real world applications rather than textbook exercises. When students participate in projects that involve client interactions, they are also required to consider the cause-and-effect of design decisions.

ASSESSMENT

Assessments for this class include in-class hands-on activities and out-of-class project assignments. While in-class activities are mostly interactive, discussion-oriented, out-of-class project activities are writing intensive and based heavily on community learning. We also made an effort to blend basic engineering design and analysis concepts into the community learning case studies.

While the student evaluation response has been positive, a limiting factor to analysis has been the small sample sizes. Future offering of the course would allow us to analyze the effectiveness of community learning in Engineering first year seminar more comprehensively.

ACKNOWLEDGMENT

The author wishes to thank the students enrolled in this seminar. We are grateful to Professors Carol Clark, Scott Smedley and Anne Lundberg, Director of Urban Programs at Trinity College, Hartford, CT, as well as Professor Tulio Valdez at Connecticut Children's Medical Center and University of Connecticut Health Center, who offered invaluable guidance and feedback to this work.

Development of a Multiple-Choice MATLAB Theory and Syntax Exam

Matthew A. Verleger
Freshman Engineering
Embry-Riddle Aeronautical University
Daytona Beach, FL, USA
mverleger@gmail.com

***Abstract*— Examinations in programming courses that require students to write code to solve a problem are an excellent method for testing how well a student has mastered language syntax, programming theory, and problem solving technique. However, if a student struggles with problem solving, it is often difficult for students to demonstrate any understanding of syntax or theory. To address this situation, faculty for a freshman engineering MATLAB-focused introductory programming course at a private southeastern STEM+Business-only university have been giving exams that are a combination of practical programming problems and multiple-choice questions. This research is focused on performing an item analysis of the questions appearing on those exams with the immediate goal being a multiple-choice exam with both topic coverage and documentation of it's ability to properly discriminate knowledge.**

Keywords—MATLAB, Exam, Item Analysis, Multiple Choice

I. Introduction

Introductory programming courses are a common part of first-year engineering curricula. Learning computer programming requires students to simultaneously understand language syntax, programming theory, and problem solving technique [1]. Language syntax is the language-specific formatting of programming statements. Programming theory represents computer programming specific concepts such as looping and decision structures, arrays, and file I/O. Problem solving is the ability to filter a problem statement into the relevant information and organize a solution using the theory and syntax elements.

Examinations in programming courses that require students to write code to solve a problem are an excellent method for testing how well a student has mastered all three aspects of programming. However, if a student struggles with problem solving, it is often difficult for students to demonstrate their understanding of syntax and theory. To address this situation, faculty for a freshman engineering MATLAB-focused introductory programming course at a private southeastern STEM+Business-only university have been giving exams that are a combination of practical programming problems and multiple-choice questions. The practical problems allow students to demonstrate problem solving and language syntax, while the multiple-choice portion allows students to demonstrate theory and syntax knowledge. The multiple choice portion of those exams have varied wildly in length, content, and topic coverage.

The immediate goal for this project is to develop a multiple choice MATLAB exam that meets the following goals as well as possible:

- Assesses the breadth of topics covered in the course.
- Adequately discriminates high from low performing students.

A secondary goal is to highlight topics that are being inadequately covered for various reasons.

The long-term goal for this project is to develop a set of generalized question models for an introductory MATLAB course that help assess student knowledge about syntax and programming theory independent of their problem solving ability. These models, after appropriate testing, can then be used, modified, and reused with minimal impact on their discrimination or difficulty, allowing instructors to create the appearance of a "new" exam with reduced concern about the exam's ability to identify differing knowledge levels.

II. Relevant Framework and Contribution

A. Framework

The framework for this analysis will be a modified form of the Item Analysis used in Classical Test Theory (CTT) as described in [2]. The modifications and their justification are described within the methods section. The two key mechanisms discussed are the problem difficulty and problem discrimination.

B. Contribution

This research-to-practice WIP is utilizing a widely accepted approach for psychological test development and applying it to a more traditional curricular content exam. Though this has been done before, there are shockingly few discussions of how it was done and even fewer instruments available. The immediate results of this research (e.g., the final exam document) will be provided at the presentation and will be available by emailing the author.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

III. Methods

A. Course

Enrollment in the Introduction to MATLAB for Engineers course is typically 200-300 students per semester. Sections of the course are limited to 28 students, with multiple faculty members teaching both the lecture and lab portions of the course. Sections are combined for the lecture and given in a large lecture hall, co-taught by the faculty members assigned to those sections. Course grades are set at 50% for 3 equally weighted exams, 20% final project, 20% homework assignments, and 10% quizzes. Faculty have individual control of specific items within each grade area, but often collaborate or use the same general methodologies.

B. Data

Since 2009, final examinations in the course have consisted of a multiple choice portion and a lab practical programming poriton. The multiple choice portion typically has consisted of both common questions for all students in the course and questions specific to each faculty member. Exams have varied wildly from semester to semester both in length and topic coverage.

Exam questions, students' answers, and students' final course grade (of which the overall final exam score including the lab practical portion represented 16.6% of the course grade) were collected. Data was converted to a common format and identical questions/answers from different semesters were grouped together, allowing for larger data pools for some questions. Each question was then reviewed by the author to identify both the correct answer(s) and what course topic(s) the question was addressing. Incomplete data (typically because final grades were unavailable) or invalid questions (typically because of typos that made the question invalid) were removed from the data set. The author acknowledges that final grades are not necessarily an accurate measure of course knowledge and that grades are not wholly independent of exam performance.

The remaining data set can be described as follows:

- 49470 responses by 777 students to 271 unique questions.
- Each question had between 21 and 777 responses, with a mean of 181 responses and a median & mode of 200 responses. Only 44 of the questions had fewer than 50 responses each.
- Final Grades were distributed as follows:
  - A – 29%
  - B – 30%
  - C – 23%
  - D – 10%
  - F – 8%

The top-heavy grade distribution is in part because students who D/F the course rarely attempt the final exam.

C. Analysis

Each response was rated as correct (1) or incorrect (0). Item difficulty was calculated as the average score of all participants on the item. Each response was also classified as either "High Performance" if the student obtained an A or B in the course or "Low Performance" if the student obtained a C, D, or F in the course. Average scores on each question were calculated for both high and low performers. A discrimination index was calculated as the difference in average score between the high and low performing groups.

Note that the above analysis is a modified version of the Item Analsysis described in [2]. Responses were grouped into only high and low performers to ensure a large enough sample for each question. With this grouping strategy, only 16 of the 271 questions had fewer than 15 responses in one of their performance groups, and the average performance group had 90 responses. The use of overall course grade (as opposed to only the overall exam grade) was done because different exams were given to different students, resulting in item weighting and relative item difficulty being inconsistant between students. While overall course grade is also inconsistant, the breadth of sources the final course grade includes represents a more wholeistic measure of student understanding than the single exam score.

D. Item Selection

Items were ranked by their discrimination index. For each of the topics, a top-ranked item was selected from the corresponding category. Items were screened to make sure that, when possible, they had a moderate to easy difficulty index (0.3 or above), though a few topics had no discriminating items that were not difficult (specifically variables and low-level files). The average difficulty level is 0.631, while the average discrimination index is 0.241. Final topics, along with the difficulty and discrimination indices are shown in Table I, presented in the order typically used during the course.

IV. Results & Next Steps

A. Primary Goal Results

30 Questions were selected with high discrimination to span the topics covered. A subset of the items are shown in Table II. The complete set of items can be obtained by contacting the author and will be provided at the presentation.

B. Secondary Goal Results

The secondary goal was to identify topics that may not be receiving adequate instruction. In sorting the questions by discrimination index, six items demonstrated negative discrimination (i.e., low-performing students performed better than high-performing students). The question with the most negative discrimination is "True/False: Microsoft Windows is an example of computer software." While the question is flawed (because Windows is both software and an operating system, resulting in confusion by students who can distinguish applications from the operating system), the item highlights that a more involved discussion of what is and is not software is important.

C. Next Steps & Remaining Work

Questions/answers to the selected items will be generalized to create a similar exam, resulting in a new set of questions that should still meet the desired goals. The resulting form will be given as a common final exam during the Spring 2013 semester. The results will then be compared to other course items, including final course grades to identify if the generalized items represent an adequately discriminating exam.

TABLE I. COURSE TOPICS AND SELECTED ITEM DIFFICULTY/DISCRIMINATION INDICES

Course Topic	Item Difficulty	Discrim. Index
Basic Computers (Hardware, software, etc.)	0.528	0.292
Problem Solving Technique	0.960	0.111
MATLAB Scripts	0.870	0.160
Basic Math in MATLAB	0.580	0.181
Variables	0.249	0.171
input	0.365	0.253
fprintf	0.321	0.180
Relational operators (<, >, <=, >=, ~=, ==)	0.694	0.424
Logical operators (&&, ‖, ~)	0.383	0.199
If structures	0.740	0.217
Switch-Case structures	0.765	0.118
Library functions (sin, sqrt, abs, etc.)	0.714	0.261
Random numbers	0.734	0.349
Rounding numbers	0.852	0.322
Mod	0.819	0.227
While loops	0.754	0.107
For loops	0.936	0.124
Arrays	0.524	0.333
Math using Arrays	0.504	0.249
Accessing array elements	0.820	0.269
Slicing, augmenting, etc. Arrays	0.657	0.345
Functions for arrays (min, max, etc.)	0.383	0.245
Plotting	0.505	0.131
xlsread	0.362	0.361
Dialog and message boxes	0.739	0.271
Cell Arrays	0.702	0.163
Programmer defined functions	0.720	0.517
Strings	0.809	0.164
String functions	0.735	0.222
Low level files	0.217	0.281

D. Next Steps & Remaining Work

Questions/answers to the selected items will be generalized to create a similar exam, resulting in a new set of questions that should still meet the desired goals. The resulting form will be given as a common final exam during the Spring 2013 semester. The results will then be compared to other course items, including final course grades to identify if the generalized items represent an adequately discriminating exam.

TABLE II. SAMPLE EXAM ITEMS

<table>
<tr><th>Course Topic</th><th>Item Difficulty</th><th>Discrim. Index</th></tr>
<tr><td>Relational Operators</td><td>0.694</td><td>0.424</td></tr>
<tr><td colspan="3">Which one of the following is not a relational operator?
a) = =   b) &&

***Abstract*—Undergraduate STEM student enrollment has declined substantially over the last decade. Specifically there has been a steady decline in retention of early engineering students working through the first half of their degree programs. Student "leavers" typically fall into two categories (i) those facing academic difficulties and (ii) those that perceive the education environment of early engineering as hostile and not engaging. The Engaging Early Engineering Students Project (EEES) is a collaborative effort between Michigan State University (MSU) and Lansing Community College (LCC). EEES functions through the integration of four component programs designed to ease the transition of high school students into engineering undergraduate programs, and, by making the transition smoother, to increase retention at the College of Engineering (COE). The programs are: (a) Peer-Assisted Learning, (b) Connector Faculty, (c) Diagnostic-driven Early Intervention and (d) Cross Course linkages.**

Keywords—Early Engineering Students; Peer-Assisted Learning; Supplemental Instruction.

I. Background & Theoretical Framework

There is a national growing concern among industry, government and educational leaders about the need to increase the number of students graduating from science, technology, mathematics and engineering (STEM) disciplines [1]. In 2006 a report from the National Science Board (NSB) indicated that the production of STEM degrees in the USA is lagging compared to similar economies. In particular NSB indicates that there is a national need to increase the numbers of engineering graduates [2].

In his Interactionalist Theory of student departure Tinto (1993) introduced the concept of academic integration to link the students' experiences both social and academic, that influence their decisions to persist and graduate from college. Academic integration includes a range of experiences both inside and outside of the clasroom such as academic succes, informal contact with faculty and social and community participation [3, 4, 5]. Ohland et al., (2009) indicate that there is a 40% departure rate of first-year engineering students [6]. In a seminal study Seymour and Hewitt (1997) indicated that these early "leavers" typically fall into two categories (i) those that are facing academic probation and (ii) those that perceive the academic and social environment of early engineering as hostile and not engaging [7, 8]. More recently, Marra et al. (2012) also concluded that academic factors such as curriculum difficulty and poor teaching and advising as well as non-academic factors such as "lack of belonging" contribute to students' decisions to leave engineering [9].

The theoretical framework guiding our reseacrh project is based on Tinto's therory and includes elements from Seymour and Hewitt (1997) studies on student attrition among STEM students. Our objective is to consider the student experience as defined by their academic and social experiences. To achieve this objective the EEES project integrates four component programs that address both categories of leavers-- those facing academic difficulties and those that perceive the education environment as hostile and not engaging.

In this work-in-progress we present preliminary results from the implementation of the Peer-Assisted Learning (PAL) and Supplemental Instruction (SI) programs at MSU and LCC respectively.

II. Project Overview

The project components and their interactions are depicted in figure 1 and include: a) Connector Faculty program to engage engineering faculty with early engineering students, b) PAL/SI to aid student learning in traditionally challenging courses, c) Dx-driven Early Intervention to provide formative assessments (gateway exams) in key courses with follow-on tutorials and d) Cross Course Linkages program to develop and exploit connections between key courses. In the following sections we will describe the implementation and preliminary outcomes associated with the PAL and SI program components.

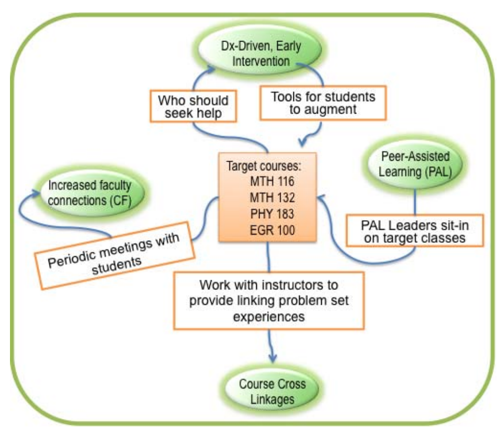

Fig. 1. The EEES Project Components: An Integrated Structure

A. *Supplemental Instruction & Peer-Assisted Learning*

The EEES project peer-tutoring programs are based on the supplemental instruction model of voluntary participation developed at the University of Missouri-Kansas City that integrates course content with active student learning in the context of peer-facilitated study sessions [10, 11]. PAL and SI target traditionally challenging courses that are barriers to student admission or transfer to the COE. Student leaders regularly schedule informal review sessions to discuss course materials. While working together in an environment that fosters discussion and collaborative work, students learn to integrate course content and study skills. The target courses at MSU include: Physics, Pre-Calculus, Math 116 (College Algebra) and Math 138 (Calculus I). LCC has had a strong and effective SI program for close to two decades. Funding from the EEES project resulted in the expansion of the courses originally covered by SI to include STEM targeted courses necessary for transfer to engineering at four-year institutions. These courses include the Calculus series (5 Math courses in total), Physics (2 courses) and a MATLAB & numerical methods course (CPSC131).

B. Data Collection and Analyses

Our data collection includes student and faculty surveys to measure participants' awareness of the program, expectations of program success, and experiences with program participation. We also collect standard course data on student learning outcomes, course grades, and attendance data including number of tutoring sessions and number of contacts. We used SPSS V 19 for all analysis and performed 1000 bootstrap iterations to estimate confidence intervals for all regression coefficients, using a 95% confidence interval for significance.

III. RESULTS

To understand what, if any, differential impact there was for participating in PAL and SI we compared the academic outcomes for students who participated vs. those who did not while controlling for other variables. To determine if there are interactions among variables that impact outcomes, we performed regression analyses for each of the target courses in both PAL and SI programs. For all regression models we used academic indicators such as math ACT, first math gateway score, math placement or prerequisite course scores, as well as PAL/SI attendance, gender and ethnicity categories as independent variables. Results include data collected since Fall 2008 through Spring 2011.

A. Supplemental Instruction (SI) at LCC

SI has been implemented at LCC in a large number of courses for several years before the EEES project; the program has been institutionalized and most students are aware of it. While participation in SI varies widely by course (between 41% and 81%), participants tend to attend frequently, suggesting that they find these sessions worthwhile. We analyzed the impact of SI on student academic outcomes for eight courses enrolling 1288 students. For Math 121, 151, 253, and Physics 251, the Beta for SI was significant ($p < .05$), meaning that when controlling for academic ability, SI participants perform better in these courses than non-participants (Table I).

TABLE I. SUMMARY ANALYSES FROM SI COURSES AT LANSING COMMUNITY COLLEGE

Course	Regression Model (R^2)	Beta for SI	Average increase in number of 2.0+ grades for SI participants	Average increase in course grades for SI participants not withdrawing
Math121	.197[2]	.071[4]	3%	.21
Math122	.173[2]	.003[1]	N/A	N/A
Math151	.292[2]	.360[2]	18%	.56
Math253	.408[2]	.272[4]	11%	.42
Phys251	.340[2]	.210[4]	10%	.34

1. Not Significant; 2. Significant $p < .000$; 3. Significant $p < .01$; 4. Significant $p < .05$

B. Peer-Assisted Learning (PAL) at MSU

The participation rate for students who had attended at least one PAL session ranges between 18% and 26% across the target courses. After controlling for academic and demographic variables, it appears that the impact of PAL is very modest, ranging from a small impact in Math 116 and Physics 183, to no-impact in Math 132. Given that the regression models account for only 16% to 23% of the variance, there are many other factors that are not being measured that may impact students' outcomes. However, the overall differences in student outcomes are slight (Table II).

TABLE II. SUMMARY ANALYSES FROM PAL COURSES AT MICHIGAN STATE UNIVERSITY

Course	Attended at least one PAL session	Women enrolled (PAL attendees)	Regression model (R^2)	PAL attendees course grade[a]
Math 116 (n=111)	12.9%	49.4% (66%)	16.4% ($R^2 = .164$)[b]	0.08 higher (beta = .072)
Math 132 (n=28)	2.3%	31.3% (64%)	23.2% ($R^2 = .232$)[c]	Not significant
Physics (n=452)	4.6%	23% (19%)	19% ($R^2 = .19$)	0.1 higher (beta = .011)

a. After controlling for all other variables.

b. Significant variables: ACT (beta = .176), Gateway score (beta = .255), MSU Math Placement score (beta = .086), White (beta = .152), and Gender (beta = -.165).

c. Significant variables: Math Gateway score (beta = .214) and Math ACT (beta = .134), Math Placement score (beta = .271).

IV. SUMMARY AND FUTURE DIRECTIONS

Our preliminary results indicate that:

- At LCC, SI is well attended and appears to have significantly positive effect on learning outcomes in most pre-engineering courses.
- At MSU, PAL is poorly attended and appears to have no significant effect on learning outcomes in most pre-engineering courses.

There is much debate on the impact of voluntary SI programs on student outcomes. It is not clear if the improved student outcomes are due to students who are more academically capable attending SI more frequently. However, reports in the literature that substantiate this viewpoint are difficult to locate. Our plan is to investigate the institutional and programmatic characteristics that promote success in voluntary peer tutoring and that might contribute to the differential success of the PAL and SI programs.

***Abstract*—In teaching introductory computer programming courses, problem solving with computers is an important topic and algorithm design is essential. We developed a team-based project to teach students solving real-world problem. Students are provided with six satellite images of the Deepwater Horizon oil spill in the Gulf of Mexico and asked to develop computer programs to outline oil contaminated areas. Working on the project in a team, students conducted initial analysis of the problem, identified patterns of oil slicks by visualizing satellite images, and designed algorithms to delineate the oil slicks. The open-ended problem allowed the students to gain experiences in user interface design, use of arrays, decision-making, and repetition with hands-on experience. The project has also been adapted in teaching classes of computer science general education and digital image processing.**

Keywords—problem solving; software development; first-year sequence; image processing; oil spill;

I. INTRODUCTION

The use of real-world projects in teaching STEM (Science, Technology, Engineering, and Mathematics) classes is not new. Research in education has shown the benefits on student comprehension and retention of projects that solve real-world problems [1] [2]. Furthermore, student's ability to see engineering's potential social contributions can stimulate female students' interest. However, real-world problems have seldom been brought in classes for incoming freshmen in Computer Science (CS) and Computer Engineering (CE). Rather, real-world projects are mostly used in junior-level CS/CE classes such as software engineering. Moore and Brennan have created a "real world lab" in their software engineering classes to foster industry-university collaboration [3]. Preston extended the labs to Information Technology education [4]. These projects have helped students to solidify and deepen their knowledge of project management, customer relations management, requirements elicitation and management, software development, database technology and communication skills.

Most real-world problems are open ended. Newman and Daniels et al. [5] have argued for the use of open-ended group projects to supplement the conventional lecture and laboratory teaching approaches. They showed that the projects can successfully get the students to think about how the ideas can be applied in practice. The use of such projects improves student learning, but, challenges exist pertaining to the assessment of team-based learning. For example, Sabin noticed the issues related to the assessments where both individual and collective contributions from students are taken into account [5].

Over the last ten years, many CS programs have seen less interest in computer science among high school graduates. Many students want to work in a field to allow them making a meaningful social contribution. It is obvious for those students to see such connections for disciplines like political science, art, biology, environmental science, or civil engineering [6]. No apparent connection exists in entry-level computer science courses, at least by the titles of courses taught in CS/CE. To address the problem, Buckley and Nordlinger et al. have introduced socially relevant computing as a new way to reinvigorate interest in computer science [7]. They believe that computing for a cause, or computing as a means to solve problems, rather than as an end in and of itself, is key to attracting this generation to the discipline.

Although solving real problems is a useful way for students to gain "hands-on" experience in college, it is still difficult to find a meaningful problem for first-year computer science students to work on. Most entry-level course sequences in CS consist of *CS1*, *CS2* and *Data Structure*, with the *CS1* and *CS2* being the first two courses taken by CS majors [8]. In both courses, students learn the basic programming elements. In teaching the entry-level courses, software life cycle is an important topic and algorithm design is essential to this cycle. The two-course sequence emphasizes a programming paradigm with a focus on problem solving and algorithm development. Still, they are programming-centered and unappealing to an increasingly diverse student groups.

In this paper, we develop a project using satellite images of the Deepwater Horizon oil spill to teach students problem solving using computers. The oil spill in the Gulf of Mexico between 21 April and 31 July 2010 was the largest offshore spill in the U.S. history. To deal with this unprecedented disaster, researchers and management agencies have used satellite images to track the spill. The objective of the student project is to design image processing algorithm(s) and implement computer software to delineate surface oil slicks on satellite images. This paper describes the project and how it was used in teaching entry-level programming classes.

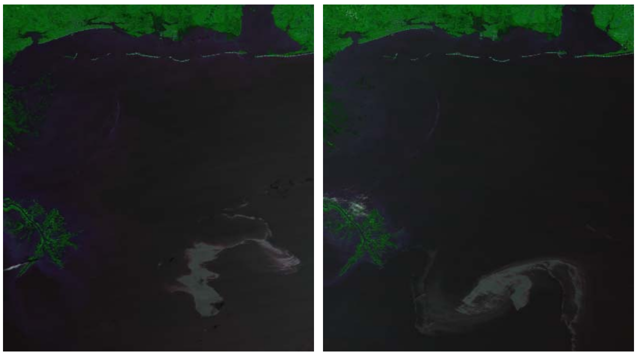

Fig. 1. MODIS images of oil slicks from the Deepwater Horizon oil spill in the Gulf of Mexico. To the left is the Mississippi River bird-foot delta, and the top right shows Mobile Bay. The oil slicks appear whitish in these images.

TABLE I. THE LINEUP OF SPECTRAL BANDS OF MODIS IMAGERY.

Band	Wavelength (nm)	Included?	Assigned Color
8	405 – 420		
9	438 – 448	Yes	
10	483 – 493		
11	526 – 536	Yes	
12	546 – 556		
13	662 – 672	Yes	
14	673 – 683		
15	743 – 753		
16	862 – 877		

A. *Deepwater Horizon oil spill*

The Deepwater Horizon oil spill was captured by several earth-observing satellites. Satellite images are used in a wide-range of civilian applications, including mapping, agricultural monitoring, environmental monitoring, disaster response, etc. MODIS (Moderate Resolution Imaging Spectroradiometer) is a key instrument aboard the Terra and Aqua satellites (http://modis.gsfc.nasa.gov/). The MODIS instruments provide images of the entire Earth's surface once every 1 to 2 days.

MODIS data covering the Gulf of Mexico were originally downloaded from the U.S. NASA Goddard Space Flight Center, and then processed using customized algorithms and software by the Optical Oceanography Laboratory at the University of South Florida [10, 11]. The processed MODIS data contained geo-referenced (or map projected) reflectance at 9 spectral bands (Table 1). Three of nine spectral bands (9, 11 and 13) were used to create Red-Green-Blue color images in BMP format. Examples of the MODIS sub-images covering the spill area in the Gulf of Mexico are shown in Fig. 1, while Table 1 lists the wavelength and the color assigned to each spectral band.

II. HANDS-ON PROJECT

Computer software development life cycle consists of five main phases, requirement analysis, program design, coding, testing and program maintenance [9]. As a user-oriented cycle, it evolves around user's requirements for the software. Though it is introduced in *CS1*, students usually work on specific problems and seldom experience the full cycle of it. As a result, many students view it as abstract and boring.

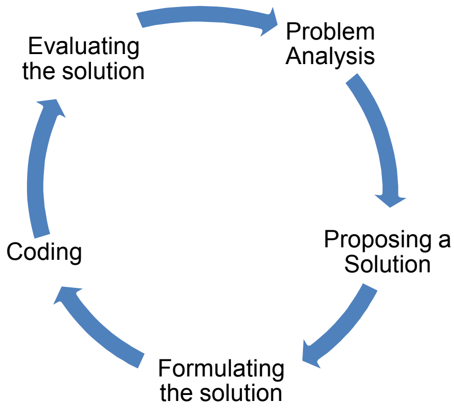

Fig. 2. Cycle of problem-solving process used in the project.

A. *Problem Driven Approach*

To bring real-world problem solving into *CS1* and *CS2*, we revised a generic problem solving process for use. The process evolves in fives phases of analyzing problem, proposing, formulating, implementing, and evaluating a solution (Fig. 2). In adapting the project, the instructor first introduces the problem, fundamentals of color image interpretation and how to display images in Java. Then, students are asked to develop a Java program to visualize ocean color satellite images during phase I of the project.

Displaying satellite images often creates excitement among students, but it does not present a direct solution to the problem. To move forward toward a solution, the instructor may ask students to suggest software functions useful for distinguishing oil from water. We would like students to consider algorithm design and software development as a problem-driven process, not just for students' self-satisfaction or as they are told to. In phase II, the instructor asks students to implement an image "sampler" to allow a user to move the cursor over an image and to click and display the color values of a pixel. Students are asked to use the implemented "sampler" to collect data for further investigation.

The phase III of the project starts with data analysis in Microsoft Excel. Students create scatter plot(s) with the data they previously collected, and develop linear function(s) to separate oil pixels. Instructor gives a lecture on the implementation of a thresholding algorithm with decision-making and repetition statements. Students will implement their algorithms and apply to the satellite images.

At the time this project is introduced, students should have learned array, decision, and repetition structures, and they should start to learn event handling and user interface in Java.

Typically, array, decision, and repetition are taught in *CS1*, and event handling and user interface are introduced in the beginning of *CS2*. For many Computer Science and Computer Engineering programs using Java in teaching an entry-sequence class, this project would be started late in the first semester or in the beginning of the second semester. If the students are not capable of developing a user interface from scratch, the instructor may provide students an initial user interface to use.

Fig. 3. MODIS image with oil spills outlined.

B. A Simple User Interface

The project is introduced to students with breaking news on the Deepwater Horizon oil spill, as there is extensive news coverage on the internet about this disaster. Instructor then introduces the problem of mapping oil slicks on satellite images, and presents a problem-solving process. Apparently, images of oil slicks need to be displayed before a solution could be found. So, the first task is to develop a Java program with user interface to visualize MODIS images.

Fundamentals of interpreting color images and how they are displayed with Java are discussed in class. The computer application has a menu bar and an area for image display (Fig. 3). A File menu consists of Open menu item which reads in an image in BMP format and Exit menu item. The primitive user interface has minimum features but is still flexible enough to allow students to add in more functions later.

- The main class will extend *java.swing.JFrame*. Its content pane, a *JPanel* object, consists of a *JMenuBar* object and an *ImagePanel* object. A *JMenu* on the menu bar has multiple instances of *JMenuItem* with each instance registered as an action listener.
- The use of *JFileChooser* allows user to browse folders to locate an image to read.
- The *javax.imageio* package has classes supporting different image formats including JPEG, PNG and BMP. Students can use *ImageIO* to read an image into a *BufferedImage* for future processing.

In phase I, students will experiment with basic user interface design and file I/O. They are provided with six MODIS images in BMP format.

C. Visualizing Oil Slick Patterns

Displaying satellite images does not present a direct solution to the problem. A solution relies on the visualization of differences between pixels contaminated by oil slicks and the rest of image pixels. Oil slicks appear "brighter" than the surrounding water on the selected images because they were collected under strong sun glint [10]. In the beginning of the phase II of the project, instructor will display the image and raise questions such as *"What makes oil slicks different from water?"* and "*What are the software functions needed in order to catch the differences?*" As the perceived color of a pixel is formed by three values, namely red, green and blue (RGB), it's intuitive to collect the color values of oil pixels and inspect. If students can collect image samples on different subjects and examine their values, they may identify the differences.

A useful software function would allow a user to click on an image and display color values of a pixel. Students can use *MouseListener* class to return the location of cursor and, then, retrieve the color values of a pixel for that location.

- Students can make an image display panel to implement *MouseListener*. The *MouseEvent* has a *getPoint()* method which returns the location of a cursor.
- The location can be mapped to row and column indices of a *WritableRaster* object.

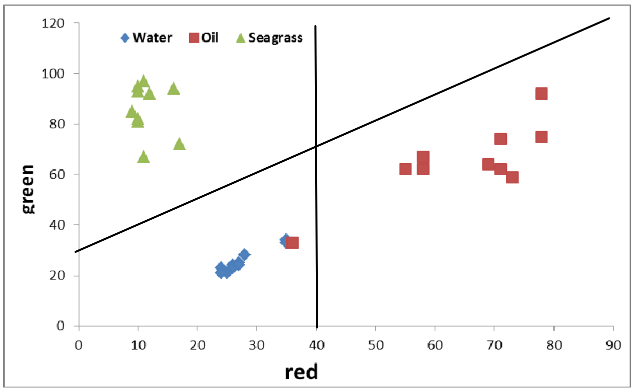

Fig. 4. Scatter plot of sample pixels over red and green colors.

By clicking on the image, students can display color values of a pixel on screen (Fig. 3). They can collect data for oil, land, water and vegetation on the image, record them in Microsoft Excel spreadsheet and create a scatter plot. A scatter plot is a mathematical graph which displays two variables for a set of data. It can suggest various kinds of correlation between variables. Scatter plot(s) of sample pixels is created using spectral bands (or colors) as variables in Microsoft Excel (Fig. 4).

With three spectral bands, students are able to create three scatter plots using different pairs of colors. Oil pixels tend to fall into a cluster, so do water and vegetation pixels. Threshold values or functions can be identified on scatter plots to separate oil pixels from other subjects. Students can create lines to separate oil, water, and vegetation (Fig. 4).

D. Outlining Oil Slicks

To outline oil slicks, students need to first formulate linear equations for the lines they have created on the scatter plots and design pseudocode to use these linear equations in their programs. The pseudocode consists of nested repetitions to iterate through each pixel on an image, and decision structures which uses image thresholding to label the pixels of targets. A sample pseudocode is given as,

```
for each row x
   for each column y
      get red color of a pixel as pixel_red
      get green color of a pixel as pixel_green
      get blue color of a pixel as pixel_blue
      if pixel_red>40 then
         //Oil
         set all color values to 255 for the pixel
      if pixel_green>pixel_red+30 then
         //Vegetation
         set green color to 255, other color values to 0
   end
end
```

Thresholding is the simplest method of image processing [10]. By thresholding, a pixel is converted into a labeling color or unchanged depending on whether the original color value is within the threshold range. The labeling color for oil pixels is white (255 for all RGB values), and green for vegetation. In Java, one can create a *WritableRaster* from the image using *getRaster()*, and modify the color of a pixel using *setSample()*.

```
WritableRaster raster = bfimage.getRaster();
raster.setSample(x, y, band, value);
```

A menu would be added to the menu bar for the algorithm. As the threshold values need to be adjusted in thresholding different images, a sliding bar seems a useful addition to the program.

The project is a good example to teach students computer algorithm design as a problem solving process. In solving a real-world problem, even a well-designed algorithm may not produce perfect result. On thresholded images, barrier islands and clouds could be mistakenly labeled as oil, and diluted oil-contaminated water are often identified as normal ocean water. Students are encouraged to do more research on the problem, research on a more robust algorithm for use. For instance, students may collect a set of mislabeled pixels, add them to the scatter plots, and redefine threshold functions.

E. Societal Impact of Computing Science

The summary lecture reviews the problem solving process, discusses societal impact of computing science and shows other potential problems that could be solved by adapting the project. Instructor may introduce several advanced methods for students to consider, where suggestions are given in the optional phase IV of the project. When the boundary of a cluster of oil pixels cannot be described precisely with a simple linear function, a higher order polynomial function is needed. Although the employment of such a function improves the accuracy of recognition, it also increases the computation time. Students should understand that there are alternative solutions to a given problem, and they should be aware of tradeoffs between different algorithms.

Computer technology is one of the greatest scientific achievements of the 20^{th} century. Its use has direct effect on our daily life as well as in our social life. Both CS and CE students need to understand the basic cultural, social, and ethical issues inherent in the discipline of computing [11]. They need to develop the ability to ask serious questions about the problems people are facing and to evaluate proposed answers to those problems. In the summary lecture, the instructor addresses the basic elements of ethical analysis and claims. Specifically, students need to learn to discuss their claims rationally based on the results of their analyses. The results of computer algorithms will not be perfect or completely accurate. Students should discuss the ad hoc of their approaches and know the limitations of computer algorithms. In concluding the project, a documentary video "Hindsight and Foresight, 20 Years after the Exxon Valdez Spill" [12] is played.

TABLE II. OUTLINE OF PROJECT WITH SUPPLEMENTARY

Course Material	Media Type
Java SE, Eclipse IDE to be downloaded	Software
MODIS images	BMP format
Lecture 1 – Introduction & News Coverage	Powerpoint & Video
Project phase I: Building a graphical user interface to display color image	Assignment & Java Solution
Lecture 2 – Event handling in graphical user interface	Powerpoint & Video
Project phase II: Sampling pixels on color images	Assignment & Java Solution
Lecture 3 – Algorithm design for problem solving	Powerpoint & Video
Project phase III: Image thresholding	Assignment & Java Solution
Lecture 4 – Summary & "20 Years After the Exxon Valdez Spill" by NOAA	Powerpoint & Video
Project phase IV: Advanced image thresholding (optional)	Assignment & Java Solution

III. ADAPTATIONS OF PROJECT

Instructional materials with software solutions in Java are available at IEEE Real World Engineering Projects program (http://www.realworldengineering.org/), and summarized in Table II. The portal is designed to disseminate high-quality, hands-on and team-based projects for the first-year electrical, computer engineering, computer science, biomedical engineering and electrical engineering classrooms.

A. Suggestions on the Use of Project

This project's target time frame is approximately eight hours. In a typical 3-credit hour freshmen class, the project will extend over 2-3 weeks. The activities of the project are following:

- 1 hour: Introduce Deepwater Horizon disaster and oil spill detection problem, explain the fundamentals of color image, review event handling and discuss image manipulations in Java. A 5-minute news report could be used in introductory.
- 2 hours: Students develop a Java program to open and display an image.
- ½ hour: Discuss *MouseListener* class, and explain how to create scatter plots in Excel.
- 2 hours: Students implement *MouseListener*, collect data and create scatter plots.
- ½ hour: Discuss how to formulate threshold functions and design pseudocode.
- 1½ hour: Students implement algorithm.
- 1 hour: Conclude the project. A documentary video may be played to the class.

The main software used in the project is Java, though solutions in MATLAB and Microsoft Visual Basic are also available. Solutions are exported as Eclipse projects (http://www.eclipse.org/downloads). The project is not to train students in digital image processing techniques. Rather, we seek to enhance our students' ability to solve problems by giving them access to the data and teaching them how to design algorithms to analyze. Pre-processed MODIS images are archived at many institutes, MODIS images of the Deepwater Horizon oil spill can be downloaded from http://optics.marine.usf.edu/ (under "Events => Deep Water Horizon Disaster"). If instructors and students are interested in images of different natural phenomena, they can download the software SEADAS (http://seadas.gsfc.nasa.gov/) and use it to process other MODIS images (http://modis.gsfc.nasa.gov/).

One can find extensive news coverage on this disaster and presents one news piece to introduce the project. We have found a documentary film titled "Hindsight and Foresight: 20 Years after the Exxon Valdez Spill" to be useful for this purpose. The documentary revisits the 1989's Exxon Valdez oil spill twenty years later to reveal lessons learned from coping with the disaster at the time. It is used to emphasize the project's societal impact and help students to understand how their own work might help others.

B. General Education Course

The project has been adapted in teaching Computer Science General Education class, *Problem Solving with Computer*, at Winona State University. This class is to introduce programming and problem solving for mathematics. It provides an overview of the principles of computer program design, and leads students through a complete cycle of problem solving using computers. Students develop programming projects to construct contemporary applications of mathematics. They learn to analyze the problem, formulate mathematical solution and actually implement it in Microsoft Visual Basic.

There were a total of 57 students who took the class in summer and fall 2012, with 48 students completing the project. Over 80% of students found "the project stimulating and intellectually challenging", 70% students agreed "their interests in the problem solving with computers has increased as a consequence of this project". Students consider the project "… very interesting…" and "… like the idea of the project and the end result …", they suggested "the project would be much more stimulating in a full semester term".

C. Digital Image Processing Courses

MATLAB is a programming language for building an interactive environment to carry out computationally intensive tasks. It is often used in teaching CS/CE/EE Digital Image Processing courses. The software has built-in functions for solving problems which require data analysis, signal processing, and several other types of scientific computations (http://www.mathworks.com/). MATLAB provides a Graphical User Interface (GUI) development environment which gives the user a simplified experience in running a program. Software solutions in MATLAB are also available per request. With MATLAB, students can build more advanced image segmentation and pattern recognition algorithms.

IV. Conclusion

We have developed a hands-on project to teach first-year undergraduate students in computer science, computer engineering, and electrical engineering in problem solving with computers. In developing a computer algorithm to outline oil slicks on satellite images, students learned to analyze the problem, propose a solution, and formulate the solution in mathematical forms and in pseudocode, and then implement and evaluate it. Students gained hands-on experience in several basic programming related concepts such as user interface, array, decision-making, and repetition. The project demonstrated how an algorithm would need to be designed rather than simply providing a solution. The project also showcased the societal impact of computing. We expect to continue and strengthen this type of project for beginning students in the coming years.

Acknowledgment

The project was partially supported by the IEEE Real World Engineering Projects program, by the GOM Research Initiative through the Center for Integrated Modeling and Analysis of the Gulf Ecosystem (C-IMAGE), and by the U.S. NASA through a grant to C. Hu.

***Abstract*—Student, experiential-learning, engineering, competition teams (SELECT) provide an opportunity for engineering students to practice engineering technical and professional skills. The low representation of women in SELECT is often rationalized as a lack of interest by individual women rather than systemic processes that discourage or exclude women. We employ a qualitative-interpretive design and a cultural constructionist lens to bring into focus the interplay of individual interests, understandings of appropriate gender roles, and structural elements that contribute to a culture of inclusion or exclusion. Primary data consist of 90-minute semi-structured interviews of eight team members and one non-member. By interpreting the narrative portraits of two female students, we show the construction of a team culture where in general women are discouraged from participation based on stereotyped gender roles, by night campus attitudes, and by peers who challenge or ignore their skills, contributions, and interests. One woman persevered through the male-dominated culture because she received the encouragement and support of male peers who engaged as comrades and champions. This paper offers recommendations for institutions to demonstrate commitment to equitable access to experiential learning and to nurture student peer cultures that challenge historic gendered ideologies and rhetoric.**

Keywords— experiential-learning; interest; competition teams; gender; culture, diversity

I. INTRODUCTION

Student, experiential-learning, engineering competition teams (SELECT) provide an opportunity for engineering students to practice engineering technical and professional skills while engaged in competitive experiential learning design/build projects. Students form teams to design and build an engineering artifact, usually some kind of vehicle. These teams may be strictly extra-curricular, co-curricular, or constitute the main focus of a complete course within the degree curriculum, usually a design-focused or capstone course. Some teams operate under close supervision of a faculty advisor, while others more closely resemble any other student-run organization where members only engage their faculty or staff advisor when paperwork needs to be signed.

As the popularity of SELECT have increased over time, institutions are dedicating increasing resources to these teams. In a time when economic pressures and accountability demands require universities to do more with less, SELECT are a visible and promotable means to provide experience-based learning opportunities. Team photos, often highlighted in promotional materials for prospective donors and students, depict students engaged in authentic, hands-on, collaborative learning in a competitive environment. A sampling of materials featuring successful SELECT reveal the overwhelming preponderance of student images are white and male.

While these experiential learning opportunities are theoretically open to all engineering students, in practice, cultural and attitudinal norms limit who may participate [1]. Participation rates of under-represented population (URP) students in many competition teams are exceptionally low, even when normalized for engineering enrollment.

With the opening of our institution's engineering design and leadership facility, teams were brought into the public view. Moving the teams into this central, high-visibility facility revealed disturbing demographics and behaviors. The absence of women and racial/ethnic minorities was suddenly visible to the public (including donors and prospective students), and culturally sensitive faculty in the College.

The absence of females on one vehicle team (V Team) was not lost on a female who did join the team. In an interview for this project she explained, "*I talked to older guys on the team and I was like 'why aren't there older girls on the team?' The guys said they've always had one girl show up and get involved and then she kind of leaves.*" Male 6 corroborated that observation, *"there weren't any women on the team until two years ago. We would have some girl show up at the first couple of meetings, but we never had anyone stick around."*

The low representation of women in SELECT is often rationalized as a lack of interest from individual women rather than systemic processes that discourage or exclude all but the most assertive women. A male student interviewed for this project explained the attrition of females from V Team: "*If they have left, it's typically not been because they were shunned or anything like that, it's just they decided they aren't really that interested anymore.*" Another member echoed that opinion but added an additional stereotype: "*The more I realize it I think they* (females) *are just not interested in that type of engineering. They don't want to get their hands dirty, which might be a trait for girls.*"

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

The male teammate quoted below brushed off language and cultural differences as an explanation for why two female international students would probably not continue on the team and grounded his explanation in lack of interest and commitment. Similarly, in his closing statement, he does not link the fact that "*engineering is male dominated*" to the absence of girls on the male dominated competition team.

Male 3: *We have two girls that are [international students], they speak [non-English]. They don't speak very much English. And we have a senior who speaks [non-English] with them. They're half way committed as much as I was last year. I don't see them sticking around or going to competitions. They show up like they are interested but I doubt for long; they won't* (keep coming). *Uhmm, just commitment, I guess also language barrier and they're just not as committed as we need them to be. You have to give up part of your life to be part of the V Team. We've never had any girls really. Not that I know of there hasn't been any consistent girls that were team members, like critical team members. Engineering is a male dominated degree I guess, and it's hard to get girls in (*engineering*). I know there are girls in my class that are engineers, (I guess) they are just not interested* (in V Team)...

Accounts like these reflect culturally normative explanations for the absence of women [2]. Explanations grounded in the rhetoric of lack of interest or stereotypes ignore the structural, ideological and social conditions that together construct learning spaces, such as SELECT, as open and welcoming or closed and unfriendly [3].

In the larger project, of which this study is a part, we seek to identify and explain what factors contribute to cultures of inclusion or exclusion among varied SELECT. This report will compare the experiences of two female students who acted upon equally strong interests in engineering and this SELECT to address the research questions: ***How do elements of gender ideology and the rhetoric of interest contribute to the peer culture for V Team? How does this peer culture create an environment that supports diversity or reinforces gendered exclusions?***

II. Research Methods

While qualitative methods have multiple traditions, contemporary qualitative methods emphasize that cultural understandings, experiences and structures are socially constituted [4]. We employ a qualitative-interpretive design and a cultural constructionist lens to bring into focus the interplay of individual interests, understandings of appropriate gender roles, and peer culture that contribute to a culture of inclusion or exclusion on one SELECT.

Interviews and observations constitute the preferred approach for studying cultural phenomenon [5]. The study we present here develops primarily from analysis of 10 semi-structured interviews of eight (majority male) V Team members lasting one to two hours, but also observations of team activities, examination of team documents, as well as web and social media sites. To provide an additional perspective on team culture, a female engineering student who had been a team member for one year and left was also interviewed.

The semi-structured interview protocol allowed the interviewer to augment standardized questions with additional probes as needed. Interviews were transcribed, reviewed for accuracy, and coarsely coded using N-Vivo qualitative data analysis software [6]. Quotations from student interviews are used extensively. Their understandings, perceptions, and language are the data for this paper, specifically their responses to questions on these topics:

- When did you first know you were interested in engineering? Who or what fueled that interest?
- Would you consider yourself a tinkerer?
- On a scale of one to ten, how would you rate your technical proficiency? What experiences inform that rating?
- Why did you join this particular team?
- What are your impressions of this team?
- How would you describe the culture of this team?

Student responses are generally preceded by a member designation assigned to that participant. Words or excerpts that appear in *italics* represent the actual language of the students. Words or phrases inside parentheses ( ) have been added by authors to add context or clarify participants response. Words or phrases inside square brackets [ ] replace or delete identifying information and are used to ensure anonymity of participants and other entities. A (L) indicates that the participant or interviewer is laughing.

III. Interest, Peer Culture, and Gender Ideology

Explanations for students' interests in particular majors and professions arise from many sources. Economists and some educators suggest that considerations of earnings potential and status attainment influence major interests [7]. Psychologists tend to focus on intrinsic factors and individual characteristics [8], [9]. Integrating elements from simplistic materialist and individual psychological explanations, Social Cognitive Career Theory (SCCT) also incorporates the notion that interest is socially constructed [10], [11]. Within this theory, interest is predicted by self-efficacy. Both self-efficacy and interest, along with outcome expectations and social influences, are directly linked to choice of pursuit and intention to persist. In other words, a student's choice of major/career path/extra-curricular activity (pursuit) derives from their interest in the activity, their confidence in performing the activity (self-efficacy), and their expectations of desired outcomes. The enabling or constraining characteristics of the social environment in which a student's choice is enacted will either support an intent to persist or lead to a decision to withdraw. SCCT defines that social environment as the choice-proximal environment and maintains that the comprising social and material supports and barriers play a crucial role in maintaining choice goals.

Experience-based activities, such as SELECT, are choice-proximal environments where interests encounter barriers and constraints. These environments are heavily influenced by peer culture, yet little is known about the processes and dynamics that make peer culture a powerful influence on student experience and desired (or undesired) outcomes. According to

Dalton and Crosby college peer culture “is the single most important influence on student learning, values and behavior in the college setting and yet remains one of the least studied and understood aspects of higher education” [12, pp.1]. Peer culture consists of the norms, language, values, practices, and beliefs that guide the behavior of members on a daily basis and serve as a frame of reference that group members use to interpret the meaning of events and actions, both on and off campus [5]. Across campuses, in the Greek system, athletic teams, student organizations, etc., peer cultures act as sites where gender, race and class stereotypes are often reproduced but sometimes challenged [13].

Many of the activities and interactions that shape student-defined culture occur during the evening and night hours when faculty and staff are not around [12]. Matthews named the resulting environment “night campus” [14]. “Night-campus” is not well-understood as this culture operates in parallel to the institutionally-defined culture in time and space that faculty rarely visit. Similarly, SELECT generally work in relative isolation with the only visible activity typically associated with special events to promote the competition or their sponsoring organizations or departments. Therefore, little is explicitly known about the team composition, interactions, and practices constructing their peer cultures. These peer cultures can be constructed in ways that promote positive outcomes and persistence (social supports) or in ways that are hostile and drive students away (social barriers).

Historically, the majority of SELECT have been male-dominated student organizations engaged in the design, construction and competition of culturally-understood-masculine technologies (race cars, airplanes, off-road cars). Female engineering students whose interests lead them to participate on male-dominated competitive teams must overcome barriers that arise from cultural notions of appropriate feminine behavior [15], [16]. Ideologies of race, gender, sexuality, etc. frame cultural understandings of appropriate behavior and label positions or actions as “right” or “wrong” and have a legitimizing function [17], [18]. Women who wish to act on interests and participate on most competitive, experiential-learning teams encounter a learning space whose peer culture is informed by masculine norms, language, values, practices and beliefs. One older male team member described the culture as a “*fraternity*”:

Male 6*: The friends I have on the team have really become my fraternity. … I’m sure some of it* (why there were no women on the team) *was that it was difficult to be in our group, just because we were so tight knit and, I don't know, we probably came off as an intimidating group, even though every year we said, 'we got to get a girl this year.' (L) Just because you see other teams every year at competition and alot of teams will have one or two.*

The fraternity-like peer culture acts as a gate-keeper – rewarding those who understand and are comfortable with the language and practices and excluding those who are not. This was the culture Female A encountered when she acted on her interests and attended an organizational meeting for V Team.

Female A*: When I walked in* (first organizational meeting) *I wasn’t really sure; it was a bunch of older guys, most of them were seniors, it was awkward, strange…I was a freshman girl, I didn’t know what to do.*

IV. Parallel Portraits of Interest in the V Team

In this section we provide excerpts from the narratives of two female students with very different outcomes as illustrative data for the peer culture they encountered within the V Team environment. These data arise from responses to questions related to the elements of SCCT. Interpretative comparisons of their experiences will follow in the next section.

Female A (member): Female A began participating on this SELECT first semester of her freshman year. As a sophomore, she served as the design lead for one of the vehicle’s sub-system. Interviewed the first semester of her junior year, Female A had ascended to an over-all leadership position with logistic and external relations responsibilities.

Female B (non-member): Female B began participating on this SELECT the first semester of her freshman year (Female A’s sophomore year). She participated for one academic year (fall and spring), but did not continue. She was interviewed first semester of her sophomore year.

A. Engineering Spark (interest):

Female A: *My grandfather was Vice-President of Manufacturing at* [aerospace company]. *So I grew up with a lot of history and background. Aerospace engineering just always seemed so interesting and innovative. Also, I was always good in math and science like my dad. Coming in, I wanted to be a designer, to design planes. Growing up my older brother did a lot with Legos and stuff and everyone thought he would be an engineer. I was more of a team-oriented person in high school; I like to be around people.*

Female B: *I decided I wanted to be an engineer during my sophomore year in high school when I went and visited my sister at her place of employment. All of the people she worked with were engineers. I got to play on a flight simulator. It was the coolest thing in the world. I was like, 'okay, how do I get to play with these toys for a living?' Then from there I kind of went and looked into engineering more, because I had never really heard about it. I knew it existed but I didn't really know what it was. I did a lot of research. I decided I wanted to be a* [major deleted] *engineer.*

B. Technical Proficiency (self-efficacy):

Female A: *Prior to joining the team I hadn't done any mechanics, other than the little my dad showed me with my car. I've never like torn apart a car or anything like that. All this* (technology) *was new to me. I never used tools around the house. I would honestly say on a scale of one to ten my technical proficiency is about a six. I do have technical experience but I don't feel like it is a strength of mine. I wasn't much of a tom-boy, I was a girly-girl.*

Female B: *What appealed to me about engineering was the technical aspect; I've always loved playing with the new toys. It's always kind of had a fascination for me. One of my favorite toys growing up was the chemistry models. I would mix those with Legos and build these ridiculous things (L). I* *would pretend that I had built something really cool though it probably looked really dumb (L). I liked the hands-on activity. I really liked the actual building of it and seeing it transform in front of my eyes from a pile of blocks to a ten story tower or whatever. Now I am really comfortable using tools around the house. Overall, on a scale of one to ten I would rate my technical proficiency at a seven…over the past few years I've picked up welding. My brother-in-law taught me and every break I get I go and weld with him on projects. I also put in wood floors for a living so I use lots of saws and stuff. I haven't got it yet, but I am working on my pilot's license.*

C. Join Team (choice):

***Female A**: I joined the team because I was really interested in the engineering aspect of it. I thought it was really cool how you could build a* [vehicle]. *That to me just sounded really cool. A lot of people join because they are interested in racing. I had no interest in that at all, I'm scared of that (L). The day I set foot on campus I never imagined myself being a leader on the Team? No, no way at all. (L). That probably is the last thing I thought I would do. No one ever believes this is what I am doing.*

***Female B**: When I came to campus for a tour, I think it was my junior year of high school, the first thing you see when you walk in the facility is this* [vehicle]. *I was like 'okay, what is this* [vehicle] *about?' And they told me and I was like, 'okay, I have to join in that.' Then, first week of school comes around and they had all this information out and I was like 'okay, I want to join.' And I did.*

D. Hope to Gain (outcome expectations):

***Female A**: I am hoping it will help my career when I get out of college. It has helped me very much know what industry I want to go into or type of job I want. I just hope when I get into industry things will be more, I'll be able to pick things up more because I have this background and experience working with people and different types of programs and software that maybe others weren't exposed to.*

Female B: (I wanted) *to learn a lot about* [vehicles] *because that was something I didn't know a whole lot about and I would like to know something about. I am very curious.*

E. Perception and Experience of Team Culture (peer culture-choice-proximal environment):

***Female A:** The thing about the team, if you are new and you want to get involved you have to push yourself to get involved. You have to be like 'hey, I want to get involved.' They don't reach out. You really have to push yourself to get involved or ask for stuff to do and if you need help you have to not be scared to ask for help.*

***Female B:** There was never anything to bring in new people. You really had to swim upstream to be able to get into it. There wasn't any training on building things. I went into it not knowing anything about* [this technology], *nothing at all. I really wanted to learn this stuff but then there was no way to jump in. It was very difficult. I was always like waiting for something to happen and then nothing ever happened. The atmosphere was kind of like 'we know how to do this and it will be faster if you aren't here.'*

***Female A:** I got close to some of the older guys and they really encouraged me to stay and they didn't see me as a girl, they saw me as a team member. I mean it could be so easy to be 'I am the only girl on the team.' But if you're treated as everyone else, what's the difference. Like the two grad students, they're not really on the team, but they are still around and they have both always encouraged me. They have always pushed me even when I felt like I didn't know anything. They always told me 'believe in yourself.' The hard time is with yourself, like 'do I want to commit all this time and am I even valued on the team'. Everyone has been at that point, whether you are a boy or a girl. I am friends with them all and I feel welcomed and comfortable. I've always been encouraged to stay and sometimes I think that is what it takes.*

***Female B:** I told them that I wanted to work in that area (*welding frame*) and they were like 'okay show up at this time' and I did and no one was there. It was just so hard to get involved in it. They had Saturday work days. We would all come in and we would just sit around. One Saturday, I went in to learn how to do CAD because we were supposed to be having a little session on CAD101, a weekend workshop. I go in and they're like 'okay, I want you to build this in CAD.' I've never used CAD, never built anything in CAD before and so 'I was like I don't know what any of these things mean,' and they just kind of left. They just handed me something and said 'build this' and left. I was like, 'I don't know how to build this (L).' I guess it was a trial by fire and I failed.*

F. Role of Faculty Advisor (choice-proximal environment):

Female A: [Advisor] *he's really good...he's someone who most of the leaders on the team are really close to.*

***Female B:** I met him twice and I don't really know much about him.*

V. How the Flames of Interest are Fanned or Suffocated Within the Choice-Proximal Environment of V Team

"Under the proper educational conditions, a spark of intrinsic interest can be nurtured into a flame of committed life purpose" (Dewey, 1897)

In these narrative portraits, Female B expressed greater pre-conceived interest in the particular design project and goals of V Team and even had a relevant skill that she assumed would be valued between the time that she first was exposed to the team during a pre-college campus visit and her matriculation to the college. She expressed stronger expectations and goals within her reasons for joining V Team. Using the rhetoric of interest, one might predict that Female B would be integrated into the team culture and become a valued member. However, the social supports and barriers comprising the choice-proximal environments encountered by these two students led to Female A persisting and Female B retreating.

Male team members recognized that the culture of V Team posed challenges for females. *Male 6 explained, "it's not that they* (older male members) *are really cold but they're not as* *open unless people really step up and so I can see where being a female and maybe feeling intimidated or just unsure, that that would come off as a 'we don't want you type thing.'"* Both Female A and B perceived entry into the team as difficult. They both recognized that the peer culture active in V Team was masculine and required new members to be pro-active or even aggressive in claiming a role or space within the team structure.

However, the team composition changed significantly between the times Female A joined and Female B attempted to join. Female A joined the team as a freshman when there was strong and competent senior leadership. Most team members had participated continuously for four years. The team had just come off an exceptionally successful competition season. Morale and confidence among senior core leaders was strong. However, membership ranks did not include many juniors. As a result, the freshman cohort of which Female A was a member had to assume the team leadership roles the following year as sophomores. The iteration of the team that Female B faced the following year was short on established members, leadership experience, technical skills and confidence.

The findings of Kvande and Rasmussen offer one explanation for the different peer cultures produced by the changing team composition [19]. In their examination of male and female professional engineers in different organizations, they found that different types of men react to the presence of women differently, resulting in either good or poor opportunities for the women. Comrades, men who have reached a certain position and confidence generally embrace the presence of women and form alliances that prove beneficial to women. Cavaliers and competitors tended to hold views that place themselves in a dominant position or in direct competition with women for status attainment. Alliances are not formed and relationships can be either patronizing or combative. Female A was able to form supportive alliances with older, technically proficient and confident, "comrades" like the following male:

Male 4: *We kept Female A around… like we tried to involve* [her] *more, tried to keep her on the team. We didn't make sacrifices but we attempted to remember her name and get her involved and we didn't treat her as a freshman who was not going to be around after the first semester. I think we all recognize that the team is all white, Caucasian males. We just go with it. But we are not closed minded to the idea of new people, minorities or sexes or anything like that.*

Female B joined V Team at a time when there were few older leaders. Younger male members were sorting themselves out and not confident in their status. With this void of team leadership, the less-confident members did not reach out in support of her interest and skills. Also, the team was short staffed in general which made it difficult to engage new participants and learn about individual skills.

Female B**:** *I never took it as malicious. It was never that 'we don't want you here', it was just 'we are not going to put out any effort to keep you here.' I think it was more the group culture, like it wasn't expected of them to do this* (reach out) *so they didn't feel it was necessary. …they were never taught how to teach or mentor. They would come up with with these ways to have us learn things, but then it was an epic fail. It was awful, it was not happening. It was just very frustrating because coming into it it was something that I was just very excited about and it was just a huge let down.*

Although Female B was not sufficiently integrated into the choice-proximal environment of the team to fully experience the gender ideologies influencing the peer culture, Female A and the male members clearly describe an environment informed by traditional gender schemas and roles. Given the masculine nature of engineering and the V Team technology in general, these ideologies make it even more difficult for female students to have their interests fanned and nourished.

Gender schemas, implicit, non-conscious hypotheses about sex differences in behaviors and preferences (interests), play a fundamental role in shaping men's and women's educational and professional lives [17]. Gender roles refer to our notions about how men and women are expected to behave [17]. Vehicle/competition-based engineering student teams operate at the intersection of two historically masculine domains: engineering and vehicles. A double-bind exists for women whose interests lead them to participate on SELECT. Current gender ideologies continue to conflate engineering, technologies, and masculinity [15]. Participation by women on vehicle-based SELECT, including V Team, challenges cultural socialization; a woman interested in V Team, according to one male team member, "*goes against the norms*".

These cultural norms create an expectation of a team devoid of female involvement. The following member is surprised by the number of females interested in V Team; yet, 80% attrition is expected and does not warrant comment.

Male 4: [Female A] *is the only involved female. Yeah,* [Female A] *is it. We had more girls sign up this year than last year. I don't know why. I remember seeing about ten sign up and I was surprised. I think there are like two still around.*

As an explanation for the dearth of females on V team, the following male team member describes a perceived conflict between female and engineers' schemas and roles. He claims that a female student's expected behavior as a girl subsumes behavior expected of an engineer and therefore she is more interested in what girls do, than what engineers do.

Male 3: *It* [V Team's project] *is different than your common perception of what a girl would want to do, I guess. Even though I know girls that are engineers, they're more girls than* [they are] *engineers I guess in that aspect they are more interested in what they were before becoming an engineer*.

Female A has persevered on the team in spite of challenges based on cultural ideology of appropriate gender behavior:

Female A: *People have looked at me and asked, 'a girl like you, why are you interested in* [the vehicle]*, why would you do that? You're not a tom-boy, you don't like* [vehicles].*' I've had people say that to me before and it's like well 'why not do it, if I'm not the person you expected, why not do it?'*

While her interest in the particular technology of V Team is seen as transgressive, Female A's assignment at competition reflects the prevailing gender schema and does not challenge appropriate female work roles [17].

Female A: *I went to competition, I did the business presentation as a freshman…I got to do it probably just because I was a girl. They wanted a girl to do it…probably to make us look…I don't know why, maybe more diverse, maybe we're better communicators? I got to do it again this year and will probably do it next year. I know the big, top teams have two girls doing it.*

Additionally, the night campus or fraternity-like aspects of V Team culture contribute to an uncomfortable or hostile environment for female team members. As this team member states, "*A lot of what the team does isn't really oriented to girls, like, you know, a group of guys are going to say jokes about your mom or things that are offensive to girls. Most girls that join the team disappear within a couple of months because they are alone.*"

VI. CONCLUSIONS

How do elements of gender ideology and the rhetoric of interest contribute to the peer culture for V Team? How does this peer culture create an environment that supports diversity or reinforces gendered exclusions?

The undergraduate engineering students' experiences revealed in our data demonstrate that these females possessed both the interest and the self-efficacy to pursue joining a competitive, experiential learning, engineering design team. They expressed and acted on this interest even though the team was engaged in the construction of technology in conflict with stereotyped notions of femininity. The choice-proximal environment or peer culture each student encountered was the most important factor influencing persistence on the team. The welcoming comradeship of the senior, secure male students supported Female A's choice to join the team and encouraged an intent to persist. With their support, Female A could ignore or forgive a fraternity-like atmosphere and communicated ideologies of appropriate gender behavior. In contrast, Female B's choice to join V team was not supported by existing team members. While not overtly hostile, the less-established, male team members did not encourage her involvement and therefore did not recognize Female B's crucial skills. Although rare among young women, her welding skills could have benefited the team and made her a valued member.

Although Female A found some acceptance on the team, she did not escape gendered work schemas. Our data reveal that gender schemas still exist in engineering, on this and other SELECT, as evidenced by the assignment of females to perform the business presentations at competitions.

These parallel portraits demonstrate how peer culture can counter messages of inclusion and inhibit access to opportunities for experiential learning. The lack of women on this SELECT is not due to a lack of interest but to structural and cultural factors that are far from inclusive.

VII. RECOMMENDATIONS

How can engineering educators and administrators demonstrate institutional commitment to equitable access to experiential learning and nurture student peer cultures that challenge historic gendered ideologies and rhetoric?

1) Understand the peer group cultures at your institution. Because of the potential for exclusionary or hostile environments within SELECT that counter institutional goals, efforts must be made to understand and monitor in-group dynamics. Institutional representatives must be particularly vigilant to identify roles and actions reflective of gender schemas, discriminatory attitudes, or the presence of cliques.

2) Interact in informal face to face ways to recognize and correct any negative manifestations of peer culture. Institutional interfaces (faculty, staff, and administrators) need to model and require a welcoming and empowering environment for diverse student team members. Supportive, approachable faculty who show interest in individual students boost student self-efficacy and confidence, which are known to lead to persistence. These factors are especially important for females and other underrepresented populations [20]. Formal (e.g. structured meetings, reports from leaders) and electronic interactions keep hidden any night campus dynamics within a team.

3) Provide appropriate and effective mentoring to develop team leaders and teachers. SELECT are promoted as experiential learning spaces; however, as student-led organizations, student-peers are responsible for leading the group to accomplish its mission and goals, as well as for teaching younger members. These dual, and potentially conflicting, roles are complicated further because both the leadership and membership change annually (at best). Essentially, these undergraduate students are fundraisers, engineers, teachers, managers, spokes persons for the group and the College, all without prior training, and successful full time college students too. As leaders, these students should be provided instruction and guidance to acquire the cultural competency to ensure a choice-proximal environment where all interested students can flourish.

***Abstract*— This paper presents a project in experiential learning where students put knowledge of software engineering processes into action in a multidisciplinary project combining computer science and biology. Visualization serves as a primary element to bind the concepts of the two disciplines. Students seeking to further their experience and strengthen their skills in software engineering may choose to complete their senior capstone course working on an ongoing project to construct a toolkit for visualization of phylogenies generated from Avida experimental data. Avida provides a complex computational environment in which the evolution of digital organisms is tracked and analyzed to help find answers to a wide range of research questions. Student projects involve extensions of existing analytic and visualization techniques, as well as the addition of new, often novel, techniques. Importantly, to be successful a visualization technique must be appropriate for the domain in which it is to be used, requiring students to also understand elements of biology. It is our premise that exposing computer science students to the convergence of these two disciplines will strengthen their ability to work at different levels of abstraction and develop new conceptual frameworks to address current and future challenges in hardware and software.**

Keywords—experiential learning; software engineering; visualization; Avida

I. Introduction

A successful software engineer must possess a core body of knowledge in software engineering. This body of knowledge has been defined through projects such as the Software Engineering Body of Knowledge (SWEBOK) [1] and SE2004 Software Engineering Education Knowledge (SEEK) [2]. Both projects assert that software engineering education should cultivate a range of capabilities, including engineering and professional practice, problem-solving and project management ability, professional ethics and relevant legal knowledge, international exchange ability, organizational and management skills, discipline and teamwork, initiative and creativity, and the ability to study independently and actively. SE2004 presents curriculum guidelines for the design and adaptation of educational programs. Even with this guidance, there are still challenges for educators, including how to prepare students as software engineers, as well as how to teach enduring principles in the context of current practice, so that students are prepared to adapt to rapid change in computing environments.

To capture the context of current practice in industry, a number of courses have incorporated projects that emulate real-world experiences, sometimes involving real clients [3-13]. The introduction of formal software engineering knowledge together with concurrent technique and skill development, can bring valuable experience to both students and faculty [5]. While it is critical that software engineering students leave the university with the technical and soft skills expected by employers [14], a single semester or two of course work may not prepare them to move into the workplace as a software engineer.

Our solution to this challenge has been to design a capstone experience that brings students into an ongoing multi-disciplinary research project as a software engineer. The role the student plays depends on the state of the project when they become involved, their previous coursework, and their individual strengths. In this paper we present information about our curriculum, the research project, which extends the Avida Toolkit with special emphasis on visualizing phylogenetic trees, and how we use this ongoing project to develop students' skills. Skills are developed in software engineering, computer science, and in a domain outside the student's expertise with the goals of expanding students' ability to think abstractly, as well as develop a library of software tools for the visualization of data generated by the Avida platform.

II. Project Context

A. Bioinformatics and Phylogeniies

In the bioinformatics domain, the amount of data continues to grow exponentially, formats change often, and complexity of results continues to increase. Researchers need tools that will assist them to effectively link, match, cleanse, transform, analyze and understand the huge volume of data (Big Data). Tools that are currently available to work with Big Data are often complex and hard to use or require resources beyond those readily available [15]. Innovation in phylogenetics and evolutionary biology has been accompanied by a proliferation of software tools, data formats, analytical techniques and web services, and creates a challenge when integrating phylogenetic and other related biological data. This creates the need for reusable software that can read, manipulate and transform this information into the various forms required to build computational pipelines[16].

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

B. Visualization

The goal of visualization is to provide insights from masses of data through visual representations [17]. Visualizations are powerful and often elegant abstractions that provide mechanisms for the discovery of potentially valuable relationships in data. Techniques for visualizing commonalities between hierarchically structured data sets have a long history in visualization, and new graph visualization techniques have been introduced to display multi-category graphs, i.e., graphs that show both connectivity and category [18,19,20,21].

C. Visualization in Bioinformatics

The use of visualization in bioinformatics is not new, and a number of successful systems have been developed. However, challenges remain in developing readily available and easy to use visualization tools that can be used with large heterogeneous datasets. Many of the current techniques for bioinformatics visualization of phylogenetic data employ node-link graphs to represent data as trees. Finding the best tree for the dataset can be a computationally intensive problem. Most of the favored approaches provide approximations for NP-hard optimization problems [22]. Though some software packages can handle the massive amount of data generated in bioinformatics work, reconstructions of phylogenies have typically been limited, primarily by running time, to sets of some dozens or hundreds of organisms [22]. As data continues to grow in size and complexity, algorithms will have to be scaled up in terms of speed and accuracy, and bioinformatics visualization tools will have to improve their ability to layout extremely large graphs, as well as label, annotate, navigate, and compare multiple trees simultaneously [22].

In spite of the fact that there are already many software systems for biological computing, active research drives unforeseen change in requirements that may arise at any moment. This creates a continuing need for tools and modular software kits that can be integrated into bioinformatics analysis workflows independent of data storage formats [16], volume, and complexity. An immediacy of the need for results often leads to the development of analysis and visualization programs by scientists whose principle education is in fields other than Computer Science or Software Engineering [22,23]. The increasing body of nontrivial software being developed by end users can be a very costly practice [22] and often a distractor of the original research initiative.

D. The Avida Platform

Avida is a software platform for digital evolution, used for studying evolutionary processes relevant to both natural and artificial systems [24]. Avida is free, opensource software written in C++, and can be easily extended to add new features and system capabilities. Avida is the most widely used digital evolution software in the world, and its users encompass a wide range of backgrounds and expertise, including biology, computer science, engineering, and philosophy. Avida places a population of self-replicating computer programs, called *digital organisms* or *Avidians*, in a user-defined computational environment. Avida is not a simulation of natural evolution, but a separate instance of evolution in its own right: the digital organisms compete, replicate, and mutate, thus satisfying the fundamental requirements of evolution [25].

Due to the extensibility of the platform and the flexibility of system configurations, Avida experiments produce vast amounts of data that need to be processed. Avida contains some limited analysis tools, but individual researchers have to write most of their own analysis tools outside of Avida itself. The computer scientists and engineers who use Avida do not generally find this situation particularly burdensome, except that writing such custom tools is time-consuming. The situation is a larger problem for researchers who are not trained or experienced programmers, such as the biologists who use Avida. Learning the tools and programming skills required to write software for basic analysis is time consuming, and presents a significant barrier for non-programmer users of Avida. Exacerbating this issue is the fact that most of the software tools used at this time to produce analysis programs are heavily command-line based. Most non-programmer users are unaccustomed to working with command line interfaces, and the added complexity of learning a new interface scheme along with programming skills makes the task even more daunting. Another difficulty in Avida experiment analysis is that, in the past, most existing Avida data analysis software was written using Matlab, an expensive propriety software product. More recently, Avida researchers have turned to Python and other freely available software to write analysis tools. Although this solution eliminates the need for high cost tools such as Matlab, it still fails to address the lack of tools available to non-programmers, or the potentially complex tool chains and configurations that may be required in order to use non-propriety software.

III. Existing Software Engineering Curriculum

The University of Texas-Pan American (UTPA) offers ABET accredited degrees in Computer Science and in Computer Engineering. The first degree is housed in the department of Computer Science, while the second is jointly housed in Computer Science and Electrical Engineering. In addition to a core body of knowledge in the domain, the educational objectives for both degree programs include providing graduates with an understanding of social, professional and ethical considerations related to their respective disciplines

Each degree requires a course in Software Engineering that may be taken after students have completed courses in advanced algorithms and data structures and in systems programming. Students in the software track of Computer Engineering are also required to take a second course in Software Engineering and may also choose an elective in software verification, validation and quality assurance. Each major requires a capstone senior project.

The majority of CS majors opt to take other advanced electives after they have completed a single semester of Software Engineering. At the same time, the majority of the CE majors opt for the hardware track, leaving very few students graduating with two or more semesters of courses in software engineering.

The first course in software engineering (Software Engineering 1) provides a formal approach to the state-of-the-art techniques in software design and development with focused discussion on project planning, requirements, specification, system design, testing and implementation, integrating the knowledge that the students have learned in their other classes. The course uses teamwork in small groups on a substantial project for a real client to provide some experience in real world environments similar to those they will be working in after graduation. The nature of the projects requires that students learn to not only apply software engineering principles, but, more importantly, develop collaborative and project management skills and expand their written and oral communication proficiency.

Projects vary by semester, but typically are real problems or challenges identified by students. Often these are challenges that they or someone they know face on a daily basis and involve concepts outside of CS and CE students' domains of expertise. Thus, projects force students to expand their existing knowledge base beyond the principles of their discipline and software engineering. Addressing a real problem adds value and motivation to the learning experience: the project becomes a challenge with multiple options for a solution, not just an exercise. Students take ownership, and the process to a solution results in identifiable learning outcomes [3,4,13]. Examples of projects include a real-time collection, reporting and analysis system for county health inspection data, a tracking and awards system for student participation, a teacher performance evaluation and student learning outcomes analysis system, and an auto tracking system for controlling and monitoring driver access to a vehicle.

The products of the first class' projects are often used as starting points in subsequent Software Engineering courses. Software Engineering II focuses on the analysis of requirements and software architecture with an emphasis on object design, and adds implementation, testing and validation, maintenance and software re-engineering. Just as in the first Software Engineering course, students work on large projects in a group situation. A third course, Software Verification, Validation and Quality Assurance, covers methods for evaluating software for correctness and reliability, including code inspections and their role in software verification, program proofs and testing methodologies, formal and informal proofs of correctness, unit and system testing techniques, testing tools and limitations of testing, statistical testing, and reliability models.

The curriculum includes a capstone senior project in which students construct a software product, following it through the stages from initial specification to the final completed project. This paper discusses the use of the capstone course for experiential learning that is designed to deepen students' comprehension of the application of the fundamental principles of software engineering while strengthening their skill in communication and collaboration through the incorporation of students into an ongoing interdisciplinary software development project focused on a research initiative [14].

The capstone course we discuss is experiential learning in the context of an ongoing software development project, Avida Toolkit. This capstone course project involves the visualization of phylogenies generated from Avida experiment data. Avida is a digital evolution research platform, with the current version developed in the Digital Evolution Lab and the BEACON Center for the Study of Evolution in Action at Michigan State University. While mathematical modeling serves as an underpinning for simulation in evolutionary biology, Avida was not designed to serve solely as an evolution simulator. Rather, Avida provides a complex computational environment in which the evolution of digital organisms is tracked and analyzed to help find answers to multiple research questions. The transparency of the Avida platform means that any experiment may result in a very large data set. A set of tools exists to work with Avida data, but the tool library is continually under revision as new research questions arise. The approach taken in the capstone course is to use a software development process model to develop a tool library that can serve as the basis for students' innovation, differentiation and growth in understanding and supplying tools for answering questions that researchers ask, so that knowledge can be gained in phylogenies and, more broadly, bioinformatics.

IV. The Avida Toolkit Project

The Avida Toolkit Project originally started to provide data analysis and visualization tools for researchers working on the Avida platform., This would allow researchers to focus their attention on the science, and so discover complex relationships in the data that would provide new insights in their domain, rather than programming and tool development. Like many software projects, new technologies, applications, and participants resulted in project evolution. Both changes in technology and environmental circumstances allowed for the addition of a second purpose for the project. The project would provide an experiential learning opportunity in which students apply the knowledge they have gained through the software engineering, computer science, and computer engineering curriculum to an ongoing software engineering project.

The Avida Toolkit project started a little over two years ago. It originated with one faculty member, whose research involves analysis of Avida data. She began working with a undergraduate student to determine the feasibility of working with the Avida data files in the existing environment using resources available at UTPA. Given acceptable results, she introduced the development of an Avida toolkit as the project for a graduate level course in software engineering to provide a real-world experience and to support the research needs of Avida platform users. At the end of the course, she had three distinct project plans, requirements, requirements analysis, design, and design analysis documents. While each set of documents contained valuable insights into the development of a toolkit, it was her original problem description and a compilation of the student documents that created an actual requirements document, along with three tool prototypes.

The next event in the evolution of this project involved the faculty member receiving a call from a colleague using Avida, currently working in China. As an evolutionary biologist, the colleague had challenges with the extension of existing Avida tools to enhance his visualization of Avida experiment data that might provide insights leading to new questions. With little formal training in software development, coming up to speed quickly on other software platforms was not a reasonable option. He was interested in working with someone more familiar in the domain of programming in computationally complex environments. Casual academic conversations and back of the napkin sketches lead to forming a team including additional faculty members with knowledge and interest in biology, evolution, artificial intelligence, information management, and visualization, a collaboration that bridged two continents and multiple domains of expertise.

As the team expanded and collaboration solidified, the project requirements began to expand. As we see in our project based classes in software engineering, each participant brought his or her own perspective and understanding of the problem, here, including visualizing phylogenies, visualizing big data sets, analyzing big data sets, evolution, and biology. It swiftly became apparent that to be successful in creating an Avida toolkit, we would have to be deliberate in our actions. We decided to practice what we teach.

Gaining insight from the experience of Schaetter, Koeglmayr, Blankenbach, and Nippa [12], we use a slightly modified incremental development process based on Boehm's spiral model [26]. Using the model, we combine the advantages of top-down and bottom-up concepts, integrating prototypes in the design process. Incremental refinement as we move through the spiral allows us to better manage the risk and keep the software development process under control. Because this is an ongoing research project with a clearly defined software development process, students in CS and CE can join the project as their capstone course. Students' specific goals, tasks and products for their capstone course are driven by the current state of the software development process for the Avida Toolkit project.

The Spiral Model is an ideal model for this project. We have the flexibility to incorporate a variety of requirements, design techniques, and implementation styles, e.g. on one cycle we may use Agile programming or XP and on another cycle we may use a version of commercial off the shelf (COTS) products to incorporate new or repurposed source code. Each iteration of the cycle allows us to refine or extend the Avida Toolkit. Fig. 1 provides a snapshot of the model as used in the project.

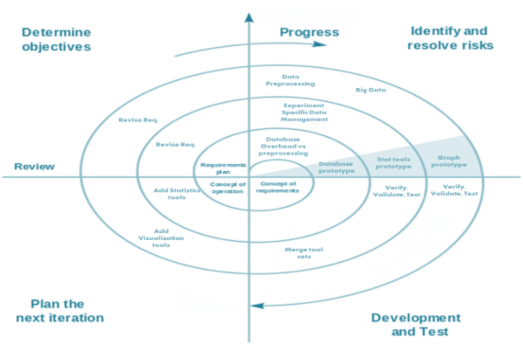

Fig. 1. Spiral model for Avida Toolkit Project

Students and faculty work together closely using this interdisciplinary approach. Students experience different roles and learn to communicate within the project team, as well as with specific stakeholders. Teamwork and efficient group communication establishes a basis for a learning community that includes both students and faculty. Most recently, two seniors in computer science joined the team. Their work involved refining requirements for Avida data management to facilitate the use of open source software libraries, including the Ape package and Biopython, to derive and display phylogenetic trees. In addition to requirements, one student focused on a comparison of software libraries, while the other prepared a prototype tool to display and manipulate phylogenetic tress in 2 and 3-D.

We are moving into the fourth iteration of the process. Using an existing toolkit for graph construction, we demonstrate the functionality available for generating visualizations of large data sets and expand our perspective on the visualization of phylogenies. We are taking advantage of our previous research in document set visualization and software developed at UTPA, InfoViz [27, 28,29]. The current functionality in InfoViz visualizations augment traditional text based search mechanisms and provide a means to make the overall data collection visualizable. InfoViz's visual representation has facilities to generate an overview of a complete document set, filter, add, and delete documents. The system also uses 2 and 3-D visualization tools to identify groups of useful documents and gain access to relevant clusters and individual documents as seen in Fig. 2. Given the obvious analogy to the size and complexity of data generated during Avida experiments, we are evaluating the potential redesign and repurposing of the InfoVIz software.

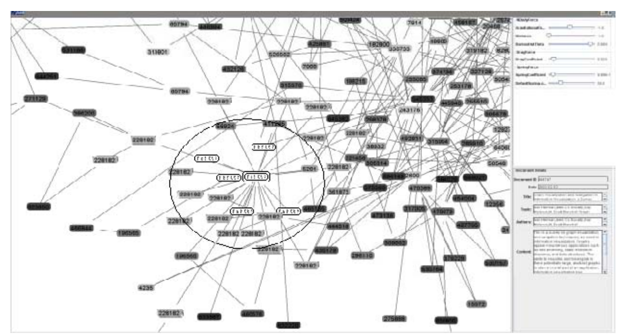

Fig. 2. An example of selective document filtering in InfoVIz.

Requirements definition will begin shortly for a new preprocessing module which allows us to complete syntactic analysis of data generated by the Avida program. Using the existing code graph layout we will develop prototypes that generate neontological time-scaled views, phylogenetic depth views, and pseudo-paleontological views of the Avida data. We will maintain the current ability to move through, refocus, zoom in, zoom out and carve out portions of the graphs. Other revisions under review include enhanced manipulation of actual node data.

This project is a real-world software development environment in an academic environment. New team members are on-boarded and off-boarded as if they were working in industry. They have to familiarize themselves with the Avida platform and quickly grasp the current state of the Avida Toolkit project. They may need to familiarize themselves with statistical analysis and visualization concepts used in the project, as well as the terminology and basic ideas involved in deriving phylogenies. They need to understand what they required to contribute and determine what they will have to learn to be successful, truly an example of experiential learning.

V. Discussion

An interdisciplinary approach and a learning method that uses the state of the project to drive the definition of the individual learning experience is not common in Software Engineering Education. Brugge and Gluhow [3] discuss the importance of finding an innovative way to facilitate the knowledge transfer process. They looked for a way to ensure that knowledge outlasted the end of the semester. They suggest that enhancing the written documentation is not enough, rather, they suggest involvement beyond the project course is important.

Given our own experience and that of others, as well as a project based course in software engineering that emphasizes learning and application of principles of software engineering together with a senior capstone project where students demonstrate their ability to complete a software project, we were able to create a framework where students extend their skills in software engineering, expand their understanding of complex computational environments and exhibit actual transfer of knowledge in computing sciences and software engineering to the solution of problems in evolutionary biology. Using a real world, faculty-driven research project, students work in a multidisciplinary team including faculty with specializations in visualization, information and knowledge management, artificial intelligence, and evolutionary biology. The project uses visualization as a primary element to bind the concepts of the disciplines through the management and display of the datasets of biology in the computing environments employed in the project. To promote deeper understanding and experience in knowledge transfer, we have designed a project plan that includes deliberate, effortful abstraction together with time to search for connections [12,30].

In this approach students are given more control over their learning than in a traditional approach and, most importantly, acquire new knowledge only as a necessary step in solving authentic and cross-disciplinary problems representative of professional practice. Students link prior knowledge with new knowledge and gain a more balanced understanding of complex situations. Furthermore, affective learning serves as a critical link between cognitive and behavioral learning that motivates students and enhances educational outcomes, learning that results in behavioral change and not just conceptual mastery [12].

The purpose of creating a real-world software development project using the spiral model is to improve the students' learning experience, while reinforcing the soft skills required in software engineering and computer science courses. It provides students with the experience of understanding and solving real-world challenges and the opportunity to understand the software development process. Students achieve defined learning outcomes and soft skills that will be important to them in their software engineering careers. In addition, students gain experience in a real, on-going research project.

VI. Conclusions

It is our premise that a single experience, even in an in-depth project based course, is not adequate for students to transfer all required software engineering knowledge and skills to other situations. The project we described allows us to instill an engineering attitude in the curriculum and the academic computing environment. Through flexibility and responsiveness to change, this approach prepares students to adapt to rapid change in the field by teaching enduring principles in the context of current practice. Exposing computer science students to the convergence of multiple disciplines strengthens a student's ability to manipulate and automate different levels of abstraction simultaneously and develop new conceptual frameworks to address current and future challenges in hardware and software engineering.

Finally, we suggest that this approach hones soft skills and reflects the reality of large development projects as seen in the workplace; team members come and go throughout the life of the project. Fortunately, this project has the advantage of a stable core of faculty whose research interests continue to drive the project forward. Future plans include using biologically inspired techniques, such as flock based clustering, to computationally based automation and computationally inspired techniques from 2 and 3-D visualization that have been shown successful in other domains, to biological problems. Using an analogy of the corporate world and their approach to visualization and data analytics may also provide additional insight to manage, understand, and take advantage of the bioinformatics data's full value.

***Abstract*— Most papers about spatial skills and their components refer to the fact that engineering, architectural and scientific jobs require a good level of spatial ability. Spatial ability has an impact on every scientific and technical field, so it's still undergoing strong development when it comes to engineering, technology, art and many other aspects of life. In the academic environment, Graphic Design teachers usually see students who have difficulties solving tasks requiring spatial reasoning and viewing abilities. The main aim of this work is the development of didactic material based on several virtual and augmented reality formats, knowing how students behave while using them, and checking if they are useful materials to improve their spatial abilities. This work present Three different technologies: virtual reality, augmented reality and portable document format to find out if they are suitable technologies together suitable methodologies to improve spatial ability and from the student's perspective, their opinion of the tool and their motivation to learn more about the aspects of 3D reality. We present a pilot study that compared the results of improvement in spatial ability acquired by freshman engineering students also a survey of satisfaction and motivation of the methodology and technology used.**

Keywords—engineering education; spatial skills; training courses; augmented reality; virtual reality.

I. INTRODUCTION

In the academic environment, Graphic Design teachers usually see students who have difficulties solving tasks requiring spatial reasoning and viewing abilities. In the curriculums of degrees where Graphic Design appears (previous to the *European Space* for *Higher Education* change), no reference is made to providing development for a student's spatial ability. As the time available for exploring the contents of the subject is quite short, teachers do not consider how a student may be able to develop their mental abilities relating to object rotation, spatial reasoning etc.

There is a void in the curriculums of Graphic Design programmes of not helping students improve their spatial ability. If that issue could be solved, we may help the students that have greater difficulties in understanding the sketching systems overcome that handicap.

Now in the curriculums of engineering field degrees in the framework of the European Space for Higher Education (ESHE), the spatial vision capability is present as a competence that should be developed by students as a foundation of all engineering degrees.

The use of technologies applied through a suitable methodology may be included in the curriculums of Engineering Graphic subjects to provide to the students a better level of spatial ability.

The main aim of this work is the development of didactic material based on several virtual and augmented reality formats, knowing how students behave while using them, and checking if they are useful materials to improve their spatial abilities.

The didactic material will always be designed under the principle of improving spatial vision abilities, learning of Graphic Design contents, and better adaptation of each technology according to the engineering field where it should be applied. This implies designing learning activities that follow the philosophies of each one of those three technologies and implementing them in the classroom to three different groups of students that belong to the same level. One of these technologies would be applied to every group and then studied to discover their spatial ability progress, inferring the influence of the tool used in the acquisition of Graphic Design knowledge.

For establishing the possible differences between these technologies, the learning between groups will be compared against a fourth (control) group which will use a traditional methodology. The control group will not use any of the three technologies that are being studied.

II. TRAINING OF SPATIAL ABILITY

Without any doubt, spatial ability is an important component of human intelligence, but there is no agreement about the sub-factors that compose this component of intelligence [1]. Some of the most accepted theories come from researchers[2, 3] that have proposed three major sub-factors for categorising spatial skills: spatial relations, spatial visualisation and spatial orientation, although some researchers don't recognise spatial orientation as a separate factor. Following

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

classification proposed by researchers from both psychology [4] and engineering [5], it has been reduced to just two sub-factors:

- Spatial relations, defined as the ability to imagine rotations in both two and three dimensions. Authors indicate that this skill includes mental rotation and spatial perception factors.
- Spatial visualisation, which is the ability to recognise 3D objects through the folding and unfolding of their sides. Visualisation is defined as the ability to mentally manage complex shapes.

To measure these components we use the Mental Rotation Test (MRT) [6] and the Differential Aptitude Test (DAT-5: SR) [7], as they are highly validated tools for measuring spatial skills. Spatial ability is something that cannot be taught, but rather trained and that training is the only way to develop and improve it. Some studies demonstrate that spatial abilities can improve by means of specific training. These abilities in engineering can improve with multimedia exercises, 3D software and other technologies used in graphic engineering [8,9,10,11,12].

Researchers like P. Connolly [13] suggested a need to develop spatial abilities in Graphic Engineering subjects. Barr [14] analysed future academic engineering plans with modern trends in mind and highlighted that the most important subject that should be included in a programme should be the development of spatial skills. Historically there has been a great deal of interest in the methods of instruction and technologies that could potentially increase the spatial skills of its users [15,16,17]. Currently, the rise of virtual reality (be it augmented, desktop or immersive) has fuelled the renewed research about the development of spatial ability.

Over the last few years we have performed several studies about fast remedial courses that try to improve the spatial abilities of engineering students in the University of La Laguna in Spain. In these courses, different tools have been tried out: classic exercises (views) using pen and paper; online multimedia web-based exercises; sketch-based modelling through a calligraphic interface [18]; use of Dynamic 3D apps [19]; and videogames as a work tool [10]. The aim is that students who take part in these courses will improve their spatial abilities and help them to have a better understanding of the contents of the subject of ‘Engineering Graphics’.

Recently there has been an important evolution in the teaching of Graphic Design in technical degrees. New incoming technologies have been essential in this evolution, determining to a great extent both the teaching and learning processes of this subject. Besides this, the steep rise in the number of students in engineering degrees is starting to make traditional strategies look outdated, such as using physical models, where students can manipulate these with their hands, turning it until they understand them and are able to develop plans to sketch them. This made us plan methodologies to reduce physical models and seek new methods aimed at students who can learn through new computer technologies that they are already used to.

III. Proposed Technologies and Didactic Materials

We have performed an experiment with three different technologies: virtual reality (VR), augmented reality (AR) and portable document format (PDF3D) to find out if they are suitable technologies to improve spatial ability, and from the student’s perspective, their opinion of the tool and their motivation to learn more about the aspects of 3D reality.

A. *Virtual reality (VR)*

Virtual reality is a set of technologies and interfaces that allow one or more users to interact in real time with a computer-generated 3D environment or dynamic world. These 3D elements and interactive environments are built through VRML language that has evolved through different versions since its inception in 1994.

The continuous improvement of tools allowing the creation of virtual reality applications, as well as the better performance of the technological equipment needed to execute them, has allowed VR to become standard in spatial ability training. For building scenes and worlds through VRML, we use resources such as low-level programming can be used, as well as the syntax and semantics of the language where an ISO spec, as well as a large bibliography. In our case, to develop this virtual world we have used 3D design programs and their VRML export abilities.

The didactic material is made up of forty exercises that were created and distributed in three levels of increasing difficulty, which are quite similar to those used in pre-university education (Fig. 1).

The exercises, based on VR, are uploaded to a web platform called Draw Help System (DHS). When an exercise is selected, the application shows a piece in the virtual environment that allows its manipulation (movement, rotation or change of position etc.) so the user can become aware of all its details.

Fig. 1. DHS main window

B. *Augmented reality (AR)*

Augmented reality uses either direct or indirect vision of a physical environment from the real world, where real elements combine with virtual elements to create a real-time mixed reality. It uses a set of devices that add virtual information to the physical information that already exists. This is the main

difference with VR, as it doesn't replace the physical reality but superimposes the computer data onto the real world.
An augmented reality scenario we have proposed for this work consists of the elements shown in Fig. 2:

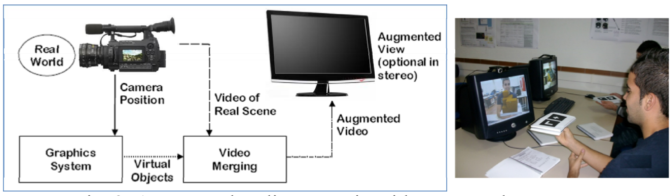

Fig. 2. Augmented reality scenario with a personal computer.

All exercises and pieces were adapted to the format used by the BuildAR Pro augmented reality application [20], which allows the creation of scenes made up of a set of images or marks that codify a 3D model. When a scene is executed, a webcam connected to the PC recognises an image that is related to the 3D model and shows it integrated into the real world. A 'marks book' is also created, where the mark is composed by a frame and the exercise's image inside (Fig. 3).

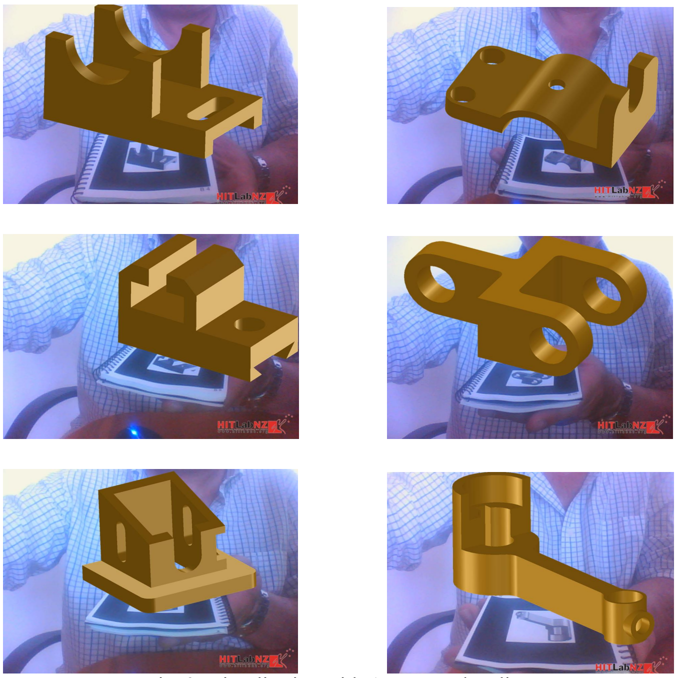

Fig. 3. Visualisation with Augmented reality.

C. *Portable Document Format 3D (PDF3D)*

The PDF format has incorporated 3D object vision capability inside its multimedia characteristics through the Universal 3D (U3D) format included in the PRO X version [21]. The portable document format (PDF) developed by Adobe Systems has become the information exchange standard for any application or computer system. It has the following characteristics:

- Open standard: the PDF format is an open standard developed under the ISO 32000 norm.
- Multiplatform: PDF files may be visualised on every platform available, including Windows®, Mac OS and mobile platforms such as Android™.
- Extendable: Many providers offer PDF-based solutions including creation, plug-ins, consultancies and technical support tools.
- Reliable and secure: the fact that there are over 150 million PDF documents available for public use online, together with the huge number of PDF files available in both public and business administrations, proves that enterprises trust this format for information transmission.
- Sophistication for information integrity: PDF files have the same aspect and show the same information as the original files, such as text, drawings, multimedia content, videos, 3D content, maps, color graphics and pictures, regardless of the application used to create them, or if they are compiled in a unique PDF folder from several formats.
- Search capability: the text search tools on documents and metadata ease searching in PDF files.
- Accessibility: PDF files use support technologies to increase access to information for people with disabilities.
- Interactive: Its new 3D manipulation capability (U3D) has helped it to become one of the best systems to distribute and share graphic information.

The same exercises and pieces were transformed into U3D format used by PDF3D, allowing them to be manipulated in an independent environment (Fig. 4).

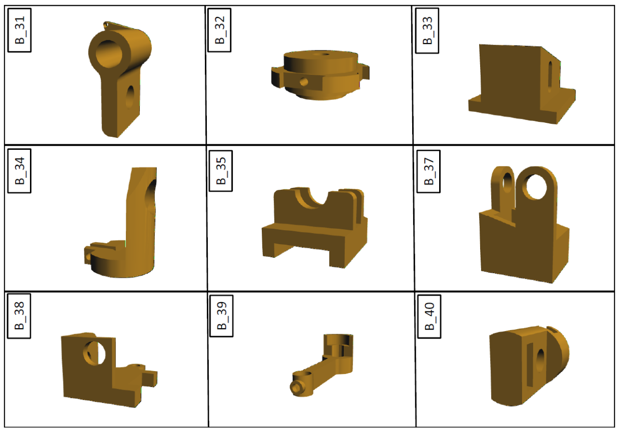

Fig. 4. PDF3D interface

The three methodologies have the same aim: the student gets to know the piece, without needing the real model in their own hands, and has all the information needed to sketch the piece and create a workshop contour plan.

The previous tools allow as a student may work on the questions stated in the exercise notebook and practice their sketching abilities.

IV. Experimental Study

A. Participants

A study was undertaken by 57 freshmen studying Graphic Design from the first course in the Industrial Technology degree in the Civil and Industrial Engineering School from the University of Las Palmas de Gran Canarias at Spain. All students completed the training phase using the same exercises using three different technologies (VR, AR and PDF3D) and three methodologies accordingly. An overall of 18 students used the VR-based tool, 20 students used AR, and 19 used the PDF material available. There was a control group of 20 students who didn't undertake any kind of training.

B. Methodology

The training was performed in the Graphic Design laboratory. The aim was to obtain data about the improvement of spatial ability in the groups using the three methodologies and to find out from the feedback of students their motivation and satisfaction.

The study was performed at the beginning of the 2011/12 academic year, so when they undertook this task these students had not attended any kind of Engineering Graphics classes previously.

The spatial abilities of engineering students were measured before and after training using both the Mental Rotation Test (MRT) and the Differential Aptitude Test (DAT-5:SR). Besides, upon completion of training, the students completed two surveys about their satisfaction with the training and their motivation while performing this experiment.

Only a standard PC and a webcam (for AR) were needed for this training. The students visualised the virtual elements on the monitor. The training had six hour duration, so they worked on it for two hours per week. The students performed it on their own, although the teacher could help them when needed.

The didactic material was composed of three difficulty levels as shown, so each student performed a level weekly.

C. Results and analysis of spatial abilities

The mean values of the MRT and DAT-5:SR tests of the three experimental groups and the control group, prior to undergoing the training (pre-test), were very similar (Table I). The analysis of variance (ANOVA) for MRT and DAT-5:SR, measured in the four groups (AR group, VR group, PDF3D group and Control group), showed that there were no significant differences between groups prior to spatial training ($F_{3,74}$=0,654, p=0.583 on MRT and $F_{3,74}$=1,055, p=0,374 on DAT-5:SR). So, all groups were statistically equivalent in spatial visualisation and spatial relation at the start of this study.

After completing the courses, spatial abilities were measured again. Table I shows the results of the pre and post-tests scores, as well as the gain for each group.

TABLE I. VALUES PRE/POST TEST AND GAIN

	Pre-test		Post-test		Gain MRT	Gain DAT 5:SR
	MRT	DAT 5:SR	MRT	DAT 5:SR		
VR Group n=18	19.00 (6.40)	30.22 (9.13)	25.33 (7.18)	38.39 (7.85)	6.33 (4.58)	8.17 (6.42)
AR Group n = 20	18.94 (9.79)	24.94 (8.78)	25.67 (10.97)	32.33 (8.76)	6.72 (4.91)	7.39 (3.82)
PDF3D Group n=19	15.47 (7.10)	27.06 (8.33)	23.53 (8.06)	37.65 (7.67)	8.06 (7.59)	10.59 (4,64)
Control Group n=20	17.44 (9.80)	28.40 (10.17)	19.22 (9.91)	33.52 (11.77)	1.78 (4.36)	5.12 (7.13)

We compared the mean values obtained pre- and post-test using the Student's paired series t-test:

- VR: MRT [t=5.872, p-value=0.00]; DAT-5: SR [t=5.398, p-value=0.00].
- AR: MRT [t=5.81, p-value=0.00]; DAT-5:SR [t=8.20, p-value=0.00].
- PDF3D: MRT [t=4.38, p-value=0.00]; DAT-5:SR [t=9.41, p-value=0.00].

In the MRT test, the Control Group obtained t=1.88, p-value=0.066; in the DAT-5:SR t=1.718, p-value=0.092.

The groups that underwent training showed a statistically-significant improvement in spatial ability levels. P-values are around 5% for statistical significance, which indicates that the students have a probability of over 95% of improving their levels of spatial ability when performing the proposed training. Besides this, results show there is no improvement in control group levels. To compare and check if there is any difference in spatial ability levels obtained by groups that underwent training, a LSD Fisher post-hoc contrast analysis was performed. This allows multiple comparisons between the three groups with a different number of individuals in each group, as seen in the results in Table II and Table III.

The results confirms that there is a significant difference in the gain between each type of training and control groups, but that there is no difference between the training groups, which underlines the fact that improvement was similar in all groups.

TABLE II. COMPARISON BETWEEN GROUPS FOR GAIN IN MRT

(I) group	(J) group	Difference between averages (I-J)	Typical error	Sig.	Confidence interval at 95%	
		Lower limit	Upper limit	Lower limit	Upper limit	Lower limit

* Difference between averages is significant at .05 level.

D. Students´ satisfaction

Bevan [22] mentions that in order to make reliable estimations of satisfaction results, 8 to 10 participants are necessary as larger samples offer a more significant value for the success rate. In our study, the evaluation of the material and the software was done by all students (57) who undertook the training.

Once the experiment was finished, they were provided with a survey to find out the level of satisfaction of each group regarding the methodology of the training used. The user's satisfaction was measured using an adapted version of the QUIS Questionnaire [23] using a 9 point Likert scale, from 1 to 9. A selection of these questions is shown in Table IV.

TABLE IV. USERS' SATISFACTION RESULTS AND QUESTIONS

	Group		
Question	**VR**	**AR**	**PDF3D**
Terrible-Wonderful	6.2	8.6	6.1
Frustrating-Satisfying	6.0	8.7	7.4
Dizziness-Natural environment	7.3	8.8	6.0
Uncomfortable-Comfortable	5.7	7.1	6.0
Not interesting-Very interesting	6.2	8.6	5.5
Difficult-Easy	8.0	8.5	8.4
Rigid-Flexible	7.1	7.4	6.9
Operation learning: Difficult-Easy	6.1	8.4	7.6
System speed: Too slow-Fast enough	8.1	8.5	8.4
Intuitive system: Not at all-Very much	7.7	8.7	7.0
Overall satisfaction: Low-High	6.9	8.7	6.7
Mean Values	**6.8**	**8.4**	**6.9**

This table shows (for each group) the mean values for each item satisfaction survey. We can see the satisfaction in the use of each of the technologies. Students using augmented reality technology show greater satisfaction on all items.PDF3D technology is perceived as more comfortable, easy to use, easy to learn that virtual reality. By contrast, VR is considered more wonderful, interesting, flexible and intuitive than PDF3D technology.

V. MEASURING MOTIVATION OF STUDENTS

In this research work, we regarded the use of a scientifically-validated tool as quite interesting to find out the motivation of students towards the training performed. The learning questionnaire **Motivated Strategies for Learning Questionnaire (MSLQ)** [24] was designed to evaluate university students' motivational orientations and learning strategies.

There are three proposed motivational dimensions related to the learning strategies:

- Expectations component: Regarding the student's skill for performing a task.
- Value component: Importance given to the performance and interest in the undertaken task.
- Affective component: Related to the student's emotional reaction to the task.

Regarding the learning strategies, the MSLQ authors regard three aspects as essential:

- Metacognitive tasks: for planning, addressing and modifying the cognitive operation in itself.
- Control of resources: Time and location, effort and help from others.
- Cognitive strategies: used by students to learn, remember and understand the studied subject.

The latest MSLQ version [25] establishes subscales for every dimension previously described, aiming to analyse in depth the factors that can influence motivation. This version is composed of 81 items, where 31 of them belong to motivational aspects and the other 50 to strategic factors. Each item is answered using a likert scale of seven levels, where one means no/never and seven means yes/always. Every item is sorted into six motivational and seven strategic scales, as shown on Table V.

TABLE V. DISTRIBUTION OF MSLQ SCALES, DIMENSIONS AND SUBSCALES.

Scales	**Dimensions**	**Subscales**
MOTIVATION	Expectations components	Control beliefs Self-effectiveness
	Value components	Intrinsic aims Extrinsic aims Task value
	Affective component	Anxiety
LEARNING STRATEGIES	Cognitive and metacognitive	Elaboration Organisation Critical thought Metacognition
	Resources management	Study time and location Perseverance/Effort regulation Seeking help and learning with others

For more information about the MSLQ theoretical approach, several previous studies can be read [26,27,28].

Table VI shows the results obtained for motivational and strategic factors. The study of motivation is carried out on total of students to determine if the use of 3D visual technologies influence the motivation of students.

Students are mainly guided through their study by aiming toward intrinsic goals as they trust their own learning skills and value the importance, their interest and the usefulness of training. They also realise that any improvement they attain through training depends on their own efforts and that they know they will be able to reach high levels of spatial ability.

Overall, they have reached a satisfactory motivation level. There is positive performance, which is reflected in motivational factors, concretely over the learning strategies scale. It is remarkable that the highest level is in anxiety, possibly as a consequence of insecurity caused by the lack of explanatory material for the proposed activities. The training is made so students can acquire basic knowledge about orthogonal views through their own finds and intuition.

TABLE VI. MOTIVATION FACTORS (SUBSCALES) –

Motivational factors	**Mean**	**SD**
Control beliefs and learning self-effectiveness	3.73	1.79
Self-effectiveness performance	3.53	1.40
Orientation towards intrinsic aims	3.98	1.82
Orientation towards extrinsic aims	3.20	1.60
Value of task	3.31	1.98
Anxiety	4.60	1.58
MOTIVATION SCALE	**3.72**	**1.69**
Strategic factors	**Mean**	**SD**
Elaboration	3.31	1.98
Organisation	4.87	1.22
Critical thought	3.42	1.72
Metacognition	3.31	1.98
Use of time and concentration	4.55	1.42
Perseverance/Effort regulation	4.88	1.37
Seeking help and learning with others	5.57	1.26
LEARNING STRATEGIES SCALE	**4.22**	**1.56**

From the data we can see in the table, it follows that students reached a good level of development in the learning strategies, but they usually made inappropriate use of them, as can be seen in the values for the strategic factors about learning approaches. Another aspect that should be pointed out is that the most developed strategic factor is help, as a consequence of the collective group work. The value obtained for making the most of the available time was also outstanding, as well as focus, which indicates the need to strengthen orientation towards self-sufficient study.

The metacognition and self-questioning scales show that students have not reached the suitable level over the control of their own study, which shows the need of a teacher's support to develop critical thought, as well as the link to other contents learned from other areas.

VI. CONCLUSIONS

The evolution of technology and the appearance of new teaching techniques have made some methodologies obsolete as they are not properly adapted to modern trends. Teaching methods must evolve and adapt to the new technologies that students are used to, and learning will clearly benefit from this.

The students are digital natives as they are used to all kinds of electronic devices and handling information in many digital platforms. Traditional teaching methodologies can cause boredom and a lack of motivation during the teaching activities.

The use of objects and physical models for working in the classroom are not enough for the volume of students who are currently attending these classes. The computer tools that allow virtual modeling and the handling of 3D objects ease teaching tasks as any piece or figure is available without needing to obtain physical models that can be quite expensive and take longer to create. The modeled object may be implemented in every format, such as virtual, augmented, PDF3D or any other.

We have introduced into the classes of an engineering degree three methodologies based on technological tools and 3D models. Overall, the students were quite satisfied with the tools used to learn. The users enjoyed the simplicity of the apps and pointed out the powerful control of tri-dimensional models. Specifically, those students using AR were more satisfied than those using VR and PDF showing the same values. According to the data observed on site, we note that students who trained using AR felt quite impressed and motivated by the use of a new technology, of which they had no previous contact as they were not aware of it. Therefore, the difference is due to the technology's novelty. The teachers observed that students showed more participation and motivation than those from groups where physical models are used, as passivity and a lack of motivation during learning was quite noticeable.

The students who used multimedia didactic material showed confidence in their own capabilities in developing tasks and showed interest while performing them. The students adopted strategies for planning, learning and understanding the upcoming subject, which denotes a high level of motivation about the work that is being developed.

***Abstract*—Enhancing a student's ability to mentally visualize and intuitively assess foundational concepts in engineering mechanics - statics can create a significant advantage for students in their pre-professional engineering courses. Concepts such as forces and moments often prove to be challenging for students lacking hands-on mechanical experience or those who are visual and kinesthetic learners. Showing students these "intangible" mechanics principles is not an easy task and usually requires proactive measures to improve learning. In an effort to improve visualization and tactile learning in a college mechanics – statics course, hands-on and visual truss models were developed based on the concept of physical manipulatives. Mathematics instructors use manipulative models to help students identify different mathematical concepts. These models not only allow the students to see and feel different objects but also to manipulate the objects to form a concrete representation of the concept. Furthermore, manipulative models help students visualize, feel, and analyze the behavior of the material being manipulated. This study examines the relationship between the use of a physical model of a truss and the students' framing of information during task interpretation to successfully attain conceptual understanding about truss analysis.**

Keywords—manipulatives; statics; task interpretation; constant comparative analysis

I. Introduction

Statics is the branch of mechanics that is concerned with the analysis of loads and forces on stationary structures and machines. It is a fundamental course that prepares students for subsequent courses such as dynamics and mechanics of materials. Studies have shown that students tend to have different conceptual understanding misconceptions in statics. Students "fail to account for the mutual nature of forces between connected bodies that are separated for analysis" [1]. One example that illustrates this difficult concept for students in engineering statics is the internal and external force analysis in a truss problem. Trusses are structures comprised of units, also called members, connected to one another through joints. These structures provide stability and shape to different larger structures and machines such as crates, cranes, buildings, and bridges. Simple mathematical analysis often leads to a solution that may not have a true intuitive meaning for the student. Manipulatives can be used as a tool tying together students' analytical capabilities and their engineering intuition. Research has indicated that the manipulatives are most effective when students' exploration is somewhat guided, either by their instructor in lecture or by homework, lab, or recitation activities using guided-inquiry approach to learning [2]. For example, mathematics instructors use manipulative models to help students identify different mathematical concepts [3]. The advantage of using physical manipulatives is the fact that manipulatives enhance spatial visualization for engineering students [4]. Nonetheless, there is a gap between how the students understand the problem and how they plan and execute solutions for the problem. Therefore, investigating the students' task interpretation during the analysis of the truss is important in order to incorporate the three layers of information construction: explicit, implicit, and socio-contextual information about tasks [5]. These three factors influence how the student creates a strategy for task understanding and execution. The framing of the information gathered through task interpretation, in terms of underlying concepts, helps students decode the requirements of a particular task [6], which, along with other aspects of self–regulated learning, help develop work habits in their learning activities. This also helps create empowering pedagogies where students can use their task interpretation in new productive and meaningful ways.

II. Analysis of Literature

A. *Physical and Virtual Manipulatives*

The challenges college students face when learning statics was investigated using learning activities [7]. The study addressed different misconceptions and problems for students in statics, including the forces between rigid bodies, moments, and forces on inanimate objects. The study described different techniques that could be used in the classroom to improve learning, especially the use of physical manipulatives to demonstrate the "invisible" and help develop mechanical intuition for the students. Instruction with these physical manipulatives was accompanied by a series of group discussions, collaborations, and feedback activities in the classroom. The authors described two core ideas: 1) students have difficulty perceiving forces between inanimate objects but physical manipulatives can help students see and feel what is "invisible" and abstract, and 2) the necessary assessment and feedback required in the statics course. The authors argued that learning modules that use physical manipulatives and other activities could be applicable to a wide variety of engineering

subjects and help students understand, observe, and feel concepts that are somewhat abstract [7].

Other studies have investigated the use of both physical and virtual manipulatives in a variety of STEM areas. These studies investigated different frameworks that would describe the best way to integrate, sequence, or "blend" the use of both physical and virtual manipulatives to understand abstract concepts. For example, the use of hands-on (physical) malipulatives helped engineering students in modeling and engineering problem solving [10]. The results from this study showed that students increased their understanding of engineering concepts when they used manipulatives and were able to see and feel reactions created by the manipulative. Another study, involving physical and virtual manipulatives, indicated that manipulatives affected not only learning but also engagement and knowledge transfer [3]. The results from this study showed that the learning of all groups in the study in all conditions increased as the result of the use of manipulatives. Students developed skills to correctly identify variables based on word problems. It was observed that students with concrete materials, or manipulatives, led to better procedural use and therefore a reduced cognitive load.

In another study, three characteristics were observed: instruction, type of knowledge gained, and the use of physical and virtual materials [11]. For this study, the researchers used "mousetrap cars" as the physical manipulative and a digital mousetrap car from a computer program as the virtual manipulative. The analysis focused on open-ended discovery, confidence, and gender effects (male vs. female). The study showed that students learned equally with either medium regardless of constraints. Students were able to increase their knowledge equally using both methods even when time spent on a task was different [11]. However, students using the physical manipulative were able to observe several mistakes with their design while students using the digital manipulative did not experience such observations due to the lack of those features in the computer simulation.

In addition, another study investigated the use of manipulatives and the ability of students to follow specific hand manipulative tasks using instructional animations [12]. The purpose of the study was to show that animated presentations are more effective than static presentations, especially if these depict human movement. The results showed that instructional animations are more effective and lead to better learning and understanding. The study indicated that participants could not imitate actions showed on static images and generated cognitive overload, thus negatively affecting learning.

B. Task Interpretation
