These two tutors were selected because they promised large sample sizes – they are both typically used early in the semester and are used by larger numbers of students than tutors on more advanced topics such as functions and arrays. At the same time, the two tutors were not duplicative – they have different user interfaces and require different problem-solving skills.

The tutors were used by students enrolled in introductory programming courses. Students from multiple institutions used the tutors each semester – an average of 12 institutions for arithmetic tutor and 15 institutions for selection tutor. All the students used the tutors over the web. The entire protocol was administered back-to-back – any student considered in this study went through all the stages of the protocol within 30 minutes, with no breaks in between. So, any change in score from pre-test to post-test is attributable to the use of the tutor and not any extraneous factors.

II. Arithmetic Expression Tutor Results

During pre-test, arithmetic expressions tutor presents 16 problems. For analysis purposes, only those students who had solved at least 10 problems during the pre-test were considered. When a student had used the tutor multiple times, data from only the first time the student had solved at least 10 pre-test problems was considered.

Data was collected over five semesters – fall 2010 through fall 2012. All the students used the same version of the tutor during these five semesters. After eliminating duplicates and students who had not solved sufficient problems during the pre-test, 1236 students remained in the study:

- 242 students "did not need to use the tutor";
- 206 students "needed the tutor, but did not get to practice with it";
- 273 students "solved practice problems, but not enough to practice any concept"; and
- 515 students who "practiced one or more concepts".

Since providing sex and race information was optional, the value of N may vary in the following analyses.

A. *Students who did not need to use the tutor*

Univariate analysis of the time per pre-test problem yielded a significant main effect for sex [F(1,185) = 6.717, p = 0.01]: Female students spent statistically significantly more time to solve each pre-test problem than male students, as shown in Table I (In the table, means are listed with confidence intervals at 95% confidence level). Since both male and female students scored 100% on the pre-test, perceived self-efficacy [14] may be one possible explanation for why female students took more time – female self-efficacy is significantly lower than male self-efficacy [15]. Similar analysis did not yield a significant main effect for race [F(1,185) = 2.082, p = 0.151], i.e., the difference between the racial groups was not statistically significant.

TABLE I. Time per pre-test problem on arithmetic expressions tutor for the group that did not need to use the tutor

	Male	**Female**
N	142	44
Mean	45.48 ± 3.66	56.83 ± 7.83
	Caucasians+Asians	**Under-represented**
N	135	51
Mean	47.99 ± 3.90	54.31 ± 7.71

B. *Students who needed the tutor*

Among the students who needed the tutor, but did not get to practice with it, there was no significant difference in the pre-test score per problem between the two sexes [F(1,145) = 0.115, p = 0.735] or racial groups [F(1,145) = 0.959, p = 0.329]. In other words, both the groups in each comparison were equally prepared before using the tutor.

Among the students who solved practice problems, but not enough to practice any concept, no significant difference was found in the number of practice problems between the sexes [F(1,213) = 0.3, p = 0.584] or racial groups [F(1,213) = 0.128, p = 0.72].

C. *Students who practiced one or more concepts*

Analysis of the number of concepts practiced yielded significant difference between the sexes [F(1,392) = 5.52, p = 0.019], but not between the racial groups [F(1,392) = 0.357, p = 0.551], as shown in Table II. Female students practiced significantly more concepts than male students, possibly because they solved statistically significantly fewer problems on the pre-test than male students [F(1,392) = 5.931, p =

0.015], and therefore, demonstrated proficiency on fewer concepts during pre-test.

TABLE II. CONCEPTS PRACTICED ON ARITHMETIC EXPRESSIONS TUTOR

	Male	Female
N	300	93
Mean	1.588 ± .14	1.933 ± .253
	Caucasians+Asians	**Under-represented**
N	289	104
Mean	1.716 ± .147	1.804 ± .249

No statistically significant difference was found on the pre-post change in score on practiced concepts, whether between the sexes [F(1,392) = 0.45, p = 0.503] or racial groups [F(1,392) = 0.031, p = 0.861]. Similarly, on the number of practice problems solved per practiced concept, no significant difference was found between the sexes [F(1,392) = 1.865, p = 0.173] or racial groups [F(1,392) = 0.101, p = 0.751].

In summary, among the students who did not need to use the tutor, female students may have exhibited lower self-efficacy. Among the students who practiced one or more concepts, female students practiced significantly more concepts than male students, possibly because they were less prepared than male students when they started using the tutor. No other difference was found between the sexes or racial groups on the number of practice problems solved per practiced concept, or the pre-post change in score on the practiced concepts.

III. SELECTION TUTOR RESULTS

During pre-test, selection tutor presents 12 problems in C++ and 9 problems in Java/C#. For analysis purposes, only those students who had solved at least 8 problems during the pre-test were considered. When a student had used the tutor multiple times, data from only the first time the student had solved at least 8 pre-test problems was considered.

Data was collected over four semesters – fall 2010 through spring 2012. All the students used the same version of the tutor during these four semesters. After eliminating duplicates and students who had not solved sufficient problems during the pre-test, 893 students remained in the study:

- 370 students “did not need to use the tutor”;
- 91 students “needed the tutor, but did not get to practice with it” or “solved practice problems, but not enough to practice any concept”. No analysis was done on these groups because of their small sample size.
- 432 students “practiced one or more concepts”.

Since providing sex and race information was optional, the value of N may vary in the following analyses.

A. *Students who did not need to use the tutor*

Univariate analysis of the time per pre-test problem did not yield a significant main effect for sex [F(1,251) = 0.474, p = 0.492], but did so for racial groups [F(1,251) = 6.908, p = 0.009], as shown in Table III. Under-represented students spent statistically significantly more time to solve each pre-test problem than Caucasians+Asians. Again, since both racial groups scored 100% on the pre-test, perceived self-efficacy [14] may be one possible explanation for why under-represented students took more time – under-represented racial groups were found to have significantly lower prior self-confidence in another study [7].

TABLE III. TIME PER PRE-TEST PROBLEM ON SELECTION TUTOR FOR THE GROUP THAT DID NOT NEED TO USE THE TUTOR

	Male	Female
N	194	58
Mean	52.85 ± 4.60	56.03 ± 7.83
	Caucasians+Asians	**Under-represented**
N	203	49
Mean	48.38 ± 4.20	60.50 ± 8.05

B. *Students who practiced one or more concepts*

There was no significant difference in the number of concepts practiced by the two sexes [F(1,323) = 1.608, p = 0.206] or racial groups [F(1,323) = 1.321, p = 0.251], as shown in Table IV.

TABLE IV. CONCEPTS PRACTICED ON SELECTION TUTOR

	Male	Female
N	253	71
Mean	1.686 ± .152	1.896 ± .289
	Caucasians+Asians	**Under-represented**
N	240	84
Mean	1.696 ± .165	1.886 ± .281

The pre-post change in learning was significantly different between the sexes [F(1,323) = 4.661, p = 0.032], but not the racial groups [F(1,323) = 0.002, p = 0.962]. Female students had a greater improvement from pre-test to post-test on the practiced concepts as shown in Table V, likely because they scored statistically significantly less on the pre-test than male students [F(1,323) = 4.252, p = 0.04]. The post-test scores were not significantly different. The interaction between the sexes and racial groups was also significant [F(1,323) = 5.223, p = 0.023] as shown in Table V, i.e., pre-post change was less for under-represented males and more for under-represented females than Caucasians+Asians.

TABLE V. PRE-POST IMPROVEMENT ON PRACTICED CONCEPTS ON SELECTION TUTOR

	Caucasians+Asians	Under-represented	Total
Male	.887 ± .033 (N=187)	.809 ± .054 (N=66)	.848 ± .032
Female	.882 ± ..060 (N=53)	.963 ± .104 (N=18)	.923 ± .061
Total	.884 ± .034	.886 ± .059	

On the number of practice problems solved per practiced concept, no significant difference was found between the sexes

[F(1,323) = 0.328, p = 0.567] or the racial groups [F(1,323) = 2.744, p = 0.099].

In summary, among the students who did not need to use the tutor, students in under-represented racial groups may have exhibited lower self-efficacy. Among the students who practiced one or more concepts, the change in score from pre-test to post-test was significantly more for female students than male students, and this made up for the fact that female students scored significantly less on the pre-test. No other difference was found between the sexes or racial groups in the number of concepts practiced, or the number of practice problems solved per practiced concept.

IV. DISTRIBUTION OF STUDENTS AMONG CATEGORIES

As mentioned earlier, students were grouped into four categories:

1. Students who did not need to use the tutor
2. Students who needed the tutor, but did not get to practice with it
3. Students who solved practice problems, but not enough to practice any concept
4. Students who practiced one or more concepts using the tutor.

We analyzed the distribution of students among these four categories by sex and race. Univariate analysis of the category by sex and racial group for arithmetic expressions tutor yielded no significant main effect for sex [F(1,938) = 0.185, p = 0.667] (Figure 1) or racial group [F(1,938) = 0.28, p = 0.597] (Figure 2). In other words, no statistical difference was observed between male and female students and between traditional and under-represented racial groups in their distribution among the four categories, including the proportions that needed the tutor and that benefited from the tutor, i.e., practiced one or more concepts using the tutor.

Similar analysis of the data collected by selection tutor again yielded no significant main effect for sex [F(1,630) = 0.373, p = 0.542] (Figure 3) or racial group [F(1,630) = 1.956, p = 0.162] (Figure 4). *So, students needed and benefited from the tutors in the same proportion, regardless of sex or racial group.*

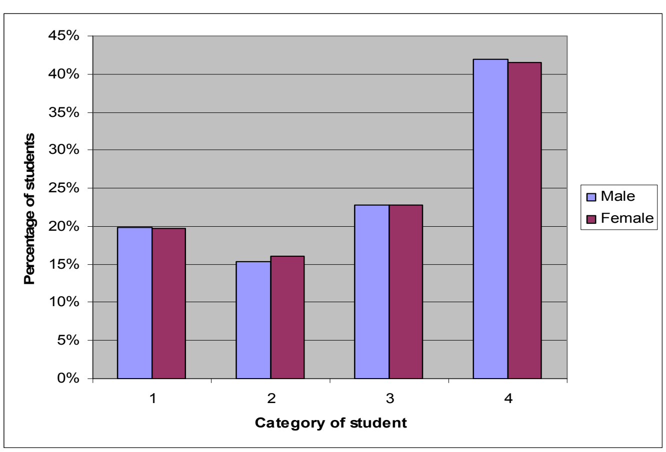

Figure 1. Arithmetic Expressions Tutor: Percentages of male and female students distributed among the four categories

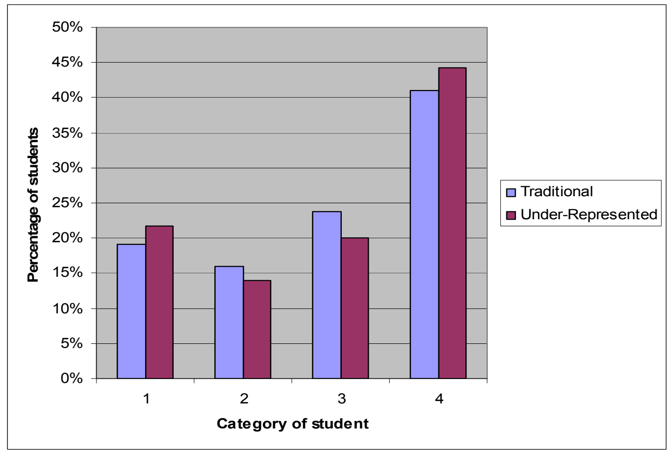

Figure 2. Arithmetic Expressions Tutor: Percentages of traditional and under-represented racial groups distributed among the four categories

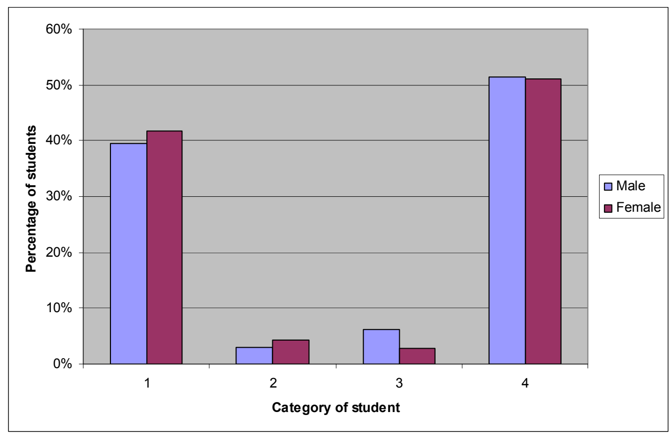

Figure 3. Selection Tutor: Percentages of male and female students distributed among the four categories

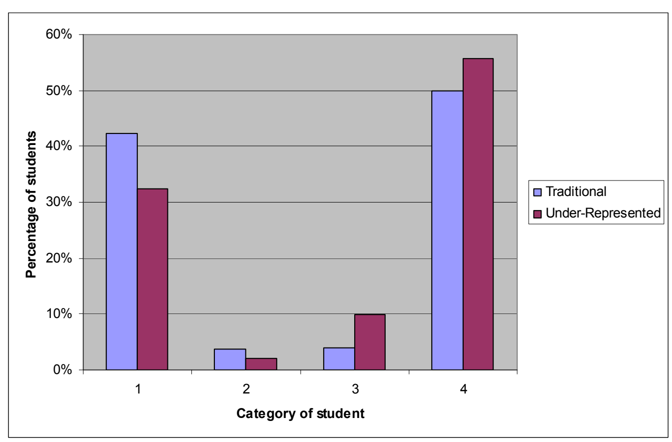

Figure 4. Selection Tutor: Percentages of traditional and under-represented racial groups distributed among the four categories

V. DISCUSSION

Two tutors were used in this study. The following summarizes the analysis of the data collected by these two tutors:

- Students who did not need to use the tutor – Among these students, whenever any difference was found, either female students or students in under-represented racial groups spent longer solving problems, possibly because of lower perceived self-efficacy [14].
- Students who practiced one or more concepts – Among these students, whenever any difference was found, it was female students who either practiced significantly more concepts when they had solved significantly fewer problems during pre-test, or demonstrated greater pre-post increase in score when they had scored significantly less on the pre-test. These results bode well – one study found that the most significant cognitive factor predicting attrition in Science was low grades earned in introductory courses [16]. Attrition of female students is of particular concern in Computer Science, a phenomenon popularly referred to as the shrinking pipeline [17]. Given that the tutors help female students improve their scores from pre-test to post-test, they might help reduce the attrition of female students in introductory Computer Science courses.

No other differences were found between the sexes or racial groups. In particular:

- No difference was found on the number of practice problems solved by the sexes and racial groups per practiced concept. So, the effort needed to practice with problets was the same regardless of sex- or racial group.
- Students needed and benefited from the tutors in the same proportion, regardless of sex or racial group.

Both these results are reassuring for the use of problem-solving tutors in Computer Science, given the significant under-representation of women and minorities in Computer Science and the push to broaden participation in the discipline.

Socially relevant themes, and teamwork and collaboration, are increasingly being emphasized along with hands-on learning as effective pedagogical approaches for engaging women in computing.. [18]. That female students learned just as well as male students by using problets seems to suggest that hands-on learning is effective on its own, even without the incorporation of socially relevant themes or teamwork and collaboration, neither of which is part of problets.

The tutors used in this study dealt with basic topics in programming. We plan to conduct additional studies with tutors on more advanced programming topics to see whether these results can be replicated or different patterns will emerge.

ACKNOWLEDGMENT

Partial support for this work was provided by the National Science Foundation under grant DUE-0817187.

***Abstract*—Since the start of the 21st century, information technology (IT) was introduced in many universities to support effective instruction. One solution intended to support STEM classes took the form of a *classroom* management system, such as DyKnow Vision™, which was different from a *course* management system (CMS), such as Moodle™. This may be because HTML editors on web-based CMSs do not easily allow both instructors and students to produce freehand scientific information such as equations, charts, and illustrations. However, *classroom* management systems require special devices such as Tablet PCs and force instructors to perform complex system operations. Moreover, in some cases these systems are not necessarily designed to accumulate learning activities for ABET or e-Portfolio. To support both writing by hand and the accumulation of learning activities in a class, the system proposed here, developed on the basis of the key concept of "No special devices in a class," makes use of sheets of paper and digitizes the papers after the class so that they can be stored in a CMS. A multifunctional peripheral with a digital watermark enables this educational setting. Our demonstration experiment for three classes functioned well. This paper presents a system overview and the preliminary results.**

Keywords—writing by hand; OCR; watermark; e-Portfolio; course management system; collaboration and learning environment

I. INTRODUCTION

To achieve more effective learning outcomes, many universities developed IT infrastructures in the 2000s. Tablet PC-based learning technologies with classroom management systems are favorable for this purpose in that they support active learning for all students in a classroom [1]. With the trend of "bring your own device" (BYOD), which became popular beginning in the 2010s, institutionally selected or recommended PCs might no longer be the best solution for institutions, in addition to their being a financial burden. If the main reason to employ Tablet PCs is to support text written by hand, a paper-based instructional method should be reconsidered that can be integrated with a CMS. Educators seem to prefer classroom management systems such as DyKnow Vision™ over CMSs such as Moodle™ because HTML editors on web-based CMSs do not easily allow both instructors and students to produce freehand scientific information such as equations, charts, and illustrations. However, classroom management systems require Tablet PCs and force instructors to perform complex system operations. Moreover, they might not be designed to accumulate learning activities for ABET or e-Portfolio. To support both writing by hand in a class and the accumulation of learning activities, the system proposed here was developed on the basis of the key concept of "No special devices in a class." Regarding the scientific and instructional feasibilities of the project, students in a STEM class can produce every form of scientific information by using this paper-based instructional method. Instructors can use a paper size larger than the display size of Tablet PCs. This system has significance for the education community because it can be applied in a broader scope, as it is applicable to STEM education as well as the humanities and social sciences.

II. TECHNOLOGY AND SYSTEM OVERVIEW

A core technology of this system is a multifunctional peripheral (MFP) that operates as a scanner and printer. This MFP also provides the technologies of a digital watermark and an optical character reader (OCR). In general, a digital watermark has been used for digital rights management or copyright protection [2]. In this study, the role of the digital watermark is to integrate with the CMS. As shown in Fig. 1, microscopic dots are printed on the background of the paper to embed 16 bytes of unique code.

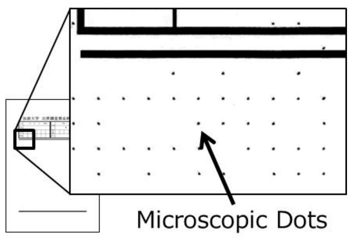

Fig. 1. Sample of a digital watermark.

The system proposed here is composed of an MFP and a CMS. The MFP employed is a network-compatible system made by Fuji Xerox Co., Ltd., Japan, featuring an OCR function and a large operation panel. At the MFP front end, a control PC is added to run developed modules with the database. The CMS is a Sakai® CLE 2.7.1 on CentOS 6.2.

III. Design To Apply The Technology to a Use Case

One of the use cases of this system is an "answer sheet," as shown in Fig. 2. This figure illustrates the process of this use case according to the steps involved. The process begins in the upper-right position in Fig. 2. To set the course code and the number on the operation panel of the MFP, an instructor prints an equal number of answer sheets as the number of students before the class commences. Then, the MFP prints the answer sheets with the unique ID embedded in a digital watermark across the surface of the sheet. At the same time, the class code is stored in the database with the unique ID as a key. In the class, the instructor instructs the students to write their answers by hand on the sheets. After the class, the instructor writes the grade and comments by hand on the answer sheet for each student, and finally scans all of them with the MFP. The MFP reads the digital watermark to obtain the unique ID and creates PDF files. Through the OCR function, the MFP simultaneously recognizes the handwritten student IDs and the scores written by the instructor. When all the data are ready, the MFP uploads the PDF files to the CMS and generates the summary data for the instructor. The students log in to the CMS and can see their scores and comments on the attached PDF. The instructor can also obtain a set of answer sheets that are sorted according to the students' IDs in a PDF and a spreadsheet file that lists the students' scores.

IV. Project Status and Results

Before we developed the system, we conducted a feasibility study to confirm the recognition capability of the OCR in June 2012 at the time of regular final examinations during the first half of the 2012 Japanese academic year. In October 2012, the preliminary system to support the use case described above was developed and became available at Hosei University in Japan. Using this system, we conducted the demonstration experiment for three classes until the end of 2012, and we confirmed that the system functioned well.

A. *OCR Recognition Rate*

Eighty-three third-year students in the Faculty of Science and Engineering wrote their answers with pens in the traditional way for a paper-based final examination. The instructor also handwrote the scores on the examination papers. The MFP scanned all the papers and recognized both the

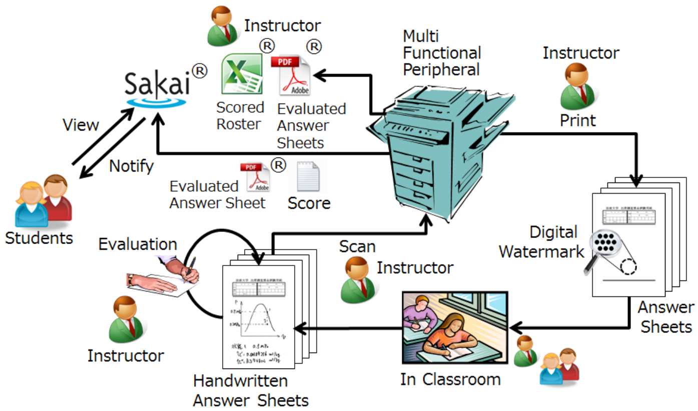

Fig. 2. System overview of the technology being applied.

student IDs written by the students and the scores written by the instructor. The results of the recognition rate are shown in Table 1. The characters "6", "0", and "5" are incorrectly recognized as "8", "6", and "3", respectively. The recognition rates are 99.4% and 99.8% for the instructor and the students, respectively.

TABLE I. Results of Recognition Rate of OCR

	Number of character images	Number of true recognition	Number of false recognition	Recognition rate (%)
Instructor (n = 1)	510	507	3	99.4
Students (n = 83)	581	580	1	99.8

However, a recognition rate of 99.96% might be achieved if this system were applied to a class of 200 students spared from the impact of a false recognition. The student ID consists of seven characters. So the MFP tries to scan a total of 1,400 characters for 200 students. If the MFP can recognize more than 1,399.5 characters, a false recognition will not possibly occur for 200 students. In that case, a desired recognition rate is expressed as

$$1399.5/1400 = 99.96\%.$$

To improve the recognition rate, the following approach will be applied in future.

- The student ID will consist of numerical and alphabetical characters. In the case of student IDs of our university, the third character from the left is an alphabetical character and the rest are numerical. So the candidate characters are reduced to match the character type when the MFP recognizes the student IDs.
- Examples of fonts that the MFP can easily recognize will be additionally provided at the bottom of the answer sheets.

B. *Task Analysis*

The total required time—from pre-processing such as obtaining answer sheets to post-processing such as returning scored sheets to the students—was analyzed by a task base. Suppose there are 100 students in a class. Comparing our method to the traditional way of returning the scored answer sheets by hand in a class, our method saves a time of approximately 10 min. If the instructor used a CMS to return the scored answer sheets as a PDF file to the students, the total required time that would be saved with this system is approximately 1 h. This is because in the traditional method, one would use the scanner to individually scan all the sheets collectively and obtain one PDF file that includes all the sheets, with a file name based on a date, such as "201303150722.pdf." Therefore, time would mainly be required to separate the files of each student, rename the files with the same name as the student ID, and upload the files to a designated place in the CMS using a Web browser.

V. Future Plans

The preliminary system has been evaluated in practicable and efficient manner, enough to be applied to a real-world scenario. We plan to deploy this system at our university step by step. First, we are certain that this system can be applied to other teaching methods such as reports and tests, mainly on the basis of the results obtained from this study. Looking toward the possibility of campus-wide implementation in the near future, we intend to develop an interface module that enables the MFP to obtain course attributes from the CMS, such as course title, instructor name, and timetable. This is possible because the operation panel on the MFP currently can display three courses given for this study. We are developing this system particularly for face-to-face STEM classes. However, writing by hand using pen and paper is still prevalent in the education field. Therefore, this system will be applied to all educational settings in which the courses are not completely online.

***Abstract*— Until the last decades, students of distance learning universities had to go to traditional and physical laboratories to acquire practical knowledge and skills. Currently, thanks to the advances in communication and computer networks and the evolution of programming languages, new eLearning tools have emerged that enable the usage of learning methodologies such as blended learning and distance learning. One of them is the remote Web laboratory. A remote Web laboratory is an application which allows students to work with real hardware or instruments. To do this, students only need a computer with an Internet connection. However, emerging technologies and other hardware such as mobile devices, cloud computing and the Internet of Things, require the design of different models to support innovative learning experiences. For this reason, remote labs are being reconsidered to smart device paradigm. Physically, the considered smart device is made of the junction of a controller (computer server) connected to physical equipment on the one hand, and to the Internet on the other hand. This paper describes the process to translate a "traditional" remote Web lab into a set of smart devices which are able to work together in the cloud and the Internet of Things.**

Keywords—remote laboratories; eLearning; distance learning; eLearning services

I. INTRODUCTION

Astronomy, biology, chemistry, electricity, electronics, mathematics, physics … any science domain of knowledge can be studied with experiments where the empirical predictions derived from the theoretical model are compared with the actual phenomena. However, interacting with real systems through computer-based devices such as workstations, laptops or mobile phones requires a proper infrastructure. Instant response to the learners' actions and an intuitive way of manipulating the remote components (i.e. modifying their parameters to view the results) are two key features. These environments try to convey creativity and ease of use. In one side, students perform different activities from any location at any time. On the other hand, instructors keep track of their progress with collected data from their sessions.

When remote laboratories were originally launched within the eLearning community, such capabilities could not be included due to the limitations imposed from programming languages and learning systems for the World Wide Web, either specific institutional applications or learning management systems (LMS).

The previously described scenario has dramatically changed, but monolithic systems with a reduced set of functionality are still the prevailing choice. Aside from slight integration at the LMS level of dynamic elements, the experiments rely on a very inflexible framework. In the following sections we will analyze these solutions tailored to online experimentation. Based on this analysis, the smart device concept is introduced as a way to extend these laboratories. Its benefits and possible flaws in comparison to other operative installations will be also addressed. As a final section, some relevant examples of such conversion will be described to support this hypothesis and future efforts.

II. DESIGNS OF REMOTE LABS FOR ELEARNING

Although many classifications of online laboratories have been proposed in the course of time, the focus of attention here is on remote labs. In this particular setting, students are able to control the actual device (i.e. it is not a simulation) or system from a long distance. Generally, a camera is installed in the physical lab room, so any variations applied to the initial and subsequent states are immediately viewed by students.

Two main types of data transmission belong into this group: interactive and non-interactive operation. The parameters of the experiment can be changed in the first group whenever a student wishes to do so, whereas the learner must wait a certain lapse of time to data being processed by the system in the other case, also called batched experiment. Viewing sensor data through a chart might be considered a third class, but it is restricted to a posteriori analysis of the visualization output.

Every single remote lab depends on its fundamental building blocks to establish the communication. The basic configuration consists of a local server connected from one side to the experiment (usually bridged with a data acquisition card) and on the opposite side to the local network or Internet, and, the client computer. A typical remote lab is completely encompassed with these basic components and some slight mutations [1].

The user interface (UI) comes next as an element of interest. Students and teachers usually identify themselves in

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

the portal of their affiliated institution. From there they can go to their course and start the experiments. Most platforms facilitate access to the experiments through a simple form-based interface [2]. Recent efforts resemble to such a degree the manual controls that is pretty difficult to tell the difference between real and virtual images [3]. An special category of labs is worthy to mention in the graphical aspect. That is the hybrid lab, where visual elements are overlapped with the original components of the view in an augmented reality [4]. If learners activate its “virtual view”, the user interface displays additional information about the experiment that would be otherwise unavailable without further calculations.

After this general review of current existing developments, it is safe to assert that remote laboratories present a common number of issues related to both user side and developer side. Among the items that should be addressed, these are the most significant points of conflict:

- Laboratory hardware and software implementations tied to specific vendors. Monolithic designs, from the user interface to the fundamental building blocks, are mostly programmed with proprietary languages and external plug-ins: Adobe Flash, Java and LabView.
- Navigation, search and discovery of single experiments, their resources –documentation, exercises, assessments, etc.– or even their associated laboratory according to some criteria such as domain, institution, difficulty or student’s age demands a fair amount of time from those people interested.
- Sharing data of the lab between different machines is not feasible because sources to get them are scarce, unstructured or even non-existent. Until recent specifications, Internet protocols were neither designed to keep a fast and stable channel of communication (or be absolutely sure that the values had been sent).
- Scheduling/reserving a lab session involves a process of authentication and authorization that it is not transparent to other devices. Many different systems (queues, slots, tokens), custom implementations and databases (administration, LMS, portal) uncover security threats that need to be carefully tackled.

Nevertheless, open standards [5] have emerged as the cornerstone to build an ever-growing network of interconnected devices that overcome these recurrent issues. Web services and widgets help in that regard.

Service oriented architecture (SOA) enables developers to abstract complex languages in local computers with different services that expose the application data [6]. A service can be defined as a process which consumes a particular set of inputs and produces outputs. W3C widgets [7] or OpenSocial gadgets [8] can be linked to those services, therefore simplifying the creation of modular apps to be deployed on different appliances. Instructors can build mashups with collections of these objects that fulfill a common goal simply by arranging them in their Web space. Reusability of the whole lab is improved substantially separating the user interface of the Web application from program logic; a critical obstacle for device to device communication is removed here.

Conversion of traditional laboratories to conform to the aforementioned specifications will be dealt with in the next sections. As a matter of fact, smart devices are going to stand out as the new paradigm with which remote experiments will verify the cited premises.

III. FROM HCI TO DEVICE-TO-DEVICE COMMUNICATION

Human computer interaction (HCI) has greatly improved in the last decade. Tactile input or voice feedback are mainstream features accessible through many handheld instruments. Although these enhancements have become very familiar in commercial technology, its implementation in remote laboratories has not yet reached that level of prevalence [9]. A pending task of remote labs is interacting less obtrusively with humans through personal learning environments or PLE (i.e. hiding the fact that humans interact with computers).

As it was pointed out before, online laboratory platforms do not allow a standard method to access and reorganize their built-in components on the screen. Neither are capable of communicating with other systems in the network to improve their global performance and robustness. As a consequence, workarounds must be put in place that help students and instructors to customize the final experience, as well as offering the best interaction achievable. Here the smart device paradigm enters the scene with its advanced capabilities, effectively acting like a nexus to interconnect remote experiments. Small dynamic blocks of content known as widgets are responsible of handling the desired flexibility and high interactivity from a graphical user interface. These couple of specifications need to be studied with more detail. From here onwards, the reference schematic that will be considered is depicted below (Fig. 1).

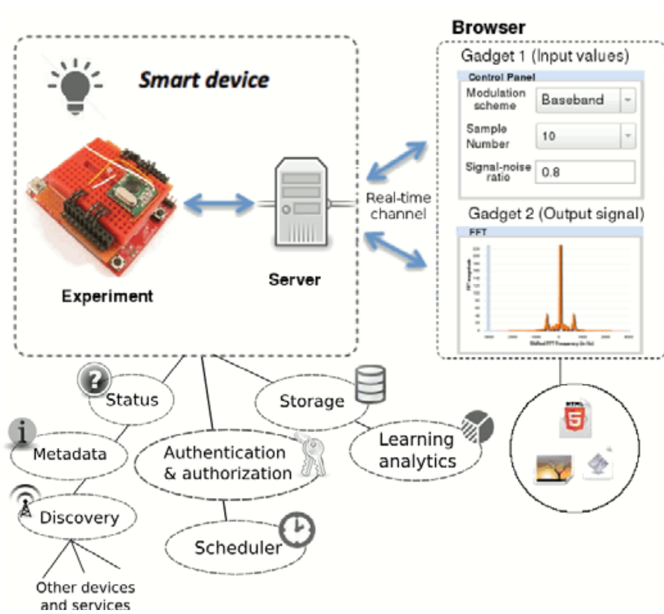

Fig. 1. Smart device structure, widgets and services of a remote experiment.

The smart device concept [10] has a tight relationship with ubiquitous computing (UbiCom). The last term refers to Information and Communication Technology (ICT) systems that enable information and tasks to be made available everywhere, and to support intuitive human usage, appearing invisible to the user. In fact, with smart environments and smart interaction, smart devices close the set of basic architectural designs for UbiCom. In this context, the vision of automatic device to device and device to service communication are summed up in a concept known as the Internet of Things [11].

Another requirement to support collaboration in the same experiment is the widget specification. Widgets consist in a combination of four very popular Web technologies: HTML, XML, Javascript and CSS. An engine, generally installed in the server-side, renders the page resulting of data extracted from external services. OpenSocial gadgets are another variant of this specification but centered in social network interactions. In the eLearning ecosystem, these blocks are not only environment agnostic, they are independent of the webapps or content publication system (e.g. blogs, content management systems, social networks, wikis). LMS can also make good use of them in learning objects through server plug-ins; gadgets are flawlessly embedded within content packages such as SCORM or IMS LTI remote tools [12]. However, PLEs stand for the preferred solutions as their user-centered philosophy is more suitable for team work in the same concurrent time space.

To build a remote lab capable of covering the conditions formerly outlined, a last element is crucial: the protocols of communication. The arrival of Web technologies oriented to real-time transmission of data, such as videoconference or online workgroups (e.g. concurrently editing documents, sharing a teacher's whiteboard with many viewers…), sending and retrieving data through a well-established protocol has become another task at hand. This efficient way of transmitting digitally codified information can be applied to the values of variables from laboratory experiments. In addition to that, compression algorithms allow members of educational networks with low speeds and limited bandwidth to achieve a satisfactory experience. Although WebSocket has become the de-facto standard for fast communications across different browsers, smart devices must support a wide array of protocols (Fig. 2).

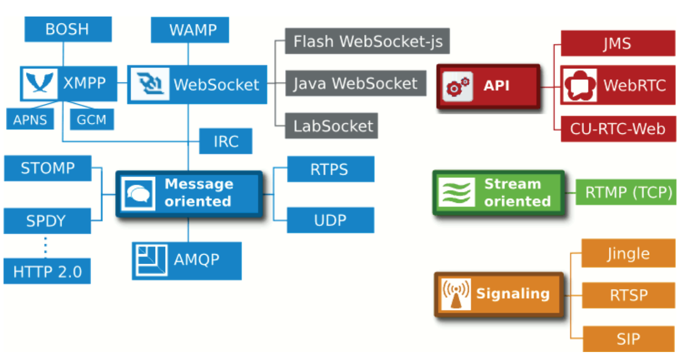

Fig. 2. Classification of real-time protocols for remote labs by data transmission method and APIs.

Finally, with all fundamental elements at hand, the general structure surrounding a smart device for remote labs is clearly defined. When the smart device is in operating mode, a set of inputs/outputs are active while learners interact with the experiment (Table 1).

TABLE I. INPUTS AND OUTPUTS OF EXPERIMENTS

	Format	**Encoding**	**Typical application**
Inputs (commands, values, user info, component selection)	Unstructured text	iso-8859-1, unicode, other codification	form-based dialogs
	Structured text		csv tables, xml metadata, json, app-associated
Outputs (measurements, results)	Structured text	iso-8859-1, unicode, other codification	csv tables, xml metadata, json, app-associated
	Static image	bmp, png, jpeg, tiff	diagrams, charts, screenshots
	Audio stream	g.711, gsm, mpeg3, ogg, opus, speex, silk	podcasts
	Video stream	divx, mpeg2/4, h.263, h.264, vp8, theora, xvid,	monitoring, conference

IV. SERVICES IN THE SMART DEVICE NETWORK

Given the relevance that services acquire in the whole infrastructure, such event gives an idea of how existing platforms will be decomposed in the new paradigm. In relation to Web services in the cloud, these external sources of data have been distributed into seven main categories with their corresponding functions:

1) *Authentication and authorization,*
2) *Discover,*
3) *Learning analytics,*
4) *Metadata,*
5) *Scheduler,*
6) *Storage,*
7) *Status.*

A more exhaustive comparison of these services with existing platforms will mark the main differences. Therefore, an analysis of how each one of the services are assembled together comes next to illustrate the architecture.

A. Authentication and authorization

Controlling which users shall access an experiment turns into a prerequisite of any remote laboratory. Statistics from usage need a unique identification of the learners that visited the lab. Generally each institution implements its own authentication and authorization system with a federated system [13]. That way administrators give access exclusively to the members stored in a personal database. Furthermore, security is guaranteed verifying their identity. Data confidentiality relies on cryptographic protocols (e.g. HTTPS). Anonymous and open access is also allowed in some environments.

The login system consists in a Web formulary. Students must type their assigned user and password values that they obtained, either by registering in the remote lab page or, if possible, retrieved from the institutional portal through a single sign on facility. This last type of authentication alleviates the tiresome task of creating a profile for every tool in an eLearning ecosystem. Other option that is spreading only requires the e-mail address to start all the process. If users have more than one address, they get an intuitive method to keep their contact info in sorted categories according to its place (home, work, university, etc.).

In the smart device network, all requests first go through the authentication service. This requirement is justified by the recompilation of learners' statistics. If every user does not have a unique id, all related data could not be correctly organized for future queries in the instructor's page. The separation of UI (widgets) and the server logic ease the place where the login form must be located. In fact, there is absolute freedom to transmit that info between other devices or services. Different types of authentication can coexist in the same *widget container* (this tool is described in the examples) while staying transparent to the user, so it is open to further experimentation. Moreover, as hiding the HCI from users has been settled as the aimed objective, form-based layouts must become a fallback option with respect to other instruments (Fig. 3). Biometric systems with a low-intrusive approach would upgrade a relatively outdated component of laboratories. Graphical password schemes also offer protection against spyware or dictionary attacks through an attractive input [14].

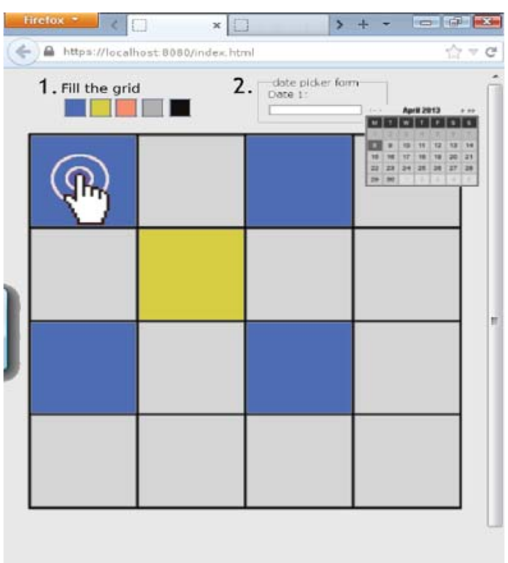

Fig. 3. Prototype of a typical graphical password system.

B. Discovery

Used by a smart device connected to a network to announce itself and to discover other devices or services, this service has not any equivalent in remote laboratories. As for the computer world and industry, that exact statement would be absolutely incorrect. The Universal Plug and Play management, discovery and control system, HAVi, JINI and the OSGi alliance [15] are initiatives that have developed interoperability guidelines for home devices. As for a SOA industrial scenario, there are currently two alternatives to be deployed at device level: Devices Profile for Web Services (DPWS), and OPC Unified Architecture (OPC UA) framework [16][17]. The SOCRADES project combines these specifications with other standards in order to promote mutual interoperability [18].

Consumer electronics such as domestic appliances include a selection of features to ease their use. For instance, TV sets are designed to automatically detect and communicate with external media players or wireless hard drives when they are located in its proximity without any action coming from the user. All these devices have an internal code (also called firmware) programmed in their hardware that is responsible of assigning a unique identifier to each object.

Smart devices are able to find other compliant device or service and share data between them. LinkSmart is an application of that technology [19]. In this context, showing different experiments through the same user interface becomes a reality with a collection of services. If the physical system broadcasts its presence, third parties receive a tool to build their custom lab explorers suited to their needs. This open network possesses a great potential for improvements, so including this feature in the smart device for experiments is necessary. An schema to identify every single device and their properties in a consistent way across contexts (e.g. terms with a well-defined meaning) is the Web Ontology Language (OWL-S) [20]. The IEEE1451 is currently working in a unique identifier for these devices.

C. Metadata

The description of laboratories and experiments exhibits an irregular implementation among eLearning environments. Nonetheless, most developments include some information about the resources in the Web portal or the LMS. Learning object metadata (LOM) and profiles based on this standard format represent the best examples [21]. As a result, some projects have assumed an important role introducing metadata formats to describe and search labs and other resources linked to them. Repositories of experiments reduce the effort in finding and exploring lab installations [22][23][24][25].

In order to other devices or services to "chat" with a smart device or some of its components, they have to know some properties about the structure: inputs, outputs, protocol, technical specifications (maximum speed, data format, compression…) and relationship with elements of the network (it is part of, depends on). Educational characteristics such as the scientific domain, age of students, difficulty and related documentation fall into this service. Taking the main classification as a reference, structural metadata and descriptive metadata are the types associated to smart devices [26].

The level of aggregation hinders the extensibility of laboratories. This service combined with widgets is a good start to increase the modularity of the complete network. It must be noted that widgets possess a specific section dedicated to their description, so sharing metadata between them and external services is viable.

There is not an universal schema to handle several descriptors and domains –it might be even counter-productive for parsing and generating high amounts of metadata interoperable with other systems. Therefore, all these characteristics may be extracted from one device in a variety of structured formats when external sources demand them, such as IEEE's Automatic Test Markup Language (ATML) [27], Dublin Core [28], Contextualized Attention Metadata (CAM) [29], Javascript Object Notation for Linking Data (JSON-LD) [30], State Chart XML (SCXML) [31] or the Resource Description Framework schema (RDF) [32].

D. Learning analytics

If one functionality stands out from the full set of modules integrated into eLearning systems, that is the tracking and assessment of learners. Instructors have constantly struggled with the high difficulty of building an attractive and simple statistics registry to gather and export results since their origins. In most cases the task was extremely complicated, as the sequencing procedure in SCORM for LMS, or practically unusable. Remote labs are not the exception. Once again, developers either use the limited internal capabilities of their LMS, or create specialized analysis tools without any connection to the outside network [33]. Other typical method of fetching information about users, but restricted only to the number of visits or their geographical origin, is the Google Analytics service.

Nevertheless, where do statistics come from? If we distinguish between client and server, there are two sources: user interactions and logs, respectively. The first kind refers to the tasks a student makes in the interface: elements clicked (e.g. buttons, slide bars, knobs), gestures used in the environment to finish a learning phase, opened pages, hyperlinks visited, etc. In the second group stands all data stored from visitors into the server drive, such as user identifiers, timestamp of sessions, or their sequence of actions. These groups are similar to the extent that both are complementary. In spite of that fact, server logs have become the main option to avoid privacy issues. On the other side, paradata or metadata of usage is acquiring importance. With widgets and an application programmable interface (API) tailored to that purpose [34][35], any mashup can register the users' actions and draw their workflow (e.g. heat maps).

This service registers a specific array of variables of the experiment. The selection of some elements of that array springs forth from the fact that instructors must filter which signals are more than enough to evaluate the progress in experiments. Other variables derived from measurements could be calculated instantly through the same service. In fact, a mashup can show graphs, bar charts and scores in a consistent user interface from a list of learners in the instructor's Web page. Generating reports exportable in popular formats (doc, pdf, csv) from a wide selection of places is a powerful feature provided by this service.

E. Schedule and reservation

A maximum number of concurrent students is the known restriction of remote labs. If that limit is exceeded, the experiment does not behave in a useful way (e.g. long delays between actions of the learner, lost packets or unexpected disconnections from the lab could happen frequently). The bottleneck comes from the network bandwidth and the physical experiment. Consequently, such undesired situation must be circumvented at all cost.

Schedulers and reservation systems take charge of limiting the number of users connected at the same time. Interactive experiments are the most restrictive, in contrast with experiments operated in batch. The latter group admits queue system where slots can be filled immediately after the task has been completed (if each task is not time-consuming). There are a fair amount of methods of scheduling an experiment depending on its interactivity: booking, queues or hybrid algorithms, among them. In fact, it has reached the status of a critical cross-lab requirement [36]. If two or more experiments from different locations are going to be watched through the portal, a widget handles the specified timeframe transparently.

F. Storage

Participants of laboratory sessions work with a remarkable quantity of digital content during the learning process. Attending to interactivity, content is divided between static and dynamic. In the first kind there are tutorials, slideshows, spec sheets or reports. On the other hand, conceptual maps, a list of hypotheses and the personal journal would be perfect examples of instances included in dynamic content. This documentation is widely distributed across the LMS and Web portal servers. However, the cost and low integration of editing tools makes dynamic resources a secondary in proportion to the former.

The storage service provides space for data. Any content that shall be saved permanently goes to this component. Validation of the supported formats, file size limits, quotas, integrity of received documents etc. are critical characteristics that must be guaranteed in the communication with the experiment.

V. Migration of Remote Laboratories to the Smart Device Paradigm

In a boundless software ecosystem, developers would presume that every single laboratory up to the current date can be decomposed in a limited set of smart devices. Unfortunately, that is not the landscape yet. For that reason, not all experiments admit a full conversion without rewriting the code, that neither is accessible to third parties in most cases. Keeping that in mind, we will explore typical situations and then propose the best approach to manage the transformation of the remote laboratory.

At this point, it is clear that there are two blocks to confront: the server-side and the client-side. Depending on the conditions owners stipulate to access the laboratory, four cases will show up. To understand the scope of upgrading remote laboratories to conform with the smart device paradigm, any changes that affect the components of the whole eLearning ecosystem will be listed. Advantages and aspects to watch after the improvements have been applied are the aspects summed up in this analysis.

A. No changes to the experiment structure

Administrators of the laboratory do not allow (or cannot provide) any sort of tinkering with the server. Neither the code of the client is available for introducing some modifications. This is the worst case that could be faced in any circumstances. *Embedding the Flash animation or Java applet in an iframe* is the only possible workaround. Students need to go through the remote lab login system and scheduler every time they load the object.

As far as the original laboratory is concerned, user id is the only new data that the widget container retrieves. Learners and instructors do not obtain benefits whatsoever. Nonetheless, once the object has been included in the container, other widgets are at the owner disposal (from the LMS or PLE). For instance, an assessment tool could be configured to support the experience if that feature was not programmed in the original experiment.

B. Client access only

In this case, developers have enough permissions to add an *alternative user interface*. This fact implies that the authentication system can also be upgraded to match the portal. Although the server is off-limits, learning analytics, scheduling and data storage are also accessible.

Single sign-on is the immediate enhancement to avoid users the inconvenience imposed by a double login (e.g. sharing security tokens across widgets of the same experiment). As for scheduling, additional adjustments to the booking system are recommended as well: one time reserves. Other temporary variables or data might be stored in the widget container.

As another result of accessing the client-side, learning analytics become available (i.e. learners can be tracked) through user interactions. Recording statistics of lab sessions securely through a Representational State Transfer (REST) service requires the installation of such functionality in an external server. The Learning record store [37] could manage this function, or an installation explicitly designed for saving such data. Building a customizable mashup for reports and charts to monitor the educational progress of students from the instructor's page is still pending further study.

C. Client access and limited server adjustments

For this particular situation, the existing server connected to the experiment admits modifications from its previous behavior. Client-side is also open to developers inspection. On the other hand, owners wish to leave an unaltered LMS as their learning environment.

At the current stage of integration of LMS and remote labs, a methodology to consistently incorporate these apps has not been successful. Specific plug-ins for each LMS represent one approach, like the Moodle version for OpenSocial apps [38]. The first steps towards an unified solution of this issue are underway. Adding the required middleware that wraps remote laboratories as services is the proposed link. This smart gateway consists of a Javascript library that translates all requests from the lab to those functions supported in any LMS. Any benefits will be restricted to the level of compliance reached between the two aforementioned software elements. Learning analytics and data storage must be processed following exactly the same procedure described before.

D. Full access to all components

If teachers want to take advantage of the flexibility that widgets and smart devices hold for eLearning experiences, this is the best path to follow. Any required services will be deployed around the experiment.

VI. Conclusions

Experimentation is essential for a material, scientific, rigorous and critical comprehension of the existing reality. The creation of attractive and engaging experiments requires high-end developers that work in a tight but conflictive relationship with teachers. Remote laboratories also demand a methodological and theoretical reflection about "how", "why", and for "whom" an idea is taught, but without being independent of "what" is taught. As a consequence, only a small number of experiments with very strict limitations is currently available.

Smart devices provide guidelines and resources that help to overcome this situation. Communication protocols and formats for exchanging and sharing data are key elements in this aspect. The described service-oriented (SOA) infrastructure makes a clear separation in roles, where the teacher and developer have their respective technical and instructional tasks clearly defined.

A compelling challenge for SOA developers and instructors is to find adequate services for solving a specific task. Future work is oriented to build the network of services that connects experiments in a simple fashion. The combination of these services with collections of attractive widgets or mashups will promote their use. Aggregating such webapps for eLearning can simplify the authoring process and customization of personal learning experiences.

Personal learning environments and remote labs also breach the barrier between university and high school, acting in the practice as a link for lifelong learning. Learners assume an active role in all the process. This space of collaboration based on services and widgets will provide a richer experience for teachers and students.

Remote labs based on the smart device paradigm is a work towards the common goal of securing and encouraging a better assimilation of science, technology and mathematics knowledge through a variety of exercises. Obtaining analytics from activities will ensure a better understanding of the students' progress (common pitfalls, ways of remediation), but also adapt the experience to different learning styles or levels of difficulty.

ACKNOWLEDGMENT

Authors are grateful to the members of the Electrical, Electronic and Control Engineering Department (DIEEC) of UNED for their continuous advice and support.

***Abstract*— One of the key issues in the education field is the acquisition of skills. This practical knowledge was usually acquired through traditional labs or standalone simulation programs. The World Wide Web and the advance in web programming language have allowed teachers to create online learning applications, such as virtual web laboratories which can be displayed by Web browser, at any time and everywhere. Currently, a large amount of virtual Web labs can be found in the World Wide Web, and these are able to cover a wide range of educational fields such as physic, chemistry, electronic, medicine, mathematics and languages. This paper describes the process of searching of these laboratories and their packing in Sharable Content Object, following the e-learning standard called SCORM.**

Keywords—Sharable Content Object; Learning Objects; Learning Management systems; Virtual Web Laboratories.

I. INTRODUCTION

Currently, it is very common to see students working with learning tools which are run for PCs, tablets or mobiles. But, until 80s, students acquired knowledge and skills through traditional resources and activities such as books, cassettes, videocassettes, face to face classrooms and traditional laboratories.

These learning resources and activities are being replaces or complemented with e-learning resources and applications, for instance:

- Books are being replaced by electronic files (Webpages, PDFs or epubs).
- Cassettes or videocassettes have been replaced by podcasts and electronic video.
- Face to face classrooms are not replaced fully, but they are being complemented with learning applications, such as learning management systems, which allow teacher to create learning scenarios. According Klebl [1] a learning scenario is a social setting dedicated to learning, education or training. It is a process of interaction between people in a specific learning situation using resources for learning within a designed environment.
- As the Face to face classrooms, Traditional Laboratories are being complemented or replace by learning application called virtual and remote Labs.
    - Virtual Labs are simulation programs which allow student to carry out experiment at anytime and anyplace.
    - Remote Labs are programs which allow student to carry out experiment with real instrumentation at anytime and anyplace.

Both electronic files, learning management systems, virtual and remote Labs be uploaded to Internet and displayed, depending on the format, over different devices, such as PC, electronic readers, tablets, or mobiles. Therefore, currently it is possible to find a great number of learning resources and applications. Each one are developed in different formats and programming languages. In the case of e-learning resources, many groups are working in the developments of e-learning standards which allow teachers to search and reuse these learning resources, such as:

- IEEE Learning Object Metadata (IEEE LOM) [2], which enables learners or instructors to search, evaluate, acquire, and use learning resources or objects across any technology supported learning systems. To do this, LOM defines the structure of a metadata instance for a learning object. This conceptual schema specifies the data elements. In the schema, data elements are grouped into nine categories: General, Cycle-Life, Meta-Metadata, Technical, Educational, Rights, Relation, Annotation and Classification category.
- IMS Content Packaging (IMS-CP) specification describes data structures that can be used to exchange data between systems that wish to import, export, aggregate, and disaggregate packages of content [3]. This structure is called package interchange file (PIF)

and it stores a set of items (images, texts, etc.), and references to items from other PIFs in an organized way.

- Sharable Content Object Reference Model (SCORM) is a collection and harmonization of specifications and standards that defines the interrelationship of content objects, data models and protocols, such that objects are sharable across systems that conform to the same model [4][5].

- The IMS Question & Test Interoperability (IMS-QTI) specification describes a data model for the representation of question (assessmentItem) and test (assessment) data and their corresponding results reports. Therefore, the specification enables the exchange of this item, assessment and results data, between authoring tools, item banks, learning systems and assessment delivery systems [6].

These and other e-learning standards have been developed to make easier the searching and reusing in learning environments, such as learning management system (LMS) or Courseware.

This paper describes the process of collecting different virtual Labs which are over Internet, packing them in Shareable Learning Object (following the e-learning standard called SCORM) and their integration with learning management system. These steps make easier the creation of learning scenarios in different LMSs without having to do many changes.

II. SCORM

As it was mentioned, SCORM is a collection and harmonization of specifications and standards that defines the interrelationship of content objects, data models and protocols. It is divided into three main sections:

1. Content Aggregation model.
2. Run-Time Environment.
3. Sequencing and Navigation.

A. *Content Aggregation Model*

It describes the components used in a learning experience, how to package those components for exchange from system to system, how to describe those components to enable search and discovery and how to define sequencing information for the components (Fig. 1). These components are:

- Assets are an electronic representation of media, such as text, images, sound, assessment objects or any other piece of data that can be rendered by a Web client and presented to a learner.

- A SCO is a collection of one or more assets. The only difference between a SCO and an asset is that the SCO communicates with an LMS using the Institute for Electrical and Electronics Engineers (IEEE) ECMAScript.

- A learning activity may provide a learning resource (SCO or asset) to the learner or it may be composed of several sub-activities.

- A content organization is a representation or map that defines the intended use of the content through structured units of instruction (activities).

- Content aggregation can be used to describe the action or process of composing a set of functionally related content objects so that the set can be applied in a learning experience.

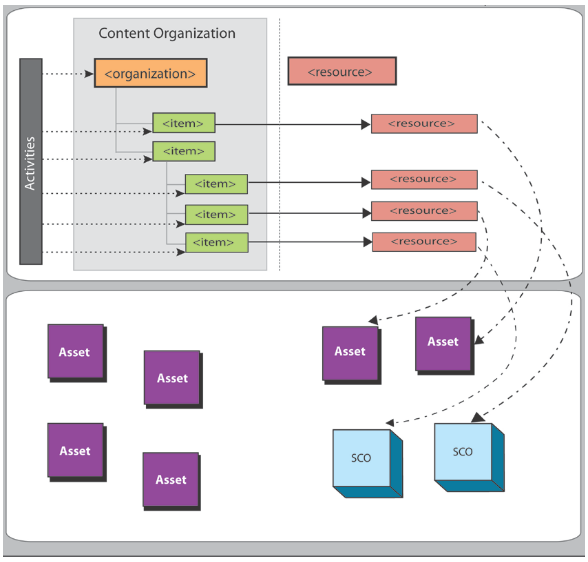

Fig. 1. Content aggregation model [4].

B. *Run-Time Environment*

It describes the learning management system (LMS) requirements in managing the run-time environment (i.e., content launch process, standardized communication between content and LMSs and standardized data model elements used for passing information relevant to the learner's experience with the content). In the figure 2 is shown how the data model exchange information with the LMS.

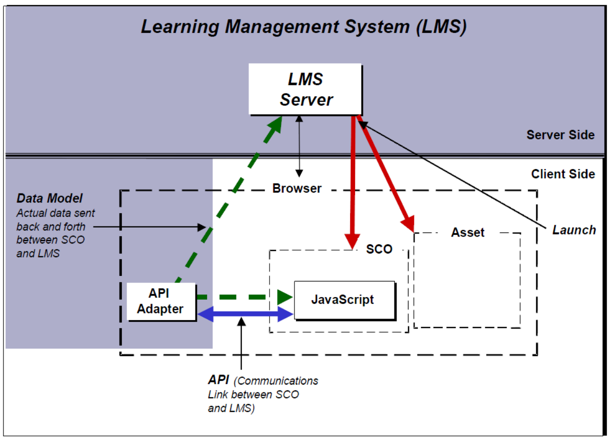

Fig. 2. Run-Time enviroment [4].

C. *Sequencing and Navigation*

It covers the essential learning management system (LMS) responsibilities for sequencing content objects (Sharable Content Objects [SCOs] or assets) during run-time and allowing those SCOs to indicate navigation requests. Therefore, it describes in detail how sequencing behaviors are applied to track learner progress.

III. Packing Virtual Labs in Shareable Content Objects With SCORM

Before describing this process, is important to describe in more detail what a Virtual Web Lab is. As it was mentioned a virtual Lab are simulation programs which allow carrying out experiment at any time and any place. The programs which are developed for the World Wide Web and displayed by a Web browser are called Virtual Web Labs (Fig 3).

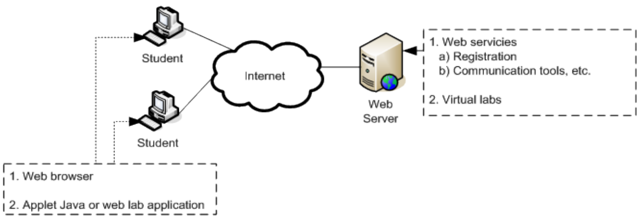

Fig. 3. Virtual Web Lab.

Therefore, Virtual Web Labs are developed in different technologies such as Java Script, Java Applets, Flash Applets or Active X and can be embedded in a HTML page and included as an asset of SCORM package.

This section describes the process of searching and packing of virtual web Labs in a SCORM package.

A. *Searching Virtual Web Labs*

Currently it is possible to find a great number of then over Internet and they cover a wide range of educational fields, such as: chemistry, mathematic, biology and physic. Therefore, many virtual web Labs are searched by internet. The results of this searching were 28 virtual web Labs, divided into:

- Six Web Labs of physic:

  1. http://www.enciga.org/taylor/lv.htm
  2. http://www.phy.ntnu.edu.tw/java/index.html
  3. http://www.sc.ehu.es/sbweb/fisica_/

B. Packing Virtual Web Labs in Shareable Content Objects

Once these Virtual Web Labs are found, the step of packing them in a Shareable Content Objects (SCOs) is carried out. To do this, there are several SCORM editors which make easier the creation of SCOs. The most well known is Reload [7].

To describe this section deeper, an example of one of the listed virtual web Lab is going to be explained:

1. Once the reload editor is downloaded in the PC, teachers can open it, doing double click in the executable file. A graphic interface is displayed with a menu of options.

2. Teacher select the option edit→new→ Adl SCORM package (Fig 4).

3. Once it created the empty SCORM package, the editor ask for a directory where the files or learning resources, which are going to be added to the package (Lab, manuals, etc.), are stored and shows the structure of package SCORM (Fig. 1 and 5). The files and resources are added and organized through drag and drop. The Virtual Web Lab is embedded in a HTML page. In the figure 5 the HTML page Laboratorio.html contains the web Labs (adding the URL as a reference or embedding the applet of active X)

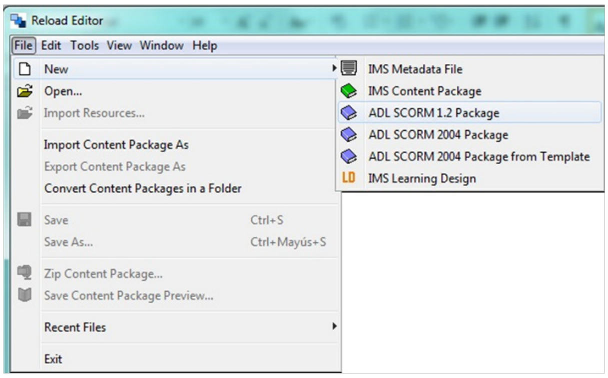

Fig. 4. Creating a empty SCORM package.

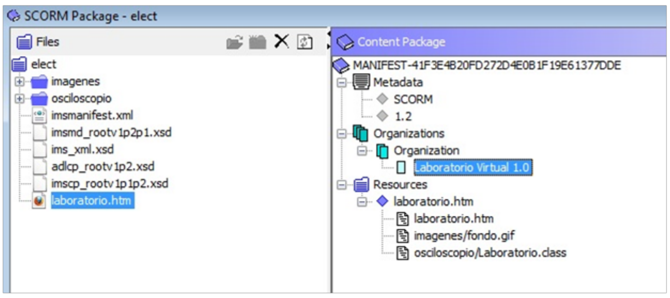

Fig. 5. Creating a SCORM package with several HTML pages.

4. Once all the resources have been included, Teachers save the package in a zip file and see a preview of the package (Fig. 6), using the editor.

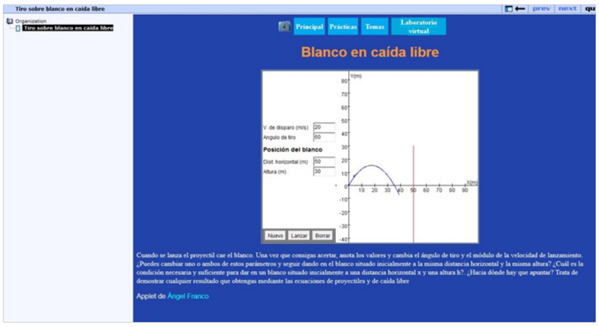

Fig. 6. Preview of packed virtual Web Lab in a SCORM Package.

IV. Adding the SCORM Package in a Learning Management System

An LMS is a framework that delivers and manages instructional content, identifies and assesses individual and organizational learning or training goals, tracks the progress towards meeting those goals and collects and presents data for supervising the learning process of an organization as a whole [8-10]. These can be classified as:

- Proprietary LMS, such as Blackboard [11].
- Open Source LMS, such as Moodle [12], dotLRN [13] or Sakai [14].

While, the proprietary LMSs only allow determined programmers to know its source code, the open LMSs allow some programmers can know its source code, modify and adapt it to the needs of the university or institution for their work.

The vast majority of LMSs provide educational tools, such as:

- Administration. It must be able to manage user registrations, roles, assign tutors, user payments, etc
- Synchronous and asynchronous Communication Tools. It must allow collaborative work. So that they can share information, opinions and experiences.
- Evaluation. The tutors and teachers must be able to evaluate the student's progress. Also the students can do test where they can see their progress. To do it, The LMS provide a set of assessments tools and in some cases these tools fulfill with e-learning standards as IMS QTI (Question and Test Interoperability).
- Tracking user. A set of tools which provide information about user activity and the results of these activities.
- Content packing. It organizes the content in a hierarchical structure and sets up a mechanism to swap content between different learning management systems. To do it, it's usually used the specification IMS content packaging or the specification SCORM (Shareable Courseware Object Reference Model).

Therefore, The SCORM package which has been created in the previous section can be added along with assessments, chats, forums, etc. without having to program anything (Fig. 7).

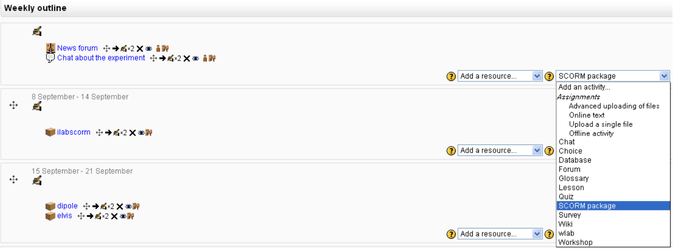

Fig. 7. Adding a SCORM package in a Moodle course and wrapping it with e-learning Tools, such as Forum, Chat.

V. Discussion

This article is focused on the idea of using Learning objects and a well-known e-learning standard called SCORM to reuse Virtual Web Laboratories. The adaptations of Web pages, which contain virtual Web Labs, to SCOs provide a set of advantages.

- The Virtual Web Labs are in a SCORM structure and around it, other web pages, videos, audio, applets are packed to provide a whole learning pack. Also it is organized following a sequence of navigation.
- Each SCORM package is described by a set of metadata which make easier the searching of Labs. For instance, it can be stored in a content management system and deployed in a LMS.
- The SCORM package can be modified with editors and it is not necessary to know about programming.
- The SCORM package can be added in a different LMS course (independently if it is Sakai, Moodle or Blackboard) and can be "wrapped" with e-learning tools such as authentication, forums, chats, assessments and file storage without programming anything.

But, this process also has a set of disadvantages, such as:

- Version problems. Not only, there is a version of one standard, For instance SCORM have several versions, such as v1.2 or v2004. These provide different features and API. So, if a teacher is working in packing a set of statics resources, then he should check the e-learning system where the content package is going to be installed.
- Standards, such as SCORM or IMS-CC, pack text, images, or even applets. Therefore, they are packing static resources. But, new e-learning resources, such as remote Labs are dynamic application which cannot pack in a zip file. To solve this, several new initiatives are emerging, such as:
  1. SCORM next generation. This project adds to SCORM a Web Service Runtime Communication Profile Standard (based on a Web Service binding of the IEEE 1484.11.2 functionality and on IEEE 1484.11.3) to exchange data between SCORM package and LMS [15].
  2. Common Cartridge & Learning Tools Interoperability Alliance. It is the merging of two e-learning Standards:
     a. IMS Common Cartridge defines a new package interchange format for learning content, able to run on any compliant LMS platform.
     b. IMS Learning Tools Interoperability (LTI) v1.0 provides a single framework or standard way of integrating rich learning applications (in LTI called Tools) with platforms like learning management systems, portals, or other systems from which applications can be launched, called Tool Consumers [16].
  3. Widgets. According to W3C World Wide Web Consortium (W3C), widgets are client-side applications that are authored using Web standards such as HTML and packaged for distribution. They are typically downloaded and installed on a client machine or device where they run as stand-alone applications, but they can also be embedded into Web pages and run in a Web browser. These can create complex applications that pull data from multiple sources to be "mashed-up" and presented to a user in some interesting and useful way (http://www.w3.org/TR/widgets/). These widgets can be combined to create online learning scenarios and activities which can be displayed in different devices, such as smart phones, tables, web browser and PCs.

To sum up, new initiatives, focused on reusing e-learning resources over Internet, are emerging. But, until these can be used, e-learning standards, such as SCORM, are good solutions to create learning scenarios in learning management systems

AREA: A Social Curation Platform for Open Educational Resources and Lesson Plans

Manuel Caeiro-Rodríguez, Roberto Pérez-Rodríguez, Javier García-Alonso, Mario Manso-Vázquez and Martín Llamas-Nistal
Departamento de Enxeñería Telemática, Universidade de Vigo
Vigo, Spain
{mcaeiro, rperez, jgarcia, mmanso, mllamas}@gist.det.uvigo.es

***Abstract*— Content curation has emerged as a topic of interest in the last few years in the Internet. It aims at discovering and ordering interesting resources from the web, and sharing them with others. From the profile and past behaviour of users, new resources that may be of interest can be recommended to them. This paper discusses AREA, a content curation platform targeted at teachers, where they can aggregate into shareboards the resources that they find in the web. Those resources can be used in educational activities, which are the building blocks for composing sequences of activities, that are in turn the cornerstones of guides (lesson plans). The educational experiences that result from the use of guides are also contemplated in the platform. The key original feature of AREA is that it extends the concept of content curation, so that, not only contents, but also activities, sequences, guides, and experiences, in addition to other resources such as persons, events and tools, are first-class curable elements in the platform. Therefore, shareboards of teachers can include any of those elements; and all of them can be shared, commented, rated, and also recommended to other teachers.**

Keywords—content curation; lesson plan; learning resource; referatory; paradata

I. Introduction

Nowadays, technological developments and innovations are producing continuous changes in our society. These changes can be seen at all levels, from children at the school to workers in companies. Technology provides many solutions to problems, but it also creates new difficulties and challenges. A specific issue is that education needs have moved the focus from knowledge acquisition to 21st century skills. In addition, children are digital natives and they seem to have a different view of the world. In this situation, teachers are required to change their teaching approaches to take advantage of the new technologies in order to engage learners and promote a more effective learning.

In this context, several initiatives have been initiated focused on supporting teachers in the acquisition of new pedagogical approaches and the development of ICT competences. In Europe, the iTEC project [1] is trying to support the adoption of technologies in schools at a large scale and in a sustainable way. The idea is not simply to get teachers used to new technologies, but also to introduce changes in the pedagogies that allow teachers to take full advantage of the affordances provided by the new devices (e.g. tablets, interactive whiteboards) and applications (e.g. social Web, smartphone apps). To this end, the iTEC project has developed a set of guidelines for innovative teaching and learning activities [2] that can be taken by teachers as a reference. In addition, it also provides tools to facilitate the application of the guidelines to particular contexts, such as authoring tools and recommenders.

In this paper, we present an initiative called AREA to support teachers in the creation of lesson plans. Following some ideas from iTEC, the purpose of AREA is to facilitate the adoption of new technologies while promoting a change in the pedagogies. This is done through the guidelines included in proposed activities, but also through a curation facility that empowers teachers as authors and reviewers of new learning resources and proposals. The key idea is not just to provide guidelines and resources, but to support teachers developing their own guidelines, taking them into practice, and sharing the ideas, resources and results with their colleagues.

The rest of the paper is organized as follows. Section II shows the features of AREA as a referatory of learning resources and arrangements. Next, section III provides an overview of AREA as an authoring application where teachers can create learning guides (lesson plans) and document learning experiences. Then, section IV introduces the functionality of AREA as a curation service. The paper finishes with a review of related initiatives and some conclusions.

II. AREA as a Referatory

A key AREA feature is that it doesn't include a repository of learning contents. Instead, it provides the functionality of a referatory [3]. This means that contents (e.g. pictures, videos, podcasts, animations, questionnaires) are not stored in the AREA database, but just the descriptive information of such contents (namely: metadata).

The decision to provide a referatory functionality and not a real repository was taken in accordance to the following reflections. Firstly, during the last years many projects and initiatives related to the promotion of new technologies in education have been focused on developing learning contents and maintaining them in repositories. A clear example of this

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

approach is the European Union eContentPlus programme [4] in which more than 50 projects were funded to produce learning contents for different fields and, in many cases the corresponding repositories. These initiatives have succeeded to a certain extent, but some problems remain to be solved, such as the poor use of the contents provided to final users. Indeed, the past year, the ODS project [5] was initiated to provide a solution through the development of a common access point to the contents and repositories of several projects. Secondly, learning contents can be found and maintained everywhere in the current Web. A key feature of the Web 2.0 and the Social Web is that anybody, either an expert or a novice, can easily create a new video, picture, slide presentation or podcast, and then to upload it and share it using online services such as YouTube, Flickr or Slideshare.

Taking into account the repository experiences and the fact that learning resources are available everywhere, we decided to provide in AREA a referatory functionality. The information in the referatory is taken from existing repositories and from the Web in general (see section II.C). In this way, AREA maintains information about learning contents (e.g. name, description, picture, type, rating, educational level, difficulty), but not store the actual contents. Every actual piece of content is maintained in other location and in AREA we just save the link (typically an URI) to it.

A. Learning Resources

Typically, repositories maintain learning contents. Nevertheless, in AREA, learning contents are just one of the several types of learning resources that can be involved in lesson plans. Following the new pedagogical approaches that guide the iTEC project, the AREA referatory maintains information about different types of learning resources:

- Contents. These are materials that contain information, such as: multimedia documents, videos, podcasts, slides, images, simulations, questionnaires, etc. These are the traditional learning materials.
- Tools. They are any kind of software application or hardware devices that can be used by teachers and learners during an educational activity. Examples of applications are communication tools, authoring tools, learning managing systems, etc. Examples of devices are video cameras, interactive whiteboards, GPS-enabled devices, etc.
- People. People from outside the school in the role of experts or examiners may be involved in learning activities. For example, the local police chief can explain some traffic rules, a doctor may talk about healthy habits, someone from the city hall may explain the local government, etc.
- Events and locations. External events might be interesting learning resources to support and complement learning activities. For example, a roman museum or an exhibition about the ancient Roman Empire can may an excellent opportunity to complement a lesson about that particular historical period.

AREA maintains in its referatory information about these kinds of learning resources. It is quite clear that it doesn't make any sense to maintain the last three types of resources in the system. The information about each resource will include a classification in accordance with different categories (e.g., type, educational level, difficulty).

B. Learning Arrangements

In addition to the learning resources, AREA also maintains a different kind of component that we name as learning arrangements. We distinguish among four different types of arrangements:

- Activities. An activity is a de-contextualized description of a teaching/learning practice with a particular purpose. Activities can include different types of proposals: teachers and learners working in the classroom, learners doing research outside of the school, learners in groups collaborating on-line, etc. A key issue about AREA Activities is that they are devised to be innovative, promoting new pedagogical approaches (e.g. flipping the classroom, working with experts, going outside the school, benchmarking, making, showing to others) and involving new technologies (e.g. tablets, interactive whiteboards, GPS devices, games, interactive environments, Web 2.0, collaboration tools). Activities are provided in a de-contextualized way (actually they are abstractions), without any reference to particular subjects or target learners. The idea is to facilitate its eventual application to different contexts. In this way, they don't include any reference to particular resources, such as specific tools, people or events. Instead, they include requirements, such as: a video-editing tool, an expert to assess student productions and provide feedback or an outside event to inspire students. Fig. 1 shows a view of an activity in AREA. It contains several sections: description, keywords, interaction, teacher motivation, student motivation, guidelines for preparation, introduction, development and assessment, ideas for using technology, and requirements related to resources.
- Sequences. A Sequence is just an aggregation of learning Activities that can be used together in a certain order to develop a larger teaching/learning experience. The Activities in a Sequence are arranged in a particular order and in some case, but we can have optional or alternative Activities. Sequences are also de-contextualized.
- Guides. The key difference in relation to the previous arrangements is that a Guide needs to be contextualized. The idea underlying in this arrangement is to describe what is intended to happen during several teaching/learning sessions. Thus, it is similar to a lesson plan, but it follows a very specific structure that involves the next sections: identification/description, technological setting, contextual setting, Sequence (or set of Activities) and for each Activity the learning Resources involved. The contextualization of the Guide is achieved through the specification of the

technological and contextual settings (see next section), namely: applications and devices available, language, location, dates, learners' age, educational level, etc.

- Experiences. This arrangement is devoted to documenting what has happened during the performance of the Guide in the classroom. AREA enables teachers and learners to attach videos, pictures or comments to Activities during the several teaching/learning sessions.

C. *Referatory Functionalities*

The AREA referatory maintains information records about learning Resources and Arrangements. Different data are maintained for each type of element. Nevertheless, AREA provides a common functionality related to the population, search, browse and classification.

There are several ways in which new learning Resources are included in the AREA referatory. First, users can introduce information about new Resources in an indirect way. Using the curation functionality described in section IV, new resources will be added automatically. Secondly, it implements harvesting and enrichment algorithms for collecting and populating the referatory in an autonomous way from repositories and sources available on the Web. Our research group has developed this functionality using semantic technologies in the context of the iTEC project [7].

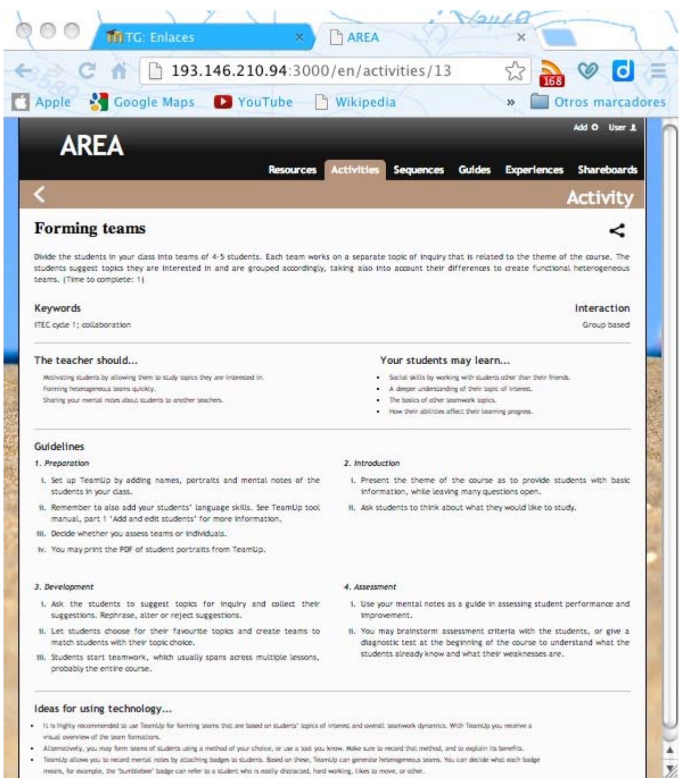

Fig. 1. Representation of an educational activity in AREA

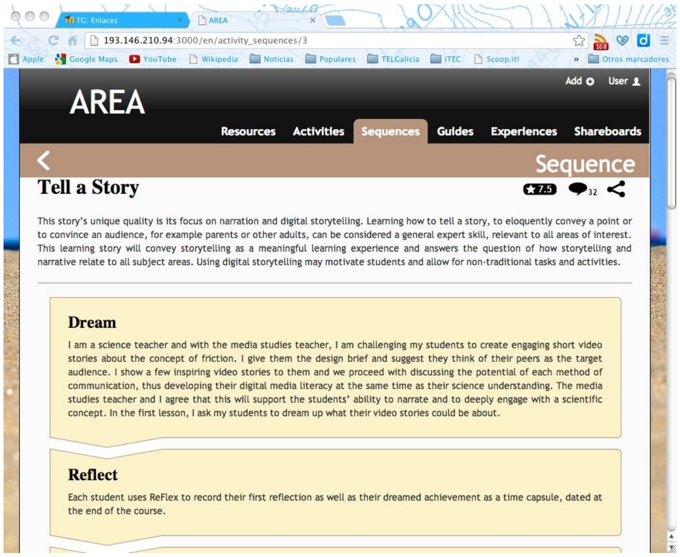

Fig. 2. Initial representation of a sequence of educational activities in AREA

Another set of AREA functionality involves searching and browsing Resources and Arrangements. Search is supported through keywords matching. Browse is supported through a set of categories in which resources and arrangements are classified. Resources and Arrangements are continuously ranked taking into account its classifications in several categories (e.g., educational level, subject, interactivity level) and real use. Indeed, every record in AREA that contains information about a Resource or an Arrangement includes a set of paradata information. This information involves items such as: the number of users that have explored the record, the number of times the element was used, the number of recommendations, the number of times it was provided as a response to a search query, etc.

III. A SUPPORTING ENVIROMENT FOR LESSON PLANS

AREA provides an authoring environment to create Guides (lesson plans) and to document learning Experiences. These arrangements are created from learning Resources and other arrangements (Activities and Sequences) available in AREA. The Guides and Experiences created by a teacher can be made private, as they are intended for personal use. Nevertheless, in case they are maintained as public, other teachers can use them as inspiration or directly as a template for the creation of new Guides and Experiences.

A. *Creation of Guides*

Using the authoring facility teachers are supported to create learning Guides. Guides can be created from scratch using the learning Activities/Sequences and Resources described in the AREA referatory. In addition, a teacher can take as a starting point an existing Guide (created by herself previously or by another teacher) and modify it to produce a new Guide.

In the normal flow, teachers create Guides before the teaching/learning process is initiated. Then, they can use the Guide as a script to know what to do (herself and her learners) during teaching/learning sessions. Nevertheless, AREA doesn't provide any functionality to support the automatic enactment of the Guide. It is not a kind of IMS Learning Design engine [8]. As it is shown in sub-section C, a Guide can just be used by the teacher to document and track what actually happens during the teaching/learning sessions. Taking into account this functionality, the teacher can modify a Guide after the teaching/learning sessions have been initiated.

Figure 3 shows the interface that enables the creation and edition of Guides. It depicts how we have divided the guide in four sections, which are: the identification, the technological setting, the contextual setting, and the sequence of Activities. It follows a description of each one of these sections:

- Identification. The first section is composed of a title and a brief description of what the teacher intends to do and achieve. It can also include an image and several user-defined tags. As any other resource in the AREA referatory, a Guide can also include paradata information that will be shown in this first section, but not during the authoring stage.

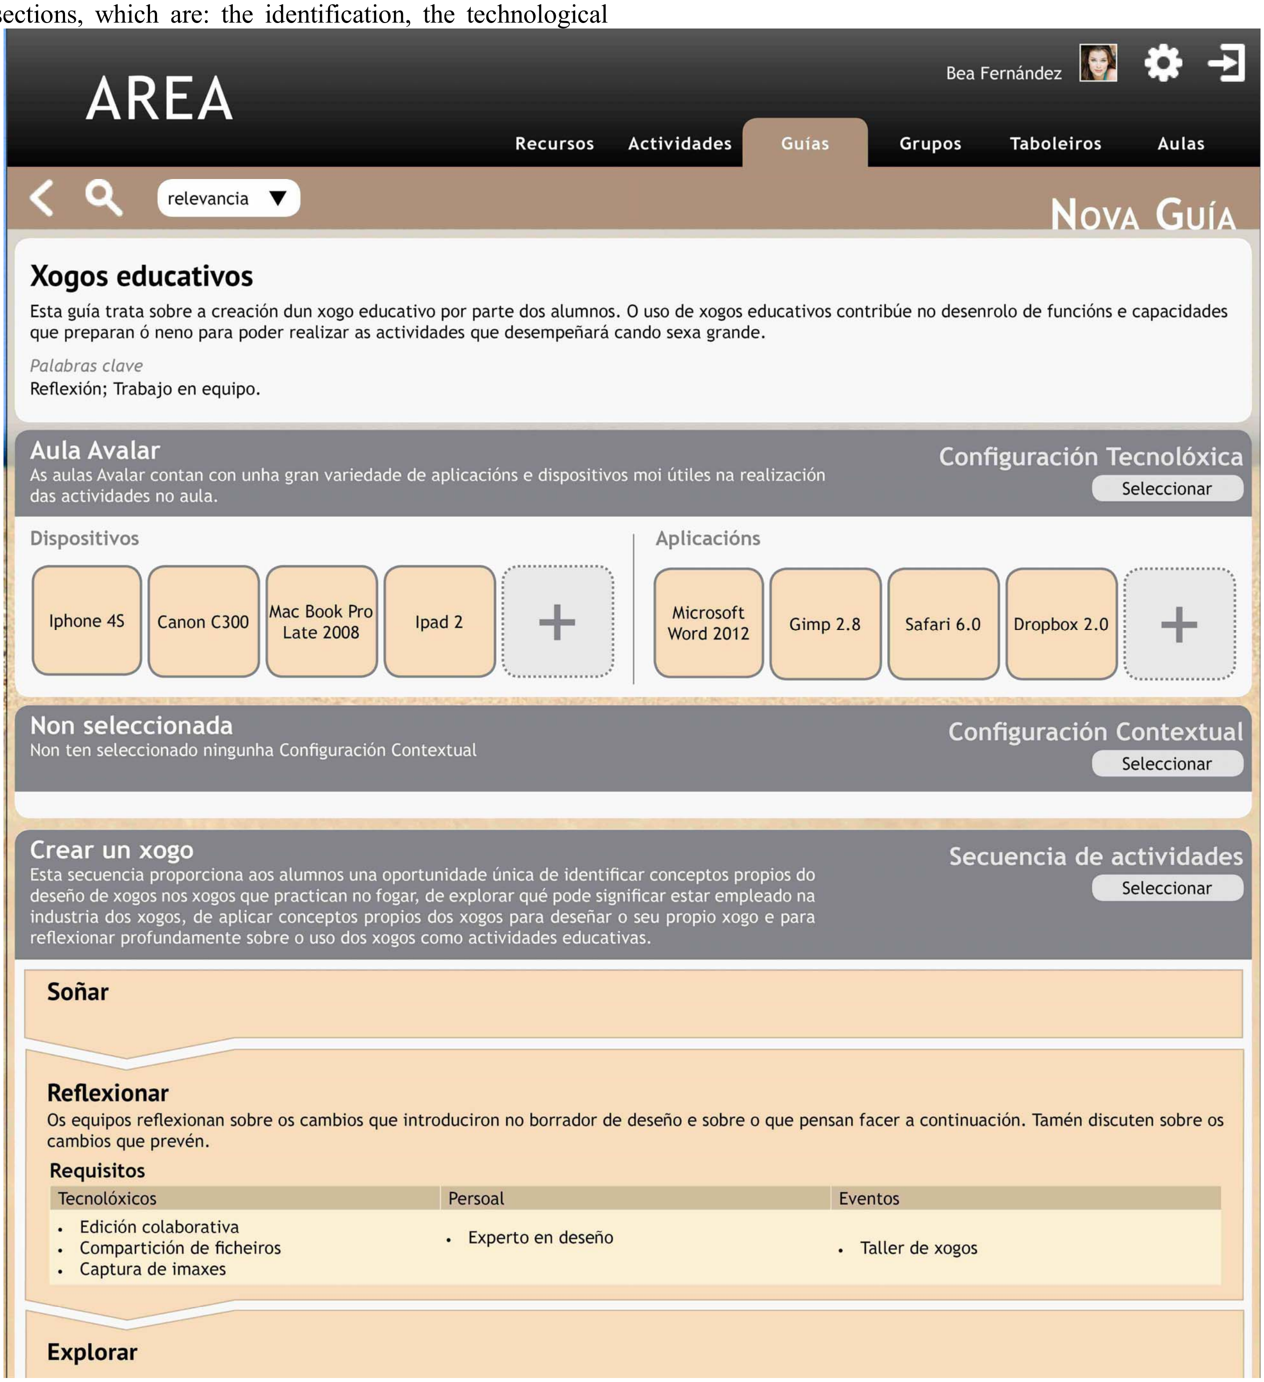

Fig. 3. Edition of a Guide in AREA

- Technological setting. This is the first part in the characterisation of the classroom and the school as the environment where the educational activities of the Guide are going to be performed. This part includes all the technological resources available for the teacher and the learners to carry out the Activities included in the Guide. The technological setting elements are divided into two categories: devices and applications. Technological settings may have been created before the edition of the Guide. For instance, a teacher in an administrator role might have been included the different technological settings available at their school, such as classroom with audio-visual equipment, or a computer room with Internet access. Other teachers may choose a technological setting from the ones available in AREA (at their school) when creating their Guides. Besides, it is also enabled to create a new technological setting using an existing one as a template, as well as to create a new technological setting from scratch. In order to support all the options listed above, an editor for technological settings is integrated into the editor for Guides. As the figure shows, this element is composed of a name, a description, and the set of devices and applications. The system also provides the user with detailed information about every available application and device.

- Contextual setting. This part completes the characterisation of the environment where the Guide will be carried out. As with the technological setting, the user can either select an existing one, to make a copy of an existing one for its later modification, or to create a new one from scratch. In the figure, we can see how the system notifies the user that he/she does not have any contextual setting selected. At this point, the system provides an editor that enables to perform the actions for modifying or creating a new contextual setting. The purpose of this part is to characterise the educational context where the experience is going to be carried out (see Table 1): the age of learners, the subject, the educational level, the working language, the spatial and temporal location, etc.

- Sequence. The system provides the teacher with a fully featured editor for learning Sequences at this part of the Guide. In AREA, a Sequence is composed of a title and a description, as well as an ordered set of learning Activities. As in the other parts discussed above, the user is allowed to modify an existing educational Sequence or to create a new one from scratch. In order to compose the sequence, the Activities in the AREA referatory can be used as building blocks. The editor for sequences allows the teacher to browse the different Activities available in the system, enabling to review all their particular features. Each activity selected by the teacher to be included in a Guide is actually copied into it, and in this way it can be particularised for the Sequence. Thus, the teacher can assign a particular title and description to the Activity and modify any data. This modification is not transferred to the original activity.

TABLE I. ITEMS IN THE CONTEXTUAL SETTING

Name	Description	Data Type
Id	Contextual setting identifier	URI
Name	Given to the contextual setting	String
Description	Short description	String
Creator	Identifier of the person who created the setting	URI
Subject	Knowledge subject to be developed in the Guide	VocTerm
Keywords	One or several works providing some specific details to the subject	String
Language	In which the Guide will occur	VocTerm
Age range	Of the learners for whom the Guide is intended	VocTerm
Educational Level	Of the learners for whom the Guide is intended	VocTerm
Address	Location where the Guide will be carried out	Object
Start Date	When the Guide will be initiated	Date Time
End Date	When the Guide will be finished	Date Time

B. *Assigning Resources to Activities*

Previous section describes the initial steps to create a Guide, but it is not the full story. To be finished, the teacher needs to select Resources that fulfil the needs specified by the Activity requirements. As it is explained in section II.B Activities are provided in a de-contextualized way, with no actual reference to specific Resources. Nevertheless, Guides are contextualized arrangements. Indeed a key part of a guide is the specification of the technological and contextual settings. Therefore, in order to complete the Guide, requirements in Activities need to be matched to actual Resources available in the technological setting and suited to the contextual setting. A key general idea underlies this behaviour: an Activity can be carried out in different settings using different Resources, in the worst case just paper and pencil.

AREA provides some specific functionality to support teachers during the matching of Resources to requirements:

- First, taking advantage of the developments in the iTEC project [9, 10] recommendations about the more suitable Resources for each requirement or for the Activity as a whole can be provided. The recommendation functionality takes into account the particular requirements for each Activity, as well as the particular context in which the activity is going to take place (specified in the technological and contextual settings). A key objective of these recommendations is to ease the inclusion of new Resources, particularly technological resources that teachers might not be aware of. Thus, the teacher can select (with the assistance of the system) the Resources that are going to be used in the Activities.

- Second, teachers can use the search and browse functionalities of the AREA referatory to look for Resources directly.

- Third, AREA is able to notify the teacher when some requirements are not fulfilled.

C. Documenting Learning Experiences

AREA also support teachers documenting learning Experiences. The key idea here is to attach outcomes and products generated during the development of the teaching/learning sessions to the Activities planned in the Guide. Users can include photos, video clips, audio podcasts, comments, etc. They can also include references to Web sites and pages used during the learning process (e.g. a Blog or a Facebook page).

This documentation can be generated during or after the development of the teaching/learning process. We hope this kind of documentation can be will promote teachers action. Other teachers can use learning Guides as a reference for carrying out innovative educational experiences in their classrooms. We think that if other teacher can see what actually happened during the development of the Guide, this could move them to use the same Guide or create a new one. In addition, the documentation of a learning Experience can be used to communicate the classroom activities to learners from different classrooms of the same school or other schools. It might even be helpful for parents to know what their children are actually doing in the classroom.

IV. A CURATION PLATFORM

AREA is also a curation platform for learning Resources and Arrangements. Teachers can create shareboards (private or public lists) and collect learning resources, learning activities, lesson plans and any kind of Web document related with their learning/teaching interests. This functionality is similar to the one available in existing platforms such as Scoop.it or Pinterest.

A. Curation of Web Documents and AREA Elements

When users browse the web, they can find interesting documents (for instance, some YouTube video, an interesting tweet, a Slideshare presentation, a photo or an info-graphic on Pinterest). At this point, users can use the AREA extension (available for Firefox) in order to add the document to a personal shareboard. Actually, the Web document is not added to AREA, but an extract of the document. In addition, user can also aggregate on their shareboards extracts from AREA Resources and Arrangements.

An extract is a summary of a Web document (also AREA documents). It includes a title, a link to the original item, a short text and an image (optional). The key point about an extract is to be as representative as possible of the resource it refers to. In other words, the user should be able to clearly remember the original element by just seeing the extract. In addition, extracts.

As it is discussed above, users can create extracts from documents that they find when browsing the Web. Then, they include and classify the extract on a personal shareboard. The user can rate the extract, comment and tag it. Once the new extract is on the shareboard of the creator, other users (those who follow the one who created the new extract) can see it and add the extract to their own shareboards. All the comments made for the same extract are viewed on all the shareboards in which the extract was included.

B. Curation Functionalities

This part of AREA is conceived as a social application where users can find other users with similar interests and create communities. A user can decide to follow the shareboards of other users, provide suggestions of resources/arrangements to friends, comment and rate resources/arrangements, etc. A reputation policy is established to promote action and participation in AREA.

The process of content curation gives to extracts (and therefore to the elements that they represent) a measure of its relevance for users. For instance, an Activity that was included in many shareboards has a lot of relevance. The same thing happens with Resources, Sequences, Guides, and Experiences: they gain relevance when they are included in shareboards. Apart from the process from calculating relevance described above (which is quite plain) AREA contemplates a (vertical) content curation mechanism, relating Activities to Guides and Guides to Experiences.

This is related to the concept of curation by aggregation during the authoring of Arrangements: when a user includes an element into another element, the former gains relevance. For instance, when a Resource is included into an Activity, that particular Resource gains relevance. The same thing happens with Activities: the more times they are included into Sequences, the more relevance they gain. Sequences, in turn, become more relevant as they are included in guides; and, the more experiences for a guide, the more relevant that particular guide is.

This curation knowledge is used to maintain a user profile and to update the information available in the AREA referatory on learning Resources and Arrangements. Eventually, taking advantage of this information, we provide recommendations to users when they are looking for a particular Resource or when they are authoring a Guide.

V. RELATED WORK

During the last years many initiatives have been provided to empower teachers creating their own course contents. Some of these initiatives are the following ones: Students Circle Network (www.studentscircle.net), Tiching (www.tiching.com), Didactalia (www.didactalia.net), Connexions (www.cnx.org), Eduteka (www.eduteka.org) and Saylor (www.saylor.org). In general, these are Web applications that support teachers providing contents, creating their own course contents through the aggregation of contents, and sharing contents and courses with other teachers. Some key differences between these initiatives and our development are the exclusive focus on contents and the lack of specific proposals to support technological and pedagogical innovation. AREA is not just about content, but also about other kind of resources: people, events, tools. In addition, de-contextualized and abstract models of activities and sequences are provided for inspiration, in conjunction with recommendation functionalities.

Some of these initiatives such as Eduteka involve a social network service than enables to relate users and their resources. Similarly, Tiching provides paradata information about the contents included. This kind of functionalities facilitates the development of curation processes and the creation of communities of interest. In AREA we have also conceived these functionalities in a similar way, but in the context of a broader set of resource and arrangement types.

AREA can also been related to other initiatives more focused on the development of electronic textbooks. In Europe the eTernity project (http://etextbookseurope.eu/) has been proposed to fulfil educational requirements for e-textbooks as a channel for creating interactive, adaptable, personalizable resources to improve learning, education and training. In Latin America the LATIn project (http://www.latinproject.org/) will encourage and support local professors and authors to contribute with individual sections or chapters that could be assembled into customized books by the whole community. These initiatives are involved in the development of open and electronic textbooks. AREA could be used as an authoring tool of electronic textbooks, but mainly the teacher version of such books.

VI. Conclusion

The approach to educational guides taken in AREA is a step forward from traditional guides, as it encourages the use of technology and innovative activities in the classroom. In this sense, one of the objectives of the system is to propose the use of different devices and applications to teachers, some of which they may not be yet aware of.

The documentation of educational experiences plays a very important role in the transmission of what is actually performed in the classroom. This information may be crucial for the elaboration of new educational guides. In a similar way, teachers may find interesting to follow a particular guide in their educational practice, basing their decision on previous experiences of other teachers with that same guide.

The AREA project will allow us to evaluate to what extent the content curation concept may be useful in real-world teaching/learning practice. In our view, the AREA approach to content curation has strengths in allowing teachers to compose new educational Guides, which can aggregate educational resources that they found in the Internet; and enabling the contribution, sharing and discovering of educational resources and arrangements, which later can be recommended to teachers in accordance with their interests and previous activity in AREA.

Abstract—**Educators have at their disposal many digital content sources, from textbook publishers to open courseware repositories (OCRs) to specialized collections to shared resources from a network of peers. It is rare one needs to go create new lecture materials, instead one can download and adapt to fit their needs. The proliferation of such resources is expected to result in great productivity for educators, particularly those in higher education where time demands relegate content development to the back-burner. But are we seeing such productivity? Are courseware repositories spawning heavy reuse? Or are issues integrating content to courses causing a loss in productivity and greater frustration? These are the questions being investigated by the Distributed Version Control for Curricular Content Management project. This work-in-progress project has conducted a local faculty survey of curricular content development and used the results to drive the initial implementation of a distributed version control tool for curricular content management**.

Keywords—curriculum development, software tools

I. Introduction

At the 2013 ACM Special Interest Group for Computer Science Education conference (SIGCSE 2013), Peter Norvig led a Google session on Massively Open Online Courses (MOOCs). In concluding his presentation, he indicated that (paraphrase) *we have to start thinking of courseware development as an engineering process, much like software development*. We agree with this perspective, as we believe there has been a significant shift in courseware requirements driven by continuous change, change in learners' content consumption behaviors, and the disruption caused by online technologies. Linear (waterfall?) workflows need revamping in the face of these forces; in fact we contend this is already taking place and it is the understanding of the engineered process with associated tool support that will drive innovation.

The Distributed Version Control for Curricular Content Management (DVC4CCM) project is a first step at applying a software development best practice to the curricular content development process. The problem of curricular content management is similar to an open source community source code control problem. In open source, the ability to take and customize the source code to meet domain requirements is central to the value proposition. The problem of an instructor obtaining, customizing, and integrating curricular content from multiple sources is not unlike the open source problem. The instructor must 1) identify resources (or subsets of resources), 2) ensure the resources are available for use in the target context (licensing), 3) adopt the resources into the learning context (formats and modalities), and 4) ensure the content flows in a seamless fashion to support learning outcomes (integration and customization). These activities are laborious and frustrating, as the time to locate, assemble, and integrate content from available sources can be as burdensome as the time it takes to create content from scratch.

The larger research question the DVC4CCM project aims to address is the understanding and improvement of curricular content management patterns for higher education instructors. The methodology uses a survey instrument to understand curricular reuse, and based on the results to identifies viable version control workflows from the software engineering community. The initial technology solution is a customized wrapper around the popular Git distributed version control system to facilitate content integration and reuse. This work-in-progress paper frames the research problem, describes the survey vehicle, and presents the initial tool implementation.

II. Research Methodology

Source code control and configuration management (CM) are established competency areas in software engineering. CM has largely evolved through client-server tools like the Concurrent Versions System (CVS) or subversion (SVN) which employ centralized repositories for software artifacts and an optimistic approach to managing change. To generalize, the centralized repository maintains the baseline copy of artifacts (the *mainline*), developers work on local copies of artifacts, and the client tool maintains metadata to describe the deltas against the mainline. The most common and accepted ([6]) workflow is a *branch-and-merge*, where developers work on shared branches, and merge changes into the mainline. The prevailing mantra is to 'check in early and check in often' to reduce the probability of long, painful, and error-prone merges. Techniques for managing long-running branches range from creating *sandboxes* to maintaining *private branches*.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

In a distributed version control system (DVCS), change is managed among multiple distributed repositories, usually by creating complete copies of artifacts in each repository (though this is not always the case). The presumed centralized repository to many endpoints model is replaced by what is effectively a peer-to-peer repository approach.

The value proposition for DVCS over the traditional centralized model is that change is allowed to proliferate, and consumers can manage what changes they want by determining which changes they *pull* from a peer repository. This is an important improvement over traditional CM, which implicitly tries to minimize change through the 'check in early, check in often' mantra. In practical terms, the flexibility to define advanced workflows opens the possibility for supporting new collaborations between artifact creators. For our initial exploration, we evaluated workflow patterns evolving in DVCS practice, surveyed department faculty to determine typical curricular creation patterns, and implemented a tool to support a workflow for curricular content management.

A. *CM Patterns for DVCS*

Software houses are rapidly adopting DVCSs and evolving best practices such as identifying appropriate workflows. We reviewed workflows for software development with an eye toward curricular content management, and summarize our thoughts on some of the potentially applicable ones here.

1. Branch per developer – In this pattern, a coach is responsible for the stability of the code base. Developers maintain a cloned local repository in which to work, and a public repository with read access to other members of the team. When a developer is done with implementation s/he commits changes to the local repository. When the developer is ready to submit changes to the mainline, s/he pushes the changes to the public repository and notifies the coach. The coach pulls changes from the developer's public repository to a local repository and verifies they meet quality standards. If they do, the coach publishes these changes to the mainline repository and notifies other team members [1]. This configuration pattern ensures the stability of codebase. It also helps in maintaining releasable version of the project at all times. This pattern is suitable for small agile teams, but the setup would be extremely complex if the team is large, and thus this pattern does not suit for medium to large teams [1].

2. Feature separation through named branches - In this pattern [2], developers create named public branches in their own repositories for working on distinct independent features. Adopters select which features to assemble into an application or system by determining what named features they wish to pull and integrate from the various public options available. The mapping of this workflow to curricular content could go like this: an educator may get materials from one of the repositories. When s/he makes changes a new named branch from the repository is created. When another educator wants to create a curricular module, s/he can pick from any named branch based on features desired. If there is a central repository maintainer, that person may choose to maintain and evolve the mainline by merging in the named branches, but there is no requirement on adopters to only use the mainline version.

This pattern helps to develop features collaboratively and also allows the user to check for which feature a given change was added. It is best suited for large to medium agile teams but does not scale up well if the project has a lot of small features.

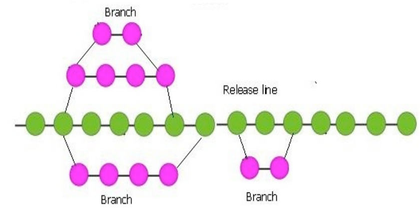

Figure 1: Feature separation through named branches

3. Working off named stable bases - Software developers often work on a project's mainline so that they get all the latest changes and do not have to deal with huge merge conflicts when committing their code. However, the mainline often has unstable and untested code, which can cause rework problems if changesets must be rolled back, potentially impacting all changesets committed after the problematic changeset. The 'Working off Named Stable Bases' pattern solves this problem by allowing developers to work off a stable tested revision instead of potentially unstable mainline. When the revision is stable it will be tagged as stable and other developers may start working off this revision.

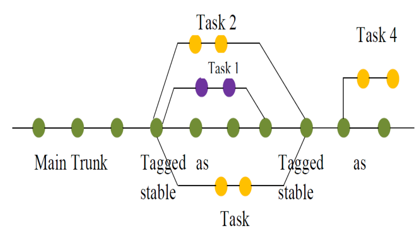

Figure 2: Working off named stable bases

This pattern is most suited for large projects where developers work on unrelated tasks. This approach might not be suitable for projects where many developers are working on the same or related tasks [3].

4. Other configuration management workflow patterns - We reviewed several other CM patterns. These were not selected as they were either too close to the workflows described above or did not fit the workflow requirements.

- Episodic Collaboration [3]
- Local Branching [1]
- Private Versioning Workflow [4]
- Incremental Workflow [4]
- Independent Development Workflow [4]
- Staged integration lines Workflow [1]
- CVS-like Workflow [2]
- One-off patch submission Workflow [2]
- Centralized Workflow [5]
- Integration-Manager Workflow [5]
- Dictator and Lieutenants Workflow [5]

B. *Faculty Survey*

In order to figure out the process used by educators perform collaborative courseware development, we created a survey for the faculty of our department The survey consists of 26 questions about the sources of course materials and how one incorporates change. 15 faculty completed the survey, though not all answered every question. Survey result highlights:

- 87% said 61-100% of materials are in electronic form.
- 87% said 21- 60% of course material changes per year.
- 67% said they have revisited older versions of materials.
- 60% said adapting outside materials is inconvenient.
- 67% said adapting outside materials takes about 1-4 hours.
- 50% said they thought of sharing course materials with others, but could not find the right platform/mechanism.
- 80% said they have incorporated changes to their notes based on contributions from others.
- 40% said they reuse course materials from colleagues.
- 75% said they use email to share updated materials back with the originator.
- All (100%) said they construct their current course materials using their last year's course materials.

Of course this is a small single-source sample, and the results expected. It is not a stretch to think this is representative of most places (certainly broader study is needed).

C. *Workflow selection and implementation*

We used these results to determine which of the workflows we reviewed might address the most significant change management issues. We determined that a combination of *Feature separation through named branches* and *Working off named stable bases* is the best candidate solution. The former allows adopters to maintain a separate space for material, so they can make available their own materials when needed and make changes at the same time. However, this might work for only a small number of materials. It will be difficult to manage if there are many borrowers and if all borrowers submit back to the originator with updated materials. The latter workflow will help solve these problems. Adopters can go ahead and submit their files to the repository and inform the originator, who can tag it as stable for future adopters. Figures 4 and 5 depict the customized workflows implemented in DVC4CCM.

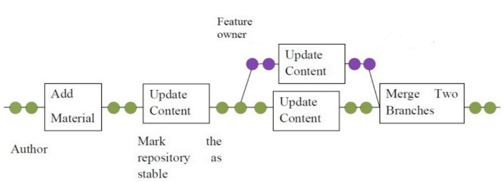

Figure 3: Custom workflow if author merges branches

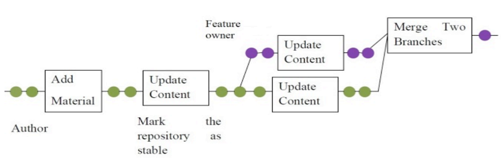

Figure 4: Custom workflow if feature owner merges branches

DVC4CCM is implemented as web application enforcing these custom workflows. The tool wraps the open source Javagit codebase (javagit.sf.net) and allows end users to perform actions based on the state of the workflow and a defined role with respect to that workflow. Users of the tool can create a repository or download an existing repository. A user who creates a repository is the *owner* of that repository and can submit content to it. When a user submits content to the repository, s/he will be asked whether to mark the repository as stable. Only repositories which are marked as stable are available for others to download. Adopters get a copy of the materials in the repository by using the tool to indicate intended use, including whether a new feature will be added. If a new feature is intended, the backend creates a new branch. Then later, once the user submits content and marks it as stable, the named branch will be available for others to download. After the feature owner submits content to the repository, both feature owner and the original author have an option of merging the named branch. If the feature owner merges, the merged changes will go to the branch, but if the author merges, they will go to main trunk (master). For now, both the branches are compared against each other and names of the changed files are displayed to the user. The user can download both the repositories and do a manual merge and submit the updated repository. Going forward, DVC4CCM will provide auto merge feature and present merge conflicts to user.

VI. Summary and Future Work

The aim of this project is to create a change management system which reduces the amount of effort needed by educators to build course materials. This system helps educators share their course materials with other educators. Similar to open source software development, educators can also participate in collaborative course development which ultimately results in better course materials. The approach is to provide a tool (DVC4CCM) that hides the complexity of DVCS from curriculum authors and adopters, and to enforce workflows to enable an innovative yet managed curricular evolution process.

There is significant work required to evolve this approach. Study of existing curricular development processes needs to be expanded, and perhaps include textbook publishing processes. The initial analysis and definition of our customized workflow should be re-evaluated in light of additional study, and data collected on the utility of the workflow in managing curricular change. The tool requires refinement and evolution based on end user study. In short, as Norvig stated, the engineering of a curricular content management solution is required, and as in software, is a process that requires maintenance and evolution.

Coexistence of Cloud Technology and IT Infrastructure in Higher Education

Laurynas Riliskis, Evgeny Osipov
Department of Computer Science, Electrical and Space Engineering
Luleå University of Technology
971 87 Luleå, Sweden
laurynas.riliskis@ltu.se

***Abstract*—Early 2012 Luleå University of Technology started a project on adopting cloud technology for implementation in the university's IT-infrastructure. This work-in-progress article describes the results of its pre-study phase aiming at understanding the feasibility of integrating and/or migrating main IT-infrastructure components into an IaaS system and opening ways for making university's resources more accessible to a wider public. Numbers of logistical, technical and education related challenges make such transition far from being trivial. The article focuses on the educational aspect of the pre-study. Specifically, work flows in education process of several courses in different disciplines in natural and engineering sciences were analyzed from the student and teacher perspectives. In the article a schematic of a sustainable IT infrastructure adjusted to the needs of higher education will be drafted. Further, technical readiness and challenges of using cloud technology for university scale IT-infrastructure are discussed.**

I. Introduction

Most of the current IT-infrastructures at Universities were designed and deployed at times of mostly campus-based education, following the "One-Solution- Fits-All" approach. Nowadays, with the growing number of courses given on distance and unique requirements on software content in almost every course in all disciplines the existing infrastructure became extremely stiff and inefficient. In many cases it fails providing flexible services with an acceptable quality both to teachers and students. Another problem appears with the all growing mobility of students: The uncertainty in number of students to be handled in each semester (even in the scope of a particular course) makes it difficult for the IT departments to estimate the need and to correspondingly dimension the IT-system. Normally, university's IT administrations over-dimension their infrastructures in order to stay competitive and provide a satisfactory quality of experience. This obviously leads to an increased cost associated with purchasing and maintaining the equipment. Besides the economical component the environmental impact becomes one of the critical factors that universities have to deal with nowadays. Universities as governmental organizations need to take environmental considerations into account when implementing European Union policies on ICT sustainability. Cloud technology and specifically the infrastructure as a service (IaaS) modality is an excellent alternative to an outdated and inefficient local infrastructures.

For Luleå Technical University (LTU [1]) with seventeen thousand students and four thousand stuff members the demand on the functional IT infrastructure is high. LTU is located in five geographically distributed campus areas, with each campus having both a general purpose and a specialized computer set-ups. Besides the standard set of applications as in a general purpose PC, the PC's in specialized labs have extra hardware and/or software depending on the course requirements. Currently more than four hundred different applications has to coexist in different configurations in order to satisfy students' needs and teachers' requirements on educational software. To ensure the compatibility of applications the requirements are collected by IT administration one semester before the course start, the compatibility is tested and custom installation images are created. Before the start of a new semester the customized images are deployed. To preserve the usability of the PC labs for students and teachers the deployment usually takes place during weekends and nights. Overall this process is expensive and not flexibility for teachers and students.

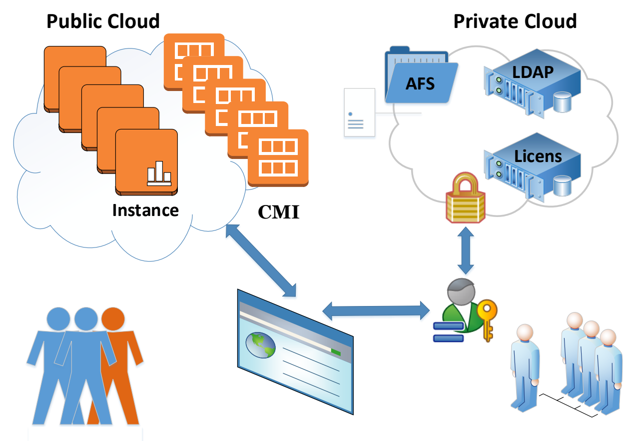

Fig. 1. Envisioned future infrastructure for higher education.

While the idea of using cloud technology in education is not new [1], the related existing work is often limited to courses related to cloud computing [2], [3] or e-Education [4] including the well-known success story of EdX [5]. Compared to other works on *education in the cloud* we address the needs for flexible IT infrastructure from the teachers, students and IT administrators perspective.

The on-going project on adopting the cloud technology for implementing the IT-infrastructure at LTU has the following objectives:

a) Students should be able access computing resources from anywhere, any time;
b) Students should be able to customize the working environment using administrator rights;
c) Teachers should be able to influence the setup of the computing resources both before and after the course start;
d) The solution should be scalable and energy efficient;
e) The solution should minimize the human resources needed to deploy, set up and maintain the IT platform for the course.

This work-in-progress article describes the results of the pre-study phase of the project aiming at understanding the feasibility of integrating and/or migrating the main IT infrastructure components to the cloud as well as drafting the initial design of the architecture.

II. Vision of a Sustainable ITS

In order to increase the flexibility of the IT infrastructure both for teachers and students we envision a scenario where each course with standard hardware requirements owns a unique software solution in a form of a dedicated virtual machine image. Further we refer this dedicated virtual machine image as course virtual image or *CVI*. This image can be started as an instance in the cloud environment or downloaded for usage on a local computer with an available virtualization software, for example such as Virtual Box [6] or VMware [7].

Figure 1 depicts the envisioned *"one-course-one-CVI"* scenario. The infrastructure is a hybrid cloud solution where the private cloud is maintained on the local IT infrastructure and the public cloud is outsourced to an infrastructure as a service (IaaS) provider. The private cloud contains services for student authentication (LDAP [8]), application licensing service (License), and distributed files system (AFS [9]). On the public cloud the course's specific CVI's are stored and run by students or staff. Students access the pre-deployed CVI from the course web page, by choosing either to launch an instance or download the image for local usage. The students' global home directory is added as a network-mapped drive to the instance. Therefore, students can store their files across all CVIs. After the CVI started, students gain administrator rights on the instance and are able to further configure it and install additional software. When students log out, the instance is stopped and resources are not wasted unnecessary.

III. Improved Process of Managing ITS resources

The current process of deploying software needed for courses is challenging. The IT service collects teachers request for the course specific software one semester in advance. The software is installed and the interoperability is tested in a dedicated testbed. The ITS personnel needs to have a deep expertise in all the deployed software to test the functionality. whenever changes in the software are needed shortly before or during the course it becomes an expensive matter for the IT administration. We advocate that this situation could be substantially improved. The envisioned future process is illustrated in Figure 2, a teacher makes a request to the local IT administrator specifying course computational need including

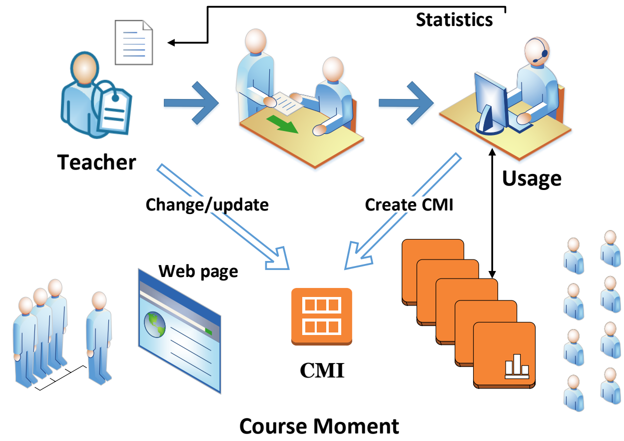

Fig. 2. A process for the creation of course CMI in the Clouds Infrastructure.

for the course needed software. The CVI is created by the IT administration and is deployed in the public cloud. Since none of the other courses would be affected, if needed, the teacher could further customize the CVI by herself. The access to CVI is enabled from the course's web page for the students. This approach not only makes the infrastructure easily maintainable and flexible but also removes the following human resource consuming steps:

- Tests related to software interoperability between different courses;
- Resolution of conflicts between different software;
- Deployment of the software on the physical machines;
- Management of student access rights on the lab computers.

From the teacher perspective the *"one-course-one-CVI"* approach gives valuable insights on the students' work load distribution during the course. This is achieved by monitoring the activity of instances within the particular course. As a matter of fact, the billing of the resource usage is based on the per-hour usage of the instances. Thus anonymous (no student names are connected to a particular instance) statistics are available on monthly bases from the public cloud provider which can be used to analyze the work load.

IV. Experience and Feasibility

As part of the project the IT needs of several courses were powered by Amazon Web Services cloud infrastructure [10]. Amazon AWS was selected as cloud service provider because it offered the desired programing flexibility and provided educational grants.

The feasibility testing was performed outside the current IT infrastructure. Three courses within computer science education were selected for the test group. Prior to the start of the courses a front-end was developed for generating log-in credentials associated with usage of Amazon AWS, and for managing the AWS resource usage. The CVI as created containing the necessary software for the course.

So far the teachers' and the students' experiences with the in-cloud IT infrastructure were positive. From the teachers and students perspective the biggest value was a ability to personalize the working environment as well as an ability to access courses' software at anytime from any location in a straightforward way. The IT administration of the course for the deployment of needed software was minimal. Several on-fly updates of the software were performed during the course which also required minimal effort from the IT administration. On the criticism side, the students using remote desktop often experienced lag. While the quality of experience could be to some extend improved by selecting a more computationally powerful virtual machine, the network delays were in many cases dominant.

The teachers highlighted advantages of cloud-based infrastructure in terms of a flexible software set up and prior to all an ability to deploy new version during the course's run. The CVI was updated and new version deployed in a matter of ten minutes. Additionally, the transition was transparent to the students without disturbing the learning process.

After a week of usage we could notice that students were not properly turning off the instances and they were left running during long time periods. Therefore an application for an individual resource usage monitoring and automating the process of stopping the instances was developed. Even though this costs additional work for the IT administrators, once deployed this add-on did not require additional maintenance. It also became clear that providing valuable statistics of resource usage to the teacher was not a trivial task and required development of customized tools.

V. Challenges and Future Work

The benefits of using cloud infrastructure in higher education are evident, the important ones are: extreme flexibility when setting up the course software, the course can be given to any number of students, the course's software is accessible from anywhere either online or locally. Numbers of logistical, technical and education-related challenges make, however, such transition far from being trivial. To the best of our knowledge there is no user and cloud management application for the integrated environment of the hybrid cloud together with LDAP, AFS and Licensing services. Such application, nevertheless, is feasible to develop on-cite. One of the next steps in the project is an investigation of economical cost for such development.

The most challenging aspect to overcome when adopting the cloud-based IT infrastructure for education is legal issues. Firstly, licensing of software used in the courses is vendor specific. While some software vendors use per-user licensing, other require users to be located on campus which makes the situation problematic. Secondly, the legal aspects related to privacy and national education laws and regulations are not obvious to resolve when matter comes to deploying the educational infrastructure to as hybrid cloud. While there are many studies about privacy in the cloud (see also references therein) our proposed solution overcomes many of them because student identification, authentication as well as their private files are stored in local infrastructure. We, however, foresee a substantial work load on the legal department in order to determine the appropriate setup.

So far we are optimistic that the benefits provided by our "one-course-one-CVI" vision outweighs the legal and logistical challenges. The next step in our work will be to make economical and legal analysis of the project as well as to deploy a pilot setup and to evaluate students' experience on a bigger scale.

***Abstract*—This paper introduces the iTEC SDE (Scenario Development Environment), a recommendation system to assist teachers in the creation of lesson plans. A key functionality of the SDE is the recommendation of people. Basically, taking into account new pedagogical approaches, this system manages information about potential lesson plan contributors and provides recommendations on the best available people to participate in specific learning activities. The SDE has been developed as a multi-criteria recommender focused on supporting learning activities in particular technological and educational contexts. In this way, it manages information about the devices and applications available in the classroom and the features of the students, such as educational level, language, age, location, etc. The final goal of this system is to support teachers creating lesson plans in which they can develop new pedagogical approaches involving new technologies and external resources, such as people from outside the school. Eventually, this will contribute to engage students and improve learning.**

Keywords—Resources beyond content, Semantic technologies, Recommender systems, Semantic enrichment

I. INTRODUCTION

Designing lesson plans at different educational levels, ranging from K-12 to higher education, involves the integration of several resources intended to improve the efficiency of the learning process. Among these resources we can find traditional tools (e.g., pencil-and-paper, books, video) but also many others available as a consequence of technological progress. Thus, it is common for teachers to consider during the design of lesson plans new technological devices available in the classroom (e.g., whiteboards, tablets), online learning objects (e.g., simulators, educational multimedia materials, assignments) or just applications available online that, according to their experience, may improve communication or the overall educational experience (e.g. wikis, blogs, forums).

Traditionally, in many areas of knowledge it is common to rely on reference works (e.g., Tanenbaum's Computer Networks in the field of Computer Science, Feynman works in physics, etc.). Further away, in the new pedagogical approaches (e.g. flipping the classroom) it is also becoming usual the involvement of external people and experts in educational activities. The global interconnectedness that the Net presently offers greatly facilitates access both to these reference works created by experts and to the experts themselves. In some areas, it is customary to include in learning activities conferences and seminars taught by academics from other institutions or industry professionals. This practice is certainly more common at higher education, however it can also occurs in elementary and secondary education. For example, K-12 student parents could be requested to participate in their children classroom activities, the police chief may visit a school to talk about drivers' education, or a doctor can be invited to virtually promote healthy lifestyle.

Currently, while there are many solutions to assist teachers in discovering digital learning objects, or even learning tools, to be included in lesson plans, these solutions are not so popular when trying to identify people who may contribute to our lectures to enhance the learning process. Moreover, traditional online search engines are not specifically designed to find people, let alone to identify people who fit a specific educational setting in a particular context (e.g., geographical proximity, language, expertise, whether they are available for online interaction, or their seasonal availability). In this paper we present a system for locating, among other resources, people who can make an effective contribution to particular learning activites. Our proposal integrates a recommendation system based on the characterization of a learning activity and the specific context in which it is developed to identify potential candidates to participate in it. The recommender system uses existing people directories as an initial source of information on which semi-automatic enrichment procedures are applied to complete the available information with data relevant from an educational point of view that is still missing. It also includes a mechanism to capture information from publicly available online sources to populate the initial database with additional individuals who may provide relevant educational contributions.

The rest of this paper is organised as follows. Next section, Section II, introduces the SDE, our recommendation system, and the context in which this recommender has been developed. Then, Section III describes the Semantic Model used to represent the information available in its Knowledge Base, including descriptions of people, which are enriched from data of external sources, as shown in Section IV. Section V explains the recommendation functionality and the algorithms used in the SDE. The paper finishes presenting the first results of its application in practice in Section VI and some conclusions in Section VII.

II. SDE: SCENARIO DEVELOPMENT ENVIRONMENT

The European Commision's FP7 iTEC project (Innovative Technologies for an Engaging Classroom) [1] is intended to provide answers to a common situation in European schools: in spite of having more and more sophisticated tools available (e.g. interactive blackboards, last generation learning management systems, collaborative tools, advanced mobile terminals), mainstream education practice has not evolved yet to be able to take the most of these new resources. iTEC aims to provide

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

solutions to this situation by developing engaging scenarios for learning. For this purpose, it declares as one of its main commitments “to build a prototype assistant for advising users on how to find, select and combine resources to support learning plans”.

The iTEC SDE (Scenario Development Environment) is a key element to fulfil such iTEC objective. It is a software agent (used from the user interface provided by a tool called Composer [2], aimed to allow teachers to make up lesson plans from learning activities) that provides recommendations on different types of resources (i.e. applications, devices, people, and events) taking into account the specific requirements of the learning activities, together with any other information.

The SDE has been designed as a Knowledge Based System (KBS), i.e. a system based on Knowledge Technologies that uses Artificial Intelligence-related techniques in problem-solving processes to support human decision-making, learning and action [3]. These systems include a repository, the Knowledge Base (KB), that stores the knowledge of the domain experts using some kind of knowledge representation mechanism (in our case, OWL [4] to represent ontologies, RDF [5] to store actual facts and SWRL [6] to register logic rules). When constructing a KBS, the correct design and characterization of the underlying semantic model is at least as important as the development of its functional components and subsystems. For this reason, existing methodologies for the development of traditional software systems such as the Software Development Unified Process [7], Scrum [8] or Extreme Programming [9] are insufficient to guide developers throughout the different stages of the construction of KBS systems. Indeed, we propose an approach that combines both Software Engineering and Knowledge Engineering techniques, previously used successfully in other projects [10] [11]. More specifically, we follow guidelines from the Unified Process for the design and development of software components and an approach close to the principles of Methontology [12], including relevant aspects of UPON [13] and DILIGENT [14], for the design of the Knowledge Base.

The SDE relies on data from existing iTEC registries [15], namely People & Events Directory, iTEC Widget Store and iTEC Composer (cf. Figure 1). This information is periodically harvested from different JSON endpoints (REST like services) and transformed according to the designed Semantic Model (which is described in the next section). Besides, the introduction of semantic technologies at the core of the SDE facilitates the integration of data from other external sources. These sources, that can expose its data in heterogeneous formats (e.g. RDF, HTML, HTML+Microformats), are used to complement the information available or to enrich the resource descriptions stored in the registries. Examples of these sources are DBPedia [16], Google Scholar [17], LinkedIn [18], etc.

III. The Semantic Model

To develop a KBS it is needed to define a proper semantic model that collect the conceptual and heuristic knowledge in the domain (Universe of Discourse). This model serves as a foundation to explicitly describe, in a way that software application can process, all the information elements involved in the system.

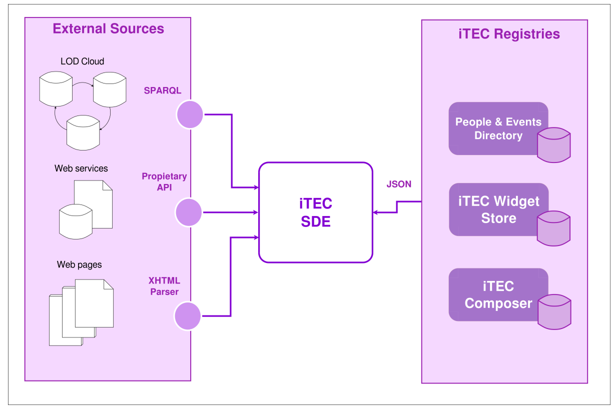

Figure 1. iTEC SDE Data Sources. Communications diagram

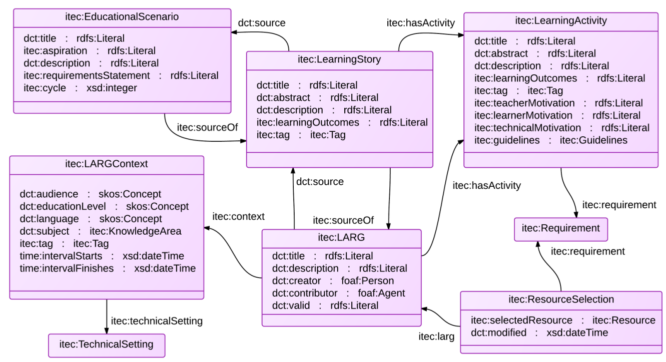

Figure 2. iTEC SDE Semantic Model. Partial view of the base classes

Our Semantic Model is composed of both an ontology, identifying all relevant terms needed to describe the existing conceptual elements and their relations (cf. Figure 2), and a set of inference rules to capture the existing heuristic knowledge that cannot be expressed using Description Logic formalisms. This model, together with the information gathered by the system from existing databases and external data sources, configures the Knowledge Base of the SDE.

As shown in Figure 2, in iTEC, the starting element for lesson plan designs are the Educational Scenarios (ESs). An ES describes a specific educational practice where activities are developed using some resources and technological elements. In some cases, the activities require the participation of specific people. The most relevant component of a scenario is its narrative part, where a real educational case is represented including real students and teachers, specific resources, etc. A typical example may be as follows [19]:

“I am a science teacher who wants to combine elements of formative and summative assessment to enhance my teaching and my students’ learning. First of all I choose a topic from the curriculum and I prepare a test to assess my students’ understanding and knowledge of this topic using a classroom response system. With this information I begin to develop a class wiki with headings based on the outcomes of my students’ knowledge and the areas that they are struggling with. Students are organised into teams (mixed or similar ability or a combination of both) and must complete assigned sections of the wiki based on the data from the classroom response assessment and other observations and evaluations I have made during the teaching of this topic and class. In the next lesson the class build the wiki using the headings as a framework, carrying out research, and using the web and other traditional resources like textbooks."

The next abstraction level includes the Learning Stories (LSs) and their main building blocks, namely Learning Activities (LAs). A LS is a narrative description of a learning proposal that is more concrete than a scenario and is more helpful to teachers when designing their lesson plans. It can be seen as the generalization of a scenario and it shows how several generic LAs may be combined to construct a consistent lesson plan. In turn, LAs can be seen as building blocks to be included in several LSs. Each LA includes information on educational objectives, motivation for the involved actors (e.g., students and teachers), proposals on technology usage, and recommendations on resources to use, indicating when resources are required, desirable or just recommended. Resources may be described either as actual specific resources (e.g., Skype, a Photo Camera) or as a collection of open requirements that may be satisfied by several resources (e.g., a synchronous communication tool, an expert on the topic covered in class that is online available). They also include teacher guides detailing how the LA should be implemented in a specific classroom (e.g., time needed, introduction, preparation, evaluation and assessment) and how to adapt the material to a specific course.

LSs and LAs are the foundation of LARG (Learning Activities Resource Guide) specifications. Teachers can customize the initial LAs and LSs introducing locally available resources to fulfil pending requirements. Moreover, they must define a particular learning context where this LARG will be deployed. This element, named LARG Context, includes both educational elements (such as the language used for teaching/learning, the particular topic/s covered in the LA, or the learner's age range) and other elements such as the tools available in the classroom (Technical Setting) or the place and the dates on which the activities occurs. Hopefully, the final outcome (i.e., the LARG) will be detailed enough to be directly implemented, and open enough to be easily adapted to different classroom settings.

The Semantic Model includes, also, the modelling artifacts to describe resources. Regarding the people modelling (cf. Figure 3), our Semantic Model reuses widely used specifications as FOAF [20] or VCard [21] and add new relationships to take into account the particularities of the project. For example, we define properties to store the person's expertise (which which can be numerically graded) and their language skills.

IV. The Knowledge Base

The people recommendation functionalities provided by the SDE depend, to a long extend, on the information available in the Knowledge Base about potential contributors to the LAs. Basically, the more comprehensive the information is the better and more accurate recommendations will be provided. Therefore, it is a key issue to have as many potential contributors as possible, and as much information about each one of the contributors.

In the context of the iTEC project, the project partners are providing the information about potential contributors through

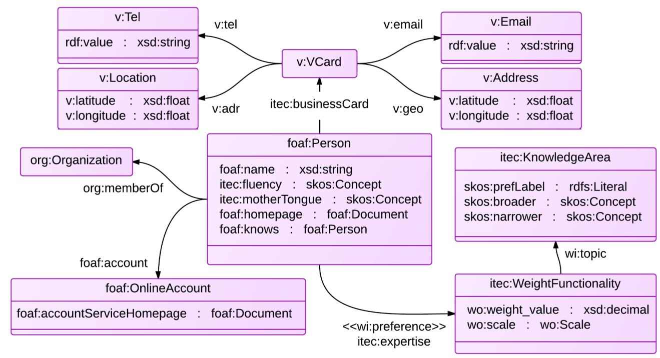

Figure 3. iTEC SDE Semantic Model. Partial view of the $Person$ class

the iTEC People & Events Directory [22]. This system is the main data source for people information in the SDE Knowledge Base and it allows to register information manually. However, it presents some drawbacks. On the one hand, this is a way to register the information, but it is a hard work and not easily sustainable. On the other hand, in practice, the information registered is not complete and further information about user skills, competences and expertise is usually missed. In order to reduce these disadvantages, we have designed a method to improve the information. Based on the Web 2.0 principles, many Web sites, social networks and applications maintain large amounts of information about people on the Internet [23]. Many times this information is freely available and reusable. Therefore, it is feasible to collect this information in a semi-automatic way and to get new data to enrich the records about potential contributors available in the Knowledge Base. This process is known as semantic enrichment [24].

A. Semantic Enrichment

We can find in the literature some experiences on the location of experts according to the information available on the Web (e.g., [23], [25]). These systems rely on information extraction techniques [26] applied to several types of information sources. The process of detecting whether two different records in two different sources deal with the same real-world object, the same individual in this case, is specially relevant in our context. This process is known as Record Linkage, and it corresponds to the foundation of the proposed enrichment algorithm.

According to our interests, available sources can be classified into semantic and non-semantic sources. Semantic sources express hosted information in a "machine-interpretable" way (i.e., they express information according to a Knowledge Representation language), like the nodes of the Linked Open Data (LOD) Initiative network [27]. These sources support information enrichment in a direct way, as fetched data don't require to be converted into RDF. Besides, there are tools available (e.g., SILK [28]) that support the automation of record linkage processes. Regretfully, LOD doesn't include all information required to enrich experts [25]. In these cases, we will have to extract information from non-semantic sources, that is, sources hosting information not expressed in a knowledge representation language, but according to another popular representation languages (e.g., HTML, XML, SQL, etc.). These sources are fairly abundant, and include rich and detailed information. To extract information from these sources, a wrapper has to be developed [26]. A wrapper is an information extraction agent that fetches unstructured pieces of data and transforms them into structured information (i.e., RDF in our case). The design complexity of these wrappers and its reliability and soundness is eventually determined by how the original information is structured [29]. For example, data expressed in XML require less complex wrappers than data expressed in HTML.

B. Enrichment experiencies

To enrich available information on experts at the iTEC People & Events directory, a collection of agents has been developed to inspect several semantic and non-semantic sources. These wrappers were specifically aimed to enrich properties used by the recommendation algorithm (cf. Section V). In this case, the main factor to determine whether an experts fits a given educational activity is his or her expertise. Typically, an indication of the expertise of individuals is provided by their scientific publications [25]. Therefore, the most relevant sources for the pursued enrichment process are those sources that provide information on academic publications in an accessible way. In any case, the recommendation algorithm will compute final rankings according to additional relevant factors, like languages spoken, location, contact details, etc. This latter information may be extracted from social platforms like Facebook or LinkedIn [23].

With respect to non-semantic sources, two enrichment modules have been developed that include the logic required to extract information from Google Scholar profiles (i.e., HTML-coded pieces of information) and through the LinkedIn's API (i.e., XML data). For these sources, already available search services are used to reduce the complexity of record linkage. This process is based on 1) triggering a search query using the expert's full name as registered in our knowledge base; 2) each name in the list of returned results is compared with the target name according to a Jaro syntactic matching heuristic [30]; and 3) profiles above a predefined similarity threshold (i.e., 0.96) are considered as corresponding to the target iTEC expert. This way, we are able to extract information on a given expert's academic publications and his or her co-authors, interests, skills, languages, location, etc.

To process semantic sources, an enrichment module has been developed that performs information retrieval on a collection of LOD nodes using the SILK tool, which has been conveniently configured according to our interests, that is, it will fetch information about real people (i.e., foaf:Person and akt:Person properties), having a name (i.e., foaf:name y akt:full-name properties) that is conveniently similar to the iTEC experts' name according to the Jaro matching heuristic (i.e. similarity threshold of 0.96). The analyzed repositories (e.g., DBLP) provide diverse information on each expert, including his or her scientific publications.

C. Enrichment results

Most of the information extracted through the enrichment process can be directly adapted to the iTEC data model to be inserted in the Knowledge Base. This is the case of properties like languages, online contact details, or experts' location. However, other factors are fairly complex to adapt and require further processing prior to their insertion in the Knowledge Base. The most apparent case corresponds to the locally defined expertises according to a pre-defined vocabulary including 37 knowledge areas. Several concepts defining skills and knowledge obtained through enrichment do not fit to any actual scheme. To infer iTEC expertises from these heterogeneous concepts we rely on the ample hierarchical scheme of universal concepts available at DBPedia. In a nutshell, for each retrieved knowledge area, 1) the homologous entity in DBPedia is obtained using SILK; 2) once detected, we seek among the parent and children concepts a concept referencing an expertise collected in the iTEC vocabulary, at a distance of no more than five hops; and 3) if such a concept is found, we infer that the target expert do have the expertise corresponding to the iTEC's knowledge area.

As the information extraction process can be automatically and periodically executed [26], enrichment enables us to periodically update available information on each iTEC expert. This way, information available on experts evolves in sync with the actual evolution of experts' experience and skills [25]. Besides, this approach also enables the enrichment of the experts directory by including experts in the analyzed online information sources that were not initially considered. However, only co-author information is used to locate additional experts. This way, enrollment of new experts is kept under control, as we know for sure that new experts will at least share some expertise with existing experts, and they will have already collaborated with existing experts in the past. We understand that profiles satisfying these criteria would be more prone to be involved in iTEC's Learning Activities.

V. A RECOMMENDER SYSTEM FOR PEOPLE

Traditional recommendation systems focus on recommending the most relevant items to users. Moreover, they usually consider a single attribute of a given item. These systems define an utility function based on a two-dimensional model: $Items$ and $Users$ [31]. More recently, Context-Aware Recommendation Systems (CARS) deal with modelling and predicting users' tastes and preferences incorporating available contextual information into the recommendation process as explicit data categories [32]. In this case, they use a three-dimensional approach (i.e. $Items \times Users \times Context$) or even a multi-dimensional model considering different contextual information as additional dimensions (e.g. Location, Time). [33] identifies relevant context dimensions for TEL applications and analyse existing TEL recommender systems along these dimensions.

A main difference in the iTEC SDE is that the user asking for the recommendations (i.e. the teacher that creates the lesson plan) is not the main role in the recommendation. The leading role is played by the learning context. The particular users' characteristics are shifted to the background and are used just to improve the characterization of the learning context, but the key issues to take into account in the recommendations are the features of the classroom, the learners and the Learning Activities themselves. Nevertheless, as discussed before, our recommender system focuses, among others, on recommendations about people. Thus, our recommender system has an utility function defined as:

$$u : People \times (LAs + Context) \rightarrow Rating \tag{1}$$

Therefore, the recommender considers the characteristics of individuals, the collection of predefined requirements defined for activities, and also the corresponding learning context where these activities will take place. Taking this information into account, the system analyses the data in its Knowledge Base to produce sorted lists of the individuals potentially more suitable to that particular situation. This process is organized into three phases:

1) Pre-processing: input data are processed, particularly learning activity requirements and LARG Context, to create a formal description of extended requirements taking into account the needs of the activities and the realization context.
2) Filtering: a set of SPARQL queries is composed using the extended requirements mentioned above. This query is sent to the Knowledge Base to fetch a list of potentially valid individuals to execute the activities.
3) Relevance calculation (sorting): in order to sort individuals in the list, the recommender computes an estimated relevance value for each of them. Next subsection explores the algorithm.

A. Relevance algorithm

The SDE semantic model includes a large number of properties. Taking into account the complexity of people descriptions (cf. Figure 3) and both the number and the heterogeneous nature of the variables included in LARG Context, our recommender system was developed according to the guidelines of Multiple Criteria Decision Analysis (MCDA) [34]. More specifically, as proposed in [35] or [36], we treat the recommendation problem as a multicriteria decision problem to model this class of problems. Thus, we use an utility function which combines several rating factors to reduce multiple-criteria recommendation problem to a single-criterion one.

The approach adopted (proposed in [34]) identifies four steps to implement the decisor: (1) definition of the Object of Decision, (2) criteria modelling, (3) global preference model and (4) decision support process. The three first steps are devoted to analysing the system in order to identify which are the best methods to be applied in each level. The four step is devoted to selecting specific implementation mechanisms according the previous analysis. We summarize below the results of the three first steps:

1) Definition of the Object of Decision: our recommender purpose is to produce sorted list including potential candidates to participate in a lesson plan. Thus, the object of decision is choice (to select the most appropriate elements) and specially ranking (to sort them according to their appropriateness).
2) Criteria modelling: we need to identify a family of criteria that enables the comparison of different candidates according to several points of view. In this case, we define a consistent family of both measurable and ordinal criteria that takes into consideration most relevant properties (included in the semantic model) to distinguish individuals to participate in a lesson plan. More specifically, we defined nine different criteria. According to each particularities we used different value assignment strategies to create its marginal utility functions, always using the interval $[0, 10]$ as general evaluation scale. Besides, to avoid penalizing some individuals against others for the lack of information, we will assign a neutral value ($c = 5$) when there is no information. Using these value assignment strategies and normalizing values for each criteria, we obtain the marginal utility functions for each factor. Table I describes each of the factors and the used strategies.
3) Global preference model: this stage is devoted to developing a strategy to aggregate the different criteria to express the preferences among several alternatives in the potential candidates set. In this case, we use an Multi-attribute utility approach, i.e. we built a value system to aggregate preferences for each criterion and, after that, we aggregate these marginal preferences into a single utility function. More specifically, we define the general utility function (u) as the weighted sum of the marginal utility functions of each criterion (f_i). According this, the total rating of an individual p, is computed from the general utility function of that person:

$$R(p) = \sum_{n} w_i * f_i(p) \tag{2}$$

where n is the number of criteria and w_i the weight assigned to i's utility function. Values of w_i are set taking into account the ratings assigned by a group of experts with both pedagogical and technological expertise (iTEC Control Boards). Table II summarizes these values.

Table II. FAMILY CRITERIA

Criteria	$\overline{w_{c_{f_l}}}$
Language	7.87
Expertise	7.78
Experience	7.17
Communication facilities	6.87
Personal relations - Trust	6.48
Organization	5.78
Rating	5.70
Location	5.30
Personal relations - Knows	4.96

VI. PRELIMINARY RESULTS

The recommender system implementing enrichment and recommendation strategies proposed in this paper has been tested in the framework of iTEC workshops through a friendly testing prototype (cf. Figure 4) [37]. This UI allows to select and to combine different predefined Learning Activities and LARG Context's variables in order to obtain best recommendations on people. In this situation, most of partners in iTEC pedagogical work packages consider that recommender has the potential to lead innovation in the classroom.

Table I. PEOPLE CRITERIA

Criteria	Description
Communication facilities	This criteria takes into account the communication tools that a person participating in a learning activity has available. Thus, this criterion prioritizes individuals whose communication channels belongs to the specified set of tools available in the LARG. According to this, it will take value $c = 1$ when none of the individual's communication channels match some of the tools included in the specified Technical Setting; and $c = 10$ when some of the individual's communication channels belong to the activity's Technical Setting.
Experience	This criteria considers the previous experience of a person, according to the learning activities performed by this person. Its aim is to prioritize people who have already contributed to some of the learning activities in the LARG. Thus, it will take value $c = 10$ when the person has already performed some of the learning activities; and $c = 1$ when this fact is not explicitly stated.
Expertise	Expertise of a person in a given subject. It should be noted that according to the semantic model, expertise is measured on a scale (including in the interval $[0, 10]$). Thus, the value assigned according this criterion is computed as the arithmetic average of the expertise measures (levels) of the individual has for each of the subjects specified in the educational context.
Language	This criteria is intended to prioritize people having as their mother tongue the languages in which an learning activity is developed. In this case, value $c = 1$ will be assigned when there is information about the individual's mother tongue(s) but none of them is specified by the requirement; and $c = 10$ when some of the mother tongues matches at least one of the activity languages.
Location	This criteria indicates the degree of geographical proximity of the person to the location of learning activities occurs. It should be noted that this factor will not be taken into account for people acting as online collaborators in a LARG. It will take value $c = 1$ when the distance between the person and the learning activities' location is larger than a predefined threshold distance; and $5 \leq c \leq 10$ when the distance is smaller than this threshold. In this case, concrete value will be assigned using the equation 3. $$10 - (distance/threshold) * 5 \quad (3)$$
Organization	This criteria is intended to prioritize people belonging to the same organization as the LARG's creator. Thus, it will take value $c = 1$ when the person belongs to a different organization; and $c = 10$ when both the person and the LARG's creator belong to the same organization.
Personal relations - Knows	Similar to trust factor, it considers existing relations between the LARG's creator and the potential candidates to participate in a learning activity. It will take value $c = 10$ for people known by the LARG's creator; and value $c = 1$ otherwise.
Personal relations - Trust	Indicates the degree of trust that the community, as a whole, has in the person to be selected. The associated value is aimed at quantifying the reliability of a person according to the trust relations provided by the user community. As this property has a binary value, it will be computed as a quotient between the number of people who rely on the individual and the total number of people in the community.
Rating	Indicates the degree of popularity of a person in the community. The associated value may be obtained from community ratings, typically using an arithmetic average.

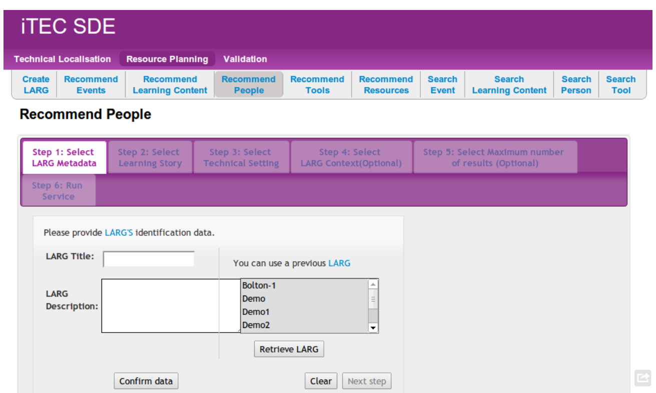

Figure 4. iTEC SDE Testing Prototype

In this first experiment, we have successfully enriched the descriptions of the 46% of the people initially available on the Knowledge Base (extracted from the CEN LTSO [38] experts directory). Among the most important enriched properties we can mention: about 1500 potential expertise properties were added (although most of them could not be directly related to the iTEC Knowledge Area vocabulary terms), 81 online accounts were included (through which it is possible to contact the experts), 56 profiles were complemented with information about its location, 50 new spoken languages were found, and 316 knows properties among people were set. In absolute terms, about 130,783 triples were extracted from external web sources.

VII. CONCLUSIONS

The authoring of quality lesson plans is not an easy endeavour for teachers. Mainly, when lesson plans are required to adopt new pedagogical approaches and to include new technologies or other resources different from the traditional ones. This requires not just to be able to define the several activities to be carried out, but to know about the more suitable tools and to get in contact with suitable people that could provide a positive contribution to the activity. The iTEC project is intended to facilitate this endeavour and the iTEC SDE is called to play a key role on it by providing recommendations to teachers that assist them in the assembling of activities and resources in lesson plans.

The literature about recommender systems in e-learning includes several developments. Nevertheless, to the best of our knowledge, there is neither any approach taking the learning activities and context as the reference element to provide the recommendations, nor people has been considered as a learning resource to be recommended. Therefore, we have been experiencing different problems. Some of them are directly related to the end user (e.g. usability, user feedback). Other problems are related to the availability of the information needed to provide the recommendations. In this paper we have shown the key ideas underlying the SDE development and some of the solutions we have been exploring to solve the lack of information issues. At this point, semantic technologies and Web information can provide a good solution to support the operation of the system in a large scale and in a sustainable way.

Should Makers Be the Engineers of the Future?

Shawn Jordan and Micah Lande
Arizona State University, shawn.s.jordan@asu.edu, micah.lande@asu.edu

Abstract - **Engineers participate in the Maker movement. Some Makers do not pursue formal engineering education but both the engineering field and their own vocational advancement could readily benefit. We seek to understand Makers and how they are inclusive or exclusive of what can be expected from engineers. From the *Engineer of 2020* list of characteristics (National Academy of Engineering, 2004), we highlight *practical ingenuity*, *creativity* and *lifelong learning* for likely opportunities to leverage the Maker experience. The mission of this research is to develop a theory, inductively grounded in data and deductively built on literature, illuminating the *knowledge*, *skills*, and *attitudes* of Makers, describing their *pathways* in formal engineering education to better inform future innovations in order to improve the *practical ingenuity* and *lifelong learning* of our future engineers. Artifact elicitation interviews, based on the method of photo elicitation and critical incident technique interviews will be administered to participants. Results from the inductive and deductive analyses will be triangulated to generate a preliminary theory of Maker knowledge, skills, attitudes, and pathways. This theory, inductively grounded in data and deductively connected to literature, will describe aspects of Makers, along with how their pathways intersect with formal engineering education experiences.**

Index Terms – making; tinkering; engineering pathways; engineering education

INTRODUCITON

A Maker is an emerging colloquial term we use to describe a group of do-it-yourself-minded individuals participating in informal communities supporting building and prototyping technical proof-of-concept exploration and ad-hoc product development. A Maker is a modern-day tinkerer, hands-on doer and fashioner of stuff. The range of expertise could be large but novices and experts alike share an enthusiasm for building and creation. Individuals and groups embark on projects of all sorts, led primarily by their interests and curiosities, informed by their skills or the skills they want to learn. They show off their work readily and share their technical recipes with those interested. Ascribed directly to Make magazine and Maker Faire festivals [1], making encompasses anyone, young and old alike, that describe themselves as part of such a community. They participate in communities of practice at Maker Faire festivals. They populate community maker spaces and hacker spaces [2] and use commercial maker venues [3] to gather together.

MAKERS AND THE ENGINEER OF 2020

The elements of the *Engineer of 2020* description that resonate with Makers include practical ingenuity, creativity and lifelong learning [4]. Can a Maker be considered an engineer and vice versa? Is the Engineer of 2020 a Maker? We aim to explore the possible overlap between what we can discover about Makers and what literature describes about engineering students and practicing engineers. The *Engineer of 2020* [4] synthesizes the characteristics wanted out of the next generation of college engineering graduates: analytical skills, management, communication, creativity, dynamism/flexibility, ethical standards, leadership, lifelong learning, practical ingenuity, and professionalism.

MAKERS, MAKE MAGAZINE AND MAKER FAIRE

A Maker creates technical artifacts, personally undertaking a project often without prior expertise. The do-it-yourself ethos is historically rooted in efforts like *Popular Mechanics* magazine demystifying everyday stuff for hobbyists and the *Whole Earth Catalog* [5] surveyed everyday tools for the counterculture movement of the 1960s. Additional real-world touchstones are the growth of Radio Shack stores and the television program MacGyver. Technology and sharing of information has greatly increased the ability for smaller communities with shared interests to coalesce and grow.The label Maker is a self-determined one assigned by affinity or involvement in a larger making community. *Make* magazine was founded in 2006 as a quarterly publication and presents "DIY Projects, Inspiration, How-tos, Hacks, Mods & More" [7]. It has published more than 30 issues and has a circulation of 300,000. *Make* is a central participant in championing making, described as "a central organ of the maker movement" ("More than just digital quilting," [8]. Maker Faire has been an outreach effort of *Make* magazine, convening flagship, multi-day fair events in select cities and supporting smaller, regional one-day events around the country. Its credo is to "celebrate arts, crafts, engineering, science projects and the DIY mindset" [7]. Cross-disciplinary workshops for informal science and engineering educators and academics and teachers have been held [1]. Topics of discussion included creativity informing K-12 education, inspiration to STEM learning and collaborations between Makers and teachers, academics and informal science community members. Different intellectual communities have focused on different aspects one can relate to making. The human-computer interaction field has

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

studied hacking and tinkering in the context of DIY and tools and practices [9,10] design research, ad-hoc prototyping and tinkering using local objects [11]. Flexible space for activity are growing in popularity at hacker spaces [2] and maker spaces in academia [12,13] and fab labs [14].

RESEARCH QUESTIONS

The constructivist grounded theory research questions are:

RQ1. *What knowledge, skills, & attitudes do Makers possess that could be related to engineering?* (Makers as engineers)

RQ2. *How do pathways of Makers intersect with engineering?* (Makers' pathways to engineering)

RESEARCH METHODS

Population and Sampling: This study samples the population of adult Makers in order to understand how their paths intersect with formal engineering education. Exhibitors at flagship Maker Faires are being recruited to create a pool of potential participants. To answer the research questions about Makers, a stratified purposeful sampling strategy [15] is being used for initial selection of the participants. Participants will be selected to maximize variation across the target strata, while oversampling for underrepresented groups and ensuring that all participants self-identify as Makers. Makers who have a formal engineering education degree will provide insight into how formal engineering education has helped them in their who have chosen pathway. Makers who have informal engineering education experience will provide breadth to the study and illuminate how informal education experiences influence engineering pathways and career choices. Following analysis of data from an initial group of participants, a Preliminary Theory is being developed and theoretical sampling done "on the basis of the emerging concepts, with the aim being to explore the dimensional range or varied conditions along which the properties of concepts vary" [16]. Theoretical sampling will strengthen the theory by purposeful selection of participants.

Screening Questionnaire: Potential participants are being asked to complete a short online screening questionnaire. The questionnaire consists of multiple choice and short answer questions check for self-identification as a maker, collect age, demographic, and years as a Maker data, determine if potential participants have formal or informal engineering education experience, and determine if potential participants have an engineering-related career or hobby. Results from the questionnaire have been used to select initial participants. A first set of study participants were recruited and interviewed in September 2012.

Artifact Elicitation Interviews: A semi-structured artifact elicitation interview [17] is conducted in person (and continued via Skype if necessary) to examine the knowledge and skills a Maker develops as a result of making creations, and the attitudes they have about making, engineering, and their careers. The interview relies on a physical artifact/creation that the Maker has created. Further questions also rely on references to the artifact to elicit "thick description" [18]. Artifact elicitation interviews extend the qualitative inquiry approach of photo elicitation [19, 17, 20, 21], where interviews that rely on photos "evoke information, feelings, and memories that are due to the photograph's particular form of representation" [17] and stimulate "latent memory, reducing areas of misunderstanding, eliciting longer and more comprehensive accounts of ideas... eliciting values and beliefs, and connecting to core definitions of the self to society, culture, and history" [22]. In addition, photo elicitation method has been used successfully in engineering education [22,23,24] and other STEM disciplines as both a research and pedagogical method. Artifacts created by Makers are similar to photos in the sense that they embody the knowledge, skills, and attitudes that Makers hold, making artifact elicitation appropriate to study the concepts in RQ1.

Constructivist Critical Incident Technique Interviews: A semi-structured constructivist critical incident technique interview [25,26,27] has been conducted in person (and continued via Skype if necessary) to examine the educational and career pathways of Makers and how they intersect with formal engineering education and careers in engineering. The interview consists of questions designed to examine college and career decision points and how they relate to engineering. Interview questions in later interviews will evolve to address emergent themes discovered in interviews with earlier participants. [27] used critical incident technique interviews to study decision making in a variety of fields, and the method have been used very successfully in engineering education research [28]. This technique aligns well with RQ2 to understand decision points contributing to pathways of engineering.

Data Analysis: Interview transcriptions are currently being analyzed in parallel both inductively and deductively to generate a theory. One part of the research team is using open coding [16] and theoretical memoing [29] to conduct the constructivist grounded theory [30] inductive analysis. Sorting and theoretical coding [29] will be used to connect the resultant themes into a theory. Simultaneously, other members of the research team are deductively analyzing the data using thematic analysis [31] based on a coding scheme derived from the relevant conceptual frameworks.

PROPOSING A MAKER THEORY

The synthesized theory will identify knowledge and skills of Makers that relate to engineering, in addition to their attitudes about engineering and how their pathways have (or have not) intersected with formal engineering education. This theory will be of particular use to the engineering education community aspiring for the Engineer of 2020 and beyond. It will be useful to researchers studying pathways, student attraction and retention, and informal science and engineering education. The theory will also be transferable to other disciplines interested in attracting Makers.

This project is a work in progress. Initial date collection occurred in September 2012 at the World Maker Faire New York with 12 participants. Interviews have been transcribed and are in process of an initial parallel inductive and deductive coding. Interesting initial findings suggest the social nature of Making and presenting and sharing work in a larger community of practice. Participants are also motived by a wide range of interests exhibited beyond traditional engineering education experiences.

IMPORTANCE OF THIS WORK

Workplace Call to Action: Faced with a dynamic world of complex problems crossing disciplinary boundaries, our country needs technical and engineering talent to solve challenges, e.g., NAE Grand Challenges [32], of the future now. The talent necessary to solve these problems largely comes from a formal engineering education system challenged with producing sufficient numbers of qualified engineers. However, there are useful qualifications beyond the expectation of the traditional. Qualities like *practical ingenuity*, *creativity*, and *lifelong learning and engagement* are indispensible to the workplace.

Broadening Engineering Pathways: A more inclusive vision of engineering crossed with making could build future engineering capacity as well as raise awareness to the general public of the work and impact such work offers. While we do not equate engineering students, practicing engineers and Makers completely, possible overlaps and stories of pathways within can be transformational. Consider the benefits to STEM and resulting societal benefits for those who have influence over student decisions like teachers, school counselors, and parents to have an appreciation of the multiplicity of pathways into such careers or the value of technical literacy, both based in problem solving or making. This may be especially true for underrepresented groups.

Informed Educational Efforts: Makers create their inventions wholly out of their imaginations. Their work is done outside the confines of established engineering education curricular activities. But their commitment and engagement is something that can be better understood to advantage our teaching in the classroom. This approach also aligns with project-based learning as a teaching method in the classroom, a call made in [33]. Engaging future engineering students may mean developing curriculum and pedagogy that allows students to apply knowledge and *make.*

Abstract - **This paper suggests that the purpose (goal) and manner (method) of knowledge application and generation usefully distinguishes engineering and scientific knowledge. This method could be significantly useful in distinguishing the scientific and engineering components of engineering education, as well as underscored the centrality of social context to engineering work, and engineering values. This paper presents a brief exploration of the epistemology of knowledge, specifically distinguishing the development of scientific knowledge from the development of engineering knowledge. It outlines a pragmatic theory of knowledge which provides a means by which to reliably distinguish, particularly in a learning environment, the critical terms of 'science', 'engineering science' and 'engineering.'**

Index Terms – Philosophy of Engineering, Philosophy of Engineering Education, Epistemology.

INTRODUCTION

A cursory introduction to the literature of the philosophy of engineering reveals competing viewpoints on what distinguishes scientific from engineering knowledge, including engineering (and technology) as applied science [2] and the influence of knowledge generation as a means to distinguish between 'scientific' and 'engineering' knowledge. When seen through the lens of a pragmatic theory of knowledge, the crucial characteristics of scientific knowledge include that scientific knowledge is theory bound, and scientific knowledge is developed to explain the way the world works. [1] Engineering knowledge can be considered a distinct form of knowledge since scientific and engineering knowledge aim at different ends. In short, science aims to explain and technology/engineering aims to create artifices. "Technology, though it may *apply* science, is not the same as or entirely *applied* science" [3].

Engineers are individuals who combine knowledge of science, mathematics, and economics to solve technical problems that confront society; "… a person who applies science, mathematics, and economics to meet the needs of humankind" [5]; alternatively defined, "Engineering is the art of directing the great sources of power in nature for the use and convenience of man" [6].

Individually, engineers are those who engage in the practice of engineering. The root of the word engineer derives from engine and ingenious, both of which come from the Latin root *in generare*, meaning "to create." In early English, the verb engine meant "to contrive" or "to create." The word engineer traces to around A.D. 200, when the Christian author Tertullian described a Roman attack on the Carthaginians using a battering ram described by him as *ingenium*, an ingenious invention. Hence an engineer is a person responsible for developing such ingenious engines [of war] [5]. At their roots, engineers are problem solvers – ingenious problem solvers. Engineers create products and processes to improve and to enhance the convenience and beauty of our everyday lives [7]. Thus, engineers are civilizers, since civilization in its most elemental sense means bringing humans physically out of the state of primitive savagery [6].

Engineering knowledge is rooted in scientific knowledge; however they appear to be separate spheres of knowledge that are both man-made [8]. Historically, each engineering sub-discipline has developed its own body of knowledge, whether codified or not [9,10,11]. Among engineering educators, it is commonly accepted that engineering knowledge, however much based on the study of mathematics, science and engineering science, is insufficient. "…there is a big gap between scientific research and the engineering product which has to be bridged by the art of the engineer. The creative, constructive knowledge of the engineer is the knowledge needed to implement that art." [3]

Beyond engineering knowledge and skill, there are the behaviors that help engineers succeed, bring honor to their profession, and make technology a force for good in the world. Engineers are expected to link effectiveness and creativity, where conscientiousness is the virtue suggested to be the most valuable for engineers [6]. In sum, engineers identify problems, construct solutions, and use their knowledge and skill to change the status quo into a new situation that is better, both individually and for mankind.

The types of knowledge produced, as well as the processes by which knowledge assimilated and utilized are different among these groups of persons. Central to these sociological distinctions and their respective knowledge generation/use is the relationship of different technological disciplines to one another, and how the technological disciplines effect knowledge generation.

SCIENCE AND ENGINEERING

'Science' and 'Engineering' are broad disciplines each with long histories and significant nuances among them. The viewpoints common to each discipline are however different. The viewpoints of science and engineering are idealistic and pragmatic respectively [12].

The nature, or goal of science as a whole, is to explain how the world works, as determined through experiments and their artifacts. Knowledge generation, from the perspective of scientists is approached via creating a hypothesis first, and testing it second. These scientific findings and related technologies are often codified, and managed by a body of scientists, and transmitted through published works and education.

The nature of engineering is for addressing human needs/problems, and generally applies domain-specific heuristics for building a system, or components intended for system deployment. [13] The lessons learned and identified technologies are often (though not always) codified, and may be transmitted informally, or formally to other engineers in the form of best practices, or where applicable, via a hypothesis that generalizes the best practice and testing of that hypothesis. In either case, the more formalized engineering findings are often codified, and managed by a body of engineers, and transmitted through published works and education.

Both science and engineering involve the identification of and development of technology, and both include significant relationship to and roots in mathematics. The tested formalizations of theory, identified technology, and best practices can lead to the creation of new branches of engineering and/or science. While these processes share significant similarities, their viewpoints make them epistemologically different; the value driving scientific knowledge development is that of explanation; the value driving engineering knowledge generation is application. These differences in value change the epistemological character of the knowledge.

EPISTEMOLOGY AND KNOWLEDGE

Briefly stated epistemology is the study of knowledge as justified belief. Development in epistemology since the work of David Hume has focused on identifying the justified true belief about what a single person knows. When applied to disciplines or communities, it also includes the requirement that to qualify as knowledge, a proposition or set of propositions must be endorsed by an appropriate community. Hence, there is both an individual and a significant sociological aspect to knowledge and justified belief. Individuals produce candidate claims for knowledge, and these candidates become knowledge, once they are endorsed by the appropriate community using agreed upon standards. [1] Components of the *method of the human mind* [14] and of Polanyi's *Personal Knowledge* [16] are outlined as foundations for individual understanding, followed by an outline centered on Polanyi, Sorokin and Vanderburg for the sociological approaches to epistemology [17,18].

Individual and Communal Knowing

Lonergan argues for what we may term a "method of the human mind," consisting of *experiencing, understanding*, and *judging*, underlies all specialized forms of knowing. This basic heuristic method or structure is tailored in various ways to meet the particular requirements of specialized contexts such as everyday practical life and the fields of mathematical and empirical science. [14]

In the "method of the human mind," experiencing provides us with data and depends upon adherence to a norm of attentiveness. Our striving to make sense of the data (e.g., "What is it?), promotes us from experiencing to attempts to understand; to finding the form, pattern, meaning, or significance of what we have experienced. Inquiry and imagination yield insights, which are expressed in concepts and definitions to provide a formulation of the understanding we have attained. Inquiry, insight and formulation embody a norm of intelligence. Because understandings may be misunderstandings, we cannot stop with them but must go on to ask the critical question, "is it really so?" The process of answering this question thematizes our desire to move through critical reflection to judgment. Judging marshals and weighs the evidence to assess the adequacy of our understanding. The evidence is adequate if it shows that the conditions necessary for something's being so are all met. If the conditions are met, within this context our knowing reaches a "virtually unconditioned" state, whose conditions for justified belief are all fulfilled. Thus the understanding is no longer is conditional and until proven otherwise, rather it must be true. The norm embodied in these operations of judging is that of reasonableness. The overall method is adjusted based on the perceived need for timeliness, precision, comprehensiveness, universality, and/or completeness. [14] This is where the viewpoint of knowledge is critical, as individual need or use for the proposition and the social context affect the manner in which something is known.

Thus knowing is a process, involving both covert and overt human actions, which involve the application of personal and social criteria. These knowledge-generation actions apply to the production of scientific and technological things. Polanyi describes covert actions to include operations such as sensing, perceiving, imagining, understanding, judging, and deciding. The overt actions include operations such as speaking, writing, drawing, calculating, grasping, shaping materials, and using tools. [16]

Individual knowing is a precursor to the community endorsement necessary for knowledge and justified belief to become part of the body of accepted knowledge. Both covert and overt actions have an internal structure that Polanyi calls a *from-to* relation. A skillful achievement, whether practical or theoretical, is the *to-* term of this relation, and the subordinated particulars constitute the from term. He suggests a movement metaphor for this relation when, in discussing the *from-to* relation in acts of knowing. [16] Sociological models of the epistemological process by which we create scientific and technological products also embody a movement metaphor. As presented in Table 1, Sorokin breaks the process into three stages, which are used here as an outline of the individual + communal knowledge development process. [17] For technical development, Vanderburg proposes a "technological cycle" with five phases. [18] In both models, the movements are from each earlier stage or phase to the next one.

Table 1. Correspondences between knowledge development stages [17], and phases of technological development [18]

Sorokin (3 Stage) Model	Vanderburg (5 Phase) Technological Cycle
1. Mental Integration	1. Invention
2. Empirical Objectification	2. Innovation and Development 3. Application
3. Socialization	4. Diffusion
	5. Displacement

This movement parallels Lonergan's proposals. According to Morelli and Morelli, Lonergan similarly "identifies the scheme of recurrence which constitutes technological, economic, and political advance: *situation – insight – communication – persuasion – agreement – decision – action – new situation – insight,*" etc.[15]

Mental Integration: In defining "mental integration," Sorokin states that the "integration of two or more meanings into one system is an act of creation occurring in the human mind." [17] This treats it as a covert act "in the human mind." Vanderburg's description of "invention" includes both covert acts, covert states, and overt acts [18], although the acts of exploring and working out details are usually overt actions, including actions such as writing, calculating, sketching, building physical models, and conversing with others.

Empirical Objectification: Sorokin's characterization of empirical objectification emphasizes the need for "empirical vehicles through which [new knowledge propositions] can be conveyed to others." [17] These can be incarnated through documents, examples, products, or other means. They key point among these processes is the development and presentation to a wider (more than individual) audience.

Socialization implies that the "empirical vehicles" are utilized to share knowledge among individuals, led by agents of socialization. He adds that most of the thousands of texts and artifacts produced never succeed in socialization, in being accepted and used by anybody but their authors. [17]. The key here is that people are the agents of socialization, and socialization efforts begin early in the process and continue throughout. When the original inventor or discoverer attempts to explain his idea to another person, he is an agent of socialization. When members of an original group attempt to persuade controllers of resources to support their project, market products, etc., they are agents of socialization.

The point of these phases is to recognize that individuals produce candidate claims for knowledge, and these candidates become knowledge once they are endorsed by the appropriate community using agreed upon standards. [19] The importance of the different stages is two-fold: first to recognize the importance of the inner mental state of a single individual, and to understand the difficulties this presents with respect to the certainty with which one can assert that someone actually 'knows' something. Among philosophers, this has led to "devising doomed criteria by which we can determine whether an individual uttering a proposition with X, Y, and Z properties can be said to 'know' something. The criteria are doomed because they ignore contingency, historical and otherwise." [1]

A pragmatic view of knowledge, on the other hand, shifts the emphasis to the criteria that the community has devised. But, even here, the criteria must meet some bottom line condition. For the pragmatist the bottom line is successful action. C. I. Lewis put it this way: "the utility of knowledge lies in the control it gives us, through appropriate action, over the quality of our future experience" [4]. This provides a key to understanding scientific knowledge, particularly in distinguishing it from other types of knowledge.

UNDERSTANDING SCIENTIFIC KNOWLEDGE

Moving from these more generalized forms of knowledge-generation to study those used in engineering and science is not straightforward. Common sense knowing is a form of the general method of the mind [14] where the process is tailored to the requirement for timely action and has less need for great precision, comprehensiveness, universality, or completeness, especially where attempting to meet such standards would only delay action unnecessarily. Common sense is content to find out only what we need to know right now, in this particular context, and to formulate itself allusively and incompletely in rules of thumb, examples, proverbs, and parables. Because its concern is our practical living, it relates things to ourselves rather than to each other, as the mathematical equations of science would do. In this sense, scientific knowing (sciences) develops from common sense and may be more or less distant from it. This distance is critical, and plays a difficult role in the development of a 'new' science. For example, botany, relying on descriptions of plants as they appear to us, is much closer to a common sense method than the current study of plant genetics. Yet, botany is a well-recognized subfield within biology, and both common sense and theoretical approaches are used in its pedagogy.

Lonergan distinguishes mathematical and empirical scientific heuristic structures. He subdivides empirical approaches into classical and statistical types. Classical approaches yield an intrinsic intelligibility and pertain to systematic aspects of reality, marked by schemes of recurrence. Statistical approaches pertain to non-systematic aspects of reality and yield no intrinsic intelligibility but, rather, probabilities, ideal frequencies around which actual events tend to cluster randomly.

The central point is that scientific claims derive their meaning from the theories within which they are associated; hence, *scientific knowledge is theory-bound.* The dynamic process in which scientists continuously revise what they are willing to endorse – and by which they examine their assumptions and their methods – is at the very heart of the strength of the sciences. This is a dynamic process that develops ever more refined approximations of objective truth, with both the challenge that it points to objective truth, and at the same time constantly criticizing the approximation as it is currently known. Thus, despite the theory-bound nature of scientific knowledge, the self-critical process of scientific inquiry ensures that the knowledge it claims is the best available at that time insofar as it is judged "best" according to community standards. The ultimate aim of scientific inquiry is explanation. Thus, in the context of a pragmatic account, the ultimate success of the use of scientific knowledge is explanation. [1]

UNDERSTANDING ENGINEERING KNOWLEDGE

Both science and technology may borrow from or rely on each other in various ways – they constitute two distinct forms of knowledge since they have distinguishably different ends. Science aims to explain and technology/engineering aims to create artifacts. Vincenti puts it this way, "technology, though it may *apply* science, is not the same as or entirely *applied* science" [3]. This is important, as the explanatory value of a scientific theory (e.g., its application) is subsequently judged by its usefulness not in accurately estimating the objective truth that may be involved, but rather for a different end: how the application of the scientific theory helps in the creation of an artifact that meets some human need.

Engineering refers to the practice of organizing the design and construction and operation of any artifice which transforms the physical or social world around us to meet some recognized need. Engineering – like science – is an *activity* with specific objectives. Consequently *engineering knowledge* concerns *the design, construction, and operation of artifices for the purpose of manipulating the human environment.* [1] One can reasonably narrow the focus of engineering knowledge to the topic of "design knowledge," by concentrating on design.

"Design" in this context denotes both the content of a set of plans (as in "the design for a new airplane") and the process by which those plans are produced. In the latter meaning, it typically involves tentative layout (or layouts) of the arrangement and dimensions of the artifice, checking of the candidate device by mathematical analysis or experimental test to see if it does the required job, and modification when (as commonly happens at first) it does not. This is a process of refinement, subject to a perceived need for timeliness, precision, comprehensiveness, and/or completeness. As such, this procedure usually requires several iterations before finally dimensioned plans/specifications/requirements can be released for production, and the effort is judged by its results – the usefulness of the design and/or product [1] [3]. This refinement process has been reasonably characterized as heuristic, and the development of such heuristics is central to the engineering method [13].

'Usefulness' is a fundamentally subjective value; it is necessarily a social construction that depends upon the social and historical situations in which the problem and those solving the problem exist. This is a challenge in engineering and to engineering education in particular, as the study of historical and social values and value construction is typically lacking in engineering curricula [6].

The concept referenced here is often referred to as 'subjective truth', that is a truth by agreement, an agreement of persons. This shows up in the engineering method as the value of the engineering artifact/effort is assessed by specific *subjects* (e.g., stakeholders); the requirement is there because the users want it, etc. In short, the 'who' of the problem is essential to solving the problem. In specific engineering sub-disciplines such as requirements engineering, incorrect assessment of the 'who' (subject) of the problem is considered a major process failure. Gause and Weinberg put it this way: "People have problems, systems have requirements" [20]. Thus, understanding and applying the 'pragmatic' approach in engineering is assessed by subjects for whom the engineering method is applied. The subject, and thus subjective truth remains central to engineering. This is another area where scientific knowledge differs significantly from engineering knowledge.

INTEGRATING SCIENTIFIC AND ENGINEERING KNOWLEDGE

Comparing the knowledge generation processes involved, engineering and science appear related, but significantly different, differentiated in both purpose and manner. This follows the distinctions suggested by Lonergan in his observations on empirical science. One of the distinctions between mathematical and empirical science/research is the empirical researcher's return to overlooked or neglected data that "forces the revision of initial viewpoints."

> "The circuit, then, of mathematical development may be named immanent; [as] it moves from images through insights and conceptions to the production of symbolic images whence higher insights arise. But the circuit of [empirical] scientific development includes action upon external things; it moves from observation and experiment to tabulations and graphs, from these to insights and formulations, from formulations to forecasts, from forecasts to operations, in which it obtains fresh evidence either for confirmation or for the revision of existing views." [14]

One of the key pragmatic distinctions between this iterative scientific approach and the engineering approach is its goal: The scientist aims at explanation: universal, reliable, comprehensive and sufficiently precise formulation of knowledge; the engineer aims at timeliness, completeness, with sufficient precision and comprehension. These values affect the knowledge generation, retention and use.

Pitt provides a similar comparison of scientific and engineering knowledge:

> "First, the characterization of scientific knowledge as theory-bound and aiming at explanation appears to be in sharp contrast to the …task-specific knowledge of engineering that aims at the production of an artifact to serve a predetermined purpose.
>
> "The second important difference between the two forms of knowledge [is]… the manner in which engineers solve their problems does have a distinctive aspect. The solution to specific *kinds* of problems ends up cataloged and recorded in the form of reference works which can be employed across engineering areas. For example, measuring material stress has been systematized to a great extent. Depending on the material, how to do it can be found in an appropriate book. This gives rise to the idea that much engineering is "cookbook engineering," but what is forgotten in this caricature is that another part of the necessary knowledge is knowing what book to look for. This a unique form of knowledge that engineers bring to problem solving. [1]

The viewpoints of science and engineering are idealistic and pragmatic respectively [12]. The nature of science explains how the world works and this can be learned though experiments (producing artifacts). Knowledge generation, from the perspective of scientists is approached via creating a hypothesis first, and testing it second. The nature of engineering is for addressing human needs/problems, and generally applies domain-specific heuristics for building a system. What distinguishes scientific knowledge from engineering knowledge is not the creation or use of artifacts/technology, rather it is the values stemming from the scientific and engineering viewpoints and how they are pragmatically applied (purpose and method). This distinction in knowledge generation is both individual and social; it affects the use of the knowledge, and shapes the manner in which it is generated.

APPLYING A PRAGMATIC THEORY OF KNOWLEDGE

The pragmatic theory of knowledge, at least as outlined here identifies purpose (goal) and manner (method) of knowledge application and generation as distinguishable characteristics that can be used to distinguish engineering foundations. Historically the 19th Century 'French' (Science and Math) and 'English' (Apprenticeship) schools of engineering have significantly influenced the training and values of current engineering training [6]. The science and math school emphasizes knowledge and knowledge generation whereas the apprenticeship school emphasizes pragmatic application. The difficulty lies in trying to integrate these schools, when the science and math approach de-emphasizes the pragmatic, and the apprenticeship approach de-emphasizes knowledge generation. The foundations of engineering, as argued in this paper, necessarily include both pragmatic knowledge and pragmatic knowledge generation. Furthermore, the knowledge-generation epistemology implies that engineering foundations are more than just the knowledge of science and mathematics, more than applied math and science, and more than pragmatic apprenticeship of an engineering design method. Engineering, at its foundations is 'both' using science 'and' pragmatic, and more than both: it is about generating and using knowledge for a purpose and with a method that is more than theory, more than descriptive: it is useful.

This 'both and' view that emphasizes both goal and method of engineering can be very useful in trying to help distinguish a particular engineering discipline from its related foundations in math and science (natural or otherwise). Similarly it can be used to help distinguish emerging engineering disciplines from their respective math and sciences (e.g., see [21]).

PRACTICAL IMPLICATIONS

This epistemological work also suggests that there is a significantly engineering philosophy that should be reflected in engineering education. This implies that an engineering approach is more than engineering knowledge – rather, that it is both knowledge and approach. The implications of applying this epistemological lens to the current practice of engineering education could be significant in several areas such as accreditation/program development, defining traits for engineering education, and for exploring affective domain learning.

This epistemological lens would be particularly useful in developing both a consistent definition for, and mechanism for distinguishing the 'scientific' and 'engineering' components of accredited engineering degree programs, such as those accredited by ABET and other national- and international boards [21]. Using this or a similar epistemological lens would allow for more consistent discussion, communication, and training for accreditors and program developers. This would be particularly useful for delineating the scientific roots and contributions of engineering sciences (e.g. Thermal Science), or sciences with significantly shorter histories than most natural sciences (e.g., Computer Science) [22].

Another area where this epistemological lens could be well applied is in helping undergraduate engineers reasonably frame and value what they actually do, Lonergan calls this self-appropriation and argues that if you "[t]*horoughly understand what it is to understand ,. . . not* *only will you understand the broad lines of all there is to be understood but also you will possess a fixed base, an invariant pattern, opening upon all further developments of understanding.*" [14]

Knowing more explicitly what it is to know and to solve problems in engineering will give undergraduate engineers fuller anticipations of the paths to solutions. They may come to appreciate more fully how the value of their work, of an engineering solution, lies in a timely, sufficiently complete, sufficiently precise solution that is in fact delivered. This shifts the emphasis onto understanding sufficiency, involves understanding and applying the social context of their work, and away from single-solution thinking, away from 'analysis paralysis' where the 'best is the enemy of the good enough.' An example of this it is not the one single, best right answer, that comprises good engineering. Rather the best *engineering* answer(s) are judged pragmatically, and routinely involve social context (e.g. a company, a customer). While this emphasis appears in common to engineering curricula (e.g. ABET), this work suggests that this is not a facet of engineering education, or a 'nice to have' aspect, but rather is intrinsically necessary to the foundations of engineering.

A third area where this approach could be useful for engineering educators lies in helping to shape discussions surrounding the affective domain of engineering. Currently, the authors' expectations are that essentially all engineering program-level outcomes, and probably course-level outcomes are routinely voiced in terms of cognitive domain outcomes. This, and related works (e.g., [1,3,6,13]) suggest that the engineering community has significant, if not universally communicated expectations for the affective domain of engineering graduates. While these philosophical perspectives provide a framework for such explorations, they strongly imply that such work in using these epistemological lenses would both inform and help guide exploration of affective domain expectations for engineers and engineering programs. This area remains to be significantly explored.

Conclusion

The pragmatic theory of knowledge, briefly presented, uses the purpose (goal) and manner (method) of knowledge application and generation to distinguish types of knowledge: engineering and scientific. The pragmatic theory of knowledge provides a means by which, particularly in a learning environment, the critical terms of 'science', and 'engineering' can be reliably distinguished.

***Abstract*— "Personal Epistemology" is the analysis of the ways in which an individual perceives what constitutes knowledge, its boundaries, how it is justified, and how it is related to learning. While investigation of metacognitive strategies used by students is now an established research topic within Computer Science and Information Technology education, the study of personal epistemology is relatively undeveloped. This is so despite there being significant epistemological issues associated with learning the subject itself, such as those concerned with the way in which programming exercises change from convergent to divergent problems, or the process by which software project management problems very quickly become ill-defined. In this paper, we describe a preliminary investigation into the personal epistemology of two cohorts of computing students. We review some models of personal epistemological development and describe an empirical study in which we investigated the dimensions of epistemological beliefs of two cohorts of computing students. The results show that there appears to be a wide range of epistemological belief amongst computing students. Finally, we make some observations about the importance of personal epistemology for learning in Computer Science and outline further work in this area.**

Keywords – personal epistemology, epistemological beliefs, learning, ill-structured problems.

I. Introduction

Personal epistemology, that is, an individual's conception of knowledge and their understanding of the process of knowledge acquisition and learning [1], has been an ongoing area of research in educational psychology for over thirty years now. While it has only recently begun to be studied as part of subject-specific pedagogical research, it has nevertheless been applied to a wide and growing range of disciplines. In part, this interest has been generated by evidence that more "sophisticated" epistemic beliefs are correlated with higher-order, metacognitive skills which may have a direct impact on learning. For example, there is evidence that epistemological considerations play an important role in the self-regulation of learning, that more "sophisticated" beliefs are often correlated with higher-order learning outcomes [2], and that epistemological factors play an important role in the solution of ill-structured problems [3].

The subject itself has been termed "the subjective counterpart of philosophical epistemology" [4]. The difference between the two is that personal epistemology investigates how the philosophical concepts affect the individual at a psychological level [5] and recent research has tended to focus on how it relates to learning and its application to pedagogy. As a research field, it may be considered to have originated in the developmental psychology of Piaget [6], while its application to tertiary education began in the mid-1960s with the work of Perry [7]. While subsequent work has reconceptualised personal epistemology in a number of different ways, there are common elements that run through the work of almost all researchers such as the recognition that an individual's understanding may develop over time. Following Perry, this may be seen as taking place in a one-dimensional, linear fashion or it may occur within some kind of multidimensional space characterised by the kinds of different epistemological beliefs suggested by Schommer [8]. Regardless of the details, this development is considered to have important implications for learning and consequently for teaching and assessment practices. Development in an individual's personal epistemology is seen as a progression from an initial phase characterised by a simplistic or naive conception of knowledge in which propositions and theories are seen as dualistic (right or wrong), to more nuanced and sophisticated "evaluative" views which take account of evidence and judgement. It should also be noted that while many researchers use these terms, there are some [9] who question the practice of using psychologically-loaded words such as "naive" and "sophisticated" and instead prefer to describe the ends of the development spectrum as "non-availing" or "availing" depending on whether such beliefs inhibit or promote learning.

Most educators would agree that one of the most important goals of a university education is to encourage the development of learner autonomy so that an individual may deal with the challenges posed by lifelong learning. There has been much recent work on the development of sets of graduate attributes which address this need for post-university, professional competences [10], many of which are based on the use of higher level, metacognitive skills such as analysis, reflection, and critical thinking. However, research has tended to show that educators struggle to promote development of such skills despite acknowledging their importance [11]. The relevance of an individual's beliefs about knowledge for such metacognitive activities may play a part in this and can be seen, for example, when considering self-regulatory skills such as planning, monitoring and evaluation, all of which involve the prioritisation and integration of information from various sources. A key element in this is the ability to engage in a process of justification of one chosen alternative over others. Such justification, however, requires the evaluation of claims about knowledge, the forms it takes, its sources, how it is constructed and how it may be apprehended. These concerns are essentially epistemological in nature and suggest that such issues play a crucial role in determining a person's fundamental orientation towards learning and the strategies that are chosen to engage with a subject.

In order to start to investigate this field in the discipline-specific context of Computer Science education, we feel that it is necessary to look at the epistemological responses found in a range of students. In previous work [12], we made a small-scale, preliminary analysis of the epistemic beliefs of a relatively mature cohort of students based on data gained from Schommer's "Epistemological Beliefs Questionnaire" [13]. In this paper we compare that data with another set from a group of first-year students who display a much greater range of responses. We believe that this gives us some understanding of the scope of epistemological belief that is present in computing students. It would also appear that there is a need for an instrument that is much more finely tuned to the subject itself.

We begin this paper by presenting an overview of some of the relevant background research in the field before describing the developmental model that underlies Schommer's questionnaire which was used to try to gain insight into personal epistemology of our students. We discuss the results of this experiment and finally we conclude by suggesting further research directions that would be relevant to Computer Science Education.

II. BACKGROUND

A. *Epistemology and Computer Science Pedagogy*

The primary motivation for our current work is consideration of the evidence that students' epistemological beliefs do indeed affect the choices they make about the way in which they learn by influencing a variety of cognitive and metacognitive strategies. These include the explicit choice of learning strategies [14], academic performance [15], cognitive processing [16], openness to conceptual change [17], text comprehension [18], moral reasoning [3], and strategy use [14]. Research suggests that the sophistication of an individual's epistemological beliefs has a strong impact on learning. Students who believe that knowledge is certain are more likely to draw absolute conclusions from contingent information [8] while those who believe that an individual's capacity for knowledge is fixed are less likely to persist in formal education [13]. Students who believed that knowledge is quickly acquired are more likely to comprehend information poorly while those who believe that knowledge is simple are more likely to settle for a memorization study strategy rather than using higher-level cognitive processes such as critical analysis, elaboration and reflection [19]. Moreover, students who view ability as innate and thus fixed may be less inclined to develop and use advanced reasoning skills when thinking about ill-structured issues [3]. An appreciation of the importance of these beliefs by teachers may therefore contribute to a greater understanding of the psychology of student learning and so may provide insights into more effective pedagogical strategies in areas for which reflection and critical thinking are required.

One such area would be the solution of divergent or ill-structured problems. This class of problems typically does not have single optimal solutions and there may only be heuristic procedures to find acceptable results among a range of possibilities. Consequently, there is a greater need to justify any option that is chosen. A number of common pedagogical practices, such as group projects, involve these open-ended problems and we would anticipate that this field of study would contribute to our understanding of effective practice in these areas. In addition, careful attention to epistemological issues may contribute to a greater understanding of the transition from convergent to divergent problem-solving that frequently arises in computer science education. Examples include the increase in complexity that occurs as novice programmers undertake more sophisticated tasks and the transition from "programming" to "software engineering". This work also connects well with our earlier efforts to develop a theory for setting up open-ended group project learning environments [20, 21, 22].

Finally, there is an important link between epistemology and perceptions of knowledge within a discipline-specific context and the concept of identity. A basic question about subject identity is what it means to be, say, a computer scientist. Is it simply a matter of studying a particular set of techniques or is there some epistemological approach or methodology that distinguishes the practitioner in that field from one in a neighbouring discipline. For example, is there a process of "learning to think like a computer scientist" which is different from learning to think like an engineer or a mathematician. A related question is how professionals from that discipline induct students into the broad community of practice in which the subject is studied [10]. These issues involve an explicitly epistemological perspective as they deal with what counts as knowledge in the subject domain, how such knowledge is acquired and an ability to reflect on how the process is justified to a wider community. It would be interesting to investigate the degree to which current members of the computer science community share a specific conception of knowledge and a common understanding of "ways of knowing" within the subject, and also how this is passed on to new graduates. This, in turn, may have practical implications for issues associated with identity such as curriculum development, academic and industry retention practices, and lifelong or lifewide learning [23].

B. Models of Personal Epistemology

While investigation into the development of an individual's conception of knowledge was a central part of the work of Piaget from the 1930s onwards, research into this area has increased substantially in recent decades. The first study, which specifically addressed the topic in the context of Higher Education, was that of Perry which proposed a general scheme in which epistemological understanding developed through nine stages, grouped together into three phases. In the initial phase, often categorized as absolutist thinking, an individual sees knowledge in polar terms as either right or wrong. Uncertainty is due to lack of analysis of suitable data and can be eliminated by straightforward procedures such as direct observation, appropriate introspective examination or through appeal to some expert authority. In the next phase, this naïve position shifts into a more relativist stance. There is a significant reaction against the previous dualistic view to the extent that knowledge is now perceived as inherently uncertain and idiosyncratic to the individual, with recognition of the possibility of multiple views, which may depend on context. The main feature of the final phase is an epistemological understanding in which knowledge is constructed by comparing evidence and opinion on different sides of an issue. Knowledge is seen as constructed through a process of reasonable inquiry leading to a well-informed understanding. It also recognizes the contingent nature of personal knowledge, exploring the implications of commitment to individual views. Perry, therefore, presents a model of personal epistemological development which is a linear spectrum ranging from initial "simple" or "naive" views to the more "sophisticated", evaluative stance which he saw as desirable in graduates.

Subsequent work on this type of developmental model has extended the analysis in a number of different directions but, as indicated by Hofer and Pintrich [24], a common element in such work is the retention of a movement from an initial dualistic, objectivist view of knowledge, through to a more subjective, relativistic stance to a final contextual, constructivist perspective of knowledge and its acquisition and justification. As pointed out by Kuhn [20], this evolutionary structure has practical implications for teaching as epistemological factors determine how students view the components of a theory and its relationship to reality. As an example, consider the development of high-level metacognitive skills such as those associated with critical thinking. At an initial, absolutist level, claims about knowledge are seen as facts which are either correct or incorrect. Critical thinking is therefore perceived to be a straightforward matter of comparing such statements to reality in order to determine their truth or falsity. At the more relativistic level, assertions are considered merely to be opinions, none of which is more compelling than any other, and so any may be selected on personal preference. At this stage, critical thinking is largely irrelevant as justification is limited to the statement of subjective views. It is only at the final, evaluative stage that assertions are considered to be judgements that can be appraised by argument and reference to evidence. As a consequence, it is primarily at this stage that critical thinking, seen as a method for promoting coherent, logical argument, will be considered useful.

C. Epistemological Beliefs

This concept of a single, integrated continuum of development was, however, challenged in the work of Schommer (later Schommer-Aikins) in a series of papers [8, 5, 26, 13] which drew on Perry's work but incorporated significant elements from other researchers. These included work by Schoenfeld on the speed of learning [27], beliefs about innate intelligence [28], Kitchener and King's work on reflective judgment [29], and Ryan's work on epistemology and comprehension [15]. While accepting the idea of personal epistemological development, she suggested that it was better conceptualised as a multidimensional belief system, the dimensions of which may be only weakly bound to each other. She retained the idea of a developmental continuum from what she, too, characterised as "naïve" views to more "sophisticated" ones, but applied it to each of the key epistemological beliefs and suggested that development may occur in each at different rates. Epistemological development, in this model, was therefore better described by a trajectory in a multidimensional space rather than by progression along a line.

The main instrument used by Schommer for this analysis was her Epistemological Beliefs Questionnaire. This seeks to establish the respondent's level of commitment to a range of statements which reflect a particular epistemological belief. Examples of these include "People who challenge authority are over-confident", "I try my best to combine information across chapters or even across classes", "The most successful people have discovered how to improve their ability to learn", and "Things are simpler than most professors would have you believe".

The questionnaire itself was based on the hypothesis that there were five dimensions through which epistemological development takes place: structure of knowledge, stability of knowledge, source of knowledge, speed of knowledge acquisition, and the learner's control of knowledge acquisition (see Table 1). The first three of these were influenced by Perry's original model. The speed of learning dimension was based on the work of Schoenfield, and the control of knowledge dimension was influenced by Dweck's work on implicit intelligence.

One difficulty with the study of personal epistemology is that we do not observe these beliefs directly but only infer them from behaviour so these dimensions are, in some sense, hidden. Moreover, several behaviour patterns could result from the same belief. For example, according to Schommer et al [5], if one considers the dimension for "structure of knowledge", the naive epistemological view is that knowledge is essentially simple and that complexity is due to inadequate analysis rather than any inherent conceptual ambiguity in the information or the interrelationships involved. If a person held this view, there would be a tendency to oversimplify complex information which could manifest itself in two ways: they could tend to focus on one aspect of the problem and neglect others, or else they could artificially reduce the complexity of the relationships between the constituents of the problem by a process of inappropriate compartmentalisation. The epistemological views about structure of knowledge therefore give rise to two subsets of observable behaviour. Using the naïve behaviour as a descriptor, these would be termed "Seeks single answers" and "Avoids integration" and the questionnaire was developed to elicit responses that could be tied to these behaviours. Using this type of analysis, Schommer identified twelve different observable behaviours for the five hypothesised dimensions of belief (see Table 1).

Table 1. Schommer's Dimensions of Personal Epistemology

Dimension	Explanation	Development Continuum	Subset Behaviours (labelled by "naïve" view)
Structure of Knowledge	How students think about the structure, relationship and organisation of knowledge in a particular domain.	From "*knowledge as isolated, unambiguous bits of information*" to "*knowledge as highly interrelated and integrated set of concepts*"	• Seeks single answers • Avoids integration
Stability of Knowledge	How students think about the contingency of knowledge and the way theories may change over time.	From "*knowledge as unchanging*" to "*knowledge as contingent and subject to continual revision and change*"	• Avoids ambiguity • Knowledge is certain
Source of Knowledge	Where students think domain knowledge can come from.	From "*handed down by authority*" to "*derived from empirical evidence and reasoning*"	• Don't criticise authority • Depend on authority
Speed of Knowledge Acquisition	How students think about the speed at which they acquire knowledge.	From "*learning as occurring quickly or not at all*" to "*a view of learning as a gradual process*"	• Learning is quick • Learn first time • Concentrated effort is a waste of time
Control of Knowledge Acquisition (Ability to Learn)	How students think about their capacity to control the acquisition of knowledge.	From "*a view that the ability to learn is fixed at birth*" to "*a view that it can be improved over time*"	• Can't learn how to learn • Success is unrelated to hard work • Ability to learn is innate

Given a dataset of responses to the questionnaire which measure the observable behaviours, the hypothesis that these behaviours are correlated with specific epistemological beliefs can be tested using the statistical procedure known as exploratory factor analysis, which looks for latent variables (factors) that underlie and give rise to the measured, observable data.

Schommer's conceptualisation of personal epistemology as a belief system has been extremely influential in the educational psychology literature as a model of epistemological development. It provides a methodology for quantitative analysis of epistemological data and can also accommodate instances in which students exhibit sophisticated epistemological beliefs in one dimension but less complex beliefs in another, something which is more problematic in one dimensional models. There has, however, been criticism of this approach due to reported difficulties associated with replicating the factor structure she described [27]. This leads, among other things, to ambiguity in the number of dimensions, i.e. important beliefs, that characterise an individual's personal epistemology Nevertheless, there are a relatively large number of studies that use the method and we have attempted to follow her methodology in our study.

III. Method

A. The Participants

Our study involved datasets from two groups of students. The first set of data was collected from a group of twenty-five respondents involved in a globally distributed group project [21]. The sixteen respondents from Uppsala University, Sweden, were enrolled in the IT in Society course unit while the nine respondents from Rose-Hulman Institute of Technology, USA, were following the Computing in a Global Society course unit. Both course units were taught in English. The students participating in the course in 2012 were aged between 20 and 38. The majority of students were pursuing a major in computer science or information technology, but some students were studying other technical majors. Most students had studied for at least three years at the university.

The second data-set was obtained from eighty-five respondents out of a class of one hundred and ten first year undergraduates in the School of Computing Science and Digital Media at the Robert Gordon University, U.K. These students were aged between 18 and 40 with the majority of them having entered university from secondary school. They were registered on a variety of computing degrees ranging from Computer Science to Business Information Systems.

The data for dataset 1 was collected at the beginning of the academic year at the start of the course when both Swedish and American students were in Uppsala. All students who were present completed the questionnaires during academic contact time. Dataset 2 was collected in the first week of the undergraduate term just after the Induction period. All students who were present completed the questionnaires during academic contact time.

B. The Instrument

The main investigative tool for the study was Schommer's Epistemological Beliefs Questionnaire, which seeks to investigate a range of epistemological commitments by asking respondents to indicate levels of agreement to a series of sixty-three statements on a five-point Likert scale. As described in section 2, these statements are grouped into twelve sections which describe different attitudes to learning and act as observed or measured variables for further statistical analysis (see tables 2 and 3).

Exploratory factor analysis was performed on this group of twelve averages using MINITAB. The aim of this technique is to reduce the dimensionality of the space of variables by looking for latent factors that underlie the structure of those observed variables. Eigenvalues of the correlation matrix for the measured variables were extracted using principal component analysis, in order to determine the number of factors, and a table of factor loadings for each set was produced. A loading for a particular variable with regard to a factor quantifies the variation of the measured variable that is explained by that factor and so a high loading indicates a strong correlation between the measured variable and latent factor while a low value indicates that the factor contributes little to the measured variable. Interpretation of the factors themselves proceeds by rotating the axes in the factor space so that the loadings show high values for a few variables and low values for the remaining ones. Following Schommer's original paper, orthogonal varimax rotation was used for this.

The communality for each measured variables was also calculated. This is a measure of the reliability of the number of factors used and is the variation of the observed variable that is accounted for by all the latent factors under consideration. So, for example, a communality of 0.75 for a particular measured variable indicates that 75% of the variation in that variable is accounted for by those latent factors.

IV. Discussion of Results

A. Number of Factors

Principal Component Analysis was used to extract the eigenvalues of the correlation matrix for each of the two datasets. In both cases, analysis of the eigenvalues suggested five latent factors underlying the measured variables. Exploratory factor analysis with five factors was carried out on each dataset, using MINITAB, and a table of loadings for each set was produced. These were rotated using an orthogonal varimax rotation and the results are displayed as table 2 and table 3.

The ratio of sample size to number of measured variables for dataset 1 is relatively small, but the communalities were reasonably high (for real data). In her original paper, Schommer used a loading threshold of greater than 0.5 to determine contribution to measured variables but, for this dataset, we used a higher value of 0.6. The size to number of variables ratio for the second dataset was better and so, here, we used Schommer's original loading threshold to identify factors. Schommer reported that four factors emerging from her statistical analysis. In both of our datasets, principal component analysis suggested five factors. Comparative analysis with four factors shows that there was no significant reason to reduce this to four in either case, although there did not appear to be a consistent interpretation of what these factors represented.

Table 2. Factor Loadings and Communalities for Dataset 1

Variable	F 1	F 2	F 3	F 4	F 5	Com'ity
1. Seeks single answers	**0.73**	*-0.11*	*-0.24*	*-0.21*	*0.29*	*0.73*
2. Avoids integration	*-0.04*	**-0.85**	*0.01*	*-0.11*	*0.03*	*0.73*
3. Avoids ambiguity	**0.90**	*-0.19*	*-0.04*	*-0.06*	*0.01*	*0.83*
4. Thinks knowledge is certain	*0.15*	*-0.06*	*0.13*	*-0.06*	**0.90**	*0.87*
5. Depends on authority	*0.14*	**-0.74**	*-0.08*	*0.28*	*-0.07*	*0.65*
6. Don't criticise authority	*0.46*	*0.26*	*0.56*	*0.38*	*0.12*	*0.76*
7. Ability to learn is innate	*0.19*	**-0.78**	*0.29*	*-0.14*	*0.09*	*0.75*
8. Cannot learn how to learn	*-0.34*	*-0.14*	*0.09*	**0.76**	*0.14*	*0.73*
9. Success is unrelated to hard work	*0.01*	*0.09*	*-0.01*	**0.85**	*-0.17*	*0.76*
10. Learn the first time	*-0.22*	*-0.10*	**0.77**	*0.06*	*0.20*	*0.70*
11. Learn quickly or not at all	*0.54*	*-0.04*	*0.53*	*-0.43*	*0.11*	*0.76*
12. Conc. effort is a waste of time	*-0.11*	*-0.18*	**0.70**	*-0.02*	*-0.49*	*0.71*

B. Identification and Interpretation of Factors for Dataset 1

An examination of the loadings for dataset 1 identifies a number of similarities and differences with the results reported by Schommer and others. The first factor (F1), i.e. the one associated with the largest eigenvalue, has a large contribution to the variables "*Seeking single answers*" and "*Avoiding ambiguity*". These behaviours seem intuitively to be related (even though Schommer categorised the first as referring to the structure of knowledge and assigns the latter to views on the stability of knowledge) and it seems reasonable to us that both behaviour descriptors relate to an avoidance of multiple representations of knowledge. We would therefore categorise both behaviours as indicating some kind of belief related to the Structure of knowledge dimension. The fifth factor (F5) is associated with the single variable "*Thinks knowledge is certain*" which Schommer categorises as pertaining to the Stability of knowledge. There also appears to be one factor (F3) which underlies the belief that if one is going to learn something then its should be possible to "*Learn it the first time*" and that "*Concentrated effort is a waste of time*". These, again, seem intuitively to be linked and Schommer categorises both of these variables as referring to the Speed of learning. A fourth factor (F4) is strongly associated with the view that one "*Cannot learn how to learn*" and that "*Success is unrelated to hard work*". Schommer categorised both as concerned with innate ability to learn, but the loading for the similar measured variable, "*Ability to learn is innate*", is small on this factor. A final factor (F2) is negatively correlated with the measured variables "*Avoids integration*", "*Depends on authority*" and "*Ability to learn is innate*", i.e. the group would tend to integrate knowledge from different sources, not rely on authority and trust their own ability, which we see as being associated with the Control of knowledge acquisition dimension. We thus have two factors capturing slightly different aspects of this dimension.

Two variables, one tracking the view that you should not "*Criticise Authority*" and one that "*Learning is quick or not at all*" do not have an above-threshold correlation with any of the five factors. This is the case even if the number of factors was increased to six. The main substantive change in this case is that "*Depends on authority*" would become a single-variable factor. Conversely, if we restrict to four factors, in line with Schommer's original paper, the high loading for "*Thinks knowledge is certain*" would vanish to be replaced with a moderate loading for this variable on F1 (0.56). However, the communality for this variable then decreases to 0.32 suggesting that this action would not be sensible.

C. *Identification and Interpretation of Factors for Dataset 2*

While principal component analysis of the second dataset also indicated that there were five factors, the pattern of (rotated) factor loadings (table 3) is quite different from the previous data, and more difficult to interpret. There is also a considerable difference between the distributions of loadings for this dataset and that reported by Schommer.

The first factor (F1) appears to underlie the variables "*Cannot learn how to learn*", "*Success is unrelated to hard work*", and that it should be possible to "*Learn [something] the first time*", which are all categorised by Schommer as referring to a naive belief about the speed of knowledge acquisition. There is also a reasonably high loading for the behaviour "*Concentrated effort is a waste of time*" which Schommer associates with the view that learning is innate, but also, perhaps, suggests a negative belief about learning as some kind time-related process. The factor (F2) has high negative loadings on "*Ability to learn is innate*" and one "*Learn(s) quickly or not at all*" which also mixes behaviour associated with a view that learning ability as innate (in the first case) and about speed of knowledge acquisition (in the second), although in a different way to the first (F1). This may suggest that the data is trying to capture two aspects of the beliefs underlying these behaviours, although not the ones reported by Schommer.

There is one factor (F3) that contributes to the variables "*Avoids ambiguity*" and "*Depends on authority*". Schommer proposed that the former behaviour was due to a belief about the stability of knowledge so this pairing may indicate that the first year students saw authority as a stabilising element for knowledge. Another factor (F4) has high loadings for the behaviours "*Avoids integration*" and "*Thinks knowledge is certain*" which seems to mix structure and stability of knowledge. The fifth factor (F5) contributes highly to behaviours "*Seeks single answers*" and "*Don't criticise authority*" which seems to mix structure and source of knowledge factors. Although there was a some degree of mixing of Schommer's factors with the first dataset, it seems much more pronounced with the first year cohort and this could perhaps be due to lower levels of academic maturity.

The interpretation of the data for the second cohort is, in general, more problematic than for dataset 1, although the sample set is bigger. It is interesting to note however that there appears to be a broad division between those factors (1 to 3) that refer to views about knowledge (which Schommer identified as coming from the developmental work of Perry et al) and those concerning knowledge acquisition (factors 4 and 5), i.e. which pertain to learning. This is found in both data sets and may reflect a basic characteristic of the results.

Table 3. Factor Loadings and Communalities for Dataset 2

Variable	F 1	F 2	F 3	F 4	F 5	Com'ity
1. Seeks single answers	*0.08*	*0.04*	*0.24*	*-0.13*	**-0.73**	*0.61*
2. Avoids integration	*0.02*	*0.07*	*0.29*	**-0.77**	*-0.23*	*0.72*
3. Avoids ambiguity	*0.08*	*-0.18*	**0.59**	*-0.33*	*-0.18*	*0.53*
4. Thinks knowledge is certain	*-0.15*	*-0.11*	*-0.31*	**-0.78**	*0.12*	*0.76*
5. Depends on authority	*-0.18*	*-0.03*	**0.78**	*0.17*	*0.04*	*0.67*
6. Don't criticise authority	*-0.18*	*-0.48*	*-0.20*	*0.05*	**-0.58**	*0.64*
7. Ability to learn is innate	*0.21*	**-0.78**	*0.01*	*-0.05*	*0.19*	*0.70*
8. Cannot learn how to learn	**0.81**	*0.09*	*0.10*	*0.09*	*-0.03*	*0.69*
9. Success is unrelated to hard work	**0.67**	*-0.05*	*-0.33*	*-0.06*	*0.15*	*0.59*
10. Learn the first time	**0.69**	*-0.23*	*-0.16*	*0.10*	*-0.24*	*0.62*
11. Learn quickly or not at all	*-0.02*	**-0.73**	*0.18*	*-0.02*	*-0.20*	*0.60*
12. Conc. effort is a waste of time	**0.63**	*-0.11*	*0.24*	*-0.05*	*0.46*	*0.68*

V. Conclusion and Further Work

Our aim in this paper has been to start to address some of the issues around personal epistemology within the discipline-specific context of Computer Science Education and the study should be seen as an initial attempt towards this goal. The main technique used is factor analysis and while this form of investigation can be quite sophisticated, we would want to emphasise the exploratory nature of the process. Our analysis does not reproduce the factor loadings described in Schommer's paper, but her work examined a much more general set of students than ours and our main interest here is not to replicate Schommer's findings but to use her work to investigate a multidimensional developmental model in a discipline-specific context. Schommer obtained four of her five hypothesised dimensions through exploratory factor analysis whereas we obtain five factors from this procedure.

We would stress some of the limitations of this study. Factor analysis requires a reasonable sample-size to variable-number ratio and the first cohort was at the very lowest limit of this. Internal consistency measures for the questions in the questionnaire were not high. Both of the groups studied were quite socially diverse and qualitative further analysis suggests that the questionnaire appears to be quite sensitive to linguistic and cultural factors. This may have contributed to rather poor internal consistency measures for the variables.

Finally, the discipline-specific nature of the group was not adequately addressed by the questionnaire. As, ultimately, one of the things we wish to investigate is whether an individual's approach to knowledge and learning contributes to a sense of subject identity and belonging to a community of practice, we believe that it is likely that an instrument with a much greater fit to the disciplinary context is needed for further work in this area.

Nevertheless, despite these issues, we anticipate that further enquiry into personal epistemology will offer significant insights into a range of problems which affect the performance of students on Computing degrees. Among the most important of these is greater understanding of the different methodologies students take when asked to solve well-structured and ill-structured problems [31, 32]. These are common across the Computing curriculum wherever there is a divergent, open-ended aspect to the solution process and some research appears to [33] indicate that different epistemological approaches are taken for each sort of problem. Further work to investigate this area is underway.

Liberating Engineering Education: Engineering Education and Pragmatism

Mani Mina
Department of Electrical and Computer Engineering
Iowa State University
Ames Iowa 50011
mmina@iastate.edu

Abstract— **The experts in pedagogical and curriculum development such as John Heywood and others have advocated that the liberating element of liberal studies are vocational elements of liberal education [1-2]. Since the 1960s, this statement constituted some of the leading work in curriculum development, managing mastery, and retraining programs of continued education in Europe and the US. It should be noted that some experts are viewing engineering education with a liberal art perspective [3-6] as well. This paper would like to argue a new twist in this argument.**

This paper will examine the following: The liberating essence of engineering education is the practical/pragmatic elements of engineering. The liberation is achieved by injecting pragmatism into engineering education. Changing our pedagogical approaches can do this liberation. We should help our students to use their knowledge gained from mathematics, sciences, and other fields to focus on making, building, examining, designing, and inventing things. Liberations for engineering come out of making change by designing, building, and inventing. This is the main missing piece of most engineering curricula.

This paper reviews research and activities in pedagogical development of engineering curriculum throughout the last century and especially after World War II. The paper reviews distinct directions and curriculum trends that dominate engineering education and will raise the main question: "What makes engineering special and different from sciences and mathematics?" The paper provides the support for this argument by examining the main trends of engineer development to prove that the practical/pragmatic aspects of the engineering fields are the true essence that uniquely distinguishes the engineering education. Consequently, the pragmatic essence of engineering (which needs to be reflected in the engineering education) has been (and must be) the unique identifier and the liberating element of the engineering curricula.

The idea of liberation is meant as a guiding concept to help educators reflect on pragmatic essence of engineering when balancing between mathematical rigor, scientific basics, engineering systems level thinking, and identifying a common knowledge base and methodologies.

Keywords-component; philosophy of engineering; pragmatism and engineering; Dewey and engineering; engineering education; practical engineering; new curriculums in engineering; liberating;essense; essense of engineering

I. INTRODUCTION

As engineering educators, our goals are well defined: To inspire, train, and educate the future engineers, enabling them to successfully embark on a lifelong journey of engagement with problems and doing engineering! We would like our students to have the right scientific, mathematical, cultural, and worldwide perspectives as well as engineering know-hows to be able to face the challenges of their generation and solve problems that our generation has not been able to solve. They will also have to face new problems. Some of these problems will be unknown problems with dimensions, perspectives, and spectra of difficulties that are not predictable from our vantage point.

Our main set of questions has to include, "What should we teach?", "Should we teach everything that we know?". It is very tempting to pack our curriculum with as many important (or what we think is important) items, basics, formulations, mathematical tools and scientific theories to make sure that they know what we do, or they know what we think is important for them to know. However, the issue of packed curricula has been one of the worries of great educators [7-11].

In this paper we would like to address such questions from a slightly different perspective. What makes engineering education unique and valuable has to be the pragmatic aspects of the education. The following example can provide a simple perspective of what is meant by the pragmatic nature of the engineering education. Students who learn how an inductor works will learn a few equations. Then by working/playing with actual inductors and measuring the terminal characteristics of inductors and using them as circuit elements, students learn much more than the set of equations that describe the element. In this process students make mistakes, learn from them, and try different things. They find out how at times things do not work exactly according to the conceptual/abstract part that is depicted by the equations (or they find out they have misunderstood the conceptual part and need to fix their understanding). During the interactions, examinations, and reflections students will not only have a working knowledge of the inductor and better understanding of the set of equations that are necessary to describe the element, they will also know more about themselves and their conceptual relationship with their respective field of studies. This is a bridge that connects the conceptual (mathematical and theoretical) parts of the learning to the personal experience and brings the general knowledge to the contextual basis for the students. This is a necessary and integrated interaction between theory and practice that is the essence and the belief structure of engineering.

Engineers should be trained as creators, designers, inventors, and practical people who can go from "thoughts to things" [12]. It is the intention of this paper to argue that what makes engineers free to create the future inventions, tools, devices, ways to do things, and get things done is the essence of practicality and the pragmatic approach that has defined engineering throughout the history. The "essence" of engineering can be defined as the conscience of engineering, the core and the spirit of engineering.

In fact we need to achieve a delicate balance between a) knowing the abstract concepts that physical sciences and mathematical rigor offer, b) engineering know-hows that have been developed over time, which includes engineering process, design, manufacturing, and all valuable knowledge, that helps engineers make things and create useful products and c) open-mindedness for creating new things, designs, products and solutions that are the practical part of engineers' lives. Finding the delicate and practical path (which is not a unique one) for students of different interests is going to be the challenge of all engineering educators and curricula developments.

II. MOTIVATION AND GOAL

The meaning and the essence (the core and the conscience) of engineering is not an easy task to be reviewed nor discussed in any single research paper. This is a humble attempt to shed light on few important guiding points that can help our decision-making throughout the development path. The author is naturally more focused on the curricular development and attempts in North American universities. It should be noted that engineering education has produced great results, great inventors, designers, thinkers, and problem solvers; the value of this education has historically been proven [13-18]. Consequently, the goal of this paper is not to invalidate the wonders and achievements of the traditional engineering education, but to see if we can ask better questions and focus on guiding essence that will help us develop future curricular approaches in more practical and effective ways.

We need to continue educating the next generation of systems level thinkers, problem solvers, and pragmatic achievers to lead the future technological developers and innovators. We have been very successful, but things are changing. There are numerous studies that are looking at ways we need to change our focus and approaches. There are various points of views: a) traditional engineering approaches (which have always been very valuable), b) various non-traditional approaches that bring new attempts to modify the traditional ways with new perspectives, and c) modern and newly innovative ways of revolutionize engineering curricula for the next century [3-6,13-24]. The question that remains is "what is the main item that makes engineering education different from all others?" In order to have a better idea we need to review where we are and how we got to this point in engineering education.

III. A BRIEF HISTORICAL PESPECTIVE ON ENGINEERING EDUCATION IN 19TH AND 20TH CENTURIES

Grayson identifies the following stages in the history of engineering education in United States and Canada [19]

- 1862 and before: Genesis
- 1862-1893: Period of growth
- 1893-1914: Period of development
- 1914-1940: Period of evaluations
- 1941-1970: Scientific period
- 1970-1990: Diversification

For the purpose of this paper we are going to identify the period of 1990-present as the turbulent time called Modern Days. Due to some technological development and advancement these years forced major revisions on engineering curricula based on multidisciplinary nature of the modern sciences and engineering needs. It is important to realize that especially during the last decade we are witnessing great changes in the global economy, global competitiveness, global interactions as well as in the society expectations and assumptions of what engineering is and what engineers can do [3,7,8].

We have already seen many changes demanded by our current capabilities and needs that require big changes in our approach to engineering education. The logical way to develop the possible paths is to re-examine the philosophical basis of engineering that will lead to effective development of engineering education [3-9,11,17].

Engineering education has gone through many great changes due to the demands of the time's political, social, and global constraints. While engineering as a creative productive field has been with us since the dawn of civilization [17-19,23], the systematic approach for educating engineering professionals did not necessarily start as early. Perhaps "the Corps du Genie" in France (initiated in about 1679 and solidified as operation in an institution in 1749) [19] is a good example of institutional engineering education attempts in western civilization. Most of the engineering training was conducted in master/apprentice interactions. To date, we do believe that working with an expert (a master) is essential for practical engineers and this model is used in our professional engineering certification. However, expanding this model to university level classes and education has been proven not trivial [24].

In North America, from the Genesis state all the way to the end of the 20th century the need for engineering that resulted in expansion of the need for engineering education were related to conflicts, industrial growth, and economical as well as political competitiveness [19].

Most of the developments all the way to late 1960's were more or less due to the demand of having skilled engineers who can do things. This was a pragmatic approach in which engineers where operators who would design, modify, build, operate, and make things happen. Many inventions, implementations, and great technological advances were attributed to such attitudes that engineers had. During such times, engineers, physicists, other scientists, and mathematicians would work together, synergize their actions to make new technologies, and create new things.

After World War II few things were clearly needed. There was a need for designing, implementing, modifying, and operating complex systems [25]. So, science and engineering educators started to work synergistically to fulfill the need.

Engineering education, due to the pragmatic aspects of the approach, were very successful in these years and one can see a notable involvement in project management, field operation, and design of the space projects by engineers and engineering graduates. In a sense, those are the golden years of engineering. These golden years of engineering (focusing on major and large scale projects) also overlapped the Cold War era, due to the need of creative and practical professionals.

World War II was a transformational time for engineering education. The development of communications and weapon systems were mostly void of engineers as project leaders. The main achievements in radar and communication and the advanced weapon systems that eventually lead to the atomic power were lead by physicists with the help of engineers. Almost all of the key leaders in weapon development, communications, and other related areas were physicists and scientists.

Upon reflection many engineering schools starting with MIT and other national leaders identified what the engineering curricula lacked. Consequently, there was an infusion of more science and mathematics in engineering education. Consequently, during the 1950's and 60's engineering faculty were instrumental in bringing mathematics and a more physical science base to engineering curricula.

Perhaps the great increase in demand for more integration of engineering, mathematics and physical sciences was triggered by Sputnik and the race for space exploration, which was followed with the very competitive phenomena of the Cold War.

Engineering and undergraduate education changed significantly after WWII and the Cold War due in large measure to federal funding to support research. With the increased emphasis on research, most college faculty were hired who could contribute to this research focus and the number of faculty with significant industry experience declined. Curriculums began to change to strengthen more theoretical basis; naturally the practical aspects did not get as much time as they used to [19].

One particularly significant change was the emphasis on engineering science. The American Society for Engineering Education had released the findings of a study referred to as the Grinter Report which provided a framework for the advancement of engineering and engineering science in 1955 which followed with other reports in the 1960's [26]. The report also suggested that the country needed two types of engineering programs: one that was a continuation of the practice oriented programs of the past with upgrades in math, science and liberal arts; the second focused on engineering science to prepare graduates for careers in research labs and academia [8-9].

The success of the space project was immense. The space project allowed huge amounts of money to be devoted to schools and university programs. Engineering programs had a good share of them and what the 1950's, 60's, and 70's showed was the practicality and capability of engineers. The Mercury and Apollo programs had engineer managers (the original Mercury astronauts all had engineering education as well as some military training and flight experience.)

In the 1960's and 70's, due to success of the space program and the large projects in communication, the power industry, manufacturing, and defense many universities tried to create environments that would attract large-scale projects that would, in turn, attract federal level funding. It should be noted that many of the grand projects that were given national funding, such as the space program, were successful synergies that would bring mathematical, physical, abstract and practical elements of sciences and engineering together. These programs overall did have a practical focus and inspiration for larger systems and interaction. Consequently, these programs drew and enabled many leaders and practitioners in engineering [19].

The 1970's and 80's was the era that large government money such as National Science Foundation (NSF) and others were granted and universities demanded a different approach from engineering professors. By the middle of the 70's some engineering departments become leading researchers in practical as well as mathematical and scientific endeavors. During this decade there was a shift from practical experimental work in engineering schools to more mathematical and conceptual work. This effort was aiming at attracting faculty and individuals who can bring more and larger research grants to the departments and schools.

In the 1990's the general trend for colleges of engineering continued to be toward producing graduates with increased math, science and analytical skills. Curricula continued to diverge away from practical skills to theoretical knowledge. The 1990's and 2000's have been years of interesting changes [1-5]. The world became more technologically competitive, and the global economy is more widespread throughout various nations. There were many opportunities for global level work in innovation, invention, and independent design agents. During all of this, one needs to wonder what should we do with the engineering curricula to encompass more of the needed thematic perspectives together with the right detail and rigor to enable our students to roam, create, compete, and invent in the new decades and beyond?

With all this change and interaction in the field, engineering schools are challenging some of the traditional basics. Do we need chemistry or biology? How much physics and in what form do we need for engineering? How much calculus and in what form and approach do engineers of the future need? These are questions that seem to be trivial in a more traditional time, but in the ever expanding, constantly changing, and always challenging world of the mega-disciplinary, where nontraditional areas are created and demand interactions, even the most basic traditions will have to be questioned.

IV. Engineering Education: What does it mean?

As times change and the various demands that are pulling engineering education away from the traditional trends are increasing, every educator is questioning what is essential and what is needed. Engineering remains to be one of the most sought STEM education fields [1-4,27-30]. Many corporations and small and large businesses are indicating the need for more engineering and technically savvy people; this need is increasing and the trend will continue in the next few decades.

On the other hand, engineering is still expanding. There are new areas in bioengineering, reengineering, renewable resource engineering, cyber-security, robust embedded programming and many other fields, which require new courses as well as new mixtures of traditional engineering classes. Currently, we are living in an expansion and mixing of engineering, sciences, social sciences, medical sciences, political sciences, and many other fields. Consequently, many schools are trying to reduce the required classes for engineers and provide more flexible educational pathways in engineering education. Students will have options to go deep in a specialized field, as well as become versatile in multidisciplinary area mixing engineering and non-engineering disciplines.

V. Engineering Education: What makes it different that other areas?

The main issue to focus on is what constitutes engineering, and what is in the core of this education that makes it different from other fields. Many fields claim similar approaches, in a liberated manner, but what makes engineering unique? In addition we should be careful to make sure that the engineering students would not get a confusing message about what engineering is.

What makes engineering education different is a balanced mixture of sciences, mathematics, technical and technological basics, engineering processing, systems level approach to learning and problem solving, design, ethics, and professionalism. Historically, what makes engineering different is the pragmatic approach to problem solving, design, and invention. Engineers are tooled with science and analytical methods to systematically understand problems, and providing working solutions based on functional requirements and constraints that defined and specify the given problem [31-32]. This is, and has to be, the essence engineering education, but at times students do not see this or any practical/pragmatic aspect of engineering in their required engineering classes. Engineering students would like to see ways to achieve what they think engineering is all about: making things, doing things, and inventing [30].

Engineering students are willing to go through the tough classes, demanding schedule, and long extended study of mathematics and physics, if they see what it all means in context. We cannot take the mathematical analysis and scientific focus out of our curricula; we need to put it in the context that is palatable to engineering training. The context that engineers are mostly interested in (has been and will be) is solving practical problems, inventing new things, designing things that will help others and possibly change the world. This is what makes them excited.

Consequently, the liberating part of the engineering education, that seems to be not clear in most of our current curricula (but the intention clearly is there), is what makes our students different from all other problems solvers and critical thinkers. It is the pragmatic part of the education and makes the difference. It is the practical essence that enables the student to modify, improve, create, invent, and design things that makes a difference in people's lives.

It is interesting to note that John Dewey, the American pragmatic philosopher, also reflects what we find interesting in the engineering pragmatism. There are numerous findings that recognize the practical importance of his work for pragmatic engineering education [10,11, 24,33-36].

The way to achieve this in our curricula is to have numerous venues in our programs to enable students in different laboratories and studio settings to design, engage in hands-on activities, play, tinker, build things, and learn the art of engineering. Our curricula need to have more room for practical experiences that allows student to design, implement, fail, and learn to overcome the failures. Tinkering, making mistakes, and learning from all the failures are the most important parts of inventions, design, and learning. Students need to have project that would get them from the thoughts to a finish projects. They need to build things.

There is openness in liberal arts education that is designed to expand the students' minds. That is why more than a few scholars have suggested the progression toward a more liberal education for engineering students [3-9]. If in the liberal education, it is the vocational parts that liberate the student to open their minds, learn, examine, expand their knowledge base and be creative, it is due to the fact that the vocational part enables the student to make a living, to make something tangible [1-2]. For engineering education, it is the pragmatic aspect of the education that will be liberating. Students will find the reason to do all the studying, the seemingly endless challenges of the classes and projects.

VI. ENGINEERING: WHAT WE CAN LEARN FROM THE GREAT PHYSICIST PAUL DIRAC

The great physicist/mathematician Paul Dirac has been one of the most influential thinkers of the 20th century. His contribution to quantum mechanics and to our modern view of the world will last for centuries [20-22]. His name will remain one of the most cited in all sciences, mathematics, and engineering fields. It is interesting to know that Paul Dirac started as an engineering student and left the field to study mathematics and physics. However, his colleagues always mentioned (he also talked about it in his invited talks) that he wished he had stayed in engineering [20]. He thought he could "DO" much more as an engineer. Dirac truly valued all aspects of doing, making, designing, and creating new things that engineers do. He thought that such activities were wonderful capabilities that should not be taken for granted.

His statement reflects his desire to "make something" and to change the world. He felt a liberating element in that essence of engineering. For him engineering offered the noble capability of doing, making, and being transformational for the society. This should be one of the philosophical themes of all of engineering educators and needs to be reflected in our curricular development. For him that was the difference between engineering and science education.

As engineering educators, most of us believe that our intentions include having a practical approach to problem solving and design that uses science and mathematics as the basis. We all know of many classes and programs that are doing very effective jobs in that direction. However, we should also self reflect and always think about the bigger picture.

The main question is: Is the core philosophical basis of our curricular approach truly pragmatic and design based? Or, are we focusing mostly on models, physical formulations, and many important facts? Things we believe all engineering needs to do, but at a level that the pragmatic approach of engineering (that would hopefully result in invention and making things) is becoming a secondary issue [17-18].

Curricular design has to be focused on major outcomes. Thinking about and engaging in design, invention, making new things, and seeking to understand the essence of engineering should be the most important goal. The truth about many programs is that while these are some of our valued objectives, they are not reflected in their major outcomes [6-9].

VII. FINAL REMARKS

This paper reviewed the general trends in engineering education and how it changed as it faced different challenges in the 20th century. The issues of the modern time - changes on global economy and knowledge connection and interconnections - were also addressed. The main goal is to find ways to achieve more effective engineering curricula approaches that will enable our students to face the challenges of the new decades. This paper argues that main point of the development that would benefit students and enable them to be better problem solvers in their future endeavors is creating numerous venues in the engineering programs for design, studios, hands-on activities, and more effective pragmatic classes and activities in the engineering curricula. This seems to be the true essence of engineering that will inspire and enable students to enjoy and benefit from engineering. The pragmatic essence of engineering education needs to be the unifying backbone of all engineering education.

The author would like to thank Professor John Heywood for his help, suggestions, and encouragement with this paper. His distinguished bodies of work in the area of education, curricular development, and philosophy of engineering have always been inspiring to the author. In addition, the author would like to thank Mr. John Pritchard and Ms. Sarah Carney for their great help, suggestions, discussion, and encouragements.

This work was partially supported by the National Science Foundation under awards: DUE 0837314 and DUE-0920164. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

Finding and Facing the Frontiers at FIE Conferences

James R. Rowland
University of Kansas
jrowland@ku.edu

Abstract—**Each year since the founding in 1971, Frontiers in Education Conference participants have sought the newest innovations and concepts in engineering education, i.e., the true frontiers at the cutting-edge of the profession. While those frontiers have obviously changed over the past 42 years, the primary objective of identifying and addressing them has remained at the forefront. This WIP paper describes what was perceived as the main frontiers in each of four periods corresponding to the four decades since the first conference by examining papers from two sample conferences in each decade. In addition to a careful analysis of selected FIE Proceedings, results of a brief survey of long-time FIE leaders and more recent participants are presented as further evidence on identifying the recognized frontiers for each period. Changes during the intervening years of the conference included more formal presentations, required reviews before accepting papers, and references to clearly show the relevance of each paper within the body of knowledge. Currently, papers are categorized as innovative practice, research-to-practice, or research; an emphasis on STEM research nationally has created engineering education departments within universities. Faculty and staff from these departments regularly present their research results at FIE Conferences. The overall goal for conference organizers and program chairs is to make certain not only that accepted papers point to existing frontiers as the major focus of the FIE Conference each year but also include invited speakers, sessions, panels, and keynote addresses that focus on other emerging frontiers.**

Keywords- true frontiers in education, engineering education, cutting-edge educational research, FIE Conference changes

I. INTRODUCTION

The ultimate success of FIE Conferences can be measured by how well conference participants identify and address the true frontiers in engineering education. Currently, FIE Conferences have matured to the point that they rejuvenate themselves annually due to the enthusiasm of first-year, five-year, and ten-year participants who seek to learn about frontiers in engineering education and present their own research in the area. NSF funding has spurred this interest over the years with workshops and conferences such as the "Mapping the Field in Engineering Education Research" conference conducted this spring by Finelli [1]. Both FIE and ASEE annual conferences continue to benefit as arenas to present research findings.

This WIP paper describes the focus of FIE Conferences over the past 42 years by showing an analysis of papers from two sample conferences in each decade [2]. Papers are grouped into categories, e.g., educational technology and self-instruction, that suggest conference participants may have regarded, for the most part, these topics as frontiers at those points in time. Continuing work is underway to identify other true frontiers in retrospection, i.e., those with few papers but ones which have become forerunners of true frontiers emerging later in time. Before presenting an analysis of papers from these four decades, results of a brief survey of over 50 FIE participants shows what they regard as true frontiers, mostly at the present time.

II. BRIEF SURVEY RESULTS

A brief survey asking only two questions was sent to over 50 FIE participants; many had limited experience with FIE and some were long-time FIE leaders, including past and present members of the FIE Conference Steering Committee. Not all FIE leaders were contacted (my apology to them) but representative responses were received. Questions were:

1. What do you regard as the true frontiers in engineering education and how have these changed since you first attended an FIE Conference?
2. How closely and to what depth are we addressing these true frontiers at our annual FIE Conferences?

Typical responses to the first question were:

- On-line learning, international issues, diversity issues (especially in student groups), and resource constraints (such as energy).
- Engineering education research and how it affects the education of large numbers of students, i.e., how best to influence learning.
- On-line and asynchronous learning that accomplishes the challenge of enhancing personalized learning.
- Focus on the K-12 scene.
- Effective teaching for large numbers of students who partially direct their own learning.
- Challenges are scalability, accessibility, credentialing, and cost control in the internet age.
- Connect research to practice in a way that positively affects the success of large-scale educational reform.
- On-demand learning technologies and methods for utilizing them effectively for distance and local learners.
- The generational shift seen in student motivation, affecting linear thinking by multi-play gaming,

hyperlinked movement through information presentation, and attention-span shifts in media-rich environments.

- Blended learning involving web, text, lecture, and lab in the areas of technology and delivery. Building on the body of knowledge in engineering education with the goal of a stronger impact on the discipline.
- Undergraduate and graduate degrees that are totally on-line, including labs associated with these degrees.
- Determining the essence of engineering that must not be sacrificed and reaffirming what our students need to learn (curriculum), developing techniques that adapt our activities to how students learn and obtain wide-spread faculty buy-in, continue to utilize technology for learning, promote women and minority recruitment and retention (stuck at 20%), promote globalization as part of professional practice, and use courses that are not "open" but have the potential of offering effective learning experiences to large numbers of students.

Responses to Question 2 on how well FIE Conferences are addressing the true frontiers varied between "There are a lot of disconnected efforts and little synthesis" to "We are doing a reasonable job but could do better". My own response is that early conferences did an adequate job and have improved considerably to very good in recent years, perhaps overly optimistic among some FIEers.

III. AN ANALYSIS OF SURVEY RESULTS

According to the survey results, the primary current frontiers in engineering education include:

- Learning with an emphasis toward on-line learning and learning strategies for large numbers of students.
- New technologies and methods that promote more effective learning, including blended learning between web, text, lecture, and labs in the areas of technology and delivery.
- Promoting women and minority recruitment and retention.

On-line courses (some leading to on-line degrees) for large numbers of students, the use of improved technology, and recruitment and retention issues remain at the forefront of frontiers at FIE Conferences in the decade of the 2010s.

IV. TOP FIE TOPICS BY DECADES

Table I shows a listing of what may have been regarded as true frontiers at past FIE Conferences. Two conferences were selected randomly from each of the four decades. As an aside, the author is one of the very few FIEers who has a complete file of every FIE Proceedings. Paper topics from the selected Proceedings were grouped into categories with the most popular topics included in the table. The table shows the number of papers, the number of sessions presented at each conference, and the percentage of the total in each case.

My own recollection was reinforced with the review of topics from these conference proceedings. Conference planners were continually asking whether the true frontiers were being addressed. Plenary sessions were held at several conferences with titles of "Trends in Engineering Education", "The Future of Engineering Education", and "Where are the Frontiers?" A diligent effort was evident in keeping the conference at the forefront of the frontiers.

Table I. Top Categories of FIE Topics for Selected Years

Year	Category	Papers	Sessions
1973	Uses of Technology	14 (13.2%)	4 (25.0%)
	Self-Instruction	13 (12.3%)	3 (18.8%)
	Laboratories	8 (7.5%)	3 (18.8%)
	Learning Methods	7 (6.6%)	2 (12.5%)
1980	Computers in Education	17 (20.2%)	4 (16.7%)
	Learning Methods	16 (19.0%)	3 (12.5%)
	Self-Instruction	8 (9.5%)	2 (13.3%)
1982	Humanities and Engineering	10 (16.7%)	4 (20.0%)
	Computers in Education	8 (6.7%)	3 (15.0%)
	Learning Methods	4 (3.3%)	2 (10.0%)
1987	Computers in Education	26 (15.8%)	5 (20.8%)
	Retention and Gender Issues	16 (9.7%)	3 (12.5%)
	Senior Capstone	9 (5.5%)	2 (8.3%)
1991	Retention and Gender Issues	20 (12.5%)	5 (12.2%)
	Design/Senior Capstone	17 (10.6%)	4 (9.8%)
	Professionalism	13 (8.1%)	3 (7.3%)
	Computers in Education	10 (6.3%)	2 (4.9%)
1995	Learning Models	50(18.7%)	10 (16.9%)
	Design/Senior Capstone	25 (9.4%)	5 (8.5%)
	Retention and Gender Issues	15 (5.6%)	3 (5.1%)
2002	Learning Models	45 (31.0%)	9 (31.0%)
	Laboratories	20 (13.8%)	4 (13.8%)
	Computer Science	20 (13.8%)	4 (13.8%)
	K-12 Issues	20 (13.8%)	4 (13.8%)
2007	Learning Models	36 (6.0%)	6 (6.0%)
	Uses of Technology	30 (5.0%)	5 (5.0%)
	Assessment (ABET)	24 (4.0%)	4 (4.0%)
	Computers in Education	24 (4.0%)	4 (4.0%)

V. AN ANALYSIS BY DECADES

Table I shows that learning methods has been a primary frontier since the inception of the FIE Conference in the early 1970s. In addition, the use of technology has continued as a primary theme. Computers are also listed in many of the Proceedings that were examined. What is less evident is that the frontiers have been increasingly NSF-driven, ABET-driven, and gender-driven. NSF funding has greatly influenced FIE participants who have reported findings in NSF-sponsored contracts at universities through the decades. It is the recent

NSF emphasis on STEM research nationally that has prompted the creation of engineering education departments within universities. Faculty and staff from these departments regularly present their research results at FIE Conferences. ABET-driven frontiers are prominent in design, senior capstone, and assessment topics identified in 1987, 1991, 1995, and 2007. Gender-driven issues, including recruitment and retention, are shown in 1987, 1991, and 1995. The author recalls attending a women in engineering FIE session at WPI in 1983 while chairing the Dasher Best Paper Committee.

VI. A NOTE FROM HISTORY

At the request of the then IEEE Education Society president, a report was presented in June 1989 at the ASEE Annual Conference in Lincoln, NE regarding the future of the Society's co-sponsorship of the FIE Conference. Serious questions had been raised at that time about the loose structure of the conference, the review process for conference papers, and whether the Education Society would continue as a sponsoring participant. Wisely, the Education Society report based on the advice of past and present FIE leaders was positive. The FIE Conference Steering Committee then readily took immediate action to resolve concerns and move the conference forward without disruption. It is my opinion that the Steering Committee continues to have excellent leadership and committee membership. My observations in this WIP paper is not meant to overstep their authority but to support their enthusiasm for a better conference. FIE participant input can always be useful, especially in view of thoughtful observations by long-time leaders.

VII. DISCUSSION

The FIE Conference appears to have "taken on a life of its own" in recent decades and reinvents itself approximately every three to five years. Table I does not reveal this observation but focuses on the history of the conference since the 1970s. A mature conference consists of many papers that are based on extrending the state-of-the-art from year to year (or less often); a mature conference has papers that cite the very recent findings as a baseline for further research; and a mature conference has many papers which are appropriate as springboards (with additional work) for journal papers. With its NSF-sponsored STEM research focus, for example, the FIE Conference has an increasing number of papers that fit this mode for a mature conference.

VIII. CONCLUSIONS

This WIP paper has discussed the quest of the FIE Conference planners and participants in their search for addressing the true frontiers of engineering education. It was interesting and informative to receive the survey results and to review the many topics covered in several conferences during the past 42 ears. It is evident that the FIE Steering Committee might be interested in knowing the responses to the survey questions.

If this WIP paper is received favorably by the FIE audience, it is planned to work with the Conference Steering Committee and expand to invited sessions/panels at future FIE Conferences. Conference organizers require cutting-edge results in submitted papers and already seek out invited speakers for identified emerging frontiers in engineering education. .A regular feature with rotating organizers (session/panel chairs) having varied perspectives could focus on identifying these true frontiers.

AUTHOR'S BIOGRAPHY

Jim.Rowland is a professor of electrical engineering at the University of Kansas where he holds a Sharp Teaching Professorship. An IEEE Life Fellow and ASEE Life Member, he currently represents ASEE as an EAC Alternate to ABET; he has made 35 visits as an ABET program evaluator for IEEE or ASEE since 1985. He has participated in 36 of the 42 past FIE conferences.

An Exemplary Design Framework: A Small-scale Prototype of Home Area Network in a Smart Grid

Wookwon Lee
Department of Electrical and Computer Engineering
Gannon University, Erie, PA 16541
e-mail: lee023@gannon.edu

Abstract—**In this paper, with a specific application to a Smart Grid system in mind, we present a small-scale prototype system of wireless networks and design details of the prototype system. From the perspective of undergraduate engineering education and learning, we describe how the project team of undergraduate students has overcome technical obstacles and challenges in successfully completing the prototype system. For an outcome of this project, we also derive a set of laboratory experiments for integration into a laboratory-based course for improvement in learning effectiveness and overall undergraduate engineering education.**

Keywords—Smart grid, utility meters, ZigBee networks.

I. Introduction

One of the recent trends in technology development in the United States is modernization of the electric power grid, or the Smart Grid. At the core of the Smart Grid vision are information and communication technologies. For the coordination of the efforts, National Institute of Standards and Technology (NIST) published its latest Framework and Roadmap for Smart Grid Interoperability Standards in 2012 [1]. Reflecting this recent trend onto engineering education, a small-scale prototype of home area network for end users in a smart grid has been developed in our lab with participation of a small group of undergraduate engineering students. The objectives of this project are 1) to develop power- and water-metering subsystems that collect usage data and 2) to develop a software-based graphical user interface (GUI) for a remote monitoring center.

Facilitating collection of energy-usage data and delivery to a remote monitoring center, this prototype is intended to provide an engineering design framework to undergraduate students for application of their classroom-acquired engineering knowledge to contemporary real-world problems and to ultimately enhance students learning experience. The primary functionality of this prototype system is for collection and delivery of energy-usage data from end users, e.g., smart homes, to a remote monitoring center. More specifically, in this prototype system, a set of off-the-shelf wireless communication devices, e.g., ZigBee [2], are employed to establish wireless links between off-the-shelf power- and water-meters and the remote monitoring center with a meter-reading GUI. The set of power- and water- meters are integrated with the wireless communication devices and installed at select target spots in a laboratory setting. The remote monitoring center communicates with its wireless communication devices that receive data from the other wireless communication devices at the meters. The GUI at the remote monitoring center is implemented on a Windows 7-based computer using LabVIEW [3] as a design tool and collects and displays the usage of water and electricity at the target spots. The physical communication link between the wireless communication device and the GUI is realized in two different modes of operation: Ethernet-based and USB-based.

In the following, more details of the prototype system are provided. We also describe how the students have overcome obstacles and technical challenges in implementing the prototype system, as well as how the outcomes of the project could be integrated into courses as a framework for undergraduate engineering education.

II. Overview of the Project

A. Conceptual Architecture of the Prototype System

The concept of this network architecture, as shown in Fig. 1, is to establish communication capability by a) attaching a vendor-specific ZigBee, also known as 485Bee [4], to a vendor-specific software through the Ethernet via RS485 or b) via a RS485 to USB converter, and 3) also attaching a more general ZigBee [2] to a LabVIEW-based GUI via USB. These ZigBees (or 485Bees) will receive signal/data from other ZigBees (or 485Bees) which will be placed in target spots to get the readings from the meters and transmit them over

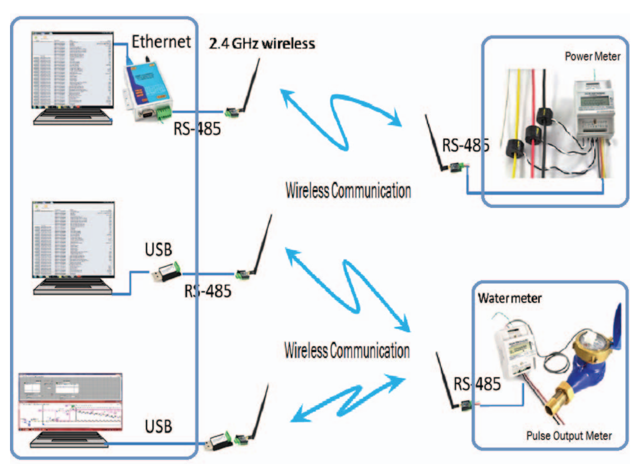

Fig. 1: Architecture of the prototype system

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

the wireless communication links to the vendor-specific meter-reading software or a LabVIEW-based GUI built in our lab for proper display of the utility data.

B. Key Components of the Prototype System

The key components of the prototype system include ZigBees, 485Bees, a TCP/IP-to-serial converter, current transformers, water meters, and pulse counters. ZigBee [2] is a type of wireless communication device that uses a protocol of IEEE 802.15.4 to transmit and receive data within a small area at the 2.4 GHz frequency band, with the maximum bit rate of 250 kbps. ZigBee follows the wireless mesh networking proprietary standard which provides high reliability and larger range in communication up to 100 meters. It is inexpensive, hence, allowing the technology to be widely deployed in wireless control and monitoring applications. The power consumption is low and thus, it is cost effective. 485Bee [4] is a vendor-specific system built around the commonly used ZigBee chips. Its features include hard-wired RS485 to wireless ZigBee, communication range of up to 200 meters with a 900 MHz antenna, and an external DC supply in the range of 6V∼42V to power up the circuit board.

A vendor-specific TCP/IP to RS485 serial converter, known as iSerial (version 2) [5], is utilized. This converter is equipped with 8051 CPU, 64 kilo bytes (KB) ROM, 32 KB SRAM, 10/100 Mbps Ethernet, and a serial port that supports hand-shaking Request-to-Send and Clear-to-Send (RTS/CTS). Its features useful for the project include 3-in-1 RS232/RS422/RS485 interface with max. 230 kbps serial interface and 10/100 Mbps Ethernet, support for 4- and 2-wire RS485 with AUTO-SEND and built-in terminator, and IP configuration by MAC address. For the pulse counter for the usage data of electricity, an off-the-shelf device, known as OmniMeter Pulse (version 4) [6], which is also known as the Universal Smart Meter, is employed. This meter works with 4 different voltage systems including 120 volts (2-wires, single-phase, 1 Line and Neutral) and its current range can go up to 5000 amps. An external Current Transformer (CT) (50/60Hz) shown in Fig. 2(a) may be needed to take the measurement.

For water usage, a Pulse Input Meter (i.e., EKM-25EDSP-N v.2) was initially used for the prototype system to keep track of the 3 output pulses produced by the Pulse Output Water Meter [7]. The pulses-to-units ratio was configurable in the meter from 1:1 to 1:9999. These pulse counts were held in the non-volatile memory. But, later, as this device became discontinued, the OmniMeter was used for the purpose of gathering the water usage data from the Water Meter. For the current transformer, split-core CT [8] is used which can be snapped around any of the load wire to take measurements of the load within the range of 1 to 200 amps with an accuracy of 0.1%. The Pulse Output Water Meter shown in Fig. 2(b) produces a pulse for every 1/10 cubic foot (approximately 0.75 gallon, or 2.83 liters) that flows through the meter. These pulses can then be picked up and counted by OmniMeter Pulse v.4.

III. Project Design and Self-directed Learning

The technical details given in this section are the outcomes of the self-directed, hard work by the project team as device manuals often do not have sufficient details for anyone new

(a)

(b)

Fig. 2: (a) Current transformer (b) Water meter

to the devices. These descriptions may still not be sufficient for some readers but are deemed to be able to facilitate easier integration of these devices when combined with the manuals.

A. Configuring ZigBees

X-CTU [9] is a simple GUI supplied by the vendor and is used to configure ZigBees with a USB cable from its board plugged into the computer. For the proper configuration, it is necessary to check first which COM port is used on the computer so X-CTU can use a correct port assigned to the ZigBee. Once X-CTU is invoked, its default screen is for PC Setting. Communication parameters are set for i) 9600 baud rate, ii) no flow control, iii) 8 data bits, iv) no parity bits, and v) 1 stop bit. Once these parameters are set, testing can be performed by clicking on the “Test/Query.” If ZigBee is communicating with the X-CTU via the assigned COM port, a message will pop up showing information about the ZigBee; otherwise, an error message is displayed such as “Unable to Communicate.” If that happens, checking more carefully the parameters in the PC Settings or changing the ZigBee and/or USB cable may be necessary. If all that fails to make ZigBee respond, it is recommended to double check the version of X-CTU as the older versions than v5.2.7.5 exhibited unstable operation on some computers during our lab testing. Then, under the “Modem Configuration” tab, clicking on ‘Read’ will import and show all configurable parameters of the ZigBee. For instance, Channel Number, Personal Area Network (PAN) ID, and/or Baud Rate can be changed. After making necessary changes, clicking on ‘Write’ saves the changes into the ZigBee chip. When all ZigBee chips for the prototype system are configured, testing is desired in a point-to-point mode to see whether two ZigBee chips are successfully communicating with each other. For this, both ZigBees need to have the same PAN ID. Connecting two ZigBees to their respective X-CTU on the same computer or on two different computers, test messages can be entered under the ‘Terminal’ tab and transmitted to the other ZigBee; if the same message is shown on the X-CTU for the second ZigBee, it means that both ZigBees are configured properly and communicate with each other.

B. Connecting and Configuring Metering Devices

Connections to an OmniMeter for metering of electricity usage require careful examination as the instruction sheet that came with the device may not be sufficient for a plug-and-play. As shown in Fig. 3, first, clamp a CT around L1, making sure that the arrow on the CT is facing towards the load. Then, for wiring of the CT, connect the black wire to Port 1 of

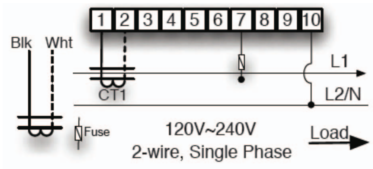

Fig. 3: Connection diagram

the OmniMeter and the white wire to Port 2. Connect a 1.0 amp, 250V fuse between Port 7 and L1 using 16-22 AWG UL standard copper wire. Connect the Neutral wire to Port 10. For connections of RS485 (485Bee), connect Terminal 20(A+) of the OmniMeter to RS485(A) and connect Terminal 21(B-) of the OmniMeter to RS485(B).

For the water meter to properly output the pulse counts, a 240V power was required for the Pulse Input Meter (but not for OmniMeter). As such, for connections to a Pulse Input Meter for metering of water usage, a European travel adaptor (converting 120V to 240V) was employed with its hot wire connected to Port 7, and the Neutral wire connected to Port 8; all positive wires from the Pulse Output Water Meter were wired to the respective Ports 11, 12, and 13, and all negative wires from the Pulse Output Water Meter were wired to Port 14 (the common ground). Then, RS485 was connected as described above for the metering of electricity usage.

C. iSerial Configuration

In order for our computer to be able to communicate with the iSerial, configuration for networking has to be performed. First, check if the Local Area Network (LAN) for the computer uses one of the predefined iSerial-specific IP addresses ranging from 192.168.1.2 to 192.168.1.254 with a subnet mask of 255.255.255.0. With the default IP Address of iSerial being 192.168.1.125, if the IP address of the computer is not in the same domain, i.e., 192.168,1.xxx, the networking parameters of the computer need to be properly changed. For this, with iSerial connected to the computer via an Ethernet cable, type in http://192.168.1.125 into the Internet Explorer for configuration of iSerial. On the configuration window, enter an appropriate username and a password. Click on tabs to go to Administrator>System IP Address, and ensure that IP Address (default: 192.168.1.125), Subnet Mask (default: 255.255.255.0), Gateway (default: 192.168.1.1), and Primary DNS (default: 0.0.0.0 and 192.168.1.1) are set properly. Note that while the IP address for iSerial can be changed, the password must not be forgotten as there is no mechanism to reset the password. These networking parameters are for the static mode of operation. If a custom router that can automatically assign an IP Address is used between the host computer and iSerial, then the Dynamic Host Configuration Protocol (DHCP) mode can be used. To update the iSerial with any changes in this mode, it may be necessary to enable and assign VLAN ID to 0001 and then disable again (to get around a bug in the control software). Then, finally, click 'Update' after making necessary changes.

The iSerial can operate in four modes: TCP Server, TCP Client, UDP Server, and UDP Client. In our case, the TCP Server mode is used. For this, in "TCP Mode" and 'DIDO' Tabs, set Port Number to 50000. On physical connections, 3 types of connections to iSerial are supported: RS232, RS422, and RS485. The default setting for metering is via RS485. The corresponding parameters can be set under UART Control tab such that Baud Rate is set to 1200, Character Bits to 7, Parity Check to 1, and Hardware Flow Control to None.

D. Meter-reading Software

The vendor of the metering devices has initially supplied a software module [10] (that is later replaced by a new software module described below) to read and display received metering data, as well as polling to solicit metering data from remotely located electricity and water meters. For configuration, after opening up the vendor-specific software, go to File>Preferences>COM Port Setup to set up the communication devices. In this setting, each line represents a communication device and the line number is the number that will be used later in the main window for the TCP Port or COM Port number. Under "Meter Type", select v.2 for the pulse meter and v.3 for OmniMeter, and under "COM Port" select iSerial for both. Then, enter "192.168.1.125" for the IP address and '50000' for the TCP Port number. Finally, click 'Save.' Note on which COM Port is listed on which line number as this information will be needed later when the software is used to read data from a particular metering device. Then, in the main window of the software, enter the TCP Port number which is associated with the line number in the COM Port Setup window. Along the line, enter the meter number which can be found on the meter itself. (e.g., for a meter serial number "S/N 000000003016," type '3016'). Before clicking "Read a meter," also enter the meter number and COM Port number right below that button.

EKM Dash [11] is a newer version of the meter-reading software that consolidates reading capability for both Pulse Input Meter (for water meters) and OmniMeter (for electricity meters). To configure, after opening up the EKM Dash, click "Meters>New Meter" to enter the meter name and select an appropriate EKM meter model from the Meter Model drop-down list. Enter the meter number in the Meter Number field (e.g., for "S/N 000000003016", type '3016'). Click on the Remote tab and type in the iSerial IP Address "192.168.1.125" and '50000' for iSerial Port. Change Read Interval from 'Disabled' to "As fast as possible." Click 'Ok' and then "Start Reading."

E. Design of GUI with LabVIEW

In addition to the vendor's meter-reading software, our own software is developed in LabVIEW. LabVIEW typically works with a dedicated data acquisition (DAQ) device from the vendor. However, in this project, the students were challenged to directly connect the USB-based ZigBee to the computer and thus the LabVIEW-based software without using any DAQ device. For this purpose, an existing LabVIEW-based design which was developed for different applications in our lab was provided to the students as a starting point. However, the existing design was for serial communication via RS232 and thus, was not directly compatible with USB. For a proper design, the student team came up with the following implementation:

1) Use **VISA Configure Serial Port** to initialize the serial port specified by VISA resource name.

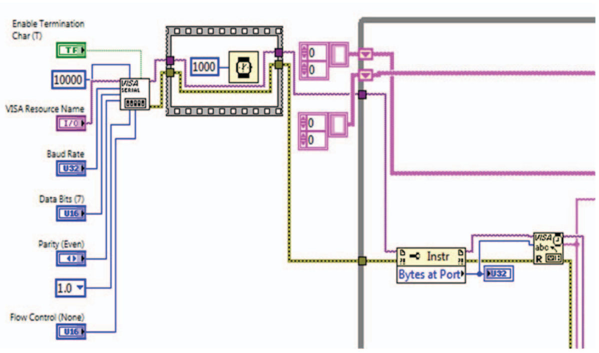

Fig. 4: Implementation in LabVIEW for USB interface

- VISA Resource Name specifies the resource to be opened (e.g., COM8, COM10, etc.)
- Baud rate is the rate of transmission
- Power Meter baud rate is 9600.
- Water Meter baud rate is 1200.
- Data bits are 7 for both Power and Water Meter.
- Even Parity is used for both meters.

2) Use **Property Node** to get or set the properties and methods on local or remote application instances. In our case, the team uses Serial Setting>Number of Bytes as Serial Port.
3) Use **VISA Read** to read the specified number of bytes from the device or interface specified by VISA Resource Name and return the data in Read Buffer.

Fig. 4 shows the implementation in LabVIEW that facilitates the USB-based serial communication.

F. Getting Data Transmitted from ZigBee Systems

As common in 3rd party devices and software, technical details are not known for asynchronous (i.e., serial) communication between the metering devices and the meter-reading software, while the design of our LabVIEW-based GUI requires all the details of such communication to be properly coded in the LabVIEW design file. The student team was instructed to explore techniques of "reverse engineering" to make reasonable guesses of such details and go on trial-and-error testing. For this, the student team placed a third ZigBee to receive metering data from one of the ZigBees attached to the metering device (e.g. OmniMeter) and used X-CTU to monitor what is transmitted between the first two ZigBees and how to synchronize the data for proper interpretation of binary data representing the metering data.

For this experiment, under PC Settings of the X-CTU, test first whether the 3rd ZigBee is connected properly and make sure the settings are appropriate to communicate with the other two ZigBees, e.g., Baud Rate set to 9600, Parity set to Even, and Data Bits set to 7. Then click on the Terminal

Fig. 7: Implementation in LabVIEW for data extraction

tab. In the next step, on EKM Dash, click “Start Reading” and see what is displayed on the X-CTU Terminal. Fig. 5 shows some logs of such communication. Then, the next step is to compare the readings collected in X-CTU and those displayed on the EKM Dash (or its previous version, if necessary) and the meter data displayed on the LCD screen of the metering device such as kWh, line voltage, power factor, etc. Fig. 6 shows the information displayed on a) X-CTU (top left), b) EKM Dash (top right), and c) LCD screen of the metering device (bottom), respectively.

To extract the data needed for the LabVIEW-based software, the Search/Split String function in LabVIEW is used as shown in Fig. 7(a). The String is the input value to the LabVIEW module, and Offset is a specific value that cuts the string into 2 parts; before and after the offset value. As further illustrated in Fig. 7(b), in our case, the offset is set to ‘5’ because the first 5 characters are not needed. The rest of the string is fed into another function to be cut again. The next offset is set to ‘9’ to draw out the meter number “300000044,’ and the value can be seen at “Substring before match” in Fig. 7(a). The rest of the values can be chopped in a similar fashion as shown in the figure.

Then, an array table as shown in Fig. 7(c) is built to process and display the data collected on the screen. Using Build Array in LabVIEW, the following values are gathered: Meter Number, Total (kWh), Reverse (kWh), Line Terminal (kWh), Reverse Line Terminal (kWh), Voltage (V), Current (A), Total Power (W), Line Power (W), Power Factor 1, Power Factor 2, Power Factor 3, Frequency, Date, and Time. Finally, the “Insert into Array Function” is used to specify the rows and columns for respective data mentioned above. The table shown in Fig. 8 illustrates the end result of the design in the LabVIEW. Some additional processing has been performed as well, using Case Structure and Boolean to allow the correct 9 digit meter number and also to make sure that the readings are from the correct meter number. Also, a While loop is used to execute the program repeatedly until the ‘STOP’ button is pressed.

G. Integration of Subsystems

Fig. 9 shows the integration of the subsystems around the GUI. As shown in the figure, one of the 485Bees was connected to the iSerial via RS485 and then to the computer through an Ethernet cable (for the meter data displayed on the EKM software). The other 485Bee was connected to the RS485 to USB converter (for the meter data displayed on the LabVIEW-based software). Although not legible in the figure, the EKM software was able to receive and correctly display the incoming data from both meters. In the data collection side, as illustrated in Fig. 10(a), the OmniMeter is powered up by the 120Vac supplied from the wall. The current transformer is clamped around the load line, ensuring that the arrow is pointing towards the current to the load. The 485Bee is then connected to the OmniMeter at terminals 20 and 21. An

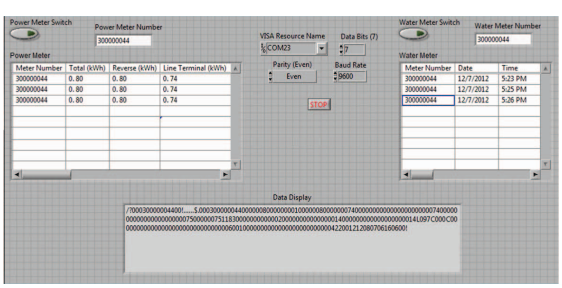

Fig. 8: Snapshot of LabVIEW-based GUI

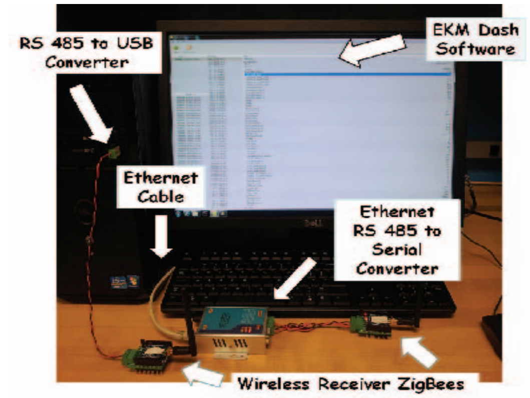

Fig. 9: Connections to GUI

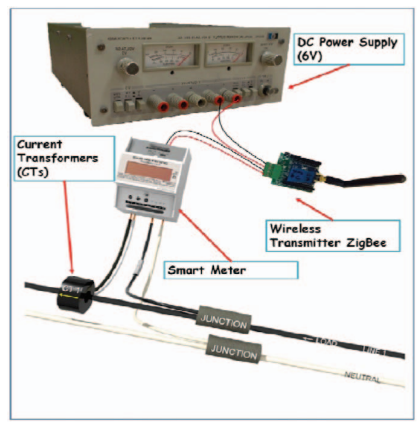
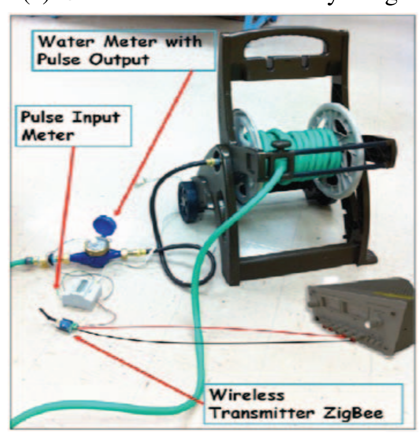


(a) OmniMeter for electricity usage



(b) Pulse Input Meter for water usage

Fig. 10: Illustrative connections of utility meters

external DC power supply of 6V is supplied to the 485Bee in order to power up the 485Bee. The Pulse Output Water Meter (or simply Water Meter) is connected as shown in Fig. 10(b) between the water hoses so as to allow water to flow through. The Pulse Output Water Meter counts and produces a pulse for every 0.75 gallon of water flowing through. From the Water Meter, there are two wires coming out which are connected to the Pulse Input Meter at terminals 11 and 12. The 485Bee powered by an external DC power supply of 6V is then connected to terminals 20 and 21 of the Pulse Input Meter. The Pulse Input Meter is powered up with a voltage supply of 230V from an AC power supply of 120Vac via a travel adapter which is used to step up the voltage. The 485Bees connected to the OmniMeter and Pulse Input Meter communicate with the 485Bees previously shown in Fig. 9.

IV. Application to Curriculum Development

As described in the previous section, the students were able to properly set up the power and water meters in order to obtain the usage data via 485Bees operating at 2.4 GHz. The team also successfully created its own meter-reading GUI in LabVIEW without using any DAQ devices. This GUI was used to replace the EKM software that came with the meters. During the project implementation, there were obstacles and issues. But all of these were believed to lead to an improved learning experience, with all the technical details down to the bottom to make the subsystems and the overall prototype correctly operate. Students expressed the appreciation of the learning from the project, quoting that up until this time they never had such hands-on work successfully completed as described in this paper.

The lab activities and technical details of this project tried with a small group of dedicated students appear to be appropriate for further development of course materials for a larger group of students. As an example, although ZigBee has been widely utilized for data transmission in hands-on projects at various levels including two-year programs (e.g., see [12]), as well as four-year programs (e.g., see [13]), it also offers another undiscovered capability as a tool to observe more details of underlying communication aspects between two communication devices. The utility meters used in this project are fairly new for adoption in engineering education, and appear to generate more students' interests in working with. LabVIEW has been widely adopted in engineering design but, as illustrated in this paper, our new attempt to not using vendor-supplied DAQ seems to create another great opportunity to enhance student learning experience. Suitable for upper division undergraduate students in electrical and computer engineering, the project activities described in this paper could better prepare them for carrying out more complex hands-on projects such as senior Capstone projects [14]–[17]. From the author's perspective, all the lab activities of this project could be applicable to creating a series of laboratory experiments for a semester-long regular course covering introductory communications aspects. As an illustration, Table I shows a suggested list of experiments. Particularly, this set of laboratory experiments combined with appropriate topic-based lectures would be suitable for an introductory communications course intended as an elective course in the first semester of the senior year in a four-year ECE program.

TABLE I: Set of Laboratory Experiments

Lab #	Lab Experiment
1	Serial communication via RS232 and signal measurement
2	Serial communication via USB and signal measurement
3	ZigBee Protocols and IEEE 802.15.4 Physical Layer
4	Point-to-Point/Point-to-Multipoint communication via ZigBee
5	LabVIEW GUI design for serial communication via RS232
6	LabVIEW GUI design for serial communication via USB
7	Application of point-to-multipoint communication to a metering system via ZigBee (& X-CTU)
8	TCP/IP protocols and data exchange
9	Integration of metering devices and data exchange via TCP/IP
10	Integration of metering devices and data exchange via ZigBee

V. Concluding Remarks

We have presented a small-scale prototype system of wireless networks applicable to Home Area Networks for the Smart Grid. In a project period of two semesters, two student teams, each with 2∼3 students for a semester, participated in the project. The student teams successfully configured two types of utility meters and the wireless devices in order to deliver the usage data from the utility meters to a remote monitoring center. The teams also successfully created a GUI using LabVIEW for the remote monitoring center. From the project activities and relevant technical aspects, a set of laboratory experiments has been derived that, when combined with appropriate lectures, would be suitable as an elective course for upper-division ECE students.

Acknowledgement

The author would like to thank the students who participated in this project, especially, those from Nanyang Polytechnic, Singapore, during spring and fall 2012.

***Abstract*—This paper describes the integration of a remote lab in a tool for educational digital circuits. Boole-Deusto is an educational software tool featuring truth tables, Karnaugh maps, Boolean expressions, finite-state machines and digital circuits. After creating the design through Boole-Deusto, the user can implement the circuit in a remote lab (WebLab-Deusto) with only a few mouse clicks. The user does not need the technical knowledge, time, hardware equipment and specialized software that would normally be required. These conveniences benefit teachers and students alike, especially those involved in basic courses in digital electronics, both at the university and high school levels.**

Keywords—remote labs, digital electronics, software design tools

I. Introduction

Current lessons on digital electronics are usually based on books, exercises, and lab practices. The learning process starts with theory. Then students design some exercises and finally some of these are implemented using different technologies (74XX IC, VHDL/Verilog, CPLD, FPGA...). With this approach, students learn how to design and implement different digital circuits.

Simulators and other educational software tools help teachers and students. However, professional tools like Proteus [1], Pspice [2] or Electronics WorkBench, EWB [3] do not always cover all the educational requirements. Some areas (such as Karnaugh maps) are often neglected. On the other hand, educational tools tend to cover those neglected areas, but to have a very narrow scope. An example of such a tool is the Karnaugh Map Minimizer [4]. Though Boole-Deusto is also an educational software tool, it tries to cover a larger base of educational requirements, including the full design of basic bit-level digital circuits. Nonetheless, Boole-Deusto should not be compared with professional tools, as their focus tends to be on the circuits rather than the design process itself.

Whether they are using simulators or not, students should eventually implement the digital circuit using 74XX IC, VHDL/Verilog, etc. To do this this, students and teachers would typically move to a purposely-equipped laboratory to carry out this experience. However, for several years, there has been another possibility: to use a remote laboratory. These labs have been considered as part of the “Five Major Shifts in 100 Years of Engineering Education” [5].

There is a high amount of remote labs for digital electronics [6 - 9], but most often they are intended for a single, particular device such as a FPGA, CPLD or microcontroller, but without a more general, educational approach.

The main objective of this work is to integrate Boole-Deusto [10][11] with the WebLab-Deusto [12] remote lab, both Open Source projects. Through this integration, teachers and students can design a basic digital circuit under the educational approach provided by Boole-Deusto (involving truth tables, Karnaugh maps, Boolean expressions…), and after this they can implement it in a remote lab with only a few mouse clicks, and requiring only Boole-Deusto and an Internet connection. The process is very straightforward, and no wiring, particular technical knowledge or hardware such as board programmers is needed, nor specialized software such as development studios.

The paper describes in Section II the Boole-Deusto software for combinational and sequential bit-level digital systems. Section III is devoted to a general perspective on the WebLab-Deusto remote laboratory. The integration of Boole-Deusto and WebLab-Deusto is illustrated with examples in Section IV. The paper finishes with the conclusions and future work in Section V.

II. Boole-Deusto Software Tool for Digital Electronics Design

Digital electronics circuits can be classified in two groups: combinational circuits and sequential circuits, depending on whether they have memory (and are hence sequential) or not. Depending on the complexity of the circuits, they can be divided in bit-level and word-level circuits (see Fig. 1). In the first case the circuit is described bit by bit using a truth table (combinational circuits) or a Finite State Machine (sequential circuits).

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

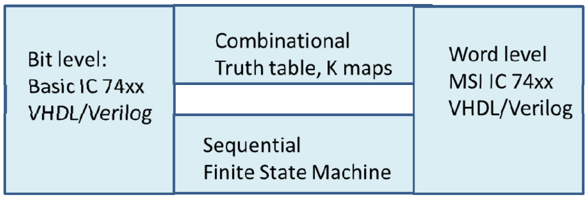

Fig. 1. Digital circuits classification

The Boole-Deusto open-source tool was deployed for the first time in 2000 [13] for designing bit-level digital circuits, both of the combinational and sequential types. The design of these circuits can be seen as a transformation along different representations of the system. These representations can be of textual, numerical, logical, graphical or mathematical nature.

In the design of a combinational circuit (see Fig. 2), the student reads the statement and after understanding it, fills the truth table. It is then converted to Karnaugh maps that are solved to obtain minimized Boolean expressions. These Boolean expressions are converted to digital circuits that can be implemented using AND-OR (or NAND/NOR) logic gates in 74xx IC or using a VHDL/Verilog approach.

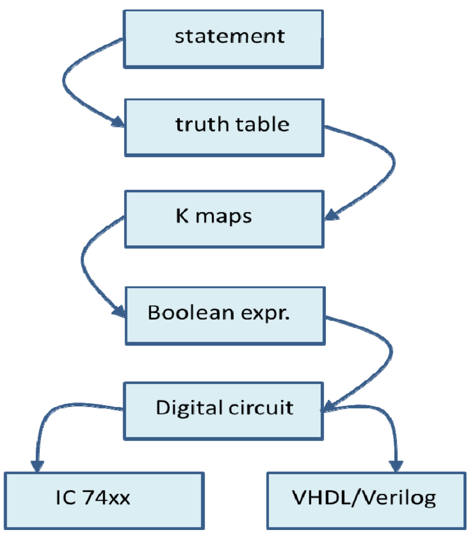

Fig. 2. Design process of a bit-level combinational circuit.

The process with bit-level sequential circuits is similar. Students will start by reading the problem statement and obtaining a FSM. After using an algorithm they will minimize that FSM. It will then be transformed into a truth table from which the K maps will be obtained. Based in the K maps, the minimized Boolean expressions will be obtained to be implemented with logic gates or in VHDL/Verilog.

Boole-Deusto focuses only on the design process. A student cannot use Boole-Deusto to see how a digital circuit evolves through time. Simulation is already covered in depth by tools such as Proteus, EWB, etc. Boole-Deusto helps freshmen in digital electronics to design and implement real and basic digital circuits. Boole-Deusto was developed as an Open Source project [11] by the University of Deusto after being unable to find an existing educational tool of this kind.

Since 2003, Boole-Deusto has been downloaded thousands of times [14]. Fig. 3 shows the download statistics from the official Boole-Deusto web page (since 2007 only – more download sources exist, so the full download count would be significantly higher).

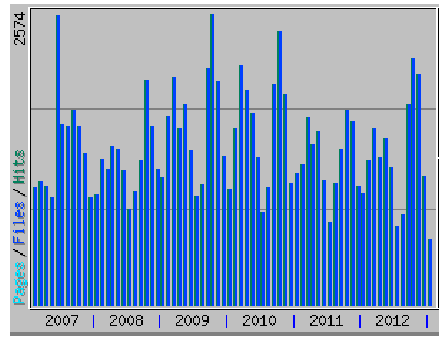

Fig. 3. Statistics of the Boole-Deusto downloads.

A. Combinational circuit example with Boole-Deusto

Figs 4-7 describe the design of a combinational circuit through its different representations. The description statement is: “Design the circuit that switches on a led if the four bits of the input are not a BCD combination”.

The combinational circuit has four inputs (BCD) and one output (LED).

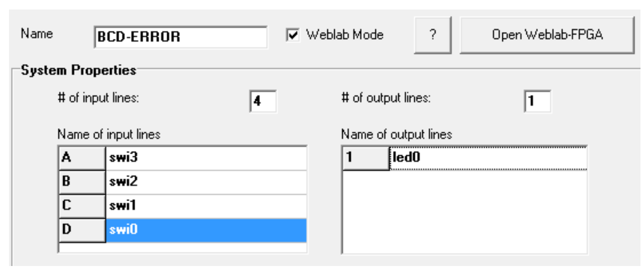

Fig. 4. Name, inputs and outputs of the example

The truth table in Fig.5 shows that the led must be on when the inputs are 1010 – 1111. 0000 – 1001 are proper BCD, so the led will be off.

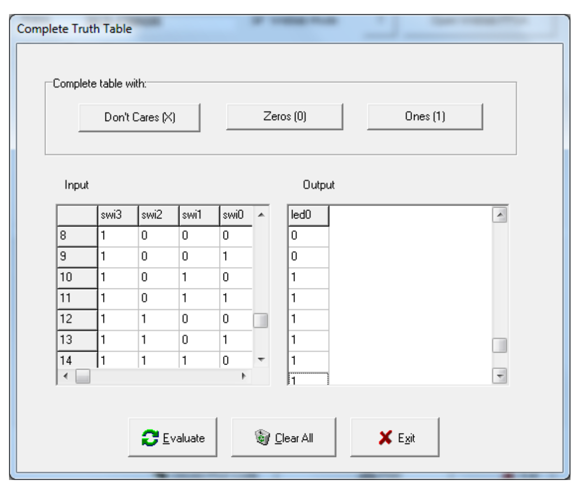

Fig. 5. Truth table of the system

When the student has filled the truth table, the Karnaugh map and the solved Karnaugh map become available. This map can be solved automatically by Boole-Deusto (Fig. 6), or the student can instead try to solve it manually using the Learning Mode.

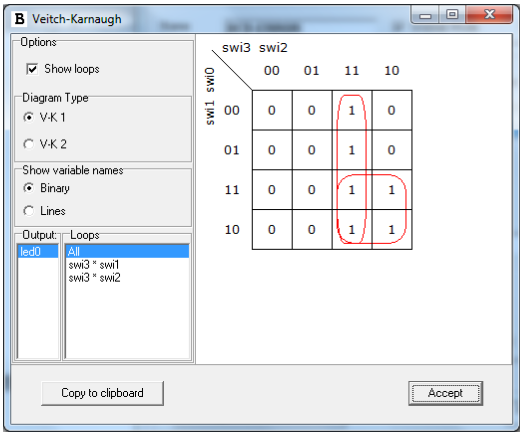

Fig. 6. Solved Karnaugh map for the BCD-ERROR problem

Finally, the student can obtain the matching digital circuit in both the AND-OR and the NAND/NOR versions.

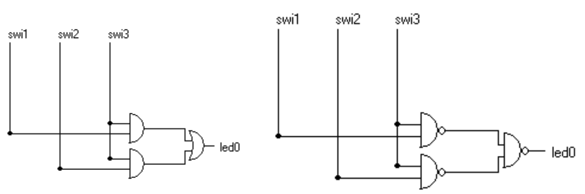

Fig. 7. AND/OR and NAND digital circuits

B. *Sequential circuit, Finite State Machine*

In this case, the student can draw the Moore or Mealy FSM using a graphical interface, displayed in Fig. 8.

The statement for this example is a sequence detector: “Design the FSM that switches on the led in the output, if three or more 1s are received in the input signal”

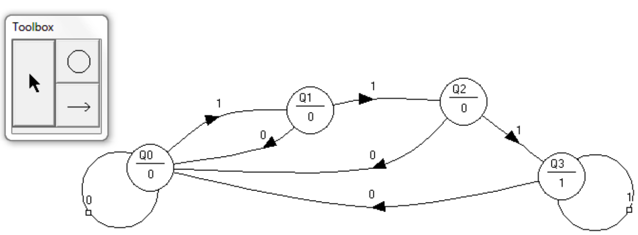

Fig. 8. Moore Finite State Machine

After drawing the FSM, the student can minimize it or obtain the truth tables (Fig. 9).

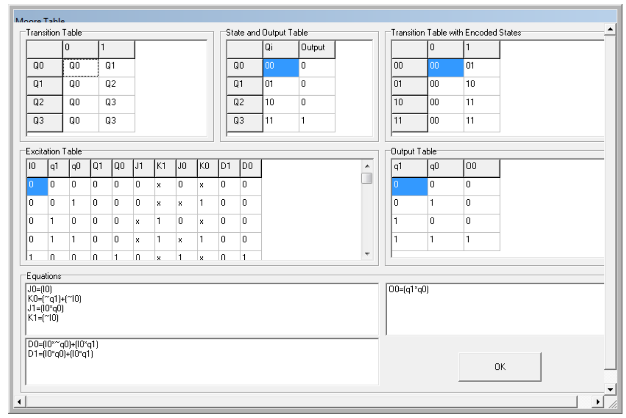

Fig. 9. FSM truth tables

The next step is to obtain the digital circuit (Fig. 10).

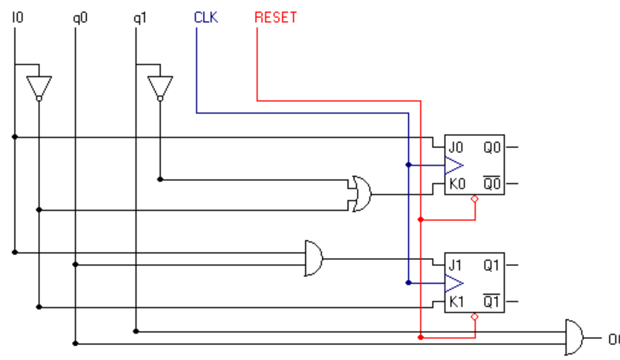

Fig. 10. FSM digital circuit with JK flip-flops

Finally, the student can obtain and download the VHDL program of the FSM.

C. *Boole-Deusto Characteristics*

Boole-Deusto allows the student to control the step-by-step design of bit-level digital circuits. The student will manage FSM, truth tables, K maps, digital circuits, VHDL code, etc.

When comparing Boole-Deusto with other software tools, the main difference is that Boole-Deusto takes the user through each step in the design process. Other tools focus only on the final result, neglecting aspects which are important from an educational perspective but not so much from a practical one. For instance, Proteus software, though certainly complete and professional, does not give students the opportunity of solving the Karnaugh maps themselves.

III. WebLab-Deusto Remote Lab

WebLab-Deusto is a remote lab created by the University of Deusto and released and developed as an Open Source project. A remote lab is a hardware & software platform that allows students to experiment remotely through the Internet as if they were in a classical lab.

WebLab-Deusto offers different remote experiments. Though it is a generic framework, currently the majority of them are related to electronics. There are also several which are connected to physics and biology (See Fig. 11).

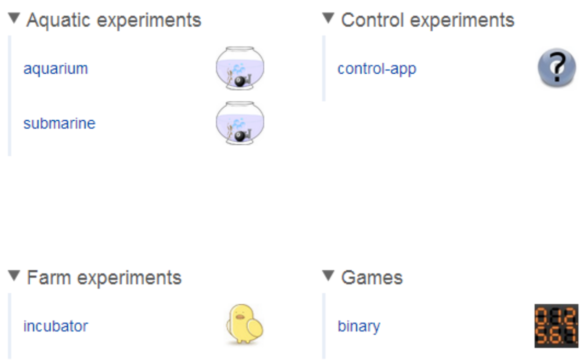

Fig. 11. WebLab-Deusto experiments (screenshot)

WebLab-Deusto supports several generic advanced capabilities [16], which are shared by all experiments. These include but are not limited to federation (experiments and hardware can be shared among different WebLab-Deusto instances, in different institutions and universities), escalation and load-balancing (the number of servers can be increased very easily) and optional integration with different technologies, such as Facebook or LMSs such as Moodle.

From a technical point of view, WebLab-Deusto experiments support any web browser (Chrome, Explorer, Mozilla, Opera, Safari…) in any OS (Linux, Windows…) and any device (tablet, laptop, smart phone…). Users do not need to install anything on their devices, and thus there are no local security issues. Some experiments are currently restricted and the user will require a user/password combination. For others, no registration is required.

A. *WebLab-Deusto-FPGA hardware description*

WebLab-Deusto offers different experiments. One of them is a FPGA:

- The experiment is based in a FPGA Digilent Board.
- The inputs (switches, buttons and clock) are controlled with a PIC Microcontroller of Microchip.
- A webcam and a lighting system are included to provide the user with a video stream of the behavior of the digital circuit.
- A FIT PC (small computer) and a modem are also included, on which the web service which interfaces with the remote laboratory framework is deployed.

All these parts are integrated in a compact, purpose-built professional box.

Fig. 12 shows the WebLab-Deusto-Box where the FPGA experiment is deployed. The same type of box is used to deploy other experiments, such as a CPLD. This WebLab-Deusto-Box was awarded in ICELIE/IECON 2009 for Best Educational Tool [15] has been deployed in different universities, including the MIT (USA).

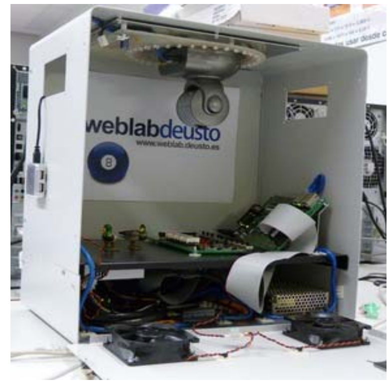

Fig. 12. WebLab-Deusto-Box for FPGA

IV. BOOLE-WEBLAB-DEUSTO

The main objective of this paper is to show readers the potential of the connection between Boole-Deusto and WebLab-Deusto. Fig. 13 shows the checkbox to tick when implementing in Boole-Deusto a system for WebLab-Deusto.

A. *Bit-level combinational circuits*

Fig. 13 shows the checkbox that should be checked by users when they wish to create a WebLab-compatible system easily.

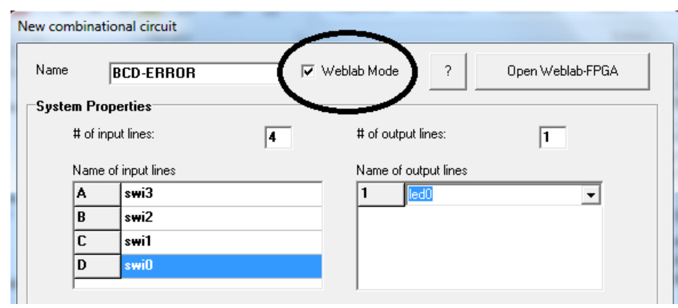

Fig. 13. WebLab Mode for combinational systems

When users are in *WebLab Mode* they may then assign, for instance, switches as inputs and leds or *seven_seg* (seven-segment displays) as outputs. After this, users should:

- Define the system: name, inputs and outputs (see Fig. 14).
- Describe the system using the truth table or the Karnaugh maps (or other means).
- Save the system to VHDL code.
- Click in “Open WebLab-FPGA” (see Fig. 13).

After this, Boole-Deusto will reach WebLab-Deusto through the Internet, directing your default web browser to the right WebLab-Deusto page. A user/pass combination for authentication is required, though it is only necessary to login once per session.

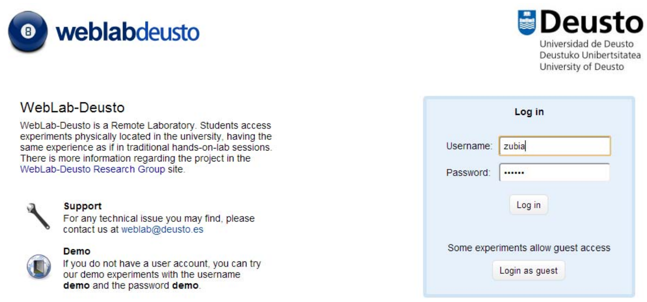

Fig. 14. WebLab-Deusto access web page

Comment for the reviewer: please use fie2013/fie2013 as the user/pass combination.

After accessing WebLab-Deusto by this means, users will be prompted to upload a file. This file should be the .VHD file they generated previously.

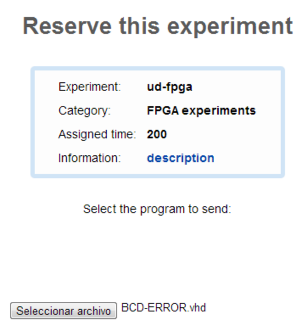

Fig. 15. Uploading the VHDL code to WebLab-Deusto

Then, WebLab-Deusto will synthesize the VHDL code with an internally provided UCF (User Constraints File) to obtain the BIT (BITSTREAM) file that will be loaded into the FPGA (see Section III.A). It is noteworthy that it generally does not matter for students if the designed system is implemented in a FPGA, a CPLD or even a microcontroller. What matters to students is to see the system running, with its inputs (switches and buttons) and outputs (leds and seven-segment displays).

During the uploading process, users will see a process bar as shown in Fig. 16.

Fig. 16. Synthesizing VHDL in WebLab-Deusto

When the process finishes, users will have full control of the switches, buttons and clock. Fig. 16 shows that with 0000 as input, the led output is off because 0000 is a BCD combination.

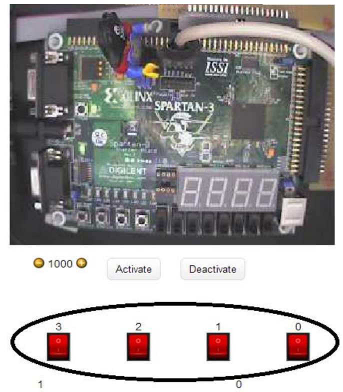

Fig. 17. BCD-ERROR system in the WebLab-Deusto

If the inputs are: 1010, then the led will be on because the combination 1010 is not BCD, as shown in Fig. 18.

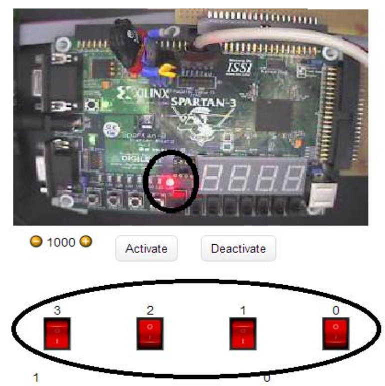

Fig. 18. BCD-ERROR system in the WebLab-Deusto

Figs. 19 and 20 show the truth table of a BCD-seven segment decoder and the remote experience with it for the input 0011.

	Sw...(3)	Sw...(2)	Sw...(1)	Sw...((	Se...(6)	Se...(5)	Se...(4)	Se...(3)	Se...(2)
5	0	1	0	1	0	1	0	0	1
6	0	1	1	0	1	1	0	0	0
7	0	1	1	1	0	0	0	1	1
8	1	0	0	0	0	0	0	0	0
9	1	0	0	1	0	0	0	1	1
10	1	0	1	0	X	X	X	X	X
11	1	0	1	1	X	X	X	X	X

Fig. 19. BCD to seven segment decoder truth table

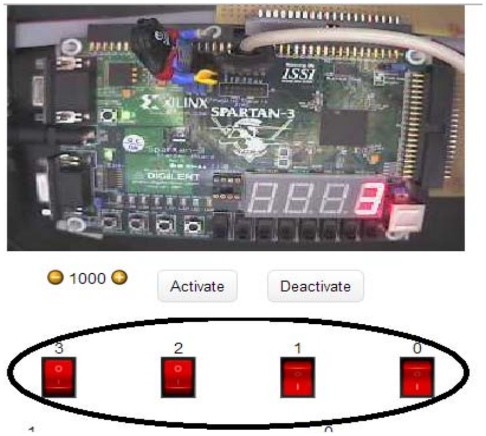

Fig. 20. BCD to seven segment decoder remote experimentation

Using this approach any basic combinational circuit can be designed and experimented with through a remote lab in just a few minutes.

B. *Bit-level sequential circuits: Finite State Machine*

With a sequential circuit, users start the process with a FSM (see Fig. 8). Then they must save the FSM to VHDL code. They can choose among four clocks (see Fig. 21):

- Internal clock. The FPGA will be controlled by its internal clock of 50 MHz.
- WebLab clock. The FPGA will be controlled by a clock offered in the web page. Its frequency can be specified within a range that goes from 100 Hz to 10 KHz.
- Switch and Button clock. The FPGA will be controlled by a clock connected to a switch (switch 9) or to a button (Button 3).

The first two options leave the system to run automatically, and the other two let the user control the speed of the system to witness its evolution in detail. The selection will depend on the particular needs of the student or teacher.

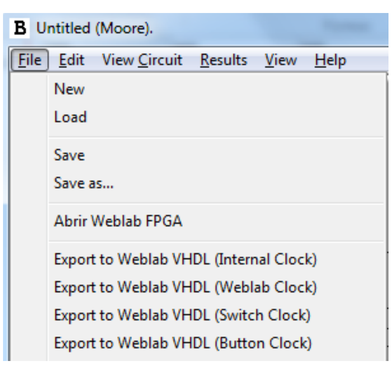

Fig. 21. Clock options

After saving the VHDL code, the user will repeat the process: Access to the WebLab-Deusto web page, upload the VHDL code, synthesize the VHDL, and finally load the bit file into the FPGA. After this, the user will interact with the system using the provided switches and buttons.

Fig. 23 shows the lit led after introducing four 1s in through the Switch 0.

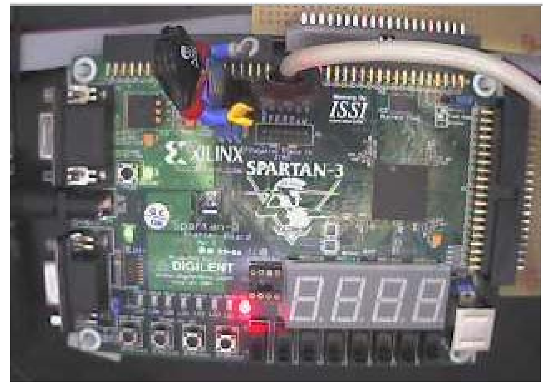

Fig. 22. FPGA board through the experiment's webcam

Other sequential systems can be designed and implemented in few minutes following the same order: FSM design, VHDL code generation, and WebLab-Deusto.

C. *Boole-Deusto and WebLab-Deusto Integration*

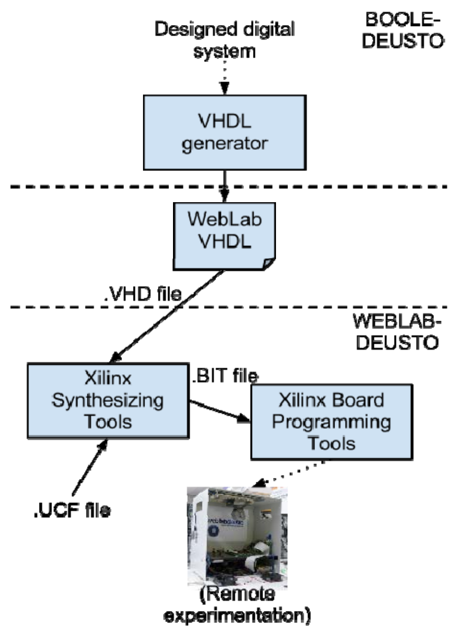

Fig. 23. Boole-Deusto and Weblab-Deusto integration

The aim has been to integrate WebLab-Deusto and Boole-Deusto in a single, mostly seamless workflow. Certain challenges had to be overcome. Fig. 23 shows how it has been implemented and deployed.

Back when Boole-Deusto was created, remote experimentation support was not an anticipated feature. Several additions to Boole-Deusto have been done. The most noteworthy is probably the capability to generate specialized VHDL code compatible with Weblab-Deusto.

Weblab-compatible VHDL code has certain requirements, such as a fixed set of inputs and outputs which matches the physical setup of Weblab-Deusto FPGA boards.

This match is described in UCF files (which, for security reasons, are fixed and located on the Weblab server itself). As fig. 23 shows, once the VHDL code for a certain design has been generated, eventually the VHDL file reaches the Xilinx Synthesizing Tools within the WebLab-Deusto servers.

Though WebLab-Deusto has long had the capability of experimenting with FPGA or CPLD boards remotely by providing a BIT file, this was not enough, due to several reasons. Firstly, obtaining a BIT file from VHDL is not a trivial process, especially for an inexperienced user. Specialized development software is required, and it has to be set up appropriately for the specific board that the remote experiment uses. And secondly, in order to obtain a BIT a UCF file is also required, linking the logical inputs and outputs to the physical ones.

Apart from an inconvenience, allowing users to provide their own UCF files can be a security issue. Misuse can lead to physical damage to the experiment's hardware board.

To prevent these issues the WebLab servers would have to be able to synthesize provided VHDL code themselves. This is done using the Xilinx Synthesizing command-line. The server also links it against the correct UCF file, which it chooses after finding (or not) certain specific preprocessor switches on the VHDL. If the process succeeds, a BIT file is obtained and programmed on the physical board.

As depicted on fig. 23, once the physical board has been programmed by the Xilinx board-programming tools, remote experimentation may begin. The board, which will be running the designed system, is now displayed and can be controlled.

V. CONCLUSIONS AND FUTURE WORK

Through the use of Boole-WebLab-Deusto students can design a bit-level digital circuit and test it in a real board straightaway.

Traditionally, this process often required hours, guidance, and access to a local laboratory with specialized equipment. Now only a few minutes and a standard Internet browser are required. Students do not need access to specialized hardware (FPGA boards) and they do not need specialized software (such as Xilinx ISE tools), as WebLab-Deusto provides both remotely.

Previous remote-lab approaches [16] did handle the hardware requirements, but they still required the user to install the software tools on their machines and to configure and synthesize the digital circuit logic themselves. Doing this was far from trivial, as the tools were several gigabytes big, required registrations and administrator privileges to install, and were significantly hard to configure appropriately.

Because Boole-WebLab-Deusto has made the process relatively simple, it does no longer need to be restricted to universities. We believe that it should be just as effective in secondary and high schools. Students can create and test their own designs easily, promoting creativity and autonomous work.

This does not mean that it is less useful for more advanced users, because Boole-WebLab-Deusto does not make the circuit design process itself different. Simply, teachers and students can now focus on the circuit design and testing itself. They do not need to dedicate their limited time to auxiliary activities which were previously required, such as reserving and moving to a laboratory, setting up the hardware, the development environment, etc. They may still want to dedicate some time to them, but it can now be done only at their discretion. They are no longer forced to.

Boole-WebLab-Deusto is now a reality, and the functionalities described here are already available [10][12]. It is expected that next year, several digital-electronics classes at the University of Deusto will start using it regularly.

In the future, one of our goals is to gather usage data from real students, to analyze the results, and to improve the system based on the findings. Another goal is to include augmented reality in remote experiments, so as to improve the learning experience of the student by improving the quality, interest, and variety of experiments in a cost-effective way. This would be done by allowing the student to use a real FPGA to control a virtual model.

***Abstract*— The four year curriculum of the Electrical Engineering program includes a fairly diverse set of classes covering topics including electronics, electromagnetics, signal processing, power & energy, digital systems, as well as communication and control systems. While these topics constitute the core components in the technical education of a future electrical engineer, a major missing component is the holistic, system understanding of these individual topics.**

This paper describes a class addressing the integration of the technical topics in addition to defining the overall architecture, the modularity of complex systems, as well as the interfaces between the different components to satisfy design requirements. The new class is a project-based, one credit-hour class with a single weekly meeting in a laboratory environment. The paper describes the assigned projects as well as their proposed solutions. The paper also includes assessment data including student feedback from the first class offering. Assessment shows a great student enthusiasm towards the class. It also shows that the class improved the student's conceptual knowledge, knowledge retention, and problem solving skills.

Keywords—EE curriculum; EE design; system integration; project-based learning;

I. Introduction

Analysis of engineering systems is an important step in the design process [1]. This topic has been addressed using artifact dissection, where a complex system is dissected into components. The interactions between different components of a system are then studied and if possible the system is put back together. A number of educators have used the dissection concepts into engineering education [2-4], some as early as a part of the freshman engineering experience [5-6]. System design concepts have been integrated in undergraduate curricula through a sequence of undergraduate engineering clinic/design courses spanning freshman to senior years [7-9]. To adapt these models would require a significant revision of the undergraduate curricula and may not be suitable for all programs.

The 4-year curriculum of the Electrical Engineering (EE) program includes a fairly diverse set of classes. Besides the general education requirements, the curriculum is usually front-loaded with a foundation of Math, Sciences, and Computer Programming classes, followed by the general engineering classes (Circuits, Statics, Material Sciences, etc.) The middle of the curriculum usually covers the core topics of the discipline including: Electronics, Electromagnetics, Signal Processing, Power & Energy, digital systems, as well as Communication and Control Systems. The final year of the program is mostly spent taking advanced (elective) classes to satisfy the depth requirement in the student's area of interest in addition to the capstone design project. Each of these classes covers the fundamental concepts as well as the analysis and the design of basic components in the respective subjects. None of these classes discusses the design of a whole system.

Some programs focus on a sequence of interrelated courses with a laboratory experience to enhance the topical depth and expand them to system related topics. Some of the examples include microprocessor and electronic interfacing [10], semiconductor materials [11], digital systems [13], and embedded systems [12]. Furse et al developed new laboratories at the University of Utah that integrate electrical engineering concepts from multiple classes throughout the ECE program [14-15]. These courses have improved students' understanding of system design and how various concepts they learn in their several classes fit together [15]. Nelson and Hung used the significant system design in their embedded systems course to assess their undergraduate program outcomes [13].

The electrical engineering program at Ohio Northern University tightly integrates the courses with laboratories. Although some of the laboratory experiments involve the knowledge learned from other classes, the emphasis of each lab is still to enhance the concepts learned in that particular course with hands-on experience. Although the electrical engineering students acquire a great deal of theoretical and practical knowledge over the course of their four year education and gain knowledge in many different areas, they never encounter many problems that require them to pull knowledge from multiple classes for one project. This is why a System Design class is important. The class addresses the integration of various areas in addition to defining the overall architecture, the modularity of complex systems, as well as the interfaces between the different components to satisfy the specified design requirements and create an effective electrical

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

system. The class introduces a few new practical concepts that are not necessarily taught in classes, but are used a great deal by practicing engineers.

In this class, students are required to create common circuit configurations such as H-Bridge, relay circuits, and filters. These configurations may be conceptualized during various classes, but learning how to implement them can be essential in some occupations. System Design has a large emphasis on the design component. Students are given a project with some guidance, but must come up with their own design to implement during class time. Overall, it is believed that this class helped reinforce the topics learned in the electrical engineering classes and teaches students practical design concepts that will be invaluable in the workplace.

This paper provides a detailed description of the class format, the class contents, and the class assessment obtained from the first class offering in Fall 2012. The rest of the paper is organized as follows: section II describes the unorthodox class format. Sections III, IV, and V describe the various assignments in the class, together with their solutions. Section VI discusses the course assessment, and the paper is concluded with a summary in section

II. CLASS FORMAT

Considering the already saturated, concept-heavy, lecture-focused electrical engineering curriculum, the newly developed System Design class was designed to be a one credit-hour project-based class. In other words, the class met only once a week and in the laboratory room instead of a lecture hall. In every meeting, the instructor assigns a new for which the students are required to research and find a solution for. At the beginning of the following meeting, the instructor collects a design report before sharing one of the many possible solutions of the problem. The students then orally share their individual designs and compare them to the one suggested by the instructor in an informal discussion setting.

For the experimental projects, students spend the remaining time of the class creating a prototype of their favorite design working on individual work stations. The favorite design of a student can be their own design or another design suggested by the instructor or a fellow student, or even a hybrid combination of multiple designs. During this time, the instructor usually tries to supply the necessary components needed for the design and also helps debugging and/or troubleshooting any faulty setup. For the research projects, (non-experimental), students spend the remaining time of the class watching an audio visual presentation about the topic of the project. The presentation is followed by an informal discussion of the individual projects.

The overall student grade is the average of their grades in each of the various projects over the span of the semester. Each project's grade is a combination of the student performance in the pre-class research and their in-class prototype implementation or project discussion.

III. CONCEPTUAL PROJECTS

A total of three conceptual projects are included in the class. The topics of the three projects are system integration, Micro Electro Mechanical Systems (MEMS), and nano scale systems.

A. System Integration

This project discusses the hierarchical nature of complex engineering systems. The instructor explains how these complex systems are broken into a hierarchy of smaller subsystems that are designed and built by different groups or, in some cases, different industries. The instructor also explains the modularity of these subsystems and the importance of suitable interfaces between them.

As an example of a complex system, computers are used. A computer can be seen as a collection of hardware and software. The hardware includes the power supply, the processor, the memory, the storage devices, and the other peripherals that are all designed by different industries. Inside the processor, there is an ALU, registers, and other components. The ALU itself is made of a set of logic gates that are made of lower level semiconductor devices. Therefore, physics/chemists, electrical engineers, computer engineers, and computer scientists must work in harmony in order to design and build a computer. One can argue the need for mechanical engineers and artists to design the casing of the computer.

For their project, students are asked to individually create a detailed block diagram for a complex system of their choice and indicate the various skills/professions needed to create each block.

B. MEMS

This project discusses the design and the manufacturing processes of MEMS. Students watch a 42 minute video entitled Making Micro Machines: an overview of micro electro mechanical systems. This video, by Silicon Run [16], discusses the design, fabrication, testing, and packaging of some common MEMS devices.

In the video, MEMS devices are separated into three different categories, each of which is presented with a real life example: Microfluidic MEMS (Hewlett Packard's inkjet printheads), Optical MEMS, (Texas Instrument's digital micromirror devices), and Sensor MEMS (Freescale's Semiconductor pressure and inertial sensors).

For their project, students are asked to individually research a MEMS device and write a report describing its operation. The report should also describe the non MEMS alternative device and discuss the pros. and cons. of each technology.

C. Nanoscale Systems

This project introduces Nano scale engineering and Nano scale systems. In the class, students watch a 40 minute video entitled Nanotechnology: The world beyond micro. This video, also by Silicon Run [16], discusses engineered Nano materials and discusses their applications and their large scale productions.

The video starts by explaining how the property of materials changes at the Nano level and continues to describe the large-scale production of various Nano scale systems such as carbon nanotubes and polymers in Nano enhanced composites. The use of Nano scale technology in applications like tumor ablation and cancer biosensors fabrication, and integrated circuit fabrication are also discussed.

For their project, students are asked to individually research a certain device that is only realizable with Nano technology and Nano scale engineering. They submit a report that also describes the societal and economic impacts of the device and the technology.

IV. EXPERIMENTAL PROJECTS

Three experimental projects are included in the class. The topics of the projects are signal conditioning, sensor-actuator control, and analog filter design and implementation.

A. *Signal Conditioning*

In this project, the problem statement describes a position sensor used to achieve a closed loop control for an electric motor. The sensor output signal indicates the instantaneous angular position α of the rotor shown in Figure 1. Based on the position of the rotor [0˚ - 360˚], the sensor output can be seen as a sinusoidal signal in the range [-1.0–1.0V].

In order to digitally control the motor, the position signal must be digitized using an Analog to Digital Converter (ADC). The digital version of the sensor signal is then fed to a digital signal processor implementing to control algorithm. According to the data sheet of the ADC, it has an input range of [0.0–5.0V]. Therefore, the project assignment is to create a signal conditioning system that will map the sensor signal to be used at the input of the ADC from the range [-1.0–1.0V] to [0.0–5.0V] without any loss of information.

The signal conditioning system must be self-contained on a circuit board and must be easy to integrate with the rest of the system as shown in figure 2.

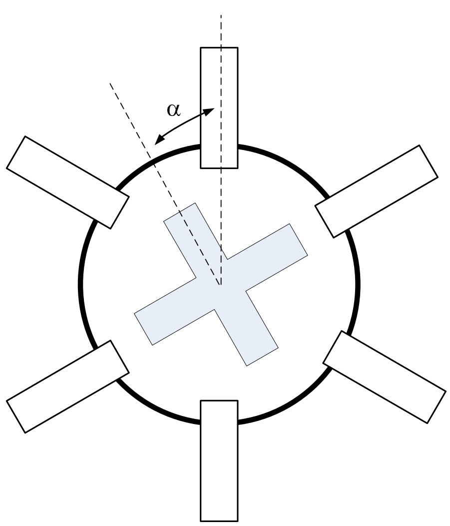

Figure 1. Rotor position in an electric motor.

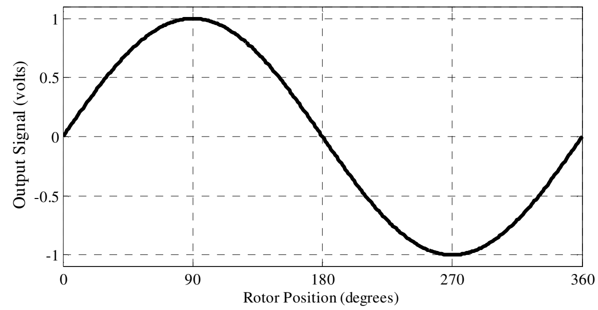

Figure 2. The output signal from the position sensor.

Solution: One of the many possible solutions to this project is to cascade two operational amplifier-based electronic circuits. The first circuit should be an analog adder that simply adds a 1.0 V to the signal to shift it to the range [0–2.0V] and the second should be an analog non-inverting amplifier with a gain of 2.5.

B. *Sensor-Actuator Control*

The problem statement of this project describes a 40V AC motor operated via a 3:1 step-down transformer that transforms the 120V, 60 Hz outlet signal to the appropriate 40V. The customer requests that the motor should be turning (electrically “on”) during the day and must stop turning (electrically “off”) at night.

The project assignment is to create a control system that automatically turns the motor on/off based on the available amount of light around it. The control system must be self-contained and easy to integrate with the whole system as shown in figure 3.

Solution: Any possible solutions to this project must include a light sensor. One of the solutions is to use a Light Dependent Resistor (LDR) in a voltage divider configuration. The voltage across the LDR, varying with the ambient light, must be enough to control a BJT switch circuit, which in turn trips an AC relay to turn the motor ON/OFF.

C. *Analog Filters*

The problem statement of this project describes an ADC where the sampling circuitry operates at 10,000 samples per second. The problem is that the ADC is generating aliased discrete-time signals in the sampling process. In other words, some of the signal components at the input are violating the Nyquist sampling criterion.

The student assignment is to create an analog filter that allows only the signal components with the appropriate frequencies to reach the sampling circuit as shown in figure 4.

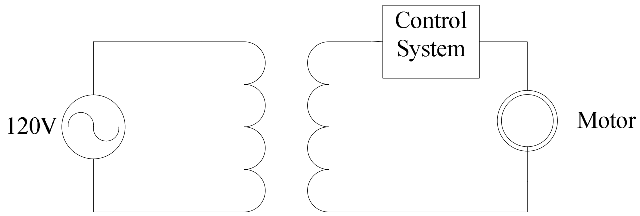

Figure 3. The AC motor setup with the integrated control system.

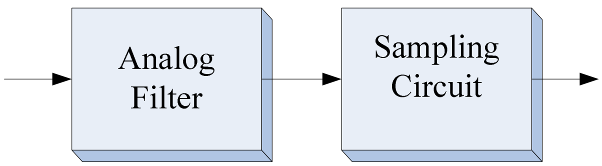

Figure 4. The anti-aliasing system.

In order to create this filter, students must determine the type of the filter to be designed (low pass, high pass, band pass, or band stop) and they also must determine its appropriate cutoff frequency/frequencies. Students are also instructed that the filter must be an active filter (use at least one operational amplifier) and that it must be an RC filter (no inductors used).

The design must be first tested using computer simulations using any available software package (Matlab, Spice, etc…) to show that the frequency response of the filter satisfies the design requirements. The project is then experimentally tested using a variable frequency signal generator and a digital oscilloscope.

This project can be extended for multiple weeks where students are asked to design and build a high pass, band pass, or band stop filters.

Solution: With a wide variety of possible solutions, the Sallen-Key filter configuration [17] is suggested for the implementations of second order filters.

V. Final Project

In the last few weeks of the semester, students still work on weekly projects. These projects, however, are designed to culminate together in a big system. The various weekly projects are described below.

A. H-Bridge

This project addresses the control and operation of a direct current (DC) motor. This type of motors, when appropriately controlled, can provide the motive power in both rotating directions. The goal of this project is to create a circuit that reads digital control signals (clockwise, counter-clockwise, and stop) and accordingly provide the appropriate voltages and currents to the motor without the need for any re-wiring or circuit modification.

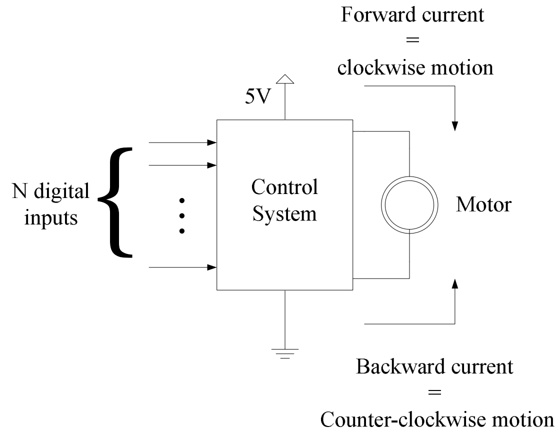

Figure 5. The control system configuration.

The system to be created must be designed to connect to a DC motor as shown in Figure 5. The system is to be powered by 5V DC and must have only digital inputs (logic on and logic off). The output of the control system is a two wire terminal that is connected to the DC motor. The output should be either +5V (forward current) to create a clockwise motion in the motor or -5V (backward current) to create a counter clockwise motion in it.

Solution: The solution of this project is the famous H-bridge circuit.

B. Signal Transmitter

In this project, students create a transmitting node in a communication network. This communication network will eventually include a combination of transmitting nodes and receiving nodes. In the problem statement, it is not enough for a receiving node to know what the transmitted signal is, but also which node transmitted it. This gives the network administrator the ability to set the receiving nodes to respond only to a subset of transmitters when needed.

The project assignment is to create a digital signal transmitter that has, in addition to the clock input port, 3 input push buttons (Forward, Backward, and Stop). A schematic diagram of this system is shown in Figure 6. When any of the three push buttons is pressed, the transmitter must generate a sequence of 7 bits. The first 4 bits designate the identity of the transmitting node (regardless of the pressed button) and the remaining three bits designate the action to be taken based on the input. A sample waveform out of the transmitting node is shown in Figure 7.

Solution: While students have the choice to select the details of implementing their system, Field Programmable Gate Arrays (FPGAs) are suggested as an adequate platform. In this platform, VHDL codes can be used to model a multiplexer that, based on the pressed input button, routes one of the hard-coded signals to the output port.

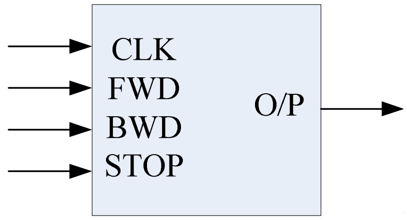

Figure 6. A schematic diagram of the transmitting node.

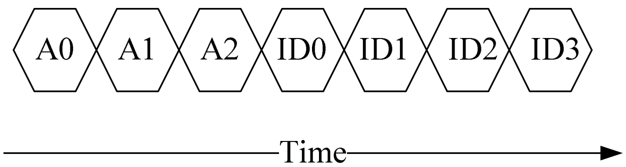

Figure 7. A sample waveform out of the transmitting node.

C. Signal Receiver

Along the same lines of creating a transmitting node, this project assignment is to create a digital signal receiving node that can detect and decode transmitted signals sent by the "recognized" transmitting nodes. The system must have a clock and receiving input ports. The receiver should also have a single output port consisting of 3 bits corresponding to the three functionalities (Forward, Backward, and Stop).

Inside the block, pattern recognition systems must be created to identify a signal transmitted by a "significant" transmitting node and decode the command.

Solution: Just like the transmitter, FPGAs are suggested as an adequate platform. In this project, VHDL codes are used to model a pattern recognition Finite State Machine (FSM). The FSM looks for the pre-determined ID pattern. When a positive ID is detected, the 3 following bits are read to decode the transmitted command.

D. System Integration

The rest of the semester will be used to integrate the various components of the final projects together to create the overall system. With different students creating different transmitting/receiving nodes, the group will get the chance to test which nodes are capable to control the operation of the DC motor and which ones are not.

VI. Course Assessment

In the inaugural offering of the class, a total of six senior level electrical engineering students were enrolled. At the end of the semester, these students participated in the evaluation of the class. The evaluation included both numerical evaluations as well as a subjective evaluation section where students can write any comments/concerns about the class.

The numerical evaluations included questions for which students had to pick one of five answers, namely: strongly agree (5), agree (4), neutral (3) disagree (2), or strongly disagree (1). Table I below shows the average value of the six different students' submissions for each survey question.

Looking at the table, one can clearly see that students appreciate the value of the course and they strongly feel that it helps their problem solving and their independent/creative thinking abilities. Students also seem to enjoy the homework & lab structure of the class. The only problem, however, is the workload of the class as many students felt that it exceeded the norm they would expect in a single credit course.

On the subjective/comments side of the course assessment, the following comments were received:

- The course did a good job of having students review material that had been learned over the years
- This course also simulated some real-life situations
- The course should be worth at least 2 credits
- I learned a lot and it helped me remember many of the past topics we learned as an underclassman
- The class was a needed addition to the Electrical Engineering schedule
- This class was the first only-lab class we have had

VII. Summary

In this paper, we discussed the inaugural offering of a novel, project-based, single credit-hour course in the Electrical Engineering program. The projects and the assignments in the class are designed in a way to combine two or more subjects from the EE topics and integrate various components in a big-picture complex system.

Assessment results showed that students appreciated a project-based class that simulated real-life situations and help them remember and integrate material from different classes. Results also showed a great satisfaction with the format of the class.

TABLE I. The numerical class evaluations

Question	Avg
This course enhanced my problem solving abilities	4.7
The homework helped my understanding of the material	4.0
The laboratory assignments facilitated my learning experience	4.5
The laboratory assignments and course material reinforced one another	4.4
The professor encouraged independent/creative thinking	4.5
The professor used teaching methods that helped me learn	3.8
The workload for this course in relation to other courses of equal credit was as expected	1.8
Overall, I had a quality learning experience	3.7

An Approach for Teaching Logic Programming based on Real-world Applications

Alexsandro S. Soares*, Carlos R. Lopes*, Paula C. Souza* and Sergio C. Peres*

***Abstract*—In this paper the authors describe their approach towards motivating students in the learning of logic programming is given. The focus here of the authors is on real world applications. Nowadays, where internet applications are still a hot topic, the development of projects related to internet applications are quite strongly motivated. Unfortunately, many of the resources used in logic programming that help us to explore the development of programs for internet purposes are not so freely available. The authors therefore had to develop much of the material used in order to be understood by first year university students, who were in fact the target group. Preliminary results showed an augmented interest in the learning of such concepts and as a result an increase in the pass rate was achieved.**

I. Introduction

Logic programming (LP) is an important programming paradigm in Computer Science. It is for this reason many Computer Science and Computer Engineering programs include logic programming in their curricula. Logic programming presents some concepts that are not present in procedural programming, which is predominant in the majority of the courses. Many students have trouble in learning the concepts of logic programming. As a result, many students fail in achieving a pass grade. This is not the only problem. Unfortunately, there is the erroneous idea that logic programming is only for academic purposes and for this reason is not utilized by the software industry. Therefore, the instructor finds that extra work and effort is needed in order to motivate students. We, the authors believe that an innovative methodology along with motivating resources should be developed to help students with the learning of logic programming. In this paper the authors describe their proposal and resources that they themselves have developed over the last years that aid students in the development of real-world applications. This is by no means an easy task as students who take a logic programming course at our university are first year university students and the development of real-world applications requires many concepts that are the content of subsequent future courses.

In order to develop our approach it was perceived that it is possible to achieve internship reports and monographs written by students in their final year. Actually, for some degrees related to Computer Science and Computer Engineering internships and monographs are mandatory and their reports are made publicly available. The authors investigated some of these reports and observed that most of them are part of actual projects addressed to companies. In general these projects consist of developing internet applications, which require tools for web development and database management. Unfortunately, there do not exist books that cover such features in prolog, a representative programming language of the logic programming paradigm. For instance, "Prolog Programming for Artificial Intelligence" [1] [2] [3] [4], which is a well known book for the learning of prolog and artificial intelligence, has no reference for internet applications. As a result, the authors developed teaching aids in order that web development and database management could be carried out in prolog. During the course, projects are proposed based on internship reports and monographs mentioned earlier. The project to be developed is a simplified version of the project described in the reports.

In order to compare our approach with that previous, the authors developed a questionnaire that was submitted to the students. The compilation of the answers led us to conclude that it was incremental in terms of learning and motivation the use of the methodology and resources developed by the authors. We believe that our approach can be used successfully for any course towards logic programming.

The rest of the paper is organized as follows. Section II describes related work. Section III provides evidence on the lack of knowledge currently available for prolog applications. A panorama of logic programming from within our institution appears in section IV. Section V describes the motivation for our approach. A description of our approach for motivating students for the learning of logic programming appears in section VI. The evaluation procedure of our approach is described in section VII. Section VIII discusses the results of our evaluation. Finally, section IX relates our conclusion.

II. Related Work

Several projects have been developed, which aim at motivating students for the learning of logic programming. Many projects are targeted at developing games and solving puzzles based on the use of artificial intelligent (AI) techniques. Examples include Robocup, Sudoku, and Ataxx.

RoboCup [5] is an international scientific initiative with the goal of advancing the state of the art of intelligent robots. When established in 1997, the original mission was to field a team of robots capable of beating the human soccer World

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Cup champions by 2050. Robots equipped with AI strategies can be used to motivate students.

Another motivation for students to learn logic programming are logic games. There are several puzzles available which are fascinating. Some of these problems can be solved effortless in prolog [6].

Ribeiro et al. [7] developed a sophisticated competition framework based on ataxx, which involved prolog programmed contenders and game servers, including an appealing GUI. Ataxx is played on a grid board by two opponents that take turns to play, each one playing with pieces of a different color. Although using very simple rules, Ataxx provides a rich and interesting environment for gameplay. The authors reported that the response obtained from students was impressive, surpassing their most optimistic expectations.

Linck and Schubert [6] understand that computer students should learn more than one programming paradigm. Each paradigm is unique and influences in the way a person reasons when solving problems. The authors argue that logic programming should be one these paradigms. In order to motivate the student, the authors suggest the use of practical applications. Moreover, the authors present a didactic plan for the learning of logic programming.

Different from previous projects, our approach relies on developing interesting applications for the software industry, where is a growing demand for internet applications. Actually, most of the students that achieved their degrees are employed by companies that develop internet applications. Therefore, the authors aim at proposing projects that consist in developing internet applications using prolog. For this reason, the authors understand that projects based on this feature are quite motivating.

Our observation is in agreement with Selby [8] findings that describes four different approaches to teaching programming. One of this is named full systems approach where the learners design a solution for a non-trivial problem, often a representatite of real life. They are immersed in the full use of language constructs and tools. The essential concepts are introduced to learners only when the solution to the problem requires their application. Selby also describes four different studies reporting success in using a full systems approach.

III. Logic Programming in the Real World

In this section we provide evidence that goes some way to explain why prolog might be considered just a programming language for academic purposes with no application in the software industry. Howevever, the authors do not consider this to be a fact and provide proof that shows the use of logic programming in several important applications.

A. *Is Prolog used only for Academic Purposes?*

It is not difficult to find some questions related to the use of prolog in the development of real applications. Next, we describe some quotations related to this issue.

“Many study Prolog in college, but I have personally not come in contact with it professionally. The traditional examples given are AI and expert system applications, but what have you used it for and what made Prolog a suitable language for the task?” [9]

“I am trying to research the use of Prolog now, outside of Academia and am struggling. I was hoping somebody could point me to some real- world applications.” [10]

Therefore, there is some evidence that the use of prolog in the software industry is not well known. Actually, there is some debate on this issue as one can see in the following quotations.

“I’ve heard that before: that many companies using Prolog commercially want to hide (or at least not openly state) that they use the language.” [10]

“Quite a few commercial users do not admit they use Prolog openly. These users are likely to have good reasons for that, but for the LP community this is an unfortunate situation. ” [10]

In fact the lack of knowledge of prolog applications contributes to the erroneous idea that LP is only useful for academic purposes and as a consequence does not help to motivate students to the learning of the paradigm.

B. *Applications of Prolog in the Real World*

Despite the lack of knowledge related to prolog applications, there are many examples of the use of prolog in the ”Real World”. Below there some quotations that show the use of prolog in the development of serious applications.

“We implemented a Prolog-based system to write a mobile phone email configuration tool. It was used by several of the world’s largest mobile phone makers as a web-based support service.” [9]

“Remember a particular project about 3 years back. For an insurance firm they used this software called GraphTalk. It has a nice OOP architecture. The programming language used was Prolog.” [9]

“The IBM Tivoli Enterprise Console is an event management system that uses a dialect of Prolog for its event processing rules.” [9]

“I am working on a Prolog and C based application for Airlines Fares processing in Travel domain. This is fares engine with around one million line of code in prolog and 1/2 million line of code in C. This application was developed by Galileo (now Travelport) and EDS (now HP) around 10 years back. Now this is in maintenance and enhancement mode. A number of airlines are hosted on this. Other than above two SITA also use this application for pricing their itineraries. This application was started in 1998 to remove the dependencies on IBM mainframe which cost for each transaction. This is using SICStus prolog. If you are interested in working in above application please let me know, I am working on this application for past 7 years and leading a team of 40 people” [9]

IV. A Panorama of Logic Programming in our University

The Computer Science degree offered by our department at Federal University of Uberlandia has a curriculum in which logic programming is offered in the first year. In terms of programming abilities, a procedural programming course is informally required before attending the LP Course. Knowledge related to building internet applications and databases management is offered in subsequent courses during the following years.

In our university special attention is given to the use of free software. Based mainly on this feature, our department decided on the use of SWI-Prolog, a well known prolog implementation [11].

Students have taken the logic programming Course over the last twenty years. Unfortunately, students have trouble in achieving a pass grade. As we stated before, many students have trouble in grasping the concepts of logic programming. This is not the only problem. Also in our university there is the erroneous idea that logic programming is only for academic purposes and for this reason is not utilized by the software industry.

V. Motivating Students: developing internet applications

In Brazil there are some degrees related to computer science. The curriculum of each one is established based on guidelines approved by the government. In most of them internships and monographs are mandatory or optional. Even when it is optional, it is a fact that most students will submit it. There is this feeling that they are quite important for completing the graduation.

Most of the programs make publicly available the work developed by students in their internships and monographs in their final year. In this way, anyone has access to them. It is possible to download all of them if someone wants to. For instance, the Information Systems Program at University of Blumenau keeps all the monographs on its web page [12]. In general, students in their final year have to write a monograph in order to receive a degree. Many monographs are result of the development of a system to solve a real problem for the business industry.

The authors downloaded some reports available in several universities. In most of the reports we found evidence that the work was related to a project developed for a real company and it was to be developed as an internet application. For instance, Rocha [13] describes the entire development of a system called Winepad, which was developed for the iOS platform. Basically this system allows establishments to show their wine list to their customers in a fast, simple and original manner. The user can choose a wine in a practical and fun way. Also, it is possible to perform a filtering by price and type of grape.

For accomplishing a job in a company, the student is trained in how to use the tools required to develop internet applications, such as:

- editors for HTML [14] [15], PHP [16], JavaScript [17] e CSS [14]. Dreamweaver [18], EasyPhp, and Netbeans [19] are widely used tools for development.
- database management tools. In many of the reports we found references for InterBase, MySQL [20], PostgreSQL [21], and DBDesigner.

The examination of reports helped us to confirm that the development of internet applications is still a hot topic today. Informally, in conversation with students, we were told that Internet is a topic that everyone is interested in working with.

VI. Details of our Approach

In this section the authors provide details about their approach. Essentially, there is a project assignment that consists of developing an internet application. In order to accomplish the task, the student has to go through some phases making use of the material we have developed.

During the course students, organized in groups, have to develop a project. Such a project is based on internship reports/monographs available in other institutions. As already mentioned, it is not difficult to find those reports/monographs. The instructor is responsible for allocating an internship report/monograph for each group of students.

The project is composed of three phases:

1) Development of the html pages.
2) Development of some features using a prolog server and management of files based on prolog predicates.
3) Integrate the application with a database manager.

There are few references that help students in developing Internet applications using SWI-Prolog. Actually, one is expected to build internet applications through the use of the manual. Even worse we have found no material aimed at developing internet applications for first year students. As a result, we had to plan and develop the required resources.

In the first phase of the project development we provide material for helping the students in the design of html pages. We showed how it is possible to construct html pages using prolog. Emphasis is given to HTLM5. It was not our goal that students become HTML programmers. Basically, the material we have developed contains the following:

- Elements of HTML5: menus and forms. The reason for giving emphasis to these two components is explained by the internship reports. Essentially, we can develop a simplified version of the application by using these two elements. We describe basic information that allows the inclusion of styles in HTML pages. Also, a basic introduction to CSS is provided.
- Description of tools for creating and visualizing html pages. We describe how to visualize html pages making use of internet browsers. Also, we emphasize that the material we released is a basic introduction to HTML. It is necessary to read more to gain a better understanding in designing HTML pages. Also, we inform that there are tools that allow the user to develop HTML pages quickly.

In the second phase we present information related to:

- Basic concepts on networks and internet. We describe the process that allows communication among computers. We show how a web page stored on a computer can be viewed through another computer. There are different types of content that can be viewed on the Internet. We focus on text and html because we illustrate prolog code that allows the dynamic creation of answers based on these two kinds of content.

- Set up a web server in prolog. We show how to create a web server in Prolog. Also, we provide examples for serving text and html. We also show at this point how to create dynamically an html page. It is interesting to note that the SWI-Prolog page is served by a prolog server.
- Interacting with prolog server by means of HTML pages and saving information in files. By means of a menu and form, it is possible to establish an interaction between an user and the internet. This interaction may involve reading data from the form and saving it in a file using predicates prolog. We provide an example showing how to implement such an interaction. This a good example because it is a motivation for the learning of input/outputs predicates.

Finally we provide instructions for integrating prolog with a database management tool. Based on the requirements for the applications described in the reports/monographs we provide the following information:

- Instructions for installing a database manager. We provide instructions for installing SQLite on windows and linux.
- a template for creating a database. We provide instructions for creating a database file and tables based on information described in the internship reports.
- a template for inserting, updating and recovering information in the database.

The material released to the students contains an example that illustrates how to use the templates. More details of databases management were omitted. The students were told that more information would be given in subsequent courses. Again, we have just provided basic information for accomplishing the requirements existing in the monographs. With the above information the students were capable of developing a project.

VII. Evaluation

The approach used earlier in the course consisted of developing projects based on XPCE. XPCE is a toolkit for developing graphical applications in prolog and other interactive and dynamically typed languages. The XPCE GUI system for dynamically typed languages has been part of SWI-Prolog for a long time. It aims at a high-productive development environment for graphical applications based on prolog. In order to compare both approaches, the one using XPCE and the other using HTML, we developed a questionnaire. A hard copy questionnaire was sent to every student who had the opportunity to work with HTML and XPCE.

In the cover letter the purpose of the questionnaire was clearly described by means of a short text. It was signed by the department head. The cover letter also contained a clear set of instructions explaining how to complete the survey and where to return it. Students had to return the questionnaire to the secretary of the department. Furthermore, emphasis was given on making clear that respondents must not provide their names.

The questionnaire was composed by 13 intensity questions based on the Likert-type answer scale. We also provided in some questions space in which answers could be written in their own words. Special attention was given to a small number of short questions with a simple language. The questions were related to the following issues:

- how easy is it to integrate HTML and prolog
- preferences between HTML and XPCE
- Preferences between saving and recovering data using management of files in prolog and a database management tool.

VIII. Discussion

Students have provided excellent feedback. All the questionnaires were returned. Based on their answers, it was possible to make an analysis on some of the strengths and weaknesses of our approach.

With respect to the material we released for working with HTML, the majority of the students understood the objective, which was to give a brief introduction on the topic. Also, they know there are many other materials to complement the learning in greater depth.

Respondents also preferred to develop a graphical interface using HTML instead of XPCE. Given that internet applications are quite motivating, we really believe that HTML is a good choice.

However, respondents showed preference in manipulating files in prolog rather than using a database manager. We believe that providing information for first year students on this topic is not an easy task. An extra effort should be made to improve the material. Some prolog instructors might like this result because working with a database manager requires less effort in learning the prolog language with respect to input/output of data. However, it is not good for our purposes as we want to develop applications that use most of the technology that companies employ to develop their products, in particular internet applications.

Figure 1 depicts that the pass rate increased with the application of our methodology. In this figure we show the pass rate in the semester before the application of our approach (label *before method*) and the average pass rate after the application of our approach (label *after method*)

IX. Conclusion

Logic programming is an important programming paradigm. In this way, efforts should be made to make its understanding easier. The development of real applications should be pursued in order to motivate students, practitioners and organizations. In this paper we made a contribution toward to this end.

Preliminary results showed an increase with respect to learning and motivation. However, it is necessary to keep monitoring the progress of students in order to verify the consistency of the results.

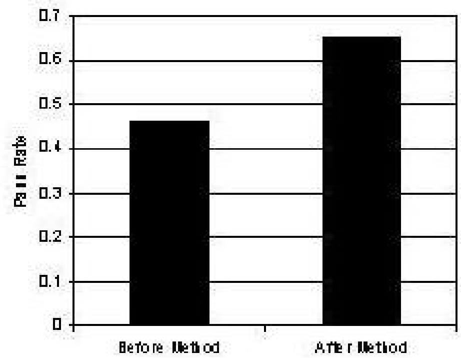

Fig. 1. Pass Rate before and after the application of our methodology

ACKNOWLEDGMENT

The authors would like to thank the pro-rectory for undergraduate studies at Federal University of Uberlândia, which provided financial support for the authors.

***Abstract* — Currently, semiconductor devices, VLSI circuit design and fabrication are specialized fields in electrical engineering curricula. Teaching microelectronics technology is dependent on the availability of resources and is mainly being taught at universities where a fabrication facility is available. As such, microelectronics engineering education is in transition. New thoughts are being given to topics such as what constitutes microelectronics process design fundamentals, how to shrink the gap between industrial and academic perspectives on process design and how to help students gain more experience and knowledge. This paper proposes and discusses an efficient teaching methodology for micro- and nano-electronics education. A Technology CAD (TCAD) course integrated with an online simulation laboratory at undergraduate/graduate level. The aims of the course are the development of theoretical and practical skills in semiconductor manufacturing using virtual wafer fabrication. It is expected that the students shall have increased affinity towards semiconductor fabrication, improved academic skills, abilities and knowledge. The impact of the proposed teaching methodology on the learning process will be presented.**

Keywords— remote laboratories; microelectronics education; TCAD; semiconductor fabrication; online learning

I. Introduction

Currently, micro- and nanoelectronic device, circuit design and integrated circuits fabrication are specialized fields in electrical engineering curricula. Due to very high cost, microelectronic fabrication facilities are available only in a few educational institutions. As such, microelectronics technology is mainly being taught at universities where a fabrication facility is available and the microelectronics engineering education now is in transition [1]. New thoughts are being given to topics such as what constitutes microelectronic process design fundamentals, how to shrink the gap between industrial and academic perspectives on process design, and how to help students gain more experience and knowledge [2].

To extend microelectronics engineering education, various approaches are being made such as, teaming with semiconductor industry partners who are willing to share their facilities with the students by providing remote access to their expensive facilities on the internet. The remote access has additional advantage of students need not physically entering the facility. Another possible solution towards microelectronic education is to use virtual laboratories [3].

Technology computer aided design is commonly used for developing semiconductor technologies. TCAD has now become an important component of modern semiconductor manufacturing and a new framework is needed for advanced microelectronics education. To meet the goal, integrated measurement-based microelectronics and VLSI engineering laboratory with simulation-based technology CAD laboratory has been reported [4].

Learning environment is continuously evolving and it is all the more important to change the present "teacher centered methods" to "student centered methods". Now-a-days, the trend in education strategies goes in the direction of learner centric learning. In learner centric learning, learners are expected to participate more actively in the learning process to improve their own learning. The objectives for the integrated technology CAD laboratory is to introduce the students to the basic and advanced processing technologies that are being used in semiconductor fabrication. This paper will discuss an efficient teaching methodology for a TCAD course integrated with a simulation laboratory at final year undergraduate and graduate levels. The main aim of the course is the development of theoretical and practical skills in semiconductor manufacturing via virtual wafer fabrication. Both laboratory and simulation experiments are used in the learning process.

II. Methodology

Laboratory courses are integral part of engineering education. Simulation is a popular teaching technique amongst educators. Simulation helps student to understand a situation, a process and the replication of real situation activities. In semiconductor manufacturing context, computer simulation brings in the real situation on the computer screen. With the capability of technology CAD tools, now-a-days, students can use softwares such as, Silvaco and Synopsys Suites to observe process detailed effects in a space through animation, just like in a real situation. Currently available commercial softwares suites are predictive which increase student understanding of the semiconductor process.

The advantages of computer simulation in designing microelectronic process are that it can boost designers' capabilities towards quickly evaluating the quality of process. If computer simulation is integrated in learning process, it is predicted that students can be more creative. It is obvious that process and device simulations are very dynamic fields and are developing rapidly, which makes them difficult even for technologists actively involved in this area to keep abreast of developments. To maintain rapid advancement, device and process designers are increasingly turning towards computer simulations of the process, design of electronic devices and circuits for solutions [5].

Advancements made in methods of communication and research is beginning to change the traditional scenarios of the classroom. The exponential growth of the Internet has promoted opportunities for new ways of teaching and learning. The Internet has now become a valuable source of information that breaks down many of the barriers associated with a traditional classroom teaching. Despite the radical changes in the context of communication, university curricula have been slow to adapt the changes. In particular, microelectronics educational programs still focus almost exclusively on teaching traditional technical skills and the students receive little explicit training in how to apply these skills in circuit design [6].

Current TCAD use is mostly limited to process and device simulations; however, it may be extended for the development of compact models, suitable for circuit and system level analysis. Compact model generally include SPICE-like parameters obtained from the device electrical behavior. Also, variations of SPICE-like parameters need to be carefully estimated to achieve acceptable model predictivity, including process yield evaluation. This paper proposes and discusses an efficient teaching methodology for microelectronics courses when "integrated" with an online technology CAD laboratory [7].The purpose of this research is to examine the effects of integrating the SPICE parameter extraction tools in technology CAD course as a subject for the design of integrated circuits.

A. Research Purposes

The dynamics of teaching and learning usually involves three entities: the teacher, domain of knowledge, and the student. The Internet has today become the fourth entity. Learning environment is continuously evolving and it is all the more important to change the present "Teacher centered methods" to "Student centered methods." The purposes of the research are as follows: (i) to identify the interest of the students in microelectronic circuit design through process/device simulations, device characterization, SPICE parameter extraction, and finally the circuit design, (ii) to study the effect of integrating Technology CAD laboratory for use in developing the circuit design process via simulation, and (iii) to study the effect of integrating class room teaching (theory) with the online technology CAD laboratory.

B. Technology CAD

Before the 1980s, numerical simulation was not considered seriously for electronic device development. Instead, the device structures and fabrication steps were modified following a set simple guideline (scaling laws). However, as the channel length is scaled below 1000 A, scaling laws no longer can accurately predict the operation of the devices due to the increasing structural complexity and small geometry effects. TCAD has become the principal tool for virtual characterization of technology development and uses computer simulation to model semiconductor process and device operation. In the deep sub-100nm regime, the increase of feature complexity and scaled geometry make it more challenging for TCAD to predict the characteristics of the devices. The design for manufacturing solution when incorporated in TCAD provides a bidirectional link between manufacturing and design. TCAD bridges the gap between the world of technology and that of circuit and system design. Conventional (core) TCAD is currently used for process and device simulations. It uses process recipe and layout information to simulate the several fabrication process steps (e.g. oxidation, implantation, lithography, deposition, etc). Originally, these tools were used as individual units to simulate individual fabrication process steps.

With increasing computer power, TCAD is being used more and more efficiently to explore new device architectures and optimize process flows. TCAD is being increasingly used in manufacturing for advanced process control and parametric yield improvement. Extended TCAD modules include the characterization (measurement) of the devices and extraction of SPICE parameters [5]. The aims of the TCAD course are the development of theoretical and practical skills in microelectronics. Both laboratory and simulated experiments are used in the learning process. Our approach addresses these issues by way of an internet accessible simulation laboratory which uses the world-wide web and the trend towards network-based computing. A typical TCAD flow for microelectronics circuit fabrication is shown in Figure 1.

C. TCAD Tools

Availability of TCAD softwares has made possible accurate multidimensional simulation of realistic device structures and processes. Advanced set of TCAD tools is available from universities and from TCAD vendors. Commercial TCAD vendors (Silvaco and Synopsys) provide an excellent collection of TCAD suites. Commercial TCAD tools may be used to show students the link between physical and electrical simulation through the mixed TCAD and electrical simulation abilities of Silvaco and Synopsys tools. Advanced TCAD suites include process simulation, device simulation, compact models parameter extraction and circuit simulation suites, interconnect simulation, and optimization to other technology CAD requirements. However, the use and maintenance of coupled TCAD tools becomes difficult and requires a significant level of user experience. Historically, all the TCAD tools developed were available on various UNIX-based platforms. Attempts have also been made for Windows versions of TCAD tools, but the use of Windows versions are very limited, as the software packages are distributed and supported by third-party vendors. Current TCAD tools accelerate advanced technology development with Process and Device modeling capabilities.

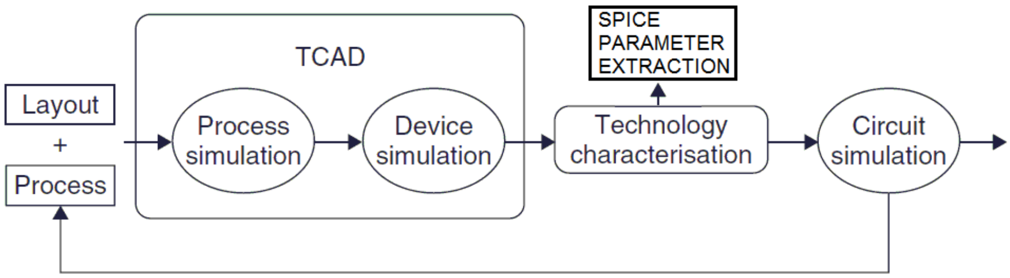

Figure 1. TCAD flow in semiconductor circuit fabrication.

D. Technology CAD laboratory

In an earlier paper [7], we have described an approach and methodology and addressed the issues arising in combining virtual device fabrication, remote electrical measurements, modeling and TCAD simulations of basic semiconductor devices. Integrated measurement-based online microelectronics laboratories with simulation-based technology CAD laboratory have been described [8]. For a TCAD course, the associated Technology CAD laboratory may include (among others) the following experiments:

1. BJT: Gummel plot
2. BJT: Output characteristics
3. SPICE Model parameters extraction for BJTs
4. MOSFET: output characteristics
5. SPICE Model parameters extraction for MOSFETs.

III. CASE STUDY: LABORATORY SESSION

Each laboratory session (duration 3 hours) generally consists of three parts. In the first, students characterize one or more electronic devices such as a bipolar transistor (BJT) or a MOSFET using the experimental setup shown in Figure 2. In the second part, they extract the SPICE model parameters from the dc characteristics obtained in first part. Finally, they are asked to prepare a short independent report that includes a brief description of the experiment, comparisons between experimental measurements, and extracted SPICE parameters.

A. SPICE parameter extraction: NPN BJT

With the extreme scaling down of devices in high volume manufacturing, it is imperative to develop TCAD based methodologies encompassing process design to device simulation, and characterization for SPICE parameter extraction. SPICE parameters are essential in integrated circuit design and the accuracy of circuit simulation depends on the accuracy of the transistor model. The four most widely used silicon bipolar transistor compact models are:

- SPICE Gummel-Poon (SGP)
- Most EXquisite TRAnsistor Model (MEXTRAM)
- HIgh CUrrent Model (HICUM)
- Vertical Bipolar Inter-Company (VBIC)

During teaching of TCAD subject, the students are taught on these bipolar device models. The accuracy of compact models in circuit simulation depends not only on the correct physical description of various physical phenomena in the device but also on a reliable, robust, and unambiguous extraction methodology for model parameters. An automated measurement system capable of accurately measuring the various characteristics of a device and extracting parameters is very important. General requirements for parameter extraction methodologies are:

- well-defined, simple, fast and reliable procedures
- standard measurement equipment
- modular - implementation enabling quick adaption to process and model evolution
- model implementation in CAD systems

Bipolar junction transistor (BJT) is one of the most widely used semiconductor devices in integrated circuits. Because of its superior speed performance, such a device has found wide applications in high speed switching and digital electronics systems. In this experiment, students characterize the current-voltage characteristics of an NPN bipolar junction transistor using the IIT-Kharagpur Lab-on-Demand [8].This experiment involves three parts: (i) measurement of current-voltage characteristics (both Gummel and output characteristics) and their plotting, (ii) SPICE model parameter extraction, and (iii) comparison of SPICE model with measurements. Main objective of this experiment is to expand students' knowledge of bipolar junction transistor devices.

In the following, SPICE Gummel-Poon (SGP) model parameter extraction techniques is illustrated. Specifically, the extraction of current gain and related compact model parameters is described. The current gain may be obtained from the Gummel plot and also the output characteristics of the bipolar transistor. An automated measurement setup that may be used for the extraction of device parameters is shown in Figure 2. An Agilent 4156C-based or equivalent system is chosen as it has the capability to measure dc characteristics of semiconductor devices. As device characteristics evaluation is the prime objective, the controller is commonly used to collect the measured data and transmit the data to the host computer for post-processing. In order to extract the model parameters, several measurements are performed at different biasing conditions at room temperature.

As a first step, the forward Gummel plot is measured. In order to measure the forward Gummel characteristics of the transistor, the Agilent 4156C is programmed as a voltage or current source. For measuring the Gummel characteristics, the instrument is programmed to sweep emitter-base voltage from 0 to 1 V. Both the base and collector currents are measured. The forward current gain is plotted as the ratio of the measured collector current to the base current. The output characteristics of the BJTs are measured using either forced base-emitter voltage (kept constant), or a forced base-current (kept constant). In the measurement collector-emitter voltage is swept and the collector current is measured. Figure 3 is a screenshot showing the Gummel plot and the extracted SPICE parameters; the current gain and other associated parameters for a NPN BJT.

The next step is the inclusion of the finite base, collector, and emitter resistances in the model. The emitter resistance is determined by stimulating the base with a current in strong saturation and measuring the collector-emitter voltage. The collector current is kept small (typically less than 1 microAmp) and the applied base current is swept up to 10 mA. The inverse of the gradient of characteristics can then be used to obtain emitter resistance. The measurement of the collector resistance is similar to the emitter resistance. Here, current is applied to the base and collector, and the collector-emitter voltage is measured. The base current vs. base-collector voltage characteristics for two collector current values is measured and the collector resistance is determined from the ratio of collector-emitter voltage difference to collector current difference. Figure 4 is a screenshot showing the output characteristics and extracted SPICE parameters; the Early voltage and collector resistance for a NPN BJT.

B. SPICE parameter extraction: MOSFET

The main objective of this experiment is to expand students' knowledge of MOSFET devices. We use modeling and simulation tools to gain deep understanding of device physics and process effects on MOSFET performance. The four most widely used MOSFET compact models are:

- Charge-Based MOSFET Models, such as BSIMx
- Surface-Potential Based MOSFET Models, such as HiSIM
- MOS Model 11
- EKV Model

The outline of this laboratory exercise is similar to the BJT experiment described in detail above. The students study the current-voltage (output) characteristics of MOSFETs using similar measurement system. From the output characteristics, the related SPICE parameter such as, channel length modulation and the source-drain resistances are extracted. Figures 5 shows the screenshot of output characteristics along with the SPICE parameters extracted for a MOSFET.

C. Student Performance Evaluation

For each laboratory session, students need to submit a project report (written report) related to the experiment and appear in an oral presentation. Although it is recommended that students work individually on each experiment, but it is also allowed to be in a group of two students for collaborative study. The written report needs to focus on the experimental/modeling results including a short description of the techniques that were used. The oral presentation should focus on presenting the results of the study. Also difficulties especially for measuring equipment and techniques need to be focused. The grade was set according to the output of each

Figure 2. Experimental setup for semiconductor device characterization. BJT output characteristics is visible on the instrument's screen.

student in these three components as mentioned above. The final assessment included the evaluation of the all the experiments performed by the student during the semester.

D. *Effectiveness Evaluation of Online Laboratory*

To understand the effectiveness of these online simulation experiments (especially the SPICE parameter extraction part) towards students' learning was to examine what motivated the students to take the online TCAD laboratory course and to assess their interest in receiving services online. The impact of the proposed teaching method on the learning process was investigated by analyzing the data collected through a online survey designed specifically for this study. In our study, student's grades were also monitored to evaluate their academic performance. Our evaluation showed that the use of online simulation experiments available in the TCAD laboratory was beneficial for the students. The authors believe that the improved students' academic performance and their positive attitude towards the course are mainly due to the integration of simulation tools in microelectronics teaching.

E. *Limitations*

This study is also not without some limitations. First, the students (learners) participating were first-time to this online laboratory. It is possible that more experienced students might have different needs than the first-time user counterparts. Second, data were collected from students enrolled in a single institution. Students using this online laboratory from other institutions may have motivations for taking online courses and may like to see different academic needs. Overall, this study provided some useful insights into the needs of learners who wish to take online microelectronics course when integrated with a TCAD laboratory.

CONCLUSION

This paper described a project that introduces university students to the high technology fields of microelectronics through the use of web-based "hands-on" experiments. It is expected that the outcomes of this study shall have significant impact on the future practices in teaching microelectronics in distance education mode. The proposed methodology allows students to explore microelectronics course starting from underlying science, to device physics, to process and extract SPICE model parameters essential for the circuit design. This research contributes to the development of an interactive Technology CAD course using "online" TCAD laboratory and conventional class room teaching. The new technology CAD course integration with the virtual wafer fabrication (VWF) in designing microelectronic devices, process and circuit simulation is shown to enhance student's interest. The authors believe that the improved students' academic performance and their positive attitude towards the TCAD course are mainly due to the integration of simulation tools in teaching.

***Abstract*—The paper considers how research in product/process design methodologies can be used to design engineering curricula. Following the Function-Behavior-Structure (FBS) framework for product design, we show how the curriculum design task can be separated into functionality of the curriculum, student behaviors and course structures. We then describe possible ways in which such a design could help us explore the possibilities of designing different types of curricula with the same functionality so that we could develop flexible, fault tolerant, scalable curricula that *evolves* with changing circumstances. These requirements are not generally included as curriculum design criteria and an approach that highlights the role of "robustness" would be useful.**

Keywords—curriculum design; design; flexibility; fault tolerant; function-behavior-structure framework; robustness

I. Introduction

Although program faculty across the world design and redesign their curricula, the authors have not read many papers on curricular design processes that apply research on product/process design methodologies. The paper intends to highlight findings from research on design methodologies, as well as observations on some important trends in education, and consider how these findings and observations are and are not applied in curriculum design processes. As a starting point in the exploration, the authors consider three very different curricula, all of which generally intend to achieve similar student learning outcomes, because the various organizations that accredit engineering programs in different global regions articular similar student outcomes.

II. Starting Point

First, consider the mechanical engineering (ME) curriculum in Fig. 1, which begins in the sophomore year, because this is often where various engineering curricula differentiate. While specific details, e.g., course names, specific course content, detailed order of courses, etc., of the curriculum in Fig. 1 differ from other ME curricula, overall the curriculum is similar to many other ME curricula in major universities around the US.

In contrast to the curriculum shown in Fig. 1, engineering students in the General Engineering program at the Iron Range Engineering (IRE) program take 15 one-credit courses in each semester of the last two years of their four-year engineering program, having completed their first two years at another institution. Over the last four semesters, IRE students complete 60 credit courses (32 technical credits and 28 professional development credits); however, they earn the majority of these credits while working on four industry-sponsored projects (one per semester) [1]. For breadth, "when the technical learning cannot be in the context of the project, another deep learning activity is chosen and executed. Typical activities include: (a) design or execution of Model Eliciting Activities (MEA); (b) student designed, conducted, and analyzed experiments; or (c) construction of an advanced computer program, e.g., expert system or simulation program" [1].

Finally, at Maastricht University the knowledge engineering program is built from blocks, 6 blocks per year. In the first two years, two of the six blocks are projects and parts of the other four blocks are projects. In the last year, two of the blocks are for a bachelor thesis, another block is project work, and a project is incorporated into another two blocks. So, the Maastricht program is "designed around the Project-Centred Learning (PCL) teaching method. It resembles the Problem Based Learning style, which Maastricht is well-known for. The PCL educational model is small-scale and student-oriented. You work in small groups on complex and challenging projects that require you to develop a variety of skills" [2]. ABET accreditation criteria would be used to evaluate the ME program and IRE program while Engineers Australia criteria would be used to evaluate the Maastricht program.

All three programs: the ME curriculum, the IRE General Engineering curriculum, and the Maastricht Knowledge Engineering curriculum are very different implementations, but all are intended to achieve roughly similar student learning outcomes. Methodologies that foster creation of very different embodiments to achieve the same desired outcomes are a focus of research on design methodologies [3-5]. The paper intends to highlight some findings from the research on design methodologies and consider how these findings are applied in

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

curriculum design. The approach has elements in common with [6] who has considered a systems design approach to instructional design but differs from it in the adoption of a Function-Behavior-Structure approach [7].

For concreteness, the paper will, at times, focus on ME curricula, although many observations will be relevant to any engineering curriculum. Also, there is another set of issues, relevant to curriculum design and change, which will not be explored in this paper. Once an engineering curriculum that is different from the existing curriculum has been designed, questions arise about how transition to the new curriculum will be accomplished. Transition introduces many logistical issues, e.g., which curriculum requirements will apply to which students during the transition. Also, course content and/or instructional strategies may be different once transition to the new curriculum is complete. Issues related to these changes may draw on research related to organizational change. However, issues that are related to curriculum and organizational change are not the focus of this paper.

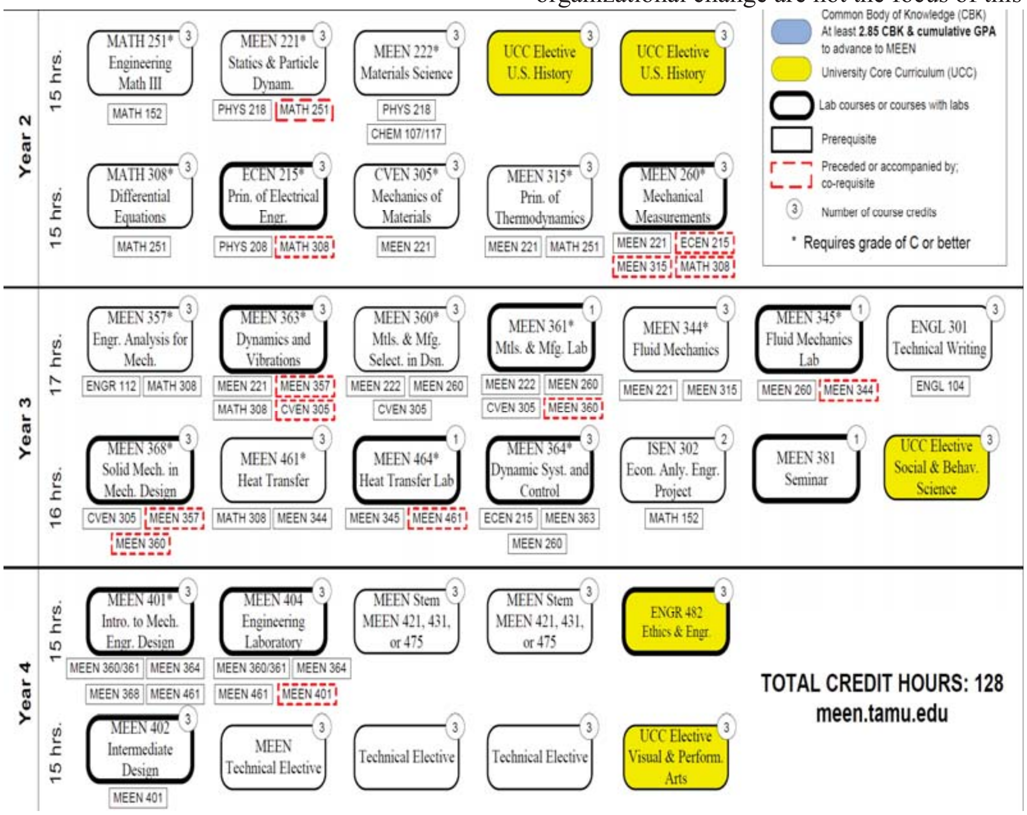

Fig. 1. A mechanical engineering curriculum (from sophomore on) together with the prerequisites.

III. Traditional Curriculum Design

Observations in this section summarize the authors' observations of engineering curriculum design. They are not results from rigorous analysis of systematically collected empirical data captured from multiple curriculum design processes at multiple institutions. Instead, they are offered to differentiate current curriculum design processes from process that might draw from design methodology research. In practice, curriculum design processes appear to draw from combinations of three curriculum design approaches:

Design by Experience: This is the de-facto craftsperson approach where the focus is on course content and faculty members fashion their curriculum design decisions or instructional approaches based on personal experience and selected empirical evidence of what appears to be useful.

Design by Trial and Imitation: Recently, more emphasis has been placed on "benchmarking", imitating "best practices", and drawing on ideas from other programs. Here, innovative faculty members became acquainted with approaches at other institutions and are inclined to try something they have observed, often based on a combination of "gut" feeling of "what works" and their sense of what could be adapted to their course, beliefs, and personality. If results from initial trial are encouraging, then they may stick with it. Later, others may choose to imitate or adapt it with varying degrees of success.

Approaches based on Research on Learning and Education: The next category is that which is based on a scientific discovery approach to curriculum design; here the system to be studied is a group of students and various hypotheses (based on discoveries made by innovators) are tested and the results are disseminated. In many cases, results show [8-10] that initial hopes for great improvement are not borne out. However, evidence on research and education does not appear to cause significant changes in how curricula are modified [8-10]. Reasons for resistance to change include: (a) research results appear to contradict the years of experience built up [8, 9] and (b) the scientific approach tends to engage critical/analytical aspects of the instructors thought process rather than collaborative, innovative aspects. It is therefore not surprising that approach (2) based on trial and imitation seems to be more successful than approach (3) in changing the hearts, minds and behaviors of instructors, i.e., curriculum designers.

A. *Observations about Traditional Curriculum Design Approaches*

All three approaches are bottom-up and based on the following underlying assumptions:

a) The basic building block of curricula is the course. Instructors bring with them all of their assumptions and experiences that accompany thinking in terms of courses.

b) Instructors and students know what a course is, they know what each course is intended to achieve, and they how it relates to overall curriculum objectives.

c) Curricula are built by assembling courses. If each course achieves its objectives, then the curriculum is successful

As a result, faculty members engaged in curriculum design expend a vast amount of effort in deciding which courses are necessary and which are not, and then modifying and optimizing courses that are selected. In this scenario, the overall curricular goals are “emergent behavior” and there is no guarantee that the requirements will be met [11].

B. *Importance of Flexibility, Fault Tolerance, and Scalability*

While curricula are intended to achieve learning outcomes, other characteristics such as flexibility or adaptability to changing external conditions, fault tolerance, and scalability are also desirable characteristics and should also be design criteria. Inability of curricula to be adaptable and scalable has been the focus of recent, widespread media attention.

A case study in flexibility, fault tolerance and adaptability , is the development of the worldwide web: While many computing technologies stagnated after a while, the web grows and evolves at an amazing rate, from simple computer sharing in the 1970s to the internet of things in 2010 [12]. This has occurred in spite of competition. Several features are noteworthy and contribute to robustness of the web:

1) **Flexibility:** The original idea for the web was not presented as a “finished product” but as a “work in progress” that invited people to contribute with open protocols and low barriers to entry.

2) By allowing web designers access to the source code, the dominant idea was to “copy and edit” not reinvention.

3) Parallelism inherent in flexible open systems enables greater exploration of the space of possibilities. But it comes at the cost of efficiency. In other words, the web sacrificed optimality of performance for robustness, openness and flexibility.

4) **Fault Tolerance:** Unlike earlier implementations of hypertext, where there was a central database of links and link failures were not tolerated, the web is based on loose coupling and decentralized service, leading to greater fault tolerance.

5) The web was able to recruit thousands of people to contribute content---this eventually overpowered proprietary corporate networks. You did not have to ask anyone to do something interesting. There was no pre-screening for access.

6) **Scalability:** Scalability is achieved through gradual learning and investment possibilities.

So, questions may be raised about how curriculum design could be done to enhance (a) robustness and fault tolerance, (b) flexibility with low barriers to entry (which result in very different metrics than retention and time to degree), and (c) scalability. Design methodologies, which are explored in the next section, can provide a framework that allows us to explore these ideas and see to what extent this could be done in curriculum design.

IV. Conceptual Design Methodology

Findings from research on design methodologies that will the focus of this paper are drawn from the Function-Behavior-Structure (FBS) approach [7]. An overview of the FBS approach, at least for the work in this paper on curriculum design, is summarized in Fig. 2.

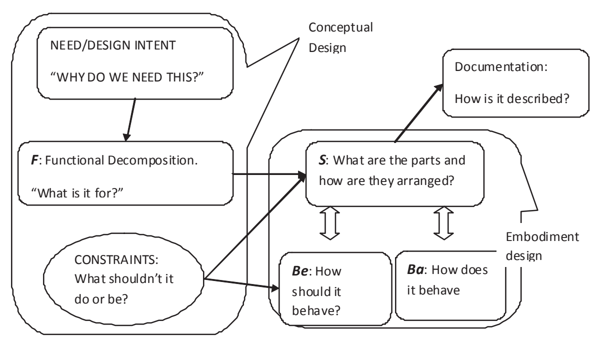

Fig. 2: Core elements of a conceptual design process. Arrows represent flow of the processes.

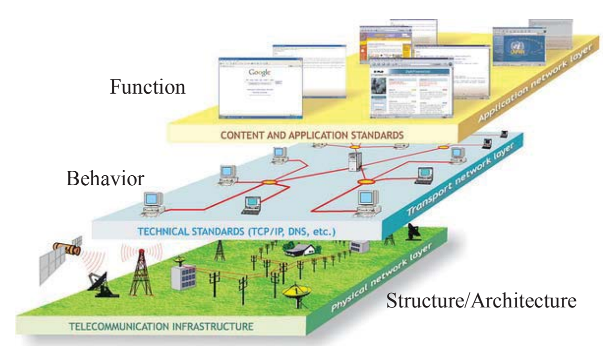

Fig. 3: The three layered architecture of the web showing FBS framework.

Function, behavior, and structure are often referred to a layers, although their interdependent relationships are often more complex than the word suggests. Interestingly the web itself has three identifiable layers that can be mapped to the three elements of conceptual design: (i) Function (Content and

Application Standards), (ii) Behavior (Technical Standards: TCP/IP, DNS, etc.), and (iii) Structure/Architecture (Telecommunication Infrastructure).

Further, although listed in a sequence below, steps in the FBS framework are implemented in complex, iterative combinations that are highly dependent on results that emerge from a particular step. However, for simplicity, steps in the FBS framework are described as:

1) **Need Analysis:** This is the highest level of the function layer development and describes desired input-output behavior of the whole system. Designers and their clients work together to identify principal client needs and constraints that restrict the range of feasible alternatives. Then, designers convert needs and constraints into an abstract, high level specification listing inputs, outputs, and transformations required to convert inputs to outputs. Each transformation is described as a functional requirement.
2) **Functional Decomposition:** Functions are hierarchically/recursively decomposed into a sequence of subfunctions (each with their own input-to-output transformations). The process stops when realizable behaviors or components are reached.

The first two steps are usually referred to as conceptual design and several systematic ways to do this have been described in the literature. At the end of a conceptual design process, clients and designers should have a clear answer to the question: "What needs to be done?"

3) The third step is to list possible alternative behaviors that could satisfy the functions in the function hierarchy that emerges from step 2. These list the expected behavior of the system. This is also the stage where the constraints imposed on the system can be made explicit.
4) This step develops potential structures intended realize behaviors from step 3 while meeting the constraints.
5) This step documents the structure, its actual behavior, and the resulting functionality.
6) Next is the evaluation/assessment step (this is akin to the sensing function in a feedback loop system). We evaluate the structure of the component or system and evaluate its actual behavior and compare with the expected behavior.
7) This is the redesign or modification step:
   a) First if there is a significant discrepancy between expected and actual behavior, then the structure or expected behavior needs to be modified.
   b) If the expected and actual functionality is different, then the behavior and/or functional hierarchy must be re-examined and modified as required.
   c) If client needs and constraints are not met, needs and constraints are re-evaluated. Also, design intent/need is re-evaluated.

Initial focus on the conceptual design process is extremely useful in capturing the current state of design intent without mandating "how it could be done". Clear, explicit description of design intent allows for greater exploration of different possible embodiments, although time is spent on conceptual design may initially appear to delay implementation or waste resources.

Example: Smartphone Input System

The FBS framework in Fig. 2 and the seven steps are stated very abstractly. Before examining implications of the FBS framework for curriculum design, a concrete illustration may help elaborate the nature of the framework and design steps.

Before 9 June 2007, smartphone designers asked the following question with respect to user data input: "How can the designer include a keypad in the phone so that it is compact, but still useful?" Phones such as the Motorola Razr or various sliding, folding, or flipping phones were considered innovative solutions to the question. However, when Apple introduced the iPhone in 2007 (along with the Samsung 700), it became apparent that the question could be framed differently, "How can a user communicate their intent to a smartphone?" If functional requirements are framed this way, then many behaviors are possible, e.g., eye-tracking. Further, a keyboard becomes only one possible embodiment (a tangible or visible form of an idea, quality, or feeling) to realize behaviors that achieve the stated function. By framing user intent differently, Apple designed a phone with no keyboard. Rather, it offered an entirely new embodiment with combinations of behavior, e.g., tapping, swiping, etc., that achieved the desired intent.

Functional/conceptual design: For example, in the phone input system example stated above, a simplistic description of the function layer would be: (i) Input: User intent; (ii) Output: Phone actions; and (iii) Function: Transform user intent into phone actions.

Behavior Layer: With this functional description of intent, it may be observed many behaviors may achieve the same functionality [13]. For example

1) Touching the screen causes it to translate and make physical contact with a circuit board completing a circuit (keyboard structure)
2) Touching the screen causes it to deform thus changing the capacitance causing a change in electric current (capacitive touch screen of iPhone)
3) Touching the screen creates a radio frequency resonant vibration which is detected using electromagnetic circuits (Wacom tablet)
4) Touching the screen causes the deformation of a layer under it whose resistivity changes which can be detected. (resistive touch screen)

Each of these behaviors results in the same primary functionality but leads to different possible structures. However, there are secondary behaviors that result that may be beneficial or not. For example the capacitive touch behavior cannot be caused by stimuli from a simple plastic stylus. So a design needs to consider these effects and then decide what changes need to be made.

With the iPhone, the behavior layer would be that physical contact with the phone surface should lead to an electrical signal that will activate certain programs in the phone to perform certain actions. The structure layer would be the keyboard layout or arrangement of the conductive layers on the phone surface. Each kind of behavior may strongly influence the structure and the combination is usually called an embodiment.

V. Mapping FBS Framework into Curriculum Design

With the preceding description of the FBS framework and process, implications for curriculum design processes can now be explored. Table 1 maps steps in the FBS design process to analogous elements in the curriculum design process.

Table 1. Mapping between FBS Design and Curriculum Design Steps

FBS design	Curriculum Design
Need/design intent	What are sources of design intent: mission statement? Capstone course learning outcomes?
Functional decomposition	Program learning outcomes, i.e., student capabilities at program completion
Expected behavior	Student activities in the classroom (attending lectures, doing homework or individual or group projects etc.)
Structure	Weekly Course outline, scheduled classroom activities
Documentation	Course catalogue, Syllabus, website etc.
Evaluation of expected vs. actual behaviors	Student Assessment, internal meetings with different groups, student evaluations etc, research into course outcomes etc.
Evaluation of expected vs. actual functionality	ABET, SEC or other external bodies.
Evaluation of overall intent and functionality	Society, Various governing boards, market survey etc.
Redesign	Usually focused on course topic redesign and occasionally course structure redesign

A. Where might curriculum designers look for design intent?

How well do department mission statements illuminate curriculum design intent? Consider, since the authors are familiar with it, the mission statement of the Department of Mechanical Engineering at Texas A&M University. Analysis of the mission statement reveals program clients are broadly described as "students, the state of Texas and the nation," and within this broad population, the mission statement highlights three subgroups: industry, government and academia. Core functions can be extracted from the mission statement: (i) preparing students for leadership positions and successful careers in industry, government and academia, (ii) advancing knowledge in mechanical engineering, (iii) spawn new economic development in Texas, and (iv) provide professional development activities. However, from an undergraduate ME curriculum perspective, these core functions do not offer anything substantive. An informal survey of mission statements of other leading ME departments around the country provides similar findings. Therefore, curriculum designers need to look for other sources for design intent, needs, and constraints.

If the endpoint of the undergraduate ME curriculum is taken as attributes of students who complete the senior capstone courses, then the learning outcomes/objectives of these courses could be used as the output of the transformation that the ME is intended to achieve. At Texas A&M, the objective of the capstone design course is: "At the end of this course, students should be able to design a system, component, or process to meet desired needs within realistic constraints such as economic, environmental, social, political, ethical, health and safety, manufacturability, and sustainability."

As stated, the course objective is specific enough for further steps. Also, it addresses part (3) of the mission statement directly and partially addresses part (1) of the mission statement. Unfortunately, if only the learning objective for the capstone design course is used as the design outcome, the outcome does not distinguish a ME curriculum from graduates of other engineering curricula. At this point, the design process is challenged because curriculum designs lack solid descriptions of ME-specific outcomes for ME curriculum design. Likely these outcomes will be related to four design and analysis streams in many ME curricula: structure, thermal systems, materials and manufacturing processes, and control systems. Course outcomes of courses in these four streams might be analyzed to determine ME-curricula-specific outcomes, but the detail involved for this analysis is beyond the scope of the paper.

Conceptual design also requires characterization of the inputs. For ME-specific curricula, i.e., the last three years, the inputs are the course learning outcomes of key first-year courses. For engineering curricula, these key courses include second-semester calculus, second-semester physics (often electricity and magnetism), and chemistry. At Texas A&M, these course outcomes can be found [14].

B. Conceptual Design: Behaviors and Functions

In the FBS framework, a core distinction must be made between "behaviors" and "functions." As described above, course learning outcomes can provide valuable starting points for extracting outcomes and inputs. However, course learning outcomes are mix behaviors and functions. For conceptual design, emphasis needs to be placed on functions. In the context of curriculum design, behaviors refer to activities and responses of the students in the course while functions correspond to student capabilities upon course completion.

For example, if one considers the course learning outcomes for ME capstone design course [14, p. 27], they are listed as a mix of behaviors and functions. Careful analysis of these course outcomes using the above distinction between functions and behaviors yields the following list of functions:

F1: Analyze client/sponsor requests in order to produce quantitative design requirements

F2: Evaluate concepts and select the most viable

F3: Analyze and address risks associated with a concept

F4: Identify the visceral, behavioral, and reflective aesthetic components of designs

F5: Assess risk in a project and assign appropriate contingency

The other course learning outcomes for the capstone design course are behavioral outcomes, since they are related to specific patterns of behavior during the course, not functional outcomes expected to be achieved upon course completion:

B1: Describe activities that occur during each stage of a design process, and distinguish among products of each stage

B2: Develop a functional representation of a design solution based on design requirements

B3: Describe differences among various logical and intuitive innovation methods

B4: Apply prescribed innovation methods to generate conceptual design solutions

B5: Identify sources of design information and differentiate among them to determine their usefulness

B6: Record all project-related activities in a design notebook

B7: Recognize ever-present roles of design in human activity

B8: Formulate methods to improve the predicted reliability of a concept

B9: Design a suitable work breakdown structure for completing a project

B10: Employ software tools to manage projects

B11: Assess project performance though a project tracking method

Learning outcomes for other courses in the curriculum can also be separated into behavioral and functional features. If behavioral outcomes are included in formulation of the conceptual design, then the conceptual design over constrains the remaining design process by mandating behaviors during the course as functional requirements. For example, it is an unacknowledged fact that actual delivery of a course may deviate significantly from the written syllabus (behavioral requirement) and the way most faculty member have taught the course, but that the functional outcomes are achieved. Undergraduate advisors in large-enrollment programs know differences in behaviors or structural embodiments, e.g., which faculty members teach different sections of the same course, and offer advice on which faculty members to pick. Students often elect to postpone a course until their senior year, even though the curriculum in the published catalog (structural embodiment) recommends taking the course in the sophomore year. So, in some ways, engineering curricula can be viewed as fault tolerant or flexible (depending on your perspective), even though fault tolerance or flexibility were not intended functional requirements. Two points are worth noting. First, flexibility and fault tolerance are rarely functional requirements for engineering curricula, even though the examples of Iron Range Engineering and Maastricht University suggest that significant flexibility is possible. Second, separation of functions and behaviors (as well as structural embodiments) in curriculum design should promote achievement of greater robustness, flexibility and fault tolerance.

VI. Inputs and Outputs of an ME Curriculum

Examination of the inputs to a ME curriculum, i.e., outcomes of key first-year courses mentioned above, and outcomes of the curriculum, which may be described at the outcomes of the senior capstone course reveals that [15-17] ME curricula take students who are able to:

I1: Isolate bodies and represent the forces on them (at a novice level)

I2: Describe and apply the rules of geometry and calculus to obtain quantities (such as velocity and acceleration) related to the motion of particles

I3: Describe and apply the conservation laws of physics to particle systems

I4: Represent the laws of physics (especially the laws of statics) in mathematical form and solve the resulting equations (typically algebraic equations)

I5: Apply their knowledge of mathematics to analyze various special problems in mathematics

I6: Explain relevance of molecular structure and properties to a wide variety of real technological problems

I7: Describe the modern model of atomic structure and its origins in quantum mechanics

I8: Apply concepts of thermodynamics to evaluate compounds as fuels or energy sources

I9: Describe connections between chemical bonding and material properties like electrical conductivity

I10: Predict or explain properties of elements (atomic size, ionization energy, chemical reactivity, etc.) in terms of electron configurations;

and transform them into students who are capable of

O1: Identify societal needs and constraints

O2: Design systems, components, or processes that satisfy (O1)

O3: Developing multiple viable alternative designs

O4: Evaluate the alternatives to see how well they meet the requirements and what are the risks to society from these design.

Thus, a significant transformation is expected in three years.

VII. Designing For Robustness

Design rules or guidelines [18] are useful for avoiding some obvious pitfalls in the course behavior and structure design. Design experience has suggested that the following guidelines are useful for robust designs:

R1: **Provide short and direct paths**: In curriculum design, one implication is “don’t layer multiple prerequisites” or “ensure prerequisite content occurs in close temporal proximity to courses expecting prerequisite content.” Teaching content that will not be applied within a short period of time violates the rule of short, direct paths and reduces robustness.

R2: **Avoid steep gradients in properties**: This relates to interfaces. In curriculum design, one implication would be “make sure that the content and presentation of the prerequisite content is similar to that of the following class.” This helps avoid failure to apply requisite content because far transfer is required instead of near transfer.

R3: **Do not over constrain**: For curriculum design, one implication is to “avoid unnecessary prerequisites.” This is directly related to flexibility and adaptability of the curriculum.

R4: **Exploit symmetry/similarity**: Curriculum design implications include teaching different content streams or threads similarly, e.g., consistent use of conservation laws or solution tricks are avoid or similar.

R5: **Separate functions**: Component designer try to avoid optimizing a component for two different criteria. In curriculum design, one implication is to focus a module on one function instead of trying to accomplish too many things at once. ***This design rule is directly related to fault tolerance and loose coupling and is a key to evolution of the design by changes being made by the actors based on their own assessments.***

When literature on how novices approach product design is studied [19, 20], analogies with novice curriculum designers present themselves:

A1: Novices in both the fields lock into to a trial and error mode early in the design process without considering the functionality or the design strategy [20].

A2: Novices in both fields persist with a single structure without frequent evaluations (comparisons with required functionality). They do not develop multiple alternatives, since they do not carry out frequent evaluations, i.e., they do not show metacognitive behavior. [19] showed that experts generated roughly 3 times more alternatives than novices.

A3: Novices indulge in structure-up sequential design, instead of function-led hierarchical design. They tend to think of the artifact as a sequence of connected parts, instead of a purposeful holistic design. As a result, designs are cluttered, not clean. In curricular design, this behavior can be seen in the packing of individual course content to meet different detailed needs rather than course contributions to overall functional requirements.

A4: Novices also tend to develop functionality at too concrete a level ("where should we put the keypad, rather than "how do we sense user intent") and hence eliminate many interesting designs. Examine most course learning outcomes for concreteness versus functionality.

A5: Design experts realize that interfaces (user interfaces, connection between parts, etc.) can make or break a design. Novices frequently ignore interfaces or consider them as an afterthought. Studies of statics and dynamics at Texas A&M [14, 15] have shown the extent of the misalignment between first-year course content and student success in the engineering courses. Careful consideration of interfaces between different curriculum segments is essential for smooth functioning.

VIII. Potential Implications of Curricula Design using a FBS Approach

Finally, a FBS approach to curriculum design might lead to "out of the box" engineering curricula. Consider the following implications:

- Sources of curriculum design intent are limited.
- Courses may disappear from curricula because viewing "the course" as a fundamental unit of a curriculum is simply a particular embodiment. However, the particular embodiment is such a pervasive dogma that MOOCs and other novel instructional strategies methods still apply it.
- A second dogma appears prevalent: "every student should exhibit the same behavior". As was learned from the iPhone example, different behaviors can engender the same functionality. For example, a student could meet functionality of senior capstone design by choosing an internship or research project provided assessment approaches have been implemented to evaluate achievement of required functionality.
- Instead of courses being used as prerequisites, specific functional learning objectives could be used. This may directly impact time to graduation.
- Finally, instead of using course grades, a student may be able to develop a capabilities portfolio and use that as a means for advancement in the program.

Lafayette, IN, United States of America
cvieira@purdue.edu, admagana@purdue.edu

Abstract—**This paper describes the outcomes of a three-day teacher professional development workshop aimed at introducing concepts, principles and practices of computational thinking. The guiding research question for this study was: How teachers implement the backwards design process embodying elements of CS Principles (i.e., computational thinking big ideas and computational thinking practices) in the context of their classrooms? The participants of this study included 15 elementary, high school and college level teachers who are also graduate students from a master program in engineering. As part of the workshop participants developed a learning activity that included a set of learning objectives, the design of computational thinking related activities considering appropriate pedagogical strategies, and the integration of mechanisms to evaluate students' performance. Here we describe (a) how participants embodied the CS Principles in the design of learning activities to be integrated into their classrooms, (b) how they used the backwards design process as a tool to implement elements of the CS Principles and (c) what is teachers' performance in integrating CS Principles to the design of learning activities as evidenced by their peer evaluations. Finally, we propose the use of backwards design process together with the CS Principles as a framework for the design of computing learning activities and the development of teacher professional development programs in computing education.**

Keywords—Computing science; education; lesson plan; backwards design

I. INTRODUCTION

Computing has become an essential tool for international competitiveness in supporting scientific and engineering developments. For instance, the use of computational tools to solve complex problems that are not solvable neither through theoretical nor experimental approaches is increasingly common [1-3]. In spite of this trend, there is a lack of well-prepared workforce with computing skills that empower them to solve these complex interdisciplinary problems. Developing countries, such as Colombia, are not the exception. Specifically, Colombia faces the threat of falling behind if it does not keep up with new technological advances [4] and the appropriate training of its future workforce.

Three decades ago the Colombian government began working on initiatives aimed at improving informatics and computing knowledge among its people [4, 6]. For this purpose, Alianza Futuro Digital Medellin (AFDM) [7], a partnership between educational institutions and the private sector, was created in order to support the transformation of technician and professional technology education through teacher professional development. Eight institutions are part of AFDM and their major goal is to provide adequate training to high school teachers. Their ultimate goal is that once high school teachers are well equipped with pedagogical content knowledge to introduce computing at the pre-college level, then these will be able to prepare high school students capable of enrolling in software-programming degrees or training courses in higher education.

One of the AFDM's strategies to accomplish their goals is by means of a teacher professional development program that supports elementary and middle school educators to complete a master of engineering degree at Universidad Eafit. This master program is focused on the area of educational technologies. As part of this program, a course called Advanced Topics is a required course to all participants. Among other topics explored, the course included a three-day workshop to introduce computational thinking concepts, practices and perspectives [20]. Along with this workshop we conducted a research study to identify how this group of teachers adopted and adapted the CS Principles [21] to the design of a learning activity guided by the backwards design process [10].

The guiding research question for this study was:

How teachers implement the backwards design process embodying elements of CS Principles (i.e., computational thinking big ideas and computational thinking practices) in the context of their classrooms?

Corresponding derived research questions are:

- What elements of CS Principles have teachers implemented in the design of their learning activities?
- How they used the backwards design process as a tool to implement elements of CS Principles?

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

- What are teachers' performances when integrating CS Principles to the design of learning activities as evidenced by their peer evaluations?

II. Theoretical Framework

Action research was used as the theoretical framework that guided this investigation. Action research has been defined as a qualitative model of inquiry in which all individuals involved in a specific situation take an active role in the process of the research study [8]. We have identified action research as an appropriate theoretical framework to approach our research question because it has the primary intent to provide a framework for qualitative investigations by teachers in conjunction with researchers in complex working classroom situations [9]. Part of the goal of the workshop was to also introduce the participants to a systematic process of evaluation and refinement of their learning experiences. The ultimate goal is for the participating teachers to be able to formulate a research plan, carry out the intervention and data collection, evaluate the outcomes, and design/re-design further strategies in an iterative fashion [10].

Action research methods informed this investigation firstly by having the researchers model the research experience to the teachers by means of this study. Specifically, the researchers designed and introduced the three-day workshop utilizing the Backwards Design process [11, 12] and then conducted a systematic assessment by identifying research questions, developing data collection instruments and collecting, analyzing and reporting the data and findings. Then, participating teachers followed the same procedure by designing their own learning experience, implementing it in their classrooms and collecting and analyzing the corresponding data. The scope of this paper focuses on the first stage of the study where teachers' designed their educational modules and then conducted peer assessment. .

III. Organizational Framework

Backwards Design [11, 12] constituted the organizational framework for the workshop and was also used to make sense of our own findings. We used this framework for the design of the study because it encompasses all elements that should be involved in any instructional intervention. We also utilized this framework as a tool for the participating teachers to develop the design of their learning activities. Also known as understanding by design, this process it is a way of thinking about curricular design and implementation of curricular innovations. It emphasizes a set of tools and practices using three main stages: (a) identifying the desired learning outcomes (the content of the lesson), (b) determining the acceptable evidence of learning (the method of assessing learning), and (c) planning the experiences and instructional approach (or pedagogy).

IV. The Learning Experience

A three-day workshop was designed to introduce relevant challenges in computer education in different contexts. For instance, we discussed topics such as the decrease in number of students who pursue computing-related degrees, the lack of female representation in these fields, and the lack of formally introducing computing related concepts at the K-12 level. We also discussed initiatives started in the U.S. aiming at addressing those challenges. For instance, we discussed the CS10K effort, aiming to have 10,000 high school teachers capable of teaching some AP-level computer science class in 10,000 US high schools by the year 2016.

In the following sections we describe in more detail the goals and content of the workshop and how we also applied the Backwards Design process to the design of the learning experience.

A. General Context

The course Advanced Topics is a graduate level course from an educational technologies master program. It intends to explore relevant topics in students' areas of interests. The format of the course is as a research seminar, which allows students to interact with experts to deepen their knowledge in diverse topics. During the spring semester of 2012, the course focused on topics such as Engineering Education, History in Engineering Education, Service Learning, STEM competences, Computational Thinking, and Computing Engineering Competences.

B. Structure of the Workshop

As mentioned earlier, we used Backwards Design process to guide the design of the workshop. These elements were instantiated as follows:

Content: The learning objective for the workshop was for the participants to identify the several available approaches to integrate CS Principles in educational contexts and to use the Backwards Design process to the design of computing learning activities. Another objective was for participants to integrate the use of Scratch to support their lesson designs and to introduce computing concepts, practices and perspectives [20] in their classrooms. Therefore, the course objectives were for the teachers to develop learning experiences aimed at introducing to their students to programming and fundamental concepts of computing.

As part of this effort, teachers described Learning Objectives and Evidence Statements grouped by Big Ideas and Key Concepts informed by the CS Principles (presented in Table I). CS Principles are part of a U.S initiative aimed at developing or supporting existing AP courses. The CS Principles were designed by the College Board through a NSF grant in 2009. Due to the lack of general agreement on a common definition of computational thinking among the computer science education community, the workshop was prepared to show different computational thinking perspectives and some examples of their application areas.

The workshop started by exploring the contributions of Seymour Papert [19] and how those are related to computational thinking. Contributions from Jeanette Wing were also discussed, particularly her major role in popularizing the term defining it as: "computational thinking represents a universally applicable attitude and skill set everyone, not just computer scientists, would be eager to learn and use." [18] Other visions were also explored such as the ones from the Women in Computer Science Alliance, the International

Society for Technology in Education, the Center for Computational thinking at Carnegie Mellon and Google.

TABLE I. CS PRINCIPLES' BIG IDEAS AND KEY CONCEPTS [21]

Big Idea	Key Concept
Creativity	A. Computing fosters the creation of artifacts. B.Computing fosters creative expression C.Programming is a creative process.
Abstraction	A. A combination of abstractions built upon binary sequences can be used to represent all digital data B. Multiple levels of abstraction are used in computation. C. Models and simulations use abstraction to raise and answer questions.
Data	A. People use computer programs to process information to gain insight and knowledge. B. Computing facilitates exploration and the discovery of connections in information. C. Computational manipulation of information requires consideration of representation, storage, security, and transmission.
Algorithms	A. An algorithm is a precise sequence of instructions for a process that can be executed by a computer. B. Algorithms are expressed using languages C. Algorithms can solve many, but not all problems. D. Algorithms are evaluated analytically and empirically.
Programming	A. Programs are written to execute algorithms B. Programming is facilitated by appropriate abstractions. C. Programs are developed and used by people. D. Programming uses mathematical and logical concepts.
Internet	A. The Internet is a network of autonomous systems. B. Characteristics of the Internet and the systems built on it influence their use. C. Cybersecurity is an important concern for the Internet and systems built on it.
Impact	A. Computing affects communication, interaction, and cognition. B. Computing enables innovation in nearly every field. C. Computing has both beneficial and harmful effects.

The three main steps of the Backwards Design process [10] were then introduced. Workshop instructors facilitated the implementation of this three-step process and guided the teachers in the design of their learning experiences. Finally, we also discussed some of the technological learning environments and tools that can support the integration of computational thinking activities such as WISE (http://wise.berkeley.edu), Scratch (http://scratch.mit.edu), and Whyville (http://www.whyville.net).

Assessment: The participants then designed and presented a lesson plan based on at least one of the CS Principles' learning objectives presented on Table 1. Peer assessment was then conducted using a rubric designed by the workshop instructors. The detailed rubric is presented in Section V.

Pedagogy: The three-day workshop combined lecture format with active and cooperative learning pedagogies. First, a lecture session with two speakers – one through videoconference and the other one on-site – was carried out. During that session, the speakers introduced the topics of the workshop, facilitated the discussion of the topics, and guided the application of the backwards design process for the design of computational thinking related activities.

Then, during a second session participants were introduced to the Scratch software (http://scratch.mit.edu/) and to the ScratchEd community (http://scratched.media.mit.edu/). Scratch software was introduced through hands-on activities where participants explored the Scratch development environment to carry out a series of structured tasks. Then, participants implemented an exercise where they had an opportunity to use several Scratch controls such as: object movement, audio for playing or recording sound, and sensors to interact with the mouse and screen borders. The software was presented with a set of worked examples.

The ScratchEd community was introduced as a resource of tools and lesson plans for the design of learning activities. During the presentation and demonstration of these resources and its capabilities it was emphasized how Scratch can be used to the development of computational thinking learning activities and how the ScratchEd community is currently working towards that goal.

Finally, participants working in dyads had two weeks of guided independent work to develop their projects. After the two-week period participants presented their projects to the entire group. During a third session participants conducted a ten-minute presentation of their designs and each of them received feedback from their peer instructors on their implementations.

V. METHODS

This section presents the findings of a case study describing how participants made sense of the CS Principles and embodied them in a learning activity with Scratch. A case study can be defined as "an empirical inquiry approach that investigates a contemporary issue in depth within its real-life context, especially when the boundaries between phenomenon and context are not clearly evident." [13, p.18].

A. Participants

The participants of this study were 15 graduate students from a Master in Engineering Program with an emphasis in Educational Technologies who are also professors of informatics at different educational levels. Table II displays the teaching levels and disciplines for each of the participants along with other demographic information.

TABLE II. PARTICIPANTS TEACHING LEVELS AND DISCIPLINE

Discipline	Gender		Level[a]		
	Male	*Female*	*E*	*H-T*	*C*
Informatics & Technology	7	6	0	11	3
All the areas	0	2	2	0	0

a. **E**: Elementary – **H-T**: High school/Technician - **C**: College Level. Some of the participants teach in both Elementary and College level

B. Procedures

At the end of the three-day workshop the participants worked in dyads to create a learning experience. The requirements for the learning experience were that they should use Backwards Design and Scratch to implement one of the CS Principles in the design of their lesson. They had two weeks to prepare the lesson plan. At the end of the two-week period participants gave a ten minute presentation, which included a description of the learning objectives, methodology, assessment, support tools and materials, and reflection.

The presentation took place in the classroom two weeks after the workshop ended and each one of the nine dyads had the opportunity to present and discuss their lesson plans with the rest of the group.

C. Data Collection Method

As part of the assessment process, a rubric was designed using the elements of Backwards Design process as elements to be assessed. The three established stages (desired results, acceptable evidence and learning experiences) were mapped to a specific assessment criterion: Learning Objectives, Assessment, Pedagogy and Materials/Resources.

Participants were required to include at least one of the CS Principles' learning objectives into the design of their lesson plans. As shown on Table III, an assessment criterion was centered on identifying the relationship between the presented lesson plan and the selected learning objective. In addition, Reflection and Coherence/Order and Presentation were also included as part of the rubric. The rubric included four levels of achievement being 1 the lowest and 4 the highest. Because of space constraints, Table III only indicates the lowest and highest levels of achievement.

TABLE III. ASSESSMENT RUBRIC (MIN AND MAX GRADES ONLY)

Criteria	1	4
Learning Objectives	The design has no relation with the chosen learning objective.	The design completely covers the chosen objective and some others.
Assessment	The assessment method for the students is not clear.	The assessment method for the students is clearly defined and is authentic. It can also be used by an expert and peer or self-assessment
Pedagogy	The selected didactic strategies are not well suited to accomplish the learning objectives	All strategies are appropriate for learning outcomes. The strategies are based on a combination of practical experience, theory, research and documented best practices
Reflection	The reflection is not realized or the answers are not coherent with the responses	Reflection is complete and it presents some examples that demonstrate clearly the results, challenges and opportunities of experience
Materials Resources and Technology	The resources and material list is not clear. The use of technology is out of context	All the materials and resources needed to complete the lesson are listed. The use of technology is relevant and clear. It also offers advantages that make it necessary
Coherence / Order and Presentation	The design is presented in an unorganized way. Every element is isolated from each other	All the design elements are aligned with each other to achieve the learning objective in students. All these elements are presented in an organized way

D. Scoring and Data Analysis

The scoring method used for the developed learning experiences was through peer evaluation. Together with the experts, the participants used the rubric to assess their peers' presentations and their own designs. Ten scores, including the ones by the experts, were averaged to determine the final score.

The artifacts produced by the participants were also analyzed qualitatively by the researchers to identify patterns in their design decisions. For this purpose we conducted a categorical analysis of participants' selected big ideas and their selected ways to implement the components of the backwards design process.

VI. RESULTS

A. What elements of CS Principles have teachers implemented in the design of their learning activities?

Most of the dyads selected the big idea "Creativity: Computing is a creative activity" to design their lesson plan. Their designs were intended to engage and empower students with CS Principles through the development of a creative project in Scratch such as a Storyteller, an Interactive Multimedia or a Traffic Light Simulator. Table IV lists the number of projects developed for each big idea and practice.

TABLE IV. SELECTED BIG IDEAS AND PRACTICES

Bid Idea	Practice	#
Creativity: Computing is a creative activity	Developing computational artifacts	4
	Programming is a creative process	1
Algorithms: Algorithms are used to develop and express solutions to computational problems	Communicating & Abstracting	2
Abstraction: Abstraction reduces information and detail to facilitate focus on relevant concepts.	Communicating & Abstracting	1

B. How teachers used the backwards design process as a tool to implement elements of the CS Principles?

Several learning outcomes and strategies were chosen by the participants for development of their projects including the combination of two or three of them in a single lesson plan. Also, all designs utilized the development of a Scratch artifact as the acceptable evidence of the learning. Most of the assessment mechanisms were designed to be conducted either by the teacher or by the students and the mechanism employed was an assessment rubric.

Based on the Backward Design process, Table V describes the most frequently chosen learning objectives, assessment mechanisms and pedagogical practices.

For example, a dyad selected the learning outcome "The student can use computing tools and techniques for creative expression." Based on this selection they defined project-based learning and collaborative learning as the pedagogical approaches to implement the chosen learning goal. They also developed a rubric including criteria such as the use of meaningful naming and convention of objects, functional compliance of the developed artifacts and number and variety of Scratch controls used.

TABLE V. COMPONENTS OF PARTICIPANTS' DESIGNS

Item	Practice	#
Learning Outcomes	The student can use computing tools and techniques for creative expression	3
	The student can express an algorithm in a language	2
	The student can use computing tools and techniques to create artifacts.	1
	The student can use programming as a creative tool.	1
	The student can explain how binary sequences are used to represent digital data.	1
Acceptable Evidence of the Learning	Rubric (including Peer and Self-assessment)	6
	Categorical Analysis	1
	Performance Indicators	1
Learning Experiences and Pedagogical Approach	Project-based learning	4
	Problem-based learning	4
	Collaborative learning	3
	Game-based learning	1
	Constructivism	1
	Critical and societal.	1
	Discovery learning	1
	Creation-based learning	1
	Trial and error learning	1

Another example can be described for the learning outcome "The student can express an algorithm in a language" where participants used three components for their assessments: cognitive (knowing), procedural (knowing-doing), and attitudinal (being), and evaluated those performance indicators through peer-assessment. The learning experience for this particular learning goal was problem-based learning, taking into account the design challenges students were presented with and how those were solved by using Scratch.

C. *What are theachers' performances in integrating CS Principles to the design of learning activities as evidenced from their peer evaluations?*

Overall, all projects obtained relatively high scores from all the workshop participants. The obtained grades were over 84% while the mean was over 90%. Table VI depicts means and standard deviations for all the assessment criteria:

TABLE VI. ASSESSMENTS RESULTS

Criteria	Mean (%)	Standard Deviation (%)
Learning Objectives	94.14	7.67
Assessment	89.07	16.57
Pedagogy	89.94	9.98
Reflection	86.67	10.12
Materials, resources and technology	91.11	10.05
Coherence / Order and Presentation	91.30	9.21
Total	90.37	7.23

The best evaluated projects were named "numbers eater" and "English names". The first one consisted of building a Scratch application with the goal of having the final user walk through a labyrinth while he/she answers math's questions. Hence, the computational thinking aspect for this project included the use of loops and conditionals while students were building their own math games.

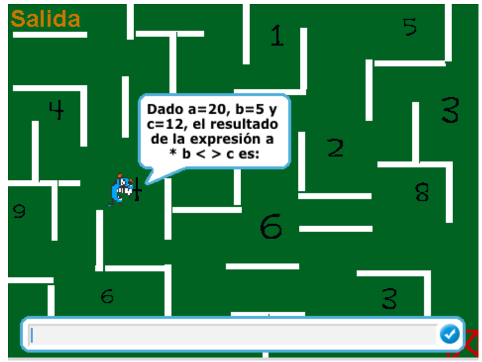

Fig. 1. Numbers eater project

The second project consisted of having students draw geometric figures, paint them with the primary colors, and write and pronounce their names in English (for elementary school-Spanish speakers). This activity was also designed to learn non-computational concepts i.e., English language, while students also learned how to program using Scratch. Both projects focused on the big idea: Creativity: Computing is a creative activity. Screen shots of each of the projects are shown in Fig 1 and Fig 2 respectively.

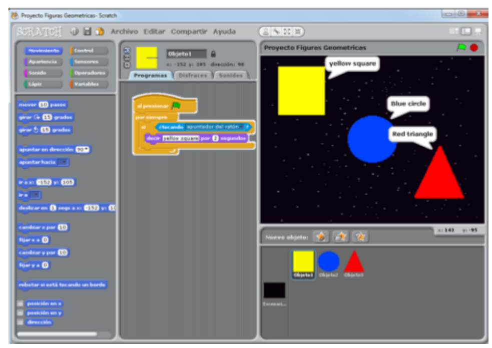

Fig. 2. English names project

At the end of the workshop participants were asked to do a final reflection of their learning experience. In their descriptions participants highlighted the advantages of integrating Scratch and the Backward Design process into computing education activities. Participants enjoyed the process and they believed that their lesson plans will help their students in problem solving, creative thinking and systematic reasoning. Other participants mentioned benefits such as collaboration, research and creativity, as well as motivation and engagement. They also indicated a high interest in having the opportunity to teach these concepts coupled with non-technology subject topics. Finally, participants emphasized their need or desire to learn more about computational thinking.

VII. DISCUSSION

The design of lesson plans using the CS Principles and guided by the Backwards Design process resulted to be a productive activity through the three-day workshop. Using the College Board CS Principles as a scaffolding method for the design of learning materials was useful for these teachers by providing them with relevant content. However, this approach may have a constraint: most dyads focused on selecting the same big idea (computing as a creative activity) even though they had other seven ideas to choose from. Participants' rationale for the selection of this big idea is unknown. We speculate that the reason why most participants selected "computing as a creative activity" as the big idea to guide their designs is the fact that it is very flexible and open to different forms of interpretation. It therefore becomes important for future workshops to promote the random assignment of different learning objectives in order to provide a whole vision for all participants of how CS Principles can be implemented and coupled with Scratch. This random assignment can provide participants with a wider view of the Backwards Design process and novel ideas about how to integrate each of the CS Principles in their curriculum.

Also, Scratch was used as the main tool for the activity but some of the projects did not limit their design to it. Participants used other tools such as Google docs, storybooks, web pages, among others. Participants also took advantage of their networks and academic settings and coupled their projects with ongoing social projects in their own schools, such as projects related to the importance of recycling and garbage separation.

Finally, further analysis of the peer assessments can be done in order to identify potential explanations for the large standard deviation. Possible reasons that can explain this result are the variety and background diversity of the target audiences. Specifically, the participants' backgrounds and areas of specialty included elementary, secondary and college level education. Also, some of the participants were focused on technology lessons while some others were focused on software development lessons. Another potential explanation could be that participants misunderstood the rubrics or specific evaluation criteria designed by their peers for their own lesson plans. Future workshops will emphasize the creation of effective and appropriate assessment mechanisms for demonstrating computational thinking including some notions of validity and reliability of assessment instruments.

VIII. IMPLICATIONS

The implications of this study relate to the use of Backwards Design process not only as a tool to develop lessons related to computational thinking, but also as a framework for the advancement of effective methods for teacher professional development in computing.

We identified that Backwards Design was proven to be helpful for these participants on a macro level, allowing the identification and alignment between content, assessment and pedagogy. However, other aspects at a smaller or micro level need to be considered as well. For instance, what are teachers' knowledge about computing in general and computational thinking in specific? How are teachers comfortable with integrating new technologies into their classroom such as Scratch? What are the most effective pedagogies to be integrated with computational thinking? And how computing content knowledge can be properly orchestrated with technology knowledge and pedagogical knowledge?

A framework that can support the design of effective professional development programs at this level of detail can be guided by the use of Technological Pedagogical Content Knowledge (TPCK) [14-16]. TPCK can serve as a framework to the design of learning experiences for teachers to help them acquire computing content knowledge and transform it into a more conceptually understandable version for their students by blending it with technological and pedagogical methods [14-16].

We believe that the acquisition of TPCK is especially needed for computing teachers to be able to effectively integrate technological and digital tools such as Scratch to facilitate proper instruction and to support the improvement of students' computational thinking. TPCK can be used for teacher professional development programs to connect their understanding of computing concepts, practices and tools and their integration with their subject domain. TPCK can also be utilized for assessment purposes on the effectiveness of professional development programs to track data on instructors' cognition [17] and their current educational practices and beliefs for integrating computational thinking.

IX. CONCLUSION AND FUTURE WORK

We believe that through the activities described in this study, which took part during the three-day workshop, computational thinking concepts and ideas became clearer to all participants. The workshop offered the participants with an opportunity to not only get to know the several existing approaches to computational thinking but also it allowed them to explore how they could integrate these concepts and practices into their classrooms. Finally, we believe that sharing their experiences with their peers enriched their learning processes through discussions and peer-evaluations.

Most of the participants are currently implementing or are planning to implement and then evaluate their developed lessons into their own classrooms during this academic year. Findings from an initial classroom implementation with fifth graders suggest that students showed a high performance and engagement when using Scratch to complete an assignment related to "computing as a creative activity." Students also found Scratch software useful and easy to use. Additionally, the corresponding teacher reported the intention to continue implementing this kind of activities at other elementary and secondary levels [22].

***Abstract*—Professional associations of engineering have recommended Service Learning environments to cultivate professional engineering skills. However, a report from ASEE published in 2012 showed that faculty did not consider these learning environments to be important. This study aims to understand the motivation of instructors of Service-Learning programs in engineering. The results can be used to propose campaigns to attract faculty toward these effective engineering learning environments.**

Keywords—Service learning, motivation, student-centered environments

I. Introduction

Experts in the field of engineering education have called for an "urgent" change in the way engineering schools prepare engineers for industry and for the future challenges ahead [1–4]. Engineering also needs not only to encourage high school students to choose engineering over other professions but it also requires to retain, engage current students understanding [5] and teach them for deeper understanding or transfer, and for long-life learning [6–9]. Chances of succeeding in making the profession more attractive, improving retention, engaging students, and preparing them for the future challenges [10] are less likely to happen if the educational model in engineering education remains the same.

A growing movement trying to change the teacher-centered pedagogies that have ruled engineering education have emerged, especially since 2005 when the Steering Committee of engineering education defined five areas of research[11]. The area of engineering learning systems seeks understanding of "the instructional culture, the institutional infrastructure and the epistemology of engineering educators" [11]. Instructional theories have shown benefits of student-centered pedagogies to reach the changes that are expected in engineering education [1], [3].

Current efforts in moving forward engineering education are focus on preparing and encouraging faculty to adopt student-centered pedagogies. The proportion of faculty members who have adopted this approach is increasing. In an study from ASEE [12], engineering faculty committees from different universities of the US were asked about the use of active and engagement pedagogies. Long standing learning environments, like labs, internships and research were reported with a high rate of adoption whereas international programs, entrepreneurship and service learning were reported with lower frequency [12].

Service learning have shown its effectiveness to prepare engineering students for professional practice, and its incorporation in the engineering curriculum is highly recommended by engineering education experts [12–14]. The big question that will be addressed in current and future studies is: "what strategy should be followed to promote the adoption of service learning by a higher number of faculty members?"

One of the phases defined to answer that question is presented in this study. This phase look to answer the following sub-question: why instructors (faculty members, staff and industry practitioners) are motivated to get involved in service learning?

II. Method

Participants

The design experiences provided by the Engineering Projects in Community Service – EPICS program are well-known and recognized in the engineering community. Instructors, or advisors, from this program will be the group of participants that will be studied. Currently, the scope is limited to the advisors of different EPICS teams in a mid-western university.

Data collection

A qualitative methodology will be used to guide the research. To reach validity the same phenomena will be observed from three different perspectives, each of those will be interpreted as phases of the study.

A. Open ended surveys

In order to have a first sight of the factors that describe the motivation of advisors (instructors) to get involved in EPICS, we will conduct an open ended survey composed of questions related to their motivation to get involved first, and a subsequent question asking why they are still involved. In addition, we will ask if their participation is related to their professional goals and if they receive any rewards for their involvement. This data will be analyzed following the principles of grounded theory, in which the data collected are read trying to find common topics and possible relationships between them to establish a theory grounded in the data.

The survey has been already piloted with the 29% of the population of advisors.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

B. Literature review

Once the first phase is finished, we will revise the literature about motivation from different perspectives so we can compare the results from the open-ended survey with what other studies have said about motivation to get involved in similar activities than those performed by advisors in EPICS. Preliminary literature has been collected after analyzing the data that was gathered in the pilot of the open-ended surveys.

C. Semi-structured interviews

The third phase of the study will validate the findings from the open ended survey and from the literature review using semi-structured interviews. The literature will be revised every time a new issue related to motivation emerges in the conversations. The interview protocol will include questions beyond the experience advisors have had in EPICS. Since motivation could be explained by intrinsic and extrinsic factors, the interview protocol will include questions that help to disclose if the advisor's motivation to be involved in service learning is intrinsic or extrinsic. Intrinsic motivation will be identify by asking to the interviewee for the kind of activities that he/she enjoyed when he/she was a child and in high school. The interview protocol also includes questions asking for meaning of life. Answers to this kind of question will be helpful to create connections with the sources of the motivation for the activities they currently do. Besides, the interview protocol will include questions to assess the value that the interviewee gives to extrinsic motivational factors. For example, one of the questions asked for the ideal job and another for the ideal compensation package.

III. Preliminary Results

The data from the pilot survey have shown that the main source of motivation of EPICS advisor is intrinsic. Some factors that were identified as source of their motivation are social interest (interviewee expressed his/her concern about others), professional growing (interviewee expressed his/ her interest in creating opportunities for employment and connection), cognitive interest (interest of advisors in learning), and personal satisfaction (the activity makes them feel better).

Some of the previous findings in the literature explain that sources of motivation could be in the interest and concerned for others (social interest) [15], in the nature of the interaction with elements of the environment [16], in their need to volunteer to improve the conditions of a community [17], and specific studies addressing the motivation to get involved in service learning in general [18].

At the FIE conference, we will present the theory that resulted after analyzing the preliminary data collected with the pilot of the open-ended survey and interview protocol. In addition, we will present a comparison between the theory that was generated by data and the existing theory in motivation.

***Abstract*— A well-designed and constructed course plan or curriculum is an integral part of the foundation of effective STEM instruction. This paper presents a framework for outcome-based course design process and its translation into a semantic web-based tool; i.e., the IMOD^{TM} system. This system guides STEM educators through the complex task of curriculum design, ensures tight alignment between various components of a course (i.e., learning objectives, content, assessments, and pedagogy), and provides relevant information about research-based pedagogical and assessment strategies. The theoretical framework is presented, along with descriptions and screenshots of the implementation of key features.**

Keywords—course design, instructional module, learning objectives, outcome-based education, semantic web application.

I. INTRODUCTION

At many colleges and universities, engagement in scholarly teaching is becoming a minimum expectation of faculty who are held accountable for the quality of the learning experienced by students enrolled in their course(s). These expectations are even greater for Science, Technology, Engineering, and Mathematics (STEM) faculty given the national demands for a well-trained STEM workforce [1]. Since education training is not typically included in the plan of study of most STEM programs, faculty who graduate with STEM degrees gain their teaching expertise post-appointment and "on-the-job". In the absence of formal training, most faculty can take as much as five years to truly become proficient teachers, and during that period, it is the students who are most affected [2].

There is a growing demand and interest in faculty professional development in areas such as outcome-based education (OBE), curriculum design, and pedagogical and assessment strategies. In response to this demand, a number of universities have established teaching and learning centers to provide institution-wide, and sometimes program specific support. This paper describes the development of the Instructional Module Development (IMOD) System, which further supports these ventures and broadens the impact and reach of professional development in the scholarship of teaching and learning, particularly to STEM faculty. The IMOD system is an open-source web-based course design software that:

- Guides individual or collaborating users, step-by-step, through an outcome-based education process as they define learning objectives, select content to be covered, develop an instruction and assessment plan, and define the learning environment and context for their course(s)
- Contains a repository of current best pedagogical and assessment practices, and based on selections the user makes when defining the learning objectives of the course, the system will present options for assessment and instruction that align with the type/level of student learning desired
- Generates documentation of course designs. In the same manner that an architect's blueprint articulates the plans for a structure, the IMOD course design documentation will present an unequivocal statement as to what to expect when the course is delivered
- Provides just-in-time help to the user. The system will provide explanations to the user on how to perform course design tasks efficiently and accurately. When the user explores a given functionality, related explanations will be made available
- Provides feedback to the user on the fidelity of the course design. This will be assessed in terms of the cohesiveness of the alignment of the course design components (i.e., content, assessment, and pedagogy) around the defined course objectives.

II. THEORETICAL FRAMEWORK

Many of the leaders in faculty development programs have identified facilitation by experts as a key ingredient in increasing the effectiveness of instructional development programs [3]. For the IMOD system, which will provide professional development with the use of an online tool, expert facilitation is embedded within its design, through the application of a framework that is informed by research in the area of instructional development for STEM disciplines. This framework translates the scholarship into a software platform that supports the development of a rich, meaningful knowledge structure that can be queried to: (1) identify omissions in a course design; (2) identify inconsistencies in the relationships between the elements of the course being designed; (3) identify relevant strategies for instruction and/or assessments; (4) provide just-in-time guidance to the user on the design process. The structure of the framework and its implementation in the IMOD™ system are discussed in the subsequent sections.

A. Previous Models of Outcome-Based Course Design

Outcome-based education (OBE) is an approach where the product defines the process, i.e., the outcomes that specify what students should be able to demonstrate upon leaving the system are defined first, and drive decisions about the content and how it is organized, the educational strategies, the teaching methods, the assessment procedures and the educational environment [4]–[6]. This is a contrast to the preceding "input-based" model that placed emphasis on the means as opposed to the end of instruction. OBE was used as the principal guide for the development of the IMOD framework. It was chosen for the following reasons: 1) Win-for-all solution – OBE is shown to improve student success, provides a structure to educators for designing instruction, and facilitates reporting to external stakeholders in an accountability education climate; 2) It supports the How People Learn framework for designing learning environments [7]; 3) Growing adoption of outcome-based program accreditation – Accreditation boards such as ABET, have moved to an outcome focused model (what students learned) to assess the quality of programs in Applied Science, Computing, Engineering, and Engineering Technology; 4) Alignment with other models that are meant to increase innovation in STEM education – OBE dictates the end and not the means thereby allowing innovation in instruction. It also provides an empirical structure to track impact and identify shortcomings.

A number of models have been developed to represent the application of OBE in the design of effective courses. Four key models widely discussed in the engineering education literature are: 1) the Effective Course Model by Felder & Brent [8]; 2) Integrated Course Design by Fink [9]; 3) Understanding by Design Model [10]; 4) Content Assessment Pedagogy Model by Streveler, Smith, & Pilotte [11]. All of these models either directly or indirectly identify four main elements that must be tightly aligned when defining a course design, i.e., course objectives, content, assessments, and pedagogy. Therefore, one of the main challenges in adhering to an outcome-based approach is maintaining the alignment between course elements. Inconsistencies in the interrelation of these elements can lead to the overall incoherence of the course.

One approach for achieving alignment among course elements is through a "backward-looking" design process where the desired results are identified first, and then assessments are designed to verify that these results have been achieved. The learning experiences and instruction are then formulated around the desired results and the assessments. The use of this approach forms the basis of the Understanding by Design model, and it is also applied by the other models. One of the key functions the IMOD system is expected to perform is the evaluation of the fidelity of the course design. To achieve this, the IMOD framework must include machine processable constructs that can be used to make inferences on the inconsistencies in the relationships between the elements of the course being designed. While the backward-looking process dictates an ideal sequencing of tasks, it is limited in its ability to support automated inferencing on course element coherence. The IMOD framework, therefore, expands on the current models with the inclusion of new constructs.

B. IMOD Framework

The IMOD framework adheres strongly to the OBE approach and treats the course objective as the spine of the structure. New constructs (not included in the models previously discussed) are incorporated to add further definition to the objective. The work of Robert Mager [12] informs the IMOD definition of the objective. Mager identifies three defining characteristics of a learning objective: Performance – description of what the learner is expected to be able to do; Conditions – description of the conditions under which the performance is expected to occur; and the Criterion – a description of the level of competence that must be reached or surpassed. For use in the IMOD framework an additional characteristic was included, i.e., the Content to be learned – description of the factual, procedural, conceptual or meta-cognitive knowledge; skill; or behavior related to the discipline. The resulting IMOD definition of the objective is referred to as the PC^3 model.

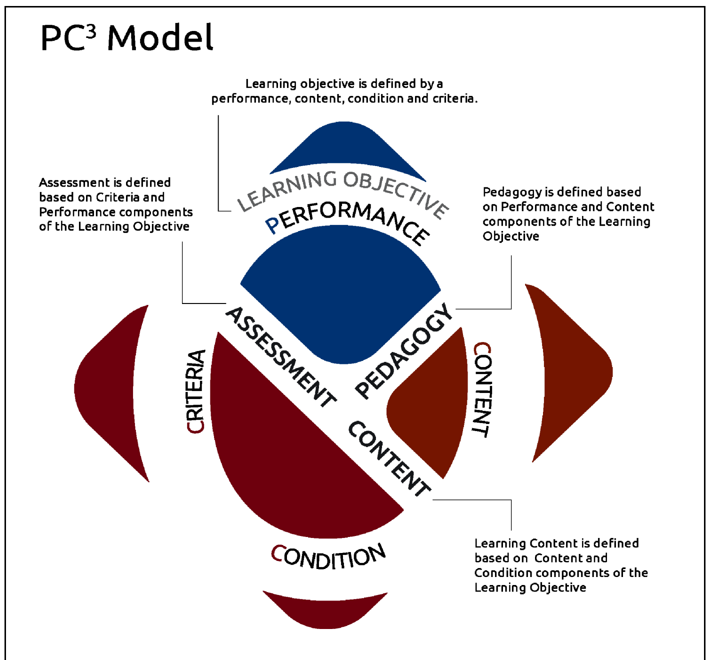

Figure 1: PC^3 Model

The other course design elements (i.e., Content, Pedagogy, and Assessment) are incorporated into the IMOD framework through interactions with two of the PC^3 characteristics. Course-Content is linked to the content and condition components of the objective. The condition component is often stated in terms of pre-cursor disciplinary knowledge, skills or behaviors. This information, together with the content defined in the objective, can be used to generate or validate the list of course topics. Course-Pedagogy is linked to the performance

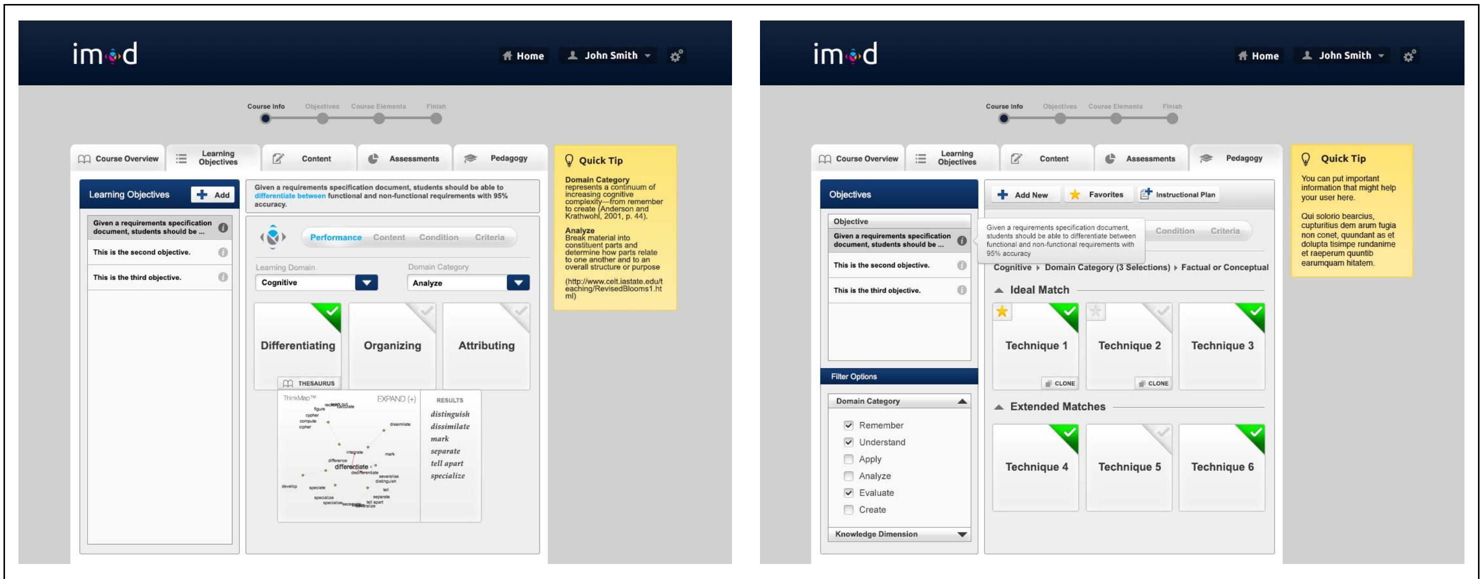

Figure 2: Screenshots of Learning Objective and Pedagogy tabs of the IMOD™ system

and content components of the objective. The types of instructional approaches or learning activities used in a course should correspond to the level of learning expected and the disciplinary knowledge, skills or behaviors to be learned. The content and performance can be used to validate pedagogical choices. Course-Assessment is linked to the performance and criteria components of the objective. This affiliation can be used to test the suitability of the assessment strategies since an effective assessment, at the very least, must be able to determine whether the learner's performance constitutes competency. Figure 1 shows a visual representation of the IMOD framework.

III. Implementation of IMOD™ System

The implementation of the IMOD system shown in Figure 2, consists of five features described below. 1) *Course Overview* – a feature used to capture information on the learning environment (e.g., type of course, meeting days and times, instructor(s) information, course policies, etc.). 2) *Learning Objectives* – a feature used to guide the user through the creation of learning objective statements that conform to the PC^3 model. Revised Bloom's taxonomy of learning objectives [13] was also used in this feature to help the user describe performance characteristics. 3) *Content* – a feature used to capture information on the course topics. The content prioritizing model by Wiggins and McTighe [10] and the Knowledge Dimension from Anderson and Krathwohl version of Bloom's taxonomy [13] are also used in this feature. 4) *Assessment* - features used to suggest relevant assessment techniques based on the type of learning and evaluation criteria specified in the learning objectives. 5) *Pedagogy* - features used to suggest relevant instructional techniques based on the type of learning and knowledge specified in the learning objectives.

IV. Future Work

The design of the IMOD system is still ongoing, and will be further described in future publications. Some of the implementation has already underway. Once the first version is completed, user testing will be conducted to test for effectiveness, efficiency and usability.

IMA-Tool: A Tool for Modeling and Automatic Generation of Educational Content

Vanessa Araujo Borges and Ellen Francine Barbosa
University of São Paulo – ICMC/USP
São Carlos (SP), Brazil
Email: va.borges, francine@icmc.usp.br

***Abstract*—In this paper we discuss the establishment and application of $\mathcal{IMA}$ *Tool* – a web-based tool for the modeling and automatic generation of educational content. The tool is based on $\mathcal{IMA}-\mathcal{CID}$ – an approach for modeling educational content, capable of addressing conceptual, instructional and didactic issues altogether, in an integrated way. $\mathcal{IMA}-\mathcal{CID}$ and $\mathcal{IMA}$ *Tool* have been applied in the development of an educational module for software testing. The preliminary results indicate the effectiveness of such mechanisms for modeling and generating content.**

Keywords*—*content modeling, automatic content generation, supporting tool, educational module.

I. Introduction

Several initiatives involving the use of computing resources have been investigated in order to ease the learning processes in general. It is the case of educational modules – concise units of study, composed by theoretical and practical content, which are delivered to learners by using innovative technologies and computing resources [1], [2].

The construction of educational modules is a complex task however, involving both pedagogical and developmental issues. Content modeling, for instance, plays a significant role in the development of such modules. Basically, it helps the author to determine the concepts to be taught, providing a systematic way to structure the relevant parts of the knowledge domain [3], [4].

Despite its relevance, there are few approaches for modeling the educational content, each one of them considering different perspectives, which can be suitable for a specific learning setting, but inadequate for others. Motivated by this scenario, we proposed $\mathcal{IMA}-\mathcal{CID}$, an integrated approach for modeling educational content [4]. In short, $\mathcal{IMA}-\mathcal{CID}$ is composed of a set of models, each one considering specific aspects of the development of educational content.

Although the results obtained so far reveal the feasibility of the practical use of $\mathcal{IMA}-\mathcal{CID}$, applying it without an automated support can be a time-consuming and an error-prone activity. In this perspective, we have worked on the specification and development of $\mathcal{IMA}$ *Tool* – a supporting tool for content modeling, particularly for constructing the $\mathcal{IMA}-\mathcal{CID}$ models. Issues of content generation and ontologies adoption have also been addressed. To illustrate our ideas, we have applied $\mathcal{IMA}-\mathcal{CID}$ and $\mathcal{IMA}$ *Tool* in the development of an educational module for software testing. The preliminary results achieved suggest the effectiveness of adopting such mechanisms in the modeling and automatic generation of educational content.

This paper is organized as follows. In Section II we present an overview of $\mathcal{IMA}-\mathcal{CID}$ approach, focusing on the construction of its associated models. In Section III we describe the main characteristics of $\mathcal{IMA}$ *Tool*, illustrating its application in the modeling and content generation of an educational module for software testing. Our conclusions and perspectives for further work are presented in Section IV.

II. IMA-CID: A Content Modeling Approach

$\mathcal{IMA}-\mathcal{CID}$ (Integrated Modeling Approach – Conceptual, Instructional and Didactic) [4] is composed of a set of models, each one addressing specific issues to structure and represent the educational content. The *Conceptual Model* consists of a high-level description of the knowledge domain, representing its main concepts and the relations among them. Two classes of relations are defined. Structural relations (e.g., *type-of* and *part-of*) are useful to set up taxonomies among concepts and make inferences about the domain, being applicable to any kind of domain. Domain-specific relations are user-defined and have their meaning associated to a particular subject, carrying their own semantics.

The *Instructional Model* aims at defining the additional information to be related with the concepts previously identified. Thus, besides concepts, *information items* and *instructional elements* should be represented as part of the domain. As instructional items, the model specifies [5]: (i) *facts*, logically associated pieces of information; (ii) *procedures*, set of ordered steps to solve a problem or accomplish a goal; and (iii) *principles*, explanations or predictions on why something happens in a particular way.

Similarly, instructional elements are also specified in different categories: (i) *explanatory elements* deal with the complementary information used for explaining a given topic; (ii) *exploratory elements* allow the learner to navigate through the domain, practicing the concepts and relevant information; and (iii) *evaluative elements* allow assessing the learner's proficiency on the domain.

Finally, the *Didactic Model* is responsible for the establishment of prerequisites and sequences of presentation among the elements of the conceptual and instructional models. Particularly, the model introduces the idea of *open specifications*, which provides support for the definition of dynamic contexts of learning. According to aspects such as audience, learning goals and course length, distinct ways for presenting the same content can be required.

A. An Example in the Software Testing Domain

Next we summarize the *IMA−CID* application in the development of an educational module for Mutation Analysis [6], a fault-based testing criterion. Shortly, this criterion is based on the assumption that a program will be well tested if all “simple faults” are detected and removed. Simple faults are introduced into the program by creating different versions of the program, known as *mutants*, each of which containing a simple syntactic change. Simple faults are modeled by a set of *mutant operators* applied to the program under testing. The goal is to find a test case that causes a mutant to generate a different output from that of the original program (*dead mutant*). A mutant is *equivalent* if no such test case exists. The *mutation score* measures the adequacy of the test set, being the ratio of the number of dead mutants to the number of non-equivalent mutants.

Figure 1 shows the didactic model of *IMA−CID* for the Mutation Analysis criterion. Consider, for instance, the `MutationAnalysis General` state. It represents an OR state, composed of two substates: `MutationAnalysis` and `MutationAnalysisDetails`. `Mutation Analysis` represents an AND state, which is composed of: one concept (`MA:concept:text`), one fact (`MA:fact:text`) and two principles (`CompetentProgrammer:principle:text` and `CouplingEffect:principle:text`). All of these elements are specified as text.

Exploratory elements are specified as well. `Mutant:example:figure`, for instance, complements `Mut: concept:text`. This example is also related to another explanatory element, `IdentifierImplementation:complementary: figure`, which provides complementary information for it.

Finally, the idea of *DD*-states is defined in order to address the navigation issues. Consider the `MutationAnalysisDetails` state. Its sub-states (OR_{DD} states) are all connected to each other by implicit transitions. That is, from `MutantOperator` we can get to the states `MutantGeneral`, `MutationScore`, `Application` and `ApproachesGeneral`, and so on for all other combinations of states of `MutationAnalysisDetails`. The same reasoning should be applied to the other *DD*-states.

IMA−CID has been successfully applied for modeling educational content in different domains. However, despite the promising results obtained, applying the approach without an automated support can be a time-consuming and error-prone activity. In this perspective, we have worked on the specification and development of *IMA Tool*, described next.

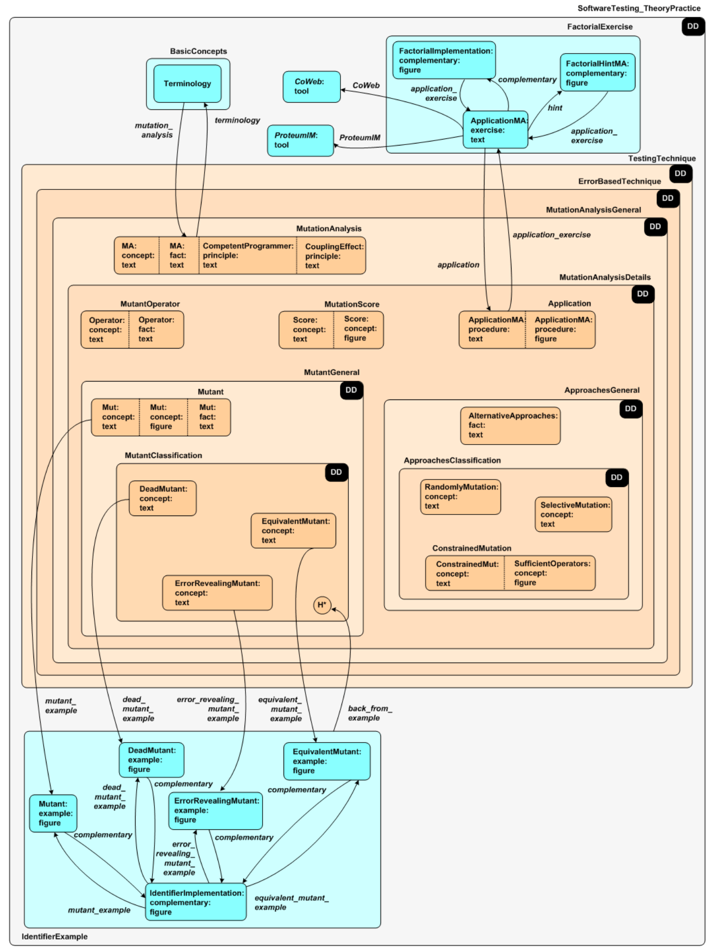

Fig. 1: Didactic Model for the Mutation Analysis Criterion

III. IMA-Tool: Main Characteristics

IMA Tool is a web-based tool designed to help the construction of the *IMA−CID* models. The modeling process starts with the definition of the main concepts and relationships in the subject domain. *IMA Tool* provides two ways to support the development of the conceptual model: (i) inserting both concepts and relations manually; or (ii) using concepts and relations defined in an ontology (i.e., importing an OWL file).

In the case of mutation analysis, the conceptual model was constructed based on an ontology of testing, referred to as *OntoTest* [7]. *OntoTest* addresses the main testing concepts and relations, such as: testing process, testing steps, testing strategies and procedures, and testing resources. Mutation analysis concepts and relations, in particular, are addressed in details in the testing strategies and procedures sub-ontology.

The next step is the construction of the instructional model. Using *IMA Tool*, the author is able to register and choose different elements to be associated to a given concept: information items and instructional elements. Media elements, classified according to the ALOCoM ontology [8], should be associated to the objects modeled as well.

Besides that, issues of hierarchical decomposition must be addressed. That is, it is necessary to define the states that compose the corresponding statechart of the model. In this direction, *IMA Tool* supports the specification of AND and OR states. Shortly, AND states are used to group information that has to be presented simultaneously whereas OR states are used to gather information of a same group but that is never presented concurrently. For instance, information related to *Constrained Mutation* (an alternative approach for applying Mutation Analysis) was defined as an AND state (Figure 2(a)); information regarding the classification of mutants (*Dead Mutant*, *Equivalent Mutant* and *Error Revealing Mutant*) was defined as an OR state (Figure 2(b)).

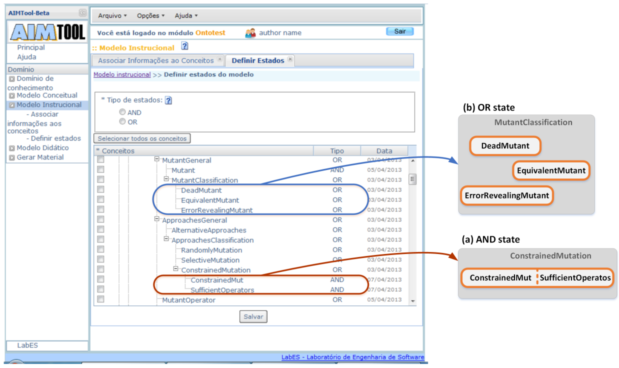

Fig. 2: Instructional Model: AND and OR states.

Regarding the didactic model, IMA *Tool* allows the author to create different sequences for presenting the same content. Basically, the concepts that will compose the educational content can be selected through the IMA *Tool* interface. The tool returns all the elements related to the concepts selected and the author is responsible for choosing the complementary information to be considered for each concept.

After the modeling phase is completed, the educational content can be automatically generated through IMA *Tool*. Based on the elements modeled according to IMA−CID, IMA *Tool* generates an SCXML file, which corresponds to the statechart of the didactic model. From the SCXML file, AIM *Tool* is able to generate and package the content (PDF-Latex and/or HTML). Figure 3 shows some slides (PDF-Latex) for mutation analysis, automatically generated by IMA *Tool*.

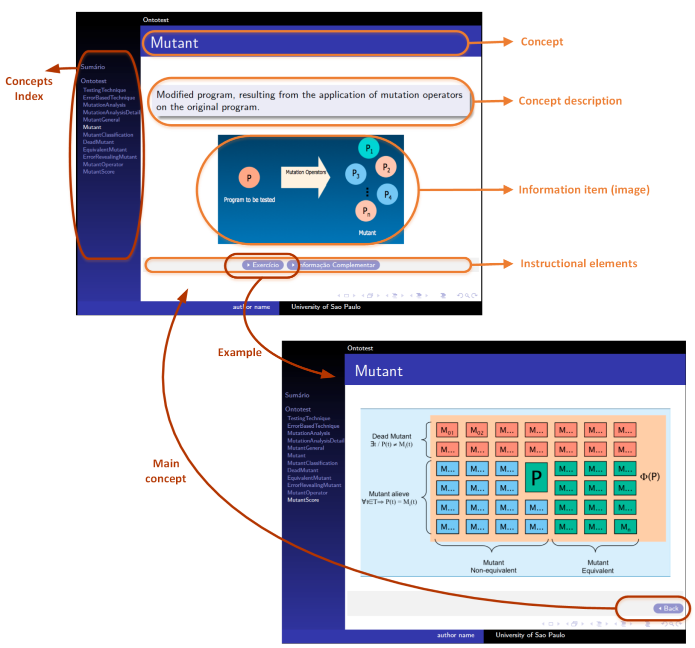

Fig. 3: Content Automatically Generated by IMA *Tool*.

The resulting content of software testing has been applied both in graduate and undergraduate courses at ICMC/USP. In general, good results regarding the learning effectiveness provided by the module have been observed in terms of the students' ability in generating test cases, covering the test requirements and detecting the existing faults in the programs under testing.

IV. Conclusions and Future Work

In this paper we discussed the establishment and application of IMA *Tool*. In general, the results achieved so far provide preliminary evidences on the practical use of the tool as an effective mechanism to support the modeling and automatic generation of content. The authors' attitudes toward the usage of the tool highlight the possibility of keeping all relevant information of a given domain in a single place, at the same time of being able to structure and generate different versions of the same content according to aspects such as audience, course length, learning goals, among others. More experienced authors (knowledge specialists) also point out the adoption of ontologies as a positive aspect in order to provide a better comprehension of the domain as well as to ease the knowledge sharing and reuse among authors/designers. Usability issues were identified as points to be improved in the next versions of the tool.

As a further work, we highlight the need of conducting more formal experiments to evaluate both IMA *Tool* and the educational content it generates. Indeed, systematic and controlled experiments have been planned and should be performed in short term. We also intend to investigate the integration of IMA *Tool* with learning environments, such as Moodle and Sakai.

Acknowledgment

The authors would like to thank the Brazilian funding agencies (FAPESP, CAPES, CNPq) and INCT-SEC (CNPq 573963/2008-8, FAPESP 08/57870-926) for their support.

Abstract— **During 2008, the Institute for P-12 Engineering Research and Learning (INSPIRE) began a research project that started with 19 teachers and more than 200 students who were educated, interviewed, and assessed for STEM learning. This longitudinal study grew fast, gathering numerous pieces of data from 168 teachers and more than 3,000 students during the five-year treatment. This information growth led to a need for data management improvement. However, there are few database structures available for gathering school-related research. This paper presents lessons learned during the process of database construction and improvement for supporting project data consolidation. The process of construction and development included structural changes to provide an organization commensurate with schools' clusters, domains, and strata, all of which occur organically in the school setting. The database construction also included program development for uploading and cleaning large amounts of information; application analysis for defining an appropriate tool; and improvements for user information visualization. The analysis of lessons learned includes a discussion of major changes within the database and benefits of creating program codes within this tool. The discussion ends addressing the implications of having a structured and automatized yet flexible database tool designed for school settings.**

Keywords—database; STEM education; K-12 education; data cleaning; data consolidation

I. Introduction

In 2006, the Institute for P-12 Engineering Research and Learning (INSPIRE) was created with the intention of improving methods of approaching STEM education at the pre-college levels. During 2008, INSPIRE began a research project focused on integrating engineering into the elementary science curriculum of a south-central United States school district. Researchers collected general data about the participants including gender, ethnicity, school, and grade. Information related to the teachers' prior experience, background, and project-related experience was gathered. Likewise, information concerning students' knowledge and perceptions was collected via pre- and post-assessments each year. The large amount of information collected drove the need for a data management system to consolidate results and outcomes. A database was needed to manage research information about the effects of STEM education in K-12 settings where the majority of the stakeholders (e.g., K-12 researchers) have little expertise in computer science or database technicalities. This context requires applications that provide user-friendly tools for organizing and accessing data. The process of designing the Research and Assessment of Students and Teachers Results and Outcomes (RASTRO) database provided experiences that led to reflections about data consolidation, visualization, and requirements used for structural and automation improvements.

II. Rising Numbers in K-12 STEM Education

A recent increase in research concerning STEM education advocacy has been identified by stakeholders such as the Academic Competitiveness Council [1], the President's Council of Advisors on Science and Technology [2], and the U.S. Congress [3]. During the last several decades, since the publication of A Nation at Risk [4, 5], the United States has focused on improving STEM education and ultimately increasing the number of professionals in STEM-related fields. Several proponents of this objective support this sense of urgency by claiming that STEM education is needed to ensure that the United States maintains a sustainable economic competitiveness in the global market [3]. For instance, the PCAST report [6] suggested that one million STEM professionals are needed to maintain the national reputation in science and technology, while the National Academy of Science [7, 8] stated that income growth in the U.S. is fundamentally due to technology change.

These analyses led to an increase in the invested budget for STEM education (e.g., the America COMPETES act [3] or the GAO report [9]) and regulation development (e.g., the new framework for K-12 Science Education [10] or the Next Generation Science Standards [11]). This heightened involvement in STEM education guided the creation of programs designed to address the gap in STEM education. More than 200 programs have been administered by 13 agencies, and more than 3 billion dollars are expected to be invested [9]. According to the GAO report, for the STEM education investment, the diversity of initiatives has not been realized due to insufficient coordination of data that has led to considerable overlap in the programs. Tools for data management specialized in these types of projects may provide a timely evaluation and reporting of outcomes that identification of new projects that complement rather than replicate existing projects.

Tools are needed at the project level that can better store and manage data and facilitate data analysis, so that data and results can be better shared and coordinated at the national level.

III. NEED FOR INFORMATION CONSOLIDATION FOR K-12 PROJECTS

This need for coordination particularly applies to K-12 STEM education where a large number of separate projects are addressing similar goals, areas of study, subjects, and strategies. These projects are unifying efforts to promote STEM education and increase the number of people pursuing STEM-related careers, but it is not yet clear how these efforts build upon each other, because of a lack of evaluation and reported outcomes [9]. Consolidating tools that allow summarizing project-impact (e.g., through number of schools in the project, ethnographic distribution, teacher background statistics) and project-efficacy (e.g., through changes in students' perceptions and knowledge of STEM) are needed for better coordination of efforts. However, there are few applications that facilitate the documentation and analysis of data.

Some existing tools offer basic organizational structures (e.g., Hep Inc. [12], Maponics [13], SAS Institute Inc. [14]), which include generic forms to describe people (e.g., customers) or products (e.g., refrigerator parts). Other existing tools are already filled with data and serve as examples but are not available as tools for others to use (e.g., ERIN Project [15], COMPASS [16]). This is problematic for K-12 research projects because of the uniqueness of school structures, which differ from industry and corporate organizations.

There are some applications in which more flexible types of data can be gathered and analyzed. This flexibility creates a level of complexity that requires trained technicians to manipulate the information. If the unique elements that exist in K-12 formal settings are acknowledged and supported by tool design, STEM education may be positively influenced, and therefore U.S. competitiveness will be promoted through innovation as suggested by the National Governors Association [17].

IV. DATA STRUCTURE AND PREPARATION FOR K-12 SCHOOL SETTINGS

Before analysis of data gathered from students, teachers, and other participants in K-12 interventions, it is important to prepare the data. Assuring data quality leads to accurate reporting and therefore advancements in school interventions. Data cleaning and integration is the first step in data mining no matter the context of the data [18, 19].

Data cleaning is a process that comprises data extraction, transformation, and loading (ETL) [18, 20, 21]; although other stages may be included in this process as well [22]. This paper focuses on the first stage (E) in which discrepancy detection and transformation occurs [21]. Discrepancies or glitches [19] are caused by human errors such as, but not limited to, misspelling, coding errors (where wrong identification numbers may be assign to a participant, low-structured entry) forms that may lead to inconsistencies, or data decay that produces errors due to outdated information. To prevent or mitigate these problems some procedures may be followed [18]. For instance, validating information during its entry and using rules and linked registries will help prevent errors when entering years, codes, or grade levels, this means ensuring data integrity and referential integrity.

Since this cleaning process is likely to take a considerable amount of time (to ensure data integrity and referential integrity) and programming [21], it should be automatized and customized for K-12 school settings to save time and resources. Although automation of data cleaning may provide assurance of data quality, school-data managers must be capable of working with these processes. Therefore, it should have user-friendly interfaces for non-technical experts who manage and analyze educational data.

V. NEED FOR A PLATFORM FOR DATA AND ANALYSIS DOCUMENTATION

The scarcity of tools addressing the unique characteristics of K-12 formal education also hinders the process of data management within some STEM education projects. For instance, INSPIRE researchers started to collect large amounts of data for a five-year project to improve STEM teaching and learning at the elementary level. Researchers needed the data to understand how the intervention designed for teaching science through engineering affected STEM education at the elementary levels. Did perceptions about engineering change? Did understanding and belief in stereotypes change? Without a suitable data management method to support answering these questions, research took far more time than expected.

This five-year longitudinal project started with 19 teachers and more than 200 students at 6 schools in one district in south-central U.S. Participants were taught, interviewed, and assessed for their STEM learning. During the second year, a considerable sample size increase (15 schools, 62 teachers, and more than 800 students) led to a need for structural growth in the project database and for increasing flexibility for data storage and management. In response to this need, researchers started to develop programs for automating tasks such as uploading information and creating records for new participants. In the fifth and final year of data collection, the project ended with a total of 168 teachers and more than 3000 students at 15 schools in the same district. Since the first automation was created, researchers continued the development of more features and systematic procedures for data management. The process has been dynamic but also challenging. Each year, new requirements were addressed while minimizing uploading-time and data-error.

VI. LEAVING OUR TRAIL FOR UNDERSTANDING K-12 STEM EDUCATION

Since its first version, the Research and Assessment of Students and Teachers Results and Outcomes (RASTRO) database has been adapted to consolidate the growth of information related to the project. The current version of the database comprises several tables linked together with information related to schools, teachers, and students for several periods of time.

In Fig. 1, tables 1–3 gather permanent data for students (gender and ethnicity), teachers (gender, ethnicity, and date of birth), and schools (school name). Fig. 1 tables 4–7 hold information that change every year for each cohort. For students, the information that varies every year is related to the academic year, existence of consent and ascent forms, tracking (i.e. student's information was updated and tests and interviews were collected), and teacher. For teachers, data that changes every year includes academic year, existence of consent form, tracking (i.e. teacher's information was updated and surveys and interviews were collected), school, grade taught, status as engineering teacher in their classroom, background, experience, teaching style, and engineering perceptions. School's information varying every year is related to the treatment (if the school was included in the engineering training program or not) and Title 1 eligibility and designation.

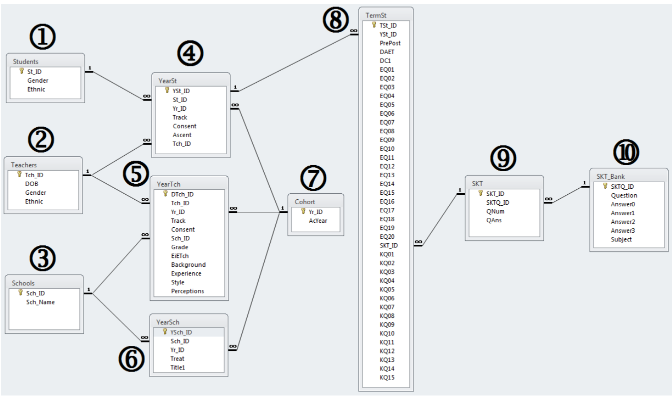

Fig. 1. RASTO structure.

Fig. 1 tables 8–10 store information that varies by semester, which is related to pre (Fall) and post (Spring) assessments for students in the engineering program. Table 8 includes the students' responses to the assessments, and the pre or post designation. Students performed three different assessments each semester; one concerns students' engineering identity development [23], a second assesses students' engineering and science knowledge [24], and the third concerns students' drawings of an engineer at work [25-27]. Table 9 holds information about the version and answer key of the knowledge test because questions changed according to grade level and term in which the test was conducted. Finally, table 10 holds the bank of items included in each of the knowledge versions with the subject assessing (engineering, technology, or science). One example of a student-registry is shown in Fig. 2.

Fig. 2. De-Identified Student-Registry

The development of RASTRO can be described as existing in three stages: its creation, its stabilization, and its improvement. The first stage of development, the creation, started during the first year of the project when the database was built. The tools were built parallel to the project development, which led to a database structure based on time of data collection instead of the system, which in this case is the school setting which includes school districts, schools within the district, grade levels, classrooms, students, and assessments. This caused a low level of data consolidation where specific test information was fractionated and a general overview of participants was difficult to capture. For the first year, development was focused on constructing an initial version of the database, learning how to systematize the process of uploading the data and how to present the information to the user. During the second year, the first automation processes were developed in open-source software for engineering and scientific applications. This upgrade was very useful for improving efficiency in a significant manner; however, automation codes were running in a separate application, which made uploading and updating data complex procedures. Between the first and second cohorts, the rapidly increasing amount of data (see Fig. 3) caused another obstacle: the database created during the first year did not fit into the application. This led to a division in the database structure, and therefore retrieving data become more complex as the amount of data in the system increased.

In the second stage of the project, stabilizing the database was the focus. This stabilization process was needed because the longitudinal data that was gathered changed during the five years of the project. A large percentage of the data gathered was highly dynamic; some project changes were related to inclusion of new schools, teachers and students, while changes within the data were caused by student name changes, inclusion of new students during the academic calendar, changes in school policies, and increasing teacher experience, among other issues. Name changes were common because of the use of a second last name (a common practice in the Hispanic community), legal status changes (using maiden or family names), or use of nicknames within rosters (e.g. Andy instead of Andrew, Andres, Andreas, etc.). Inclusion of new students during the academic year was also an issue because new entries were required within the database; often there was not enough information to identify whether the participant was new to the project, new to the school but a returning student, or was an existing student who changed classrooms. School information was also changing. For instance, some schools that were Title 1 changed their eligibility during the project. Another example of the high level of dynamism within the data was related to teacher experience. Years teaching STEM, years teaching at the elementary level, teacher assessments, and other information changed over the course of the project. Some information such as teacher experience within the project or age was easily stabilized by changing the data collected from age to birth date or from years within the project to dummy variables tracking teacher involvement year by year. Teachers updated some of their data periodically (e.g., teacher assessments or years teaching STEM); these types of information could not be stabilized.

The automations were migrated to the main application that was developed as an Excel file. Visual basic macros were created to accomplish the previously programmed-tasks for uploading data and identifying if a participant was new to the project. These tasks were improved with more flexible capabilities that allowed the program to handle a small amount of human error. Likewise, new macros were designed to complete new procedures such as double-checking old information against new information, correcting the entry of assessment responses, homogenizing assessment versions, and checking for the existence of homonyms for assigning identification numbers and uploading information for the correct participant. Another aspect of stabilization was consolidation of similar types of data within the same table, and creating links between tables with related data but different typology.

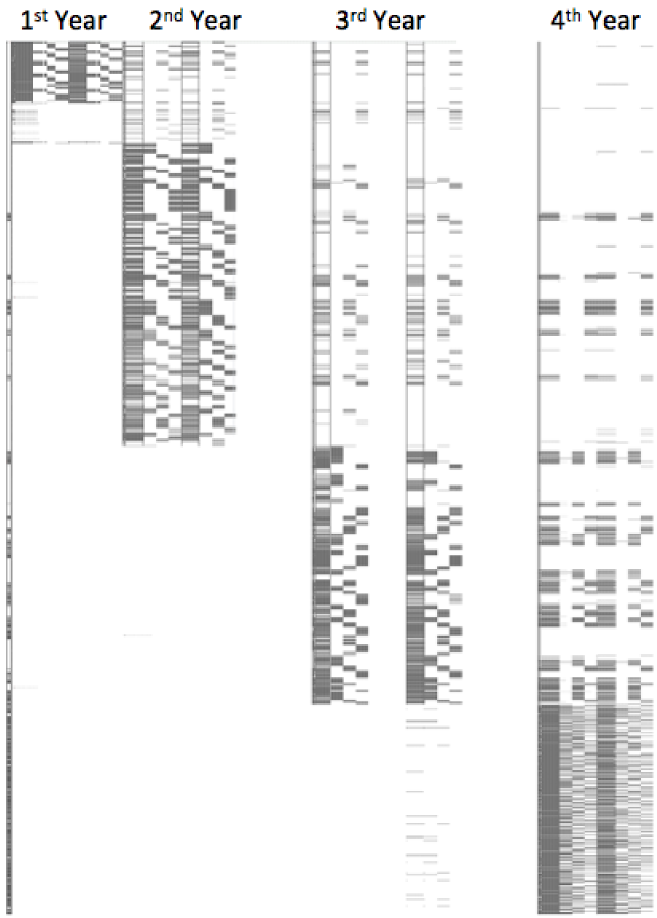

Fig. 3. Data growth between 2008 and 2012

The third stage of RASTRO improvement is currently in progress and is informed by the experiential knowledge gained during the first two stages. This stage includes more consolidation and automation advances for the database. The central goal is to increase the application robustness. This is explained in more detail in the following sections.

VII. Data Analysis

The first two stages of RASTRO database development provided an opportunity for reflection about what has worked and what needs to be improved for data analysis and reporting to happen in a timely manner. In the following three sections, the main areas of database improvement for data cleaning are discussed in relation to the unique characteristics of the K-12 setting.

A. Data and Process Consolidation

Recording data in a study is not as simple as just copying the information into a shared space where researchers can look for information. It is far more complex than that, and requires an understanding of how the data is collected, if is quantitative or qualitative, and if the collection occurs through clusters, strata, or domains. It also requires an understanding of how different types of data are connected [18, 21]. After almost five years of data collection, cleaning, and analysis, several conclusions were drawn based on what has or has not worked for this and other K-12 projects within INSPIRE.

All school settings are highly similar, no matter the state or school district involved. States, counties, and school districts function as clusters where characteristics between subjects within the same cluster are more similar than not. Likewise, classrooms may be identified as clusters on a smaller scale. Grade levels (corresponding to age ranges) between schools may be perceived as strata in which one or several levels may be studied. Lastly, gender, ethnicity, and experience (among other demographic characteristics) may be studied as domains. Therefore, it is possible to design a database structure that fits the school setting and its particular needs, taking into account how to link and validate information entered.

The research design for diverse K-12 studies may have some similarities where, impact of an intervention or improvement of an assessment tool, are common research topics. This means that pre and post data may be collected for each participant (e.g., student, teacher, administrator, parent, or community member involved in the school). In these types of studies, the information gathered could be qualitative or quantitative; however, within RASTRO only quantitative information can be gathered. Other research designs such as ethnography or case studies are common performed in school-related research; this type of information can be fit into RASTRO structure when it is coded.

The process of data digitization and entry should be systematized. This organized procedure facilitates optimizing the quality of the data gathered and therefore minimizes the time needed for crosschecking and cleaning [18, 20]. High quality data was the objective for the INSPIRE project, where data collection was arranged with teachers and administrators and collected by part of the research group twice each year. As soon as data arrived at INSPIRE, a sub-group of researchers started to digitize the information using predefined formats for each type of data. During this process different persons created the template, entered the data, and double-checked the information. After the data was double-checked, another researcher consolidated and introduced the data into the database. This process was highly automatized, which assured high upload speeds, error identification through data crosschecking, homonym identification assuring a correct link between students and their data, and auto-correction of some of the assessment response entries.

B. Usage of Appropriate Applications

Understanding the requirements for the database was not an easy task. The process of introducing data, expanding the database structure, and addressing the different challenges as they arose changed each year. Database managers needed to prevent problems related to application limitations, and they needed to anticipate potential problems with further growth in the database (e.g., researchers working with a identification scheme that would run out possible character during the third year of data collection). The technical knowledge gained from this five-year project has helped to document other K-12 projects within INSPIRE, but there were several technological challenges along the way.

The first technical problem was having the data in one application and the automatized programs in another application. The second application was more specialized; therefore, new people had to be trained before they could use it. Also, having two different applications made data-sharing more complex, leaving some room for incompatibility problems. Taking this risk into account, we decided to migrate all automation programs into the same application where the data was stored. The application where the data was being stored was chosen because it was much simpler than the application where the automatized programs where running; it was flexible and programmable, but user-friendly. Since individuals with a wide range of technology aptitudes and backgrounds constitute the research group (e.g., engineers, educators, psychologists, biologists), the decision of having RASTRO developed in a general application was based on identifying a tool that was not too limited or too complex for the database development.

A second technical challenge presented during the development of RASTRO was the space limitations of the application itself. Choosing a non-specialized application necessitated fractioning the data already consolidated so it could fit in to the application. Fortunately, this problem was easily solved because a newer version of the application was expanded and consolidated data fit it. Although solving this problem was not an issue for the development group, it raised awareness of the need for an application that prevents future limitations due to the amount of data gathered.

C. *Data Redundancy*

Data management requires backing up information in case the data is lost due to unpredictable crashes [28]. However, having a backup should be an alternative approach for data storage (where the copy is saved) and not a parallel procedure for data updating (where same information is uploaded more than one time), otherwise data management tasks will at least be doubled. The first versions of RASTRO database had several data redundancies due to its backup process but also due to its design. The aim of storing a replica of the original file is useful for preventing data loss; however, redundancies associated with the design create potential risks for data error. For instance, the fractioning caused by the growth of data gathered in RASTRO drove the database design to duplicate information linked to students, teachers, and schools. Each student entry had information related to his or her demographics, but also their teacher experience and school information; therefore, updating teacher experience implied updating information for each of the students in that teacher classroom. Although information should be highly accessible for the user, data redundancy should not be present within a single version of the database [21]. That is why newer versions of RASTRO minimized this data replication and instead developers created links between related data.

D. *Information Visualization*

The next problem was how to best present the data to the users. Since the research group involves several individuals, data is handled by different people and is retrieved for several different analyses. The importance of creating a user-friendly interface was identified as one of the core requirements for the database development. The first step for addressing this challenge was to clean redundant data while providing redundant visualization of that data. Many applications provide high levels of accessibility and data navigation when presenting information to the user [28]. Likewise, RASTRO was improved in order to communicate the information in more than one way while avoiding data redundancies present in initial versions of the database.

VIII. RASTRO Improved

After five years of data collection, data analysis, and database development, some changes have been made to the structure and automation procedures of the database. The analysis of lessons learned has led to major changes within the database and users have perceived benefits of automatized tasks and more stable structures.

A. *New Structure*

Understanding the general structure of school-based research is crucial for data characterization and categorization. For instance, a separation of data was performed for improving schema design [18, 21] based on levels of confidentiality, information related to student demographics, student assessments, teacher demographics, teacher assessments, and school information.

Demographic information for teachers and students included consent, gender, ethnicity, grade, and school. Besides this general information, students' data also included ascent forms (required for minors), primary teacher, and secondary teacher. These two teachers were the homeroom teacher and the teacher who implemented the research-based intervention for that classroom. Teachers' general information also included data about the treatment or control group. Although information related to schools was initially part of student and teacher data, during the stabilization stage it was entered separately to avoid redundancy and provide a consolidated dataset for schools. Finally, data gathered from student assessments and teacher assessments was stored in separated tables within the database. This separation was made to optimize space and enable the creation of assessment-specific automations for correcting and storing assessment responses.

B. *Uploading, Updating, Crosschecking*

The database development also included the development of programs to automate tasks. This was necessary due to the large amounts of data that needed to be uploaded or updated every year. At the start and end of each academic year, data were collected from as many as 15 schools, 168 teachers, and 3,388 students. Basic information such as student identification and assessment scores was needed quickly to provide teachers with feedback and researchers with results for analyses. In the first year of the project, those tasks were easily performed because all students were new, and just 227 of them were part of the project. Challenges in performing those tasks arose in the following years. During the second year of data collection, new students joined the project while some students remained, and identification of homonyms and returning students become essential for uploading information accurately. Every year thereafter, new students joined, some old participants changed schools but remained in the project, and still some others supplied homonyms or changed their names. This increased the probability of error in student identification and data decay [18]. The program that was developed for addressing this risk performed a crosscheck between approximately 3,200 unique participants and each group of students within each participating classroom. Tasks that took a researcher several minutes per student assessment are now performed by the program within just few seconds using rules for uniqueness and consecutive values [18].

Similarly, tasks such as scoring an assessment took a significant amount of time for researchers, even when templates were used for scoring each assessment. Scoring took a large amount of time because three different versions of one assessment were conducted with students, and translating those versions into one unified form was a complex process. Automatized tasks for scoring were developed based on uniqueness, consecutive, and null rules and regression outcomes from previous researches [18, 23-25], diminishing the time for this process from a couple of minutes per assessment to few seconds. Other automatized tasks included assignment of a student identification number to each assessment, consolidating assessment information, identifying inconsistences between information provided in class rosters, pre-assessment and post-assessments, and identifying spelling errors in participants' last names for participant data-recognition. This process of core-task-automation significantly shortened times between raw data collection and clean data consolidation.

IX. Further Work

Although several versions of RASTRO have been developed and many challenges have been addressed, there is much room for improvement.

The RASTRO database should be migrated to a stronger data-management application, one that has the ability to link related data, assure data integrity, and therefore allow for the creation of simpler queries for data retrieval. One of the principal advantages of this upgrade will be the reduction of time to enter and retrieve data and errors in the database. This migration will also assure that data will fit into the application. Although several applications meet these requirements, it is important that users with diverse backgrounds will be able to manipulate the data.

Other developments for a future version of RASTRO may include better user-interfaces. For instance, data entry can be performed through forms directly linked to the database information, providing automatic crosschecks before the data is stored. Another improvement for the user interface is the creation of automatic reports, created for retrieving the data in a user-friendly report. This is only possible if a database application is used. Finally, the creation of a formal procedure for data digitization, consolidation, and retrieval can help avoid common mistakes such as those overcome in this project.

X. Implications

The development of RASTRO has led to insights on data management for school-related research. The design process incorporated new structures for data gathering that where more compatible with the characteristics of K-12 settings. This also increased the flexibility of the database to manage some human error and particularities while automatizing the primary tasks needed for data entry, updating, and crosschecking. This insight may be useful to other school-related projects, not only in STEM education, but in other fields using similar research designs. Having a structured and automatized, yet flexible, database tool may contribute to other projects in shortening times for entering, cleaning, and retrieving data. Using a flexible and user-friendly interface will assure that the tool can be managed by people with a wide range of technical knowledge.

Assessing the Impact of Service-Learning on First-Year Engineering Students' Understanding of Human-Centered Design

Roy B. Melton[1], Monica E. Cardella[1], William C. Oakes[1,2], Carla B. Zoltowski[2]
[1]Engineering Education, [2]Engineering Projects In Community Service (EPICS)

West Lafayette, IN U.S.A.

***Abstract*—This paper represents an update of a three stage research project that culminates in investigating the impact of the service-learning pedagogy on students understanding of human-centered design. The first two stages of the project were disseminated in previously published papers where we discussed the discovery of distinct ways in which students experience human-centered design, along with another published paper discussing the development of an assessment task that would expose and capture students' understanding of human-centered design.**

Keywords*—*human-centered design, assessment, service-learning

I. Introduction

As the engineering education community has become increasingly concerned with engineering design education, research has been conducted to understand various issues associated with the complex phenomenon of the design process. Investigations into design have included; expert-novice differences in engineering design process [1], expert-novice differences in knowledge about the engineering design process [2], methods for assessing or measuring engineering design process and understanding (e.g. TIDEE) [3], and approaches for teaching engineering design [4]. In this project, we investigate these three issues: (1) different "levels" of understanding of design, (2) how to assess understanding of design, and (3) service-learning as an approach for helping students develop design skills, following Pellegrino's Content, Assessment, Pedagogy triangle [5].

II. Previous work

This work is a continuation of a three stage project that examines the learning of human-centered design. The project investigates three research questions:

1. What are the dimensions associated with having an understanding of human-centered design?
2. What is the impact of service learning on students learning and understanding of engineering design, and more specifically, on having an understanding human-centered design?
3. What are the attributes of service learning courses that help students develop an understanding of a human-centered design process?

The research focuses on human-centered design (HCD) as a version of an engineering design process which has a focus on, not only considering, but constantly involving stakeholders throughout the design process, and has been linked with innovation [6]. In earlier papers, we described a phenomenographic study in which we characterized seven different ways in which students experience and understand human-centered design to help us to articulate different stages in a learning trajectory [7,8] and are shown in Figure 1.

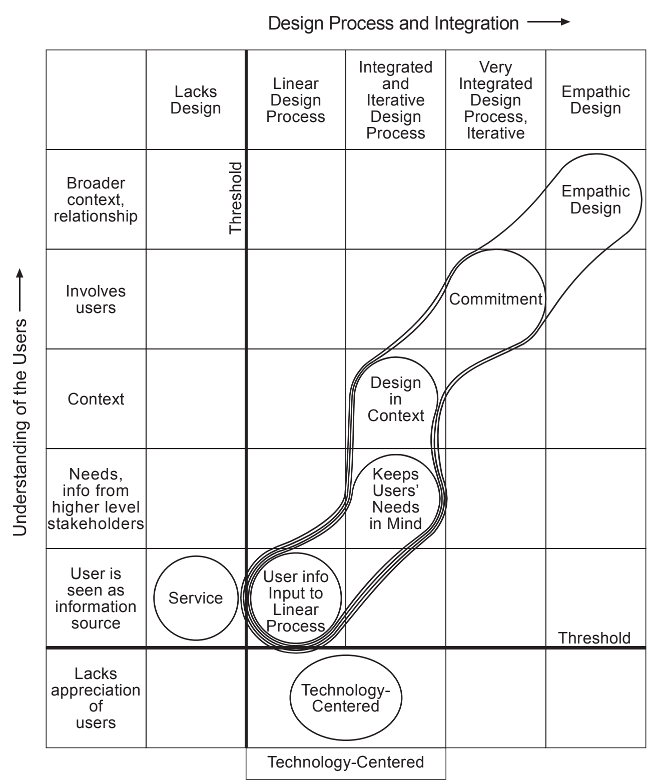

Fig. 1 Outcome Space for Students' Ways of Experiencing Human-Centered Design [7]

This work was made possible by a grant from the National Science Foundation (EEC 0935077). Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation..

The categories of experiencing HCD described were: technology centered, service, user as information input to linear process, keeping the users' needs in mind, understanding the need in context, commitment to involving stakeholders to understand perspectives, and empathic design [8]. Respectively, as the categories are stated, they represent a continuum of increased understanding of HCD [8]. With evidence of a HCD learning trajectory in hand we endeavored to create an assessment task that would also be capable of exposing students' understanding of HCD.

We next began to develop an assessment task that would elicit and capture students' understanding of human-centered design [9,10]. The purpose was to create an in-class assessment that could be used by any educator teaching design without using interviews as was done in the phenomenographic study [8]. This assessment tool provides a mechanism for researchers and educators to map a student's understanding of human-centered design to one of the seven stages identified in the phenomenographic study, without the use of extensive qualitative methods of analysis. Thus, the tool could be useful not only for potential research purposes, but more importantly could be used easily by design educators interested in providing students with quick feedback on their understanding of human-centered design. The creation and validation process of the assessment task followed a HCD process where stakeholders were involved, including many students and design educators. The assessment task underwent several iterations of pilot testing and revisions which included the task being reviewed by design educators and being reviewed by design education experts at an FIE special session in 2011. The final assessment task consists of a design task and reflection questions, which are to be completed individually and consecutively. The design task consist of a design scenario, blank paper for students use as they see fit, and a detailed table for students to indicate the various activities to be completed to address the concerns presented in the scenario (The assessment task development is discussed in detail in [10]). The final pilot included collecting data with students from two different institutions, one of which has an undergraduate degree program in human-centered design.

After completing the multi-stage validation process, we administered the assessment task to two groups of first-year engineering students at Purdue University. One group of approximately 110 freshman students were introduced to the engineering design process through more traditional pedagogical approaches such as an 8-week design project for an unspecified client, augmented with lectures, in-class activities and homework assignments aimed at developing specific design skills. The other group consisted of approximately 110 freshman students who were introduced to design through a service-learning experience. Each group of students was given approximately 60 minutes to complete the task and reflection questions. Students were introduced to HCD principles through some lectures but primarily worked with a real client. Design was mainly learned through the design of a deliverable for the client.

III. ANALYSIS

Analysis of the first-year engineering data is currently underway, with the guiding research question of: *Do students who learned design through a service-learning experience demonstrate a more comprehensive understanding of human-centered design than students who did not participate in the service-learning experience?*

Answering this question will help us to better understand the impact of service-learning experiences on students' learning of human-centered design skills and knowledge, and help inform decisions made by engineering institutions nation- and world-wide as other engineering education leaders consider adopting service-learning models. To date, we collected data from the first-year students at the end of their first-semester (after they either had the service-learning design experience or the more traditional experience).

To analyze, or code, the collected responses, we "place" each response into one of the seven categories described by the phenomenographic study [8]. The analysis approach we have taken has been to search the artifacts (the students written responses to the task) for evidence that would justify putting a student's response in a certain category. For example, we would look for stakeholder involvement in the design process or what type of information students were getting from stakeholders and how that information was integrated into the design. As we developed our analytic approach, each member of the research team scored a task individually, and then we each discussed the reasoning for each placement. This process not only helped us come to a consensus about what was being captured by the design task, but the discussions about the minute and distinct differences between the categories also helped to lay the ground work for an analytical rubric that is currently in development. In line with creating an in-class assessment, it would be necessary to have an analytical rubric to consistently and confidently rate each response. Once the analytical rubric has been developed we will calculate inter-rater reliability and score the 220 first-year students' responses.

IV. PRELIMINARY FINDINGS

To date, two coders have coded 70 design tasks, about 30% of total data set (35 students with service-learning design experience and 35 students with the more traditional design experience). Very preliminary results do show a variety of responses ranging from categories 1 thru 5, respectively; (1) technology centered, (2) service, (3) user as information input to linear process, (4) keeping the users' needs in mind, and (5) understanding the need in context. Preliminary results also show the service learning group has a higher concentration of responses that were coded to be in one of the higher categories, namely, (4) keeping the users' needs in mind. The preliminary results also show that the service learning students also tend to use the blank space provided in the design task more often than the non-service learning students.

V. Future Work

In the future we will need to administer the task to similar groups of students at the beginning of the semester to examine the possibility that the service-learning students may exhibit a more comprehensive understanding of human-centered design on the task because of differences in the populations. That is, there is a limitation in the study presented in this paper in that students self-selected into either the service-learning first-year engineering course or into the more traditional first-year engineering course. Hence, we need to determine if the students who chose to participate in a service-learning course as first-year students might start with a more comprehensive understanding, or perhaps appreciation, of human-centered design because they are more interested in designing for others than students taking the more traditional version of the class.

We will be collecting data from seniors, some with service-learning experience and others with limited or no service-learning experience. Comparing responses to the assessment task for these two groups will give us insight into what impact a continued service learning experience has on students understanding of human-centered design. It will also be interesting to note if some students not involved in the service-learning context are assessed to have a high level of human-centered design understanding and investigate that class structure and the methods of the design educator.

At the FIE conference, we will present our preliminary findings and analysis of the first-year engineering data. We will also report on the progress of the study of the data collected from the senior students.

A Pilot Study: Documenting Engineering School Systems that Support High Student Retention

Brian L. Yoder, Ph.D.
Department of Assessment, Evaluation and Institutional Research
American Society for Engineering Education
Washington, D.C.
b.yoder@asee.org

The American Society for Engineering Education (ASEE) has engaged with the engineering education community to define and pilot the current best approaches for systematically collecting and analyzing student success data. Out of these efforts, ASEE has developed a survey that provides reliable, broad-based data for national retention and time-to-graduation benchmarks. ASEE plans to build on its retention and time-to-graduation survey and work collaboratively with engineering schools using a design-based implementation research approach [1]; and plans to document engineering school systems that support high student retention, with a pilot that focuses on schools that excel at retaining engineering students who are from the regular majority (i.e., schools that admit students through less selective admission requirements but are able to retain those students at high rates).

Keywords— (*student retention, engineering students, design-based implementation research approach****)***

I. Introduction

Since 2008 the American Society for Engineering Education (ASEE), with funding from the Sloan Foundation, has engaged with the engineering education community to define and pilot the current best approaches for systematically collecting and analyzing student success data. Out of these efforts, ASEE has developed a survey that provides reliable, broad-based data for national retention and time-to-graduation benchmarks. Schools that participate in the survey can measure their retention success against both a national benchmark and an aggregate retention of selected peers. ASEE plans to field the survey annually, increasing the number of schools that participate each year. During the summer of 2012, 123 engineering schools participated in the survey with 97 schools providing retention and time-to-graduation data.

ASEE plans to build on its retention and time-to-graduation survey and work collaboratively with engineering schools using a design-based implementation research approach [1]; and plans to document engineering school systems that support high student retention, with a pilot that focuses on schools that excel at retaining engineering students who are from the regular majority (i.e., schools that admit students through less selective admission requirements but are able to retain those students at high rates). From the 97 schools that submitted retention and time-to-graduation data in 2012, ASEE will create a subgroup of public schools with less-selective admission requirements. We will look at the distribution student retention and time to graduation for this subgroup of schools. We will select one of the schools to work with to pilot data collection from the subgroup that is consistently at the high end of the distribution for retaining and graduating students. The results from the pilot will feed into a full proposal, due September 2013, requested by the Sloan Foundation to document the systems of other engineering schools.

II. Pilot to Focus on Less-Selective Public Schools

ASEE will focus on less-selective public schools who educate the regular majority. We know from the work of Vincent Tinto that student persistence can be attributed to the interaction of student pre-college attributes, such as quality of high school education, parental socio-economic status, community where the student lived; with the college system after they begin attending college, in particular college academic and social systems [2]. More selective engineering schools can admit students that have a greater predisposition to persistence, thus contributing to a high student retention and graduation rate, and historically engineering schools have focused more on recruitment than retention [3]. Less selective public schools, because of their school mission, may not have the flexibility to recruit and select students for their engineering programs that have a high propensity to persist, but these schools can focus on structuring their programs to contribute to high student retention. Less selective schools, because of school mission, may not want to focus on recruitment as much as retention, and, if engineering is to become more diverse as a discipline, more emphasis should be put on student retention [4].

III. Documenting "Systems" that Support Engineering Student Retention

ASEE recently asked representatives from over 350 engineering schools to submit their student retention practices to ASEE. ASEE received over sixty submissions from more than forty schools. Two outcomes from this study include: 1)

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

schools reported utilizing multiple retention best practices to retain students in engineering, and, 2) these best practices are implemented holistically, in a manner that could best be described as a system.

ASEE proposes documenting engineering school systems that support high student retention, first through a pilot with one school. ASEE will document the engineering school's system through reviewing school documents, and utilizing a series of inductive and deductive data collection processes drawing on on-line surveys, interviews, and structured focus groups to document the perceptions of those who are in the system – school of engineering administration, selected faculty and students.

We will use a process similar to one developed by William *Trochim* called concept mapping. Concept mapping is a structured process, focused on a topic or construct of interest, involving input from one or more participants, that produces an interpretable pictorial view (concept map) of their ideas and concepts and how these are interrelated. [5]

We will use concept mapping to create a pictorial view of the system that supports high student retention, as well as a written report on the system. As ASEE found through its documentation of retention best practices, and as cited in college retention research literature [i.e. 6,7,8,9], schools employ multiple strategies to retain students, and how these strategies are implemented and how these strategies work together as part of a system will be important to understand how schools can better retain engineering, in particular, students from the regular majority as well as students from groups that are under-represented in the field of engineering.

IV. CONNECTING THE DOTS – PRACTICE TO RETENTION RATES

Documenting school systems that support high student retention will help the engineering education community connect retention strategies and systems that support high student retention. Leaders in engineering schools whose systems have been documented will be encouraged to make presentations on their system within their school to interested peer schools. Peer schools that want to innovate their retention strategies by adapting what they have learned from their peers, can measure the success of their innovations in their school's retention rate by participating in the ASEE Student Retention and Time-to-Graduation Survey.

For engineering schools that are interested in increasing their student retention rates, they will have knowledge of successful systems that support student retention. Additional, ASEE will encourage schools to experiment at their own schools to implement what they've learned to increase their retention. Schools will be able to experiment and test the result of their experiments through ASEE's national retention and time to graduation survey.

***Abstract* - Designing for others is a paramount focus of teaching user-centered engineering design. This paper presents a novel engineering design brief presented to undergraduate engineering students to design for extra-terrestrials scheduled to visit their collegiate campus. Through this alien-centered design approach, students are pushed to develop empathy for a group of users quite different from themselves and to conceive and design within such an given context. A detailed plan of action is described for both cases with detailed deliverables aligned to course learning objectives. Examples of the interactions students make with their extra-terrestrial users are listed and examples of student work and final deliverables are highlighted. Reflections from the end of project are also included from students and instructors alike. The work presented here may serve as a building block to these types of successful engineering design projects in the classroom.**

Keywords – alien-centered design, user-centered design, empathy, context, engineering design projects

Introduction

Context and empathy are hallmarks of user-centered design practice [1]. Both engineering students and professional engineers early in their careers often have an initial mindset of designing for themselves rather than others. This can result in products that may not adequately meet the needs of their imagined users. This paper presents a novel engineering design brief presented to undergraduate engineering students to design for extra-terrestrials scheduled to visit their collegiate campus. By having students design for aliens rather than humans, students are challenged to develop empathy [2] and design for the needs of their users rather than for themselves. This paper compares two classroom implementations of this alien-centered design pedagogy: a freshman introductory design course and a junior electrical engineering design course.

This paper will present details about each of the stages of the design process in the two implementations, as well as the rationale for each of the teaching decisions, and how the activities map to principles of human-centered design. Additionally, we will provide more details about the different types of projects students worked on, and discuss how this technique could be adapted to other courses.

Case 1: Freshman Engineering Design Course

I. Context

At a large Midwestern research university, user-centered design has been a major focus of the first semester first-year engineering course taken by all engineering students. Students tackle an engineering design project in response to a given Request for Proposals (RFP), working in teams of 4. The focus of design projects change each semester. For Spring 2012, the course instructional team for one section challenged students to consider a new, inter-galactic student exchange program planned with students from the planet Xenos.

II. Course Design

In the second half of the semester (8 weeks), the 117 students in the section worked in teams to identify an aspect of the Midwestern University (MidwesternU) student experience that would need to be modified to accommodate the extra-terrestrial students. They posed questions to gather information that would help them learn about the "user group" and learn more about the context of the challenge. The instructional team wanted support the practice of asking questions so responses from the aliens were developed. Students were directed to identify all of the major stakeholders impacted by their project ideas and brainstorm multiple possible solutions. Teams were guided to use a systematic process for selecting a solution and created 2- and 3-dimensional models of their solutions (using SketchUp for the 2-dimensional models and everyday materials to create rough prototypes). Teams presented their final solutions through oral presentations and a written report.

Student teams also responded to feedback and new information throughout their project process. In particular, they needed to respond to updated information that the instructors received via "intergalactic correspondence with the Xenos (student) aliens." At times, the interpretation of information provided to students changed and even contradicted information that students had received earlier. As students were finalizing their project, they were given an opportunity to ask a last question "What one piece of information would help you the most as you finalize your project?"

III. Examples

Project initiation: Students were provided with the following prompt in the RFP:

MidwesternU will be piloting a new student exchange program this Fall: Students from Planet Xenos will be spending 9 months taking courses at the University as part of their intergalactic studies program. The MidwesternU would like your input—from the perspective of a student and perspective as an engineer—on things that the University can do to help the alien students adapt quickly. Proposals will be evaluated based on their ability to identify a critical need that is important for a successful alien student exchange experiences. The need may be associated with a broad range of topics: transportation to/from or around campus, a physical building space (internal and external), access to food, etc. Each team may define different needs. Your solution should not cost more than $10,000 to build or implement. We encourage you to imagine solutions that are considerably less expensive.

Project milestones and "design guides": Throughout the 8 weeks, students received design guides that scaffolded the design activities required for the project, putting the first-year engineering students on a path to successfully complete the project on a time. This scaffolding strategy has been found effective in moving students from being *beginning designers* to being *informed designers* [3]. The design guides serve as a tool to communicate with the students the instructional team's expectations for a particular stage of the project. In Spring 2012, there were 5 milestones, listed in Table 1.

TABLE 1
FRESHMAN DESIGN PROJECT MILESTONES

Milestone	Description
1.	Needfinding: Day-in-the-life of an alien story, photos of possible needs
2.	Problem Scoping: the team's focus, goals, constraints and criteria
3.	Concept generation
4.	Concept reduction and selection
5.	Concept detailing and prototype

Figure 1 shows an example of the Milestone 1 design guide. In previous semesters, students were provided a "checklist" outlining the elements they should have in each deliverable they produce at each milestone. However, a graphical representation of the expectation was found, in a less formal way, to be an effective technique to foster creativity and imagination in students' work. This was found to be especially necessary in the context of the alien-centered design because of the non-traditional way of working invoked. Students were encouraged to "play" with ideas and transform to innovations as opposed to rigidly following a predetermined checklist.

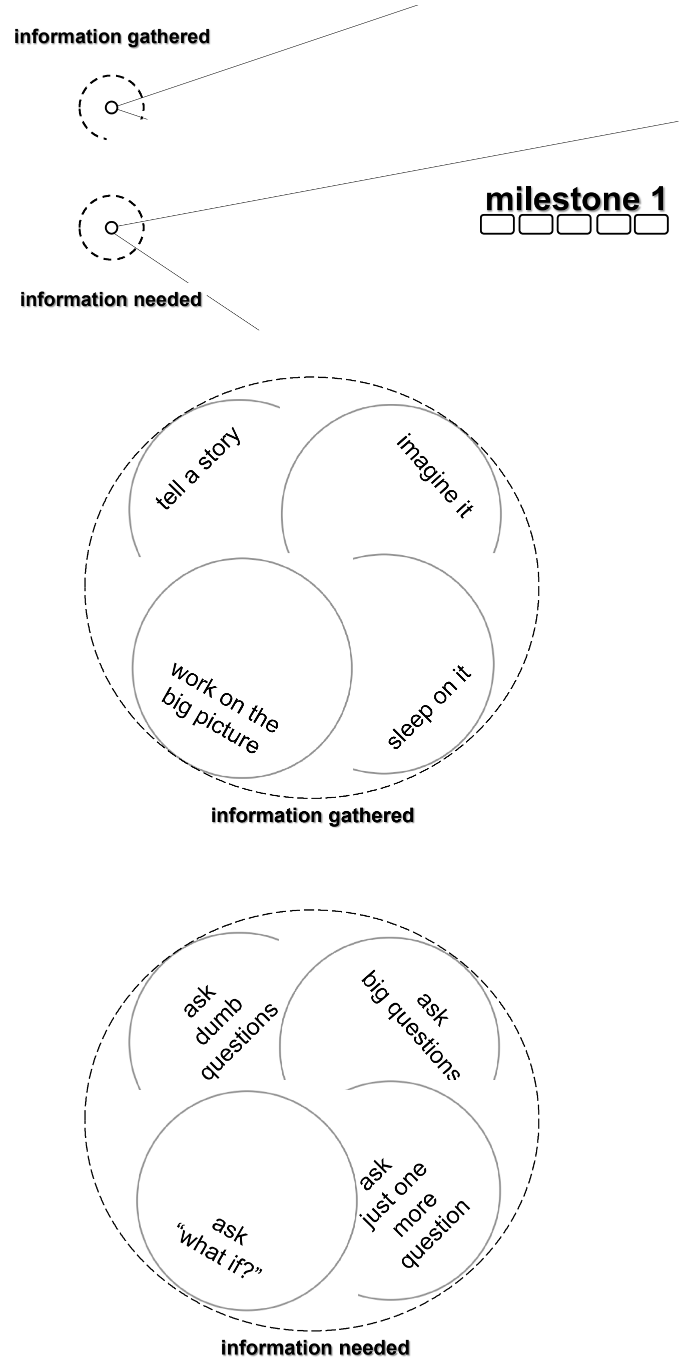

FIGURE 1
MILESTONE 1 DESIGN GUIDE.

Correspondence with the alien: With the completion of the first milestone, students gathered photos from around campus for situations identifying critical needs to be addressed. A story was written on each picture, describing the critical need in the context of "a day in the life of the alien," and elaborating on the design opportunities. Figure 2 lists two examples of pictures from around campus, and stories around the pictures describing critical needs that need to be addressed before the alien's visit.

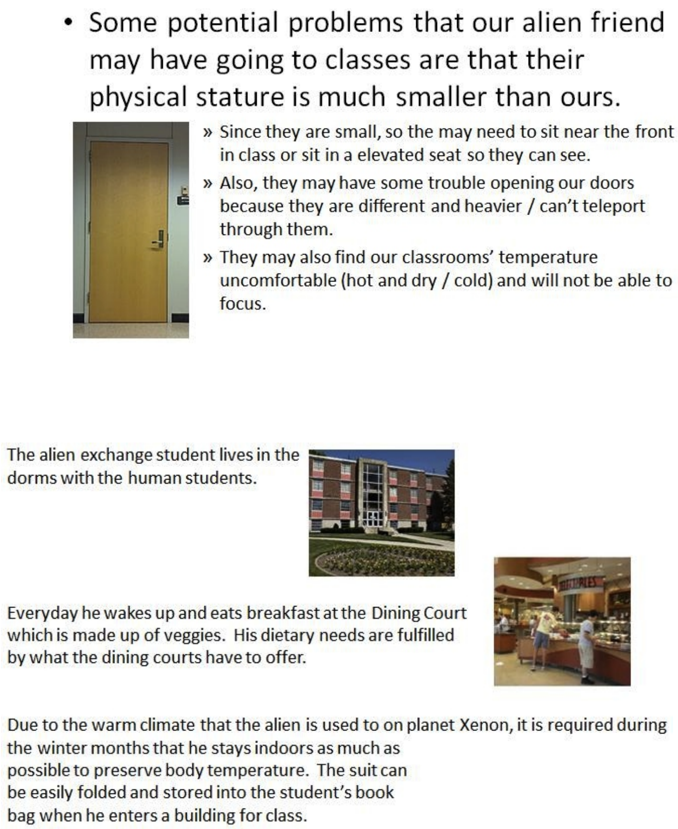

FIGURE 2
EXAMPLE STUDENT PHOTOS AND STORIES

TABLE 2
EXAMPLE OF SAMPLE COMMUNICATION WITH THE ALIEN

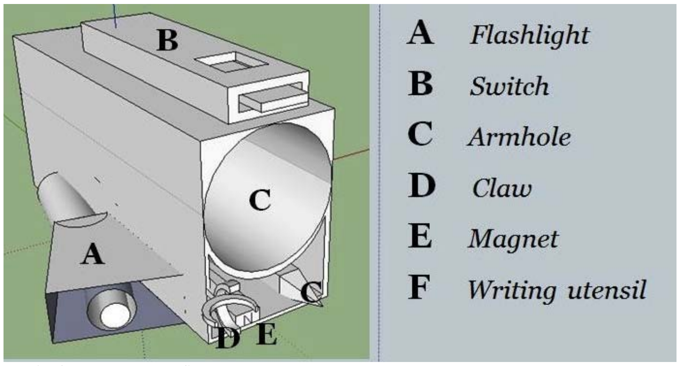
Questions and answers
Q: How do you look like?
A: Essentially, I can morph (change shape) to any of the basic volumetric shapes
Q: What do you do in your spare time?
A: After doing some research about your planet Earth, I figured that we have different concepts of time. My planet rotates twice as fast as your planet. We can, naturally, move three times as fast as you can. However, we are slow in accomplishing what we do, roughly half of you. So, I'm really not sure what you mean by spare time here.
Q: What kind of technology do you have?
A: It depends on where you are from Xenos; people in villages, for example, and given your previous question on time, use something similar to what you call sand clocks. In the advanced metropolitan areas, however, people can travel from one point in the universe to another through tunnels connected via black holes. These tunnels are sometimes being manufactured, and, some other times, they exist naturally, simply because of the physics of our universe. We figured out how to do all this. Does this make sense?
Q: How long and wide should the new keys of the piano be to fit alien's fingers?
A: How did you humans come up with the idea that we have fingers in the first place? I love music, though! I doubt I will be able to learn how to play your music that fast..
Q: Do we need to change the temperature control systems to fit your alien's body condition?
A: Nope! I'm fine!

The instructional team used this activity as an entry to direct students in the design activity. At the end of each story submitted, students were asked to provide questions they have for the alien. This technique simulates interacting with a direct user in a regular user-centered design. It is flexible, yet effective to enhance students' abilities to explore the design space by asking users about their needs (and remember that the users are very different from themselves). The Teaching Assistant compiled the questions and responded to them, playing the alien's role. This step was not as trivial as it may seem. It requires (1) providing design opportunities for projects that would last about 8 weeks; (2) providing incomplete information that are open to interpretation, simulating as much as possible a normal design situation; (3) showing the students that the design opportunities that they have shared are expandable, promising, and, most importantly, are listened to and communicated with the alien (i.e., the instructional team) so that they feel there is a response to their design work from the early stages of the design process. We felt that this was essential to the success of this design process; that is, the fact that there is a two-way communication between the designer (the student) and the alien user (the instructional team). An example of the importance of the step in directing students' projects is shown in one of the questions in Table 2. Some students were asking about temperature control. The instructional team knew that this may not be a fulfilling project for students in their freshman year, as it requires disciplinary knowledge beyond their grasp at this stage.

Students were also given the opportunity to ask one last question of the aliens as they were finalizing their design solutions: "What one piece of information would help you the most as you finalize your project?" This was done to simulate usability testing. The professor responded to each of these final requests.

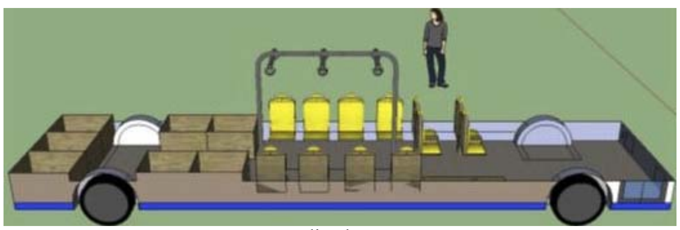
IV. Sample of Students' Work

Students were able to creatively respond to possible design opportunities. Projects ranged from assistive devices to fully functioning drinking fountains to orientation programs. Figure 3 shows both the range of scope and the modeling and rapid prototyping activities student teams undertook. Figure 3a shows an example of a platform that the alien can use as fingers (aliens did not have ones in the scenario provided). Figure 3b shows a non-functional prototype of a device that provides sustainable supply of energy from light (aliens needs a sustainable source of energy). Figure 3c shows a solution for the alien's use of the bus system (aliens could morph to basic volumetric shapes and needed to be supported while riding the bus). Figure 3d shows a design for an alien cycling machine (aliens could change shapes while exercising). Figure 3e shows a solution for the alien's need to understand time on Earth (aliens had a different perception of time; Table 2). Students' solutions were not constrained to physical products. In one of the solutions, and in order to help the aliens adjust to Earth culture, a brochure was suggested which includes information

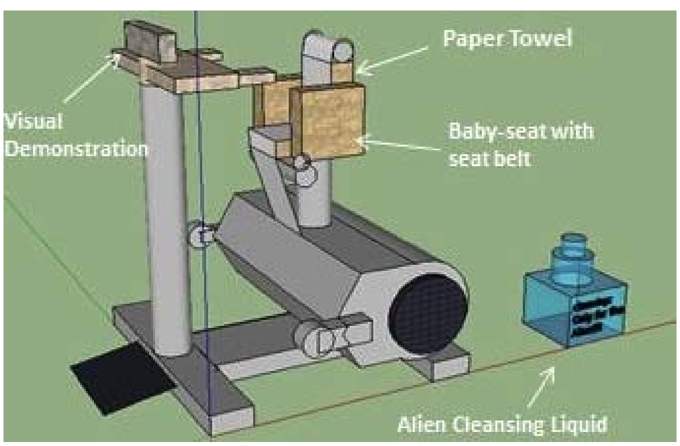


a. platform to use as fingers

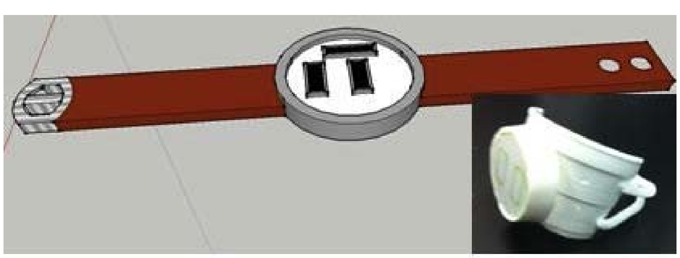
b. sustainable source of energy



c. alien bus system



d. alien cycling machine



e. alien time telling device

FIGURE 3
EXAMPLE STUDENT SOLUTIONS

about the person they will live with, as well as several tips about the local culture. The students in this project designed a sample brochure and demonstrated how an alien user would interact with it (interaction design).

V. End of the Semester Reflection

During the last class session of the semester, the professor conducted a debrief session where she introduced the ideas and terminology of user-centered design formally (through a lecture with PowerPoint presentation) and connected the major ideas of user-centered design with the projects the students had just completed (the students had given their final presentations in the previous class session and had submitted their final reports). For example, aliens the Teaching Assistant provided the students with the second set of “responses from the aliens,” where some of the information in the second set of responses conflicted with the information from the first set of responses. The professor connected this experience of receiving contradicting information (and the frustration that students experienced when they received conflicting information) to the experiences that engineers and designers typically experience while designing for customers, clients, or bosses that either change their mind about what they want, or have a difficult time describing their expectations or needs.

CASE 2: JUNIOR ELECTRICAL ENGINEERING DESIGN COURSE

I. Context

At a large Southwestern research university (SouthwesternU) in a project-based ABET-accredited general engineering program, students take full-term project classes every semester. Freshmen and sophomores take multidisciplinary project classes focusing on learning user-centered design from the top down, learning prototyping methods and developing empathy with real users in the community and developing world. Juniors take disciplinary project classes based on their chosen specialization (electrical, robotics, mechanical, or civil), and seniors take a year-long multidisciplinary sponsored capstone project. This section highlights the junior electrical and robotics specialization project course, offered in the Fall 2012 semester. This is the first specialization course that students take in the program, and in many cases provides their first exposure to embedded systems design beyond using Arduinos in their freshman year.

The context of the course was an exchange program with the Methanian aliens, who would be visiting SouthwesternU from their planet Arcturus IV as part of an intergalactic studies program [4]. Students were challenged to draw on their experience as both college students and student engineers to propose and prototype adaptive devices to help the Methanians during their time at SouthwesternU. Methanians have different physical characteristics, hear and speak at different frequency ranges than humans do, and have slower reflexes. Information on the characteristics of the Methanians was presented to students in the form of ancillary documentation.

II. Course Design

Over the course of 16 weeks, 20 students in groups of 4 used an engineering design process to *identify critical needs* (for interface, improvement, innovation, translation, etc.) of the

Methanians that could help them adapt to a semester on Earth, *pitch their invention ideas* to the class for feedback, and *go through a traditional embedded systems design process* to choose components, design circuits, create a printed circuit board, design and write software, and design and build product packaging. The final goal for each team was a fully-functioning prototype meeting the following requirements:

- Be an alien-centered design for the Methanians from Arcturus IV
- Use a Cypress Programmable System on a Chip (PSoC®) 5 Development Kit
- Be constructed on a custom printed circuit board
- Be programmed in C
- Receive input from at least one sensor
- Control at least one actuator based on input from the sensor(s)
- Be tested with a surrogate alien at least once
- Be documented with a poster describing how it solves the problem
- Stay within a budget of $60 per team member
- Meet additional requirements as defined and agreed upon by the team and the professor

The project requirements were designed to require a minimum level of technical rigor in all projects to meet course learning objectives while still allowing students to pursue their individual interests. Following discussion of requirements, teams completed the following major deliverables over the course of the semester:

Invention Pitch: teams presented 2 identified needs of Methanians based on the supplied medical charts and overview of Arturus IV, recommended inventions that addressed those needs within the constraints of the project, and received feedback from the class to help them choose one

1) *Problem Definition:* criteria and constraints
2) *Major Component Selection Rationale:* written report comparing and contrasting options for major electrical components
3) *Block Diagram, Electrical Hardware Design (schematic, bill of materials, power budget), Printed Circuit Board Layout, Software Design, Mechanical Design:* teams must create and maintain these design artifacts for their projects
4) *Gantt Chart:* requirement for project planning updated throughout the semester
5) *Design Review:* each design was reviewed in depth by faculty members and classmates
6) *Proof of Parts:* teams must submit proof that all parts they need have been sourced to avoid delays
7) *Progress Demonstrations:* teams must demonstrate to the class what they have working, share what they have learned so far, and describe next steps for their project
8) *Final Presentation and Demonstration:* team presentation in which the project results are reviewed in depth by faculty members and classmates
9) *Final Report:* team report documenting the project design, implementation, and evaluation
10) *Project Repository:* shared electronic repository containing latest versions of all deliverables
11) *Weekly Reflections:* students individually completed reflections on what went well in the last week, what could be improved, and what they will do in the upcoming week

III. Examples

Invention Pitch: based on provided medical records and survey information on Arcturus IV, teams identified a number of needs related to Methanians creation of and receptiveness to sound, sense of time and reaction time, dislike of light, and necessity of maintaining a reasonable temperature in order to nurture babies (see ***Error! Reference source not found.***

TABLE 3. EXAMPLE INVENTION PITCHES

Category	Inventions
Sound	• *Noise-canceling headphones* to minimize background noise that distract Methanians • *Speech compressor* to eliminate Methanian sounds that will hurt human ears • *Sound amplifier* to amplify weak Methanian voices
Time	• *Wristwatch alarm clock* to remind Methanians to attend class after sleeping for 34 hours at a time • *Robotic joint* to assist with slow Methanian reaction time
Light	• *Sunglasses* to filter the excessive ambient light present in the Southwest
Temperature	• *Cooling vest* to maintain Methanian pouch babies at a comfortable cool temperature

Problem Definition: each team clearly defined the problem and how their team's invention would solve it. For example, the Methanian Portal team decided to "design an apparatus which will provide easy access for the Methanian visitors, in and out of [SouthwesternU]'s buildings" to address the slow movement of Methanians that may cause them to get stuck in automatic doors. The Methanian Portal team's criteria and constraints are listed below in Table 4 and Table 5.

TABLE 4. METHANIAN PORTAL PROJECT CRITERIA

Criteria	Rationale
Have sensors to detect presence of a Methanian in front or back of the door	Need to allow the door to function automatically
Include safety features to prevent harm to the Methanians	Closing door has enough force to cause injuries, which are undesirable
Use a linear actuator to open & close the door	Since we were given an actuator, if we can make use of it, we save some of our budget
Build the door in an 'Iris' style	Will add a level of technical complexity that's more interesting to build than a standard door
Physical door must be scaled down in size, yet large enough to illustrate the concept	If we were to build a full-size iris door, we would likely have too much weight to move, and the cost would be prohibitive

TABLE 5. METHANIAN PORTAL PROJECT CONSTRAINTS

Constraints	Rationale
Designed for Methanians from Arcturus IV	The group in need of our design
Use a Cypress PSoC® 5 development kit	Microcontroller specified by instructor
Design and implement a daughterboard (PCB)	To interface the PSoC® with our additional components, sensors, actuators, etc.
Have at least one input device/sensor	Required by project definition
Control at least one output device/actuator based on data from the sensor(s)	Required by project definition

Electrical Hardware Design: One concern for adding significant context to a technical course is reducing the technical rigor. However, as shown in Table 6, all teams met or exceeded the technical requirements of the course.

TABLE 6. PROJECT TECHNICAL RIGOR

Team	Technical Characteristics
Methanian Alarm Clock	• *Sensors:* Matrix keypad • *Actuators:* LCD screen • *Other circuitry:* Backup battery • *Other features:* Real-time clock chip
Exoskeleton Methanian Arm	• *Sensors:* Limit switches, potentiometers • *Actuators:* Motor • *Other circuitry:* H-bridge motor controller • *Other features:* Screw drive for joint control
Methanian Noise Filter	• *Sensors:* Microphone • *Actuators:* Speaker • *Other circuitry:* Audio amplifier • *Other features:* Direct memory access-based analog to digital converter
Methanian Cooling Vest	• *Sensors:* Thermistors • *Actuators:* Water pump • *Other circuitry:* MOSFET pump control • *Other features:* Hand-sewn cooling vest
Methanian Portal	• *Sensors:* Ultrasonic rangers, buttons • *Actuators:* Linear actuator • *Other circuitry:* H-bridge motor controller • *Other features:* Iris-style mechanical door
Methanian Voice Compression Unit	• *Sensors:* Microphone • *Actuators:* Speaker • *Other circuitry:* Audio amplifier • *Other features:* Software/hardware FFT

Mechanical Design: All teams completed CAD drawings of their designs, in addition to creating fully-functioning prototypes of their mechanical and electrical systems. An example of the CAD drawing and picture of the Methanian Portal are shown in Figures 4 and 5.

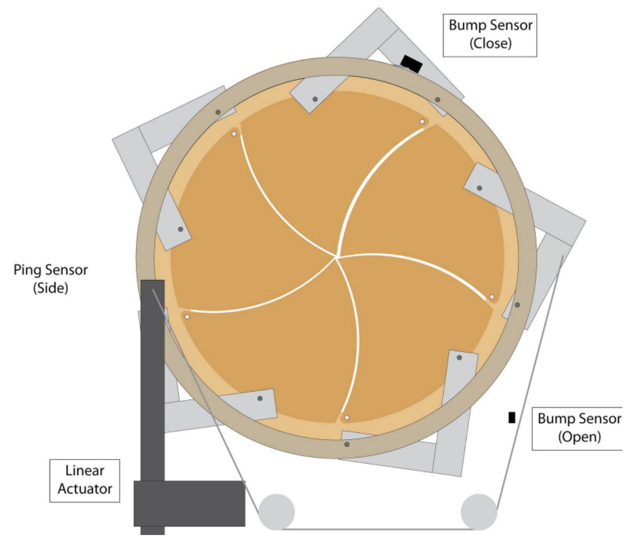


FIGURE 4

METHANIAN PORTAL PROTOTYPE

DISCUSSION AND CONCLUSIONS

Presenting an alien-centered engineering design challenge to imagine and make a solution for visitors to a college campus gives students both a familiar starting basis of understanding and a wonderfully out-of-this-world beginning point to reconsider what needs might be present for their extra-terrestrial friends. In consideration of specific learning objectives of the freshman introductory engineering course and junior electrical engineering course, both classes allow for creative and innovative student-directed projects while learning process-focused and technical-focused content.

I. Concentric Rings of Context

Some engineering design project courses serve to introduce or practice an engineering design project where students naively design a solution for themselves or someone very much like them; the context in which they work is implicit. By introducing a fantastical situation where the place and application is known but the user of such a system is not, make explicit that some of the stakeholders are beyond our familiar populace. The discovery of what needs can be addresses may then start with the familiar but then divergent brainstorming is sure to follow when introducing some of the unique constraints borne by Methanians at 7 feet tall and arms down to the floor. A use-inspired scenario is not enough – the student engineering design teams then must consider the place, things and people/extra-terrestrials to for whom to design.

II. Fostering Empathy

The necessary act of understanding an alien race in the context of human-centered design encourages students to truly examine situation from points of view different from their own. Admittedly in an extreme fashion, students are charged to problem solve with an uncertain user in mind. Since (as far as we know) aliens have not, in fact, visited us on Earth, the project can be considered a toy real world problem. With some direction, presentation of information about our extra-terrestrial friends, and a "conduit" through faculty to ask questions about their lives and needs, a mindful approach to respectful understanding and scaffolds to empathy exists. With scant given knowledge, it is seemingly impossible to dismiss the framing of the design challenge and it is necessary to adopt an alien-centered design process to discover needs and wants (ala user-centered or human-centered design processes popularized by IDEO and others in product development and experience design).

III. Intro to Engineering Design vs. Intro to Engineering

Such alien-centered engineering design challenges may serve to support slightly differing learning objectives. With the assumption that freshmen do not have previous exposure to an engineering design process, alien-centered design gives an introduction to engineering design, the processes and skills by which one problem solves as an engineer. The junior-level students designing for aliens have had previous introduction to an engineering design process and the project serves to be an introduction to engineering, specifically the discipline of electrical engineering. With the work presented here, it is most useful to note that this type of open-ended design project is flexible in scope and can benefit the students in either construction. The requirements and expectations of how far students are asked to take their ideas and level of refinement in the prototypes is of a number of parameters that might need to be adjusted depending on the epistemic audience.

IV. Balancing Breadth and Depth

The tasks students might focus on may very well differ depending on the level at which they are working. It is of the very nature of the specific course learning objectives as to how breadth and depth may be applied. For freshmen students, stepping through the steps of an engineering design process from scoping to initial concept, might only give enough time to select a concept and produce a rough conceptual prototype. For juniors in electrical engineering however, their imagined application and concept is the quick starting point and much of their time is spent developing detailed designs and seeing them through to a pre-production prototype proof of concept. Across these two course cohorts, the priorities within the learning goals for the instructors as well as the priorities of the actions of the students may be widely varying. The freshmen cohort are engaging in the breadth of a design process, aiming to go from the design prompt to solution. The juniors are quickly using a similar starting point to quickly dive into the technical depth expected of their solutions.

V. Allowing for Creativity, Motivation, Novelty & Fun!

For both sets of students engaged in alien-centered design, it was an opportunity to work on a divergent, open-ended problem. For many, the minimum of constraints allowed for their creativity to come forward. In addition, many student teams took their solution towards an area of concern that they found personally interesting and were motivated to consider what such a solution may be extended out into the near or long-term future.

With such a crazy starting point, alien-centered design projects can also allow for a greater (perceived) freedom in the student cohorts to aim for more novelty than project in which they might be designing for themselves. Alien-centered design projects also serve as audacious stories of engineering work for students relating this experience to fellow students, friends, family and prospective employers

VI. Appeal to Broader Applications

Extending the alien-centered design project approach, there are possibilities to connect to other, more traditional avenues for class engineering design projects. Designing for the developing world or universal design approaches have similar contexts of creating for users that may be less that accessible. The work presented here may serve as a building block to these types of successful engineering design projects in the classroom.

Preparing Future Engineering Students through Math Competition in Inland Area

Ziliang Zhou
Mechanical Engineering Department
California Baptist University
Riverside, California
zzhou@calbaptist.edu

Abstract*— MATHCOUNTS is a national program aimed at enhancing problem solving skills for middle schools students through a series of math competitions at the local, state and national levels. Currently in its 30th year, MATHCOUNTS is one of the country's largest and most successful education partnerships involving volunteers, educators, industry sponsors and students. As an extracurricular activity, MATHCOUNTS recognize and reward students for pursuing a deeper understanding of math concepts and their applications in science, technology, and engineering (STEM) fields. In this paper, I shall describes the effort made by the College of Engineering of California Baptist University in organizing the annual MATHCOUNTS Chapter competition for Inland Empire area and encouraging engineering careers among the local middle school students. After initial background introduction of the MATHCOUNTS program, the paper will focus on the growth of the MATHCOUNTS program in Inland Empire area during the last five years, the detail aspects of organizing this important competition, and the linkage between the competition and the career choices among the students involved in the competition. The long term goal of organizing this competition is to further promote and improve K-12 STEM education so that more students will choose engineering as their future careers and more students will be better prepared for the engineering careers they choose.

Keywords—MATHCOUNTS, STEM

I. MATHCOUNTS IN INLAND EMPIRE

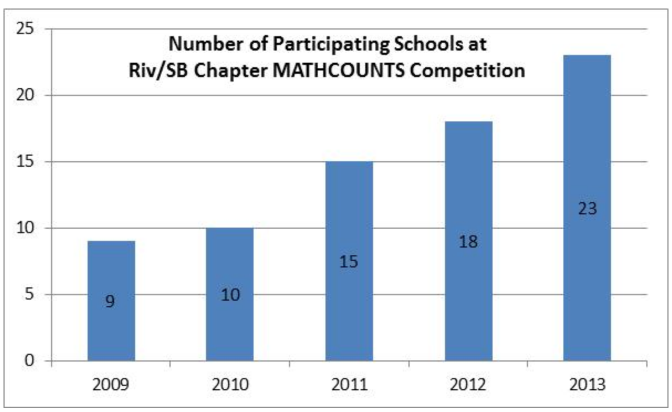
In its 30th year, MATHCOUNTS is an annual extracurricular program for 6th-8th graders. Each Fall when the school semester begins, the participating schools register with the national MATHCOUNTS office and assign a coach, usually a math teacher or sometimes a volunteer parent, to lead math club activity either after school or during the 7th period of the school schedule. The coach receives the annual MATHCOUNTS School Handbook and previous year competition materials to train students on topics and problem solving skills usually not covered in school math classes. The topics include arithmetic, algebra, geometry, number theory, and combinatorics. The level of difficulty of those math problems increases gradually as the students progress through a series of organized math competitions at four different levels: school, chapter, state, and national. The competition problems at all four levels are issued by the MATHCOUNTS National Office every year. The school round of competition is usually administered by the coach and is used, along with other performance measures at the discretion of the coach, to select the team members to represent the school for the next round of competition. At chapter level in February, each school is allowed to send maximum one team consists of four top students and 6 additional students competing as individual for a total of 10 students. In Inland Empire, the Riverside County and San Bernardino County form the local chapter. The winning teams and individuals at chapter competition move on to the state competition in March. The number of teams and individuals allowed to compete at state level is determined by the number of participating schools at chapter level. Then, the top four individual students at state competition move on to the national competition held in May. Each competing student at national level receives a graphic calculator in addition to a trophy. All members of the national winning team and individual receive a laptop, a expense-paid trip to Space Camp, and a meeting with the president in the White House. The participating students at different levels all receive valuable training in logic thinking and problem solving skills. Many of them continue math related activities and competition at high school and choose a career in STEM when selecting a college major. Most of them cited years later the positive impact of the program in their life.

Based on the number of participating schools and the competition performance, Inland Chapter is lacking behind in comparing with other neighboring chapters, such as Orange County and San Diego County. About five years ago, the chapter was even having a hard time to find a willing organization to host the chapter competition. The California Society of Professional Engineers Education Foundation (CSPEEF), who has been leading the California MATHCOUNTS program since the beginning, approached College of Engineering of California Baptist University (CBU) and found a warm welcoming home for the annual Inland chapter MATHCOUNTS competition. The College assigned a faculty member to be the coordinator and later become a board member of the CSPEEF.

II. ORGANIZING MATHCOUNTS CHAPTER COMPETITION AT CALIFORNIA BAPTIST UNIVERSITY

CBU's College of Engineering has been hosting the Inland MATHCOUNTS chapter competition for the last five years in each February at its beautiful campus in Riverside. The engineering students act as proctors and graders as part of their engineering service activity. Among students, teachers, parents, and siblings, this annual event attracts several hundred people to the campus on a Saturday between 8am to 3pm. Many of the youngsters set their feet on a college campus for the first time of their life, creating excellent marketing opportunity to promote university's programs. The Dean of College of Engineering offers $10,000 scholarships to winners of the competition if they choose to attend CBU's College of Engineering upon graduating from high school.

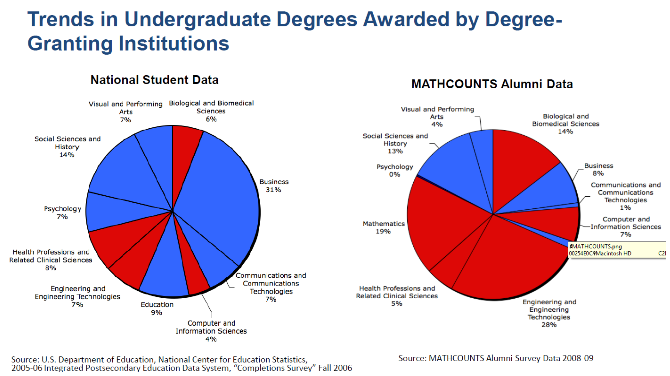
To attract more participation from local schools, the coordinator keeps close contact and communication with the coaches, encouraging and reminding them for timely registration. Due to the recent economic hardship and state educational budget cut, many schools participated before but decided not to continue due to $240 registration fee. To help the situation, the coordinator worked with a local community college and offered a mini-grant to cover the registration fee for eligible schools. Because of those efforts, the number of participating schools has increased steadily each year (showing below). For the 2012_2013 academic year, there were 23 schools registered the chapter competition, a record attendance. With over 50 school districts between two counties, this number still represents a small percentage of students involved in this activity. However, the number of attending schools is now at par with its neighboring counties, such as Orange and San Diego.



One of the highlight of chapter competition is that each competing student is treated a free lunch between written round competition and the countdown round competition at the CBU cafeteria, which is known in the community for its food quality. All costs of running the chapter competition is covered by CSPEEF through fundraising from local professional engineer societies. As we promote the program and increase the participation, it becomes a tougher task to fundraising about $2000 annual budget to cover student lunch and award toughies. At the present time, the coordinator is actively seeking funding sources to support the ever increasing participation from the local schools and welcoming support from local organizations.

III. Impact of MATHCOUNTS Program and Engineering Careers

CBU's College of Engineering has been hosting the Inland chapter MATHCOUNTS competition for the last five years. The first group of competing students is in their senior year in high school and is ready to begin their college life this fall. Therefore, we do not have the data to make a direct connection between CBU's chapter MATHCOUNTS competition and the career choices those competing students choose. At the national level, however, there are data to make a connection between the two. The following chart illustrates the career choices by students who had MATHCOUNTS experiences versus who did not [1].



It shows clearly that the overwhelming high number of students who had MATHCOUNTS experience choose to pursue career in STEM field. Another study conducted by Education Next, an education policy journal, found that by boosting students' math and science skills, the U.S. would add approximately two-thirds of a percentage point to the GDP each year [2].

From CBU's College of Engineering perspective, the long term goal of organizing this competition is to further promote and improve local K-12 STEM education so that more students will choose engineering as their future careers and for those who choose engineering as their career will be better prepared. Plan is under way to follow the students into high school and organize the annual AMC10/12 math competition.

***Abstract*—The main focus of this ongoing effort is to compare the learning propensities of 10 through 12 students for data analytics education. Towards this end, a Microsoft Excel based university-level environmental engineering module was taught in a high school classroom with students in grades 10 through 12. The module focused on understanding the current trends and challenges in environmental pollution management and policy. Students were required to procure, analyze, and visualize data in order to propose an environmental policy that was aimed at reducing pollution. Initial data collected from the assessment of the student work alludes to the fact that despite being taught the same material by the same professor and teaching assistant, the success of the students, as measured by their final grades, varies substantially with their academic year. The underclassmen in high school did not display the academic maturity and comprehension that was displayed by the high school seniors. On the other hand, seniors demonstrated a strong propensity to learn and perform well.**

I. Introduction

Data analytics is a vital skill for STEM students. The main focus of this ongoing study is to codify the learning outcomes of 10^{th} through 12^{th} grade students for data analytics education. This effort will introduce in high schools, several 5-week data analytics modules taught at Drexel University's (DU) College of Engineering (CoE). In general, these modules cover topics that provide students an introduction to the technical challenges in several branches of engineering.

Specifically, we present initial results of a data analytics module that covers concepts from environmental engineering. Environmental engineering has been shown to help raise students' knowledge and change their attitudes in perspective of environmental issues. In [1], the authors present efforts wherein curriculum was developed for high school and university engineering students dealing with environmental issues involving fuel and vehicle technologies.

Furthermore, this work is support by the National Science Foundations's GK-12 program [2]. The GK-12 program features innovative collaboration between graduate students, university professors and high-school teachers. This practice has yielded positive results in the past as evidenced by the host of success stories mentioned in [2]. Additional evidence of a successful collaboration between university professors and high school teachers is found in [3]. In [3], the authors present efforts that were based on collaboration with a university professor to bring the idea of "wonder" into a 9th grade science classroom. Two classes were taught, but only one was taught with a sense of trying to evoke "wonder". The general results of the project were both qualitative and quantitative through journals and tests showing that through the phenomena of "wonder" there was evidence to show that it provides better retention and understanding of the material, thus resulting in a a more effective learning process.

Ultimately, the content and empirical results generated from this effort will be shared on a web portal to help inform 1) the engineering data analytics education community of the benefits and limitations of introducing data analytics concepts in high schools, and 2) the ongoing national dialogue on big data education, thereby helping all stakeholders better align their STEM educational efforts.

II. Method

A sophomore level engineering module was conducted in a high school classroom with students in grades 10 through 12. The group of students were chosen as a class that was involved in the National Science Foundation GK-12 program. This class was more specifically chosen because it was an engineering focused class with a diverse group of grade-level students. To the best of our knowledge no student had previous Excel experience and the assignments were part of the students' grade for the semester. The module was taught twice a week for a five-week period. This module focused on data analytics exercises as applied to environmental engineering.

The instructional and learning strategies utilized in this effort were inspired by the observations and recommendations derived from the National Academy Press Report on How People Learn (Bransford, Brown, and Cocking, Eds) [4]. The lectures were designed to introduce environmental engineering concepts. During lectures, the instructor introduced data analytic topics in a contextual manner using Powerpoint slides, demonstrated data procurement, analysis, and visualizations using Excel, and provided general insights about the topic being covered. This instructional strategy is in line with the recommendations of [4], wherein the instructor presents "some

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

subject matter in depth, providing many examples in which the concept is at work."

During the lecture, the instructor presented several fundamental questions pertaining to the technical challenges of environmental engineering and invited the students to discuss possible answers. The students take over the discussion while being gently guided by the instructor to arrive at an answer. By doing so, the instructor used the findings of [4] wherein the authors note, "students come to the classroom with preconceptions about how the world works and it is necessary to engage this initial understanding". This instructional strategy allowed the instructor to draw out and work with pre-existing understandings that students bring with them [4].

The labs sessions were designed to enhance students understanding of the topics covered in the lectures. Students worked in groups of 2 on biweekly lab assignments that featured open-ended questions about the following topics:

1) Global Emissions of Carbon Dioxide
2) Historical New Jersey temperatures
3) Particulate matter data from an environmental monitoring system installed in Philadelphia
4) Emissions due to the transportation sector in the US
5) Emissions due to the energy sector in the US

The open-ended questions were designed such that when answered via appropriate data analytics, the answers provided the building blocks of the environmental policy mentioned earlier.

Websites that host datasets required to perform this analysis were provided to the students. However, students were responsible for driving their own learning with minimal or no input from the instructor. They were encouraged to search for data sources, select the appropriate amounts/types of data, apply the relevant data analysis techniques, and generate visualizations and insights to answer the questions. They were also encouraged to refer to online journal articles, chapters of seminal textbooks in the field, the slides that was presented by the instructor, as well as any other reputed online resources that they could find. Students were also encouraged to talk to each other to share ideas, information and knowledge.

A. Lecture and Laboratory session organization

There was a 65-minute lecture and a 65-minute lab period per week. Students used Microsoft Excel and data analytics concepts such as descriptive and predictive statistics to analyze, visualize, and summarize the key trends for the aforementioned topics. The 5-week module consisted of two biweekly assignments and a final environmental policy. Each assignment consisted of an excel workbook as well as a one page memo of their findings.

B. Personnel

The college professor and the teaching assistant who taught the sophomore level engineering class also taught the high-school class. The professor, Pramod Abichandani, of the class, Evaluation and Presentation of Experimental Data (EPED) at Drexel University (DU), collaborated with Mr. Matthew VanKouwenberg, a high school engineering teacher at the Science Leadership Academy (SLA) for this effort. The material covered at the SLA was the same as that taught at the sophomore level in DU's EPED class. Also the GK-12 fellow, Jamie Kennedy, ran the labs at both DU and the SLA. Students were required to work in pairs during labs.

III. Preliminary Results

A total of 8 groups (16 students) at the SLA were part of the effort thus far. These were divided into the following two cohorts:

1) Cohort A: This group consisted of students from grades 10 and 11 at the SLA. A total of 5 such groups were part of this effort.
2) Cohort B: The remaining 3 groups consisted of grade 12 students at the SLA.

The assessment tools consisted of a combination of analytic and summative rubrics. All assessment was done by the GK-12 fellow. The difference between the final scores of Cohort A and Cohort B was substantial. The Cohort B was at 71.6 percent average grade while the Cohort A was at 45.3 percent average grade. There was improvement upon the Cohort B group with the averages of the assignments increasing from 27.7 to 54.0 percent throughout the 5-week period.

IV. Discussion and Future Work

The results allude to the fact that despite being taught the same material by the same professor and teaching assistant, the success of the students, as measured by their final grades, varies substantially with their academic year for the group of students involved in this effort. The Cohort A students did not display the academic maturity and comprehension that was displayed by the Cohort B and sophomore college students. On the other hand, seniors demonstrated a strong propensity to learn and perform well.

One possible reason for such a substantial difference can be the difference in the emotional intelligence of students. In a related study [5], the authors examine the relationship between emotional intelligence and academic achievement in the transition from high school to university level. The results showed that academic success was strongly related to several dimensions of emotional intelligence. Furthermore, in [6], the authors examines the relationship between emotional intelligence and academic retention in the transition from high school to university level. The experiment was done over the course of two years tracking students that remained enrolled with university studies over their first couple years and students that withdrew. Results showed that students that remained enrolled with their studies had a broad range of emotional and social competencies.

In summary, the initial comparison alludes to the fact that despite being introduced to the same environmental data analysis concepts and material, the seniors (12th grade students) performed relatively well in comparison to the underclassmen (10th and 11th grade students) as witnessed by their final grades. At this stage of the effort, several reasons for this difference in performance are hypothesized. These include difference in emotional intelligence (as discussed earlier) and motivation for the class. Furthermore, the difference may be a function of the technical focus (environmental engineering and/or data analytics) of the effort. Future work will focus on understanding the possible causes of differences in student propensities. As more assessment data is collected during these modules, we anticipate gaining a better understanding of the learning propensities of 10 through 12 students.

***Abstract*— In the pre-university setting, computer science course assignments are often project-based, but seldom do they include real-life problems in real time. Many assignments are strictly dictated by what textbooks suggest as valuable learning experiences, as long as they can be completed in just a few class periods. The number of students taking a computer science course continues to dwindle, as does the number of teachers certified to teach computer science.**

Building on two case studies of EPICS High in computer science classrooms, this paper will open discussion and explore novel ways of engaging computer science teachers and students through compelling community-based service-learning projects using engineering design concepts. As it is EPICS High's mission is to be a leader in developing, disseminating, and supporting service-learning models that engage high school students in engineering and computing-based design projects that meet the needs of their communities, EPICS High intends to build relationships with computer science teachers to learn the best way this model can be implemented in their courses and help these teachers pilot an EPICS project that connects with their community.

Keywords—Computer science, design, service-learning, K-12

I. Introduction

The decrease in the number of K-12 students engaging in computer science courses poses a problem, as there is a critical need in the U.S. for more computer scientists and engineers. President Obama has called for a new generation of STEM professionals that will maintain the country's leadership in the world economy. Added to this, there is a call in the computer science education community to have computing in 10,000 high schools taught by 10,000 well-qualified teachers by 2015. (Otherwise known as the NSF funded CS 10K Project [1].) New approaches are needed to achieve these goals. The literature predicts that service learning could attract more students into engineering and computing by introducing it through community-based projects. The results from service-learning confirm this. [2]

One exemplar of service-learning that includes computing is the EPICS Program, founded and headquartered at Purdue University. [3]. The EPICS Program is an innovative service-learning approach to teaching design where teams of students partner with local community organizations to identify, design, build, and deliver solutions to meet the community organization's needs. Data from EPICS shows that it is attracting traditionally underrepresented populations of students and increasing students desire to continue in engineering and computing. The potential to significantly impact K-12 pathways into engineering and computing motivated the creation of EPICS High in 2006. EPICS High is an adaptation of EPICS into the pre-university setting. It has been implemented in over 50 high schools in 11 states engaging over 2000 students per year. Student surveys have shown that the EPICS High projects are attracting students with no or little interest into STEM career pathways. An example is Jessica Roggenbuck who was an EPICS High project leader and featured in an article for the ASEE *Prism* Magazine

Jessica Roggenbuck is a student the University of Toledo. If you had told her as a high school freshman that she would be studying chemical engineering, you might have gotten a puzzled response. "Engineers? I thought they were train drivers," she admits with a laugh. But during her junior and senior years at rural Harbor Beach High School in Michigan, Roggenbuck developed a new appreciation for engineering while leading a team of 6 female and 1 male students in an after-school computer science based project [EPICS High]. The team of students designed a computer program that allowed charity food pantries track their inventories, "It helped me understand what an engineer does," says Roggenbuck. It also influenced her decision to pursue an engineering degree."[ref]

Jessica is not unique and her team is not unique. EPICS High is attracting women and underrepresented students at significantly higher rates than traditional program. Females represent 44% and underrepresented minorities are more than 50% of EPICS High students. The approach of EPICS is positive and there are examples of successful computing projects such as the one at Harbor Beach. There is, however, a lack of computer science teachers participating in this program who are integrating the concept into their curriculum or after school programs.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Figure 1 EPICS High Computing Team from Harbor Beach, Michigan Partnered with local food bank

EPICS High has the potential to change the curve into and through computer science pathways on a national level. There is a compelling need for more computer science professionals but current approaches are showing only incremental changes. The EPICS approach of linking computer science learning with authentic and compelling human and environmental needs in the local communities of participants is consistent with diversity literature. The National Academy of Engineering's report "Changing the Conversation" discussed the need to change the perception of engineering and computing [4]. EPICS High projects align with these themes and result in tangible projects for the entire K-12 community to see what engineering/computing is and can be.

II. NON-TRADITIONAL CONCEPTS

Service-learning is not a new concept, nor is the computer science field void of any implementation of service-learning. However, most opportunities exist at the collegiate level instead of engaging high school students in these same valuable experiences [5, 6, 7]. One such attempt has undergraduate students mentor high school students as their service-learning, but only in a summer camp setting, engaging them in computer science activities and programs, not in service-learning activities [5]. Another research study initiated service-learning computer science courses for the lower level undergraduate courses, in hopes that participation would transition to retention. This concept worked well, and showed favorable results, but there was no mention of future work matriculating into the pre-college environment to see if similar results could be had with early exposure and engagement in service-learning [7].

The approach of EPICS High is to engage students and teachers in long-term partnerships where students develop solutions to local needs. There are many opportunities for computing projects. The Harbor Beach team mentioned earlier worked with the local food bank to increase its efficiency and effectiveness through the use of software tools. EPICS has taken the successful university approach to design using a human-centered approach, shown in Figure 2, and adapted it to the high school environment. Curriculum modules have been developed in the areas of design, community partnerships, teaming, project management, communication and ethics and culture. Teacher professional development equips teachers to lead student teams. EPICS staff and faculty work with the teachers to adapt the EPICS model into their schools. Some schools implement EPICS as an after school club or activity. Others integrate EPICS projects into science, math or technology courses. Still others have entire courses where EPICS is used to introduce students to engineering, STEM and design. Local professional are often used to mentor students and to supplement the expertise of the teachers in guiding students through the design process and into product delivery.

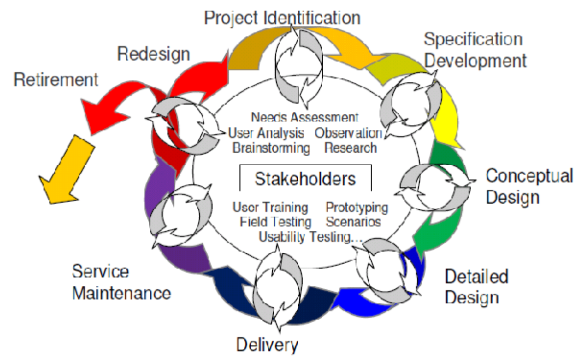

Figure 2 EPICS Human-Centered Design Process

There are many opportunities for computing projects within communities but there is a dearth of EPICS High projects in pre-college computer science courses. Typically, EPICS High has been merged into traditional science, technology, or engineering courses, with little focus on engaging computer science teachers.Even without a directed effort to promote the EPICS model in computer science, two EPICS High schools have begun to incorporate computer science into a community-based, service-learning program within their schools. This work in progress presents these two models as case studies and the presentation will explore the progress to date.

A. School 1: Park Tudor Upper School

Park Tudor is a college preparatory school located in Indianapolis, Indiana for students in grades 9-12. Park Tudor has an enrollment of 418 students with a 78% Caucasian population [8]. Students enroll in existing computer science courses but have the opportunity to work on EPICS projects with real users in the community. Projects include web design for a community non-profit group, cell phone application development for intra-school needs, or computer program development for course registration. The projects are offered as an option to the students within the courses.

B. School 2: George Westinghouse College Preparatory School

Westinghouse High School is part of the Chicago Public School system and draws students from over 300 schools in the Chicago, Illinois area. Westinghouse has an enrollment of 1,115, 89% of which are underrepresented minorities [9]. The school has created a separate EPICS course that is based on computer science with community applications. The class has partnered with Garfield Park Conservatory whose staff was having an organization problem with the plants. The goal of the project is to help them by organizing the plants according to their history and similarities with a new database. This, like all EPICS projects, involves interaction with the users and stakeholders and a plan for hand-off of the project to the community partner including user manuals and supporting documentation.

III. Lessons Learned

Even though there are just two schools in this case study, there are still many lessons that can be applied to a potential expansion of EPICS High into computer science courses. While there is a vast difference between the students in each of these two schools, each EPICS team has successfully delivered computer science projects that make an impact in their own community. This speaks well for a potential widespread implementation of a community-based service-learning component in computer science courses. Additionally, we can conclude that schools of varying sizes and demographics have equal opportunity for community impact.

IV. Future Work

Using the projects from our two case study schools as examples, the EPICS High program plans to recruit 5-10 new schools for the 2013-2014 school year to pilot the EPICS High Program in computer science courses. These schools will help establish best practices and create a model for service-learning computer science courses. These best practices will also be aligned to the CSTA K-12 Computer Science Standards so as to unburden the curriculum. Ideas for recruiting and retaining school participation, as well as dissemination, will be solicited from the audience for this presentation as well as future presentations at other engineering and computing education conferences.

Once best practices and standards alignments are achieved, additonal schools will be recruited to expand the reach of EPICS High and to engage more teachers and students in computer science design and service-learning.

V. Conclusion

This work in progress appeals to those interested in K-12 engineering and computer science education as well as those interested in novel applications of service-learning and design. As stated, there is little to no formalized computer science service-learning taking place in the pre-college environment. This is an enormous opportunity. The picture of the project team from Harbor Beach does not look like a typical computing project team. While that team was not in a formal computer science class the literature and the data from current EPICS High participants indicate that service-learning can be a significant tool in increasing interest and diversity within the computing fields. With the development of best practices aligned to the standards, this may well open the door to new career pathways for students to meet industry and societal demands. The presentation will include opportunities for discussion on how to implement such an approach on a national level. A successful pilot would present opportunities for research and contribute to the CS 10K project.

Acknowledgements

The authors sincerely thank The John Martinson Foundation, Motorola Solutions, Rolls Royce, and Google for their generous funding of the EPICS High program. Additionally, thanks goes out to Ryan Ritz, teacher at Park Tudor and Dan Mostyn, teacher at Westinghouse Prep for leading the way.

***Abstract*—The purpose of this paper is to provide a framework for NICERC's Advanced Math for Engineering and Science (AMES) curriculum that will lead to a series of studies on various aspects of the curriculum. Included in the paper is a description of the content, an explanation for the integration of AMES with other curricula, and a description of the professional development for AMES. AMES is a high school curriculum aimed at integrating multiple disciplines in order to provide context for the mathematics concepts used daily by engineers and scientists.**

This paper begins by discussing the structure of AMES. The structure is based on an analytic geometry approach to concepts taught in high school and post-secondary institutions combined with a multidisciplinary approach providing the context. Additionally, the paper outlines a broad description of the content in AMES and how multiple disciplines such as history, physics, and American government are incorporated into various lessons. This paper then demonstrates how other curricula are interwoven into AMES. Lastly, the paper includes a description of the professional development component of AMES. This section discusses how the professional development engages teachers prior to implementing the course.

Keywords—mathematics; interdisciplinary

I. Introduction

Secondary mathematics is usually presented as a subject that stands alone and is not related to other subjects taught in high school such as history or English. However, students enrolled in interdisciplinary classes experience advancement in metacognitive skills and critical thinking [1]. This suggests that classes should contain interdisciplinary components. Furthermore, there has been a recent push for teaching engineering in K-12 schools to foster higher achievement and greater interest in science, technology, engineering, and mathematics (STEM) courses and fields [2,3]. Along with this, as the Common Core standards are being implemented throughout the United States, curricula must be created that support these new standards. The Cyber Innovation Center, a 501c3 not-for-profit, is currently developing Advanced Math for Engineering and Science (AMES), a curriculum that integrates various STEM and liberal arts disciplines and meets mathematics and English language arts standards set forth by Common Core.

II. Curriculum Structure

The Advanced Math for Engineering and Science curriculum is being created using an analytic geometry base. The content, however, stretches past analytic geometry in order to integrate seamlessly with other engineering and science topics as well as topics in liberal arts disciplines.

Analytic geometry was chosen as the base due to the widespread use of representing geometric models in an algebraic form in order to solve engineering and science related problems. Evidence of this can be found in entry level engineering classes. For example, in the Statics and Mechanics of Materials text book by Riley, Sturges, and Morris, the first 70 pages are devoted to topics such as vectors, free body diagrams, and finding rectangular components in more than one dimension [4]. Another example of this can be found in "Engineering Dynamics" by Kasdin and Paley. Four out of the five major parts of this text are titled, "Particle Dynamics in the Plane," "Planar Motion of a Multiparticle System," "Relative Motion and Rigid-Body Dynamics in Two Dimensions," and "Dynamics in Three Dimensions" [5]. All of these are titles that suggest the student should be highly competent of coordinate systems and comfortable with switching between a coordinate system and the algebraic representation of the figures in that coordinate system.

The incorporation of other disciplines in AMES provides a new aspect to mathematics in the high school classroom. An example of this integration is that students will be required to learn the history of the mathematics they are studying throughout the course. They will be required to keep a timeline that includes major historical events, such as the opening of certain trade routes and notable national and international conflicts. The purpose of this is for students to provide a context for the discovery of new mathematics ideas and when these ideas were first studied. Another example of this multidisciplinary approach is a lesson devoted to applying mathematics to governing laws through axiomatic methods. The purpose of this is for students to apply higher level mathematics concepts to tangible ideas and practical scenarios.

III. Curriculum Content

Studies have shown that post-secondary freshmen and sophomore students lack essential mathematics skills required

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

in engineering and science courses [6]. For example, in a study done by Aung, Underdown, and Qian, freshmen and sophomore engineering students received low scores when quizzed on the equation of a line, finding the dot product of two vectors, and working with matrices [7]. Because of this, the designers decided to include three essential threads: Coordinate Systems; Vectors, Matrices, and Axiomatic Methods; and Conic Sections. Each thread is composed of multiple units (e.g., Cartesian coordinates or polar coordinates), and each unit is composed of various lessons relating to the topic of the unit. Lessons include items consisting of the lesson notes, research assignments, the historical construction of mathematics, hands-on projects, and supplementary exercises intended to be used at the teachers' discretion.

More specifically, the mathematics content includes but is not limited to the following:

- Cartesian/Rectangular Coordinates
- Polar Coordinates
- The Imaginary Plane
- Three Dimensional Space
- Vectors
- Matrices
- Axiomatic Methods
- Conic Sections

Although several sections cover topics students may have already discussed in the past, the curriculum takes a different approach, or point of view, to the learning process. For example, in the unit on polar coordinates, students are required to derive the sine and cosine values of the special angles given a pair of sine and cosine values of one angle instead of being given a completed unit circle with each sine and cosine value previously computed. This will allow the students to practice pattern recognition, a fundamental concept in mathematics.

In some lessons the students are required to research various mathematicians and the history/creation of mathematics topics and present their findings. The purpose of this is to have students discover how the mathematics of the past developed over time into the mathematics used today. By doing this, students are also taught to communicate the mathematics they are learning in a variety of ways such as papers, presentations, and informally through group work.

Lastly, the students are required to complete hands-on projects that allow them to see where the mathematics occurs outside of the classroom. This project-driven approach in AMES curriculum allows the students to focus more on the mathematics being taught instead of the project being completed [8]. For example, the students will create a tension mechanism and study the forces in the system while studying vectors and vector components. While it is fun for the students to construct the mechanism, they will spend more time drawing free body diagrams, calculating tension, and finding vector components when various weights are applied to the system.

IV. Integration of Other Curricula

NICERC has previously developed its Physics curriculum and Cyber Science curriculum. While developing the AMES curriculum, NICERC is also developing a middle school course, STEM Explore, Discover, Apply (STEM EDA). Since mathematics is not a topic that exists alone, the developers of these curricula are integrating each previously developed course with AMES. This integration will provide connections for the students who are simultaneously taking or have previously taken these courses and provide potential research opportunities. Although these courses can be used to build upon each other, AMES could function as a stand-alone course as well. Also, in order to meet the changing standards, Common Core State Standards (CCSS) will be used throughout the course.

The Physics curriculum takes a project-driven approach to teach electricity and magnetism, work and mechanics, waves and sound, light and optics, and thermal fluids. The AMES curriculum will integrate with the Physics curriculum by focusing on the mathematics fundamentals used in Physics. This will allow students to deepen their understanding of the underlying principles that describe the physics phenomena being studied. The desired outcome is that students will enter college feeling comfortable about the mathematics used in the physics topics listed above.

The Cyber Science curriculum teaches cyber concepts and fundamentals to high school sophomores and juniors. In order to do this, the students use a robotics platform and conduct ethical and historical discussions about cyber. The AMES curriculum expands upon the skills Cyber Science students developed holding ethical and historical discussions and focuses them on mathematics. This allows students previously enrolled in Cyber Science to continue to develop their technical communication skills. Where applicable, the same robotics platform will be used to teach the application of mathematics topics included in AMES.

The STEM EDA course focuses on using the engineering design process as a guide for engaging middle school students in STEM. AMES will take the engineering design process and apply it to mathematics with the intent of showing how the engineering design process can be used in various disciplines, showcasing the interconnectivity of these disciplines, and reinforcing the engineering concepts they have previously learned.

As it is pertinent to new curricula, AMES will meet several of the standards set forth by the Common Core State Standards. Keeping in mind that many of the topics covered in AMES are more advanced than the topics covered in the CCSS, several of the lessons will exceed CCSS for mathematics. Also, since several topics students have previously learned are covered in more depth, AMES contains a cross course overlap of CCSS. Furthermore, there will be several lessons that will satisfy many of the CCSS for English Language Arts for 11th and 12th grade since the students will be constructing content specific documents throughout the AMES curriculum [9].

V. PROFESSIONAL DEVELOPMENT

Often, teachers are given little to no training with unfamiliar curricula they are required to teach. Similarly, teachers typically do not have the opportunity to provide feedback on the curricula. AMES will provide teachers with professional development training that allows them to become familiar with and provide input on the curriculum. The professional development is immersive in the sense that the teachers can learn about the content from a student's point of view. Also, after the professional development workshops and throughout the year, the teachers will be asked to provide feedback on the curriculum in order to make improvements. Furthermore, the professional development provides an overflow of information to allow the teachers to learn the structure and content of the curriculum deeply. Finally, during the professional development workshop, teachers will be given all the physical and cognitive tools needed to teach the course.

VI. CONCLUSION

Since the Advanced Math for Engineering and Science curriculum is still in development, the various aspects mentioned in this work are subject to change between now and the piloting of the course. The first professional development workshop will occur during the summer of 2013. The course will then be piloted at the schools that have teachers participating in the summer workshop.

What is the Role of MOOCs in Engineering Education?

Susan Finger
Amy Chan Hilton
Jeremi London
Division of Undergraduate Education
National Science Foundation
Arlington, VA, USA

Cynthia Young
College of Sciences
University of Central Florida
Orlando, FL, USA

***Abstract*—This paper is a description of the FIE workshop on the role of MOOCs in undergraduate engineering education.**

Keywords—MOOCs, undergraduate engineering education

PANEL DESCRIPTION

MOOCs (Massive Open Online Courses) are a recent phenomenon that, some believe, will transform higher education. With their low cost and potential to reach a large number of students, MOOCs have the potential to broaden access to education at all levels. The capabilities of the technology and its widespread distribution make interactive online learning possible at any time, in any place, at any pace. MOOCs have infiltrated higher education at such a rapid pace that there has been little time for large groups of educators to have meaningful discussions about how MOOCs can be leveraged to support student learning. This special session is designed to meet this need.

There are two main goals of this interactive session. The first is to bring together a panel of diverse experts and engineering educators to provide an opportunity for them to exchange ideas about the potential of MOOCs to transform engineering education. A second goal is to initiate the build of a community of engineering educators interested in MOOCs, and identify a set of research questions regarding MOOCs and student learning. In light of these goals, the intended audience for this session is engineering faculty interested in learning about and using MOOCs.

This interactive session will have two main parts: panelist presentation and discussion; and alternating small-group and large-group discussions. The panelist will present and discuss during the first 40 minutes of the session, and the remaining 50 minutes will be spent in alternating small-group and large-group discussions (i.e., approximately 10 minutes in small group discussions answering a question, then 5 minutes to discuss as large group; then repeat until the 50 minutes is complete). Three experts from different perspectives will be on the panel: a Learning Scientist that studies STEM learning in online contexts, and two NSF Grantees/Engineering Educators using MOOCs in their course and/or other pedagogical approaches that involve online learning.

Essentially, the panelists will be asked to respond to two main questions: 1) What potential do MOOCs have for improving student learning in engineering? 2) What research do we need to do on MOOCs to make further gains in student learning? After the panel of experts shares their responses, the participants will be given an opportunity to respond to similar questions as part of small-group discussions with their colleagues. The insights from each group will be documented, synthesized, and summarized in a report that will be written after the conference. This pilot workshop is the first of a series of workshops that will take place at engineering conferences to build a community of engineering educators interested in MOOCs.

The expected outcomes or future work as a result of this session include a report to the National Science Foundation that summarizes highlights from the presentation and group discussion, along with a charge for the next series of panels at other engineering education conferences. This will be a public report that will be made available to the session participants and the general public within a month after the session. Another outcome of this session is the creation of a listserv that will be used to capture the initial interest of engineering faculty interested in MOOCs, and to distribute information (including a copy of the report provided to NSF).

This session is the beginning of an effort to develop a community of practice that will interact after the conference. It brings together experts both within and outside of engineering to share ideas that engineering educators should be thinking about as we identify ways to leverage MOOCs in engineering education.

ACKNOWLEDGMENT

Defining and Assessing Engineering Ethics

Carla B. Zoltowski[1], William C. Oakes[1,2], Patrice M. Buzzanell[3]
[1]Engineering Projects In Community Service (EPICS), [2]Engineering Education, [3]Communication
Purdue University, West Lafayette, IN, USA

***Abstract*— The motivation of the special session was to allow engineering educators and researchers to experience two different instruments intended to assess ethical reasoning--one which measures general moral reasoning, and one that is situated in the engineering context—so they can identify the knowledge, skills, and attitudes that are specific to engineering. This will inform how we teach and assess engineering ethics, and equip educators with tools for using these instruments as part of the student learning. The special session format will allow for discussion and debate on the relevance of the approach and appropriateness for our own classrooms.**

Keywords— engineering ethics; moral reasoning; assessment

I. Goals and Outcomes of the Special Session

The primary goal of this special session is facilitate a conversation around different approaches to defining and assessing engineering ethics. An expected outcome of this session will be an increased understanding of what specific knowledge, skills, and attitudes (KSAs) are needed to be able to make ethical decisions within an engineering context, if any, and what assessment tools are available to measure these. This will help educators and researchers develop and assess effective engineering ethics curricula. The discussions will lead to future research collaborations.

II. Special Session Description

A. Session Content

The need for understanding and enhancing engineering students' ethical development has been the subject of numerous publications and has been embedded in ABET criteria. Engineers in today's global society are interacting with ever more of the world's peoples and cultures. These interactions are introducing greater social and ethical complexity to the profession than has been incorporated previously and are raising the importance of practicing engineers becoming capable ethical decision makers. As engineering educators, we are responsible for helping to develop these ethical decision-making skills in our students so they might transfer them into practice in the profession. However, to determine whether or not students are developing these skills as would be practiced in engineering, we must be able to assess assessing student's development in ethical decision making within an engineering context.

This interactive session will explore strategies to assess ethical moral reasoning in this complex engineering context by participating in both a general instrument of moral reasoning [1-4] as well as in an engineering ethical reasoning instrument [5-6]. The session is designed for participants to experience the assessments and prompt discussion around the assessment tools and relevant questions for our community. What are the important issues that engineers need to consider? What aspects of ethics do we need to be teaching? Do we need our own engineering ethics materials or are more general ethical materials and tools fine?

The session will include a review of the developmental framework which has provided the basis for assessing moral reasoning, a discussion about what knowledge, attitudes, and skills are needed by our graduates, and a brainstorming session for the participants to collectively consider possible future approaches for engineering ethics assessment in education and research contexts. This session will also provide a forum for the active exchange of ideas around the questions mentioned above. The session will help to develop a network of engineering educators concerned with both teaching and research related to engineering ethics.

B. Session Agenda

Time	Cum. Time	Activity
2 min	2	Introduction of the facilitators and the goals of the session
5 min	7	Introduction of participants
18 min	25	Small group: Each small group, organized by tables, will first individually complete a *general* ethics instrument question; then complete the question together as a group; they will additionally reflect on the knowledge, skills, and attitudes (KSAs) which are assessed in the instrument.
10 min	35	Discussion: Small groups will share their experiences taking the instrument individually and as a group, as well as the KSAs assessed by the instrument
18 min	53	Small group: Each small group, organized by tables, will first individually complete an *engineering* ethics instrument question; then complete the question together as a group; they will additionally reflect on the knowledge, skills, and attitudes which are assessed in the instrument.
10 min	63	Discussion: Small groups will share their experiences taking the instrument individually and as a group, as well as the KSAs assessed by the instrument
5 min	68	Presentation of the developmental framework underlying both instruments
10 min	78	Small group: How do we teach ethics in an engineering context versus ethics in general? Is it different? If so, how? Groups will create lists of teaching

This work was made possible by a grant from the National Science Foundation (DUE-112374). Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

		activities and methodologies for teaching within this context, as well as describe what is unique, if anything, about engineering ethics.
10 min	88	Discussion: Small groups will share their ideas for teaching engineering ethics.
2 min	90	Wrap-up—thank participants for attending the session.

C. Anticipated Audience

The session is designed to reach educators and researchers who are concerned with teaching and measuring ethics in an engineering context.

ACKNOWLEDGMENT

We would like to acknowledge work of Craig Titus in developing the EERI, as well as our collaborators at our partner institutions: Alan Mead, Kemp Ellington, Jill May, and Danny Gandara at Illinois Institute of Technology; Mary Raber at Michigan Technological University, and John Ochs and Lisa Getzler-Linn at Lehigh University.

***Abstract*—Engineering workplace problems are complex and ill-structured. Students should be faced with this kind of problems during their studies in order to be better prepared for the workplace. However, there is still little evidence on the strategies to support students' learning during workplace problem solving. The general objective of our on-going research is to identify teaching strategies that would best support students in solving ill-structured problems while preparing them to step into the work environment after graduating from the conventional engineering curricula. To this end we designed the professional practice course for final year Information and Communication Technology (ICT) engineering students. Educational principles applied include problem and project based learning, workplace simulation and experiential learning. In this paper we describe the research design that centers on determining the challenges that students perceive during different phases of ill-structured problem solving process, with relationship to their learning styles and skills development.**

Keywords—ill-structured problems; teaching strategies; workplace simulation; engineering practice

I. INTRODUCTION

Engineering practice means solving workplace problems that are complex and ill-structured, and students should be faced with this kind of problem solving during their studies in order to be adequately prepared for the industry [1].

The need for the engineering curricula to comprise training in problem solving and soft skills in order to achieve competencies for engineering practice has been emphasized by professional engineering bodies dedicated to the education and accreditation worldwide (such as ABET, FEANI, IEAust). In Serbia, where the conventional engineering curricula are taught at most universities, this need has been recognized by the academy, industry and students themselves [2].

It has been shown that learning experiences that best support the development of expert professional practice include those where students engage in authentic engineering projects [3]. Providing feedback on the learning processes is crucial for students to understand what they can do well, and what they need to improve. Preparation for future engineering work should also include fostering competencies for problem solving, independent and collaborative learning by using complex ill-structured real world problems in a problem based learning setting [4]. Literature on problem-based and project-based learning is comprehensive (e.g. [5][6]), with abundant examples of implementation practices (e.g. [7]).

However, the research on how to design courses in order to support student engagement and learning during ill-structured problem solving in engineering is still limited [8] [9]. One of the few studies conducted with this objective is a longitudinal study conducted with 130 first-year engineering students [10]. This study identified the most salient out of the set of 6 pre-defined challenges that were experienced by students during design problem solving. These challenges appear as overlapping waves during a design task. Another study investigated students' difficulties in solving ill-structured problems on a smaller scale of 10 students in first-year computer programming course and found that students present difficulties in the interpretation of the problem, formulating questions to enlighten the problem, analyzing the problem constraints and registering effectively the new problem information [11].

Understanding well the issues and challenges during ill-structured problem solving and the pedagogical strategies to deal with them is crucial to producing effective instructional designs for teaching and learning in the context of preparing students for the workplace. In order to confirm issues identified in previous studies, and to further explore them in the context of workplace problem solving we designed and implemented

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

the Project planning and organization in engineering practice course at the School of Electrical Engineering of the University of Belgrade. The general objective of our research is to identify best teaching strategies to prepare students to enter the work environment immediately after graduating from the conventional engineering curricula.

For our research we chose the action research approach as an active investigative method which enables its participants to take part in a dynamic educational process, with the aim of strategic improvement of practice [12]. In the iterative process we focus on collecting evidence about the extent to which the practice is consistent with the pedagogical aims, identify inconsistencies between the aims and the practice and reframe both the research and practice for the next research cycle. Action research thus integrates research and practice into one process by generating and testing new forms of action and reflexively guiding the pedagogical enquiry.

In the first phase of our research we identified major challenges that students encounter during the problem solving process and opportunities students perceive as a result of this learning experience [13]. The challenges found included: a) where do I start? Defining the ill-structured problem; b) learning to ask questions in requirements gathering; c) connecting theory and practice; d) self-guided study and information gathering; e) facing the reality: site survey; f) dealing with ambiguity; g) dealing with constraints and trade-offs; h) learning to communicate clearly; i) dealing with failure. The findings of the first phase were based on the qualitative data collected during three ten-week courses with participation of 46 final year telecommunications engineering students. As a result of the first phase of our research some questions were raised that we intend to explore in the next phases of the research.

In this article we present the research design for the second phase of our action research that centers on examining main challenges that mark different phases of ill-structured problem solving process, and the corresponding skills development as perceived by students. We also examine any relationship they may have to the students' learning styles.

II. DESCRIPTION OF THE LEARNING ENVIRONMENT

The Project planning and organization in engineering practice course is designed in such a way to resemble the real-world situations that are particularly found in small and medium enterprises (SME) where an engineer is often required to combine the roles of a system designer and project manager in different phases of the product or service development. Course objectives include experiencing and fostering processes of project planning, organization and basic systems engineering design, while developing problem solving, teamwork, communication, presentation and idea generation skills.

Educational principles applied include problem-based and project-based learning, with an emphasis on constructivist approach to learning [14] and experiential learning inspired by Kolb [15]. The simplified reality of the workplace and its essential functions are represented through a role-play simulation.

Kolb's experiential learning theory emphasizes the central role that experience plays in the learning process, claiming that knowledge is created through the transformation of experience [15]. According to this theory, learners need four abilities for effective learning: a) concrete experience, b) reflective observation, c) abstract conceptualization, and d) active experimentation. On this basis Kolb identified four prevalent types of learning styles that can be determined using Kolb Learning Styles Inventory (LSI) and that can determine the ways students respond to different teaching strategies.

Role play simulation is an effective technique that facilitates teaching and learning of professional skills supporting the process of preparing engineering students for entering the industry [16].

In our student-centered approach the instructor (the first author) is a facilitator of learning, she works with students on the creation and development of knowledge and skills, guides and stimulates discussion and monitors group processes. The emphasis is not on teaching content, but on guiding students in their experience of "how to work". The students own the problem; they find solutions by themselves with minimal help but with an always present and supportive instructor. In the role play the instructor takes the roles of client, boss, sub-contractors or any other third party that needs to be covered. Real suppliers are contacted throughout the course but in the absence of their feedback the instructor takes their role too.

The course is organized in three- and four-hour classes and lasts a total of 80 hours. Students are divided in teams of 3-5 to work on a project with the task of presenting a wireless system proposal in response to a tender, including preliminary design of the system, detailed project plan and final budget for design, supply, installation and commissioning of the system.

III. RESEARCH DESIGN

Based on the first phase of our research, following research objectives were identified for the second phase of our the study: (1) to explore what are the challenges that students perceive as the most important during different phases of the ill-structured problem solving process; (2) to examine students' perceptions on the skills that they develop in different phases of the learning experience; (3) to determine if their skills development and challenges perception are related to their learning styles (4) to re-define teaching strategies based on the results (1-3).

The participants of the second phase will be15 to 20 final year students in the summer semester 2012/2013.

The research is a mixed-method research. It combines qualitative and quantitative research as defined by Creswell and described in [17] where qualitative and quantitative data are collected concurrently or sequentially, are given a priority, and involve the integration of the data at one or more stages in the process of research.

We shall use some of the instruments from the first phase of the study: protocols for structured participant observation, open-ended questionnaires, scaled-type surveys for overall skills development and Kolb LSI for learning styles. Additional instruments that are created for this phase include challenges and skills lists that were developed based on the results of the first phase of the research and tested in the pilot study [13]. Students will be asked to fill in their perception of the major challenges and levels of skills development in the challenges and skills lists that they will fill in every two classes (corresponding to 7-8 hours of project work). In the challenges list students will select and prioritize (from 1 to 5) five greatest challenges that they faced in the previous period. Skills list is a scaled list where they will select the level (from 1 to 10) of their skills development in the same period.

Collected data will be analyzed applying qualitative and quantitative data analysis. Qualitative analysis will include analysis of the open-ended questionnaires and participant observation protocols filled in during field work. Quantitative analysis will include analysis of the scaled type surveys, Kolb LSI and challenges and skills lists.

IV. EXPECTED RESULTS

With this study we hope to contribute to the research on how to support students during ill-structured problem solving process, that has been called for in the literature and on previous FIE Conferences [8][9]. Our goal is to determine major challenges students perceive during ill-structured workplace problem solving and corresponding skills that students develop. We hope to obtain results that could inform future research regarding the relationship between students' learning styles and challenges students encounter or skills they develop in the problem solving process, with the general objective of defining teaching strategies that would best support students while preparing them for engineering practice.

ACKNOWLEDGMENT

The authors would like to acknowledge support of the School of Electrical Engineering and Department of Telecommunications that made this research possible. We owe special thanks to all the students that participated in the research and to Hay Group for the research grant that allowed us the use of Kolb Learning Styles Inventory. This paper forms part of the Interuniversity Doctoral Program in Environmental Education of the Autonomous University of Barcelona and of the "Identification, measurement and development of the cognitive and emotional competences important for a Europe-oriented society" project.

Information and Communication Technologies literacy from engineering students at the University of Buenos Aires.

Osvaldo Clua
School of Engineers
University of Buenos Aires
Buenos Aires, Argentina
oclua@ieee.org

Maria Feldgen
School of Engineers
University of Buenos Aires
Buenos Aires, Argentina
mfeldgen@ieee.org

***Abstract*— A survey concerning literacy in Information and Communication Technology (ICT) was held at the School of Engineers of the University of Buenos Aires. The overall aim was to state if ICT literacy could be considered as an existing background among our student population. In addition we wanted to identify possible environments where students and faculty can interact and learning is possible. Building such environments is highly dependent on previous experience of students to ICT and its breadth of use. In this work we detail the survey results, draw some conclusions and outline some considerations on how to deal with ICT in the classroom.**

Keywords—ICT Literacy, freshmen, computer in the classroom, background skills

I. Introduction

In his work "Teaching Digital Natives: Partnering for Real Learning" [1] Prensky states that "... *students who don't concentrate in school will sit for hours ... totally focused in movies or video games*". He concludes that students' tolerances and needs have changed learning to focus only on what interests them. The author characterizes these young people as *deeply and permanently technologically enhanced* and labels their generation as Digital Natives, and endorses today´s teachers as Digital Immigrants.

Prensky's concepts of Digital Natives and Digital Immigrants and the classification according to the age has and is been challenged by solid research data [2,3]. However it remains clear that the use of Information and Communication Technologies (ICT's) will influence the way these students learn. A simple example is that, being our students commuters, chat-rooms eases a lot team meetings when some teamwork must be done.

Supporters of this digital native/immigrant distinction tend to assign broad characteristics (e.g. a specific learning style, amount and type of technology used and/or a set of learning preferences) to an entire generation and suggest all young people are expert with technology. The date of the beginning of this generation seems to vary from 1980 to the late 90's according to the availability of ICT's in the population under study.

However, while the proportion of young people who use the Internet and other new technologies is higher than the older population there are significant differences in how and why young people use these new technologies and how effectively they use them [4] Also, the complexity and diversity of use of new technologies by young people tends to be ignored or minimized in many arguments in support of the digital native thesis.

In the University of Buenos Aires, the School of Engineers Faculty attitude towards ICT varies. Some argue that, as with proficiency in English, ICT literacy is a skill we shall ask them to manage but do not have to teach. English as a foreign language is offered free of charge in six levels for all students, along with a set of other languages. The Engineering curriculum asks for a level in English and the Language departments is responsible for the testing, but no course is mandatory. These faculty members expect that non -specific ICT's should be dealt with in the same way.

On the other hand, some Faculty members believe that special time must be allotted in Lab to teach the use of general ICT that can support the academic life. These ICT include social networking. However they understand that teaching tools is not the aim of their courses and that can be a controversial task. Advanced students might get bored and lose interest while other may get stuck in syntactical (surface) detail not grasping the purpose of the tool.

There is a third group that believes that the familiarity with ICT's is related to the field discipline (majoring) our students choose. These faculty members propose to deal different with students whose majoring is related to ICT (Computer, Software and Electronics Engineers).

Our institution decided to offer grants in using ICT's in the classroom, and we applied and obtained one aiming to foster ICT in the engineering courses. It is related to general ICT tools such as social networking, simulations, group-work and personal technology; not to specific field discipline software such as calculus where the tools are long incorporated in the courses.

Study supported with grants 2002011010094, 2002100100333 and the UBATIC programs of the University of Buenos Aires

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

In order to begin the project we decided to learn how familiar our students are with the ICT technology in their academic and social life.

II. The Survey

A. Research Questions

We posed three research questions to be answered with a survey:

1) Can we expect students to learn core ICT skills independent of the curriculum, as is the case with English language?

2) Is there a preference in core ICT tools ready to be integrated in the course to enhance student´s experience?

3) Is there any difference in ICT literacy according to the majoring our students choose?

Answering these questions will provide us an overview on the approach our students have to the ICTs. This overview will allow us to prepare a plan for integrating ITCs in the courses, beyond the standard use of course related tools

B. Data collection Methodology

The data was collected using an on-line questionnaire during the first term of 2012. It was hosted on a free server dedicated to surveys. Students completed the survey during a 30 minutes period in their Lab course time. After completing the surveys the normal activity was resumed and 20 minutes before the end we held a group interview addressing the survey. Our aim was to learn how the student understood the different survey questions in order to aid us in the data interpretation.

The survey was anonymous and the only the age and course was mandatory information. The students were able to skip questions at will.

The survey comprised four sections

1) Personal details: gender, age, course, Internet access at the place of residence; working hours, Internet access at the place of work, types of devices owned and used regularly.

2) Technology formally used on the courses: including tools that are part of the institutional online campus (moodle) and other tools and systems either personal (e.g. laptop, media player, etc) or are openly available online (e.g. Wikipedia, social networking sites, etc.).

3) Technology used for learning but that is not formally required

4) Technology used for recreational purposes.

Course's faculty worked with us in the survey and interpreting the results. We knew in advance the technology required in their course asked in section 2. However the answers from the corresponding section differed with the reality. This discrepancy was addressed in group interviews and provides a cue on the perception students have of the class or the way they answer to survey questions.

III. Survey Results, Personal Data

A. Demographic data

The survey was responded by 337 students of the School of Engineers of the University of Buenos Aires. Ages range from 18 to 48 (303 students chose to answer) from 18 to 48 with an average of 22.1 and a SD of 4; 39 students were over 30. There were 225 male and 82 female students with similar average age.

We divided the students in two groups according to their field of study: those who pursued engineering field disciplines non related to ICT (Information and Communications Technology) and those who did (Electronics and Informatics Engineers). There were 74 non-ICT students (53 male and 21 female) and 263 ICT students (202 male and 61 female).

All non-ICT students were sophomore students. The ICT students were a mix of freshmen, sophomore, Junior and Senior.

TABLE I. Demographic Data

	Non-ICT		ICT		All Answers	
Total	74		263		337	
avg(age)	20.4		22.9		22.1	
Male	53	71.6%	202	76.8%	255	75.7%
avg(age)	20.6		22.6		22.2	
Female	21	28.4%	61	23.2%	82	24.2%
avg(age)	20		24.7		23.17	

Internet access at home or place of residence was up to 88.1% with little variation and Internet at work was present in the 95% of the cases. Only 13% declared to have filtered Web access, mostly from educational institutions. For the population under study, Broadband access from 4+ Mb/sec is a commodity.

B. English Knowledge

The question was posed in two terms: "Can you read and understand an English study text?" And "If you answered Yes to the preceding question, do you feel comfortable studying from an English text or do you prefer studying from a text in your native language?".

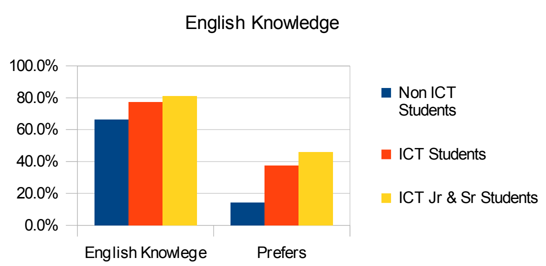

Fig. 2. English as Preferred Language

Of the non-ICT students, a 66% asserted proficient English knowledge but only 14% stated it as the preferred text language. Figures change to 77% for ICT Students and 37% as the language of choice. In the Junior and Senior sub-category 81% declares proficiency and 49% chose the English written texts. Obviously they have already had experience with translation misunderstandings.

C. Devices Owned

As a last Item in the Personal Details section we explored the devices owned and regularly used by the students.

The most popular devices were CellPhones, Computers, Audio & Video equipment (including mp3/4) and Digital Cameras. Smartphones come next with a logical increase of ownership with age (and working status). We detected very few game consoles and tablets and practically no e-readers or portable game consoles. Only 50 of the 337 students (14%) did not declare to have some kind of Personal Computer.

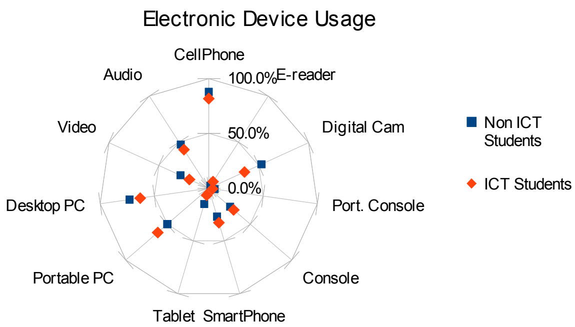

Fig. 2. Student Electronic Device ownership and usage

A networking analysis figure like Figure 2 shows no particular clustering or difference neither between non-ICT and ICT students.

The result raises several questions. We assume they under-reported the gaming devices, which we could not confirm without the interviews. We also suppose there is some serious overlap with the functionalities of the devices, e.g. audio or video players, digital camera and CellPhones. As we were interested in ICT we instructed specifically to take the devices as functions and tally every function they own. In the group interview we discovered that most of the students did not follow these instructions.

IV. Technology Formally Used on the Courses

The students are assisting to courses whose faulty form part of the research group. That means we already knew the answer to this part of the survey. We included it in order to evaluate is students were able to record the kind of tool they were using.

The following tables summarize the answers (ordered by declared use)

TABLE II. MANDATORY TECHNOLOGY USED IN COURSES NON ICT STUDENTS

Item	*n*	*%*
e-Campus	60	81.08%
Course Web Page	54	72.97%
e-mail	54	72.97%
Groups	47	63.51%
Online Reading	41	55.41%
Document Sharing	38	51.35%
Simulations	34	45.95%
Slides	30	40.54%
Animations	30	40.54%
Google	27	36.49%
Video	26	35.14%

TABLE III. MANDATORY TECHNOLOGY USED IN COURSES ICT STUDENTS

Item	*n*	*%*
Course Web Page	177	67.30%

Simulations	70	26.62%
Video	64	24.33%

There are some problems with these figures. All the courses have a Web Page and every piece of news about the course is published in it. However the fraction of students that answers using the Web Page is less than expected. E-campus use is non- mandatory but all the non-ICT courses used in the survey were using it, again this fact is under-reported. Less than half of the students assert the course uses slides as part of the material for students, and all the courses did. E-mail and groups are overlapped, several students cannot tell apart a mail-group address from a Google or Yahoo group.

Used as a control question, student´s answers allowed us to evaluate the accuracy of the other sections. We have to be cautious with the answers because students do not understand the words we are using or the services we are referring to.

V. Technology Used for Learning, Social Life and Recreation

A. Note taking and Learning.

Students need to take notes. Note taking and reviewing are labeled in the literature as encoding and external storage respectively. Encoding is described as generating a personalized written record of the lecture or the class activity. Storage is keeping this written record during the gap between presentation and evaluation and to use the record for review or study guide [5].

The potential productivity of reviewing notes is limited by the encoding function of the note taker. Students are notoriously incomplete note-takers, generally recording less than 50% of the critical ideas [6] [7]. These facts are addressed by providing students with instructor's notes in the form of course slides. In all the courses we provide the slides in advance of the corresponding lecture. We had some previous experience in researching the way notes were used [8].

We asked students how they used the technology as an aid in taking notes, in class and out of class when preparing to sit for tests.

Results are summarized in Fig 3 and 4

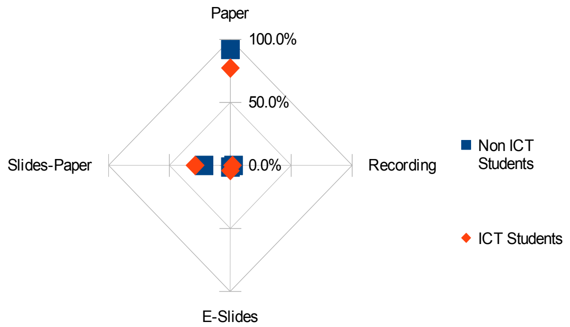

Fig. 3. In class Note Taking

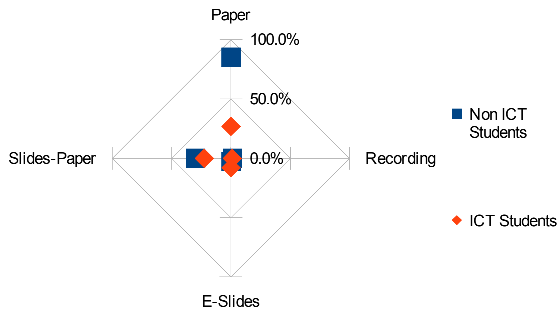

Fig. 4. Note Taking when studying

Slides are clearly under-used, ICT Students use an editor (not necessarily a note taking software) but very few used the e-slide as basis for electronics annotations. They are introduced to this kind of tools in class and teachers use e-annotations in lectures. Also they do not report recording a class. The overall schema seems very traditional and poorly affected by the technology.

When we ask for the most popular ICT aids used in both groups, the same Items appear. The difference in the positions is accounted for a greater heterogeneity of the ICT Students population, in age and courses. Students rely on e-mail as the preferred communication method. SMS are less used as teamwork seems to be done using the ad-hoc software available in the e-campus or general sharing technology such as Google or Yahoo groups, Dropbox or Software Configuration Management (SCM) Tools.

TABLE IV. TECHNOLOGY USED WHEN STUDYING NON ICT STUDENTS

Item	n	%
Course Web Page	55	74.3%
e-Campus	55	74.3%
e-mail	55	74.3%
Online Reading	49	66.2%

Doc Share	138	52.5%
e-Campus	132	50.2%
Code Share	127	48.3%
Slides	116	44.1%
Google	112	42.6%

Simulations and Videos regarded as very helpful by faculty are low in student's use. Students also do not seem to search for similar material at other Universities. It is remarkable because the authors spent a lot of Lab-time showing material from sister institutions, playing with simulations and videos to underline key concepts and using the online backup facilities to recover past classes information.

B. Social life and recreation.

Again students seem here to under-report some activities such as gaming and over-report others such as book reading. They do not specify what they understand as “file sharing” and in the group interview they further refined the activity as “sending interesting stuff”.

A few of the students integrate several activities under a social networking tool such as Facebook. Students regard Facebook as a publishing tool, but when they want something to reach somebody they resort to e-mail or messaging. From interviews with high-school teachers, this trend will change as younger people integrates their messaging in the social networking software.

We did not ask about the legality of downloads or the precedence of the movies or the proper attribution of credits.

TABLE VI. ICT USED IN SOCIAL LIFE AND RECREATION

We found no difference or clustering regarding majors an academic maturity

VI. DISCUSSION

A. General remarks

Some Items such as gaming appear to be under-reported and some such as books are clearly over-reported. We attribute this to a response bias [9] where students responds wishing to please an engineers image of themselves.

English language is perceived as a mandatory skill among students. In the case of ICT students where data form higher courses is gathered, it can be seen that mastery in English increases as they progress in their careers. It is usual for teachers to make students read material in English and the awareness of the importance of the language increases with this practice.

This is not the case with the ICTs. Analyzing the reported data on mandatory technology and comparing it with the technology we know is used in the courses, we found that a lot of technology went unnoticed. In the group interview we could state that students did not identify the used technology with the survey Items.

Sometimes a tool is introduced in class either in an explicit way such as explicit asking Software Configuration Management tools in sophomore year of ICT students or in an indirect way, such as using it in a lecture. Survey data shows that the tool is not integrated into the student baggage of skills. They do not appear using it afterwards unless they are asked to.

B. The Research Questions

For the first research question, *can we expect students to learn core ICT skills independent of the curriculum as is the case with English language?,* our answer is that we cannot rely on external sources to teach technology to our students. We must allot class time to show and explain the use and advantages of the technology, balancing it with the course context. We cannot expect an independent awareness such as we do with English reading proficiency.

Regarding the second question, *is there a preference in core ICT tools ready to be integrated in the course to enhance students experience?,* we did not found any preferred ICT tools which students masters ready to integrate in the teaching and learning process. Students showed experience in browsing, messaging, mailing and file sharing. However this experience has to be enhanced with grouping, virtual meeting and forum participation. Also supporting technologies such as on-line backup and on-line annotations must be shown and used in lectures to help students to incorporate their use.

For the third question: *is there any difference in ICT literacy according to the majoring our students choose?* We found no difference neither among different major's cohorts nor among different stages of their academic career.

The main difficulty with ITC tools seems not to be related to the mastery in the technology but to the approach to the learning experience. Students favor passive technology such as online reading to more active such as the use of simulations to explore possible outcomes. When using ICT as a recreational or social resource students also rely on passive technology and as a way of connecting among themselves. There is little evidence of the use of technology in collective creative way. This is in line with the research data that rejects the notion of Digital Natives [3].

C. ICT Literacy

Literacy has no single or universal definition and its meaning has changed over time from an elementary 'decoding' of written information to a range of more complex and diverse skills and understandings [10].

Literacy tends to be viewed either as an individual attribute or a social practice and is considered a set of practices which have the potential either to empower (by enabling critical analysis) or disempower (by merely reinforcing existing unequal relationships within the community) individuals [11].

In international policy papers referring to ICT three terms are used -skills, competence and literacy-. *Skills* and *competence* are particularly common in the industry, adult education and professional training sectors and are based on step-by-step systematic model of instruction. They emphasizes the achievement of clearly pre-specified and measurable skill levels rather than a broad conceptual understanding of ICT features and its potential in various domains. In contrast, the term *literacy* has become increasingly more accepted because it is perceived as broad and open enough to include a full range of cognitive and non-cognitive human attributes

ICT literacy can be defined as a *transferable set of capacities related to ICT use* [12]. Being 'transferable' points out that ICT literacy is a generic tool that could be applied for a variety of purposes and in a diverse array of situations. ICT literacy includes not only knowledge and instrumental abilities, but also personal and interpersonal attributes, as well as capabilities to apply them in specific contexts.

We collected data about the amount of use of ICT, a more specific survey for ICT literacy has to be done by evaluating problem solving using ICT's. Although students do use the ICT's on a regular basis, our analysis does not support the view that they can be regarded as computer literates.

A UNESCO document [13] referring to a model curriculum of ITCs in secondary schools describes four stages in the way students and teachers learn about and gain confidence in the use of ICT. These four stages are *discovering learning how to use, understanding how and when to use* and *specializing in the use of ICT tools*. From the survey we can conclude that most students are somewhere between discovering and learning how to use the tools.

VII. FUTURE WORK

The partial literacy of students and the disparities of their skills, if not attended to, might seriously compromise some students' ability to succeed. Faculty cannot assume prior knowledge IT skills. The inconsistency in student skills makes it difficult to design effective technology-enhanced instruction.

A first step is to investigate each course needs of ICT and compare the needs with student´s skills periodically. With the surveyed data an action plan to better integrate technology into courses and help students access academic information from their many and diverse devices and platforms must be created.

The plan's goal is to give students different options for interacting with the academic material and with instructors. Blended/hybrid learning environments must be developed to meet students' preferred styles of learning.

***Abstract*—Class instruction is a living and ever evolving process aimed at providing students with a quality education. Instructors are responsible for analyzing their courses to ensure that delivery of information is effective. Changes made are usually based on student assessments; however, our reactions to assessments are flawed without student insight. One method to obtain student feedback is through muddiest point reflections. This activity asks students to reflect on what was just taught allowing students the opportunity to share what was “muddy”. This mixed-methods study provides vignettes from faculty members on their use of muddiest point reflections and an assessment of what value students associate with such an intervention. Faculty members who have used this approach say it drives change within their classes. The analysis of student value beliefs revealed muddiest point reflections as an intervention that positively impacts interest, attainment, and utility value without negative cost. The appeal of muddiest points was also evident with 77% of students hoping to see muddiest point reflections in another class and 93% agreeing to recommend their course experience to a friend. These findings suggest that students agree more than disagree that muddiest point reflections are a valuable addition to their educational experience.**

Keywords – muddiest point reflection, curricular change, formative feedback, associated value

I. INTRODUCTION

One of the primary roles of faculty is the responsibility to teach students. Additional responsibilities can sometimes diminish the priority level placed on teaching, which in turn prevents many faculty members from putting in the necessary time to evolve their teaching practices. Preparing courses, especially those taught year after year, can eventually lead faculty to fall into the trap of simply using notes or slides from past years to save time. This approach may save time, but fails to meet the changing needs of our students who have high expectations from their instructors.

One very simple method to improve teaching is to employ *muddiest point reflections*. Muddiest point reflections involve simply asking students to anonymously reflect on what was “muddy”, i.e. confusing, during class and to rank their level of confusion. Reflection can occur by providing students with a document to record difficulties throughout the class or by dedicating five minutes at the end of class. This intervention provides an opportunity for students to reflect in a way that is beneficial for both them and instructors; students reflect on what they understood from the class, while instructors obtain valuable insights into what was confusing for students. This direct feedback allows instructors to instantly reflect on how well they taught the course content and how they may change their delivery or pedagogical approach next time. Additionally, taking five minutes of time at the beginning of the next class meeting provides instructors with an opportunity to cover the material again in an effort to address student concerns and misconceptions. This short, noninvasive effort not only addresses students falling behind, but also shows students a commitment to their education especially when the instructor puts direct student quotes on the screen. In effect, the “muddiest point” technique establishes a critical student/instructor dialogue.

The following study reports the use of muddiest point reflections in three material science and manufacturing courses. These reflections have revealed many confusing topics such as secondary bonding, Miller indices, and eutectic phase diagrams to name a few. Emerging muddiest point topics have led to various changes in the course content and delivery for these instructors as well as increased interest from other faculty members. Specific efforts undertaken by these three instructors include creating YouTube Muddiest Point video tutorials, building a FAQ resources website, implementing preview problems based on the next class’s content, and embedding active student-centered pedagogical approaches. These efforts have shown dividends in a short

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

period of time as demonstrated by the over 33,000 hits in less than seven months for the twelve video tutorials posted and the 93% of students who indicated the videos supporting their learning.

The goal of this paper is to share instructor experiences with muddiest points focusing on how these reflections have impacted their courses. Additionally, this paper will investigate the following research question:

What value do students place on muddiest point reflections?

II. Background

A. What are Muddiest Point Reflections?

"Muddiest points" are unclear concepts generated by students. In 1988, Frederick Mosteller first implemented muddiest points through the solicitation of responses to the following three questions: 1) What was the most important point in lecture?, 2) What was the muddiest?, and 3) What would you like to hear more about? After analyzing the student comments, Mosteller addressed issues using both class time and handouts. Anecdotally, Mosteller stated that although this activity required class time, the students enjoyed the exercise and he was able to modify 15% of his class behavior [1, 2]. Also in 1988, Angelo and Cross highlighted "muddiest points" as a subsection of one of thirty classroom assessment technique classifications [3]. It has been suggested that the collection of most interesting points is a beneficial addition to balance perceived negativity by focusing only on muddiest points [4]. In summary, the seminal publications of Mosteller, Angelo, and Cross launched the widespread, but under-analyzed, use of "muddiest points" today.

B. Motivation for using Muddiest Points

The use of muddiest points is evident by the over 8,200 hits revealed when searching Google Scholar. The success of "muddiest points" is due in part to its ease-of-use and large impact. Muddiest point requires very little time and minimal change to the syllabus. It allows students to reflect, retain, synthesize and build knowledge. Muddiest points not only benefits students but faculty as well. It allows faculty to more effectively question students, assess their difficulties, identify next steps, and help modify lectures for future semesters [5].

C. How to Collect Muddiest Points

Muddiest points may be implemented through a few simple steps, outlined by several groups [5-7]. First, instructors should hand out muddiest point sheets/cards at the beginning of class and remind students to begin filling them out, anonymously, 15 minutes before the end of class. Instructors should then collect and record responses (in an Excel spreadsheet, for example). The responses must then be analyzed so the instructor can identify the most relevant issues requiring a strategized response. We are proponents for use of direct quotes when responding to student misconceptions as "student voice" strengthens student-instructor interactions[8].

D. Cyber Implementation of Muddiest Points

The original method of collecting muddiest points used blank index cards [5]. Today, there are many media that can be utilized to collect muddiest points. For this study, researchers used custom forms requesting both muddiest and interesting points which facilitated the use of student quotes when responding. Alternatively, others used in-class clickers and online multiple-choice forms with generalized topics as choices to quickly and quantitatively assess the muddiest points [9, 10]. Similarly, there are many options for responding to muddiest points including the creation of screencasts and podcasts [10-12].

E. Impact of Muddiest Points

Although the use of "muddiest points" is widespread, limited work has been done to determine the student value of this exercise. King determined that the "muddiest points" technique was favored by the majority of the students as demonstrated by their response rate. More specifically, 75% of students that answered other subject-based clicker questions also answered the clicker question on the muddiest point. King's study also uncovered that, although the majority of topics were conceptual, the majority of students had trouble with quantification [9]. Pinder-Grover, et al. showed that final grade correlated with frequency of use of muddiest point screencasts [10]. Here, we hope to further characterize the impact of "muddiest points" on engineering students by examining the efficacy of determining its value and cost to students.

Our efforts are supported by expectancy-value theory and the significant body of work indicating that the value of learning a specific domain predict the amount of effort they will put into learning and the quality of that learning [13-17]. Expectancy-value theory states that associated value is determined by the level of interest, capability of attainment, utility toward goals, and cost associated with a given activity. Research has clearly demonstrated that college student' effort and achievement are influenced by the connections they make between the content of their courses and their personal futures [18, 19]. Belief about the utility of learning activities for achieving future goals is called *Perceptions of Instrumentality.* If students believe that mastering the content of their coursework is important for their future, then they will be more willing to put forth effort. Students who are interested in the short-term value of what they are learning are more likely to use learning strategies that facilitate quick learning, rather than deep understanding. Students will also expend less effort trying to master the tasks at hand [20].

III. Methods

The following mixed methods study is broken up into two distinct components. First, we include three vignettes by instructors discussing the impact and perception of muddiest points from the their perspective. Second, we surveyed students in the three instructors' courses to assess their perceptions of associated value toward muddiest point reflections.

A. Instructor Sample

The instructors include three faculty members teaching materials science and/or manufacturing courses in three different engineering degree programs. Each faculty has utilized muddiest point reflections for a minimum of two semesters as a way to impact change within their class.

B. Student Sample

Our student sample included 109 students enrolled in the three material science and manufacturing courses described in the faculty vignettes. Students ranged from sophomores to seniors across various engineering majors.

C. Instrument Design

An instrument was created for this study to investigate student beliefs towards the value of muddiest point reflections. The developed instrument used three sources to establish items: 1) literature regarding value and motivation [17, 21-28], 2) a value survey previously used to assess grading system beliefs and impact of peer mentoring [29, 30], and 3) an uncharacterized attitudinal survey developed by one of the instructors for his course. The instrument consisted of four broad questions with additional items associated with the first two questions (see Appendix I).

Each item was placed on a 4-point agree-disagree Likert scale (completely agree – agree more than disagree – disagree more than agree – completely disagree). Items included in questions 1 and 2 were derived using the previously described expectancy-value theory. The remaining two questions were included to determine whether students would like to see increased use of muddiest point reflections and if they would recommend the course they are currently taking to a friend.

D. Data Collection and Analysis

The survey was administered by the instructors in their classes; two instructors administered the survey using paper and pencil while the third administered the survey online via Qualtrics©. Student identities were completely anonymous. Each respondent was required to answer all of the questions to complete the survey. The results were tested for validity and reliability using factor analysis and internal consistency (Cronbach's α). Mean score differences were then used to assess the value students believed muddiest point reflections had for their respective courses and future goals.

IV. Results

A. Instructor Vignettes

Through autoethnographies— "studying one's own culture and oneself as part of that culture" [29]—we provide vignettes of three instructor experiences using muddiest points in materials science and/or manufacturing courses.

Vignette 1 – The first vignette looks at a course titled "Structure and Properties of Materials". This course covers the basic concepts of material structure and its relation to properties contextualized by real-world engineering applications. It is a required course for Mechanical, Industrial, and Materials Engineering majors usually taken freshmen/sophomore year.

"Initially, when I started to use 'muddiest points', the goal was to elicit confusing concepts from students in order to respond to them; however, over six semesters, the 'muddiest point' strategy has evolved into much more than responding to student issues. It opened a channel of communication and mutual trust between the students and me, which turned an instructor's monologue into a student-instructor dialogue. As such, the interaction enhanced the student learning experience as well as the teacher's instructional experience. Much more than 'muddiest points' are elicited from comments including alternate conceptions, vocabulary issues, rushed teaching, bad handwriting, questions of curiosity, and comments on related student experiences. Students can reflect on their learning over a class as well as discover the issues their fellow students are struggling with. With student 'muddiest point' input, improved teaching strategies can help diminish previously difficult conceptions. Overall, 'muddiest points' enhances both student and teacher metacognition about learning and instruction, respectively."

Vignette 2 – The second vignette looks at a course titled "Engineering Materials and Manufacturing". This course is a required fundamental sophomore course taken by students enrolled in a Bachelor's of Science in Engineering program. The course covers the characterization, structure, and properties of materials, manufacturing processes, engineering metrology, quality assurance, and cost modeling.

"My foray into using muddiest point reflections began when a colleague suggested the tool as a method to engage students. After two semesters of using muddiest point reflections, I've come to the realization that the tool provides mutual gains for both my students and me. Muddy points revealed in my first semester have led me to make changes not only during the current semester, but beyond to the following year. The knowledge gained from my students has encouraged me to try new approaches including video tutorials, jigsaw activities, and in-class activities. As a professor, I like to believe that I can generally tell when something isn't clear. Muddiest points is the tool that helps confirm or deny my intuitions"

Vignette 3 – The third vignette looks at a course titled "Modern Engineering Materials". This course covers the role of materials in engineering, properties of materials, nonferrous and ferrous systems and applications, heat treatment and strengthening mechanisms, various polymeric, ceramic, composite materials biomaterials and their applications, failure theories, characterization, corrosion and environmental issues, and project work involving selection and design with various material systems.

"Working with a close colleague, I was encouraged to try addressing the current needs of students by using their own strengths and weaknesses. The 'muddiest points' technique is a form of Just-in-Time Teaching (JITT) that I find is much less intimidating than traditional JITT. The entire lecture is not modified to suit the previous students' comments but the

students do feel they are a part of the process when their own words are used to clear up muddy points. Students are made a part of the learning team; they are the players and the faculty member is the coach unlike in a traditional classroom when the faculty is a performer on stage and the students are mere audience members."

B. Value Survey Validity and Reliability

The survey was first tested for validity and reliability. Factor analysis revealed three factors with weights ranging from 0.710 to 0.890 (Table I).

TABLE I. FACTOR ANALYSIS

Item	Factor 1	Factor 2	Factor 3
1a	0.749		
1b			0.869
1c	0.783		
1d	0.721		
1e			0.832
1f			0.890
1g	0.779		
2a		0.710	
2b		0.785	
2c		0.858	
2d		0.847	
2e		0.861	

Expectancy-value theory was used as a means to obtain construct validity. The construct of value described in the theory was tied to each of the three factors: Factor 1 – Intrinsic & Attainment Value; Factor 2 – Utility Value; and Factor 3 – Cost. Factor 1 included both intrinsic and attainment value as suggested by previous research using similar surveys [17, 18].

C. Associated Value of Muddiest Points

The data from the validated instrument was then used to assess student beliefs pertaining to the value of muddiest point reflections. To simplify the presentation of the results, *agree* and *agree more than disagree* responses as well as *disagree* and *disagree more than agree* responses were separately pooled together and presented as percentages (see Tables II – IV).

1) Interest/Attainment Value: Interest or intrinsic value is an individual's anticipated enjoyment of engaging in a particular activity. Related to interest value is attainment value or an individual's perception of how the activity contributes to the conception of who he or she is fundamentally. Results suggested that the majority of students found muddiest point reflection to positively impact their experience in the class.

TABLE II. INTEREST/ATTAINMENT VALUE RESULTS

Interest/Attainment Value	Agree	Disagree
motivated me to do well in the course	62%	38%
was an effective way to increase my engagement in the course	81%	18%
helped me better understand my own personal learning	71%	29%
increased my level of responsibility	64%	36%

2) Utility Value: Utility value is an individual's perception of the advantages that result from engaging in the task for future goals or rewards. Results suggest that students overwhelming found the material learned in their course to be of value to them in their current and future endeavors as learners and professionals.

TABLE III. UTILITY VALUE RESULTS

Utility Value	Agree	Disagree
will be of value to me after graduation	83%	17%
was useful in my pursuit of my career and/or graduate school goals	79%	20%
helped me see the relevance of engineering to the real world	89%	11%
helped me learn the importance of materials science to engineering	94%	6%
helped me learn the importance of manufacturing to engineering	90%	10%

3) Cost: Cost represents an individual's perception of the sacrifices required, including effort, time, and psychological impact, for successful impact of an activity. Results suggest that students did not find muddiest point reflections to be a frustrating activity that took too much time and effort.

TABLE IV. COST RESULTS

Cost	Agree	Disagree
required too much effort	17%	83%
made me frustrated and anxious	11%	89%
required too much time	14%	86%

4) Appeal: The final two questions pertained to the students' desire to see muddiest point reflection used in other courses as well as whether they would recommend a course with this muddiest point reflections to a friend. The majority of students (77%) agreed that they would like to see this tool used in their other courses, while overwhelmingly (93%) recommending the course to a friend. This final result is likely impacted by more than just the muddiest point reflections including the course content and the instructors themselves.

V. DISCUSSION

The use of muddiest point reflections is a simple intervention capable of major impact on the delivery of course content. The benefit to such formative feedback is the associated gain for both instructors and students. The instructor vignettes frame muddiest point reflections as a catalyst for change in pedagogical practice. The vignettes report muddiest points providing a "channel of communication and mutual trust" with the students. That channel provides a way for students and instructors to have a dialogue between one another, in turn restructuring the course from teacher as "performer" to teacher as "coach". This role change allows students to voice their opinions as a means to impact course content delivery. Instructors can then use student opinions to "confirm or deny intuitions" about what is being assumed to need changing.

From a student perspective, the survey revealed overwhelmingly positive value associated by students toward the muddiest point reflections. Students saw this opportunity as a way to positively impact interest, attainment, and utility value without too much negatively associated cost. Such results suggest that students found muddiest point reflections to improve the course in a way that made the course more enjoyable and valuable. This increase in value resulted in high appeal for the course by students and a likelihood of recommending the course to a friend. While this final result is likely impacted by the course content and the instructors themselves, the instructors can still appreciate that students view using such activities as a means to obtain positive student reviews.

VI. Concluding Remarks

Our initial research demonstrated that reflections have affected pedagogical changes in the classroom. Students found interest, attainment, and utility value in muddiest point reflections, while not costing them too much time and effort.

Our future work will focus on better quantifying improved student enrollment, achievement, and attitude due to implementation of muddiest points. Further, our continued goal with this research-to-practice effort is to bring greater awareness of muddiest point reflections to STEM faculty in an effort to continuously improve higher education.

APPENDIX I: STUDENT VALUE OF MUDDIEST POINT REFLECTIONS SURVEY

Directions: Please read each of the following statements and indicate your level of agreement based on your class experience. Do NOT choose multiple letters for one question (Ex. B/C).

A: completely agree   B: agree more than disagree   C: disagree more than agree   D: completely disagree

1. The "muddiest points" daily reflections used in this course…

   a. motivated me to do well in the course. _____

   b. required too much effort. _____

   c. was an effective way to increase my engagement in the course. _____

   d. helped me better understand my own personal learning. _____

   e. made me frustrated and anxious. _____

   f. required too much time. _____

   g. increased my level of responsibility for my own learning. _____

2. The material learned in this course…

   a. will be of value to me after graduation. _____

   b. was useful in my pursuit of my career and/or graduate school goals. _____

   c. helped me see the relevance of engineering to the real world. _____

   d. helped me learn the importance of materials science to engineering. _____

   e. helped me learn the importance of manufacturing to engineering. _____

3. I would like to see muddiest point reflections used in other courses. _____

4. I would recommend this course to a friend. _____

Learning from Industry by Using an Inquiry Based Learning Approach

***Abstract*—Inquiry based and constructivist activities can motivate students to take charge of their own learning, understand multiple perspectives and develop high level reasoning skills.**

This paper describes a case study of six year teaching practice in one of our Master courses. The course requires the students to acquire critically analysis, evaluation and research skills. The course also requires the students to acquire the techniques and technologies related to many aspects of an enterprise website. There are only 32 hours for class meetings so the students have to work by themselves in most of the time. The best way to achieve the course requirements is to use the constructivist activities, let the students individually or collaboratively to work with the relevant partners and build the required knowledge and skills gradually. An assignment was developed which requires the students to investigate different aspects of an enterprise website. To complete this assignment, the students need to use an inquiry based learning approach.

The practice is evaluated by using a set of survey data, a set of data observed from the marking reports and the industry feedbacks. The practice is effective, while the practice is improving; the students' abilities of planning, investigating, analyzing, communicating and reflecting are improving as well. The students' contributions are valuable to the industry. The paper also includes a discussion which links the teaching practice with the relevant theories.

Keywords—teaching and learning; inquiry based learning, industry inquiry; website.

I. INTRODUCTION

Inquiry based and constructivist activities can motivate students to take charge of their own learning, understand multiple perspectives and develop high level reasoning skills [1]. Bruner's educational theory argues that learning is an active process and knowledge transmission depends on the individuals' participations and reconstructions [2]. We need to work both independently and in collaboration to create engaging learning communities [3]. Much education literature emphasizes the shift away from teacher-centered education to student-centered learning. Interactions, communications or collaboration with more capable peers during problem solving will enhance the learners understanding [3, 4]. When students manipulate artifacts themselves and think freely about problems, they become more actively involved and generally more systematic and scientific in their discovery of laws.

This paper describes a case study of six year teaching practice in one of our Master courses. In a subset of the requirements, the course requires the students be able to

- identify the most common system architecture;
- critically evaluate and determine technologies/tools for developing and maintaining enterprise websites;
- research design issues related to content, appearance, media and architecture;
- analyze the usability & accessibility for an enterprise website;
- investigate server-side administrative issues;
- evaluate client-side considerations;
- analyze security problems;
- explore management issues relating to security, encryption, verification, site auditing, certification, privacy and copyright.

In summary, the course requires the students to acquire critically analysis, evaluation and research skills. The course also requires the students to acquire the techniques and technologies related to many aspects of an enterprise website. There are only 32 hours for class meetings so the students have to work by themselves in most of the time. The best way to achieve the course requirements is to use the constructivist activities, let the students individually or collaboratively to work with the relevant partners and build the required knowledge and skills gradually. In the inquiry based learning, students are typically presented with a task to do and have to discover for themselves, with teacher facilitation as appropriate, what knowledge gaps they may have and the skills they may need to develop [5]. Inquiry skills improve student ability to acquire knowledge [6] and these skills are particularly important for Master students, so an inquiry based approach should be adopted.

Based on the above understanding, an assignment was developed which requires the students to investigate different aspects of an enterprise website. To complete this assignment, the students need to use an inquiry based learning approach. In

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

inquiry based learning, students can also gather information by conducting interviews with local experts, family and community members [1]. The inquiry happens in two ways: using various web based online testing tools and communicating with the administration team of an enterprise website. Students are responsible for arranging their own communication, although suggestions and help may be gained from the lecturers. The students then will report their findings and critique their findings. Creating and demonstrating new knowledge require students gather data but go beyond simply reporting their findings [1]. Students are encouraged to reflect and think independently and critically. This study covers the teaching practice in the time period from the second semester of 2007 to the second semester of 2012. Each semester, we have one class in this course. The student numbers are various from 10 to 27 among the semesters.

The data were collected by observation, informal survey and informal conversations. The data were analyzed to find students' learning in planning, investigating, analyzing, communicating and reflecting. Only one of the classes was surveyed and the questions were around the students' attitudes, practices, the tools used and their industry partners' reaction.

This paper discusses the possible improvements and links the practice with the relevant theories. It also discusses the strategies to overcome the challenges experienced.

In the following sections, the teaching practice is described first, that is followed by the presentation of the data and analysis, then the teaching practice and the relevant theories are discussed, a summary is in the last section.

II. THE TEACHING PRACTICE

A. The Assignment

It is an individual assignment and the students are required to work on an existing enterprise website of their own choice with the condition that each student must work on a different website from the rest of the class. The students are required to research aspects of design, architecture, development, administration, management of the website, and then critique. The assignment mainly consists of five components: Technical Report, Architecture Report, Industry Policy Report, Critique and General Presentation. In the first component, the students are asked to investigate technique information such as usability, accessibility, popularity; in the second component they are asked to investigate architecture information such as visual design and content organization. Self-testing and online testing tools are the important instruments for the first two components. In the third component, the students are asked to investigate the management policies of the website such as system maintenance policy, security policy as well as privacy and copyright policy, industry inquiry is the main instrument for this component. In the fourth component, the students are asked to critique on the information gathered from the first three components. The most productive and worthwhile inquiry-based activities require students to gather data but go beyond simply reporting their findings [1].

The tools used include HTML validation tool, CSS validation tool, accessibility testing tool, popularity testing tool (e.g. NetCraft, Alexa), SEO analysis tool (e.g. The Reaction Engine) and technology look up tool (e.g. BuiltWith)

The assignment experienced two main structure changes in the time period covered in this study. Initially, the critique was only required on the information presented in the technique report. It was suggested that the assignment was too easy at Master level. In response to that, since the first semester of 2010, the critique has been required on all the three components: technique, architecture and industry policy. Lately, it was raised that the assignment work load is too heavy, as the students have to submit three reports for this assignment. To address this issue, the three were merged into one report and the critique was integrated with each of the first three components in the second semester of 2012. In the second semester of 2011, the following guideline for the whole process was introduced:

- Gather Information
  - Source Code and Page Extensions
  - Online Tools
  - Client Side Tools
  - Self-testing and Browsing
  - Industry Inquiry
- Report Information
  - Organise
  - Present
  - Analyse
  - Interpret
- Critique by Applying Relevant Guidelines/Principles
  - Brief/Refer Information Gathered
  - Link to Relevant Guidelines/Principles
    - Books
    - Research Literature
    - Common Practices
    - Online Technique Reports

The case studies of deconstructing website from Smashing Magazine were also introduced and discussed in the second semester of 2011.

B. The Industry Inquieries

The students are responsible to arrange the communications with their industry partners. Initially, the students send a request to express their interests to study their website as part of the assignment and ask for their support. If the response is positive, the collaboration starts. The students then send a set of questions. The industry partners may not be able to answer all the questions and they may refer the students to their colleagues or their business partners for further inquiry. The students then start to write their reports; they are usually welcome to go back to their industry partners if needed.

C. The Classroom Activities

A number of group classroom activities were designed to equip the students with the required knowledge and skills for the assignment, including news portal evaluation, server monitoring evaluation, web hosting evaluation and search engine optimization activity. The students work in group first and then report their findings to the whole class, there may be inter-group discussions at this stage.

D. The Challenges

From the practice of 2012, some of the challenges stood out, which are mainly related to the practical constraints of the learning context, such as it's hard to find an industry partner who is willing to support the assignment, the website management was reluctant to reveal some of the technique and management information due to confidentiality and etc. We encouraged the students to negotiate with their industry partners and get as much information as possible. We also encouraged the students try more options including those oversea websites.

III. The Data Analysis

A. The Survey Data

The students from 2010 Semester 1 were surveyed, among 20 students, 16 answered the questions. The survey started with a few general background information questions regarding their experiences related to website, it then focused on the industry inquiry. All the questions related to the industry inquiry and their answers are listed in Table I. All the questions are multiple choice questions except Qj. The participants may select multiple answers for Qg and Qi.

- Qa How easy to gather the data required for your industry report from the administration team?
- Qb How important your industry report to the website administration team?
- Qc Does the administration team appreciate your industry report?
- Qd Does the website administration team appreciate your critique on their management policies?
- Qe Will you provide your industry report including the critique part to the administration team?
- Qf How many staff have you communicated with from the administration team to gather the data?
- Qg In which way did you communicate with the administration team?
- Qh How much have you learned about website management policy from this process?
- Qi How would you like to learn website management policy?
- Qj If you have any other comments on this topic, please write here.

TABLE I. Collaboration Learning

Questions	Answers			
Qa	Easy	OK	Hard	Other
	2	10	3	1
Qb	Very important	Important	Don't know	Not important
	7	7	2	0
Qc	Yes	No	Don't know	
	10	1	5	
Qd	Yes	No	Don't know	
	9	1	6	
Qe	Yes	No	Don't know	
	12	1	3	
Qf	1	2	3	>3
	5	7	2	2
Qg	Email	Phone	In person	Other
	13	6	7	0
Qh	Nothing	Little	Average	Plenty
	0	1	2	13
Qi	Industry	Literature	Lectures	Other
	12	11	10	1
Qj	In general, they needed more guidance.			

The responses to question Qb, Qf, Qg, Qh and Qi are also depicted by a pie graph and bar graphs. Fig. 1 shows the responses to Qf and Fig. 2 shows the responses to Qg. According to Fig. 1, 69% respondents communicated with more than one staff from their industry partner. According to Fig. 2, 81% respondents used email for the communication; 38% used phone and 44% communicated in person. A student might use multiple ways for the communication. No other methods were specified in this survey, however, according to the informal feedbacks from the students, online chat is also an important method used by the students to communicate with their industry partners. Although the assignment is an individual assignment, collaboration is happening as well. Electronic tools, particularly email, play an import role in this collaboration.

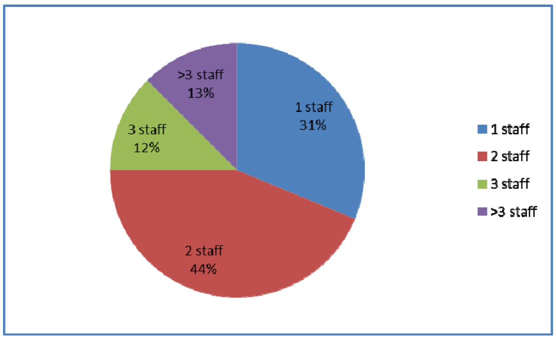

Fig. 1. The number of staff communicated by the students.

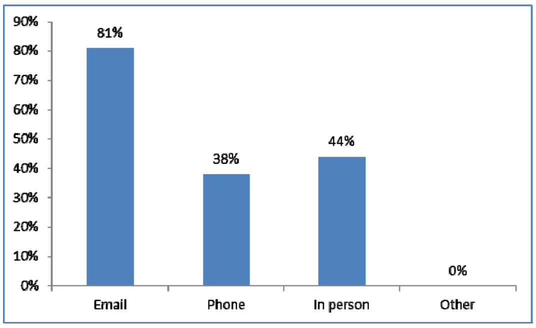

Fig. 2. The methods used to communicate with the industry partners.

The responses to Qb can be found in Fig. 3, which show that 88% respondents believed their reports important or very important to their industry partners. The responses to Qe in Table I show that more than 75% respondents would provide their reports to their industry partners. These suggest that the students are not only learning from the industry, their contributions are valuable to the industry as well.

Fig. 4 shows the responses to Qh which solicits students' opinions on their learning from the industry inquiry process. The answer is positive, 81% respondents believed that they have learned plenty from this process. All the respondents believed that they had learned something from this process. Fig. 5 shows the responses to Qi, which asks the students to select different learning approaches for website management policy. According to Fig. 5, the respondents valued the three given approaches closely, where the industry inquiry was the most favorable (75%) and the lectures was the least favorable (63%). These suggest that the students believed that inquiry based approach is more suitable for them to learn website management policy although the other supplementary approaches are still needed. One student specified that they also can learn it from previous experience.

In addition to the answers to the multiple choice questions, some students made extra comments, such as "Very good paper, has relevance to industry. Even with my experience, I learnt quite a lot of things regarding importance of policy", "Very enlightening, great impact on website owners and helpful", "This assignment promotes learning", to express their satisfactory. One student made comment of "subject literature should be discussed more in the class" which is interpreted as the students need more guidelines.

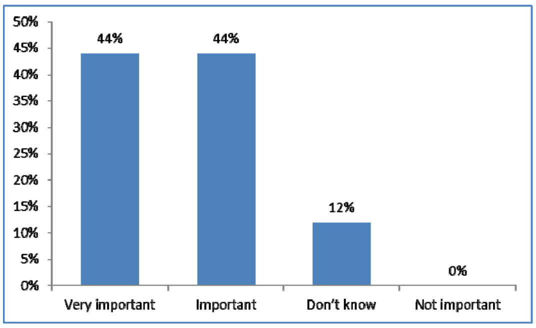

Fig. 3. The students' views on the importance of their reports to their industry partners.

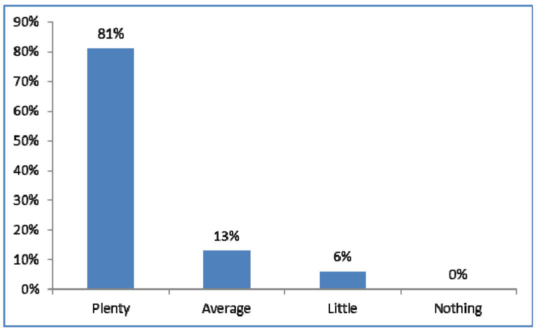

Fig. 4. How much the students have learned.

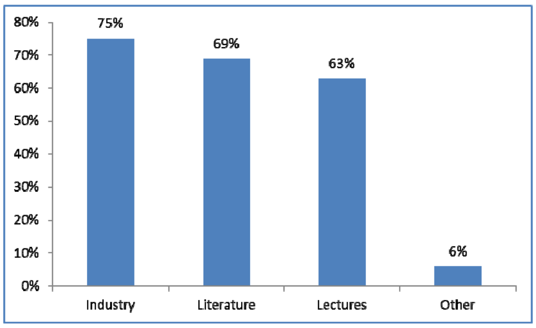

Fig. 5. The learning approaches selected by the students.

B. The Marking Report Data

After changes and improvements, the assignment was getting mature since 2010. The structure of the assignment was stable from 2010 Semester 1 to 2012 Semester 1. The marking reports in this time period was analyzed to evaluate the student learning from this inquiry based process. Only the marks for management policy report and critique report were analyzed as they are the most relevant part for planning, investigating, analyzing, communicating and reflecting. The students need to plan a set of questions before the industry inquiry and then investigate the website management policies by communicating with their industry partners. The students also need to analyze and reflect on the information gathered in their critique reports. Table II shows the data observed from the marking reports.

From Table II we can see that the marks of the critique reports were relatively low in 2010s1, which were improved in 2010s2 and were further improved later. The standard deviation were larger initially and getting smaller. On the other hand, the marks of the management policy reports had been consistently good in these five semesters. In 2011s2, the marks were further improved.

There is a need to review the improvements introduced in this time period. In 2010s2, the instructions for the critique report had been improved. It was

You should give reasons for your opinions and back them up with specific examples.

TABLE II. DATA FROM MARKING REPORTS

Semester	Policy Mean (30)	Critique Mean (30)	Policy STDEV	Critique STDEV
2010s1	22.58 (75.25%)	18.55 (61.83%)	2.60	3.41
2010s2	22.56 (75.21%)	21.25 (70.83%)	2.76	3.55
2011s1	22.06 (73.54%)	20.31 (67.71%)	2.80	2.96
2011s2	24.04 (80.12%)	22.26 (74.20%)	2.42	3.05
2012s1	23.47 (78.25%)	22.47 (74.91%)	2.22	2.06

In the survey conducted in 2010s1, a student expressed that they need more guidelines on these reports. In response to that, more research articles were introduced and discussed in the classes in 2010s2 and the instructions for the critique report became:

You should give reasons for your opinions and back them up with specific examples. You should summarize the facts you are critiquing and then apply the principles given in the lectures or literature with proper referencing.

Table II suggests that the above changes had a positive impact on the marks of critique report and had no impact on the management policy reports. In 2011 Semester 2, a guideline for this assignment was introduced. Table II suggests that the guideline had a positive impact on the marks for both of critique reports and management policy reports. The standard deviations for the marks of management policy reports were quite consistent and they were further improved since 2011s2. However, the standard deviations for the marks of critique reports were larger at the beginning and they became smaller since 2011s1. These suggest that while the teaching practice is improving, the students' abilities of planning, investigating, analyzing, communicating and reflecting are improving as well.

C. The Industry Reaction

The industry reaction was gathered by student feedbacks and the emails voluntarily sent by the industry partners.

Initially when the students express their interests to study a particular website, the administration teams may not response at all due to their busy work or confidentiality. Then the students have to try next option. According to the responses to Qa in Table I, more than 75% respondents didn't think it's hard to find an industry partner. As a matter of fact, some of the website administration teams are very happy to support the students, "It's my pleasure to help you out regarding on your research. Also it was glad that you have selected my project for you assignment".

After the students start to ask questions, some of the industry partners start to hesitate due to certain sensitive questions. We encourage the students to negotiate with their industry partners and get as much information as possible. If it's still difficult, we encourage the students try more options including those websites hosted overseas. Online communication tools can help for remote collaboration [7]. According to Fig. 2, most of the students have used phone and email in their communications, more tools used in [7], such as online chat, online forum and peer-to-peer messaging can be used by the students to communicate with their oversea industry partners effectively.

If the inquiry goes well, finally, most of the students will present their reports to their industry partners. According to the responses to Qd in Table I, more than 56% respondents believed that their industry partners appreciated their reports and their critiques. This is confirmed by the emails from three industry partners, "Your report looks great, awesome work. Your paper is quite timely as we are going through a redevelopment project of the website because of a lot of issues you have outlined", "Thank you for your report document – it is an interesting read!", "I am quite impressed by the work had been done. The reports contain high amount of useful information and analysis that are needed in our system. We could update some information about what knowledge of current student learning. At same time, we could have opportunity to refresh our knowledge of IT field".

IV. DISCUSSION

According to [5], the characteristics of inquiry based learning include:

1. The task is based on an open problem – open in the sense that there are numerous approaches to solution;
2. Initially, the student(s) are presented with the problem, and must discover for themselves the nature of the problem, and in particular to identify what knowledge and skills they will need to investigate and develop in order to solve the problem;
3. Where students are required to demonstrate self-analysis and critical thinking in order to choose between a number of possible solutions and approaches;
4. Where the teacher or lecturer acts as a facilitator in the process – but avoids simply providing solutions or being prescriptive in approaches.

Interpreting the above in the context of our teaching practice should help to validate the practice:

1. The students are asked to investigate the technique and management aspects of an enterprise website, which is an open problem;
2. Initially, the student(s) are presented with the assignment, the students need to identify their industry partner, the students need to decide what tools they need to use and what questions they need to ask;
3. Where students are required to demonstrate self-analysis and critical thinking in their reports;
4. The lecturer acts as a facilitator in the lectures and class activities, and provides outside classroom support.

Based on above, the teaching practice does have the characteristics of inquiry based learning.

“A WebQuest is an inquiry-oriented activity in which some or all of the information that learners interact with comes from resources on the Internet” [1, 6]. WebQuests are designed to use learners’ time well, to focus on using information rather than looking for it, and to support learners’ thinking at the levels of analysis, synthesis and evaluation [1]. Although our teaching practice was not designed in a WebQuest format, these purposes are consistent with our initial considerations. It should be helpful to check the teaching practice with the WebQuests to formalize this process and to identify the merits and demerits of the teaching practice for future improvements.

The outline of a WebQuest given by [1] includes:

- Introduction
  - To prepare and hook the students
- Task
  - What the student is going to do
  - A description of the culminating performance or product
- Process
  - How the learners will accomplish the task
  - Clear steps to accomplish the tasks
  - Tools and resources they will need to gather and organize information
- Evaluation
  - Criteria needed to meet performance and content standards
- Conclusion
  - To bring closure
  - To encourage reflection
- Teacher’s page
  - Information to help other teachers implement the WebQuest:
  - Targeted learners
  - Standards
  - Suggestions for teaching the unit
  - Sample student work (sometimes)

The WebQuest used in [6] contains the following stages:

1. Introduction—sets the stage; provide background information about the scenario.
2. Pooling knowledge—an opportunity for students to discuss the issue, drawing on, and combining, prior knowledge, and to stimulate critical reflection.
3. The team—allocation of specific roles for group members.
4. The task—explanation of the expected outcome from the group.
5. Where to look—students working in role, individually or in pairs, research links to appropriate web resources.
6. Getting together—time to share and synthesize findings within groups, and put together a presentation.
7. Share and Review—group presentations and questions.

Both of the WebQuests from [1] and [6] include *Introduction* and *Task* parts. [1] contains *Process* part and [6] contains *Where to look* part. [1] contains *Evaluation* and *Conclusion*; [6] contains *Getting together* and *Share and Review*. [1] contains *Teacher’s page*; [6] contains *Pooling knowledge*. While these two versions share many common components, [1] emphases the process and allows more flexibility, for example, the inquiries are not limited to the Internet; the students can also get information from their community experts; [6] focuses on group activity. WebQuests are usually collaborative ventures, requiring students to work in groups, often with particular assigned roles [6]. Our assignment is an individual assignment which is supported by the class activities and accompanied by the collaboration with the industry partners. A mixed version should reflect this teaching practice better. The following is a WebQuest with the context of our teaching practice:

1. Introduction—define the assignment requirements discuss them with the students in the classes.
2. Pooling knowledge—relevant class activities to equip the students with required knowledge and skills.
3. The tasks—explain what are expected from the students’ reports.
4. Industry Partner—the students to find a website they will study and the administration team they will work with.
5. Process—a guideline for the whole process is given; a set of tools are provided for the students to decide which tool to use and what information to collect. The students will analyze and organize the information gathered. The students will critique on the information presented by applying the principles found from various sources (lectures, literature and etc.)
6. Evaluation—a marking guide is provided in the assignment and is discussed in the classes.

The above list validated our teaching practice from WebQuest perspective. However, a *Review and Reflection* step seems missed. Adding this step by asking the students to do a presentation on their report should improve the teaching practice.

Research showed that university–industry links often rely on informal and formal social links [8]. Matching between universities and firms rarely occurs as the result of a search involving complete information on the whole range of options available to a firm [8]. This explains the challenge some students are having: it’s hard to find an industry partner. A possible solution is to encourage the students to use their social network. Another possible solution is for the lecturer to maintain a potential industry partner pool. Initially, the pool should contain those industry partners collaborated with the past students, the pool should be regularly updated by removing those who are not interested to participate anymore and adding new industry partners who are interested.

On an individual level, the question is how the academic researchers and industry staff can be aligned to produce mutually beneficial results [8]. This explains why many students have got their industry partners without difficulty. The students' contribution is valuable to the industry partners. As a matter of fact, providing their final report is the condition of their industry partners for most of the students.

The similar practice should be applicable to other subjects which are closely related to industry at Master level. The teaching practice should be adaptable to the third year undergraduate courses as well by making necessary modifications to the required tasks and evaluation criteria to accommodate the analyzing, critique and collaboration abilities of undergraduate students.

V. SUMMARY

The findings of this study showed that this inquiry based learning approach is effective; the students valued it more important than classroom lectures and their own literature research.

In this inquiry based learning process, the learning is mutual between the students and their industry partners. The students not only learn from the industry, their contributions are valuable to the industry as well. The industry partners welcome the students' reports and think they are valuable to their business.

A number of ways were used in the communications and email was the most popular one. More online tools could be used to facilitate remote communications.

While the teaching practice is improving, the students' abilities of planning, investigating, analyzing, communicating and reflecting are improving as well.

The teaching practice is validated with WebQuest. Adding a *Review and Reflection* step should improve the practice.

To deal with the difficulty in finding an industry partner, we encourage the students try more options including those oversea websites. The students should also be encouraged to use their social network. Another possible solution is for the lecturer to maintain a potential industry partner pool.

The similar practice should be applicable to other subjects which are closely related to industry at Master level. By making necessary modifications, it should be adaptable to the third year undergraduate courses as well.

***Abstract*—The design of distributed systems is a rather complex and difficult task. Distributed systems are complex systems that can be characterized as wicked problems because they involve an intricate combination of changing relationships between their various components. Research shows that it takes a lot of deliberate practice to move from the mindset of a novice to the mindset of an expert. To start cultivating experts design mindset we designed a cognitive support system consisting of a suite of mechanisms characterized by mentorship and social interactions around a real-world project. In a problem-based learning environment with cased-based reasoning, students have to follow a systematic approach using a common system of activities of "ritualized" activity structures. The systematic approach is based on the Rational Unified Process, CATs (Classroom Assessment Techniques) with rubrics, and scaffolding: questions prompts, peer-review, expert modeling, and self-reflection. This paper describes the challenges faced by novices and instructors in wicked problems design tasks in the context of developing a prototype and its framework and middleware for a complex distributed application while learning distributed systems concepts. It also outlines our interactive learning environment to scaffold the design and developing process improving student's problem-solving skills and time on-task to reduce frustration.**

Keywords—component; complex systems; distributed systems; Problem-based Learning; scaffoldings; wicked problems.

I. Introduction

Today's software engineer is expected to develop, maintain and comprehend highly complex distributed systems (HCDSs) of unprecedented size and complexity. HCDSs must be capable of delivering timely information to increasingly large numbers of users into an environment in which software and hardware are changing at an increasing rate. HCDSs are characterized by a large number of mission-critical, heterogeneous interdependent subsystems executing concurrently with diverse and often conflicting quality of services (QoS) requirements. To ensure that users experience the best QoS according to their needs and specific contexts of use, HCDSs need to be context-aware, adaptable, and dependable. HCDSs must support heterogeneity of the underlying communication infrastructure, mobility inducing changes to the availability of resources and continuously evolving requirements. [1] [2]

HCDS or systems of systems, as defined by Fisher[3], depends on distributed control, cooperation, influence, cascade effects, orchestration, and other emergent behaviors as primary compositional to achieve its purpose. Emergent behavior is the inevitable consequence of the independent management, operation, and evolution that characterize this type of systems and is unavoidable in the presence of autonomous constituents. Recognition of the importance of emergent effects in determining the global characteristics of systems imposes a change in perspective on the scope of a system. New software engineering methods and approaches are needed that manage emergent behavior and exploits emergent effects and offer the possibility of cost-effective and predicable solutions. [3]

HCDSs exhibit the characteristics of wicked [4] or ill-defined problems [5]. The design and integration of complex software components can be construed as an evolution from previous models of software design, and therefore becomes a wicked problem also.

Ill-defined problems refer to the fact that the design problem is incomplete and has no one single solution, while wicked problems are progressively defined during the design process. Wicked problems are essentially unique and each can be considered to be "a symptom of another problem" [5]. Wicked problems require an ongoing iterative analysis between problem and solution to begin to understand either, and to find the best possible compromise between design constraints when an optimal solution is impossible [6].

The decision-making strategies commonly taught in Software Engineering curricula and employed by novice software designers are not effective when applied to large, wicked real-world problems. Research shows that novice designers tend to think linearly and concentrate only on the problem at hand. Novices also tend to use trial and error strategies and lack confidence in their design decisions. [7].

Teaching distributed systems principles, paradigms, software engineering techniques, and engaging students in problem solving do not ensure the development of expertise. Research shows that it takes a lot of deliberate practice to move from the mindset of a novice to the mindset of an expert [8].

In this paper, we will describe our mentoring approach and scaffoldings to improve our novices' design skills in an interactive learning environment. We will show and analyze

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

our data comparing how the addition of scaffoldings helped us to reduce the time it takes to develop expertise in our students and use in-class time and time on-task more efficiently to reduce students frustration.

II. Scaffolding

A. *The original notion of scaffolding*

Wood, Bruner and Ross [9] defined scaffolding as an instructor or expert "… controlling those elements of the task that are essentially beyond the learner's capacity, thus permitting him/her to concentrate upon and complete only those elements that are within his/her range of competence "(intersubjectivity). The expert is the domain expert as well as a facilitator who is knowledgeable of the skills, strategies and processes required for effective learning. The key features are intersubjectivity, ongoing diagnosis, tailored assistance and fading [9].

A shared understanding of the goal of the activity provides motivation. Both expert and learner collaboratively redefine the task (combined ownership) that the learner needs to accomplish.

Appropriate support becomes a scaffold only when it is based on ongoing diagnosis of the learner´s current level of understanding. The teacher provides assistance in a timely and effective manner to the learner's present focus, thereby helping the learner with his/her current difficulties. The expert should have knowledge of the learner's capabilities that changes as the instruction progresses, as well as allowing learners to play a role in negotiating interactions. However, if the learner lacks the necessary skills, the information is outlined around the expert way of accomplishing the task. Scaffolding should be removed gradually and then removed completely when mastery of the task is demonstrated. [10]

The notion of scaffolding with individualized support explains the multifaceted nature of learning appropriate to deeply learning new concepts and skills and their applicability, in parallel with learning cognitive, social, and communication skills. However, by broadening the notion of scaffolding to the entire class of students, the one-to-one interaction between teacher and student is not possible [10].

B. *Broadening the notion of scaffolding to the entire class*

Recent design research on interactive learning environments has adapted the notion of scaffolding into classroom communities with students working in small groups. Hogan [11] defined an instructional scaffold as "a tool for acculturating students into the thinking patterns of experts". Puntambekar and Kolodner [9] defined distributed scaffoldings for science students, as a learning support addressing the need to provide multiple types, sources, methods, and amounts of supports to increase a student´s ability to perform a skill. An interactive learning environment based on a socio-constructivist model, such as inquiry and project-based approaches situate learning in complex tasks. To help students with such tasks, classroom activities are designed so that peers can scaffold each other. Support and scaffolding is provided through different resources and tools. Tools provide support for solving problems, for the processes in completing an activity, for understanding the domain, to help them to develop scientific arguments by scaffolding the process of constructing an argument and to reflect on the process [12].

The classroom embodies a community-of-learners approach [9]. Several discussion tools can be used to support the occurrence of discourse among students in the classroom and to provide prompts that enable them to think about the processes and reflect on their learning, and encourage dialogue among groups of students [10, 13]. Classroom events such as design discussions [14] enable students to share, review and critique design ideas. The more knowledgeable peers contribute by raising important issues providing clarifications and less knowledgeable members play an important role by bringing up questions and asking for clarifications.

The focus of ongoing diagnosis needs to shift to the group as a unit. Online discussion tools can help a teacher examine group's progress over time and analyze whether students' dialogue shows an increasing depth of knowledge. [10] Ongoing diagnosis and fading scaffolding are closely coupled. The aim in designing support is to ascertain that students learn the necessary domains and skills and are able to generalize them to other contexts. Teacher's role is to maintain a delicate balance between guidance and discovery and intervene removing or changing scaffolding tools after students/groups make progress. [10]

III. The Distributed Systems Learning Environment

A. *Complex Systems Challenges.*

To teach distributed systems design we have to answer some questions: How can the "wicked" problems posed by complex systems be addressed? The first step in coping with a wicked problem is to recognize its nature and their properties.

Rittel and Webber [4] describe the nature of wicked problems as a set of ill-defined problems that are too complex to be solved by rational systematic processes. Wicked problems have no definitive formulation and no optimal solution because problem definition and solution co-evolve. The solving process is inherently nonlinear. The solutions are never true or false but instead are qualitatively judged as better or worse. The realistic goal is a "satisficing", i.e. combining satisfy with suffice or "good enough" solution.

Novice designers have a tendency to treat all problems as tame because of their previous experiences, these problems are easier to solve, reinforced by the lack of understanding about wicked problems dynamics and the approach they require. A tame problem [4] is one for which the traditional linear process is sufficient to produce a workable solution in an acceptable time frame. Many traditional exercises in Concurrency and Introductory Software Engineering courses fall into the category of tame problems.

Students do not think beyond the written description of the problem. They shift rapidly from problem analysis to solution generation and failed to elaborate solution alternatives. There are some deep principles that underlie many complex systems, [15, 16], such as function, behavior, structure, and emergence. The other question is: How can we help students to view a complex system as emergent or causal depending on the point of view one is taking?

B. Cognitive Challenges

Some research studies [15, 17] have found that one of the major issues affecting students' ability to learn about complex systems and other challenging topics is their cognitive, metacognitive, and self-regulatory processes. It is to a great extent dependent on the deployment of such processes to plan, sustain, and reflect on the complex mechanisms underlying learning about complex systems. Researchers argue for the importance of experience with complex systems. Also, they argue that discovery alone is not sufficient. Students need scaffolding to guide their exploration and experience. Open-ended learning environments offers the potential to foster student's learning, but due to the complex nature of learning about these environments, it is necessary to support student's learning by providing embedded scaffolds designed to support certain learning and inquiry processes.

PBL is an open learning environment in which students learn through facilitated problem solving. PBL is designed to help students to construct an extensive and flexible knowledge base which integrates information across multiple domains in long term memory; to develop effective problem-solving skills; to develop self-directed, lifelong learning skills; to become effective collaborators; and to become intrinsically motivated to learn [18].

In addition, students' interaction with others is not only guided by the learning task, it is also shaped by their emotions, perceptions, and attitudes [17]. Some social-emotional processes are beneficial for learning others are not [19]. Therefore, the relationships between motivation, peer interactions, and wicked problem solving are worth further attention to answer the questions: How much time might it take to develop expertise in our students? How could we improve the process? The successful guidance of PBL is largely dependent on the availability and skills of instructors who can scaffold students' problem-solving activities [18].

C. Our PBL course.

When we designed our first PBL course, we acknowledged that we would find the challenges outlined above and some hurdles. The domains of distributed systems themselves span and integrate a vast range of subject matter. Students have never directly experienced complex systems concepts before. Our PBL focused on a design project following the software engineering best practices. We match the form and complexity of the problem to a real distributed problem to contribute to the realism of the experience. The engineering best practices suggest to develop a middleware that, through the provision of proper features, supports distributed applications by masking the distribution and heterogeneity of the execution and networking environment. Different software engineering techniques, such as software architectures, middleware, component-based development, service-oriented systems, etc. were introduced to deal with this type of systems. [1]

Having a small number of students each semester, we were able to use diagnostic assessment tools exhaustively in order to have a close observation of our students' learning process. In order to reach our course goal to develop independent learners with professional (expert) design skills, we arranged additional out-of-class meetings to help students to develop common positions on relevant issues when they did not meet the in-class meeting goals. We were there for office hours, kept scheduled appointments, and made time for students/teams when they needed additional help. We arrived at class early and stayed after class.

After each semester we answered the questions we pose as ongoing diagnosis, reviewed literature and transformed our cognitive support system (scaffoldings) for improving the process and using the in-class time more efficiently. Our support system in 2008 included CATs with report feedback, meetings, peer-review with a facilitator and feedback, and in-class experiments. In 2009, we added the self-reflection writing activity and rubrics. In 2010, we added question prompts, in 2011, the expert modeling scaffolding and in 2012, a PBL approach with Case-based Reasoning (CBR) focused on a design project. [20, 21,22]

Our PBL approach with CBR focused on an in-class design project, from the initial statement of a real world distributed problem to a working prototype for the whole class. We gave twenty students (our novices) the problem statement and material to work with. Students had to follow a systematic approach using a common system of activities, called a tool of "ritualized" activity structures, as suggested by Kolodner et al. [14] for solving the problem.

Kolodner et al. [14] defined "ritualizing" as articulating and normalizing a sequence of activities and setting expectations about how and when to carry out them. It is a way to incorporate aspects of design expertise as a potential strategy for helping novices solve ill-structured problems in more expert-like ways. The tool would be designed to engage novices in deeper analysis and understanding of the macro-system in which the problem and possible interventions were embedded [23].

We complemented PBL's self-directed learning with lectures. Students had to search and analyze algorithms, but complex design techniques and key concepts about distribution's complexity, concurrency, and synchronization were difficult to master by students by themselves. These concepts were introduced after the need to learn them has been established in the context of observed phenomena or unexpected system behaviors during design and implementation on a "just-in-time basis" [19].

Our PBL approach has four stages. Each stage represents a different aspect of the design and requires different student's abilities and skills. Students are repeating the cycle while revising and improving each time. The stages are based on the traditional Software Development Process RUP (Rational Unified Process Software Development Process [24]). For documentation, students had to use UML diagrams as recommended by RUP and, state transition diagrams and protocol design recommendations. The stages are:

1st stage: *Start point*. It is a pre-session preparation as in a Case-Based Learning approach [25]. The aim is to establish a community of learners and engage students in reasoning based on previous experience.

2nd stage: *Application prototype and framework API development*. This stage comprises the first iteration of the software development process of the in-class project. The first prototype of the application has to be developed using concurrent models and patterns using CBR. The prototype has to show the expected behavior of the system, the concurrency, synchronizations between processes and performance issues in a centralized environment. Framework APIs have to be developed. The APIs has to support the needs of communications, coordination and synchronization of the application processes or objects. The prototype has to be implemented using the framework APIs. The outcome has to be a working prototype in a centralized environment.

3rd stage: *Middleware design and implementation*. This stage comprises the second iteration of the software development process. The application processes will be distributed and a middleware to support the frameworks API will be developed. Students have to develop the communication, coordination and synchronization protocols. The outcome has to be a working distributed prototype.

4th stage: *Student team's project*. For a giving middleware specification, students have to find a suited application, to propose a distributed solution, and to develop the solution (as in stages 2 and 3). We have included this stage in order to foster the skills they have learned. It assesses students' skill at synthesizing what they have already learned about the field as they plan their own project [26]. Scaffoldings are removed in this stage, but students are permitted to ask for guidance in out-of-class appointments.

IV. Our Tool of "Ritualized" Activity Structures

Our tool is an outline of the activities of design process steps using the RUP Software Development Process and guidelines with embedded scaffoldings [20, 21,22].

Students like to have formal processes or procedures to use for problem solving, but the UML formal procedures they learned to use in former subjects do not work well with ill-formed problems. Experts use UML diagrams only after they make the final design decisions for the RUP phase. A flexible and adaptable "design thinking" process for guiding design decision-making would provide an alternative to these formal procedures. This process could explicitly incorporate scaffoldings for looking at the big picture of the system, the use of rules, principles, and/or practices for examining the design and generating solution alternatives, selecting and evaluating candidate alternatives, and reflecting on what has been accomplished in an iterative approach.

We are supporting this design thinking process using the CATs (Classroom Assessment Techniques) related to Assessing Skills in Problem Solving [26] for the "ritualized" activity structures in the form of reflective writing and sketching activities. Students working in teams, have to follow the guidelines and activities of the corresponding RUP phase. The Assessing Skills in Problem Solving CATs are: Problem Recognition Tasks, What's the principle?, and Documented Problem Solution.

CATs are mandatory homework. CAT's requirements are UML diagrams, state transition diagrams, informal diagrams or sketches, annotations (textual and graphical), corrections, alternatives, etc. to communicate ideas and decision arguments to support student's design thinking process. Students have to write their arguments and the collected evidence for their positions in argumentative essays. The CATs activities are based on Quellmalz's [27] key strategies of critical thinking.

Cross [11] calls sketching an "intelligence amplifier" and enumerates how sketching helps design thinking. It enables designers to handle different levels of abstraction simultaneously, enables identification and recall of relevant knowledge, assists in problem structuring through solution attempts, and promotes recognition of emergent features and properties. Informal diagrams and sketches offer a great way to examine the relationships among objects in the different problem domains, as well as their interactions. Sketches hide students from making premature design decisions because the UML notation pushes them to think of abstractions and focus on understanding the problem space.

Explicit strategies for developing arguments has been introduced using the basic tools for writing argumentative essays at the beginning of the course and out-of-class time has been scheduled to help them with these reflective writing activities [28].

Software design is a collaborative activity and developers work in face-to-face settings. CATs act as the coordination mechanism to support the design dialogue during the discussions and peer-review sessions. CATs and rubrics also act as formative assessment tools for ongoing diagnosis, to give feedback, and for "just in time" mentoring for reflection during the meetings, in the sense of thinking about something again [20, 21,22].

Rubrics assessment purposes are to improve the reliability of scoring written assignments and active participation during meetings. Rubrics convey goals and performance expectations of students in an unambiguous way, convey "point values" and relate them to performance goals, and engage students in critical evaluation of their own performance [29]. Rubrics are also a guide of how to do the work.

A. Assessing skills in Problem Solving CATs

The Problem Recognition Tasks CAT assesses students' skill at determining what kind of problem they are faced with, so they can choose the appropriate solution [26]. Students have to describe the problem using the requirements analysis and analysis diagrams of the software development process to solve the problem following the guidelines and activities of the CAT. Particular problem types, characteristics, variables, boundaries, etc. must be recognized and identified.

The What's the Principle? CAT assesses students' ability to associate specific problems with the general principles used to solve them, i.e. how they use models and abstraction in our subject [25]. Students have to decide what principles to apply in order to solve the problem and their alternatives using models and patterns of the design phase.

The Documented Problem Solutions CAT [26] assesses how well students solve problems and how well they understand and can describe their problem-solving methods and strategies. Students have to decide how they implement the solution using the designed framework APIs, algorithms, interprocess communication tools and distributed algorithms.

B. Scaffoldings.

We introduced additional scaffoldings to improve novices' problem-solving skills [22].

1) Question prompts.

In addition to the problem-solving outline, the students are receiving prompts consisting of elaboration and metacognitive questions for each activity [30]. Research reported in [30] had found question prompting to be an effective instructional strategy for directing students to the most important aspects of a problem, as well as encouraging self-explanation, elaboration, planning, monitoring and self-reflection, and evaluation.

2) Peer review.

The peer review mechanism was designed to enable students to see multiple perspectives from peers' reports and help them notice things they might not have thought about previously. By reviewing their peers' thinking, students are supposedly compelled not only to attend more closely to their peers' ideas, rationales, plans and solutions, but also to their own for self-reflection [30].

3) Expert modeling.

Expert modeling are provided by presenting students with expert's reasoning during discussion meetings. This support mechanism is expecting to offer students an opportunity to observe the expert's reasoning, which they would compare with their own reasoning. It has been assumed that the comparison would result in disequilibrium [30].

When students are immersed in a design activity, they are often unable (or unwilling) to acquire knowledge that cannot be immediately put to use. If they do not see the need for help, it is unlikely they will ask questions. Experts notice features and meaningful patterns of problem solving that are often not noticed by novices; they organize knowledge in ways that reflect a deeper understanding of their subject matter and they have varying levels of flexibility in their approach to new situations [30].

In 2011, we included the expert-modeling scaffold to be able to help novices to focus on hidden relational properties of the problem during the in-class meetings. We are introducing them in practices of reasoning about systematic exploration of possibilities (finding gaps, or finding unexplored relationships between problems and potential approaches) and scenario-based reasoning to explore assumptions and consequences. This scaffolding has reduced student´s frustration during the first two stages of our PBL approach.

4) Self-reflection

A meeting ended with a self-reflection writing activity with a few reflective questions. Self-reflection is an important mechanism to supplement the expert modeling mechanism and allowed students to observe an expert's reasoning facilitating students' reflection on the gaps between student's and the expert´s reasoning [30].

5) Agenda and goals

A collaborative design session is more likely to succeed when designers agree on ground rules for conducting the session. By setting time limits and achievement goals, designers can force themselves to focus on the fundamental problems.

V. STAGES AND SCAFFOLDING

A. Start Point or pre-session preparation.

Our students have no expertise in case-based reasoning. CBR refers to reasoning based on previous experience [31].

We adapted an approach used with medical students [25]. Students in informal teams have to solve assigned small real-world cases applying background knowledge of concurrency concepts, models, patterns, and software engineering techniques as homework. Each case is an open-ended problem with a few alternative solutions to solve with the provided CAT's guidelines and activities.

The goal is helping students to "re-index" old experiences and to abstract out generalizations from experiences and reviewing background knowledge with a different approach [25]. Students will need CBR to design and build the first prototype of the class project.

As have been reported in [31], failure at applying an old case in a new situation triggers explanation that might result in reinterpreting (reindexing) old situations and/or discovering new kinds of interpretations (indexes). Crucial to interpreting failure is useful feedback from the world, to evaluate a solution, allowing indexing that discriminates usability of old cases and allowing good judgments later about reuse.

Case discussion in class using the CATs of the interviewed team, (peer-review scaffolding) begins with a discussion of the case requirements and the proposed solutions using provided guiding questions (questions prompts scaffolding) with the other teams. Instructor and students may call time-outs at key times to discuss the ongoing discussion content to help the interviewed team to solve the problem. During time-outs other students provides feedback and assistance to this team. Instructors (expert modeling scaffolding) provides guidance and ask questions when the students seemed off track or unsure about the content to facilitate discussion.

The session ends with a self-reflection writing activity summarizing the case characteristics (domain, variables, constraints, etc.) and selected solution. The next activity for the team is implementing the solution.

Reports (CATs, self-reflection writings, annotations, etc.) and programs have to be shared using some web tool, such as DropBox; to have a resource library for the next stages of PBL as is mandatory for a community of learners.

B. Application prototype and framework API development..

This is the most challenging stage for novice designers. Students are not aware that a nontrivial portion of a software team's work for the initial stage involves improving their understanding of the problem domain from a succinct problem statement (design brief) and a vague set of requirements to produce a design that addresses users' needs. More than half the cost of the development of complex software systems is attributable to decisions made in this initial phase.

Students and novice designer find it difficult to cope with problem scoping and information gathering. These are aspects of design activity that involve identifying criteria, constraints, and requirements; framing the problem goals or essential issues; gathering information; and, stating assumptions about information gathered. CATs, instructor's guidance and scaffolding can facilitate the problem solving process and enables students to bridge the gap between their current abilities and the intended goals of expertise.

In the past semester, we scheduled several meeting for peer-review with question prompts, expert modeling, and self-reflection writing to discuss the "The Problem Recognition Tasks" CAT. Expert modeling were used to help them to learn how to use CBR effectively with expert reasoning as outlined in the CATs.

Experts are able to activate mental models that connect relevant previous experiences with domain specific knowledge and skills. They activate a mental framework for representing the problem and seek solutions. Experts integrate given information with prior knowledge and experiences to make inferences that go beyond the state information [32]. Design activities would more or less creative according to conceptual domains evoked sources. Experts can refer to intra-domain or inter-domain sources in order to engage in analogy making for solving the design problem. [33]

Lectures for "just in time" concepts were given to complete student's knowledge or "expertise" about patterns and frameworks, and analogies.

Another aspect of design behavior thought to be important and difficult to master by students is the generation and consideration of alternative solutions. Students tend to focus on one design and tried to make it work. The "What's the Principle?" CAT helps them analyze the interrelations and connections of the complex system, and generated alternatives. In our experiences, at this time, students had accepted peer-reviews, expert modeling and writing as tools for support and confirm facts and ideas. Students are becoming aware of the need of help or information.

Once students have conceived alternative solutions to the design problem, they are applying their technical knowledge to the proposed solutions and using the results to decide which solution to carry out. They are validating system goals, constrains, and connections, and interrelations. They are documenting the solution using the "Documented Problem Solutions" CAT. Then, we are dividing up the class into programming teams to build the prototype and framework APIs.

C. *Middleware design and implementation*

Experiments and programming exercises in the lab are introduced to check and exhibit distributed systems complex behavior against student's expectations and to show students how a population of asynchronously executing processes without central top-down control can exhibit unexpected or "emergent" behavior at the system level. Paradigms and protocol design approaches are introduced with examples.

Students are following the same set of CATs, with peer-review and question prompts. Expert modeling occurs when students are seeking for the opinion of an expert or cannot reach consensus about the solution.

Office= Out-of-Class Office hours/week for mentoring *Extra= Extra Meetings (Additional Out-of-Class Meetings)*

VI. RESULTS AND DISCUSSION

We use a standards-based grading system where each student, as shown in Table I must meet a determinate level of achievement. Each step is evaluated in points from 1 to 10 using a grading rubric. These are formative assessment earned points for ongoing diagnostics and feedback. In the five terms, the points' statistics are similar, meaning that student's achievement level remained reasonably high. The difference appears in the mentoring office hours and additional (extra) meetings we held with the students/teams to reach this achievement level. In 2008, we use 78 in-person office hours in 15 weeks for mentoring of only 8 frustrated students claiming for hints and clues to understand where and why they failed.

As described by Carver et al. [34] "one of the frustrating things about learning software engineering for students is that there is no definitive right answer to many questions, against which their own answers can be compared. Mistake time estimates cause a great deal of frustration and even anger on the part of students, who might feel less intelligent for not being able to get the task done in an arbitrarily short period. If subjects become frustrated, the data provided may be of lower quality because subjects may either quit before completing the task. If students learn a new process and it requires more effort than the estimate they are given, they may become disillusioned with the benefits of software process and see only that process is time-consuming and provides little benefit".

Problems should promote conjecture, argumentation, and peer criticism, by lending themselves to multiple interpretations or solutions, sometimes depending on which of a variety of conflicting perspectives students take on. Students need to work out the problems together and have an authentic need to ask each other to justify their points of view [31]. Open-ended learning environments with embedded scaffolds designed to support the learning and inquiry processes meet the goal to develop student's expertise reducing frustration.

Supporting our learning environment with scaffoldings and introducing students in CBR reduced the used office hours to 24 hours in 12 weeks for 20 students. Office hours were used for team conflict mediation, for helping students to reach agreement about the use of some tool or diagram.

Using a Competency-Based Instructional Approach in Thermodynamics

Brent Nelson
Department of Mechanical Engineering
Northern Arizona University
Flagstaff, AZ.
brent.nelson@nau.edu

***Abstract*— Many engineering classes are highly sequential, causing students that fail to grasp initial topics to struggle as courses progress. Despite instructor exhortations to master fundamental subjects, students often continue to struggle instead of investing the time to review. Because students do not proactively re-learn initial content, a competency-based approach was implemented in a highly sequential thermodynamics course. In the approach, students scoring below 80% on the first exam were required to pass an online review quiz in order to take subsequent exams. Only 3 out of 135 students were unable to take the second exam, but all were able to pass by the time of the third exam. Significant increases (p<0.01) were achieved in both the average course grade and average grade on the third (final) exam as compared to the previous offering of the course, with the average grade on the final exam rising from 66.5% to 74.0% and the overall course grade rising from 76.2% to 83.2%. The competency-based structure forced students to review fundamental material that is necessary both later within a course and in subsequent courses, and seems to particularly benefit the poorer performing students. This may have impacts on student retention and persistence.**

Keywords—competency; student success; persistence

I. Introduction

For many topics within science and engineering, later content builds heavily on initial content. Prerequisite courses abound, with various mathematics classes being necessary for many engineering courses, physics being necessary for statics, statics being necessary for mechanics, thermodynamics being necessary for heat transfer, and so on. Additionally, courses themselves are often sequential, with later content building heavily on content introduced at the beginning of the course.

Students that fail to grasp initial topics necessarily struggle with later topics. In the context of the progression of multiple courses, falling behind can negatively impact student progression and persistence, as failure to master prerequisite courses increases the difficulty of subsequent courses [1-3]. Additionally, students that fail to master initial content within a single course will continue to struggle as more complexity is added to the analysis. In statics, a student struggling to draw correct force body diagrams will have a difficult time calculating moments and reaction forces [4]. In calculus, a student that struggles with basic derivatives will have a difficult time using the chain rule to take more complex derivatives. This struggle with basic steps has multiple ramifications. Homework assignments take longer when what should be 'easy' steps continue to be a challenge, which may increase the incidence of incomplete homework assignments or copying. Moreover, students often fail to see the path to the solution when they lack the mastery of the steps necessary to get there.

While an instructor can emphasize the importance of the initial content to students, students frequently do not heed the advice given them. Additionally, an instructor can discuss the importance of the initial content to students that struggle on early exams, but few students will actually resolve the misconceptions and lack of understanding that caused their poor performance. Because various factors compete for students' time, they expend their effort on the tasks they deem most valuable. Since any efforts made by the student to review the initial content are typically not graded, getting students to see the value of reviewing previous material is difficult. Thus, students often do not recover from struggles with initial course content and their struggles perpetuate.

Engineering thermodynamics is one subject for which content is particularly sequential, with every topic building directly on previous topics. Students that fall behind consistently do nothing to re-learn initial content, and as a result they often continue to fail for the rest of the semester. Realizing that students would not proactively put in the effort to re-learn initial content, a competency-based approach was implemented in the Spring 2012 offering of Thermodynamics I at our institution. This paper describes the effect of the approach on student performance.

II. Methods

A. Thermodynamics I Course Content and Sequence

At our institution, the Thermodynamics I course begins with an overview of how energy is transferred and transformed in engineering systems. Because energy is often transferred into and out of fluids, the course then discusses the typical

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

phases of matter (solid, liquid, vapor, ideal gas), and how phase is affected by energy transfers. In particular, students learn to use tables and equations to relate the energy of a substance to other properties like temperature and pressure. After students learn how to relate substance properties to each other, they then learn to perform energy balances, applying the first law of thermodynamics. Energy balances are used to relate energy changes within a substance to energy transfers to and from the substance. Without being able to relate substance properties to each other, students will be unable to perform energy balances.

The course then discusses the second law of thermodynamics, which has various formulations but basically states that things tend towards disorder. One implication of the second law is that the property entropy, which is a measure of disorder, can be balanced and used to determine the energy of a substance or energy transfers, which can then be used in conjunction with energy balances to determine energy transfers and substance properties. Without being able to utilize energy balances, the information from the entropy balance is not useful.

Throughout the course, each step is foundationally important to the later content. Students must master early content in order to be able to succeed later in the course.

B. *Course Structure*

The competency-based approach described in this paper was implemented in the spring 2012 offering of Thermodynamics I. The course was a typical lecture-based course, with frequent in-class discussions and exercises, in addition to homework assignments every 1-2 weeks. The course had two sections, with enrollments of 60 and 75. Homework assignments constituted 16% of the course grade, and three exams constituted 28% each. The first exam covered only the use and evaluation of properties, the second exam covered energy balances, and the third exam covered energy balances together with entropy balances, reflecting the three major foundational topics of the course. Because each concept built so heavily on previous content, a progressive grading scheme was used for the exams. The overall exam grade was set to be no lower than the grade on the third (final) exam, and the first exam was dropped if students improved on the second exam. This grading scheme was justified because a student necessarily would have had to master and utilize the content from the first two exams in order to be able to complete the third. A benefit of this scheme is that students that received low grades on early exams could still have hope for improving their course grade rather than being anchored by poor initial performance.

C. *Competency-Based Approach*

Because students often did not review initial content and instead continued to fail, the system implemented in spring 2012 actively forced students to re-learn initial content that they failed to master and demonstrate their competence before moving on. Since the use of properties was required for everything else in the class, students were required to demonstrate competence in evaluating substance properties. Students that achieved above 80% on the first exam were exempted from any further review. Those that scored below 80% on the first exam had to either take an oral exam with the instructor during office hours or retake randomized online makeup quizzes until they achieved above 80%, and they were not allowed to take any subsequent exams until they had done so. The grading policy for this course was a key element enabling this system, since a student could take a zero on the second midterm and still have their exam grade determined by the final exam.

Only one online quiz was made available each week. Students were allowed a single attempt at each quiz in order to encourage them to actually review the material rather than repetitively take the quizzes while blindly hoping for a better outcome. The online quizzes were implemented using the randomized question bank feature of Blackboard Learn®, an online interface. In this feature, a pool of questions can be generated from which the online quiz draws randomly. Thus, a single bank of questions could be made while still ensuring that students had different quizzes each week, and different quizzes from each other.

While the content for the second midterm (energy balances) was also a foundational skill for the class, the competency-based approach was only implemented for property evaluation so that we could do an initial trial on a fundamentally important topic that was easy to implement in an online quiz format.

D. *Data Analysis*

Student performance data were evaluated and compared to the previous offering of the course with the same instructor, which occurred during spring 2011. The instructor was experienced in teaching the course, and the student course evaluations were highly positive and comparable both semesters. A t-test was used to compare data between the two semesters. Only the third (final) exam and course grade were used in the comparison because a slight reorganization in the course sequence caused the first two exams to cover different ranges of topics between the two semesters. The final exams were not identical but contained similar problem types. While the scores for the final exam in Fig. 1 exhibit two peaks, the bimodality coefficient is 0.40, below the value of 0.55 that is indicative of bimodality. Thus, the data is not considered bimodal, and the t-test is valid.

III. Results & Discussion

In terms of demonstrated competence with property evaluation, only 3 students failed to achieve above 80% on the online quizzes before the second midterm, but all three were able to achieve it by the time of the third exam. In contrast, approximately 15-20% of students were still unable to evaluate properties on the third exam during the previous offering of the course.

A significant improvement ($p<0.01$) in performance was seen in the average course grade and average grade on the third (final) exam upon implementation of the competency-based structure as compared to the previous offering. Table 1 shows the average exam and course grades for the two semesters. The average grade on the final exam rose from 66.5% to

TABLE I. AVERAGE EXAM AND COURSE GRADES

	Exam3	Course Grade
Spring 2011	66.5%	76.2%
Spring 2012	74.0%	83.2%

74.0%, while the overall course grade rose from 76.2% to 83.2%.

The normalized grade distributions for the third exam and course grade are shown in Fig. 1. During spring 2011, the grades on the final exam exhibit two peaks, with one of the peaks occurring in the 'F' range and the other in the 'B' range, as Fig. 1 shows. This prevalence of students failing the final exam is indicative of the number of students that were still struggling to grasp fundamental skills required throughout the course. During spring 2012, this occurrence disappeared, but the peak remained in the 'B' range. This implies that the competency-based approach was particularly effective in helping students that were struggling to grasp basic concepts, and an improved performance resulted especially among the worse students. The overall course grades for both semesters were close to a normal distribution, however a significant shift towards higher scores was seen during spring 2012 when the competency-based approach was implemented.

An additional benefit of the competency-based approach is that students seemed to gain a greater appreciation for the importance of building proficiency with basic skills. One student in the end-of-semester course evaluation commented "*I felt that the makeup exams were very useful in helping me understand how to use the property tables. I think the idea of having to get above an 80% on the test is an effective way of making students learn the material and not just try to get by*." Another student commenting on the retakes said *"This forces people to confront their struggles with initial material which is critical to success in the rest of the course."* No students complained about the extra workload of re-taking online exams, as they seemed to grasp the importance of the skills they were practicing.

In the current offering of the course (spring 2013), the minimum score to exempt students from retakes was raised to 85%. Additionally, the same exam re-take requirement was implemented for the second exam in addition to the first exam.

The competency-based approach seems to result in improved performance, particularly for those students that would otherwise perform poorly due to a failure to grasp the fundamental concepts required for the remainder of the course. While the sequential nature of thermodynamics makes it particularly well-suited to this type of approach, a number of analogous approaches could be implemented in other classes. Rather than giving tests and assignments where students merely receive a grade, setting minimum scores and requiring

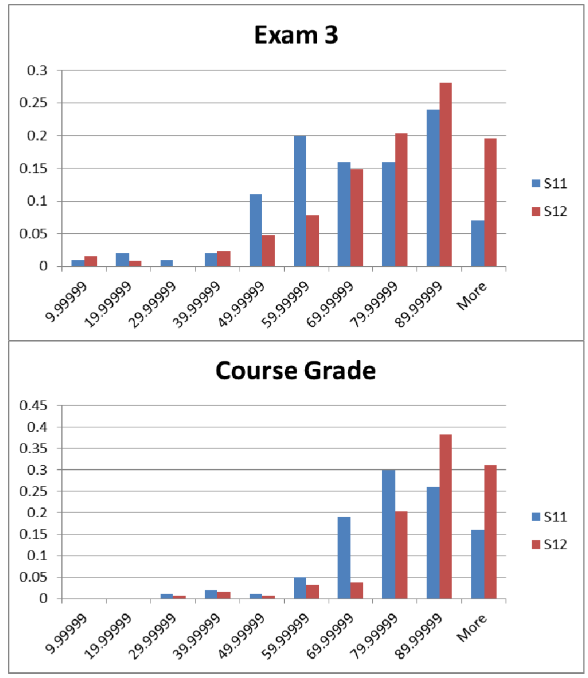

Fig. 1. Normalized grade distributions for the third exam (top) and overall course grade (bottom).

students to redo the assignments until they are proficient will enforce competence. While the repetition creates a higher workload for instructors or graders, online resources such as randomized quizzes that are automatically graded may enable such approaches to be more widely used.

Moving to a competency-based course structure forces students to review fundamental material that is necessary both later within a course and in subsequent courses. Such a format offers potential to improve student retention and student performance, aiding those that would otherwise allow themselves to continuously struggle through class after class, always remaining a step behind. Future work includes evaluating the impact of such an approach on performance in subsequent classes rather than just within a single class and expanding the approach to other engineering courses.

***Abstract*—Literature suggests that note-taking activity helps students in their learning process and successfully increases performance. Previous studies also have suggested that collaborative learning facilitates students to learn from different views of interpreting information. Although many studies have revealed positive correlations between collaborative learning and student performance, few studies have been conducted to investigate peer-review activity, students' performance, and self-regulated learning skills while engaged in shared note-taking using electronic enhanced guided notes. The main research question of the current study was to investigate how students' review frequency of peers' enhanced guided notes and learning performance reflected on their self-regulated learning skills. With regards to this question, we specifically explored differences among students according to their peer-review activity and performance and how the differences reflected on their self-regulated learning skills. Our findings revealed four groups of students based on those differentiation factors. Data analysis showed that while sixty percent of participants were willing to review their peers' enhanced guided notes regularly, sixty-eight percent of participants performed very well on the exams. Results also suggest that willingness to review peers' guided notes positively correlated with planning and cognitive strategies. Implications of the use of shared note-taking in an engineering classroom will be discussed.**

Keywords—electric circuit concepts; enhanced guided notes; self-regulated learning; shared note-taking

I. INTRODUCTION

Research suggests that students learn best when they take an active role in learning through discussion, practicing, games, and applying concepts and ideas (e.g., [1, 2]); however, these activities are often impractical to conduct, particularly in large classes. A recent study involving engineering students found that active learners achieved greater levels of learning and motivation than did their passive peers [3]. The use of guided notes can facilitate active learning in a more practical way. Guided notes are prepared by instructors and contain incomplete text, diagrams, and graphs. Students must listen to their instructor and think critically in order to answer the prompted questions and fill in missing parts of the information. The benefits of note-taking activities include development of higher-order thinking skills [4, 5] and improvement of an individual's concentration [6]. Literature also suggests that note-taking activities help students in their learning process and successfully increases learning achievement.

While the idea of note-taking is not new, studies regarding the use of an electronic or a handheld device to support note-taking is still in the preliminary phase. The rapid development of hardware, software, and the internet has impacted the innovation of technology and computer use in the classroom. Design of instructions has been adjusted by applying technology-enhanced applications for teaching and learning. Previous studies also suggested that collaborative learning facilitates students to learn from different views of interpreting information. Although many studies have revealed a positive correlation between collaborative learning and student performance, few have been conducted to investigate students' profiles on shared note-taking activity and learning performance reflected in their self-regulated learning skills. The main objective of this study was to investigate how students' learning performance and review frequency of peers' guided notes reflected on self-regulated learning skills while using electronic enhanced guided notes.

II. LITERATURE REVIEW

A. Shared Note-Taking Using Electronic Enhanced Guided Notes

Standard guided notes, which are also called seminotes or skeleton-notes, have been used in undergraduate teaching. Unlike the guided notes introduced in many studies (e.g., [5-7]), the enhanced-guided notes (EGN) used in this study include questions that prompt students to assess their self-regulated learning (SRL) skills (see [8]). This component is not present in the standard guided notes. The questions appear throughout the guided notes, including the introduction of each topic, elaboration of the theoretical concepts, and during

This material is based upon work supported by the National Science Foundation (NSF) under Grant No. 0942942. Any opinions, findings, and conclusions or recommendations expressed in this materials are those of the author(s) and do not necessarily reflect the views of the NSF.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

problem solving. The EGN can be used as a tool to encourage students to plan appropriate strategies to solve problems, monitor their understanding, and adjust strategies when difficulties occur.

The electronic EGN is another format of our guided notes to facilitate students who have been using electronic pads such as an iPad or Android tablet. A network attached storage (NAS)-based online system was set up to enable students to complete and edit their guide notes and to facilitate note-sharing submission (see Figure 1; [9]). Student completion and editing of the EGN were performed on PDF-formatted files using an iPad 2TM device. Students could take as many notes as they liked on the EGN provided. When homework was due, the students submitted their group's copy of the EGN through a repository server.

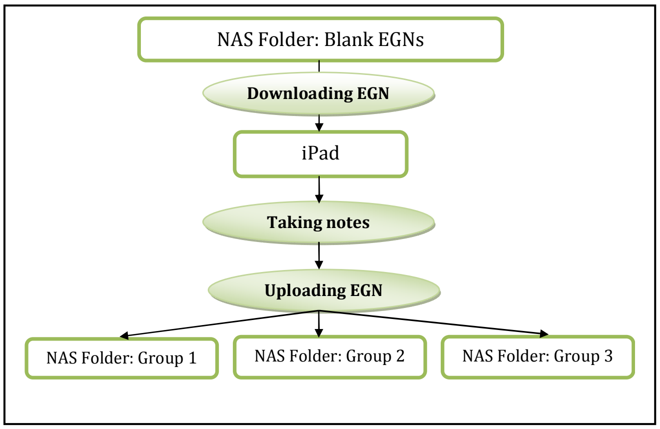

Fig. 1. System architecture of electronic-based EGN for shared note-taking using Network Attached Storage (NAS) and iPad.

The electronic shared note-taking was used as an approach to implement our enhanced guided notes in this study for three reasons: First, for each topic, there are aspects of the course materials that are not covered during the lecture. The materials may be part of the course materials, but insufficient time is available for detailed coverage during lectures. The second reason is to help students to become familiar with different views and clarify information with their peers. Collaborative learning is particularly important during several hours of study per course hour that is expected of engineering students. When the faculty is unavailable, access to information occurs through the shared note-taking activity. Third, electronic shared note-taking encourages new learning experiences for students. The students can take advantage of information and communication technology for learning.

B. Self-Regulated Learning and Student Performance

According to Zimmerman self-regulated learners are "metacognitively, motivationally, and behaviorally active participants in their own learning process" [10, p. 329]. While many theoretical perspectives of self-regulated learning (SRL) have been offered [11-14], this study chose Butler and Cartier's model of self-regulation. The model characterizes SRL as a complex, dynamic, and situated learning process [11, 15-17]. The model consists of eight features that interact with each other: layers of context, what individuals bring, mediating variables, task interpretation, personal objectives, SRL processes, cognitive strategies, and performance criteria. The current study will focus on three main features including task interpretation, SRL processes, and cognitive strategies.

Task interpretation is the heart of the SRL model insofar as it shapes key dynamic and recursive self-regulating processes. Students' interpretation of task demands is a key determinant of the goals set while learning, the strategies selected to achieve those goals, and the criteria used to self-assess and evaluate outcomes. Students manage their engagement in academic work by using a variety of SRL processes: planning, monitoring, and adjusting approaches (or regulating) to learning. Students prepare their learning activity, select strategies for task completion, self-monitor progress, and adjust goals, plans, or strategies based upon self-perceptions of progress or feedback and performance. These strategies are iterative and dynamic endeavors. Furthermore, the term cognitive strategies refers to students' cognitive activities employed as they engage in learning that is planned, monitored, and adjusted through self-regulating strategies.

Previous studies suggested that self-regulated learning strategies benefit students in their learning activities (e.g., [18, 19]). Zimmerman and Pons found that consistency in employing self-regulated learning strategies is highly correlated with student achievement [20]. When students engage in learning concepts or solving problems, self-regulated learning skills emerge. Schoenfeld argued that a lack of success in problem solving may result from the absence of assessment and strategy decisions [21]. Thus, our goal in this study was to investigate students' task interpretation, cognitive strategies, and self-regulated learning strategies and also their performance while learning using electronic-based shared note-taking.

III. STUDY

Thirty engineering students enrolled in the Fundamental Electronics for Engineers course participated in this study. The course covered the study and application of direct DC/AC and digital concepts including circuit fundamentals, theorems, laws, analysis, components, digital design fundamentals, and combinational circuits design, equipment, and measuring devices. Students worked in groups of three during the spring 2012 semester to complete the EGN using an iPad 2. Six student-completed EGN, from EGN #6 to #11, were collected to be evaluated. The use of these enhanced guided notes was intended to replace the one-way communication that was typical of class meetings. Students were asked to fill in the blank spaces found on the pages. The enhanced guided notes prompted students with what/why/how questions regarding the material covered to exercise their SRL skills.

A self-regulated learning survey instrument developed using Butler and Cartier's SRL model was used to capture students' task interpretation, SRL processes, and cognitive strategies. The SRL survey was adapted from the Inquiry Learning Questionnaire (ILQ) by Butler and Cartier based on their theoretical model [15-17]. Students were asked to rate themselves on a 4-point Likert scale (1 = *almost never*, 2 = *sometimes*, 3 = *often*, 4 = *almost always*). Five subscales were developed to capture students' SRL skills at end of semester. The subscales were task interpretation, planning, monitoring, regulating, and cognitive strategies. Subscales of the questionnaire had Cronbach's Alpha scores ranging from .637 to .870 (see Table I for samples of the SRL questionnaire items).

The cluster analysis technique was used to investigate differences among the participants based on their learning performance and review activities on peers' EGN. We evaluated students' learning performance in two regular and final exams. Review activities on the EGN were counted from a system log on a repository server. A hierarchical cluster analysis using Ward's method was used in the cluster analysis to find relatively homogeneous clusters based on measured parameters. Three phases of cluster analysis were conducted to come up with student groups. Phase 1 was conducted by running the cluster analysis using learning performance data, then review frequency on peer's EGN data. Phase 2 was the opposite, running the cluster analysis using review frequency on peers' EGN and learning performance data. Phase 3 was conducted by comparing the results from Phases 1 and 2, and excluded unmatched data. Five sets of data were deleted as a result of this process.

TABLE I: SRL FEATURES AND EXAMPLES

Features	Examples
Task Interpretation (*TI*)	• When I have to learn and solve math, science, or engineering problems involving new concepts, *I find important details or facts (e.g., symbols, units)*.
SRL Processes: *Planning Strategies* (*PS*)	• Before I begin the activity of learning and solving math, science, or engineering problems involving new concepts, *I start by choosing a method for completing the problems*.
SRL Processes: *Monitoring Strategies* (*Mon*)	• When learning and solving math, science, or engineering problems involving new concepts, *I check whether I can describe the main topic of the subject*.
SRL Processes: *Regulating Strategies* (*Reg*)	• When I have difficulties learning and solving math, science, or engineering problems involving new concepts, *I check to make sure I have completed everything required for the activity*.
Cognitive Strategies (*CS*)	• While I am learning and solving math, science, or engineering problems involving new concepts, *I pay attention to underlined or bolded words in learning resources, if there are any*.

Furthermore, nonparametric statistical analyses such as Mann-Whitney and Wilcoxon tests were used to analyze students' learning performance, peers' review activities, self-regulated learning skills, and supporting data from a system log on a repository server. Spearman tests were also carried out to investigate correlation scores between students' performance, review frequency, and self-regulated learning skills.

IV. FINDINGS

A. *Differences among Students According to Review Frequency of Peers' Enhanced Guided Notes (EGN) and Learning Performance*

Our findings revealed four groups of students named as Group 1 (high performance and review), 2 (high performance and low review), 3 (low performance and high review), and 4 (low performance and review). According our data analysis, Group 1 included students who reviewed their peers' EGN at least once per EGN and performed very well on their exams. Group 2 included students who reviewed their peers' very rarely and also had very high performance. Characteristic of Group 3 was students who reviewed their peers' EGN at least two times per EGN, but they did not perform well on their exams. Last, students who almost never reviewed their peers' EGN and had low performance on their exams were categorized into Group 4 (see Table II).

TABLE II: MEAN DIFFERENCES OF REVIEW FREQUENCY ON PEERS' ENHANCED GUIDED NOTES AND PERFORMANCE

Groups	Average Review per EGN	Average Performance
1 (*n* = 11)	9.91/6 = 1.65	91.64
2 (*n* = 6)	2/6 = 0.33	92.69
3 (*n* = 4)	15.75/6 = 2.63	69.54
4 (*n* = 4)	1/6 = 0.17	74.37

As shown on Table II, a majority of the participants were enthusiastic to participate in the shared note-taking activity. The system log on our repository server showed that more than half of the participants (15 students or 60 percent) frequently reviewed their peers' guided notes and only 40 percent of the students very rarely reviewed their peers' EGN. Furthermore, our analysis on students' learning performance in two regular and final exams showed that, on average, 17 students (68 percent) had very good learning performance (see Groups 1 and 2). We further evaluated students' learning performance of the four groups as we found before (see Figure 2). The findings revealed that, despite the increasing level of difficulty of the learning contents, Groups 1 and 2 showed a high performance and significant increase of their exam scores, from the first to second regular exams ($p < .05$). In contrast, no significant improvement was found for Groups 3 and 4 (see Figure 2 and Table III).

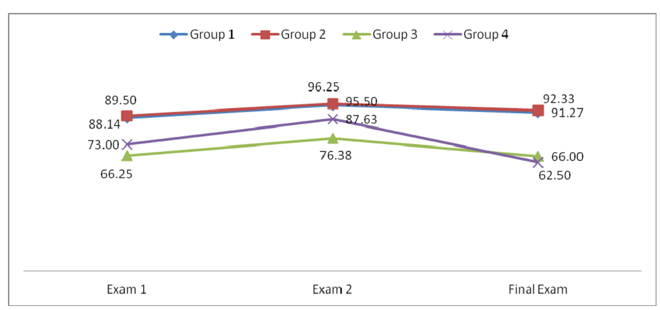

Fig. 2. Distribution of exam scores of Group 1 (n = 11), Group 2 (n = 6), Group 3 (n = 4), and Group 4 (n = 4).

TABLE III: SIGNIFICANT DIFFERENCES BETWEEN EXAMS SCORES

Groups	Exams 1-2	Exam 2- Final Exam
	***Z* (*Sig.*)**	***Z* (*Sig.*)**
1 (n = 11)	-1.852 (.032)**	-1.339 (.095)
2 (n = 6)	-1.890 (.029)**	-1.014 (.310)
3 (n = 4)	-1.604 (.054)	-.730 (.433)
4 (n = 4)	-1.604 (.054)	-1.461 (.072)

Note: ** Significant at $p < .05$ (1-tailed).

Furthermore, a series of Mann-Whitney tests suggested that Group 1 outperformed Group 3 on all exams ($p < .01$). Group 1 also outperformed Group 4 on the first exam ($Z = -2.070$, $p < .05$) and final exam ($Z = -2.866$, $p < .01$). The tests also revealed that Group 2 outperformed Group 3 on the first exam ($Z = -2.412$, $p < .01$), second exam ($Z = -2.096$, $p < .05$), and final exam ($Z = -2.574$, $p < .01$). Furthermore, Group 2 outperformed Group 4 on the first exam ($Z = -2.606$, $p < .01$) and final exam ($Z = -2.566$, $p < .01$; see Table IV).

TABLE IV: DESCRIPTIVE STATISTICS OF PERFORMANCE

Groups	Exam 1	Exam 2	Final Exam
	***M* (*SD*)**	***M* (*SD*)**	***M* (*SD*)**
1 (n = 11)	88.14 (10.89)	95.50 (5.32)	91.27 (8.06)
2 (n = 6)	89.50 (6.78)	96.25 (3.39)	92.33 (3.88)
3 (n = 4)	66.25 (10.71)	76.38 (14.87)	66.00 (11.66)
4 (n = 4)	73.00 (6.36)	87.63 (11.25)	62.50 (10.63)

B. *Self-Regulated Learning Skills of the Groups of Students*

Data from self-regulated learning (SRL) questionnaires were analyzed to investigate students' SRL skills during the semester. On the previous findings, we reported four groups of students according to their performance and review frequency of their peers' EGN. The mean value of each SRL skill was used to describe students' SRL profile that belonged to those groups. We were interested in understanding whether the groups had different levels of SRL skills at the end of semester. Differences between groups were interpreted based on mean differences. Since the number of data sets was very limited, we did not expect to find significant differences on data analysis. Descriptive statistics of groups' task interpretation, cognitive strategies, and SRL processes while learning electric circuit concepts using electronic EGN can be read in Table V below.

TABLE V: DESCRIPTIVE STATISTICS OF SELF-REGULATED LEARNING SKILLS

SRL	Group 1 (*n* = 11)	Group 2 (*n* = 6)	Group 3 (*n* = 4)	Group 4 (*n* = 4)
	***M* (*SD*)**	***M* (*SD*)**	***M* (*SD*)**	***M* (*SD*)**
TI	2.98 (.29)[a]	3.30 (.24)[a,b]	3.15 (.50)	2.95 (.25)[b]
PS	2.66 (.45)	2.29 (.66)	2.81 (.38)[c]	2.25 (.35)[c]
Mon	3.12 (.24)	3.20 (.23)	3.39 (.36)	3.18 (.22)
Reg	2.95 (.49)	3.03 (.29)	3.04 (.44)	3.13 (.16)
CS	3.22 (.32)	3.10 (.44)	3.31 (.41)	3.06 (.13)

Note: (a) Group 2 scored significantly higher than Group 1 on TI ($Z = -2.031$; $p < .05$); (b) Group 2 scored significantly higher than Group 4 on TI ($Z = -1.901$; $p < .05$); (c) Group 3 scored significantly higher than Group 4 on PS ($Z = -1.845$; $p < .05$).

Three interpretations of findings are reported from the data analysis. *First*, students who regularly reviewed their peers' EGN reported higher scores on planning and cognitive strategies compared to other groups who rarely reviewed their peers' guided notes. Related to this finding, students' who performed very well on their exams and regularly reviewed their peers' guided notes (Group 1) reported relatively higher scores on task interpretation, planning and cognitive strategies than students who did not perform well and rarely reviewed their peers' guided notes (Group 4). *Second*, although Group 3 had low performance on their exams, they seemed to benefit from reviewing their peers' EGN as they reported the highest scores on SRL skills compared to the other groups. Group 3 also outperformed Group 4, students who had low performance and did not regularly review their peers' EGN, on planning strategies. *Third*, students who performed well on exams, but did not regularly review their peers' EGN, outperformed Groups 1 and 4 on task interpretation.

Moreover, Spearman tests revealed that performance had a positive relationship with SRL skills, although not significant ($r = .119$, $p = .286$). On the other hand, willingness to review peers' guided notes had significant positive correlations with planning ($r = .557$, $p < .01$) and cognitive strategies ($r = 364$, $p < .05$). These findings were supported by Mann-Whitney tests, that students who regularly reviewed their peers' guided notes reported significantly higher scores on planning strategies than those who did not engage in peer-review activity ($Z = -2.023$, $p < .05$).

Since our SRL questionnaire items captured students learning activities related to conceptual understanding and problem solving, we further investigated artifacts of student learning on a repository server's system log and copy of groups' submitted EGN: uploaded EGN to the repository server; downloaded EGN from the repository server; and completed the EGN. Uploading the guided notes reflected students' awareness of taking notes and sharing with their peers. Downloading EGN reflected students' awareness of learning from their own note-taking or making some revisions. Furthermore, completing the EGN reflected to what degree students' filled in the blanks on their guided notes. Either they completed the notes in class by themselves or after reviewing their peers' EGN. Our findings revealed that Group 1 was outstanding in uploading, downloading, and completing their own EGN. It is also interesting to note that Group 4 was below Group 1 in those activities (see Table VI).

TABLE VI: STUDENT ACTIVITIES WHILE USING THE SIX ENHANCED GUIDED NOTES (EGN #6 TO #11)

Groups	Upload EGN	Download Own EGN	Complete the EGN (%)
	***M* (*SD*)**	***M* (*SD*)**	***M* (*SD*)**
1 (n = 11)	15.91 (4.35)	14.45 (5.96)	86.91 (13.67)
2 (n = 6)	13.17 (5.74)	11.67 (6.02)	79.00 (12.34)
3 (n = 4)	5.75 (5.91)	5.75 (5.91)	52.25 (27.79)
4 (n = 4)	13.25 (4.86)	11.75 (7.59)	83.75 13.40)

V. CONCLUSION AND DISCUSSIONS

The majority of the participants were enthusiastic to participate in shared note-taking activity; our data analysis of the system log found more than half of the participants regularly reviewed their peers' guided notes (60 percent) and only 40 percent rarely reviewed their peers' guided notes. From the standpoint of learning performance, findings revealed that, on average, 68 percent of participants had very good learning performance in two regular and final exams in this context of learning activity. We were also interested in investigating how students' peer-review activity and performance while learning using electronic EGN reflected on their self-regulated learning skills.

In general, we found that shared note-taking activities benefit students in exercising their self-regulated learning skills. Groups 1 and 3 who regularly reviewed their peers' EGN reported higher planning and cognitive strategies than Groups 2 and 4 who very rarely reviewed their peers' guided notes. Spearman tests also revealed a positive correlation between frequency of review of peers' guided notes and SRL skills, in this case planning and cognitive strategies. However, it is interesting to note that although Group 3 regularly reviewed their peers' EGN and reported high scores on SRL skills, they did not perform as well as Group 1 on performance. Our supporting data showed that Group 3 had low frequency on uploading and downloading their own EGN from the repository server. They also scored a low percentage on completing their EGN. Furthermore, although Groups 2 and 4 had relatively low planning and cognitive strategies, their scores on monitoring and regulating strategies were relatively the same as Groups 1 and 3. We suspect that it happened because they regularly uploaded and downloaded their own EGN for review or learning purposes. Also, they completed the content of EGN more than 75 percent of them. These findings suggested that students may achieve greater benefits while using electronic EGN (i.e., gaining high scores on exams) if they do not only review their peers' EGN but also actively complete the EGN, review, and learn from their own EGN. These activities will enhance their skills in understanding concepts and solving problems.

Based on our findings, there are at least two implications from this current study. *First*, educators may need to persistently encourage their students to participate in a collaborative learning setting. Our evaluation found that willingness to review peers' guided notes significantly correlates to planning and cognitive strategies. *Second*, educators may need to encourage their students to regularly review both their peers' and own guided notes. Our findings suggested that students who balance the review of their peers' and own guided notes may achieve higher scores on their exams. They also reported a higher awareness on their self-regulated learning skills.

Since some of our findings were suggestive and this study included a limited number of participants, interpretation should be done with caution, and future work in this area is highly recommended. Three directions are proposed for the improvement of future work. *First*, studies should be conducted with a larger sample size to determine generalizability of the findings. *Second*, future research should compare shared and nonshared note-taking activities using an experimental research design. *Third*, having a better understanding about comparisons between electronic- and paper-based enhanced guided notes would be beneficial.

***Abstract*— Successful group work requires that students transfer relevant prior knowledge to solve problems. This paper establishes a method to assess dynamic knowledge transfer in a group setting through analysis of a group project in a biomechanics class. Transcripts of student-student and student-instructor interactions were coded for evidence of target tools (students identifying relevant problem features), source tools (students activating prior knowledge), answers (stopping points), external inputs (resources and prompts from individuals or the instructor), and workbench explanations (student explanations of connections between source tools and target tools). Knowledge transfer was identified when a source tool and a target tool were coded within a phrase. The frequencies of codes were quantified to provide an overall picture of knowledge transfer for each group member throughout the project. Analysis for one group (a sophomore and junior bioengineering student, and a freshman engineering student) revealed that the junior was the largest contributor in the group, followed by the sophomore and freshman. The group mentioned source tools most frequently, followed by external inputs and target tools. The analysis provided evidence of knowledge transfer within the group through their identification of target tools and use of prior knowledge to explain their observations.**

Keywords— knowledge transfer; group work; prior knowledge

I. Introduction

Studies have proposed advantages to teamwork or group work-based methodologies with university students [1]. From work in group environments, students are able to acquire skills they will need in future jobs such as, leadership, communication, problem-solving, and time management [2–5]. Positive effects have also been shown in terms of students' academic performance, motivation, and attitudes toward learning [6], [7], especially for students who find group activities to be more interesting and engaging compared to traditional teaching [8]. While previous work has examined the effect of group work on cognitive performance and attitudinal changes, there have been few studies seeking to understand how group work influences students' use of prior knowledge when solving problems.

Traditional studies of knowledge transfer, or the application of prior knowledge to novel situations, have examined students in sequestered problem solving environments with students being expected to arrive at an expert's solution [9–16]. Results of these traditional transfer studies often show limited evidence of students' abilities to reach such solutions, resulting in failure to transfer. There has been an emphasis in the literature to move away from traditional transfer methodologies towards student-centered models. Student-centered transfer identifies what prior knowledge students *are* transferring [17–21] rather than *if* students can obtain an expert solution. Educators can use this student-centered approach to understand what students are transferring to problems, and take this information to further develop students' learning [22].

While various research studies have sought to improve group cognitive products and problem solving performance [23], [24] it is still unclear what prior knowledge students are transferring while working in groups [25]. An important factor in team success is students' ability to transfer relevant prior knowledge to aspects of the team project. This study seeks to understand what student interactions with resources, group members, and problem features may facilitate knowledge transfer. In order to address this need, a coding scheme was developed to assess the knowledge that students dynamically transfer into a group problem solving scenario, and what prompts transfer to occur.

II. Theoretical Framework

Two models of transfer were adapted to this work: preparation for future learning [21], and dynamic transfer [26]. Unlike traditional models of transfer, Bransford and Schwartz [21] suggest an alternative perspective in which transfer is thought of as "preparation for future learning" (PFL). PFL shifts the focus from sequestered problem solving to understanding people's ability to learn when surrounded by resources. PFL was used as a basis to design a biomechanics course. This design was selected to encourage students' application of prior knowledge to a self-selected final project. The PFL framework allows us to examine students' learning trajectories and learning goals [21].

Rebello and colleagues [26] utilized the PFL framework to analyze how physics students worked with an instructor to solve physics problems and applied prior knowledge to problem features. Rebello's work uses a student-centered approach that examines what students do transfer into a learning environment, allowing for identification of what connections students have made to prior knowledge and how these connections are used [17–19], [21], [26]. This model for examining transfer is referred to by Rebello as dynamic transfer [26]. Using a dynamic transfer approach allows the researcher to identify mediating factors [26] that might provide insight into interventions to promote productive transfer. This method relies on the identification of similarities by the learner instead of similarities perceived by the researcher [19]. Rebello's coding scheme [26] was adapted for this work to assess the dynamic transfer of knowledge by group members working through a problem.

III. Research Methods

Audio recordings were collected during the final group project of a course entitled "Movement Science in Biomechanics," to determine how students utilized their prior knowledge in relation to the problem features. The students were instructed to use audio recording devices during any group work inside and outside of the classroom. These recordings were then transcribed and coded based on the dynamic transfer theoretical framework previously mentioned.

A. Course Description

Movement Science in Biomechanics was designed for undergraduate engineering students as part of a five-week study abroad program during May and June of 2010 in Brussels, Belgium. This five-week program incorporated six credit hours of instruction divided between a technical elective (Movement Science in Biomechanics) and a humanities course based on the culture and history of Belgium and the surrounding area. Two members of the research team taught the Movement Science in Biomechanics course. Twelve students attended this class for three hours a day, three days a week, usually between the hours of 9:00 am and 4:00 pm.

Based on elements of the PFL theoretical framework [21], this course applied principles and concepts of biomechanics, including statics, dynamics, and physics, to human motion analysis. Students were expected to utilize various bioinstrumentation tools to collect human motion and loading data, and apply biomechanics concepts to quantify and characterize these motions and loads. This active learning course was designed to give students the freedom to apply their prior knowledge, and make connections to new material concerning movement science and biomechanics. Throughout the course, students constructed and executed experimental designs based on conceptual information learned in class through problem-based scenarios. Students designed their final project around a research question developed within groups and approved by the instructor to synthesize learning objectives in the syllabus. These learning objectives included:

- Characterize the centers of mass and ranges of motion for the human body segments and their limitations in certain pathologies.
- Determine displacement, velocity, and accelerations from experimental measurements of human motion.
- Compute net forces, moments, power, and energy on joints based on reaction force measurements.
- Relate human motion to muscle recruitment using electromyography (EMG).
- Formulate design objectives and design experiments to measure and calculate different aspects of human motion.
- Evaluate experimental results and apply to current human motion pathologies.
- Defend conclusions in discussion based on experimental results and applicable human motion theories/principles.
- Develop a presentation culminating human motion principles learned during the class and apply to a current bioengineering issue.

B. Population of Students

For the purpose of anonymity, pseudonyms were used for all of the students in this study. Twelve students from Clemson University participated in Movement Science in Biomechanics (5 females and 7 males). Within the class, the majors included: 9 bioengineering students, 1 mechanical engineering student, 1 chemical engineering student and 1 general engineering student. Analysis of one of the four groups ("Frisbee group") is presented in this paper, whose members included Frank (a junior student who had completed two semesters of physics and statics, and two years in bioengineering), Andy (a sophomore student who had completed two semesters of physics, one semester of statics, and one year in bioengineering,) and Nancy (a freshman student who had completed one semester of physics and one year of a general engineering program). Frank was also on an Ultimate Frisbee team. This group compared kinematic and muscle activity parameters for a backhand, forehand flick, and overhead "huck" Frisbee throw. Data for wrist and elbow motion were collected via EMG and electro-goniometry.

C. Coding Scheme

Audio transcripts were coded and analyzed using R Qualitative Data Analysis (RQDA), a qualitative data analysis software program [27]. A codebook was established and constant comparative analysis was used to ensure consistent coding. Reliability of the knowledge transfer coding scheme was established by two researchers independently coding and comparing representative samples of audio transcripts. Agreement was considered when codes were identified by both raters within the same phrase. Inter-rater reliability was found to be 81% for this study, within acceptable qualitative research limits [28].

In this work, problem features identified by students were coded as target tools (Tt), while prior knowledge was coded as source tools (St). Connections between source tools and target tools are identified as instances of transfer, when occurring in the same phrase. Source tools are activated by students to make sense of the new problem scenario [26], [29], [30]. As seen in Fig. 1, students may not be able to independently make connections between source tools and target tools preventing them from moving forward when facing a problem, thus arriving at a stopping point. They may then seek *external inputs (Ei)* from another group member or the instructor, who can point out relevant target tools and/or source tools to help students transfer, or make appropriate connections between prior knowledge and problem features (prompts). These interactions are important to understand how students utilize external resources when they are unable to transfer.

Student explanations of connections between source tools and target tools are coded as a *workbench (W)*. This workbench explanation can lead to an *answer (A),* which is defined as a "stopping point in the reasoning process" [26]. Answers do not necessarily require a workbench explanation, and can take the form of a statement or question. Even stating "I don't know" would mark a stopping point in the reasoning process and could prompt the student to seek external input to move forward. Students may find themselves at a stopping point at any time while working through a problem.

Additionally, Redish observes that students can explain their work in common sense terms based on their "fabricated" experiences, in contrast to "propagated" knowledge that learned from an authoritative source such as an instructor, textbook or a prior class [31]. When evidence was present in the data, source tools were coded either as "fabricated" or "propagated" [32]. Certain source tools utilized both "fabricated" knowledge and "propagated," and were co-coded as such.

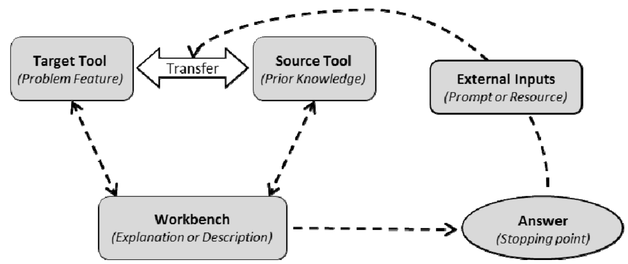

Fig. 1. Elements of the coding scheme showing how external inputs can prompt transfer through activation of target tools and/or source tools, leading to a workbench explanation and answer.

IV. Results

A. Quantification of codes

Although this case study is qualitative in nature, quantification of the codes within groups provides an overall idea of the contributions made by each member during their final project and the relative frequency at which the codes appeared in the group's transcript. Instances of codes for the Frisbee group are shown in Fig. 2.

It is evident that Frank is the largest contributor in the group across all categories, with Nancy and Andy evenly sharing the remainder of the contributions. The team mentioned source tools the most frequently, followed by target tools and external input prompts. This would indicate that they were discussing more of their prior knowledge than particular problem features during their work on their final project. This scenario would play out if they were discussing a particular target tool, such as the wrist motion during a particular Frisbee throw, and determining the appropriate source tools that would adequately describe that motion, for example angular displacement, velocity, or acceleration.

As can be expected during group work, group members prompt each other to notice target tools or use a particular source tool as part of a workbench explanation. For this group, the members had a fairly even distribution of prompts although Frank had the most prompts and the instructor had the least. Out of all of the coding categories, the instructor had the most contributions coded as external input-prompts followed by target tools and source tools. This would indicate that the instructor pointed out source tools or target tools to the group and prompted them less frequently with workbench explanations or answers. Also of note is that source tools were coded more often as "propagated" (coming from an authoritative source such as a textbook from another course). With that said, the group also had 125 instances of source tools coded as "fabricated" from their experiences during the class or outside of class. Specific instances are expanded upon in the qualitative analysis.

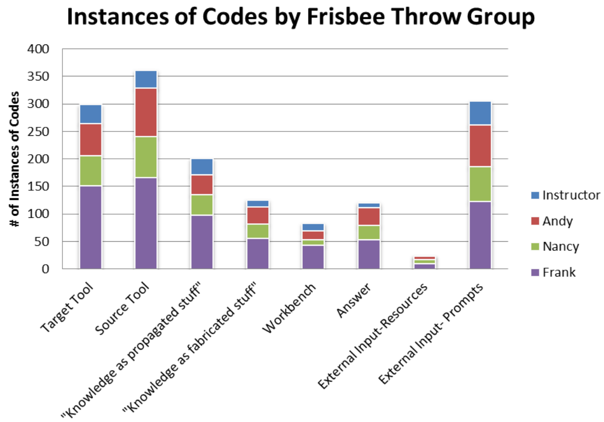

Fig. 2. Contribution of group members and instructor for the Frisbee throw group, demonstrated through instances of codes.

B. *Qualitative results*

Qualitative analysis of the transcripts was used to get a more comprehensive view of how the students interacted with each other and their instructor. From the transcripts, it was evident that the students typically identified several problem features (target tools) and then would discuss how their prior knowledge (source tools) explained what was happening. The students debated over source tools that would be appropriate to explain the motion of the wrist while throwing a Frisbee. Using data from electronic goniometers, students generated graphs to represent wrist motion in different planes (flexion-extension and radial-ulnar). Students used the generated graphs as target tools to grapple with and understand this wrist motion. Concepts of radial-ulnar and flexion-extension motion are "propagated" source tools because they were learned in class lectures. In contrast, descriptions of motion based on previous Frisbee throwing experiences are "fabricated" source tools, for example a forehand flick and "huck" (overhand throw).

During their data analysis, students began to comprehend that, although the motion of the Frisbee is in one plane, the wrist has two components of motion for the throw to occur. The following excerpt is an example of the students' discussion of what motion is occurring at the wrist during a forehand flick Frisbee throw. Codes noted at the beginning of phrases are represented throughout the entire phrase. Otherwise the codes are denoted immediately following the words of interest. Abbreviations of codes are provided in Table I.

TABLE I. CODE ABBREVIATIONS, USED TO REPRESENT CODES THROUGHOUT THE TRANSCRIPT EXCERPTS

Code Abbreviations	
Code	***Abbreviation***
Source Tool	*St*
Target Tool	*Tt*
Workbench	*W*
Answer	*A*
External Input	*Ei*

Frank: *(Ei,W)* "So the thing is that I think with this one, this is going to sound really weird, but I think the radial ulnar *(St,Tt)* and the flexion extension *(St,Tt)* were on the same plane *(St,Tt)* which I know sounds impossible."

Andy: *(Ei)* "That's impossible."

Frank: *(Ei,W)* "But I think what it is, is the radial ulnar *(St,Tt)*, … you turn your hand *(Tt)* and now it's flexion extension *(St,Tt)*."

Andy: "Ohhh."

Frank: *(Ei,A)* "I think they're in the same plane *(St,Tt)*; they're just not in the same …"

Andy: *(Ei)* "…so you're saying you're starting out radial ulnar *(St)* and then you completely…"

Frank: *(Ei,W)* "…Yeah. Yeah. Because if you look at this right here the peak for the ah, elbow *(St,Tt)* starts happening right here. The peak for the radial ulnar *(St, Tt)* starts happening right here and the peak for the flexion extension *(St,Tt)* happens right there. It's like there's one after another …

(Ei,St) Yeah, but it's like elbow starts, wrist starts and that starts…"

Andy: *(Ei,W)* "…No, no. For this graph *(Tt)* proves you wrong because it's showing that both of them, you're still, you're moving both at the same time *(St)* meaning that…"

Frank: *(Ei,Tt)* "…only for a very short period of time though."

This is an example of complex connections that Andy and Frank make, peeling back layer by layer to identify crucial ties between source tools and target tools. Before they can understand the data (graphs), they are reenacting a slow motion "flick" and what that means in terms of wrist flexion-extension, wrist radial-ulnar and elbow flexion extension motions. They are determining if there is enough significant contribution to include the elbow in their calculations. Frank argues there is definitely extension but Andy argues that because it is not in the same plane, it should not be included. Nancy, a freshman general engineering student, stays more to periphery asking questions, and observing the discussion between Andy and Frank. At a stopping point in their reasoning process, they consult the instructor to gain a better understanding of the connections between the source tools of slow motion reenactment, "propagated" planes of motion and the target tools of the graphical data.

Frank: *(St)* "…calculating velocity *(Ei)* so [instructor], is it possible with *(St,Tt)* the method you've been using with the [electronic goniometers], to calculate tangential velocity? *(A,W)* Is it possible to stay on the flick throw *(St)* to consider the contribution of both flexion extension *(St,Tt)* and radial ulnar *(St,Tt)* because they're not both on the same side – the elbow-wrist plane *(St,Tt)* …. This is the change in the angle *(St,Tt)*. So looking at this you can actually tell that the flexion-extension *(St)* is the yellow *(Tt)*. It's actually contributing because this right here *(Tt)* is …"

Instructor: *(W)*"…and then it's flipping through *(Tt)*. So vector analysis *(St)*… *(Ei,A)* So you're flicking *(St)*. So really your plane *(St,Tt)* is like this, right?"

Andy: *(Ei)* "Yes."

Instructor: *(Ei,St,Tt)* "So which is like you're basically doing some of this and some of this [demonstrates wrist motion]."

Andy: *(Ei,A,W)* "You're doing mostly [demonstrates wrist motion], because it's like a little of both."

Instructor: *(Ei,W)* "So the way you define an omega *(St)*…so call this like an X, Y [axes] *(St)* right? So this is your omega X, this is omega Y and so *(St)*… if you could tilt it you really have some arbitrary omega *(St)*. If you could you would have really just a rotation about the one point, right *(St,Tt)*? So in other words, like I'm doing some of this and I'm doing some of this [demonstrates wrist motion]."

Andy: *(Ei,A,St,Tt)* "And the resultant in that [plane]."

Instructor: *(Ei,A)*"And the resultant *(St)*, right. So basically what I want to do is find the resultant of this *(St,Tt)*."

Andy: *(Ei)* "Okay."

Instructor: *(Ei,A)* "So what I would do is take the two values *(Tt)* and um, you can do a vector sum *(St)* of that."

The instructor provides the missing source tool of "vector analysis" as a way of explaining how two different planes of motion (flexion-extension, radial-ulnar) can contribute to a "resultant". Although these are concepts students have studied in previous courses, such as physics and statics, they were unable to transfer this knowledge to the context of the wrist flicking motion. This is the type of discussion that is important according to the preparation for future learning framework upon which the course design was based [21]. Instruction is designed such that the same concepts are applied in contrasting cases (flick, backhand, overhead throws) so that students can learn to connect the same source tools (prior knowledge) to different target tools (problem features).

V. Discussion and Conclusions

Defining knowledge transfer as the ability to apply prior knowledge to new situations, and achieve a defined answer has led to more evidence of failure than success. This study utilized a revised definition of knowledge transfer that focuses on what knowledge students transfer into a new situation rather than if they transfer knowledge based on a prescribed expert solution. The long-term goal of this research is to understand what student interactions with resources, group members, and problem features may facilitate knowledge transfer in a group setting. To that end, a coding scheme was developed to assess the knowledge that students dynamically transfer into a group problem solving scenario, and what prompts transfer to occur. The coding scheme, based on Rebello's dynamic transfer framework [26], successfully allowed for assessment of individual group members' interactions with each other and external resources. The methodology presented here also allows for the assessment of both prior knowledge activation (source tools) and problem feature (target tool) identification by individual students within the group.

This methodology stands apart from other transfer methodologies in that students guide the instructor through problems forcing the researcher to take an actor-oriented approach [19]. Additionally, we have examined how students prompt each other to solve a problem in a more typical student group setting instead of how an individual solves a problem in a clinical or teaching interview [26].

This study focused on the interactions observed within a single group working on their final project in a biomechanics course. Recordings of the group's meetings were transcribed and coded using the coding scheme presented, identifying source tools, target tools, external inputs, workbench processes, and stopping points.

Quantification of the codes revealed that the group discussed their prior knowledge (source tools) more than they discussed problem features (target tools) or external input prompts. This quantification also showed that group members contributed in different ways. While the quantification of the codes only provided a limited view of the interactions that occurred within the group, it gave a useful overview of the interactions providing a general idea of the group dynamics. It can be assumed that different members of a group would contribute in different ways, and results confirm this assumption. This coding scheme provided evidence of which group members discussed their prior knowledge, mentioned problem features, and/or provided prompts.

As the quantification of codes does not take into account underlying reasoning behind the statements, qualitative analysis was used to gain a more detailed understanding of how student interactions with resources, group members, and problem features may facilitate knowledge transfer. Qualitative analysis revealed that the students often negotiated within their group about how their prior knowledge fit with the problem features they had identified. This analysis also showed that the students consulted their instructor, asking for guidance, when they were unable to move forward in order to gain a piece of knowledge they were missing. The students were able to transfer the information provided by the instructor to the problem statement. This allowed the students to continue working towards an answer. These are important evaluations that inform how a student will contribute to a group and what prior knowledge students activate in each other. As they work through a problem scenario, this analysis provides insight into how students utilize resources in a group environment to get beyond an intermediate stopping point, facilitating knowledge transfer.

VI. Implications for Instruction

From an instructor standpoint, the time to transcribe, code, and analyze each group to understand all the intricacies of these connections of knowledge and use of resources is typically not feasible. But if used as formative assessment, the instructor can evaluate in real time the source tools of the student in relation to the problem features they may be struggling with. Instead of providing assistance at the first opportunity, the instructor can evaluate how the student utilizes resources by their requests for guidance and also determine how their external input contributes to their connections between concepts. Based on this methodology, an rubric could be designed to assess group interaction and connection of knowledge.

Instructors often want feedback on the use of external inputs such as new technology and how it may hamper or enhance instruction. It is important for the instructor to evaluate meaningful interactions with the technology being used by identifying activated source tools and target tools in the problem solving process. As can be seen from the students' use of electronic goniometers, technology can be evaluated based on how it prompts students and instructors use of source and target tools.

Utilizing this methodology allows assessment of how students make connections to new scenarios while working in a group setting. Breaking down these complex interactions into understandable terms and concepts will provide evidence to inform pedagogy in ways that help students make the connections intended by instructors.

***Abstract*— The study reported herein considered three questionnaires available for assessing learning styles, viz., Kolb, Honey-Alonso, and Felder-Soloman. The questionnaires were implemented in a spreadsheet with automated results, and distributed to subjects of both genders, and varying age, and academic background. The aim of the work was to determine which questionnaire, if any, would be preferred by respondents. The respondents were asked to answer all three questionnaires, examine the results and indicate their satisfaction by grading each result, using a scale between 0 and 10. While the results given by each questionnaire do not allow a complete comparison, partial agreement was possible to identify. Answers provided by 52 respondents have been processed, which show that, while there is no statistically significant difference among the preference of respondents regarding the three options, a slight preference for the Felder-Soloman questionnaire is discernible.**

I. INTRODUCTION

Learning style assessment coupled with faculty mentoring has been found to help the development of effective study skills [1].

The use of learning style preferences for developing curricula has been supported in order to create an "effective, contemporary learning environment". The use of a variety of teaching approaches has been recommended to enable learning to occur for all learning styles [2].

Seventy-one apparently different approaches, or learning style models, were analyzed [3] and more than fifty were classified into five families:

- Constitutionally based, i.e., inherent to a person;
- Reflect a person's cognitive structure;
- One component of a personality type;
- Flexible learning preferences;
- Learning approaches instead of styles.

In the present work, it was decided to consider approaches in the "flexible learning preferences" family, since it has been reported [4, 5] that learning styles may change during a person's life.

There are several tools available for the assessment of learning styles, usually in the form of questionnaires. Thus, the work reported herein sought to identify a preferred questionnaire, based on user perception. It is assumed that users are sufficiently aware of their preferred modes of learning in order to be able to judge the assessment results provided by these questionnaires.

II. LITERATURE REVIEW

Kolb [6] observed that the process of learning is different among individuals. The varying psychological structures that govern learning, and their different combinations, allow the creation of unique individual adaptive processes. The author further defines learning based on experience as the process in which knowledge is created through the transformation of experience. One is not merely exposed to an experience, it influences attitudes, desires, and ultimately changes the objective conditions under which experiences are had.

According to Kolb [7] the study of knowledge is based on how individuals learn, assimilate information, solve problems, and finally make decisions. Stemming from this analysis and the experiential learning theory, he created a learning styles inventory (LSI) in order to identify individual learning styles. Experiential learning is conceived as a four stage cycle, composed of:

- Concrete experience (CE) or "feeling": learning through concrete experiences, getting involved. Abilities in this area include good interpersonal relations and sensibility towards personal values of all parties involved;
- Reflective observation (RO) or "observing": learning through observation, seeing, listening, and internalizing;
- Abstract Conceptualization (AC) or "thinking": learning through pondering, use of logic, concepts, theories, principles, and ideas. The systematic planning and consequent action is based on the intellectual comprehension of the given situation;
- Active Experimentation (AE) or "doing": learning by taking action, and making decisions. The strategy is to work with real situations and obtain practical results.

The LSI initially consisted of 9 questions in 1976, then was expanded to 12 in 1985. The questions which make up the inventory present the respondent with four different options each. Each set of four statements must be ranked by the respondent, from 1 to 4, in order of increasing preference.

After the questionnaire is filled, a score is given to the respondent for each learning mode, CE, RO, AC, and AE. Two combination scores are also generated by subtracting the scores for pairs of opposing styles, AC-CE and AE-RO, which indicate the extent to which the individual emphasizes abstractness over concreteness and active experimentation over reflection, respectively.

With these combined scores, a learning style type grid was created by Kolb, and four learning styles defined based on the quadrants results fall under. The four styles are the **diverging**, the **accomodating**, the **assimilating**, and the **converging**. The diverging (reflective) is situated in the first quadrant with low AC-CE and AE-RO. Individuals with this learning style prefer observing, listening to, and sharing ideas. They are skilled in observing situations from different perspectives and organizing a multitude of relations in one explanation. They perceive information through the impression it causes on them, sensorially (CE), and process it in a reflective manner (OR), without the need for actively experiencing it. These are creative and innovative individuals that recognize problems and propose alternatives, in addition to understanding their peers.

The opposite of the diverging is the converging (pragmatic), located in the third quadrant. People with this type of learning style can easily solve problems and make decisions. They use experience to find solutions to practical problems. Information is understood through abstract conceptualization (AC) and processed actively (AE). They tend to converge or make decisions quickly, searching for the correct answer or a crucial piece of information efficiently.

The assimilating (theoretical) is situated in the second quadrant. Individuals with this learning style are more interested in ideas and concepts, than people. They perceive information through intellectual comprehension (AC) and process it reflectively (RO). These learners distinguish themselves by their ability to create theoretical and abstract models, by analyzing, organizing, assimilating, and integrating different pieces of information in a concise and logical manner.

The opposite of this is the accommodator (active), situated in the fourth quadrant, who trusts intuition, and tends to act based on feeling rather than logic. These individuals understand information through concrete experience (CE) and process it actively (AE). They are drawn to new challenges and experiences, learning by practice, executing plans, and adapting to different circumstances.

Honey and Mumford [8] employed the theories proposed by Kolb to develop their own work with the four stage cyclic process of learning. Initially, they developed an instrument targeted towards the business setting, the "Learning Styles Questionnaire".

They propose a learning scheme composed of four phases: the individual realizes experiences while learning, reflects on them, elaborates hypotheses, and applies this learning in other situations. According to them, people's main characteristics can be summarized in four basic learning styles: active, reflective, theoretical, and pragmatic. In each individual, evidence of all styles can be found, yet there is one dominating style.

Individuals of the **active** style are sociable, open minded, enthusiastic about new experiences, constantly involved with others in group projects, usually at the center of activities, interested in challenges as well as solving problems, and, in general, quite impulsive. **Reflective** people observe experiences from different perspectives, using observation and analysis to reach conclusions. They prefer to listen more and act later, being focused on reflection and constructing meaning. Information is registered from their own experience as well as others', and they are more pensive than active. Constituting the **theoretical** style are individuals that tend to establish relations, deduce, and integrate observations from logical and complex theories. They strive for rationality, objectivity, and logic, enjoy analyzing and summarizing, are uncomfortable with subjective conclusions, and are generally perfectionists. Last, the **pragmatic** style, is characterized by people who enjoy putting ideas, theories, and techniques into practice. They tend to avoid reflection and become uneasy with long discussions, are more practical and their ultimate goal is functionality.

Alonso, Gallego, and Honey [9] modified the Honey and Mumford questionnaire, LSQ, for use by university students and translated it to Spanish, creating the "Cuestionario Honey-Alonso de Estilos de Aprendizagem" (CHAEA).

The CHAEA is composed of 80 questions, as is the LSQ, with four groups of 20 questions, corresponding to the four learning styles, which are randomly distributed.

Each of the learning styles was defined according to the concepts presented by Honey and Mumford [10] and further elaborated on [9] in order to clarify the concepts of each style. To each, a list of characteristics describing the associated skill set was added.

Individuals who are predominantly **active** may have traits or skills such as: liveliness, improvisation, innovation, creativity, renewal, spontaneity, adventurousness, experience, leadership, participation, competitiveness, risk inclination, desire to learn and change, problem solving, and idea generation. They like experiencing situations, as well as directing debates and meetings.

Characteristics more associated with **reflective** individuals include: pondering, observation, care, analysis, receptivity, patience, argumentation, detailing, investigation, assimilation, and prudence. They prefer to listen, observe, and think before acting, are extremely attentive to details, and create alternatives.

For individuals that are predominantly **theoretical**, main traits or skills are: objectivity, criticism, organization, logic, order, planning, discipline, systematization, and summarization. They are generalists, rational, and search for hypotheses, models, theories, concepts, questions, and clear objectives. They are questioning, enjoy feeling intellectually challenged, and search for connections between models, concepts, theories or whatever they have heard.

The primary characteristics of **pragmatic** learners are: practicality, effectiveness, experimentation, technique, being realistic, usefulness, organization, actualization, efficiency, decision making, knowledge application, problem solving, and planning. They prefer learning techniques that offer practical advantages, enjoy experimenting with what was learned, and experiencing simulations of real problems.

Felder and Silverman [11], concerned about the performance of engineering students, developed a learning model which consists of two successive phases: reception and processing of information. During the reception stage, external information (captured by the senses) and internal information (which arises introspectively) become available to the individual, which selects the information to be processed and ignores the rest. Processing may involve memorization, or inductive or deductive reasoning. The learning styles are, thus, characterized by the different means of achieving learning, receiving and processing information.

In order to determine the learning preferences of an individual, based on the four dimensions of the Felder and Silverman [11] model, the Index of Learning Styles (ILS) was developed by Richard M. Felder and Barbara A. Soloman [12], at the North Carolina State University.

In the ILS two learning styles were defined for each of the four dimensions: active or reflective, sensing or intuitive, visual or auditory, and sequential or global.

Processing, either active or reflective, is related to the mental operations through which information perceived is converted into knowledge, which can be active experimentation or reflective observation. **Active** individuals prefer to experiment with ideas, processing information during activities, whereas **reflective** ones would rather process information individually, thinking and reflecting about concepts [13].

Sensing or intuitive perception allows individuals to become aware of and interpret what happens around them. The **sensing** type prefers to abstract information through sensing, uses data, facts, experiments, and memorizes information easily. The **intuitive** uses imagination, speculation, and guesses, being partial towards dealing with theories, concepts, and principles, does not like repetition, is attentive to details, and is interested in challenges.

Input, either visual or auditory, regards how people receive information through channels that can be divided into three types: visual, auditory, and synesthetic. Each person has different preferences and tends to retain more information through one of the channels. **Visual** individuals assimilate more of what they see, such as figures, diagrams, pictures, flowcharts, graphs, movies, and demonstrations. **Auditory** ones prefer written or oral explanations, and can extract more information from a discussion.

Sequential or global understanding classifies how individuals prefer to address a new subject. The **sequential** person learns in a linear fashion, through sequential steps, in which the subject becomes progressively more complex. A **global** person assimilates information randomly, without finding connections, and can intuitively skip steps during the solution of problems, perhaps not being able to explain how she/he reached the solution afterwards.

Preferences in the four proposed dimensions are assessed through the Felder-Soloman ILS questionnaire. This tool defines a score on a bipolar scale of 12 points for each dimension. The authors define three result ranges, which determine the predominant or preferred style of the respondent:

- Scores between 1 and 3 indicate a balanced preference between the two opposite learning styles;
- Scores between 5 and 7 indicate a moderate preference for a certain learning style;
- Scores between 9 and 11 indicate a strong preference for a certain learning style.

Ortigosa, Paredes, and Rodriguez [14] developed an adaptive hypermedia (AH) questionnaire, based on the ILS, to determine learning style. They sought to reduce the number of questions needed to determine a person's preferred learning style, compared to the 44 questions of the Felder-Soloman questionnaire. Their goal was to develop a system capable of determining the learning style of a student with the least number of questions possible. They showed that each learning style dimension may be determined with 4 or 5 questions, with accuracy ranging between 95.7% and 98.6% depending on the dimension. Since the ILS examines 4 dimensions, the AH-questionnaire is able to reduce the number of questions to less than half the original 44.

III. METHOD

Several limitations have been identified [3] in the questionnaires employed to determine learning styles, especially with respect to the possibility of misinterpretation of questions by the respondent. The present work selected questionnaires which, in the opinion of the authors, were composed of clearly stated questions.

Thus, three questionnaires for assessing learning styles were selected, viz., Kolb [15], Honey-Alonso [16], and Felder-Soloman [12]. The questionnaires were implemented in a spreadsheet with automated results, and distributed to subjects of both genders, and varying age and academic background. These questionnaires were selected due to their widespread use as reported in the literature, and also due to their increasing number of questions, which might signal an also increasing diagnosing capability.

Kolb's questionnaire, or Learning Style Inventory, consists of twelve questions, each involving the analysis and classification of four alternatives. Thus, the subject needs to make 36 decisions, three per question, and fill 48 cells. The result is given as a preferred learning style among four possibilities: Active or Reflective or Concrete or Abstract. In order to take the Honey-Alonso test, the subject needs to make 80 decisions, and fill 80 cells. The result is given as a pair of preferred learning styles: Active or Reflective, and Concrete or Abstract. Answering the Felder-Soloman questionnaire, or Index of Learning Styles (ILS), requires that the subject make 44 decisions, and fill 44 cells. The results are presented as four preferred learning styles: Active or Reflective, Sensing or Intuitive, Visual or Verbal, and Sequential or Global.

The respondents were asked to answer all three questionnaires, examine the results and indicate their satisfaction by grading each result, using a scale between 0 and 10. Gender, age bracket, and academic background were also recorded. Most respondents were male (59.62%). Age brackets were defined in five-year intervals, and ranged from 11-15 to 66-70. The most populated bracket was the 46-50, with 10 respondents, followed by the 36-40, with 9 respondents, and 21-25 and 31-35, both with 6 respondents each. Questionnaires were distributed to present and past students of two authors, both undergraduate and graduate, colleagues and family members. Most respondents (82.69%) had finished an undergraduate program, 32.69% had finished a graduate program, and 36.54% were in graduate school. Science and technology graduates made up 42.31% of the respondents, while health and social sciences both had 15.38% representation each, with business graduates accounting for 13.46% of the total. A graduate degree in Environmental Management was most common (24 respondents), as expected, since the work reported herein was conducted by students and faculty of such a program, as part of their activities in a Faculty Development course [17].

The results for each questionnaire were presented as short answers indicating the learning style, and interested respondents were directed to detailed online descriptions of each possible result. The questionnaires were not supposed to be answered in any specific order, neither at one sitting, but it is likely most respondents did it in the order presented: Kolb, Honey-Alonso, Felder-Soloman.

IV. Results

Answers provided by 52 respondents, and summarized in Tab. I, show that, while there is no statistically significant difference among the preference of respondents regarding the three questionnaires, a slight preference for the Felder-Soloman questionnaire is discernible. This is evidenced by the higher average score and lower standard deviation observed in the assessment of the ILS by the respondents.

TABLE I. Average and standard deviation of scores assigned by respondents to each learning style questionnaire.

Questionnaire	*Average*	*Standard deviation*
Kolb (LSI)	7.65	2.28
Honey-Alonso (CHAEA)	7.56	2.37
Felder-Soloman (ILS)	8.58	1.13

Considering the possible results of the application of each questionnaire, as described above, Tab. II proposes a correspondence among the results of the three questionnaires considered here. The visual/auditory and sequential/global dimensions of the ILS were not listed since they do not have correspondences neither in the LSI nor in the CHAEA.

Comparisons show a 69% agreement between results of the Kolb and Honey-Alonso questionnaires, 47% agreement between Kolb and Felder-Soloman, 59% agreement between Honey-Alonso and Felder-Soloman in the active/reflective dimension, 45% agreement between Honey-Alonso and Felder-Soloman in the pragmatic/theoretical dimension. Full agreement between the two comparable Honey-Alonso and Felder-Soloman results was observed in 27% of the responses, and at least one agreement between corresponding Honey-Alonso and Felder-Soloman results was observed in 76% of the responses. Agreement in the results of all three questionnaires was observed in only 16% of the answers. Tab. III summarizes these comparisons.

TABLE II. Correspondence among the possible results of the three learning styles questionnaires tested.

Kolb (LSI)	*Honey-Alonso (CHAEA)*	*Felder-Soloman (ILS)*
Diverging / Reflective	Reflective	Reflective
Converging / Pragmatic	Pragmatic	Sensing
Assimilating / Theoretical	Theoretical	Intuitive
Accommodating / Active	Active	Active

TABLE III. Agreements among results of the different questionnaires.

Questionnaires compared	*Dimensions compared*	*Agreement in results*
Kolb and Honey-Alonso	Single Kolb result	69 %
Kolb and Felder-Soloman	Single Kolb result	47 %
Honey-Alonso and Felder-Soloman	At least one agreement	76 %
Honey-Alonso and Felder-Soloman	Active / Reflective	59 %
Honey-Alonso and Felder-Soloman	Pragmatic / Theoretical	45 %
Honey-Alonso and Felder-Soloman	Active / Reflective and Pragmatic / Theoretical	27%
All three questionnaires	Single Kolb result	16 %

Based on the scores respondents assigned to each questionnaire, their preferred resulting learning style was inferred, active or reflective, and theoretical or pragmatic. Thus, results given by each questionnaire were deemed correct or incorrect according to the respondents' preferred results. With these assumptions, 59% of the LSI results were correct, 71% of the CHAEA results were correct in the active/reflective dimension, and 69% were correct in the theoretical/pragmatic dimension. Similarly, 86% of the ILS results were correct in the active/reflective dimension, and 76% were correct in the theoretical/pragmatic dimension. Considering CHAEA and ILS results correct only when both active/reflective and theoretical/pragmatic dimensions are correct, 53% of CHAEA results are correct, while 73% of ILS results are correct. Tab. IV lists these results.

TABLE IV. RESULTS DEEMED CORRECT BASED ON RESPONDENTS PREFERRED RESULTS.

Questionnaire	*Results correct*	*Questionnaire*	*Results correct*
Kolb (LSI)	59 %		
Honey-Alonso (CHAEA) Active / Reflective dimension	71 %	Felder-Soloman (ILS) Active / Reflective dimension	86 %
Honey-Alonso (CHAEA) Theoretical / Pragmatic dimension	69 %	Felder-Soloman (ILS) Theoretical / Pragmatic dimension	76 %
Honey-Alonso (CHAEA) Both dimensions	53 %	Felder-Soloman (ILS) Both dimensions	73 %

Taking the rank assigned by each respondent to the questionnaires by means of the assigned scores, and noting that some ties did occur, the ILS figured in first place in 67% of the answers, while LSI and CHAEA topped the rankings in 49% and 43% of the answers, respectively. Conversely, ILS figured in last place in only 6% of the answers, while LSI and CHAEA did so in 24% and 22%, respectively. Tab. V shows these rankings.

TABLE V. RANKINGS ASSIGNED TO QUESTIONNAIRES BY RESPONDENTS

Questionnaire	*Ranked first*	*Ranked last*
Kolb (LSI)	49 %	24 %
Honey-Alonso (CHAEA)	43 %	22 %
Felder-Soloman (ILS)	67 %	6 %

Finally, it was looked at the learning styles of the respondents in an attempt to understand their stated preferences. LSI results showed 15.7% active; 29.4% reflective, 41.2% theoretical, and 13.7% pragmatic. CHAEA results indicated 5.9% active, 84.3% reflective, 7.8% active or reflective; 23.5% pragmatic, 68.6% theoretical, 7.8% pragmatic or theoretical. ILS results showed 51.0% active, 49.0% reflective; 74.5% pragmatic, 25.5% theoretical; 90.2% visual, 9.8% verbal; 41.2% sequential, 58.8% global. Thus, considering that most respondents (90.2%) were visual learners, the fact that ILS results were the most visual of the three, with the four dimensions represented as rulers, certainly contributes to its achieving the best results. Tab. VI summarizes these results, with blocks bordered by thicker lines indicating groups which should add up to 100% in each column.

V. CONCLUSIONS

Deciding which questionnaire to apply, if one must choose among the three options considered here, should also take into account the ease of understanding the questions, the time needed to complete the questionnaire, and how the results are presented. Considering the results reported herein, the authors are inclined to indicate the adoption of the Felder-Soloman questionnaire. The ILS was ranked first among the three by 67% of the respondents, and achieved the highest average score and corresponding lowest standard deviation. Also, the ILS's 44 questions are likely to take less time to answer than the CHAEA's 80 and the LSI's 12, since the latter require ranking four alternatives each.

TABLE VI. RESULTING DISTRIBUTION OF LEARNING STYLES AMONG THE RESPONDENTS.

Questionnaire → *Learning style ↓*	*Kolb (LSI)*	*Honey-Alonso (CHAEA)*	*Felder-Soloman (ILS)*
Active	15.7 %	5.9 %	51 %
Reflective	29.4 %	84.3 %	49 %
Active or Reflective	-	7.8 %	-
Theoretical	41.2 %	68.6 %	25.5 %
Pragmatic	13.7 %	23.5 %	74.5 %
Theoretical or Pragmatic	-	7.8 %	
Visual	-	-	90.2 %
Verbal	-	-	9.8 %
Sequential	-	-	41.2 %
Global	-	-	58.8 %

Once assessed, the learning styles of students may be used by instructors to devise teaching strategies. The results should also fuel self-analysis by students, and guide learning strategies. There is conflicting evidence in the literature regarding the efficacy of changes in teaching style to accommodate for different learning styles. Dinçol, Temel, Oskay, Erdoğan, and Yilmaz [18] considered the effect of matching learning and teaching styles, and concluded that it has no significant influence on student success. On the other hand, Iurea, Neacşu, Safta, and Suditu [19] hold that if a teacher adapts his/her teaching style to the students' learning styles, academic performance will rise.

McMillan and Dwyer [20] questioned whether students should adapt to teaching strategies, or teachers should cater to the learning styles of students. They cited Dixon [21], who recommended that teachers should create a learning environment which accommodates diversity, and students use the learning style information for better learning.

Arthurs [22] considered the challenges nurse educators face to manage the wide range of learning styles in a large group of students, and suggests teaching strategies to accommodate different learning styles.

Tulbure [23] showed that employing teaching strategies suited to learning styles produces better learning outcomes. It was shown that graphical organization of information is best for assimilators, cooperative learning and investigation work best for convergers, debate and problem solving suit accommodators best. Students with diverging learning style did not show exceptional performance for any teaching strategy tested, but did achieve better results when debate was employed.

Mixed results have been reported in the literature, with some authors despairing over the apparent chaos, such as Martin [24], who examined the results obtained with the application of LSI-2 (LSI modified by Kolb, Osland, and Rubin [25]) and LSQ, concluding:

> *"Teachers in these schools would have as much information if they assigned the learning styles randomly to students rather than using the Kolb test. They might have more confidence in the LSQ, but the factor structure shows there is still much cause for concern about this scale."*

Young [26] investigated the perception of language teachers and learners with respect to the usefulness and validity of learning styles in a multicultural classroom. Teachers were almost evenly divided, with most individuals on the negative side questioning the validity of the learning style assessment, and unsure about how to use the results. Learners, on the other hand, were satisfied with the profile given by the learning style assessment and considered it useful.

Theoretical psychological evidence has been sought to validate learning style assessment. Duff and Duffy [27] examined the psychometric properties of Honey and Mumford's learning style questionnaire and concluded that it had limited reliability and validity for the population analyzed, which was composed of undergraduate business and health students.

It must be noted that changes in learning styles have been reported. Nielsen [5] reported changes in learning styles of Business Administration and Psychology students over one, two, and three years of study. Thus, it may be concluded that periodical reassessment of learning styles is recommended for better design of instructional activities.

Learning in Style

Correlation of Learning Styles with Problem Comprehension and Perceptions in an Introductory Chemical Engineering Course

Elif Eda Miskioğlu, David W. Wood
Chemical and Biomolecular Engineering
The Ohio State University
Columbus, Ohio, USA
miskioglu.1@osu.edu, wood.750@osu.edu

Abstract—**Learning styles are emphasized as being preferences for how an individual learns and indicators of how studying should be approached, rather than indicators of success. This has not, however, prevented researchers from exploring whether student performance can be dependent on matching question type to learning style. In a study of medical students, Cook et al. failed to establish such a correlation. However, small sample size and the inherently high inclination of the sample population to succeed were likely high contributing factors. Further, preferences are adaptable by education, and this study was conducted with advanced students. We are interested in the correlations between learning style preferences, task perception, and student performance in the context of an introductory chemical engineering material balances course. Assignments have a natural degree of learning style bias, and we are looking to see if student preferences correlate with their performance and perceptions when these biases are considered. Results will provide evidence regarding whether learning styles can affect student performance, as well as identify naturally occurring biases in chemical engineering problems that are translatable to other fields. A better understanding of student background and learning preferences is invaluable in developing improved curriculum, especially in the ever-changing modern classroom.**

Keywords—learning styles, ILS preferences, student performance, perception

I. Introduction

The validity of learning style indicators has been a point of contention in education since their establishment. While accepted as indicators of preference for specific learning practices, there is question of whether learning styles can also be a predictor of student success. Studies on learning styles have largely focused on the use of hypermedia, rather than traditional classroom lectures, as a teaching technique. We are interested in exploring the correlation between learning styles and student performance on, and perception of, tasks in the context of an introductory chemical engineering course taught in the traditional lecture format.

II. Felder-Silverman Learning Styles

In 1988, Felder and Silverman published their model of learning and teaching styles [1]. The Felder-Silverman model identifies five dimensions of learning styles: active/reflective, sensing/intuitive, visual/auditory (verbal), sequential/global, and inductive/deductive. While we will focus solely on the learning styles, Felder and Silverman also further proposed parallel teaching styles: active/passive, concrete/abstract, visual/verbal, sequential/global, and inductive/deductive, respectively.

A. Active vs. Reflective

As the words themselves suggest, active learners prefer actively doing something with and reflective learners prefer thinking about a new topic. Active learners are generally thought to prefer working in groups while reflective learners prefer working individually [1]. They are further described as approaching learning through "active experimentation" vs. "reflective observation" [1].

B. Intuitive vs. Sensing

This dimension correlates highly with the Myers-Briggs personality indicator dimension [1]. Learners with a preference towards sensing prefer facts and generally prefer concrete, numerical, practical problems over theory [1]. Intuitors, on the other hand, prefer to consider the possibilities and more abstract relationships rather than concrete facts [1]. They tend to dislike the traditional "plug-and-chug" type problems in favor of more theoretical questions [1].

C. Visual vs. Auditory (Verbal)

This dimension describes how students prefer to receive their information. Visual learners prefer to see diagrams, graphs, and cartoons, whereas auditory/verbal learners prefer words, be they written or oral [1]. In a June 2012 preface to the original publication of the Felder-Silverman model, Felder officially explains the change in terminology from auditory to verbal, to better encompass that these individuals learn better from words, auditory or written. From here forward we will refer to this dimension as visual/verbal.

D. Sequential vs. Global

Sequential/global is a dimension that describes how the students view the material in the context of the greater picture. Sequential learners prefer calculated steps and are able to focus and follow details without having to grasp the big picture [1]. Global learners tend to learn in a less stepwise

This material is based upon work supported by the National Science Foundation Graduate Research Fellowship under Grant No. DGE-0822215

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

fashion and need to grasp the big picture before they can focus on the details to see where those details fit [1].

E. Inductive vs. Deductive

Inductive vs. deductive describes the reasoning processes of learners. Inductive learners process information from details such as observations and measurements, and they construct generalities such as laws and theories from these details [1]. A deductive learner begins at the theoretical level and subsequently "deduces" the possible results [1]. In the preface of the June 2012 publication, Felder explains the reasoning behind later omitting the inductive/deductive dimension. Felder cites induction as the more natural human learning method, while deduction is commonly what faculty use in teaching. While he continues to believe that the two are distinct learning preferences, Felder explains that he has removed this dimension from his model to prevent instructors from being "able to determine somehow that their students prefer deductive presentation and use that result to justify continuing to use the traditional but less effective lecture paradigm in their courses and curricula" [1].

F. Index of Learning Styles (ILS)

The Index of Learning Styles (ILS) is a 44-question survey designed to identify student learning preferences in the four dimensions of the Felder-Silverman model [2]. The questions are spread evenly across dimensions, 11 for each, with two possible answers for each question representing the opposing preferences of the dimension [2]. Answers are scored on a scale from -11 to +11, where positive and negative correspond to the opposing preferences [2]. For example, for the active/reflective dimension, answers showing an active preference are considered +1, and answers showing reflective preference are considered -1. If a student answers 7 questions with the answer corresponding to an active preference, and 4 with the answer corresponding to a reflective preference their score would be [(+7) + (-4)] or a +3, which shows only a slight inclination towards active learning. A score with an absolute value from 1 to 3 is considered "balanced", 5 to 7 a "moderate" preference, and 9 to 11 a "strong" preference [2].

Studies done on the reliability and validity of the ILS have shown strong student agreement with results [2][3], and the instrument has been utilized in fields ranging from engineering and computer sciences to internal medicine [2][4] [5].

III. Learning Style Preference Vs. Performance

Learning styles are emphasized as being student preferences for how they learn and indicators of how studying should be best approached [6], rather than indicators of success [2]. This has not, however, prevented a few researchers from exploring whether or not student performance can be dependent on matching question type to learning style. In a study by Cook et al. 89 medical residents and students were administered a web-based learning module [5]. Some were presented with questions that matched their learning style, while others were given questions that were designed to be a mismatch [5]. The focus of the study was on the active/reflective dimension, and no statistical significance was found in student performance regardless of whether they were matched or mismatched for question type [5]. The authors offer a number of reasons why this study may have failed to establish a connection between learning style and performance, including small sample size and the inherently high inclination of the sample population to succeed regardless of circumstances [5]. Also of consideration is that this study was conducted with students in an advanced point in their educations, and preferences can be influenced (adapted) by prior education [2].

IV. Learning Styles in ChBE 2200

Chemical and Biomolecular Engineering (ChBE) 2200, Process Fundamentals, at The Ohio State University (OSU) is the introductory course in chemical engineering. Commonly known as materials and/or energy balances, this course is traditionally taken in the sophomore year of undergraduate study and determines whether students remain in the major. Since learning style preferences are adaptable (*i.e.*, they can change over the course of a student's career with repeated exposure to specific teaching styles [2]) we are interested in looking at students in this introductory course because of the inherent diversity of their educational backgrounds. Still relatively fresh out of high school, and having spent their first several semesters in a variety of elective and general science and mathematics requirements, these students have yet to be affected by their forthcoming shared chemical engineering curriculum. Thus, in theory, they have a greater potential for variation in learning styles. Further, 150-250 students take ChBE 2200 over the course of an academic year, providing a good sample size for study. A considerable fraction of these students (nearly a quarter) do not pass the minimum course requirements, and thus do not continue as chemical engineering majors.

A. Course Description

ChBE 2200 is a lecture-based course with assessment provided through homework, quizzes, and exams. Homework is completed both individually and through specifically assigned groups. Groups are randomly assigned by the instructor at the start of term and retained through the course. Homework problems are assigned as "individual" or "group problems", to be completed accordingly. Our study focuses on the individual work only.

B. Study Design

We are interested in the correlations between student learning style preference, academic performance, and perception of homework, quiz, and exam problems to identify any effects of problem bias. Data collected are student ILS responses (administered at the beginning of the term), grades (for individual work only), and surveys regarding self-efficacy to gauge perceptions of assigned problems.

1) Preliminary Work, Spring 2013: In the spring semester of 2013 we have worked with two sections of ChBE 2200 to gather preliminary data and develop a usable survey. Initially, we polled students about every problem they encountered.

However, this is difficult to do effectively in a short (*i.e.,* no longer than one page) survey. We have changed our approach to selecting the most distinct and representative problems from each assignment and asking more thorough questions. Questions include rating the student's confidence in their solution, ease of achieving the solution, and perceived fairness of the question. Positive and negative versions of the same question ("I am confident in my solution" and "I am uncertain I completed problem x correctly") are used to gauge consistency of answers. Comparative questions are also included to determine student preference when problems demonstrating a distinct bias within a learning style dimension are available on the same assignment.

2) Challenges Identified: The primary challenge identified, as with any research involving human subjects, is compliance. It is difficult to get students to voluntarily complete a task without incentive. Furthermore, while the study is designed to not effect course content or create additional work for the instructor, it is important to have the instructor involved in order to keep students engaged and completing perception surveys. Lack of compliance proved a great hindrance to the study in Spring 2013, as students completed the surveys too sporadically and infrequently to provide robust data. The responses received did, however, prove useful for insight into survey usability even if they are not sufficient for assessing the correlation(s) of interest. Thus, the preliminary work has provided us with ideas for an improved survey design and insight into protocol execution. In future semesters, we will (with instructor agreement) assign a small number of points to the survey completion. It is important here to note that, as IRB exempt research, this study is designed such that all students complete the same tasks (same homework problems, same surveys) regardless of participation. Only data from students consenting to participate is/will be analyzed. Teaching assistant or grader support is also critical in collecting grade data for individual problems.

3) Fall 2013 and Beyond: With the insight provided in the spring term, we look to conduct a more robust study in Fall 2013 and subsequent terms. The variables of interest are difference in learning styles, with each dimension considered separately. The study will be conducted during ChBE 2200. Each learning style dimension will be investigated through assignment biases and follow-up surveys. These assignments are part of the regular course homework and will thus be administered throughout the semester. This will allow for repetition of the study with different difficulties of assignments, as learning styles may be more significant as learning and problem solving demands become more complex. Student performance on these assignments will be the quantitative measurements obtained from the study, with each student's overall class performance and GPA taken into consideration when comparing across the class. The corresponding surveys will be a brief set of questions on a 1 through 5 Likert scale (strongly disagree to strongly agree), evaluating the student's response to the given task.

V. Desired Outcomes

The correlation between learning styles and student performance or perception is not well-established, especially in the context of engineering education. There is an understood degree of "discipline bias" in material that is accepted to also influence the "type" of person who enters each field. If such a bias is shown, and student performance seen to be correlated, this would open an avenue for more informed curriculum development in the context of chemical engineering that is translatable to other fields. By developing curriculum and respective materials that are adapted to a variety of learning styles, we can not only make our disciplines more diverse and inclusive with respect to learning styles in the students (later to become professionals) that they draw, but also develop students with an ability to process information presented in a greater variety of ways. This would help develop a generation of more versatile problem solvers.

Acknowledgment

We would like to acknowledge Drs. Andre Palmer and Jessica Winter, the Spring 2013 instructors of ChBE 2200, for their cooperation in allowing us access to their course.

Identifying Misconceptions Held About the Engineering Design Process

Susan K. Donohue
University of Virginia, susand@virginia.edu

Abstract – **The primary goal of the research presented in this work-in-progress paper is to identify misconceptions held about the engineering design process. Identification is the first step in the development of a concept inventory, an instrument for assessing misconceptions. While there are several methods for assessing misconceptions, concept inventories are an excellent method for assessing a group of students. The distractor questions identify misconceptions and possible causes for them. Misconceptions coded from student responses to incomplete scenarios of the engineering design process include the idea that engineering is solution driven instead of problem/client need driven and that engineering is merely fabrication. Future work will develop, test, and validate a concept inventory for engineering design with questions based on identifying these misconceptions as well as misconceptions identified through follow-up work.**

Index Terms – Concept inventories, engineering design process, misconceptions, P-16 engineering education.

INTRODUCTION

A critical pedagogical task is the identification of learners' misconceptions. Instructors cannot assume that every student possesses correct conceptual knowledge regarding core and discipline-specific concepts, or that s/he can identify the correct relations among various concepts in a coherent fashion, at any point in a program of study. This assessment should be separate from traditional learning assessments, since it is well documented that students with hazy conceptual understanding can nonetheless develop strategies to perform well on tests using questions that rely on knowledge recall or elimination strategies for completion, such as true/false and multiple choice [see, for example, 1].

Without a clear understanding of the correctness of students' conceptual knowledge, it is difficult, if not impossible, to gauge comprehension and preparation for succeeding courses. Additionally, work in developing instruments and strategies for correcting misconceptions cannot proceed without knowing what the misconceptions are. The identification of misconceptions about the engineering design process is the main goal of the research presented in this work in progress paper. The overall research goal is the development of a concept inventory to identify student misconceptions about the engineering design process.

ENGINEERING DESIGN PROCESS

The engineering design process is at the heart of the discipline. ABET Student Outcome 3(c) directly addresses the need to know and apply the process. The cornerstone and capstone model, providing design education at the beginning and completion of the undergraduate engineering program, is widely used. Yet, we acknowledge that assessment of student learning in design classes is an admittedly difficult process and as a result, students may go through their undergraduate careers without having their misconceptions corrected, much less identified.

There are many models in use, but for the most part they have several features in common: engineering design is problem-based and starts with the identification of and research on an issue; a design space is defined; solutions are developed and evaluated; the best solution is selected for prototyping; an internally iterative cycle of build-test-evaluate occurs; and, when a stopping rule is encountered, the artifact is reviewed to determine if it meets, within tolerances, expectations or whether the design team needs to re-enter the process at a phase appropriate to the amount of redesign that needs to occur. Throughout, there is communication among team members and with client(s).

A representative model is displayed in Figure 1 at the end of the paper. It was developed based on my assessment of other models [see, for example, 2 – 5] and my experiences as an instructor of ENGR 1620, *Introduction to Engineering* at the University of Virginia and in K-12 outreach.

MISCONCEPTIONS AND METHODS FOR IDENTIFYING THEM

It is important to understand the process of cognition in developing definitions of concepts and misconceptions. The most basic definition of cognition is the "process of knowing…and the content of those processes." It is a **fundamental** concept in the science of learning, since learning is dependent on prior knowledge and the nature of changes students can make in both processes and content. (see, for example, [6]; emphasis added) The primary components affecting a person's level of cognition are declarative knowledge and procedural knowledge. Declarative knowledge can also be defined as "semantic information…(knowledge about ideas)" and procedural knowledge as the "complement" of declarative knowledge; together, they "represent categories for describing knowledge in general" [7, p. 28]. The interplay between the acquisition and application of sets of related declarative and procedural knowledge helps students identify and internalize

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

underlying concepts. However, students may internalize concepts incorrectly for a variety of reasons, and the resulting misconceptions can be a factor in student disengagement and other negative (re)actions.

A concept, therefore, is a mental construct or model that helps a person organize knowledge. It is inductively built from interactions and experiences [8]. Misconceptions, also known as an alternative framework or invented theory, develop from a flawed development process and can be resistant to change [1, 8, and 9].

There are several validated methods for evaluating conceptual knowledge; the most commonly used are concept inventories, direct interview, and strategy writing.

Concept inventories, multiple choice tests used to assess misconceptions in a variety of subject areas in science, technology, engineering, and mathematics (STEM), were pioneered by physicist David Hestenes and his colleagues at Arizona State University beginning in the 1980s. The first concept inventory addressed student misconceptions with respect to Newtonian forces. A discussion of the history, development, reliability, and validity of concept inventories, accompanied by descriptions of engineering and related science concept inventories, is provided in [10]. ciHUB [11] and the Foundation Coalition [12] are repositories of concept inventories.

Streveler, *et al*. [13] presents an overview of the results of fundamental and applied research performed in the area of the development and application of conceptual knowledge in general and in science (more specifically, physics) in particular, with an acknowledgment of the range of topics for which concept inventories have been developed. Concept inventories are recommended for the rapid assessment of conceptual knowledge; however, the instrument's available answer choices may not truly reflect all misconceptions held by students and therefore may provide an incomplete assessment. The authors support the use of alternative assessment methods that are "research-oriented, in-depth studies of small groups of students, which explore prevalent patterns of thought or mental models of phenomena" – that is, directed interviews – to capture engineering science (mis)concepts as fully as possible (p. 281).

An application of these results is "strategy writing," a qualitative problem solving method in which a student's initial focus is on concepts instead of equations [14, 15]. The outcome is a written solution protocol with three main components: identification and discussion of the main concept(s) or principle(s) involved, arguments justifying the applicability of the concept(s) or principle(s) to the problem's issue(s), and procedures for using the concept(s) or principle(s) in solving the problem [15, p. 6]. In short, a strategy is a document containing the "'what,' 'why,' and 'how' of a problem's solution" [14, p. 1496].

METHODOLOGY

Course assessments are a rich source of qualitative data, as review of essay answers and reflections can serve as proxies for direct interviews. The code list is emergent, and is originally based on a review of the literature [see, for example, 16 – 19], classroom observations, and discussions with colleagues.

The data come primarily from students in ENGR 1620, *Introduction to Engineering*, at the University of Virginia (UVa). In 2011, I reviewed and coded answers, using an emergent code list, from seventy-five first year students (25 females, 50 males) to a midterm question that asked for a response to a scenario based on an incomplete description of the engineering design process, after [15]. The result – that 26 students (35%) perceive the engineering design process as solution, not problem, driven – is reported in [16]. By the end of the semester, the number of students holding that misconception dropped to six. Partial validation of these results comes from responses to a similar question posed to twenty-two students (3 female, 19 male) in EGR 120, *Introduction to Engineering*, at Piedmont Virginia Community College (PVCC) in Spring, 2013. A related observation is that almost all students felt compelled to try to fit every part of the process in their analyses even though it is clear that only parts of it are being addressed.

Additional data come from responses to exams questions and scenarios and end-of-semester reflections of eighty-one first year students (28 females, 53 males) in ENGR 1620 in Fall, 2012 and the 2013 EGR 120 students.

The questions are provided in the Appendix. Student demographics are reported in [16 and 20].

PRELIMINARY RESULTS

TABLE I
MAIN MISCONCEPTIONS ABOUT THE ENGINEERING DESIGN PROCESS

	Female	Male
Solution-based process / engineer as fabricator	7	18
Linear, one-pass process	4	12
Engineering is only math and science	3	7
No process or resource limits or boundaries	1	6

The main misconceptions regarding the engineering design process are listed in Table 1. Additional misconceptions include the levels of complexity, definition, and organization in the process, including the need to have a process; the engineer's role in the process and the interactions s/he has; the degree of value for soft skills engineers need to have in order to conduct a successful design project; and the role of creativity throughout the process. The term "misconception" is used instead of "misunderstanding" due to the former's importance in the constructivist philosophy of education, and anecdotal evidence points to students having built a flawed conceptual framework of what engineering is based on their experiences in K-12 formal and informal learning environments. Identifying and understanding these experiences is a future research direction.

ACKNOWLEDGMENT

I am grateful to Teri Reed and PK Imbrie, the leaders of the Second Annual National Meeting on STEM Concept Inventories, sponsored by the National Science Foundation (DUE 0920589), for the opportunities to network with other researchers interested in concept inventories; to current and former first year engineering students for their ideas about the engineering design process; to Reid Bailey, Ali Bouabid, and Edward Berger for the opportunity to teach these courses; to Larry Richards for mentoring and guidance; and to the reviewers for their feedback and recommendations.

APPENDIX – EXAM REFLECTIONS, QUESTIONS AND SCENARIOS

UVa 2011 Midterm Scenario: You are a general consulting engineer. A prospective client asks for help in building a prototype of the device he's sketched out. You make a copy of the signed and dated sketch so that you can evaluate the situation and possibly draw up a project schedule and cost estimate if you think the project is a good fit with your skill set. Evaluate *wrt* the engineering design process.

UVa 2012 Midterm Q and PVCC Final Q: Revisit the IDEO Deep Dive video, and critique what you see in the video *wrt* the engineering design process.

UVa 2012 and PVCC 2013 Final Reflection: What are two ideas or conceptions about the engineering design process you had at the beginning of the semester? Have they changed? If not, state that. What process or project do you think helped most in either reinforcing or changing these ideas or conceptions?

PVCC 2013 Test 1 Scenario: You are a general consulting engineer. A prospective client comes into your office asking for help in building a prototype of the device he's sketched out. You build the prototype and deliver it to him. Refer to (an earlier version of Figure 1, above). What steps are involved in the above scenario? Which steps are not?

The Effects of Direct Observation on Student Responses in the Renewable Energy REU Program at Colorado School of Mines

Scott A. Strong
Department of Applied Mathematics and Statistics
Colorado School of Mines

***Abstract*—The Cornell Office for Research on Evaluation (CORE) Systems Evaluation Protocol (SEP) is a step–by–step guide to evaluation, emphasizing systems modeling principles, facilitating the creation of evaluation plans with clear, specific and measurable outcomes. In 2011, CORE SEP techniques were applied to the Renewable Energy Materials Research Science and Engineering Center (REMRSEC) National Science Foundation (NSF) funded Research Experience for Undergraduate (REU) site and revealed two very different pathways leading to the critical outcome of students obtaining post–baccalaureate jobs in technical fields related to renewable energies. While the experiences within a student's research group defined a clear evaluation pathway, a second pathway characterizing student attitudes shaped by the REU community at–large also emerged. This created an interesting question on the effects direct observation has on evaluation data. In response the REMRSEC REU SEP evaluation plan saw different implementations from 2011 to 2012. While both employed similar measures, the 2012 evaluators intervened only digitally. In this paper we summarize the REMRSEC REU and its CORE SEP evaluation plan. We conclude with comparison of the two evaluation implementations and speculate on how evaluator role affects the gathered data. Lastly, we discuss plans to hybridize previous implementations into the 2013 cycle, which we characterize in terms of evaluator role theory.**

I. Introduction

Ideally, an evaluator's role within a given program is clear and accepted. In practice, however, this is rarely the case because roles are contextually dependent concepts endowed with complex dynamics [1], [2]. These tenets of sociological *role theory* have been echoed and incorporated into the evaluation discipline where evaluators no longer identify as sterile auditors but as participatory social scientists [3], [4]. Patton, in 1997, attempts to classify such roles with 14 roles, 19 styles and 46 characteristics [5]. Regardless of the reasons for this cultural shift, or the impact, its existence naturally raises the questions:

1. What shapes the *evaluator role*?
2. How does evaluator role affect their evaluation?

Assuming that an evaluator is subject to heavy *role change*, stemming from the influences of their many roles, we ask how an evaluator's role is created and shaped by the program. Upon arriving at a particular role, it is highly likely that the evaluator is member of a larger community that defines the program they seek to evaluate. That being the case, it makes sense to consider how a participatory evaluator affects the program and, in turn, the overall evaluation. Scientifically, evaluator integration generates a feedback mechanism where the system responds to itself or in other words, a nonlinear system. While it is hoped that one day these questions may be addressed by nonlinear feedback analysis, we do not attempt to do so in this paper. Instead, we seek to texture and advance the ongoing conversation on evaluator role and effect by an analysis of recent evaluations conducted on an ongoing research experience for undergraduates (REU) focused on renewable energies. Here changes in evaluator role are primarily due to refinements in the program's evaluation plan and can be reasonably quantified.

At the Colorado School of Mines (CSM) there exists an National Science Foundation (NSF) sponsored Renewable Energy Materials Research Science and Engineering Center (REMRSEC), which is focused on transformative materials science advances that greatly impact emerging renewable energy technologies. After a two–year pilot program, the NSF sponsored a ten–week, eight–student REU Site starting in 2011 and lasting for three years. The goals of this REMRSEC REU are twofold

i. provide participating students with high quality research experiences in renewable energy and
ii. increase undergraduate student's interest in pursing advanced degrees in the discipline.

To address the first goal, the REU introduces talented undergraduate students to vibrant research led by teams both from CSM and the nearby National Renewable Energy Laboratory (NREL). To support positive student attitudes and academic success in these endeavors, the REU contains programmatic elements focused on communal and professional development. The importance of community as a factor in student attitudes was identified, by the REU Director, during the pilot program. Upon NSF sponsorship, efforts were made by REU program managers to better understand these aspects through the use of a more comprehensive evaluation plan.

The Cornell Office for Research on Evaluation (CORE) Systems Evaluation Protocol (SEP) is a step–by–step guide meant to support evaluators in their assessment endeavors. Through the application of systems modeling principles, the

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

SEP seeks to facilitate the creation of thoughtful evaluation plans. In 2011, CORE SEP techniques were applied to the REMRSEC REU Site. As part of the planing process, program stakeholders were interviewed and a functional flow diagram, or logic model, of the site was produced. From this model, it was concluded that there were two very different logical pathways leading to the overarching outcome of students obtaining post–baccalaureate opportunities in technical fields related to renewable energies. It was expected that a student's experience within their research group would have a strong affect on their attitudes towards academic research. The emergence of a second pathway characterizing student attitudes shaped by the REU community at–large was reasonable but unexpected. In particular, the evaluator found the theme of community to be central in all stakeholder interviews. Moreover, this pathway created an interesting question of evaluation scope and nonlinear feedback. That is, the evaluator may be an obvious member of the at–large REU community and, as such, affects the system which they seek to evaluate.

Since the REMRSEC REU was well established by 2011 and knowing that previous evaluations characterized the student research experience as high–quality, the 2011 and 2012 cycles sought to understand how the program evaluator affects aspects of evaluation implementation. Consequently, the SEP plan saw different implementations from 2011 to 2012. While both employed similar quantitative and qualitative assessment methodologies, the 2011 cycle incorporated evaluators in REU program elements, which is in contrast to 2012 where evaluators intervened only digitally. The outcome of this is two sets of evaluation data, consistent with one SEP plan, whose primary difference is in the role of the evaluator within programmatic elements. A comparison of these data indicate that when the program evaluator is incorporated as a communal member, the respondent participation increases while other characterizations stay relatively the same. From this perspective, it seems, an important communal function of the evaluator is to facilitate participant self–reporting. This conclusion provides some closure to the previous sociological questions, at least as it relates to the REMRSEC REU, we outline plan to further investigate this role in the 2013 cycle.

In the following we first summarize the REMRSEC REU and its implementations from 2011–2012. Next we consider CORE SEP modeling of the REMRSEC REU and present salient features of the associated evaluation plan. In addition we compare and contrast the two evaluation implementations in an effort to understand how the incorporation of evaluation personnel affects evaluation results. In particular, we study the participation rates, and volume of a subset of evaluation data gathered by each implementation and from these data we draw conclusions about the effect of "evaluator presence." We conclude by discussing how these results find application in third–year CORE SEP REMRSEC REU evaluation implementation.

II. THE CONTEXT: REMRSEC REU

In 2008 the NSF awarded CSM a six–year grant to establish REMRSEC, which consists of an interdisciplinary team of CSM faculty from Departments of Chemical Engineering, Chemistry and Geochemistry, Liberal Arts and International Studies, Metallurgical and Materials Engineering and Engineering Physics, in addition to faculty from Academic Computing and networking; Center for Assessment of Science, Technology Engineering, and Mathematics; Center for Engineering Education; and the College of Engineering. REMRSEC faculty collaborate closely with scientific staff at the National Renewable Energy Laboratory (NREL) and also with Center for Revolutionary Solar Photoconversion (CRSP), a research center of the Colorado Renewable Energy Collaboratory, which involves NREL and Colorado universities in an industrial consortium with approximately 15 companies with business interests in alternative energy technology [6], [7]. The center consists of two Interdisciplinary Research Groups (IRGs):

- Photovoltaic IRG: Specializes in research and development of future generations of photovoltaic and opto–electronic materials.
- Advanced Membrane IRG: Emphasizes micro–structural design of ion–transport membranes and composite membranes with improved stability, operational range, impurity tolerance, and transport efficiency and selectivity.

To support the research missions of REMRSEC and these IRG's the REMRSEC REU solicits exceptional undergraduate students to participate in a ten–week summer interdisciplinary summer research program focused on material science issues related to renewable energy. While the delivery of a high–quality research experience, which increases student interest in renewable energy fields, is a primary goal of the REMRSEC REU, a secondary goal is to increase the participation of underrepresented groups. Table I provides demographic data for all participating students, NSF funded or otherwise, during the 2011 and 2012 cycles. These data show the existence of a socially diverse undergraduate collective that when coupled to the 40–50 CSM faculty and staff forms an ad–hoc community for the duration of the REU.

In addition to their involvement in research projects led by CSM/NREL faculty and staff, the REU students are asked to attend various functions focused on professional, academic and communal development. Table II provides a listing of the events and their frequency associated with the 2011–2012 cycles. The goals of the aforementioned programmatic elements are to provide a construct in which students gain a breadth of understanding on post–baccalaureate opportunities in the field of renewable energy science and also the professional tools for successful pursuit of them. That said, the overarching theme of all program elements is the bringing together of members of the ten–week ad–hoc community. That is, beyond their proposed function, they are social in nature. This was noticed

by REU programmers and led to several post–pilot changes emphasizing communal engagements, which are reflected in the programs evaluation plan.

III. THE EVALUATION: CORE SEP

During 2011–2012 the author participated in Phase I and Phase II training offered by the Cornell's Office for Research on Evaluation (CORE) Evaluation Partnership (EP) sponsored by the Cornell University Cooperative Extension and the NSF. The EP seeks to develop and extend the capacity to make good choices about evaluation, which will ultimately lead to improved programs, and facilitates this with in–person and web–based training on their System Evaluation Protocol (SEP) [8]. The SEP is a standard procedure that an assessor uses to construct a thoughtful evaluation plan for arbitrary systems (Phase I) and implementation methodologies (Phase II). The result of application of CORE SEP to a system yields a logic diagram, consistent with stakeholder opinions, that connects activities to clear, specific and measurable short/medium/long–term outcomes. This informs the creation of sensible evaluation questions and data collection strategies for various time–scales that triangulates the affect of a program on its participants.

The emphasis of CORE SEP is on program modeling. The CORE SEP is organized into three broad phases which are further subdivided into smaller stages:

- Phase I (Evaluation Planing): Stage 1 – Preparation, Stage 2 – Modeling, Stage 3 – Evaluation Plan creation
- Phase II (Evaluation Implementation): Stage 1 – Implementation Preparation, Stage 2 – Data Collection and Management, Stage 3 – Data Analysis
- Phase III (Evaluation Utilization): Stage 1 – Reflection and Plan Revision, Stage 2 – Reporting

A more detailed discussion of the application of CORE SEP Phase I to REMRSEC REU can be found in our previous work [9]. In summary, the program evaluator interviews key stakeholders and from their input constructs a rough outline of the overall program. This outline is then distilled into a *logic model*, a set of activities and outcomes central to the stakeholder view of the program that, when supplemented with interdependencies, creates a *program pathway model*. A pathway model is a visual representation of the program and informs the evaluation by highlighting critical programmatic elements relevant to a programs current life–cycle. The SEP logic and pathway models for REMRSEC REU are given in Figures 1 and 2, respectively. On the logic model we see a listing of program elements, as gathered from the stakeholders, with the condition that activities must lead to short–term outcomes, which then lead to medium–term outcomes and so on.

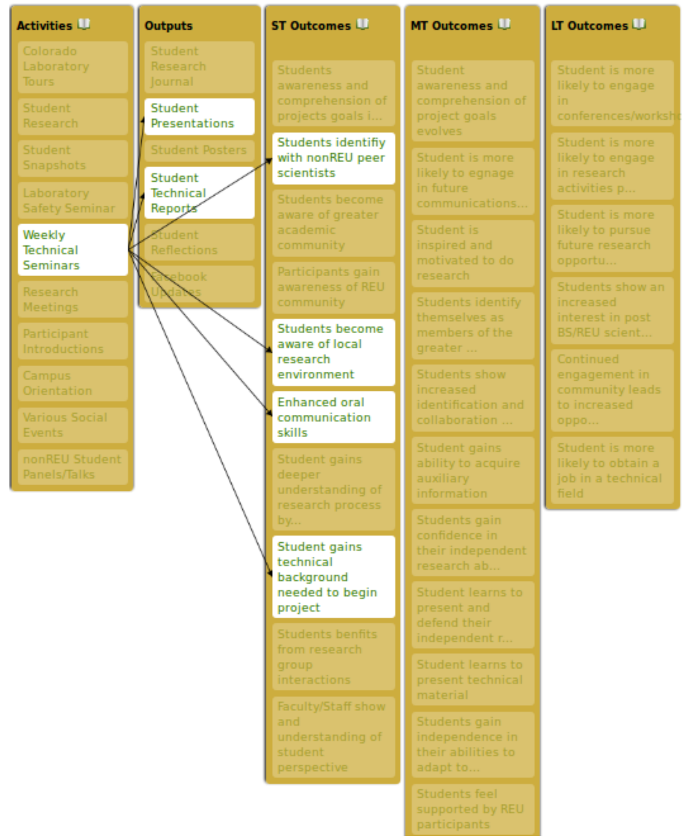

Fig. 1. CORE SEP Logic Model of REMRSEC REU

Through the Evaluation Netway (EN), a web–based utility created in conjunction with the EP, a system of interconnections can be made, which is highlighted in Figure 1 where we see that the Weekly Technical Seminars influence several student outputs/deliverables as well as some initial outcomes. Once this data is encoded, the EN can generate a Pathway Model, see Figure 2. While the interconnections/arrows may be somewhat difficult to untangle, the EN groups program elements based on causal relationships and what results is visually distinguishable paths that connect elements with thematic commonality.

In the case of REMRSEC REU there are two dominant paths, which we will call an upper–path and lower–path. The lower–path begins with activities such as laboratory training, student research and research meetings. That is, they are all academic in focus and are natural precursors to the stated medium–term outcome, "Students gain independence in their abilities to adapt to evolving research," which is related to a high–quality REU experience. However, what we also see in the pathway model is that this outcome is related to several other activities that generate an upper–path. In this upper–path we see that various social aspects, some of which are academic in nature, of the REU community lead to participants identifying with each other as well as a broader community of renewable energy scientists. It was the existence of this upper–path that evolved the REMRSEC REU evaluation, in 2011, to include methodologies that would help the evaluator better understand the effect of communal interactions on student attitudes.

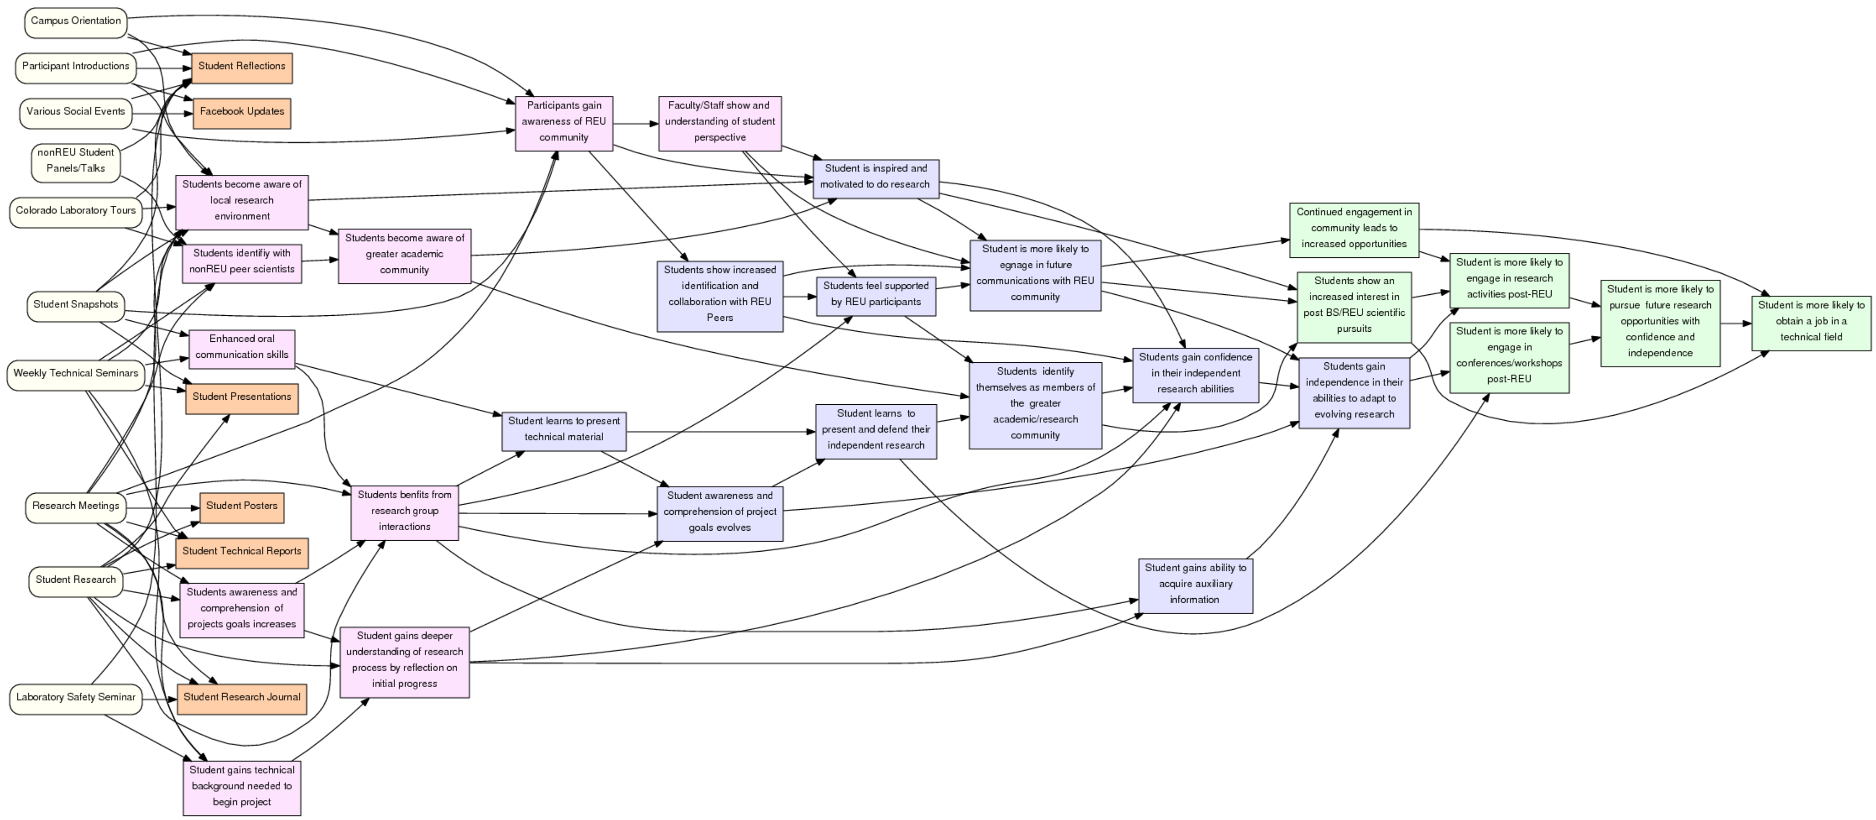

Fig. 2. CORE SEP Pathway Model of REMRSEC REU (Color Online): White represents activities, orange represents outputs generated by participants, pink are short–term outcomes, blue are medium–term outcomes and green are long–term outcomes.

A. Evaluation Implementation: 2011

In 2011 the author in conjunction with EP training in the CORE SEP created an Evaluation Plan for REMRSEC REU that exposed the existence of a pathway of outcomes which are nontrivial factors in facilitating independence in undergraduate research. This pathway starts with activities that are social in nature and are felt to lead to participants who increasingly identify renewable energy scientists as professional role models. It is expected that these attitudinal changes combined with suitable research training contributes to long–term outcomes associated with the placement of students in renewable energy fields post–baccalaureate. The success of the lower–pathway associated with those outcomes related to a high–quality research experience have been well–studied during the REMRSEC REU pilot phase, 2009–2010. The 2011 evaluation implementation sought to solidify these findings and move towards evaluating outcomes associated with communal activities. To this end we posed the following evaluation questions on the topic of community:

a. How do REU participants characterize/describe their experience in their CSM research group?
b. What is the effect of CSM research group interactions on the students research experience?
c. How does the frequency and/or quality of research group meetings relate to the students attitudes about research?
d. How does the frequency and/or quality of research group meetings relate to the students research experience?
e. How often do REU participants interact with their peers throughout the duration of the program?
f. What is the nature of the peer–to–peer REU participant interactions, i.e. voluntary or mandatory, professional or personal?
g. To what extent are REU students identifying with each other?
h. To what extent are REU students identifying with the local scientists?

To answer the previous evaluation questions we have chosen four measures. Currently, not all of the measures are fully implemented. However, we provide a detailed explanation of each in the following and conclude this section with a description of their 2011 implementation.

1. Frequency Charts: Student engagement can be characterized by the quantity and quality of their various interactions. These interactions form a shared construct for multiple evaluation questions. We plan to quantify these interactions through the use of frequency charts, which will be taken to measure student–student and student–research group interactions. In detail, we plan to have a third–party record types and frequency of interactions during social engagements and a have a group member do the same for research engagements. This, which will partially address evaluation question (e).
2. Internal Surveys: If the frequency charts are meant to measure the quantity of student interactions then the internal surveys are meant to measure their quality. We will survey key members of the students research group to characterize the perceived attitude towards and independence of student research. Specifically, we will ask these research group members how their interactions with a student contributed to the completion of a given task. This measure, will address evaluation questions (b) and (f).
3. Student Journals: In order to triangulate these previous measurements we will ask students to keep journals chronicling their REU experience. Prompts will be supplied to encourage student self–reporting consistent with the evaluation questions. These journals will then be sampled periodically and analyzed for important statements, themes and use of technical vocabulary. Of particular importance will be responses concerning evaluation questions (a)–(d) and (f), which can be compared against data from measures #1 and #2. However, the information found within the journals will go beyond these evaluation questions giving the REU organizers deeper insight into the student experience, which will be invaluable to future incarnations.
4. External Survey: The first three measures are primarily concerned with determining the nature of the dynamic REU experience as seen through peer/mentor interactions, student attitudes and research abilities/achievements. The Student Assessment of Learning Gains (SALG) is a standard online post–measurement evaluating student outcomes of REU. This self–report will end–cap the REMERSEC REU and provide both qualitative and quantitative data that will be used to both determine the REU outcomes as well as provide comparison to measures one through three on evaluation questions (b)–(d) and (g).

The 2011 cycle saw the implementation of measures #2 and #4 as well as aspects of #1 and #3. Our current goal is to further explore measure #3 because of its ability to provide rich and textured information. In conjunction with these mixed–method measurements, the evaluator was introduced at the start of the REU and attended several REU functions. For the most part these functions were driven by survey administration and interaction observation. Beyond this "presence" the evaluator attended a purely social function early on in the REU timeline. In the 2012 implementation, many of these measures would be used again but everything would take place in a purely digital format.

B. Evaluation Implementation: 2012

In the 2012 cycle the REMRSEC REU Evaluation would take a slightly different evaluation and because of this we can attempt to understand how evaluator role affects an evaluation. Specifically, this implementation saw continued use of measures #2–#4 from the 2011 cycle but now all data acquisition was handled electronically and the evaluator was known to the participants only digitally. Interestingly, that this comparison can be made is because of both a role change in the evaluator and the REMRSEC REU participants.

The evaluations conducted from 2011–2012 acquired a vast amount of data, some of which is still being processed. In the following we offer a snapshot of some simple data that motivates further discussion of evaluator role and effect. Later, in Section IV, we compare these data and offer some interpretation before discussing the implications on future evaluations. First, however, we summarize some results from the SALG standardized post–test in Table III where we see that, with the exception of response rate, students responded roughly the same, to questions about both their research and social experience from 2011 to 2012. In terms of response rate

TABLE III. STUDENT ASSESSMENT OF LEARNING GAINS: 2011–2012

	2011	2012	%–Δ
Response Rate	57%	35%	−39%
The research experience overall (4–Excellent, 1–Poor)	3.5	3.57	+2%
Pursue graduate study in materials science or engineering? (5–Extremely More Likely, 1–Not More Likely)	3.35	3.57	+6.6%
Overall program organization or logistics (4–Very Satisfied, 1–Very Dissatisfied)	3.21	3.43	+6.9%
Group social activities (4–Very Satisfied, 1 – Very Dissatisfied)	3.07	3	-2.6%
Average % (Total): Here a percentage is given where 100% would indicate a completely favorable view, on average.	79.1%	82.1%	+3.2%

TABLE IV. REMRSEC PRE/POST TEST RESPONSE DATA: 2011–2012

	2011	2012
Average Words Used Per Pre–Test: Q1	71.3	67.2
Average Words Used Per Pre–Test: Q2	55.2	58.6
Average Words Used Per Pre–Test: Q3	43.1	58.2
Average Words Used Per Post–Test: Q1	36.3	41
Average Words Used Per Post–Test: Q2	30.5	32.3
Average Words Used Per Post–Test: Q3	27.6	22.5
Percent Response Pre–Test	100%	85%
Percent Response Post–Test	66.7%	40%

TABLE V. BI–WEEKLY STUDENT UPDATES (STUDENT JOURNALS): 2011–2012

	2011	2012
First Collection Response Rate	61.9%	82.5%
Second Collection Response Rate	52.3%	77.5%
Third Collection Response Rate	52.3%	71.6%

we see a dramatic decrease from 2011 to 2012. Turning our attention now to Table IV we consider a comparison between a pre–test and post–test given to the students concerning their perceptions of scientific research. In particular we asked students to respond to the open–ended questions:

i. Describe what academic research is and what academic researchers do.
ii. What skills and resources are needed to successfully conduct academic research?
iii. What skills and resources do you possess that are aligned with those needed to successfully conduct academic research?

With these data we consider both the response rate as well as the average response length. The results of this are recorded in Table IV. Lastly, we consider the response rate associated with responses to three prompts given to participants for their journals:

I. Describe your current understanding of your research project.
II. What are your goals, associated with your research project, for the next two weeks.
III. What are you planning on doing to meet these goals?

Responses were gathered three times throughout the course of the REU. The response frequency is recorded in Table V.

IV. DISCUSSION AND CONCLUSIONS

Considering these data from Table III–V we notice a significant drop in response rate during the course of each REU. We expect that there are two reasons for this. First, as students get farther along in the REU they become more invested into their own research and less interested in program evaluation. Second, as surveys become repetitious, a certain fatigue sets in an consequently response rates drop. That said, a comparison between the two data sets shows:

- Table III indicates that while the overall response rate is dramatically lower from 2011 to 2012, responses concerning participant overall experience were roughly the same.
- Table IV shows that the response rate again favors the 2011 implementation, by 20.9%, while at the same time the 2012 participants tended to be a few words more verbose.
- In contrast to the two previous response rates we have data from Table V, which shows that the total number of 2012 participants in student journaling greatly exceeded those in 2011 by an average difference of 21.7%.

These data show that respectable response rates are possible through purely digital methodologies but, at the same time, there is not overwhelming evidence to conclude that evaluator presence is the dominant factor in low response rates. This does not preclude the notion that the evaluator facilitates participant response and it could be that a lack of communal engagement contributed to the substantial decrease in response rate for the 2012 post–test. In order to better understand this effect, the 2013 evaluation implementation will by a hybridized version of previous implementations. Specifically, we plan to introduce the evaluator at the onset with a brief discussion of evaluation plan/implementation and its purpose. After this the evaluator will again assume an entirely digital presence but facilitate increased collaboration and community through the use of web–logging tools. Journals will be collected digitally and anonymous content will be posted which, we hope, generates increased interest and relevant discussion points. This evolution of evaluator role can be characterized in terms of Patton's taxonomy pgs. 128–129 [5]:

- 2011 Cycle [Roles 5,7]: A collaborative evaluation facilitator who is available and involved reporting to diverse stakeholders and program staff.
- 2012 Cycle [Roles 2,3]: A investigative researcher who is independent and appealing to funders and academics.
- 2013 Cycle [Role 8]: A empowerment facilitator who is a resource person to program participant and community members.

Essentially, we hope to realize, in the 2013 implementation, an evaluator role that non–invasively facilitates participant self–reporting and is largely independent of program context. If such a role can exist then it is believed that the goals of CORE EP can diffuse more rapidly into the STEM disciplines.

ACKNOWLEDGMENT

The author would like to thank the NSF who supports this work through grants DMR–1063150, 0820518 (CSM REMRSEC) and DRL–0814364 (CORE EP).

More Graph Comparison Techniques on Mind Maps to Provide Students with Feedback

Peter Jamieson

Abstract—**One of the limiting aspects in education research is the techniques available for determining if a student has learned something. In this work, the goal is to extend our exploration of how mind maps can be automatically analyzed using their graph properties to reflect student learning. In particular, a set of student mind maps are created three times during a class in both 2011 and 2012 on digital system design using a common technical vocabulary. These mind maps are analyzed by extracting graph metrics by comparison with a criterion mind map, which is an expert created mind map. The metrics are derived from traditional graph metrics (average degree and graph density), three sets of difference metrics analyzed with a internally created tool, and a graph metric invented for comparing proteins. The results of this exploratory analysis is that five of the six metrics can be used to evaluate if a student is learning and connecting the vocabulary in a given subject over time. Additionally, these five metrics are correlated to one another. This result is promising, but we emphasize that these metrics do not correlate directly to class performance based on student grades over the course, and therefore, the current goal for this measurement technique is to be used to provide the student with automated feedback on their mind maps as related to the technical vocabulary of a course.**

This work extends our original work by increasing the number of graph metrics that are used to automatically analyze student maps to a criterion map. The idea is to find a number of graph metrics that can then be combined to help analyze a students mind map and provide them with useful feedback. Even though our results show that compare 5 metrics and each metric can be used to observe student improvement, each of these metrics differs in how the metric can be interpreted and related to the process of learning. Therefore, our goal is to find a number of these metrics so that they can be combined to provide the student with a variety of feedback results to help them understand their errors in terms of the structure of their mind map.

I. Introduction

One of the limiting aspects of educational research is the techniques available for measuring if a student has learned something. Engineers and their respective research fields, however, are skilled at finding and using measurements to help improve a system. For this reason, it is the author's belief that the community might be best suited for providing more measurement tools to help in improving student learning.

Concept maps [1], [2] and mind maps [3] are useful tools in education, and they can be used both in lectures as classroom assessment techniques (CATs) and outside the classroom for the learner to express ideas in a visual form. Mind maps are words/concepts connected by lines where a line indicates a relationship between the words, and concept maps have similar structure except the connecting lines tend to have directionality (indicated by arrows) and have associated prepositional phrases that indicate how the words are related. For this work, maps are mathematically called graphs, and therefore, this research can be leveraged in the understanding and characterization of graphs to automatically analyze mind maps.

The two overarching goals are, one, to create tools so that learners can receive automatic feedback on their understanding of a topic, and two, to provide researchers with measurement tools that can be used quantitatively evaluate if an intervention is improving learning beyond existing tools such as tests and surveys. To quantify learning in a map, either the map can be evaluated by an expert, or the map can be compared to a golden map generated by an expert (also known as the criterion map). In this work, the later is used since the first of these evaluation options is very difficult for computers to perform at present. However, this work is a precursor to evaluating open maps.

Over a semester course on digital design, student mind maps were collected at three intervals during the course (course beginning, post exam I, and post exam II). These mind maps were CATs where students had 10 minutes to create mind maps that consisted of 20 technical terms, where these 20 terms are introduced throughout the semester. Each student's mind maps was then digitally encoded and analyzed using various tools. These tools calculate a number of metrics that might reflect learning including:

- A metric based on average degree in a graph
- A metric based on graph density
- A metric based on direct comparison between the two maps for missing and extra connections and words
- A metric of similarity, called Relative Graphlet Frequency distance (RGF-distance)

A more detailed description of these metrics is described including what they are, how they are calculated, and how they might relate to learning within a student's mind map.

The exploratory results show that two of these metrics are highly correlated with each other and that three of these metrics can be used to measure if a student is learning and developing a deeper understanding of the vocabulary over the time of a course. These metrics are checked for correlation

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

with student grades, but results show that correlation is low and not statistically significant. This is, likely, due to the fact that course grades and deep understanding of the course's vocabulary are not closely related in the chosen course, and a student can perform well in this course independent of vocabulary knowledge.

Some of these ideas were first presented last year at FIE'2012 [4]. This work has been extended to include more data as well as more graph metrics of comparison. The analysis presented in this work shows only the 2012 subjects as the conclusions from the analysis are roughly the same for both 2011 and 2012.

The remainder of this paper is organized as follows. Section II reviews scoring techniques and technical vocabulary. Section III introduces the metrics of measurement in more details and relates how these metrics might be related to student understanding in a mind map. Section IV describes the experiment, and Section V shows results. Finally, Section VI concludes the paper and suggests future work.

II. Automated Map Scoring and Technical Vocabulary

As a precursor to automated map analysis, various methods of scoring a map have been proposed by researches, and a brief list of scoring methods in the literature include the following:

- Concept map - count the number of valid propositions, levels of hierarchy, examples, and crosslinks [1] where weights can be introduced to each count ([5], [6])
- Concept map - a measure of *hierarchiness* which relates hierarchy in the map [7]
- Mind map - compare the scores on tests to the technique [8]
- Concept map - the more important a concept, the closer it is to the top of the tree [9]
- Mind map - have two independent experts score (sometimes with a rubric) the mind map on a scale two times with one week delay and compare correlation of ratings [10]

The scoring of maps has been challenged by many researchers in the literature [11], [12]. Kinchin and Hay [13] criticize the shortcomings of strict scoring of concept maps as a motivation to propose qualitative analysis of maps. Interestingly, one of their key contributions in this qualitative approach is looking for *spoke*, *net*, and *chain* like structures in a map, and these structures are internal graph structures that are captured by what will later be described as graphlets.

Early attempts at automating the analysis of maps and providing feedback focused on hint like mechanisms. A criterion map (called a scaffold in these works) provides student creators with hints for their maps on what is missing and what does not belong [14], [15]. Conlon [16] built a system that used Novak's scoring mechanism and other artificial intelligent concepts to build an open concept map creation system that provided feedback to students. Our goal is study modern graph analysis tools for similar purposes.

A. Technical Vocabulary

In our previous work we reviewed what mind maps and concept maps were and how these maps can be classified and evaluated. For the sake of space we guide the reader to our previous paper [4].

A body of work has focused on the vocabulary and its importance to reading and learning. In this work, there is no attempt to cover this literature, but we provide a short discussion on technical vocabulary. Nation [17] and Coxhead [18] report that the technical vocabulary in a field consists of approximately 5% of the words used in related publications. Chung *et. al.* [19] elaborate on the calculation of this number. Technical vocabulary is more specific than academic vocabulary, and a number of researchers have investigated the impact of specificity and academic vocab on student learning [20], [21], [22], [23].

Though there is a connection between concept and mind maps to vocabulary, there is a limited number of research papers that link or research the combination in any major detail. Beyer *et. al.* [24] describe there work of using concept maps to help new teachers learn and understand the technical vocabulary of education.

III. Graph Analysis and Relation to Learning

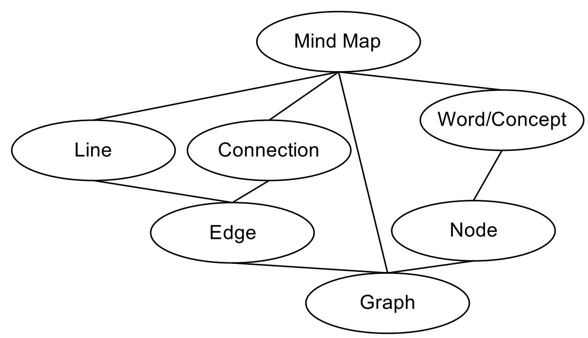

Fig. 1. Example of a mind map on the relationship between mind maps and graphs

Mind maps [3] are a visual tool that can be used to represent the connections between a number of concepts. Figure 1 shows an example mind map that expresses the author's understanding of mind maps and how they relate to mathematical graphs. The words/concepts that are in a mind map are the nodes of a graph (circled bubbles), and the connecting lines between these words are called the edges of a graph. Mind maps are classified as undirected graphs, which means that the edges do not have a direction, normally indicated by an arrow. In the rest of this section, the graph metrics are discussed including some discussion on why and how each metric captures student understanding. Note that mathematical formulas and definitions are provided in graph notation, but the reader does not need to understand this notation to understand this work.

The first metric is related to *average degree*. The degree of a node is the number of adjacent nodes, or the number of edges that connect to other unique nodes. For example, in figure 1 the degree of the "Mind Map" node is 4 and the degree of the "Connection" node is 2. The average degree is the total number of edges ($|E|$) divided by the total number of nodes ($|V|$). For this example, the graphs average degree is 9 divided by 7 or, approximately, 1.29. The greater this metric, the more connections on average a node has to other nodes. To make this into a metric of comparison against the criterion map, the following equation is used:

$$AverageDegreeSimilarity = \frac{AverageDegreeStudent}{AverageDegreeCriterion} \quad (1)$$

The *density* of a graph is defined as the total number of edges ($|E|$) divided by the maximum number of edges that a graph could have ($.5*|V|*(|V|-1)$). For the graph in figure 1, the maximum number of possible edges is 21 and the number of edges is 9, so the density is 9/21 or, approximately, 0.43. The greater this value, to a maximum of 1, means the more connectivity between the nodes within a graph. A value of 0 means there are no connections, and a value of 1 means the graph is a fully connected graph. This metric of comparison is similar to the previous and follows:

$$DensitySimilarity = \frac{DensityStudent}{DensityCriterion} \quad (2)$$

These first two metrics are measures of how much connectivity there is between the two compared graphs. In terms of relating this to mind maps, the hypothesis is that the more connected a mind map is then the more tightly related the topics are. Comparing student maps and criterion map based on how close the metrics are to one another is an expression of similar global connectivity. The problem, however, is the structure of the mind map is not captured with simple metrics and students might be making wrong connections that somehow make the comparative metrics more equal. Similarly, if a map varies between densely connected areas and sparsely connected areas, then the density and average degree metrics do not capture this and only show the average connectivity.

The third metric is a edge by edge comparison between the student mind map and the criterion map. Since the nodes in both graphs are identified uniquely by a label (the word that the node represents is the unique label), the two graphs can be compared in linear time and record statistics about the missing edges ($MissE$), missing nodes ($MissN$), extra edges ($ExtraE$), and matching edges ($MatchE$) for the student map compared to the criterion map. If the two graphs are the same, then these statistics will show this since all edges will match and nothing will be missing. These statistics are combined in the following equation:

$$GranularSimilarity = \frac{MatchE}{MissN + ExtraE + MatchE} \quad (3)$$

The idea of this equation is it is a number that has the value between 0 and 1 where the closer the value is to 1 means that there are less missing and incorrect edges. At present, missing nodes are not included in this equation, but it might be added to the denominator to decrease the similarity factor.

The last metric in this exploration is the RGF-distance, but before defining RGF-distance, graphlets are introduced. Graphlets, formally, are "a connected network with a small number of nodes" [25] and these small graphs are non-isomorphic induced subgraphs of a larger graph. Figure 2 shows all the graphlets of size 2, 3, and 4. Note that the graphlet of size 1 is a single unconnected node and is not that useful.

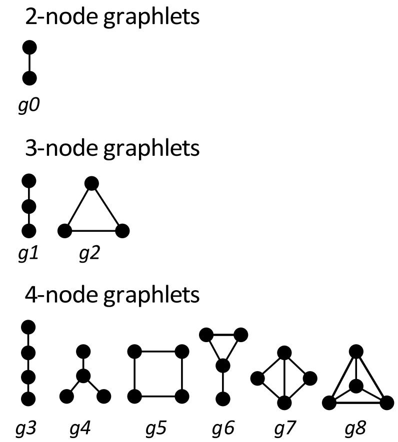

Fig. 2. Graphlets of size 2, 3, and 4

The power of the graphlet is how it can be used to analyze a graph. The procedure developed by Przulj *et. al.* [25] is to search for all graphlets of size 3, 4, and 5 in a given graph. Based on the count of each type of graphlet, a signature is constructed in the form (g1, g2, g3, g4, g5, g6, g7, g8, ..., g28, g29), where g1 is number of the first type of graphlet of size 3 shown in figure 2 and g29 is the count for the last graphlet of size 5. This signature can be compared to another graphs signature to get a measure of similarity, and Przulj *et. al.* used their technique to compare graphs representing biological structures such as proteins.

RGF-distance is a measure of the difference in frequency of graphlets of g1, g2, g3, ..., g28, and g29 appearing in the two graphs being compared. A detailed equation is presented in Przulj *et. al.* [25] and the reader can find the details on the calculation of RGF-distance. The reader should understand that GraphCrunch II will calculate this metric, and the smaller this metric gets means the more similar the two graphs are.

A. Hypotheses on How each Comparison Metric Relates to Learning

Given each of the metrics described above, a set of hypotheses are made to why each metric might capture student understanding in a mind map. Note that it is not expected that any of these metrics can perfectly quantify learning, and the order in which they are presented relates directly to our hypothesis on which metric is, likely, the best choice for measuring learning.

The $AverageDegreeSimilarity$ is a connectivity metric that extracts how much connectivity is in the graph on average for both the student and expert generated mind maps. Considering the student mind map, then there are three situations that might emerge as it relates to the criterion map: under-connected, over-connected, and equally connected. In all cases, the average connectivity reflects a student understanding of how the words are related to each other as measured by an average, but this metric does not extract specifics of individual connections. For example, even if this metric results in "equally connected" (a value of 1), it is possible that the two mind maps are still different, and therefore, this metric only captures a rough estimate of the similarity between student and expert. Note, neither over-connected nor equally connected occurred in the results.

$DensitySimilarity$ is a similar measure of connectivity compared to the first metric. It captures a rough measure of student understanding for the same reasons as described above. In both cases, if these two metrics are considered as feedback tools to a student, then a student might just add or remove edges in their mind map until the metrics equaled one. This is not a true reflection of understanding.

The $GranularSimilarity$ metric is created based on an edge to edge comparison between two mind maps, and the breakdown of the metric (as in the instances where an edge is missing or is not needed) would be useful for giving direct student feedback. As a single combined value, the metric reflects a measurement of learning in terms of correctness divided by errors. Both the correct and incorrect edges are valued in terms of one-to-one matching where the measurement reflects how many one-to-one connections have been made correctly. This metric, hypothetically, is better than the previous two, but it does not reflect deeper ideas where the connectivity of a number of words suggests deeper understanding of how these ideas are interrelated.

Finally, $RGF - distance$ captures the comparative structure of two graphs, and in terms of comparing student mind maps to the criterion map, the hypothesis is that the lower the RGF-distance means that students better understand the relationships between concepts/words since their maps have more similar structure compared to the expert's criterion map. Consider the G2 graphlet; this graphlet is a triangle that shows the interconnection between three words, which is a deeper level of understanding then knowing that their is a one-to-one mapping between these words.

IV. Semester Mind Map Experimental Setup

For this work, the goal is to analyze student created mind maps over a semester long course and test the respective metrics to see if they quantify how these students are learning the course vocabulary. The focus course for this experiment is a digital design course offered at the 200 level. The course starts with how transistors can be organized to make basic Boolean gates and ends with designing finite state machines using a hardware description language (HDL). From a perspective, the most challenging aspect of the course for most students is the application of HDLs to design hardware as this design language differs significantly from sequential programming languages that students are much more familiar with. However, mind maps only play a small part in understanding how to use HDLs.

These mind map experiments are on closed mind maps. Specifically, a list of 20 technical terms are provided that are introduced in the course. The list consists of 20 terms introduced over the course, but the displayed words are randomized when the students see them.

During the second lecture in the course, mind maps are introduced using an illustration of constructing mind maps for countries. It is demonstrated how a mind map can be constructed differently depending on if we are treating it as about geographical location, oil supply, or military alliances and enemies. After this basic training, the list of 20 terms is shown and the students have 10 minutes to create their first mind map. This is repeated after exam I and exam II with the same terms and the same amount of time. This means each student who has chosen to participate (IRB approved protocol allowed students to remove their participation agreement any time in the semester before final marks were released) could have created up to three mind maps over the semester.

V. Experimental Results

Three mind map exercises are done over a semester to compare the metrics and analyze how they can measure learning based on three questions. First, do any of these metrics have a strong correlation to grades? Second, is there any correlations between the metrics themselves? Finally, in the last section, how do the metrics change on a per student basis over time as a reflection of learning?

A. Metrics Correlation to Grades

The first hypothesis is that vocabulary understanding measured by the proposed graph metrics will have a correlation with grades.

TABLE I. Correlation results between comparison metrics and grades

	Correlation Values			
Metric	Exam I	Exam II	Exam III	Final Grades
	$AverageDegreeSimilarity$			
Pre	0.04	0.04	0.14	0.22
Post Exam I	0.03	0.04	0.04	0.01
Post Exam II	0.02	0.18	0.04	0.04
	$DensitySimilarity$			
Pre	0.01	0.10	0.05	0.21
Post Exam I	0.02	0.00	0.19	0.06
Post Exam II	0.01	0.12	0.09	0.04
	$GranularSimilarity$			
Pre	0.07	0.23	0.07	0.25
Post Exam I	0.09	0.18	0.06	0.11
Post Exam II	0.05	0.09	0.07	0.00
	$RGF - distance$			
Pre	0.16	0.12	0.09	0.20
Post Exam I	0.19	0.13	0.01	0.01
Post Exam II	0.11	0.19	0.13	0.06

Table I summarizes the results of the correlation data between comparison metrics and grades. The first column contains the labels for each metric calculated with the mind maps from Pre, post Exam I, post Exam II. Columns two through five contain the correlation coefficient calculated between the comparison metric and the students grade on Exam I, II, III, and their final grade. The bold values are statistically significant for $p < 0.01$ where the populations are n = 41 for Pre, n = 39 for post Exam I, and n = 36 for post Exam II (two-tailed test).

From these results, there are no statistically significant points. In general, we state that there does not appear to be a strong correlation between the comparison metrics and grades. These results suggest there might be some deeper connection that might need more investigation if the technical terminology is directly related to course grades.

Since the course studied does not have a strong dependence on technical vocabulary and is graded based on the performance of the students in designing and solving problems, we don't think there should be a strong correlation. However, we are, presently, looking at other courses where there is a stronger connection between grades and understanding of technical language to see if there is stronger correlation between our metrics and grades.

B. Correlation between Comparison Metrics

In this section, the question is how do the different measurement metrics relate to one another. Earlier discussion described how average degree and density are similar graph metrics in terms of connectivity. Here, any close relationships between all the metrics is explored.

Table II shows the correlation of each of the four metrics to each other as compared based on the same mind map creation time. Column 1 contains the time when the mind map was created, and columns 2 and 3 contain the label of the measurement metric being compared. Finally, the last column contains the correlation value where bold values indicate the correlation is statistically significant for $p < 0.01$. The population values are the same as the previous analysis.

The results show that there are a number of statistically significant correlations, but to consider that two metrics are closely related to one another we would expect correlation over all three time points. This happens in the three way relationship between $AverageDegreeSimilarity$, $GranularSimilarity$, and $RGF - distance$, which suggests that these three metrics are capturing similar results.

C. Per Student Metric Analysis

Since there is no strong correlation between grades and our comparison metrics, quantifying learning might be viewed from the perspective of an improvement in individual performance. In this analysis section, we plot the metrics for each student's map over time with the hypothesis that the metric will change for the better as the student progresses and learns in a course. Since there is a significant amount of data for this analysis, we will only show students who finished our course with a grade between 80% and 90% who did all three mind maps (n = 15 students). These results have similar behavior for all students in the class and demonstrates some interesting trends.

Before looking at the results we must make an assumption to interpret them. The assumption is that students will, on average, create mind maps that are more similar to the criterion map as the course progresses. This assumption is debatable, but from our qualitative experiences with student mind maps we believe this assumption is true.

Figure 3 shows the four graphs, one for each comparison metric, plotting a line that represents a students performance over time related to the respective metric. In each case, the x-axis is time in terms of when the mind map was created (Pre, Post Exam I, and Post Exam II), and the y-axis is a scale for the respective metric. The values on this scale on not very important, but we briefly describe how the change of a metric reflects improvement relative to the criterion map. In other words, how should the metric change to show that the student mind map is more similar to the criterion map. For $AverageDegreeSimilarity$ and $DensitySimilarity$ plots (upper left and lower left in Figure 3) an improvement in understanding happens when the metric approaches 1, but the value can be greater or less than 1 since the metric is a ratio between student and criterion maps. For $GranularSimilarity$ plot (upper right in Figure 3), an improvement in understanding happens as the metric approaches 1 (where the value can only be less than 1). Finally, for $RGF - distance$ plot (lower right in Figure 3) an improvement in understanding happens as the metric decreases in value.

Of the four metrics, the two plots for $GranularSimilarity$, and $RGF - distance$ show that on average these students are learning as the students respective metric measurements show improvement. This can be observed quite clearly for $GranularSimilarity$.

$AverageDegreeSimilarity$ and $DensitySimilarity$ do not follow this clear pattern of improvement, and from the results, we conclude that this metric do not offer an easy visualization of learning. For the graph $DensitySimilarity$, it appears that the trends are random, and we can conclude that this metric, as yet, can not capture learning. On the other hand, $AverageDegreeSimilarity$ has some trends (and as previously shown, correlates to the good metrics), and therefore, this metric should be further studied to be used as one way of reflecting improvement.

Another interesting observation from the two most appropriate graphs for visualizing learning ($GranularSimilarity$, and $RGF - distance$) is the shape of a students line. In some cases, the student has made a more similar mind map compared to the criterion map after exam I then to after exam II, and this might be phrased as the student seems to have lost some of their knowledge. For example, student 12_11 and 12_37 show this behavior. Their are a number of hypotheses that could be made. For example, the mind maps created after exam II included more vocabulary, which the student was unsure how to connect with previous vocabulary. This is a question for future work.

VI. Discussion and Conclusion

The last analysis shows that three comparison metrics can show that a student is learning the technical vocabulary from automated analysis. However, as discussed in earlier sections we believe that both the $GranularSimilarity$ and $RGF - distance$ metrics are the most useful in terms of giving students automatic feedback about the quality of their mind maps and as a visualization tool it seems clear that $GranularSimilarity$ may be the best visualization tool.

From the perspective of using this tool in educational research, at present the three metrics can be used to provide a true/false answer on whether a student's understanding of concepts as reflected by their mind maps has improved. As of yet, there is no quantity that can be associated with this improvement as in percentage improvement. In the future, as we increase the data sets and improve these metrics, we may be able to provide such quantities. At present, though, we believe that these techniques should be used to validate if students are improving, but these techniques should neither be used for

TABLE II. CORRELATION BETWEEN METRICS

Time	Metric 1	Metric 2	Correlation
Pre	$AverageDegreeSimilarity$	$DensitySimilarity$	0.27
Post Exam I	$AverageDegreeSimilarity$	$DensitySimilarity$	**0.86**
Post Exam II	$AverageDegreeSimilarity$	$DensitySimilarity$	**0.95**
Pre	$AverageDegreeSimilarity$	$GranularSimilarity$	**0.58**
Post Exam I	$AverageDegreeSimilarity$	$GranularSimilarity$	**0.70**
Post Exam II	$AverageDegreeSimilarity$	$GranularSimilarity$	**0.76**
Pre	$AverageDegreeSimilarity$	$RGF - distance$	**0.82**
Post Exam I	$AverageDegreeSimilarity$	$RGF - distance$	**0.84**
Post Exam II	$AverageDegreeSimilarity$	$RGF - distance$	**0.83**
Pre	$DensitySimilarity$	$GranularSimilarity$	0.07
Post Exam I	$DensitySimilarity$	$GranularSimilarity$	**0.56**
Post Exam II	$DensitySimilarity$	$GranularSimilarity$	**0.73**
Pre	$DensitySimilarity$	$RGF - distance$	0.11
Post Exam I	$DensitySimilarity$	$RGF - distance$	**0.66**
Post Exam II	$DensitySimilarity$	$RGF - distance$	**0.83**
Pre	$GranularSimilarity$	$RGF - distance$	**0.59**
Post Exam I	$GranularSimilarity$	$RGF - distance$	**0.64**
Post Exam II	$GranularSimilarity$	$RGF - distance$	**0.63**

formal assessment of grades nor a quantitative value of how much has been learned.

A. Conclusion

In this work, an exploration of the value of four comparison metrics was studied that could be used to automatically analyze student's mind maps compared to an expert's criterion mind map. Each of these metrics was described including how they might be related to learning. Student mind maps were analyzed from a class to understand if these metrics provide any useful measurements.

The results show that there is no strong correlation between grades and any of the metrics. Additionally, there is some relation between all of these metrics as shown by correlations between them. Most importantly, it was observed how these metrics change over time on a per student basis. These results suggest that three of these metrics, $AverageDegreeSimilarity$, $GranularSimilarity$, and $RGF - distance$ can be used to determine if a student is improving their understanding of the relationships between vocabulary.

For future work, we are extending this experiment to other disciplines and their respective courses as we can find interested faculty members. In this process and with our new matching metric, we have learned that one of the key issues for further research is how to select the technical vocabulary to include in an experiment. Our plan is to further investigate this question and learn to provide a good methodology for teachers to select their vocabulary among other additional questions identified in the paper.

***Abstract*—The assessment of learning outcomes is a key concept in the European Credit Transfer and Accumulation System (ECTS) since credits are awarded when the assessment shows the competences which were aimed at have been developed at an appropriate level. This paper describes a study which was first part of the Bologna Experts Team-Spain project and then developed as an independent study. It was carried out with the overall goal to gain experience in the assessment of learning outcomes. More specifically it aimed at 1) designing procedures for the assessment of learning outcomes related to these compulsory generic competences; 2) testing some basic psychometric features that an assessment device with some consequences for the subjects being evaluated needs to prove; 3) testing different procedures of standard setting, and 4) using assessment results as orienting feedback to students and their tutors. The process of development of tests to carry out the assessment of learning outcomes is described as well as some basic features regarding their reliability and validity. First conclusions on the comparison of the results achieved at two academic levels are also presented.**

Keywords—Learning outcomes assessment, higher education, competence based education, assessment of learning, problem solving

I. INTRODUCTION

The assessment of learning outcomes is a key concept in the European Credit Transfer and Accumulation System (ECTS) since credits are awarded when the assessment shows the competences which were aimed at have been developed. ECTS is the credit allocation system for higher education used in the European Higher Education Area (EHEA), which involves all the countries engaged in the Bologna Process, 47 at this point in time. Its main role is to make higher education systems transparent and comparable, thus helping to bring to reality some crucial EHEA concepts such as mobility, student centered education, employability or educational quality among others. Most Bologna countries have adopted ECTS by law for their higher education systems [1]. In Spain, additionally, a decree passed in 2007 [2] establishes the generic competences which any student with a university degree must have developed; these include understanding basic and gradually more advanced scientific texts; problem solving; looking for, selecting and using information to solve problems or making decisions and, finally, the capacity to learn independently, all of them in the students' specific fields of study. But more generally, basing higher education on the development of key competences and measuring them is a strong international trend in higher education as, for instance, the OECD funded AHELO study shows [3].

This paper describes a study which first was part of the project of the Bologna Experts Team-Spain (http://www.expertosbet.es/) and then evolved as an independent study. It was carried out with the main goal of gaining experience in the assessment of learning outcomes and, more specifically to: 1) designing some procedures for the assessment of learning outcomes; 2) testing some basic psychometric features that an assessment device with some consequences for the subjects being evaluated needs to prove; 3) an issue of special interest for us was testing different procedures of standard setting; 4) finally, we were interested in using assessment results to give feedback on competence development to students, their tutors and the institution which holds them.

In order to achieve our goals, participants from degrees representative of different fields of knowledge (Biology, Psychology, Computing, Economy and History) were invited to take part in the study. In this paper we shall focus on the work done in the degrees of Computing and Mathematics & Computer Science. The sample of students includes 1st and 3rd year students from three different schools with a degree in computer science and we shall report specifically on one of the competences, namely problem solving at the level of university studies. We shall describe the process of development of the test and discuss some measures taken to guarantee an acceptable level of objectivity and validity of the data. Then, we shall report some results of data analyses carried out regarding results achieved at the two participating academic levels. Finally, we shall discuss our experience in the use of these procedures as well as the implications for the development of this kind of tests and its crucial role in higher education reform.

II. CONTEXT AND BACKGROUND

In the context of higher education, a competence may be understood as the combination of skills, knowledge, attitudes, values and abilities that underpin effective and/or superior performance in a professional area. In this way, when we try to assess student performance, we are interested in assessing not only knowledge, as has been the case in traditional education, but also what the student is able to do using this knowledge (and how). By how, we understand adhering to disciplinary methodological standards and values. Thus, competence or learning outcomes assessment includes the assessment of knowledge, but is not limited to it. It is normally assessed through complex, representative disciplinary tasks that imply knowledge and are often complemented with students' reflections whereby students justify the decisions they have taken on a theoretical and/or disciplinary base, and take into account their consequences or the values that inform them.

The starting point for this study were the basic transferable competences which, according to the Spanish Decree 1393/2007 [2] every higher education graduate should have developed by the end of his or her studies. They were selected since they are common to all degrees although every discipline is expected to further introduce its own particular coloring and nuances. For this reason, they were considered to be at the same time a good basis for independent work and also for making interesting comparisons related, for instance, to fairness. On the one hand, we could learn about the particularities of the assessment of learning outcomes regarding different disciplines; on the other, if the structure used for the tasks was similar, we could explore to which extent assessment criteria and standards were used in similar ways.

III. RESEARCH QUESTIONS

As mentioned above, our aim was to design assessment procedures to assess the basic competences which all graduates must have mastered by the end of their undergraduate academic life according to the Spanish law. This should be complemented by the development of assessment criteria that would allow enough objectivity when correcting and eventually grading students' work. We also tried to validate the tasks as appropriated for the measure of these basic competences in various ways.

Some additional questions arose from a pilot study performed previously to the work reported in this paper. This pilot showed to us many valuable things such as the importance of correctly wording the questions, since light nuances in language can make dramatic changes in how students understand them; how to test administrations procedures need to be very clear and strictly followed if we want to work together and compare or sum up results from different schools or teachers; or how rating criteria for open questions need to be very carefully developed if a basic level of objectivity is to be assured. As a starting point, we deeply believed in constructed responses for the assessment of competences, since they usually represent more complex tasks. However, we were also aware that open questions are more difficult and costly to rate, so we opted for a mix of both kind of questions so their results could be summed up and eventually compared. As a means to assure some basic common conditions, we also opted for computerized tests.

IV. METHOD

A. Objetive

This paper presents the process of development of a procedure to assess a transferable competence basic for learning and academic life: problem solving. It further describes how basic objectivity and validity data were assured and finally adds some results on how the two academic levels participating in the study compare. Other comparisons of interest are internal consistency of the test, as well as closed vs. open questions.

B. Development and nature of the task

In order to develop the appropriate tasks to measure in a comprehensive way the learning outcomes associated to these transferable competences, they were in the first place analyzed it their facets or components. The various questions included in the tests were then mapped on this scheme, as can be partly seen below for problem solving:

- Problem identification
- Come up with a strategy to solve the problem
- Determine additional information if necessary
- Applying knowledge needed for problem solving
- Evaluating adequacy of solution and, if not found acceptable, re-start cycle.

In the second place, computing science teachers elaborated a task to assess this competence. When designing this task we had in view that first year students should have some difficulties in solving this task but it would be easier for third year students. The goal was to measure improvement in performance when the two academic levels were compared. Of course the task should include the facets mentioned above for problem solving.

After the presentation of the problem, the task contained two types of questions: 9 open questions which implied a constructive response and 11 closed multiple choice questions which required choosing from 4 alternatives. Table I contains examples of these two types of questions.

TABLE I. SOME SAMPLES OF OPEN AND CLOSED ITEMS

Open question:	What is recursivity? What aspects should a definition of recursivity include? Or how can the concept of recursivity help in solving this problem?
Closed question:	To differentiate between an iterative system and a recursive system the key if to identify: (options a, b, c & d follow)

C. Developing scoring criteria

As a first step to develop clear scoring criteria for open questions, 2 teachers prepared the best possible response to each question, discussed them and agreed on the criteria which make a highest scoring response. Then second best, third and unacceptable responses to the same questions were described. Finally, these criteria were validated against 10 exercises from the pilot sample which were scored separately by the two judges. All disagreements were taken as a basis to refine the scoring criteria. Next, they validated the new criteria against a new sample of 20 exercises until perfect agreement was reached. These were subsequently considered expert ratings.

In this process, examples of each of the 4 alternative ratings for each open question were also selected and included along the scoring criteria.

D. Experts' judgments on content validity of the assessment task

In order to estimate the content validity of the task, it was given to experts who had to answer two questions: 1) which one of the basic competences the task measured? And 2) which facets covered by the task analysis did each questions measure? This last question was meant to address whether all relevant facets of the competence were covered by the task in a comprehensive way.

Two judges participated in this stage. Both of them were specialists in higher education and had experience in competence based education.

The results of this phase were as the follows. The judges reached a 100% agreement regarding the competences we were trying to measure by means of the test. However, one of them also mentioned other competences which we thought were marginal for the task at hand. The same was true for the facets we identified in our tasks: 100% of the facets we identified were also found by the judges who, whoever, introduced some additional ones. We can thus conclude these results essentially validate our task analysis regarding this test.

E. Administering the task to students

The student sample who took the test is described in Table II. Although the size of the sample is not very large, its varied nature should be emphasized, since it makes it more representative. However, unfortunately the size of both academic levels it is not well balanced at this point in time.

TABLE II. DESCRIPTION OF THE STUDENT SAMPLE

UNIVERSITY	Gender (N, %)		Age (mean)	Year (%)	
	Male	*Female*		*1*	*3*
UAM	n= 9 (75)	n=3 (25)	21.5	41.7	58.3
UCLM	n=21 (87.5)	n=3 (12.5)	20.21	66.7	33.3
UPM	n=26 (74.3)	n=3 (8.6)	18.31	82.9	17.1
TOTAL	N=56	N=9	20.06	70.42	29.57

F. Training human judges to rate open questions

Once the expert scoring criteria were agreed upon as described above, we needed to train the judges who would rate the students' work. Of course, this was also an opportunity to observe how objectively these criteria could be learned and used by other raters. The raters were 2 master students who, in the first place, and before any rating, answered the test in order to understand its demands. Then they started rating the same exercises used to develop the expert ratings. They first received 10 of them together with the assessment criteria they were asked to use and their ratings were compared to the expert ratings, discussing any difference that was encountered. In a second stage, they received a new set of 22 exercises and the agreement of their ratings with that of the experts was calculated using Cohen's kappa coefficient in order to remove random agreement. The process continued until the agreement was satisfactory. This was usually reached in all tests with 20 to 30 exercises.

Following this procedure, inter-rater reliability for 2 judges and 22 exercises, using Cohen's kappa [4] was found to be 0.497. The SPSS statistics software was used for the calculation of this coefficient. According to Landis and Koch [5], we can conclude this is a moderate level of agreement.

Once a fair level in the objectivity of ratings was achieved in this way, the judges were given the exercises of the whole student sample. Throughout the whole grading process, they were aware of the fact that some exercises, unknown to them, were randomly distributed to all judges and their reliability was being continuously monitored.

V. DATA ANALYSIS

A. Open and closed questions and total score

As mentioned, the test consisted of a section with constructed or open questions (OQ) and another one with closed or multiple choice questions (CQ). The total score of the test is the sum of the two parts. The maximum score for the whole test is 38. The mean and standard deviation for the two academic levels are shown in Table III.

Constructed response items, or OQ, seem to reflect better the nature of the competences but they are also more costly to score in a reliable way. So, it was interesting for us to compare the OQ with the CQ and find out what each of them adds to the whole test. The OQ section includes 9 open questions which may be valued 0-3 by human judges. So, the maximum score is 27 and the minimum 0. Regarding the CQ section, it contains 11 questions with 4 alternatives with a value of 1 each; the maximum score is thus 11 and the minimum 0. Table III shows the results we found for our sample.

As can be seen these means increase from the 1st to the 3rd year, but in both cases leave ample space for improvement, especially in the case of the OQ and Total scores. Moreover, there is an indication that OQ would seem to be more difficult, since their mean is far from the mid-point of the score range (19), while the CQ questions seem easier since they come somewhat closer (6). However, this question will have to be postponed to more specific item difficulty analyses.

TABLE III. RESULTS FOR 1ST AND 3RD YEAR STUDENTS

	1st year students	**3rd year students**	**Score range**
Total Test Score	Mean:4.76 SD: 2.34	Mean: 8.90 SD: 4.04	0-38
Open questions	Mean: 0.96 SD: 1.31	Mean: 2.90 SD: 2.45	0-27
Closed questions	Mean: 3.80 SD: 1.81	Mean: 6.00 SD: 2.30	0-11

B. Internal consistency

When we look at the internal consistency of the total test, that is, the way in which the items seem to measure the same construct, we found a value for Cronbach's alpha of 0.689 for the whole test (0.622 for the OQ and 0.520 for the CQ). The meaning of this index depends on the kind of test and in our case it seems to be a medium value which seems to confirm the reliability of the test.

C. Comparison of results in two academic levels

When we compare the results of the 1st year students with those of the 3rd year, our results seem to be in line with our expectations, since they seem to reflect a development between these two academic levels from the 1st to the 3rd year when we look at the mean total score and also when we compare the different sections of the test (see Table III).

When we performed a t test for independent samples, in order to ascertain whether these differences were significant we found they are indeed for the whole test ($F= 13.63$, $p < 0.005$) as well as for the open ($F= 15.57$, $p \leq 0.002$) and multiple choice questions ($F= 2,14$, $p \leq 0.005$). So, we can state the test discriminates very well between the two academic levels.

VI. DISCUSSION

Competences and learning outcomes really seem to play a pivotal role in higher education reform. In this regard, the quote by Resnick and Resnick [6] "you get what you assess" seems in order. No matter how much we strive to help students develop the competences they will need in their professional lives, it is difficult to achieve them, al least in a general sense if we do not take the pain to assess them. Assessment determines the real goals that must be achieved by students to be successful and at the same time is a rich opportunity for learning if criteria are clearly understood and shared by students and can be worked upon. In other words, educational reform can be a void effort if it is not reflected in the way assessment is performed.

The main achievement of this project seems to be that indeed we have succeeded, at least in a first phase, in the development of a procedure to measure learning outcomes and more specifically problem solving which in light of the present results can be considered reasonable and can be taken as a sound base for future developments. However, it must be acknowledged this process takes much time and effort, as shown in this paper, and is probably best approached as a multidisciplinary endeavor.

Of course also many difficulties arose along the way. Maybe the first worthwhile mentioning are the difficulties found in the administration of these tests to natural groups of students. Teachers as well as authorities did not seem to be clear about the benefits of this administration and at times simply considered it a loss of time. The practical result of this is that, despite our efforts to the contrary, they were taken mostly by students who volunteered and the sample size was below what we expected. Moreover, since this procedure usually selects the best students, it may be considered that these results represent an overestimation. This is interesting considering the modest mean we found in a very basic competence for engineering such as problem solving.

No doubt the process of developing learning outcome assessment devices, as described in this paper is long and costly. However, it seems efforts of this sort need to be done in order to guarantee that students are assessed by means of procedures which have proved their objectivity and measure what they are supposed to measure. This is especially so when important decisions are taken based on this information, as is the case when they are used for certification purposes.

Several lines of reasoning seem to be relevant in this respect. Of course, once procedures of this type are developed and adopted by an institution they do not need to be so costly for subsequent use. Maybe the crucial question is whether they need to be developed at each institution, taking into account its costs and multidisciplinary nature of the effort needed, or they should be developed elsewhere, maybe for more general use at least in some specific cases [7]. We are aware this second option raises the question of the limitations of standardized tests vs. more open, qualitative and situated alternatives [8-11]. It also raises the question of the fact that, if the procedures have not been developed at an institution, its members do not feel ownership over them. Indeed, some of the resistance we found in tutors seemed to be related to the use of results for external evaluation and control.

It must be emphasized the experience of development and use of the procedures described was most enriching for all participants and it was a great opportunity for teachers' professional development and prompted them to use similar procedures for developing competences. For students alike, it was an opportunity to understand in a practical way what competences are about.

To summarize our experience to date, this work has been long and costly, but also very rewarding for those who directly participated. In fact, they readily used the tasks and others developed following this example in their daily activity. In this sense, the tasks seem to be very intuitive and stimulate educational activities geared to develop valuable competences.

Finding a balance between the effort needed to develop this kind of assessment devices and the possibility of not measuring them or doing so in less reliable and valid ways is something the academic community will need to consider seriously.

ACKNOWLEDGMENT

This study was possible thanks to funds from the Spanish Ministry of Education's tender for Actions Oriented to the Improvement of Student Support and Employability, reference CAIE012 (Resolution December 12, 2011) and scholarships provided to students who acted as raters by the Vice Rector's Office for Undergraduate Studies of the Autonomous University of Madrid

Abstract—**The dynamism and intensity of the adoption of practical learning problems (PBL) provide adverse effects contrary to traditional learning approaches. The difficulty in defining clear educational objectives aligned to appropriate forms of assessment is also a recurring challenge in the management of learning environments. As a response to this state of affairs, this paper presents an approach to a system for managing learning based on PBL that makes use of Bloom's revised taxonomy to support planning and assessment activities. The model was implemented using prototypes with low-fidelity screens and its applicability with regard to the conduct of teaching using PBL was found to be valid.**

Keywords—PBL; Systems for Managing Learning (SML); Bloom´s Taxonomy – Revised; Planning and Assessment Processes.

I. Introduction

The dynamism and intensity of problem-based learning (PBL) [1] provide adverse effects in the teaching method, especially about teaching practice. On the one hand, a lack of control over teaching activities, the essential elements of which are processes (i.e. managing the application of the teaching methods), people (especially new roles involved) and tools (the teaching environment itself and the availability of the technology needed), can negatively affect the PBL approach and its principles. On the other hand, the difficulty in defining clear educational objectives aligned to appropriate forms of assessment can undermine the perception and evaluation of the results of teaching and learning.

Therefore, it is believed that many of the challenges that PBL presents are linked to new ways of "teaching" and how "assessment" is aligned to PBL principles. The dynamism inherent in teaching method keeps focus on solving problems, and owing to this argument, more appropriate ways to assess students should be considered. For possessing a subjective feature, assessment in PBL has been a constant point of discussion [2]. The flexibility and unpredictability present in practices lead to control being lost over the planning and monitoring of tasks and the results of teaching and learning.

As a response to this state of affairs, this paper presents a systems approach to managing learning based on PBL that makes use of Bloom's revised taxonomy to support planning and assessment activities.

This approach argues that Systems for Managing Learning (SMLs) can be used to determine what resources need to be used to facilitate how teaching activities are managed, especially the planning of teaching and the assessment of students. Besides directly aiding faculty in their teaching practice, SMLs are powerful tools because they facilitate collaboration and communication between those involved in this process.

Even though the use of SMLs has been little explored as a support to the PBL method, the literature has already recorded some advantages of implementing and using them, especially with regard to the ease with which they can be used to oversee and monitor learning. In the context of PBL, support to the monitoring of group tutorials is "better" via a SML [3], because less time requires to be spent on facilitating in addition to which an SML provides faculty with the means to monitor and offer guidance by making observations and giving feedback continuously. However, as is well-known, the success of management systems heavily depends on the processes thus implemented being regarded as effective.

One of the most critical processes in PBL is to align educational objectives to assessment. As these objectives are statements that express changes to be brought about by learning, checking whether such objectives have been achieved can be ensured by ensuring that appropriate assessment instruments are applied.

It happens that in practice, the assessment process has been used inappropriately with a view only to classifying knowledge. In addition, it has been established that these elements are incompatible. The real point of assessment is to assist teachers to identify what difficulties students have when they are learning. It is to seek to meet these objectives that the definition of processes within the systems approach is based on Bloom’s revised taxonomy [4], the purpose of which is to support teaching practice. The idea is to ensure that educational

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

objectives are aligned to assessment during the planning of teaching in the real environment of learning, thus contributing to the planning and monitoring of teaching processes being conducted continuously.

To evaluate its applicability, the model proposed was implemented as an extension to the Amadeus SML by prototyping a technique that uses low-fidelity screens.

Since the teachers involved agreed to implement the model and accepted the results obtained from doing so, this showed that aligning educational goals and assessment can be achieved. This made teaching practice in this environment easier and therefore given that the results were positive this shows that this approach is effective.

II. TECHNOLOGY APPLIED TO PBL EDUCATION

A process inherent to learning in PBL is to tackle problems which have a complexity that is similar to real situations. This fosters students´ motivation as well as their developing the skills and attitudes needed to solve them [5]. Learning tasks which are primarily functional ones keep students immersed in practices which are always supported by content. By considering themselves to be active agents in the process [6], students focus on solving problems through collaborative learning by debating with each other and expounding their ideas.

The dynamism, flexibility and unpredictability associated with this approach to learning require greater attention from teachers, mainly to ensure the approach is being effective. Because its essence is to be strongly oriented to processes [6], it becomes necessary to consider how to manage them. Thus, adopting this approach to teaching can only be effective when teaching is planned and monitored such that the alignment between the content (theory) and the problem (practice) may be guaranteed. In addition, assessment must be appropriately applied.

Just like learning, assessment in PBL takes different forms. Self-assessment and constructive peer assessment are considered important for the metacognitive process, because this enables a student to undertake an assessment of his/her perceptions, strengths and weaknesses, as well those of his/her peers [7]. Furthermore, the possibility of assessing how the student applied his/her knowledge and performed during the resolution process is stressed. Besides these, authentic assessment [8] as a strategy inherent in PBL aims to stimulate critical thinking and insight during problem solving, and to train students to reflect on different ways to solve a problem.

Therefore, this article argues for the idea that the effectiveness of the approach depends on its processes being managed efficiently. Similarly, management of the conduct of teaching practice should consider the relationship that exists between the educational objectives, procedures and assessment in order to ensure the quality of a degree course in PBL. In this context, the application of appropriate technology to support these processes could be make a great difference.

Technology is ever present today and this includes new teaching practices being driven by it. However there is only a small number of studies on learning that refer to the use of management systems as support to learning based on problems. According to [9], computational tools and computers have not been explored extensively for PBL. Therefore, this section briefly presents studies that evidence there are systems that target the application of PBL.

A collaborative learning environment deemed a PBL-VE, the acronym for Problem-Based Learning Virtual Environment, is presented in [9]. This system enables PBL tutorial sessions to be supported both face-to-face and at a distance. The participants in the initial applications, which aimed at improving the development of the environment, were Computer Engineering students from the State University of Feira de Santana (UEFS).

The "PBL Manager" is a support system for education on the Web which sets out to provide a teacher with the facility of storing problems in a shared database [10]. With a view to computerizing the process of drawing up problems, the system also allows editing, searching for and sharing information.

In [11], a proposal is put forward for an environment based on PBL principles and on the CBR (Case-Based Reasoning) approach and which, by using the DUMBO system, seeks to facilitate the teaching of Computer Networks. The AAERO (the acronym in Portuguese for a Learning Environment for Teaching Computer Networks Oriented towards Problems) considers functions that are basic to the actors of the teaching and learning process. In addition to supporting student learning and the PBL process, by making various resources available, the environment provides such functions as "developer of the problem", "tutor" and "assessor" to the teacher. Its construction draws on the researcher's analysis of other environments specific to PBL, such as BELVEDERE, CROCODILE, CALE, CoMMIT and Munics.

The thesis of [12] puts forward a strategy model of teaching and strategy based on PBL and was applied in a virtual learning environment. The model is integrated with different resources that can be customized to the different actors of the process as a means to facilitate their interacting with each other in the environment. In addition to the collaboration tools, in which what prevail are activities using forums, chats and discussion lists, there is "My Space", "Support" and "Help". The first relates to managing and organizing information and provides the "Personal Library", "Notes" and "My Data". As for the support, this supplies resources to search for data cataloged in the environment as "ABP Bank", "Solve APB", "Guide Bank for solving APB" and "Guide to resolution."

The results of these studies showed support activities that involve teaching practice were superficial, especially regarding the planning of teaching and consequently the assessment process. To ensure effective with the adoption of the PBL method with LMS, the alignment between planning and evaluation should be considered. The management systems as support to learning presented do not contemplate the possibility to establish educational objectives aligning them into the most appropriate forms of assessment. Even though it was confirmed that performance was being monitored in order to support the assessment, there is no means to ensure that performance is being defined and monitored appropriately in these environments.

Therefore, this article emphasizes the importance of encouraging planning in the management system itself by clearly defining the educational objectives in addition to aligning these to the different forms of assessment. It is evident there is a need to develop management systems for a total PBL application, i.e. systems that can support not only student learning but also teaching practice. Towards an appropriate model to set this aim, the revised version of Bloom's taxonomy is adopted with a view to seeking to ensure that the model that sets this aim is appropriately designed. This tool is suited to PBL education because the philosophy behind is broad, ranging from metacognitive aspects to constructivist theories, as required by PBL, and emphasizes the relationship of knowledge with awareness of how the individual learns.

III. Bloom´s Taxonomy – Revised Version

Bloom´s taxonomy [13] is a classification scheme that enables educational objectives to be formulated and organized at cumulative and dependent levels, as shown in Fig. 1.

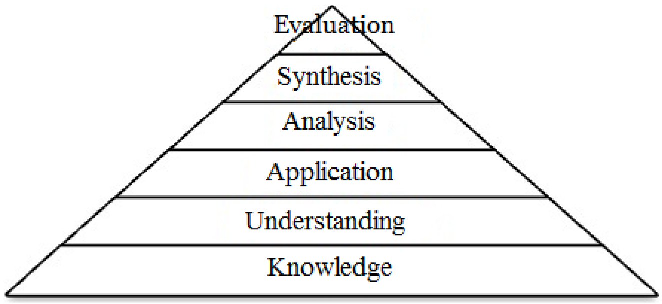

Figure 1. Bloom´s Taxonomy of Educational Objectives.

The educational objectives are represented by statements that express what the student can be expected to achieve, and makes modifications to learning explicit for the teaching and learning process [13].

When considering metacognition and self-learning, the taxonomy undergoes considerable changes and is deemed the "revised" version [14]. Having been made to fit the new forms of learning, including PBL itself, the taxonomy aims at "knowing how to" deal with the procedures in solving problems rather than "knowing what" to do on what content.

A very noteworthy change in its structure, with regard to cognitive processes and knowledge processes, can be represented by a two-dimensional table (see Fig. 2).

	Dimension of the cognitive process				
Dimension of Knowledge	**Remember**	**Understand**	**Apply**	**Analyse**	**Create**
Effective/ Factual					
Conceptual					
Procedural					
Metacognitive					

Figure 2. Bidimensional Table of Bloom´s Taxonomy Revised.

From the cognitive point of view, each one of six verb forms has a specific meaning and is associated with verbs in the gerund:

- *To remember*: to recall, to recognize or to reproduce ideas and contents. Associated verbs: Recognizing, Reproducing.
- *To understand*: to explain an idea, concept in one´s own words. *Associated verbs*: Interpreting, Exemplifying, Classifying, Summarizing, Inferring, Comparing and Explaining.
- *To apply*: to apply a piece of knowledge, a procedure to a new concrete situation. *Associated verbs*: Carrying out, Implementing.
- *To analyze*: to divide information into parts and to understand the inter-relationship between them as well as in the overall structure. *Associated verbs*: Differentiating, Organizing, Attributing, Concluding.
- *To evaluate* (representing of Assessment): to undertake judgments based on criteria, standards and norms. *Associated verbs*: Checking, Critiquing.
- *To create* (representing of Synthesis): to reorganize elements in order to create a new vision, solution, structure and coherent model, from knowledge and skills previously acquired. *Associated verbs*: Generalizing, Planning, Producing.

From the knowledge point of view, the model has four dimensions:

- *Effective/Factual:* This type of knowledge is very useful for enabling familiarization of a discipline to be gained by using the basic contents. *Subcategories:* Knowledge of the Terminology; Knowledge of specific details and elements.
- *Conceptual:* Knowledge related to more elaborate contexts. The students can explore / discover the interrelationship between elements. There is evidence of explicit knowledge regarding classification and categorization as well as knowledge of theories and structures. *Subcategories:* Knowledge of classifications and categories; Knowledge of principles and generalizations and; Knowledge of theories, models and structures.
- *Procedural:* Knowledge related to the use of techniques, methods, criteria and algorithms. This type of knowledge refers to "how to do something." Use of criteria of "how" and "when" to use a specific procedure. *Subcategories:* Knowledge of the skills specific to the disciplines and algorithms; Knowledge of specific subjects with techniques and methods; Knowledge to determine the criteria needed to show that procedures are being used appropriately.
- *Metacognitive:* Knowledge related to interdisciplinarity. To use previously assimilated (interdisciplinary) knowledge to solve problems and / or to choose the best method, theory or structure.

Subcategories: Strategic Knowledge; Knowledge about cognitive tasks, including contextual and conditional knowledge; Self-knowledge.

The idea of a two-dimensional table is to interpolate the categories when educational objectives are drawn up, by combining the type of knowledge to be acquired with the cognitive process (skill to be performed). In this case, it is considered that it is essential both to understand and differentiate between cognitive and knowledge processes.

IV. Aligning Educational Objectives and Assessment

With the purpose of supporting PBL teaching practice, an alignment model seeks to ensure that the educational objectives and assessment remain aligned throughout the teaching and learning process. Based on the revised taxonomy along with the two-dimensional table, the model facilitates the planning of teaching as it supports defining the educational objectives, in addition to checking the alignment of these components. The following sections describe the alignment steps defined in the model, including a framework for defining the educational objectives, which relates cognitive processes to those of knowledge and associates a form of assessment with this. In addition it applies this model to the Amadeus SML.

A. Stages of Alignment

To guarantee alignment in the PBL approach, the model was structured into four distinct stages: (1) Defining educational objectives; (2) Defining assessments; (3) Providing inputs for the two-dimensional table (Fig. 2) and; (4) Checking the alignment and identifying points for improvement.

Given that educational objectives are statements that express expected changes in learning, they should be structured by joining "verbs" and "nouns" as shown in Fig. 3.

Figure 3. Structure of an Educational Objective.

The structure of an objective is initiated by a "verb of mental activity". These verbs express the intended action more efficiently, so what they enable to be defined is what cognitive process is expected to be reached by the educational objective, assuming the levels of "to remember", "to understand", "to implement", "to analyze", "to evaluate" and "to create". After determining the intended action, a "noun" is added which enables an item of content to be associated with the action. Then, the "verb in the gerund" clarifies "how" it is expected that this objective may be achieved and concludes with the "noun" which associates the gerund with one of the categories of the knowledge process, thus concluding the description of the objective. There still remains the relationship of the verbs of action and their associated verbs, in the gerund, as shown in Section III. When defining an objective, the choice of the verb of mental activity is crucial to defining how the objective will be achieved, and is always associated with the verb in the gerund.

Fig. 4 illustrates an example of an educational objective as per the structure proposed. Note that the verb of mental activity "to remember" is associated with "recognizing", a gerund, which shows the real intention of the educational objective.

> To remember + the terms most used to define problems common to the functioning of a software program + by *recognizing* + the distinction between them during the tests.

Figure 4. Example of an Educational Objective.

The step "To define assessments" aims to associate a form of assessment with each objective. In addition, the teacher should predict the time needed to do it, by setting a time befitting its complexity. In order to solve problems, for example, it is considered that the more complex the problem is, the more time should be set aside to resolve it and to conduct the assessment itself.

The step "To provide inputs for the two-dimensional table" aims to fill in the cells of the two-dimensional table, the inputs being the elements "Objective, Assessment and Time". Since the cells are formed by the intersection of the dimensions of the table, they can be filled in with two or more educational objectives. Similarly, the educational objective can occupy two or more cells in the two-dimensional table (Fig. 2).

The step "To verify alignment and points of improvement" aims to guide the teacher as to his/her planning. After having completed the entries in the table, the teacher can verify and assess the alignment and/ or misalignment of the elements mentioned by means of the "macro" vision provided by the two-dimensional table. The idea is to identify areas for improvement, such as "where" and "how to" improve the choices of planning actions in addition to reflecting on learning opportunities lost because of the presence of empty cells.

It is believed that these steps guide teaching practice, especially regarding how the structure defines the educational objectives. This enables the object to be adequately associated with the contents and the assessment. Since the table reflects a dual perspective, an argument is thereby made about the importance of teachers using it because this enables a) the impacts of the assessments and the consistency of the curriculum to be examined; b) help to be given to aligning the objective elements and assessment; and c) the activity of the objectives to be differentiated [4].

B. Application of the Model in the SML

The alignment model was implemented in Amadeus SML by using prototypes with low fidelity screens. It was noticed that Amadeus does not have a module that allows teaching to be planned based on defining educational objectives and monitoring these. In this context, the prototypes presented in this section propose *Planning* and *Monitoring* activities in PBL as per the latest version of this system. Since the prototypes were originally written in Portuguese, they were adapted to this study so as to emphasize only the actions of planning. What mainly stands out is how to set educational goals and to integrate them into an assessment, besides checking that these elements have been aligned when planning teaching.

Planning is structured into three integrated steps. Planning begins by creating a "learning module", into which subjects can be put, activities defined and problems set up. After this has been drawn up, the teacher should establish educational objectives and relate them to the module (Fig. 5). The structure, as per Fig. 3, assists the teacher in this action and enables "what students need to do" to be associated with the content, as well as how this will be acquired and the type of knowledge.

Planning is effectively concluded when the teacher defines the actions regarding assessment. The form of assessment for each defined objective should be selected, as should the criteria and time, as shown in Fig. 6. A problem may still be associated with the assessment stage after the objective has already been created, which means that the proposed problem, in a way, is related to the objective that the teacher wishes to achieve.

Having defined these actions, the teacher should check if the elements are aligned and/or misaligned (Fig. 7). After the terms "objective, assessment, and time" have been filled in, the two-dimensional table enables a teacher to identify cognitive processes that have not been explored, which makes teachers reflect on their planning. Because of the flexibility of the revised taxonomy, note that the educational objectives are located in two or more cells (Fig. 7) i.e. what is most expected from a student in terms of the mental activity he/she is expected to acquire.

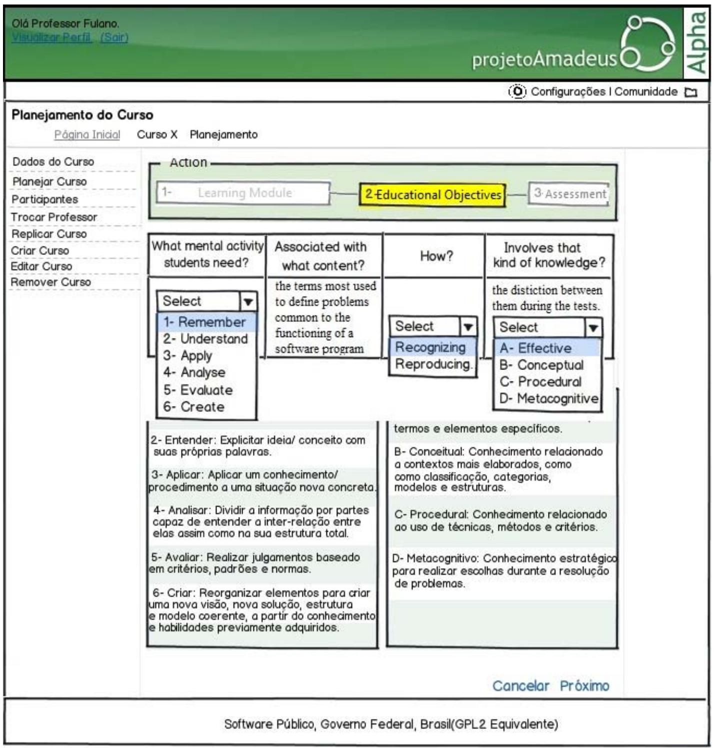

Figure 5. Screen for drawing up educational objectives.

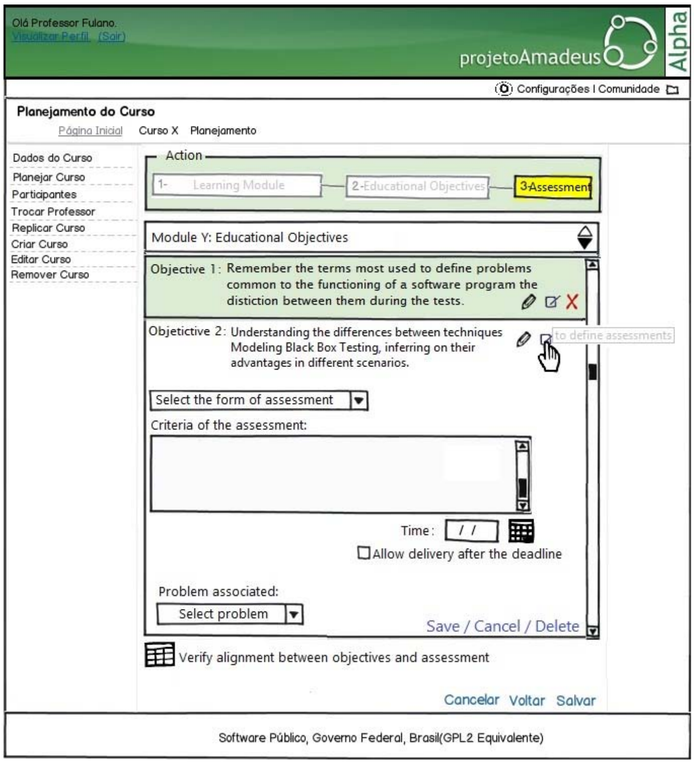

Figure 6. Screen for defining assessment.

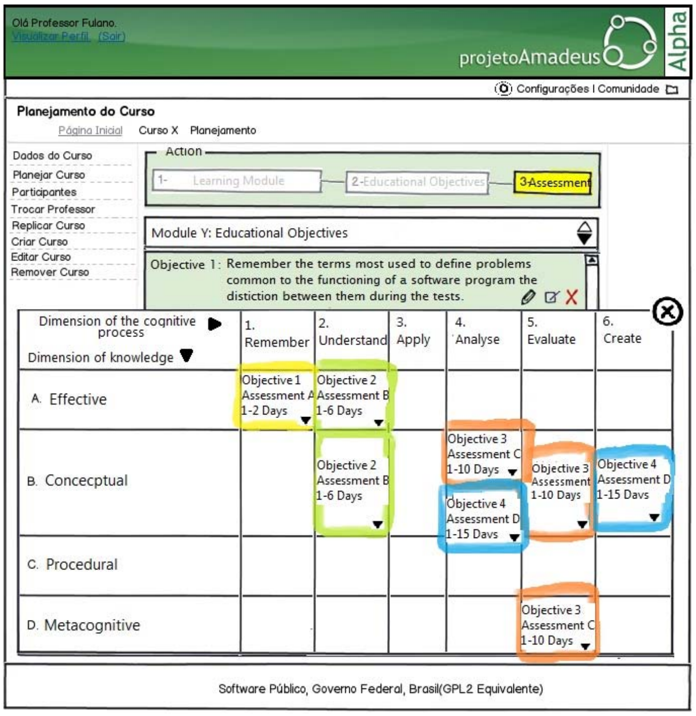

Figure 7. Screen for verifying alignment.

V. VALIDATING THE MODEL

The validation of the model was based on interviews and supported by a questionnaire the purpose of which is to assess the suitability of the model. The screens that were designed served as an instrument of analysis in this process. In the questionnaire, besides the objectives of the screens, two assertions were associated with each of the objectives, with predefined values, using the Likert scale (1 – "I strongly agree"; 2 – " I agree"; 3 – "I´m undecided"; 4 – "I disagree"; 5 – "I strongly disagree"), followed by a question for comments. To make this clearer, the assertions of the screens shown in Figures 5, 6 and 7 are summarized in Table 1.

TABLE I. EXAMPLES OF ASSERTIONS PER SCREEN.

Screens	Assertions
1. To define Educational Objectives	1. The definition of an educational objective in planning, of the form proposed, is presented sufficiently intuitively. 2. A lot of understanding is needed to establish an educational objective in planning.
2. To define Assessment	1. It is possible to define clearly and objectively elements associated with assessment in each objective proposed. 2. The relationship of the elements of "objectives", "problems" and "assessment" are established coherently.
3. To verify Alignment	1. The table provides ways that guide planning. 2. The alignment/misalignment between the actions established can be identified visually

Validation involved the participation of seven experienced teachers, mostly at undergraduate level and who had basic knowledge of the Amadeus SML and basic knowledge (3), intermediate knowledge (3) and advanced knowledge (1) of the PBL approach.

To define educational objectives, for the first assertion, five of the total (7) strongly agreed that the proposal is intuitive enough for the teacher. Excerpt from the conversation during interviews can be highlighted:

E5: "Strongly agree, I think it's pretty clear why this question is here (referring to the column "what mental activity students need?") and the answers that you can choose. This is also easy (referring to the column "associated with what content?") because the teacher will know what content is going to associate to the goal and relate".

Considering the second assertion, five participants agreed (I strongly agree (3), I agree (2)) with the ease of understanding in this action. Those who disagreed with this statement emphasized:

E2: "I disagree (...) is an educational objective and you need to understand about this and not fill anyway";

E7: "I noticed which is necessary to distinguish the verbs of cognitive process and relate these verbs to the knowledge. And that don't represent the low understanding. Maybe the first few times that teacher go set targets he has some difficulty (referring to use of the verbs and types of appropriate knowledge) and gradually he learns".

Considering the assertions to define assessment, both have prevailed in total agreement (I strongly agree (4), I agree (3)) considering the clarity and consistency of the objective elements, objectives, problems and assessments.

To verify the alignment, all the participants strongly agreed with the assertion that the table helps the teacher for direction of planning. For the second assertion, the participants agreed with (I strongly agree (6), I agree (1)) to visual form which facilitates verification of the alignment or misalignment of planning actions (i.e. goals aligned to a proper evaluation), defined by the teacher in the SML. Some excerpts highlight the participants' opinion for this action:

E2: "It has a macro view, because it has the objectives and assessment, then you ask: - That's what I want to accomplish?";

E3: "When you see the screen, it makes clear the connection of cognitive process with the knowledge process. And it is a way to organize the planning. (...) I think it was easier to understand visually. Was organized because then if I want to see the objectives I can see the detail of it";

E4: "When are you going to use the table as a representation, helps a lot the understanding of people";

E5: "It's great because this screen has a broad view of everything".

Table 2 summarizes the evaluation of the participants per each screen of the prototype. Due to limitations of space, the other subjective comments have been omitted.

TABLE II. SUMMARY OF THE VALIDATION RESULTS.

Screens and assertions		Likert scale				
		I strongly agree	**I agree**	**I´m undecided**	**I strongly disagree**	**I disagree**
Access to Amadeus	1	42.9%	42.9%	14.3%	0%	0%
	2	71.4%	14.3%	0%	0%	14.3%
Registering the course	1	28.6%	28.6%	14.3%	14.3%	28.6%
	2	14.3%	14.3%	28.6%	14.3%	28.6%
Planning the course	1	42.9%	0%	0%	14.3%	42.9%
	2	71.4%	0%	14.3%	14.3%	0%
Defining problems	1	71.4%	14.3%	14.3%	0%	0%
	2	14.3%	51.7%	0%	0%	28.6%
PBL Process	1	71.4%	28.6%	0%	0%	0%
	2	100%	0%	0%	0%	0%
Defining the Ed Objectives	1	71.4%	28.6%	0%	0%	0%
	2	42.9%	28.6%	0%	0%	28.6%
Defining assessment	1	57.1%	42.9%	0%	0%	0%
	2	57.1%	42.9%	0%	0%	0%
Checking alignment	1	100%	0%	0%	0%	0%
	2	85.7%	14.3%	0%	0%	0%
PBL monitoring	1	85.7%	14.3%	0%	0%	0%
	2	57.1%	28.6%	0%	0%	14.3%

It is believed that, although static, the prototype allowed the information from the model to be expressed by means of representing the design conceptually via arrangement of the contents, buttons, flow of the screens and support to planning activities.

In summary, the results obtained present in their totality the teachers' acceptance and/or satisfaction with the screens and their goals. When considering the screen for setting educational goals, the teachers agreed that the structure is intuitive and that a coherent relationship is established between the elements. Besides understanding the proposed action, the teachers report they were able to relate the essential elements to their definition. Moreover, they also managed to identify the dependency of the objectives to the assessment on the "planning / defining the assessment" screen and they confirmed that the fields were clear and that it was easy to undertake the action. As to verifying the alignment, the teachers agreed that the two-dimensional table not only guides planning but also enables the alignment between the objectives and the assessment to be visualized.

VI. Conclusions

The purpose of this article was to present a management systems approach to education in PBL based on Bloom's revised taxonomy. With an emphasis on teaching activities, what stands out is the alignment model and the possibilities for defining clear and coherent educational goals associated with the learning module and the assessment itself. The implementation of the model proposed as an extension to the Amadeus SML was performed by using the prototyping technique. Since the teachers involved accepted both how to implement the model and the results obtained from doing so, this showed that aligning educational goals and assessment can be achieved. This made teaching practice in this environment easier and therefore given that the results were positive this shows that this approach is effective.

As to future actions, the functionalities of all the screens of this model are being incorporated into the new version of Amadeus after having been approved by its managers who did so based on this study.

I. INTRODUCTION

New issues related to the teaching/learning process in the field of higher education, especially on-line or distance evaluation, are currently a hot topic of research, and it is of a great interest due to the growing use of the Internet [1]. In particular, the evaluation procedure is a key element within the learning process. Basically, it allows faculty to check whether educative objectives are accomplished, not only by students, but also by all the participants involved in an educative program [2]. As a consequence, lecturers must make pedagogical decisions to adapt the curricula to students' needs or level of knowledge, enforcing or extending it if necessary, and following the framework of the European Higher Education Area (EHEA) [3]. The importance of evaluation is even more important at distance Universities, as our case is, since students are more independent and self-demanding, they have no strict schedules. By means of evaluation, faculty is able to select the most suitable evaluation criteria and dynamically adapt the content resources to students [4].

As a consequence, some specific techniques are needed for defining the students' knowledge-level and analyzing their interactions with the educational platform to be used during the process of customization. One of the most recent research areas for these types of learning experiences is *Learning Analytics (LA)* [5], [6]. Its main goal is to discover and organize the existing information in order to extract useful knowledge during the teaching/learning process. An interesting general approach that uses LA for monitoring the learning activities occurring in a student personal work-space can be found in [7]. Within the area of LA, our work focuses on the field of evaluation by using data mining techniques. In this case, the process of LA will be focused on the information gathered from the educational system. In order to perform the evaluation process more efficiently, it is desirable to develop customized systems that ease the automatic selection and adaptation of the assessment resources to students' needs. Each of them has to be created with different levels of difficulty.

Therefore, this work presents an educational system for the automatic adaptation of the evaluation resources to the students' needs in the context of Higher Engineering Education. As an example, a subject focused on the configuration of network services has been chosen to implement our proposal. The system includes three types of roles: *administrator*, *lecturer*, and *student*. Administrator basically manages the activation or deactivation of users. Lecturer specifies the knowledge base by choosing the most relevant pedagogical resources and assesses the students' activities. From the student's perspective, the proposed system will automatically adapt evaluation contents to each student's knowledge-level and have perfect knowledge of the students' progress, since all the information is registered in the tracking tools. That is, the system will contain quantitative and qualitative information about the students' level of knowledge and skills. In particular, some data mining techniques from the Weka libraries [8] were adapted and calibrated to our purpose of adapting the evaluation criteria. Finally, a satisfaction survey was completed by a group of students belonging to a post-degree subject in Computer Science, as a proof of concept. The system was found easy to use and useful.

The rest of this paper is organized as follows. In Section II,

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

the motivation of this work is described. Section III presents our proposed adaptive system for the evaluation of network services. The evaluation results of the system are detailed in Section IV. Finally, Section V highlights our final remarks and suggests guidelines for future work.

II. Motivation of our Work

Over the last years, adaptive hypermedia has been widely used for the development of customized Web-based courses in the field of Education [9]. Therefore, the students' learning process was guided, adapting both pedagogical resources and learning ways to specific user's features. Since lecturers (or automatic systems) adapt course materials to students' skills and usage data dynamically [10], they were able to acquire more knowledge in less time. ELM-ART [11] and TANGOW [12] are some examples of traditional educational adaptive systems. The students' interaction in these types of architectures is different from face-to-face students [13]. On-line students have to be able to adapt their communication way to the user interfaces of the adaptive systems. Additionally, it is essential to ensure that the proposed activities within the system are correctly adapted to the students' needs [14], so that they feel comfortable interacting with the educational environment.

On the other hand, it is also convenient to adapt collaborative issues taking into account the students' behaviors. The most relevant research works related to adaptation in Computer Support for Collaborative Learning (CSCL) systems are COALE [15], WebDL [16], and COL-TANGOW [12]. COALE is a collaborative environment where different exercises are recommended to students. However, students are free to choose the next exercise to be performed. The main goal in WebDL is to facilitate user access to services. It focuses on adaptive support for navigation. COL-TANGOW is also a system that supports the dynamic generation of adaptive Web-based courses. These courses are generated at run time by selecting, at every step and for each student, the most suitable activities to be proposed.

Nowadays, the evolution of the Web 2.0 allow us to develop more sophisticated techniques to analyze more efficiently the students' learning process, so improving the learning contents and structure of a course. One of the most recent research areas is *Learning Analytics (LA)* [5] in order to discover and organize the information contained in the educational platform. Figure 1 depicts all the phases which follow this process, as described in [6]:

1) *Data Capture*. The existing information must be captured in order to perform an intelligent data selection. Computer theories can be used, such as algorithms for clustering, collaborative filtering, Bayesian networks, etc.
2) *Data Processing*. At this stage, computational techniques for analytic processing are usually employed, such as associative rules, decision trees, neuronal networks, or machine learning.
3) *Knowledge Application*. From the processed data, new knowledge must be acquired and applied in order to improve the educational process. In addition, the new knowledge must be used as a starting point at the first phase of this process.

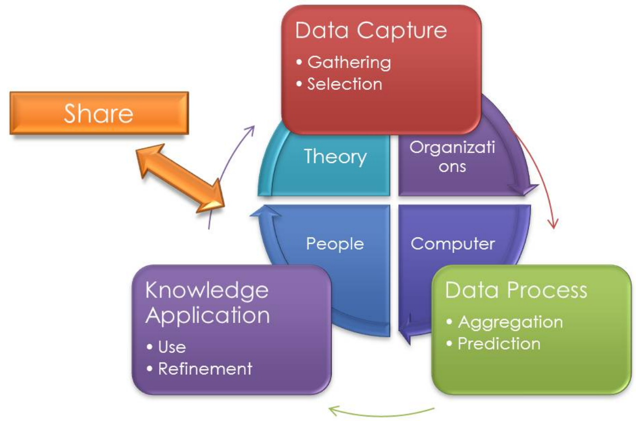

Fig. 1. The Process of Learning Analytics.

4) *Sharing*. The new knowledge extracted from the captured data and applied to the students' necessities may be shared to other contexts. As before, the new data can be used as a starting point at the first phase.

Within the area of LA, our work focuses on using data mining techniques in the field of evaluation. Data mining techniques [17] have led to a gradual replacement from data verification to knowledge discovery. These techniques can be divided in two groups: *supervised* and *unsupervised*. The supervised (or predictive) techniques are based on predicting the value of an attribute from a set of data, by using other known attributes. They are composed of two phases: training and testing. On the other hand, when predictive techniques are not enough to infer new information, unsupervised (or knowledge discovery) techniques could be employed in order to discover patterns or trends in the current data.

The most recent proposal related to assessment and customization can be found in [18]. The system proposed, named *askMe!*, supports and compensates deficits in students' individual learning by considering the students' strengths and preferences. In this work, the system core and the adaptation model employ rules in order to guide them in the evaluation process. Its main drawback is that it does not consider both the students' knowledge level and progress in order to adapt the evaluation resources to students. Additionally, this system has not been tested yet by a set of students. In contrast to this, our proposed system automatically includes both criteria and, also, it has been tested by a set of students in terms of ease of use and usefulness.

III. The Proposed Adaptive Evaluation System

The principal objective of this paper is to present a new service-oriented educational system for the automatic adaptation of evaluation activities to each student's knowledge level and progress. The Adaptive System, *AdaS* (*in Spanish*, named Sistema Adapta), will be able to guide students during their evaluation procedures. This fact can become useful since it is more difficult to dynamically keep track of the students' progress at a distance University, as our case is. In particular, we detail the architecture and user interfaces of our proposal and, then, the requirements and user models of this approach with a particular example.

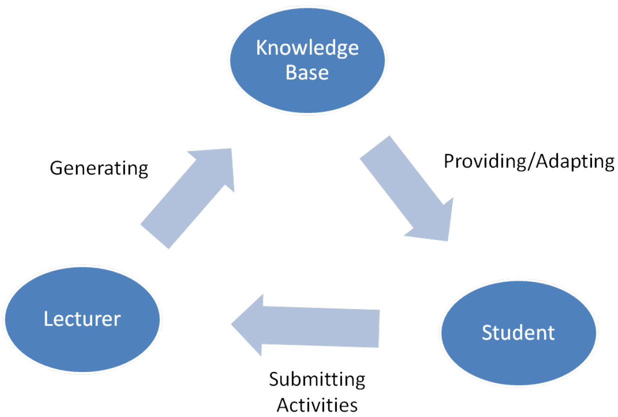

Fig. 2. Main Components of an Educational Adaptive System (EAS).

A. Adaptation and Levels of Proficiency

As shown in Figure 2, an educational adaptive system (EAS) must be composed of three main components: *knowledge base*, *lecturer*, and *student*. The knowledge base contains all pedagogical resources necessary to make possible the process of adapting the course to students. In our case, we define the evaluation resources to be included in *AdaS*. Note that, in order to adapt these resources for several levels of knowledge, each activity has been created with different grades of difficulty, so that one version or another is offered to students depending on their knowledge and particular progress in the course. Students can also rate the usefulness of each performed activity in order to improve the quality of the system.

Our system implements several user models for the customization of the evaluation criteria. To achieve this, some data mining techniques from the Weka libraries [8] were adapted and calibrated for our purposes. We use two combined ways to perform this adaptation, which are complementary:

1) The initial information for the students' customization is provided by themselves based on an initial survey. Each student is classified as *low*, *low-medium*, *medium*, *medium-high*, *high*, and *expert* according to his/her level of knowledge for each required skill and competence of the learning syllabus. Clustering techniques are used in order to establish the students' classification depending on their level of proficiency. We have employed the Expectation Maximization (EM)) [19] algorithm to make this classification possible. This statistic algorithm calculates the probabilities of each element to belong to a particular group of elements.
2) The information is automatically obtained from the previously performed interaction with the evaluation activities. Associative rules are employed to modify the student's knowledge level and, in this case, his/her skills (in terms of experience gained in the system). To make this possible, the OneR [20] algorithm have been chosen, as a first approximation of other works based on the use of rules to make user adaptation [18].

A new knowledge base is built and tested as follows. First, lecturers have to determine the pedagogical contents to be included in the knowledge base depending on the students' skills and competences to be gained for a particular context. After that, they must design the evaluation activities for each set of competences. For each activity, lecturer includes several statements with different levels of difficulty. So, a particular statement will be shown to the student taking into account how he/she was initially classified.

In our case, when students are activated in the system, they must answer a survey of initial knowledge, which contains several questions for each competence of the subject. As a result, students are established a personalized level of knowledge for each pedagogical competence. Each question will be weighted by lecturers depending on its quantitative importance to acquire the competence (or skill) in the context of the EHEA.

As a consequence, the system will offer a range of evaluation exercises based on students' particular knowledge. Note that, a student can be classified with a different level of proficiency, depending on the competence or skill to be gained. After that, they can download and perform the proposed activities for their submission. After the submission of some activity, students are required to indicate their grade of preference with regard to it. Therefore, the system will be able to adapt the evaluation exercises to students depending on their level of knowledge, progress, as well as the quantitative learning outcomes of students (from the evaluation activities rated in the system by lecturers).

Finally, lecturers will grade each activity and check the students' preferences as for the pedagogical evaluation resources offered to them. From these information, they can test and tune the system in order to improve the knowledge base.

B. Architecture of the System

Figure 3 depicts the architecture of our Web-based system. Users can access the system and perform their role-specific tasks using a web browser. The web gateway to the clients is provided by the Apache Tomcat [21], an open source application container. Additionally, the Tomcat server together with STS (Spring Source Tool Suite) [22], an open source framework for building Java-based applications supporting the Model-View-Controller (MVC) design pattern, hosts our Web application. In particular, the web application is implemented with the Grails [23], which is a framework fully-supported by Spring, and it uses Groovy as a programming language. Groovy is a high-level language based on Java.

The MVC pattern allows us to separate the architecture of the proposed system in three different layers: *Controller*, *View*, and *Model*. The Controller in the MVC pattern handles the HTTP requests from the client side, and gives information for further processing to the business logic of the application. The View compiles and presents results dynamically retrieved from the business logic. In our case, Groovy Server Pages (GSPs) are implemented. Also, some JavaScript functions are performed in the Web Client for validation purposes.

On the other hand, the Model in the MVC design pattern represents the business logic. In particular, it manages user data and roles. This component also handles evaluation resources, and controls the automated adaptation to students' needs. For the purpose of persistent storage of data and states, the open source framework Hibernate [24] was used. The underlying data are managed by the free available database system MySQL [25].

Figure 4 shows the diagram of the principal use cases for *AdaS*. Users can access the system and perform their role-specific tasks using a Web browser. The system considers three profiles: *administrator*, *lecturer*, and *student*. Administrator manages users' information, by activating or deactivating users as desired. Previously, both lecturers and students must register in the system, with the option of modifying their profile as necessary. The application has a private area for lecturers where they are able to create, modify, and remove the knowledge base with different pedagogical evaluation resources to be used. In addition, lecturers can evaluate the activities submitted by students. Also, they may communicate with students through the application.

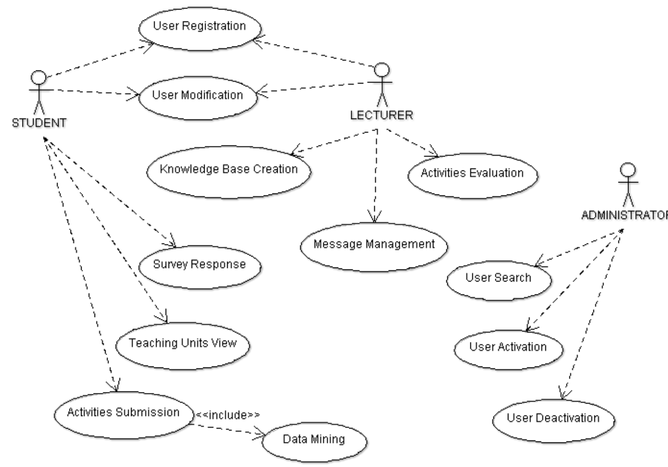

Fig. 4. Diagram of Use Cases in *AdaS* (Focuses on the Main actions of Student, Lecturer, and Administrator).

C. A Network Services' Example at UNED

The chosen subject to illustrate our approach is named "Management of Network Services in Operating Systems" (NetServicesOS), and it belongs to the "Communication, Networks, and Content Management" post-degree program in the Faculty of Computer Science at Spanish University for Distance Education (*in Spanish*, Universidad Nacional de Educación a Distancia, UNED) [26]. The scope of our proposed system is much broader, since this system has been designed and implemented as a modular system, which is independent of the design and implementation of specific activities. Therefore, it is not difficult to transfer the system to other contexts (e.g. Health, Humanities...).

Our NetServicesOS subject provides students with an advanced knowledge on the configuration of the network services provided in a local environment. The UNED University has a virtual campus [27], named aLF, with more than 220,000 students. This on-line campus is based on the dotLRN platform [28]. All subjects belonging to degrees and post-degrees at UNED are also adapted to the context of the EHEA [3], [29]. Its maintenance is a task that not only implies the deployment of sophisticated hardware and software, but also allows the inclusion of new application services, in our case, new procedures for evaluation.

Next, some of the user interfaces of our proposed system will be shown. Graphical interfaces have been developed in

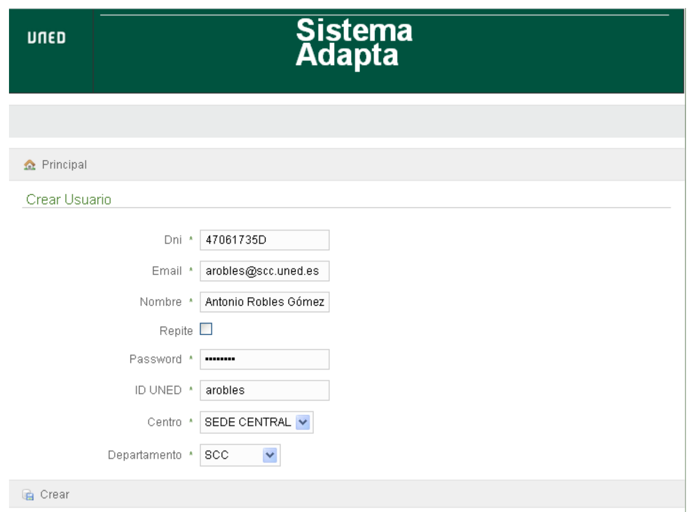

Fig. 5. Interface for the User Registration.

order to interact with the system easily. As first example, Figure 5 shows the interface of a user registration (both lecturer and student). Here, the user role is selected, apart from other parameters, such as name, surname, identification number, e-mail, and so on. Once the user submits this form, the administrator will receive a message requesting the activation. After the administrator accepts this request, the user can access the system.

From the lecturers' view, lecturers can organize the evaluation resources. For instance, as Figure 6 shows, they can create a new resource to be added to the knowledge base. In this screen, the most relevant parameters of each activity for the students' adaptation are selected. From the students' view, as we can observe in Figure 7, they must answer in an initial survey, so that the system analyze their initial level of knowledge. Additionally, the system is able to adapt its evaluation activities to each student' progress in the course in terms of new acquired knowledge and experience, as observed in Figure 8. In our example, knowledge is related to the

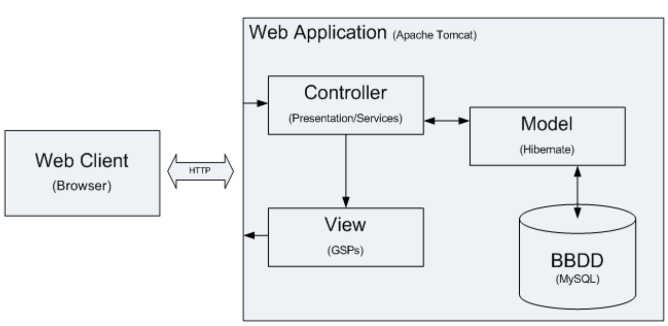

Fig. 3. The Proposed Architecture.

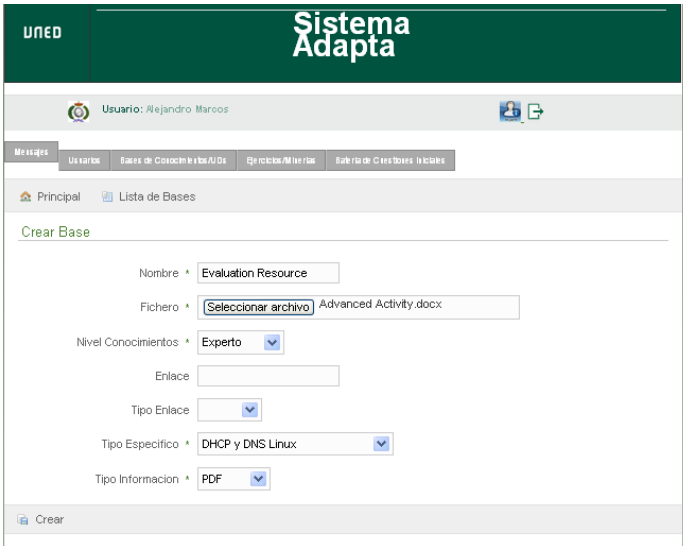

Fig. 6. Interface for the Creation of an Evaluation Resource for the Knowledge Base.

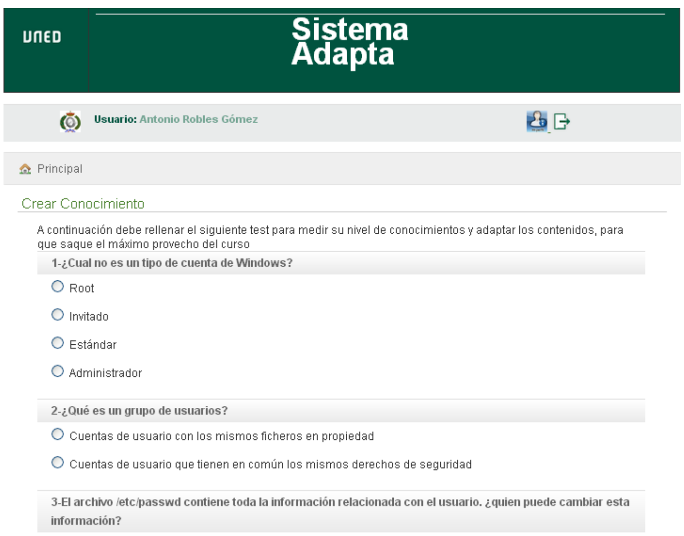

Fig. 7. Interface for the Students' Knowledge Survey.

configuration of network services on two of the most widely used platforms, namely Windows and Linux operating systems.

IV. Survey Results

In this section, the results from surveys conducted among students are presented. This has been done in order to obtain feedback from the students about the proposed *AdaS* in terms of the ease of use and usefulness of the system. The criteria used to choose the survey questions follows traditional guidelines as seen in other previous studies, such as [30], [31]. The survey has been conducted on 10 students of the NetServicesOS subject during the current 2012-2013 academic year. Each question has a five-point Likert-type scale, being 5 the best and 1 the worst.

Table I shows the questions of the survey along with the results we obtained. It can be observed that students are highly satisfied with the system and its user interface – 60% of

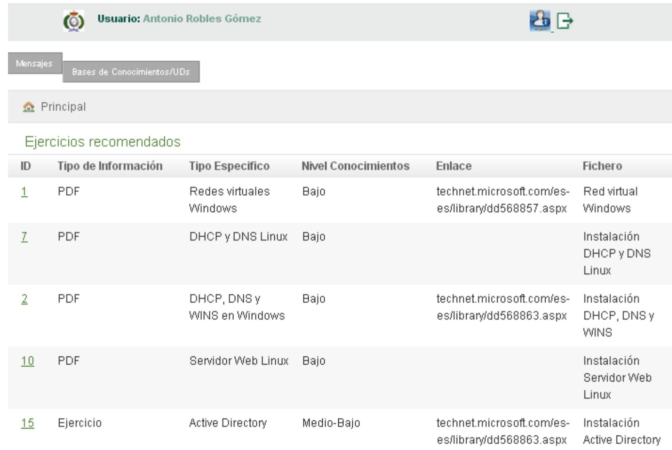

Fig. 8. Interface for a Student's Evaluation Activities.

students totally agree with their general satisfaction, and the rest of them agree. In this sense, only the 40% of students had strong previous experience on the use of this type of systems (they answered 5 to question 1). Furthermore, 80% of students are totally satisfied with the students' interface of the system. The rest of them partially agree with this issue.

As for the usability of the system, students think the system is useful; the 90% of students totally agree and the 10% of them partially agree. Also, 60% students partially agree about the ease of use of the system, and the rest of them totally agree. On the other hand, when students are questioned about the suitability of their interaction with the system, the 40% of students totally agree, and the rest of them partially agree (answered 3 o 4 to question 6). Finally, the 80% of students think these types of systems are very interesting for the education in Engineering. The rest of them think the system is really interesting.

These results underline the high quality of the system we developed, and encourage the use of this system in other subjects in Engineering Education.

V. Conclusions and Future Work

On-line education is nowadays supported by using e-learning platforms, which allow faculty to improve the process of teaching/learning. Some specific techniques are needed to analyze the students' needs and progress in order to make relevant improvements to a web-based course. Within the area of LA, our research focuses on using data mining techniques in the field of evaluation. In particular, this proposes an educational adaptive system, *AdaS*, that dynamically adapts the course evaluation resources to the students' knowledge level and progress. This system has been used for the evaluation of activities belonging to the NetServicesOS subject, but it would be easily transferable to other environments.

By means of this tool, the learning process can be automatically adapted to the students' knowledge level and skills (in terms of experience) in the system. Therefore, lecturers can dynamically follow the students' progress and grade their achievements for each proposed competences of a subject, in the case of Spain, in the framework of EHEA. Students are also able to rate the suitability of an evaluation resource, so

TABLE I. STUDENTS' SURVEY (5—THE BEST; 1—THE WORST).

Questions	1	2	3	4	5
1. Did you have any previous experience with these types of systems?	—	—	30%	30%	40%
2. What is your general satisfaction with the system?	—	—	—	40%	60%
3. What is your satisfaction with the user interface of the system?	—	—	—	20%	80%
4. Do you think this system is useful for their purposes?	—	—	—	10%	90%
5. Do you think this system is ease of use for their purposes?	—	—	—	60%	40%
6. Do you think your interaction with this system is suitable?	—	—	10%	50%	40%
7. Do you think these types of system are interesting for Engineering Education?	—	—	—	20%	80%

that lecturers receive feedback in order to improve the system or detect weaknesses of students. Moreover, we conducted a survey to test the quality of our developments in terms of its ease of use and usefulness. The main conclusions we obtained from the survey is that *AdaS* is easy to use and useful, which encourage its use in other subjects in Engineering Education.

As a future work, we plan to improve the functionality of the system by using alternative data mining techniques for the adaptation of activities to the students' needs, this way improving the adaptation of the evaluation resources to achieve a more intelligent curricula. Some of them can be sequential pattern mining, Markov models, and probabilistic latent variable models. On the other hand, our proposed approach will be integrated with our institutional educational platform in order to exhaustively be compared to other tutoring systems. Finally, different frameworks or contexts from EHEA, as the proposed ones by the ASEE Educational Research Methods (ERM) Division [32], could be explored within the *AdaS* environment in order to analyze if the results obtained are similar and/or it is need of making some changes.

ACKNOWLEDGMENT

Authors would like to acknowledge the support of the following European Union projects: RIPLECS (517836-LLP-1-2011-1-ES-ERASMUS-ESMO), PAC (517742-LLP-1-2011-1-BG-ERASMUS-ECUE), EMTM (2011-1-PL1-LEO05-19883), MUREE (530332-TEMPUS-1-2012-1-JO-TEMPUS-JPCR), and Go-Lab (FP7-ICT-2011-8/317601). Furthermore, we thank Spanish Ministry of Science and Innovation for the Project TIN2008-06083-C03/TSI and the Region of Madrid for the support of E-Madrid Network of Excellence (S2009/TIC-1650). Moreover, authors gratefully acknowledge D. Alejandro Marcos Barreiro for collaborating within implementation tasks of the system, as well as the student participants that took part in the survey.

Once Again Around the Double Triangle

A Multi-Rater Assessment of Capstone Design Skills

Dr. Daniel Knight and Dr. Daria Kotys-Schwartz
Department of Mechanical Engineering
University of Colorado Boulder
Boulder, CO, USA
daniel.knight@colorado.edu, daria.kotys@colorado.edu

***Abstract*— The Senior Capstone Design Course serves for many engineering students as an opportunity to develop crucial skills in professionalism and design that are necessary for succeeding in industry post-graduation. This study delves into the effectiveness of a senior Mechanical Engineering Capstone Design Course for the development of professional and technical skills including: project management, design, engineering methods, communication, and teamwork. A triangulated assessment was performed to evaluate the development of student skills using a survey administered during the middle and end of the Senior Capstone Design Course. This survey was administered to the students, team Faculty Advisors and team Industry Mentors. After analysis, it was found that teams made a significant gain pre to post in engineering methods, project management, and design skills. Communication skills remained at an acceptable level while teamwork skills dropped significantly in the second semester due to difficulties resolving interpersonal conflicts.**

Keywords—Capstone design, industry partnerships, skill development, assessment

I. BACKGROUND AND RESEARCH QUESTIONS

The determination of skill development in Capstone Design courses typically occurs as students are close to graduation. For many schools, the Capstone experience is the only project-based design course in the curriculum and provides a unique opportunity to develop and assess important skills related to professionalism and engineering design. [1] The team based, project based nature of many Capstone courses constellates a variety of skills sets necessary for delivering a functional design ranging the gambit from hands on fabrication skills to the nuances of interpersonal conflict. [2] The research question for this study is whether a Capstone design experience is successful in building key professional and technical engineering skills that do not always receive developmental attention in the early portion of an engineering curriculum. What makes this research unique is the way that these skills are assessed.

Historically, skill development in Senior Capstone Design is often measured via student self-reported data. While this data is easier to obtain and has been found valid, criticisms have been leveled at self-reported student data as a standalone evaluation of student skills. These criticisms target the biases inherent in the limited experiences of a 22 year old student evaluating their own professional development. [3] One alternative to reduce bias is to implement triangulated assessment methods where three parties measure the same set of skills. [4-5] While this method provides additional perspectives, it is still difficult to determine technical and professional skill development from assessment conducted during a single assessment period. [6] Previous work by the authors looking at student rated skill development uncovered a need for a triangulation method to calibrate the ratings of the students' self-assessment against industry professionals and faculty advisors. [7] Similar efforts have been conducted at Stanford with data collected from multiple sources to evaluate a course on team based design with corporate partners and at UC-Berkeley where team design journals, faculty evaluations, and ratings from external judges are used to predict the success of design teams. [8-9] The present study offers an improved and innovative model—a multi-rater, triangulated assessment to investigate gains in skills between mid-term and the end of the Capstone year.

The Senior Capstone Design (SCD) course investigated in this study is a mechanical engineering, two-semester, industry sponsored course at the University of Colorado Boulder where students work in teams on a year-long, client-based design project. The course is presented as a model where the SCD experience is framed as a *transitional space*, connecting the chasm between a student's engineering education and a career as a practicing engineer. Instead of seeing Senior Capstone Design as a culmination of undergraduate engineering, we see it as a forward-looking event—*beyond Capstone*—launching students into the industry career that 80% of our nascent mechanical engineers pursue.

The key test-bed and housing structure for this Capstone transitional space is a state-of-the-art design center. Approximate 24 projects (~130 students/year) are fashioned in facilities with over 10,000 square feet of design space including student module work bays, material testing instrumentation, composites fabrication space, a student machine shop, and a student computer lab. Center curriculum for the SCD course is focused around an industry-education partnership between a university academic department and sponsoring partners from industry and government. Capstone teams operating out of the center meet weekly with two assigned mentors, one of which is university faculty and the other an industry representative from the sponsoring company. The projects culminate in an end-of-year design competition and expo.

II. METHOD

Data were collected for this study across a four-year period. Triangulated assessments were developed targeting specific course objectives and conducted for the course at mid-year and end-of-the-year with ratings carried out by Faculty Advisors, Industry Mentors, and team members themselves. Rating categories used 2-4 ratings per category with ratings made on Likert-type scales. Each rating was supported by qualitative responses to an open-ended question related to the rated skill. An example question from the teamwork category is, *"Was the team able to resolve interpersonal conflicts in a satisfactory way?"* The unit of analysis for this study is the team, with each team rated on the following five skills sets:

- **Engineering Methods**: The necessary technical background to complete a *long term, industry-sponsored* project and be able to apply a knowledge *of relevant manufacturing skills and computer software,*
- **Design**: The ability to demonstrate an understanding of the *iterative design* process and *contextual considerations* of design,
- **Communication**: The production of high quality communications including *oral presentations* and *written reports,*
- **Teamwork**: The adeptness to building *group cohesion* and *resolution of conflict,*
- **Project Management**: Demonstration of professional skills including proficiency at *project management*, planning, organizing, goal accomplishment and general *professional conduct* becoming of an engineer.

Mid and post-test mean scores were calculated and subjected to an independent samples t-test to determine statistical differences in triangulated skills between the two assessment times. Ratings from all raters were combined for this analysis.

III. PRELIMINARY RESULTS AND DISCUSSION

Results from the statistical analysis are presented in Table 1. Across raters, teams made significant gains mid to post in Design skills, Engineering Methods, and Project Management skills while Communication skills, team, written and oral, maintained an acceptable rating level (> 4.0/5). The strongest gains were in the area of *Engineering Methods: Fabrication methods* and *Project Management: Accomplished project goals*. Qualitative feedback supports these ratings with one student commenting, "I liked manufacturing all the parts for our project the most. I really enjoyed learning how to make parts using the mill and lathe." Regarding project management skills, one Faculty Advisor rated the best part of the course as, "seeing the team mature into a strong working unit and delivering the goods." Similarly, one Industry Mentor reported, "This group showed a strong bond of teamwork from the start and were motivated throughout the year to achieve the design objective. I met with the team every week and enjoyed seeing their progress, how each member was contributing to the project, and discussing ideas together. The best part of this experience for me was working with a great team and believing that they would do well, which they did."

An area for growth is in *Teamwork skills: Interpersonal conflict resolution*, where student ratings significantly dropped during the second semester related to their ability to resolve team conflict. One student commented on the post-survey that, "A lot of the team members were not very confrontational so a lot of the problems near the end were let go. They should have been dealt with." Similarly, a Faculty Advisor commented, "Team basically worked around a member by the end because of complete lack of their interest in project."

Another area of concern is in the area of Project *Management skills: Execute project schedule* and specifically, teams that did not achieve an average rating above 4.0/5 at the post-test. Along these lines, one industry mentor commented, "It would have been nice to have enough time left to run another set of tests to confirm the issues that they found on the initial tests."

A third area to consider for future development is the relevant technical background for the project (*Engineering Methods: Relevant Preparation)*. One Industry Mentor requested, "Curriculum needs to include more GD&T, CAD skills, and following a project from requirements definition through integration and test." Similarly, a Faculty Advisor reported, "I harangued the students about their writing because so many issues I have with my colleagues boil down to communication and quite often we communicate via e-mail. Please help them with this." Students reflected their concerns in a more straightforward fashion, "Help us find who we should talk to for our difficult, technical questions."

Implications of these results include the need to maintain curriculum that produced the strongest gains, including a continued emphasis on hands-on fabrication skills in the machine shop and a goals driven focus that seeks to produce a quality design for a paying client in time for the end-of-the-year design expo. Results also imply the need for curriculum modifications including the need to integrate additional conflict management training and coaching throughout the year. Industry partners have recommended and facilitated training opportunities with conflict management consulting firms and these are planned for future iterations of the course.

Also, additional project management training is under development to help students stay on their design schedule including adding workshops specifically for team members in the project manager role. Students' technical backgrounds are being addressed through efforts to add additional design curriculum to the sophomore and junior years. It is expected that earlier design experiences will catalyze and develop skills necessary for project-based design in advance of the senior year.

This study qualifies as a work in progress because data analysis is still preliminary. Future work will focus on disaggregating ratings by raters to determine the difference in industry, faculty and student perspectives. Further data collection will allow for a larger Faculty Advisor and Industry Mentor sample size to complete significance testing within raters rather than aggregated across all raters only. Additional work also needs to be accomplished on the assessment tool as the rating system was developed for assessment purposes. For obtaining research quality, the assessment tool should be more fully tested for reliability and validity, including a test for interrater reliability between raters.

TABLE 1: RESULTS FROM MULTI RATER, TRIANGULATED ASSESMENT

Objective	Rating Categories (All Raters)	n	Mid-year	n	End-year
Communication Skills	Oral presentations	303	4.24	307	4.33
	Team communications	260	3.95	231	4.01
	Written reports	263	4.22	328	4.21
Design Skills	Met project constraints	264	4.42	265	4.57
	Understand design loop	262	4.34	264	4.43
Project Management	Accomplished project goals	263	3.75	264	4.01
	Meetings effectively run	262	3.94	230	4.15
	Execute project schedule	261	3.60	232	3.72
	Professionalism	304	4.34	328	4.32
Skill at Engineering Methods	Fabrication methods	260	4.15	263	4.44
	Design/analysis software	261	4.13	262	4.27
	Relevant preparation	304	3.83	330	3.90
Teamwork Skills	Satisfaction with team's progress	304	4.20	329	4.36
	Fulfilled assigned roles	261	4.48	232	4.42
	Interpersonal conflict resolution	242	4.53	220	4.38

***Abstract*—Virtualization tools, useful softwares that enables tests and evaluation of functionalities, have been used in computer network classes to provide an environment for practice experiments. Although some papers describe these tools and their technical benefits, they do not provide quantitative information about its effectiveness. This paper presents a proposal for systematic use of this category of tools in computer classes and a evaluation of the Netkit tool use in computer network classes. It will be shown how tutorial sections have been developed to these courses, the receptivity from the students through surveys and a statistical analysis of how much students grades can be improved by applying such tutorials. Finally, it will be possible to conclude that, in fact, the use of such tools is strongly advised.**

Keywords—Netkit, Computer Education, Computer Network, Effectiveness Evaluation

I. INTRODUCTION

Virtual computer networks are wide-spreading along researchers, administrators and teachers all around the world. These kinds of tools provide a solution for creating low-cost experiments that students can run in their personal computer, even if they have a modest configuration [1]. Particularly, in the context of distance learning, when the student does not have, essentially, access to an adequately equipped computer network laboratory, these tools are indeed valuable. Although some educational institutions are already using virtualization tools in their computer network classes [2], no consolidated practice about the use of these tools is available and, currently, no bibliography describes how much effective they are when applied in teaching and learning processes.

A particular set of these tools are based on a special version of Linux Kernel, the UML (User Mode Linux). UML is used by Linux developers to allow kernel and file-system debugging in user space mode. So, if a critical modification needs to be performed, the computer itself will not crash [3]. Some examples of virtualization tools based on UML Kernel are *Netkit*[3], *VNUML*[1] and *GINI*[5]. They are relatively easy to use for create experiments [1] and they also need only a few computer resources [1].

From the educational perspective, from academic to industry expectations, the professional formed by industry needs to be prepared to handle a large number of issues [3]. In computer network domain, this means that the recently graduated professional will need to perform configuration of servers, security hardening of networks, routers configurations, among other tasks. Certification exams, like CCNA (*Cisco Certified Network Associate*) from Cisco Company, show what a starter, recently graduated computer network professional, needs to know [9].

Unlike other computer science disciplines, such as programming languages and algorithms, databases, operating systems, that usually require little computer resources and a few software tools, a deep study of practical computer networks requires access to a laboratory with specialized hardware, like switches and routers, beyond some computers. Simulators like *Cisco Packet Tracer* [10] enable some level of experimentation. However, such simulators have a strong limitation. Students are unable to install free and wide spread software used by network administrators, like Bind DNS Server [11], Apache Web Server [12] or MRTG management tool [13].

In this paper we discuss the use of *Netkit* tool in computer network practical courses. Also, we discuss how educational modules were developed using IMA-CID (*Integrated Modeling Approach - Conceptual, Instructional and Didactic*) [14]. From the conceptual model developed using IMA-CID, tutorials were developed to cover the course program, together with theoretical lessons, which could be streamed over Internet in distance learning courses or taught in traditional classroom courses. Finally, we presents an effectiveness evaluation conducted at ICMC / USP (Institute of Mathematics and Computers Sciences, University of São Paulo), from both quantitative and qualitative perspectives of the course, discussing how *Netkit* improved the student's apprenticeship.

The next sections of this paper are organized as follows: The Section II presents some related works that explores simulators and virtualization in computer sciences courses. The Section III presents IMA-CID and how computer network topics were modeled. The Section IV describes how *Netkit* topics were translated into tutorials and how they were used in the classes. A learning effectiveness evaluation of the course using *Netkit* will be present at Section V. Finally, Section VI summarizes our conclusions and future work.

II. Related Works

Gadelha et al. (2010), present the OS Simulator, which consists of a simulator file system to support the teaching and learning of operating systems. The authors' work describes the tool and analyzes the students positive attitude feedback obtained through questionnaires. No information is provided regarding the effectiveness of learning when using the tool [4].

Fuertes and Vergara (2007) present the VNUML, a virtualization tool similar to *Netkit* for virtualization of computer networks, VNUML has very similar features and based on UML as well. The authors show a comparison of performance among the VNUML, Netkit and other similar tools. However, tools for teaching computer networks are not the focus of this paper. This work lends to the choice of *Netkit* as a environment for development of tutorials teaching networks. Thus, in comparison with other tools for network virtualization, *Netkit* tool has better memory utilization, good processing performance and presents itself as a friendly configuration environment [1].

RCOS.Java simulator [7] is an open source operating system presented by Jones and Newman (1996). The paper shows the authors' motivation to create the tool, although it was not evaluated in a course to detect the apprenticeship level at the time of its publication. This work has contributed significantly to the educational foundations explored in the tutorials developed for teaching computer networks.

Bogo et al. (2009) discuss the use of Netkit to teaching routing algorithms. However their study is quite simple, showing the possibility of exploiting the tool for teaching a full course. The present study extends Bogo et al. study, making tutorials and also evaluating the level of student learning through practical experimentation [2].

Dobrilovic et al. (2012), present a study evaluating the use of VNLab tool. VNLab is a permanently virtual network hosted at Technical Faculty "Mihajlo Pupin", University of Novi Sad, Serbia. The students are able to connect to the virtual laboratory using a remote access tool and make experimentations. The paper describes hardware requirements and a list of network exercises, and a usability evaluation showing how much of the curriculum is covered by the tool. There is a major difference between both proposals. VNLab provides a stable, managed environment for experimentation, but the paper does not cover how a large concurrency is handled. Netkit experiments can be run at students own computers, giving them total privileges to study, modify, and even crash the whole network [15].

These studies show the relevance of using computational tools, in particular simulators, to support the teaching and learning process. Fuertes article, in particular, compares various tools that could have been chosen to achieve the same goal. However, Netkit little memory consumption was a relevant factor in its choice, according to some idealized scenarios. It is important to point out that there are several simulators of computer networks. However, none is used with the aim of improving the quality of teaching and learning level of the students, especially the way it is presented in this article.

Also, it is important to note that the authors of this paper are not the creators of the *Netkit* tool; the authors created the tutorials and applied a formal evaluation of the effectiveness of using this teaching method and tools, corroborating results demonstrated in other areas of knowledge to teaching and learning computer networking process. Some studies are referred, although they were applied to other areas of knowledge, helped in the development of tutorials and evaluations performed in this paper.

III. IMA-CID: An Integrated Approach for Modeling Educational Content

Educational modules are concise units of study, composed by theoretical and practical content, like books, papers, websites, multimedia resources, program code, software documentation and for the matter of this paper, virtual laboratory files. These content are integrated in term of learning materials, and require an infrastructure to be correctly created and delivered to students.

For systematically developing educational modules, Barbosa et al. (2004) define some supporting mechanisms for their development. A Standard Process for Educational Modules and an integrated modeling approach for educational content (IMA-CID – Integrated Modeling Approach: Conceptual, Instructional and Didactic) were established [14].

This process works with three models. The first one, the conceptual, is a description of the domain being researched. An instruction model can be used to design additional information, like examples, presentations, multimedia content and other resources that can facilitate the learning process. Finally, the didactic model gives a sequence of the elements generated or used in prior models. IMA-CID considers aspects like audience, goals, length and resources available.

IV. Netkit as a Tool to Support the Teaching and Learning of Computer Networks

4.1. Netkit: An Overview

Netkit is an emulator that enables the creation of experiments in virtual computer networks, including the hardware devices required for their support, as well as the creation of virtual links interconnecting them. Netkit started to be developed as an open source, in 1999, in Rome Tre University, Italy, later receiving support from the scientific community [2]. The virtual machines provided by *Netkit* are initialized with real software that, once running, provides

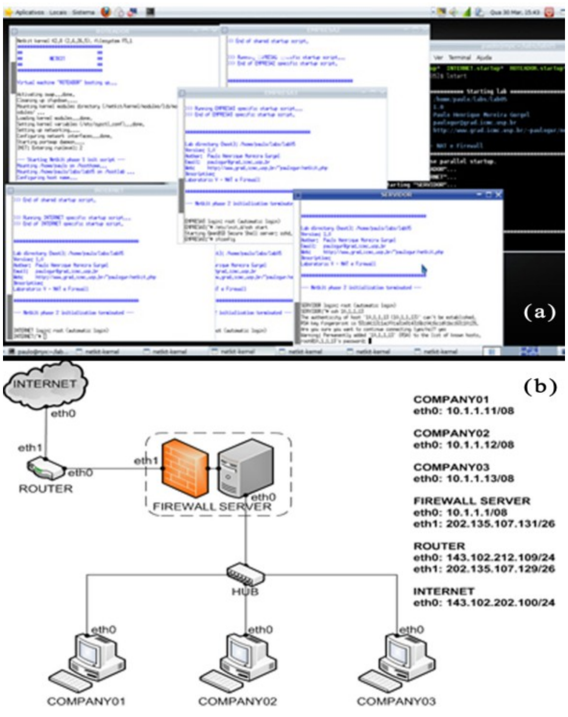

Fig. 1. (a) virtual laboratory in execution; (b) network topology emulated

practical experience to students, even if they has only one computer in their home. Fig. 1a shows an example of virtual laboratory in execution, as Fig. 1b shows the network topology implemented by this laboratory.

The choice of free software to run such experiments is relevant, because it enables institutions with low financial resources and students themselves on using the tool without worrying about the costs arising from a marketed product. In short, a virtual machine is started by Netkit as a full computer running a Debian GNU / Linux in single user mode. To transform this virtual machine on a specific device it is necessary only to run the appropriate software [3]. The basic system files accompanying the *Netkit* bring several tools preinstalled configuration for different network topologies, administration, management and security.

4.2. The use of Netkit at ICMC / USP

To carry out the practical activities in disciplines SSC-0142 (Computer Networks) and SSC-0152 (Administration and Network Management) courses at ICMC / USP, 11 virtual laboratory activities were developed. A virtual laboratory activity, simply called *lab* (acronym for *Basic Learning Laboratory,* in Portuguese), consists of a tutorial for implementing the activity and a set of files necessary for activation of the scenario studied in the laboratory by virtual Netkit. The tutorial, formulated in simple and accessible language, has the following sections:

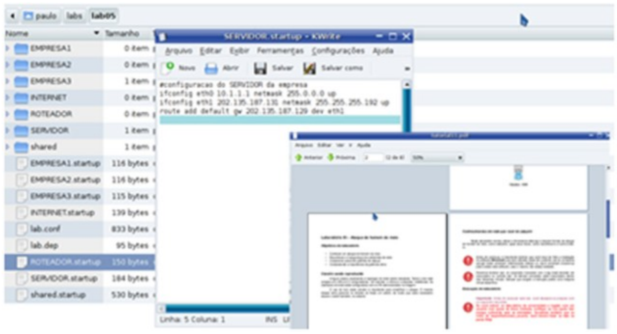

Fig. 2. Laboratory file structure and content

1) A presentation with the experiment goals;

2) A scenario explanation explorer by the virtual laboratory;

3) A brief explanation of the concepts of networks and / or network administration being studied in the tutorial;

4) A sequence of instructions for carrying out the practice;

5) Alternative proposals for experiments that can be performed on the stage;

6) Theoretical and practical exercises related to the subject being studied;

7) An explanation of Linux-related content and Netkit for student support.

SSC-0152 course is mostly practical. Firstly, a theoretical part is presented at the beginning of each class. Later, tutorials are implemented by students. The teacher and an assistent follow the experimentation and solve any doubts. Figure 2 shows the file structure of one of the labs, its content and a tutorial.

4.3. Laboratories applied

The tutorials, in Portuguese and English language, are available at http://www.paulogurgel.com.br/netkit.php. All the tutorials can have instructions that intentionally do not succeed. The idea is not only display successful situations to the students, but also failures and common configuration mistakes. Meanwhile, in all the tutorials, the student must perform capture of network packets used for communication and further study using the graphical tool Wireshark, where they can view the contents of the packet headers and the formation of the major network protocols being studied [17]. The following is a list of topics covered by tutorials:

1) Broadcast network: The first lab shows a rather simple scenario, with one hub, where the students need to configure addresses and test communication.

2) Peer network: This lab demonstrates the difference between broadcast networks and point to point through the use of a software switch.

3) Static Routing: In this lab, the student has contact with the Linux command *route* and learns how to manually configure routes and gateway.

4) Dynamic Routing: This tutorial presents a network with 5 *Quagga* routers. Students have contact with RIP (Routing Internet Protocol) for dynamic routing.

5) Firewall and Network Address Translation (NAT): This tutorial leads the student by setting a complete firewall, internet sharing and TCP port forwarding to internal network computers.

6) Domain Name System (DNS) with Bind9: This tutorial explains the process of configuring the DNS service and reverse DNS server provided by Bind9, the most widely used software for DNS [18].

7) Servers: This tutorial describes how to assemble an infrastructure of Linux servers with software Apache 2.0, MySQL 5.1, PHP 1.3 and ProFTP 5.3.

8) SysLog and Simple Network Management Protocol (SNMP): This tutorial shows the service configuration logging and SNMP agents for network management.

9) Multi Router Traffic Grapher2 (MRTG): The MRTG tutorial demonstrates the installation and configuration of a tool that allows monitoring of traffic and other information issued by SNMP.

10) The man in the middle attack: This tutorial presents a attack known as "man in the middle attack" using "Address Resolution Protocol (ARP) spoofing" technique.

V. APPRENTICESHIP EVALUATION

To evaluate the learning effectiveness of using *Netkit* and practical tutorials developed, two evaluations were performed. There were considered both a quantitative and a qualitative approach. For the quantitative approach, a particular issue was to find similar evaluation in bibliography, even on another computer science discipline, once qualitative evaluations are usually preferred. For this reason, techniques of statistic performance evaluation such as applied in information systems and softwares were done [16].

5.1. Quantitative approach

For a qualitative evaluation, a comparison between two classes of discipline SSC-0152 (Network Administration and Management) held at ICMC / USP, with equivalent prerequisites and the same professor were performed. The first class, called class A, with the participation of 40 students, was taught in the first semester of 2010 and took classes using only the physical structure of the network laboratory of the university, without the use of Netkit. The second class, called class B, had 27 students, was conducted in the first half of 2011, the Netkit being used to carry out the lessons. The classes of both disciplines occurred in the same laboratory.

Considering the course syllabus, at its conclusion, students should have early knowledge about management and network management, configuration of servers and routers, security aspects and network management. Each of these topics could be studied in depth in a specific course. Table 1 illustrates the possible levels of depth of the topics covered during the course and how these topics were evaluated. The column 4 contains a weight adjustment factor, used to calculate the knowledge levels. For level 1, the weight should be zero since the subject was not assessed. The purpose of this weight is readjusting the effect of a simple question about a topic that could be explored extensively.

For evaluation purposes, four discrete levels of acquired skill, denominated knowledge levels, were stipulated. Each student had they skills evaluated in every course topic, though exams and assignments. The weighted grade, considering the depth level, allows the discrete classification of a student skill. The knowledge level, the necessary grade and a description of what skills are expected from the student are presented in **Table 2**.

TABLE 1. DEPTH LEVEL

Level	Name	Description	Weight
1	Superficial	The topic was briefly mentioned, presenting what is, and what it is indicating bibliography for further self-study. The knowledge was not charged under evaluation.	0,00
2	Theoretical	The matter was presented to the student theoretically, during the course or course prerequisite. Theoretical knowledge is evaluated.	0,70
3	Practical	The subject was required to perform practical activity oriented. Theoretical knowledge is evaluated.	0,85
4	Full	The subject was charged in individual or collective practical work and written assessment.	1,00

TABLE 2. KNOWLEDGE LEVEL

Level	Name	Description	Grade
1	Unknown	Students at this level of knowledge cannot describe the usefulness of certain tool, protocol, or network service.	From 0.0 To 2.49
2	Acknowledged	The student understands the purpose of the tool, service or protocol in theory, but would not know how to apply this knowledge in practice	From 2.5 To 5,49
3	Maintainable	The student not only knows the purpose, as it is able to make small and medium adjustments and adaptations, as well as utilize the tools and network services.	From 5.5 To 7.49
4	Critical	The student is not only able to make adjustments and adaptations, as it is able to deploy new tools and features, carry out projects and evaluate the performance of the system and deployed solutions.	From 7.5 To 10

Table 3 presents the results obtained by comparing the level of depth to the knowledge level of the A and B classes. Asterisk (*) indicates topics not assessed from students. In the table is also presented the standard deviation (SD) as additional information. As can be inferred, the class B has a depth level (DL) greater than, or equal to the depth of the topics covered in class against class A. In fact, Netkit provided a more depth coverage of topics and intensification of practical activities. Although a deeper subject study could, intuitively, increase the subject difficulty degree, Netkit use showed a overall average improvement of 1.4 points and a reduction of 0.7 points on the standard deviation, demonstrating greater homogeneity in learning.

It is also possible to check that *Class A* weighted averages are penalized by the low level coverage during the course. Comparing the average absolute items "Tools" and "DNS", *Class A* has better overall average. The better results in these subjects are explained by the simple assessment of the class tests compared with *Class B*. For all other topics, even without the correction factor, the overall average was improved.

Problems caused by inadequate environment, perhaps exacerbated by the higher quantity of students, may have negatively influenced the performance of the class A. To ensure this evaluation accuracy, tests were applied at start of each class term to verify different levels of foreknowledge. Due to similar preparation, no significant averages or standard deviation differences were detected.

TABLE 4. SURVEY GRADES

Question		Average
Q1	What is your level of prior knowledge on the subject?	1,400
Q2	How would you rate the clearness of the tutorial?	4,025
Q3	What degree of difficulty in understanding the proposed scenario?	3,175
Q4	What is your level of satisfaction with the proposed practice?	4,250
Q5	How do you evaluate the presentation prior to the tutorial?	4,150
Q6	How much do you believe on your evolution on the subject?	3,650

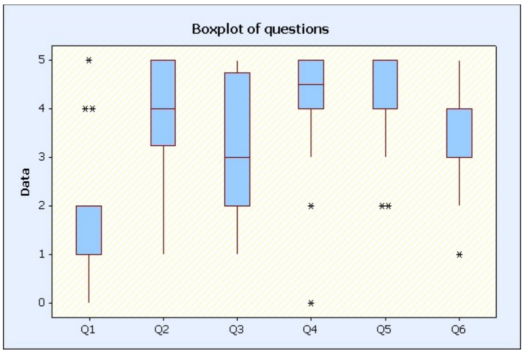

Fig. 3. Grades Distribution

5.2. Qualitative approach

Apart from quantitative research, qualitative research was applied through a survey conducted with students in two practical activities at Class B. These surveys, anonymously answered, were passed to get direct feedback from students' expectations.

The students were asked to give a grade for each question, from 0 to 5, with 5 as the highest rank. The questions and the average grade of each question based on student's replies are described in **Table 4**. Both activities are being accounted in the presented data. **Fig. 3** shows a boxplot chart of answers distribution.

Only three students stated that had prior knowledge about the subjects evaluated, and they evaluated with good grades their satisfaction with the practical activities. It is important to note that the majority were satisfied and believed in their own evolution.

VI. CONCLUSIONS AND FUTURE WORK

This paper discussed the use of Netkit, a tool that enables institutions and students without financial resources to execute computer network experiments, needing no more hardware than a single personal computer. It is also presented a evaluation of apprenticeship in computer networks through Netkit virtualization tool, and what strategies can be used to improve learning, proposing a working method that can be used in the classroom, or even in the students' homes in case of distance education courses disciplines.

The main contribution of this paper is to demonstrate the effectiveness of using the tool as a mean of teaching and learning process in the computer networks courses. Meanwhile, there was the development of study material available at website www.paulogurgel.com.br and they are the first study material using Netkit available in Portuguese, for the full course of networks.

Regarding the difficulties encountered, performing an effectiveness evaluation was challenging since no similar evaluation was found for the use of simulators / emulators in computing disciplines. It is possible to completely observe the benefits of network virtualization in education, and in particular the use of Netkit tool in expanding the depth of content taught and the effectiveness of practical learning facilitated by the tool.

Further comparative studies shall be done, to verify the results here presented and improve methods for evaluating the effectiveness of the methodology applied. From a technical point of view, it is necessary to do a continuous review of tutorials, seeking to detect spots where comprehension difficulties are perceived and adding new labs to address topics other than those listed in Table 3.

ACKNOWLEDGMENT

The authors would like to acknowledge the Brazilian funding agencies FAPESP (2012/14867-3), CAPES and CNPq, for the financial support provided to this research.

Abstract— Peer-Led Team Learning (PLTL) is a recognized model for teaching and learning in which select students in a course return in later semesters to serve as peer leaders who facilitate small learning groups. At our institution (a small, private, research-intensive university), this technique is adopted in Workshops; our peer leaders meet weekly with small groups of students to guide them through sets of exercises designed by the instructor(s) of the course. Peer leaders receive instruction and support in pedagogy and group dynamics in a course jointly taught by a learning specialist from the Center for Excellence in Teaching and Learning (CETL) and the instructor of the course. Workshops have been adopted in many courses, ranging from Chemistry, Biology, Earth Sciences, Physics, and Optics, to Economics and Business. This paper describes the use of Workshops for several years in an Electrical and Computer Engineering (ECE) course intended for non-ECE majors.

We discuss the processes and pitfalls for initiating the use of Workshops in this and other courses, present an example of Workshop problems and questions currently in use, and discuss the value of the Workshops to students, peer leaders, and faculty as told to us in surveys, course journals, and reflective sessions held after the course.

Keywords—Peer-Led Team-Learning, collaborative learning, circuits, non-majors.

I. Introduction

Students majoring in mechanical engineering and optics are typically required to complete at least one course on circuits, often without an explanation of the importance of this course. At some institutions like our own, they are then told that they can satisfy this requirement by taking an electrical circuits course designed for those who are not electrical and computer engineering (ECE) majors. Therefore, a significant fraction of students enter the course not knowing why it is required or what good it can possibly do them. Even worse, many already know they hate circuits (they have seen them in high school and in physics, after all, and seldom fully understood them there), and they wish they could be taking a course more relevant to their real interests. Too often, the response to this dilemma is an overreliance on the instructor's capacity to be profoundly inspirational and personally engaging as s/he works through the necessarily esoteric mathematics on the board in front of the class.

We began with the premise that there must be a better way to engage and motivate students in this service course. We had several requirements in mind: (1) we wanted to employ an approach that introduces students to the discussion format typical to research groups, (2) we wanted to engage the students for longer periods than a short lecture class can accommodate, (3) we sought to use methods proven in other contexts, and (4) we wished to provide immediate and active feedback and direction so the students use their time most efficiently. From the start the goal was not just to improve grades, as this is more an "enrichment" course than a "core" course for the major. As will be seen, we did find a positive correlation between grades and participation in the intervention.

II. Workshops

Our small, private, research-intensive university was one of the original development sites for the Workshop, or Peer-Led Team Learning, a recognized model for teaching and learning[1-6]. The initial implementation here was in organic chemistry[7]; subsequently, it has been adapted at our institution to many other courses, ranging from biology, earth sciences, optics, and physics to business and nursing.

Workshops at our university meet once a week outside of regular lecture hours for two-hour sessions. All students in the course are members of a Workshop; these groups of five to twelve students meet with their Workshop Leaders, who distribute the problem(s) of the day and guide the students in their analysis and discussion of each problem and the issues it raises. (An example problem is given in Appendix A of this paper.) Often the problems are worked on in subgroups and then presented to the larger group. Other times, one student serves as a scribe at the board while the rest of the group offers suggestions on how to proceed. The key is to engage as many students as possible in generating solutions and discussions. Another goal for the Workshop is efficiency; unlike lectures, during which students typically take notes to facilitate their study of that day's concepts at some later point, the Workshop is designed to promote on-the-spot learning of the material, with guidance from an experienced learner. The Workshop Leaders are paid a small stipend for this part of their activities, and they receive course credit toward graduation for the leader training course.

Workshop Leaders are undergraduate students who have done well in the course and return in later semesters to serve as

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

peer leaders to facilitate small learning groups. These peer leaders direct small groups of students through sets of exercises designed by the instructor(s) of the course[8,9]. Workshop Leaders receive instruction in pedagogy and group activities in a separate course, originally designed by the second author[10]. This course is jointly taught by a learning specialist from the Center for Excellence in Teaching and Learning (CETL) and the instructor of the parent course.

Formatted as a two-credit course, the leader training program is designed to prepare Workshop Leaders for their role as facilitators. Each of the 90 minute weekly class periods is equally divided between a discussion of teaching and learning strategies and a review of the material for the upcoming Workshop sessions[8]. The pedagogical portion of the session covers a variety of issues over the semester, e.g., techniques for facilitating group discussions[11], question-asking strategies[6], and student development theory[12,13]. It also provides a venue for leaders to talk through any problems encountered during their recent sessions with their own students. In the content review portion of each class session, the instructor of the parent course rehearses the pertinent material with the leaders for their upcoming Workshop sessions and also points out the higher level ideas and concepts to be illustrated. (See the "Notes given to the Leaders" in Appendix B for an example of the details Leaders are provided about Workshop problems.) The leaders write journal entries each week about their experiences and also carry out a project to investigate a related topic of interest to them; they have created projects like "Increasing Involvement of Women in Engineering" or "How do Students at this University Perceive Engineering: Results of a Survey." The last few meetings of the semester are devoted to poster presentations by the leaders, a simulation of the usual entry-level presentation at scientific conferences.

In the Workshop sessions themselves, it is important that the material and techniques or reasoning processes provided to the students are reflected in whatever assessment tools are used in the course, whether they are exams, papers, or portfolios. If the material from the Workshops is seen as separate from the course, or disconnected from assessment, then it will not be taken seriously, and students understandably will not believe they should participate.

The design of the Workshop program is intended to mimic the organization of a university research group, in which an experienced director works with less experienced people to guide them in finding interesting questions to ask, figuring out how to collect information and evidence to address those questions, and formulating appropriate answers. An important point is that those activities are usually not carried out in isolation, but as part of a group, and that the answers are not known in advance but must be worked out. The Workshop program applies the same model to learning a subject (for the students) and learning about teaching (for the leaders).

Over many years and many courses in diverse areas, we have found that Workshop groups of six to eight students with one Leader generally work best. This is small enough to allow personal interaction with the Leader, but has possibilities for multiple subgroups (pairs or trios) to be formed to work on problems. This target Workshop size then determines how many Leaders are needed for a particular course. The course described here has ranged in size from 100 students (we arranged for 12 Workshop sessions by having some of the eight Leaders conduct two sessions per week) down to about 50 students (we had 6 Leaders that semester.)

III. ASSESSMENT

To examine the effect of this model on student performance, the second author and others[14] have compared course sections across time, i.e., examining student performance data in semesters prior to the implementation of Workshops and after the inclusion of this model. Other studies have included two sections of the course, both with a large number of students, taught by the same instructor, covering the same material, and with Workshops implemented in one section and not in the other. The same assessment tools and opinion questionnaires are used in both sections, and the grades and survey answers are compared. Studies on Workshops performed in this way typically have demonstrated the positive impact of Workshops on student performance[3,10,15,16]. Our opportunities for a comparison study were precluded for this particular course, as when the Workshop model was first taken up the instructor had not taught the course many times and the content was still changing. The instructor was able to offer only one section, the students could not have accommodated separate courses within their schedules, and the number of students in each section would have been too small to allow definitive conclusions to be drawn.

Instead, we began offering Workshops to all the students in this course. In the initial two years attendance was optional, and in subsequent years we began counting Workshop attendance as a part, usually 10%, of the course grade. We allow each student to miss two Workshop sessions with no penalty, then begin removing points, essentially 1% per Workshop missed. In addition to usual assessment practices (homework problems, laboratory participation, and examinations), we also administer surveys to the students to collect their reactions to the course, including Workshops.

We consciously strive to make the problems used in the Workshop sessions illustrate concepts and techniques that will be included in the assessments and have found that designing Workshop sessions to prepare for laboratory sessions are especially appreciated and useful. In addition, the Workshop Leaders point out both real-life examples and situations in later classes that rely on the concepts and techniques being covered.

IV. OUTCOMES

The reaction of students to the Workshops is understandably mixed. There are students who, rightly or wrongly, believe they learn well on their own, or have had a fairly strong background in electrical circuits in high school; they at least initially may be harder to engage in this format. Others may have formed informal study groups on their own, or have other coping mechanisms in place. These students usually know a good thing when they see it, and make use of the Workshops to reinforce their learning; they also know the adage that you never learn something as well as when you teach it. They often become informal "assistant leaders" and help others in the Workshop who are having problems understanding the material, knowing that they may need help on the next section of material. They do everything that is expected of them and do it well, and often become Workshop Leaders themselves in subsequent semesters.

There is another group of students who probably would pass the course but may not grasp the material well enough to apply the ideas and techniques to new situations. This is one of the groups we are most trying to reach through Workshops. By having them work with the concepts and materials of the course at a deeper level than usual homework problems, we believe we help the material come alive for them.

These groups above typically make up a large fraction of the students enrolled in this course. They are in their third or fourth year of a demanding and rigorous program, and most students without the mathematical or engineering background to succeed in the course typically have already decided to leave engineering.

Then there is the group of students (usually a very small number) who will struggle with the material or will believe throughout the course that they are "doing OK" when, in reality, they are failing. Through Workshops, we hope to help these students resolve any conceptual difficulties so they can succeed in the course.

An important observation is that most students vote with their feet and go to Workshops regularly, as can be seen in Figure 1, in contrast to the thin and sporadic attendance typical of standard recitations when not required.

More information about the impact of Workshops on students can be found in our student surveys. These surveys are anonymous, so we cannot correlate comments made by students with their performance; instead, we review these comments individually.

In general, we receive encouraging comments:

Workshop was AWESOME!! The best experience in a workshop ever!

Workshops and labs are well integrated.

Workshops were excellent in supporting material.

In response to the question "What are the major strengths of this [overall] course?" students often reply with comments that refer to Workshops:

Workshops. Fair tests and grading.

Workshops

Workshops are good.

Workshops were the one good thing about this class.

Workshop!!! In class demonstrations.

Workshop. Labs were decent.

Labs and workshops were very helpful w/understanding of material.

In response to another question "What are the major weaknesses of this course?" we sometimes hear about the length of the Workshop sessions:

Workshops do not need to be 2 hours long.

We collected data for five years and were able to correlate final course grade with Workshop attendance, and found a positive, although small, correlation (see Figure 1). Over these years, we sometimes did not give credit for Workshop attendance and some years we did, so the portion of the grade for attendance has been removed and the grade re-scaled for the graph.

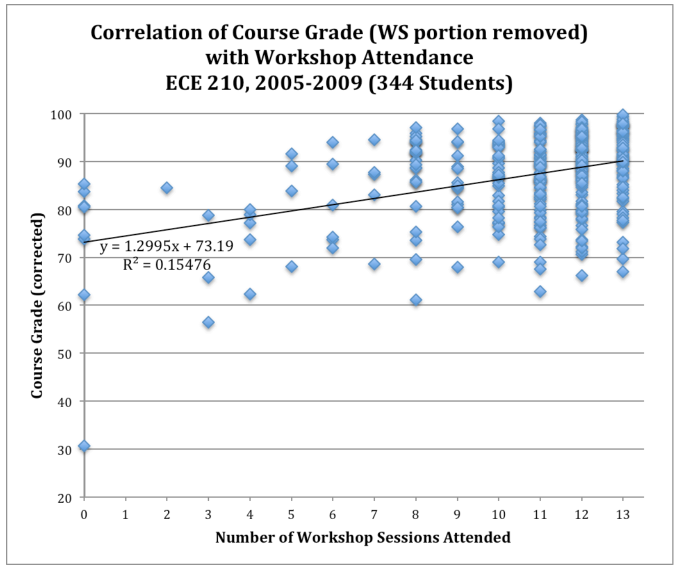

Figure 1 – Correlation of Course Grade (Workshop contribution removed) with the number of Workshop sessions attended for 344 students between 2005 and 2009. As can be appreciated from the low value of R^2=0.15476, the correlation is not very strong. As noted in the text, most students both attend a substantial number of Workshop sessions and ultimately do well in the course, so large changes or very high correlations were not expected. The Workshops provide an alternative learning environment that some students find very useful.

V. DIFFICULTIES ENCOUNTERED

Like any change to the status quo, there can be difficulties with implementation of Workshops. One we found is that it requires the instructor to begin preparing for the course during the previous semester. Workshop Leaders must be recruited and selected, preferably about the time students register for classes for the next semester, which at our institution happens about halfway through the current semester. While Chemistry and other departments often have an excess of applicants for Workshop Leader positions, leading to competitive hiring practices and extensive interviewing, within Engineering there tends to be a smaller applicant pool, resulting in less selectivity in hiring and larger than optimum Workshop groups. This may be due to the fact that upper-class engineering majors tend to be very busy with internships, design projects, etc.

Another difficulty is that instructors must develop their own set of Workshop problems for each course, and they often need to be modified and updated from year to year. This is best done by the instructor, with input from the Workshop Leaders, so that the class work remains in synch, uses the same terminology as the Workshop problems, and includes the topics in Workshops in lectures and assessments. The time for this development is, of course, largest in the first year of adoption.

VI. (UN)INTENDED CONSEQUENCES

We anticipated that some students would benefit from Workshops and the additional teaching style and structured time with the material, that Workshop Leaders would benefit somewhat from the review of the material in a course they had already taken, and that the leadership and teaching opportunities would be fruitful. One thing we did not anticipate is that virtually every leader who has subsequently gone on an interview, either for a job or a professional school admission, has reported back that the interviewers were both intrigued and impressed by the Workshop program, and that most of their interview time was often spent describing and reflecting on their Workshop Leader experience. Having been a Workshop Leader is now recognized as a useful experience.

VII. CONCLUSIONS

The high attendance in Workshops, the modest increase in student performance that correlates with Workshop attendance, and the expressions of satisfaction by students, student leaders, and instructors is sufficient to motivate those who have adopted this model to continue its implementation.

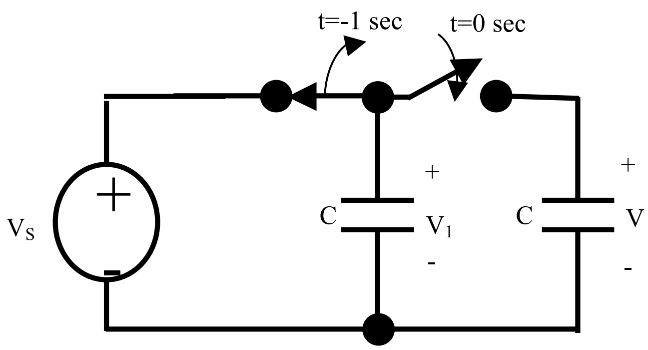
VIII. Appendix A: Example Workshop Problem (given to students)

Consider the circuit shown below, which contains two identical capacitors:



The capacitor on the right is initially discharged (V_2=0), and the one on the left is charged to a voltage V_S. The switch on the left is opened at t=-1 sec, and the switch on the right closes at t=0 sec.

A.

What energy is stored in the capacitor on the left between t=-1 and t=0 sec?

B.

What is the voltage on the two capacitors a long time after the switch on the right closes (say at t=10 sec.)? (HINT: Consider conservation of charge q.)

C.

What energy is stored in the two capacitors at t=10 sec (individually and the total)?

D.

Compare the energy in parts A and C. What happened to the extra energy?

E.

Let's figure it out. First, allow there to be a resistor in the "top" wire connecting the two capacitors:

Will the presence of the resistor change any of the Initial and Final Conditions you found above?

F.

What is the time constant of the circuit for the time regime AFTER the second switch has closed?

G.

Derive an expression for the voltage across the resistor for the time regime AFTER the second switch has closed.

H.

Write an expression for the POWER, p(t), dissipated in the resistor for the same time regime.

I.

Integrate the POWER from t=0 to ∞ to find the total ENERGY dissipated in the resistor. How does it compare to the values you found in Part D? Does it depend on the value of the resistor?

Appendix B: Notes given to Leaders in Review Session

Some students have asked for a more complete explanation of the "charged capacitors" problem. Here are points to consider: When charged, the left capacitor has a charge q of $q=CV_s$, and a long time after the switches are thrown that same charge is evenly distributed across the two capacitors (by symmetry if nothing else, why would one of two identical capacitors have more charge on it than another? Also, they have the same voltage across them, so they must have the same charge on each.) So, $q=q_1+q_2$ and $q_1=q_2$, so $q_1=q/2$, and $V_1(\infty)=V_2(\infty)=V_s/2$. The total energy stored in the left capacitor at t=0 was $W(0)=(CV_s^2)/2$, and the total stored at t=∞ is

$$W_1(\infty)+W_2(\infty)=\frac{1}{2}CV_1^2+\frac{1}{2}CV_2^2=C\left(\frac{V_S}{2}\right)^2=\frac{1}{2}\left(\frac{1}{2}CV_S^2\right)$$

or one half the original energy.

To see where the "extra" energy went, allow there to be a resistance R to the wire in the top of the circuit. Now we have two capacitors in series and a resistor in between, so the effective capacitance C_{eq} is $C_{eq}=\frac{CC}{C+C}=\frac{C}{2}$, and the time constant for the circuit will be $\tau=RC_{eq}=\frac{1}{2}RC$. We can now find the power dissipated in the resistor, P_R, and integrate over all time from t=0 to t=∞ to find the total energy dissipated, W_{dis}.

$$P_R(t)=I^2(t)R$$

$$I(t)=\left[I(0)-I(\infty)\right]e^{-\frac{t}{\tau}}+I(\infty)=\left[\frac{V_S}{R}-0\right]e^{-\frac{t}{\tau}}+0$$

$$P_R(t)=\frac{V_S^2}{R^2}e^{-2\frac{t}{\tau}}R=\frac{V_S^2}{R}e^{-2\frac{t}{\tau}}$$

Integrate over all time to get

$$W_{dis}=\int_0^\infty \frac{V_S^2}{R}e^{-2\frac{t}{\tau}}dt=\frac{V_S^2}{R}\left(\frac{1}{-2\frac{1}{\tau}}\right)e^{-2\frac{t}{\tau}}\Bigg|_0^\infty=\frac{V_S^2\tau}{2R}=\frac{V_S^2RC}{2R(2)}=\frac{1}{2}\left(\frac{1}{2}CV^2\right)$$

NOTE: The amount of energy dissipated is INDEPENDENT of R, so half the initial energy is dissipated in the wire, no matter what the resistance is!

The question sometimes arises "What if we made this out of superconductors, which we all know have truly zero resistance? How would that circuit dissipate the extra energy?" The answer is that superconductors have their limits as well, one of which is a "critical current density" specific to the particular material serving as the superconductor. When the critical current density is exceeded the superconductor "goes normal" and becomes a normal conductor again. If we built this circuit of superconductors and put the whole thing in a liquid helium bath and then tried to do the experiment, we would find that the instant the second switch closed the (infinite) current would exceed the critical current density and the wire would become normal. The necessary amount of energy would be dissipated, then the current density would drop to zero and the wires would return to being superconductors again. The only thing one would notice is that a little extra helium would boil off due to the resistive heating, and everything would return to its regular condition.

We can even figure out how much helium would boil: Assume V_1=50V and C=1μF, for starters. The energy dissipated is then going to be 625 μJ, which, given that the heat of vaporization of helium is 0.0845 kJ/mol, means that only 7.4 μmol, or 166μliter, of helium will boil away due to the dissipated energy, probably not enough to notice.

Concept Maps: An Automated Support for Monitoring the Learning Process

***Abstract*—It is vital for a constructivist teacher to monitor the apprenticeship of each student in order to facilitate the definition of the next steps in the development of a discipline. This is a very time consuming and it requires a theoretical framework to support the observations of the teacher. This monitoring would benefit from certain automated tools to expedite parts of the process. Different pedagogical approaches say that the use of concept maps can help students in the processes of signification of new contents or in the resignitication of those already learned. The epistemological position of Piaget states that the development of a student's logical-mathematical structures is related to the learning of concepts, forming in this way a conceptual system. In the construction of concept maps we create, ultimately, what Piaget calls "significant implications" that evolve according to the semantic nature of the conceptual relations that we create. We propose here an environment for the automatic identification of the significant implications, using a family of software agents guided by an ontology. The analysis of maps will be made based on Piagetian theory. A prototype is under development and will be used to support the analysis of maps produced.**

Keywords—concept map; ontology; intelligent agent; learning environment; constructivism.

I. Introduction

It is essential for a constructivist teacher to accompany the learning process of each student in order to be able to define the necessary steps to be taken in the further development of a discipline. This task, however, is very complex and arduous, it is very time consuming and requires a theoretical framework to support the observations of the teacher. Traditional techniques used in the monitoring of learning (portfolio, performance test reports, interviews etc.) give it the characteristics of a classical assessment. Constructivist researchers and educators have demonstrated dissatisfaction with the efficiency and reliability of these methods, because the problems related to learning processes are generally diffuse, complex and often intractable by conventional techniques [11].

Alternative techniques to accompany learning have recently started to appear. Among them, the Concept Maps [12, 13] occupy a prominent position. Computational tools to facilitate the use of concept maps have been developed by research groups in order to meet the needs of interventions in the processes of learning. The results demonstrate the ease and precision the maps represent in tracking the changes that occur in a student's cognitive structure during learning.

Here we present a proposal for a tool with the goal of providing computational support to a theoretical investigation. It is based on a Ph.D. thesis [1], which proposes a reading of concept maps incorporating Piaget's bias. We do not intend to discuss here all the theoretical aspects addressed in this thesis, but just focus on one of several that may redefine the importance of maps in the process of knowledge construction. This tool constitutes for us an important step in the development of technologies to assist the constructivist educators in their pedagogical tasks.

The tool discussed here will be one of a set of tools, some of which have already been developed [16,17,18]. They are a part of our project called Portal of Knowledge, which is based on Concept Maps under a constructivist approach. We want to emphasize the use of technological resources to support educational practices focused on meaningful learning. The scope of the Portal is to develop appropriate computational support for the construction of concept maps. This support will improve the efficiency, reliability and validity of the use of concept maps as a tool to accompany and evaluate students' progress, as well as to intervene in the processes of learning, based on cooperation and collaboration.

This article is organized as follows: Section 2 presents the conceptual maps and some ways to use them; Section 3 is a brief description of Piaget´s significant implications, the motivating concepts of this work; Section 4 combines these implications with concept maps; Section 5 displays the specifications for a prototype of the proposed tool; and finally, Section 6 offers some conclusions.

II. The Concept Maps

Concept maps are graphical representations of relationships between concepts. They have been used in many different fields of knowledge. In particular, they have attracted the interest of educators worldwide. Novak [6], the inventor of concept map, defines it as a tool for organizing and representing knowledge. The concept map, based on the meaningful learning theory of Ausubel [7] is a graphical representation of a set of concepts constructed in such a way that the relationships between them are evident. Concepts appear in boxes while the relations between concepts are specified by means of phrases that connect the concepts. Concepts are defined by nouns while linking phrases must have a verb or a verbal composition. Two or more concepts connected by linking phrases creating a semantic unit, we call a proposition. Each proposition defines a truth, a fact, detachable and understandable by itself. The propositions are a particular feature of the concept maps as compared to other similar structures, such as mental maps or flowcharts. According to Novak, a concept map is a hierarchical tree structure, where the more general, or inclusive concepts appear at the top and the more specific ones in the lower parts of the tree. New knowledge is anchored to the old by semantic affinity.

There are different pedagogical approaches [3] where the use of concept maps can help students in the processes of signification of new contents or even in the re-signification of concepts already learned. This happens, because the maps allow students to locate and establish relations of composition, similarity, differentiation, and/or equivalence between what they are learning and the concepts already present in their cognitive structure. Therefore, various researches are being conducted and new tools developed to enable the use of concept maps for different pedagogical practices [4, 5].

Concept maps put Piaget's vision of concept into a different paradigm from the one established by the cognitivist view of Ausubel and Novak. According to Piaget's Genetic Epistemology [8], the knowledge is acquired by mechanisms involving a process of assimilation: an external element is incorporated into a scheme of action or a concept of an individual. This process occurs when the individual starts an active coordination of his/her actions, while coordinating the observable characteristics of an object. The process of assimilation occurs when there is a mechanism of accommodation, which allows the individual to incorporate the particularities of the object. This process results in a transformation of the individual systems of signification. It updates the so-called "prior knowledge", a precondition for integrating - and not just "anchoring" - the new knowledge.

According to Dutra [1], we can follow the representation of the system of significations of a student in the dynamics of building a concept map. In this system we also recognize relating subsystems supporting each other for the construction of these significations.

It is essential to emphasize the central role of linking phrases in a concept map. When we compare concept map with Piaget´s knowledge structure [14], we can conceive of the linking phrases as the structuring functions, because they are responsible for the laws of composition of the system represented by the map [1]. Jonassen [15] stresses the effort to choose a phrase that represents a relationship between two concepts, both due to the large number of possibilities as well as the need of placing such a relationship in the context in which the two concepts are presented.

As learning processes are the result of student-student and student-teacher partnerships, we understand that concept maps can also serve as an important guide for students, alerting them to more and more possibilities to qualitatively enhance the cognitive concepts and relationships in the process of acquiring knowledge.

As we said in Section 1, our interest here is in a single aspect of Piaget's constructivism: the regulations in the conceptual systems arising from the logical operations between concepts. These issues are briefly discussed in the following section.

III. THE SIGNIFICANT IMPLICATIONS

We, as humans, construct knowledge through our senses at every moment of our existence. In fact, cognitive processes occur even independently from our will. Through our sensory system we identify a new object and, almost instinctively, want to define its properties. Upon these definitions, we can manipulate and apply the knowledge we acquired of the object and we can start to discover its interactions and relations with other objects of our interest.

A transitive implication sentence $A \rightarrow B \rightarrow C$, in Piaget approach, means that if at least one signification of C is contained in any of B's, therefore it is also contained in any of A´s. Piaget [9] classified these as levels, and the set of them, as significant implications. A signification is all that can be said of an object, such as a description of its properties, as well as all we can observe on it. Furthermore, one implication is also all we can think of objects (sorting them, establish some kind of relationship etc.). For Piaget, all significations imply activities of the individual. These significations allow us to identify the degree of knowledge of a individual on a given domain. The following is a brief description of the implications.

- **Local implication -** It is local when the knowledge does not go beyond the object's observable properties in a given context. One local implication only characterizes an object. See examples in Figure 2.
- **Systemic implication -** It exceeds the limits of the observable. A systemic implication reveals object properties that are inferred or derived from some action on it. This implication displays relations of cause and effect without, however, revealing why it occurs. These relationships occur in general by the establishment of a relation of the object under study with some other object. Examples in Figure 3.
- **Structural implication –** It extends the previous implications because it contains the reasons, and explanations. Piaget speaks of endogenous understanding of the reasons and in the discovery of the relationships needed to occur the effect [9]. Thus, more than knowledge of causes and consequences the structural implications establish conditions which are essential to certain statements, distinguishing them from those that are just sufficient. The sum of the actions of several objects relating to the occurrence of another action establishes the existence of the implications of this new level. Examples in Figure 4. The concept map of Figure 1 illustrates the evolutive difference in the levels of the significant implications.

IV. THE IMPLICATIONS AND THE MAPS

It is important to mention that for the construction of concept maps we assume, that when we are choosing a relationship between two concepts we are doing, ultimately, a significant implication as suggested in [1]. This equivalence led us to adapt the characterization of the levels of the significant implications for analyzing the systems represented in concept maps. Because of this, we chose sets of verbs that best represented the implications.

For building a concept map representing each of the levels presented in the previous section we will show, as an example, concept maps produced by a master's student in computer science. The first map is shown in Figure 2.

The maps are a conceptual representation of his dissertation. Their conceptual nature approaches them to the requirements analysis of a system. Minor modifications to the sequence of maps displayed here were necessary in order for each map to represent one significant implication.

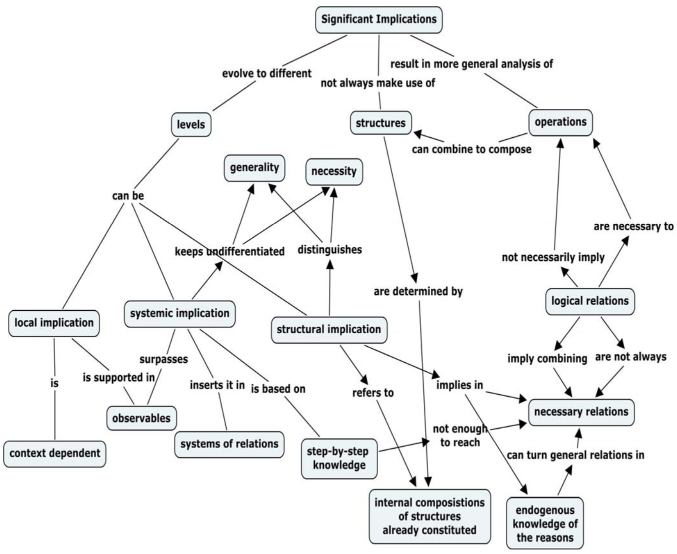

Figure 1 – The significant implications and their conceptual relations.

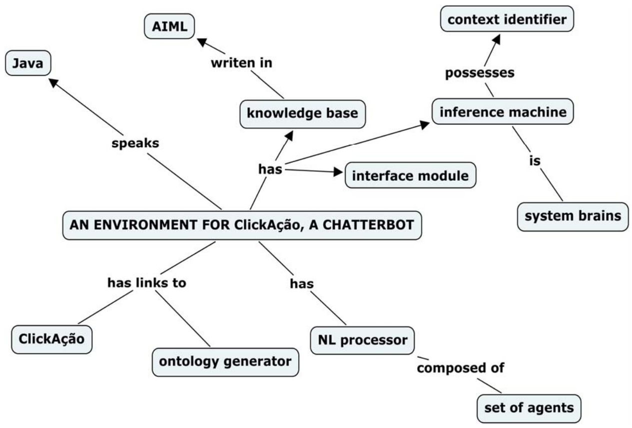

Figure 2 – Halysson´s map equivalent to local implications.´

We now extend the map to incorporate the knowledge of the next level of implications Figure 3 shows the result.

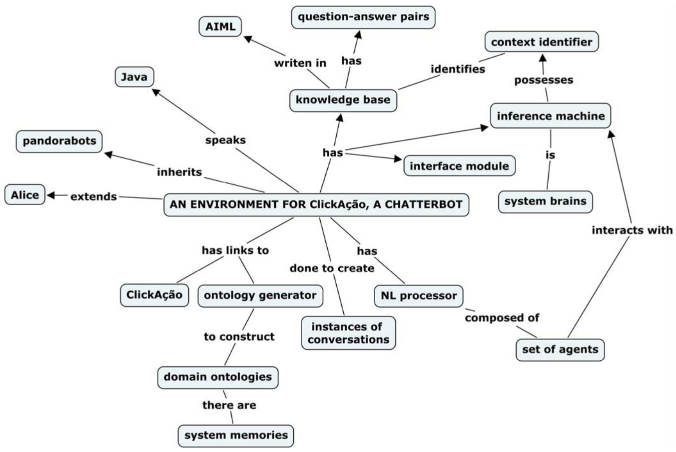

Figure 3 - Previous map with systemic implications.

Let's now add the third level of knowledge. The map would be:

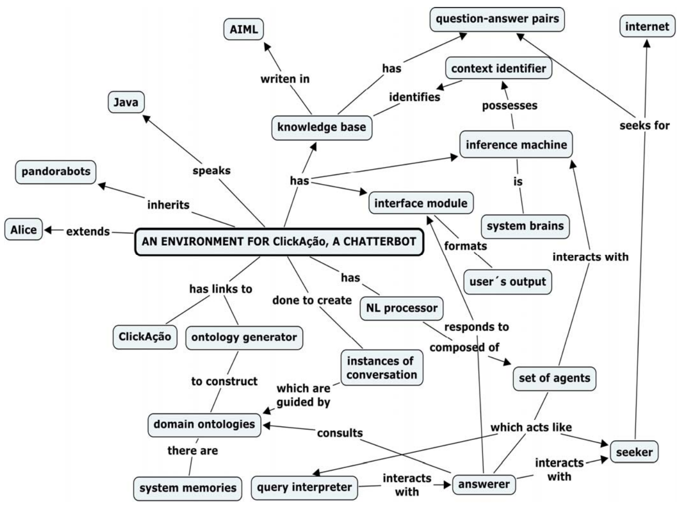

Figure 4 - Previous map with structural implications.

One can note how complex the map is, even when showing very simple relationships. Having a class of about 30 students, a teacher would have the task of identifying the cognitive profile of each student. He/she would have to identify on the maps the three levels of implications. This would be very cumbersome and time consuming. And, unfortunately, the teacher can still have many other activities such as:

- Organizing students per group of knowledge.
- Suggesting readings that are out of the ordinary for each group.
- Joining advanced groups with other less advanced.
- Establishing an average of knowledge of the class by comparing results at different times.
- Creating new maps.

In the following, we present a tool that can help both the teacher and the student.

V. THE TOOL

Based on the characteristics of the situations previously described, the architecture of the tool would consist of some databases, one knowledge base, and a software agent that uses these deposits. The agent is also responsible for interfacing with the users. An ontology of a domain chosen by the teacher guides the formation of concepts. The databases contain maps with their implications properly marked, and groups with their suggested readings. The knowledge base contains the significant implications with their features.

A. A preliminary requirements specification

We present here an initial specification only to guide the construction of the prototype. The prototype, in turn, will lead to a better specification. Our central problem in this activity consists of identifying patterns in existing concept maps capable of providing the necessary conditions for matching the knowledge base with the elements of the maps. We also want to emphasize that the patterns presented here are strictly temporary and, therefore, subject to much future research.

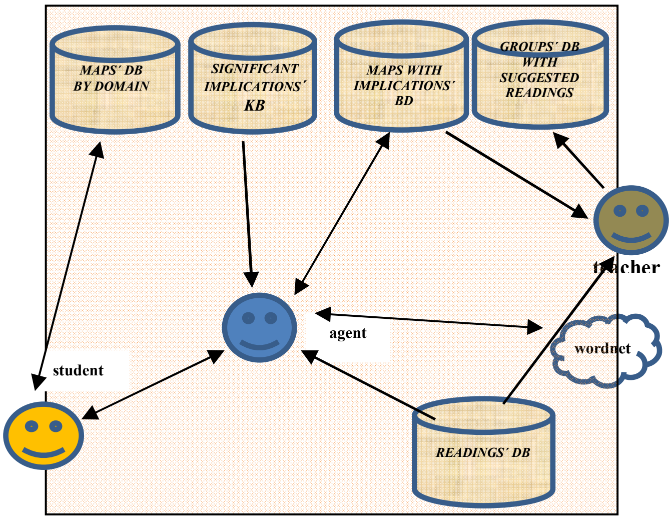

Figure 5- The preliminary architecture of the tool.

A concept map can be described as a well-known data structure called graph. A graph consists of vertices and edges labeled by strings. The vertices correspond to the concepts while edges denote the relationship between a pair of concepts.

The main idea presented here is to develop a tool to navigate the graph edges. The navigation is performed by a software agent that is guided with the aid of two bases. One contains a domain ontology for identifying the nature of the vertices. Another base contains the knowledge about the significant implications for the identification of edges.

For the pattern matching edge-implication we will use two different ways. For local and systemic implications we will use only the verb contained in the sentence designating the edge. Local implications will be identified by the occurrence of the verbs "be" or any other indicating possession or composition, such as “have”, “compose" etc. Systemic implications will be identified by any transitive verb.

The structural implications, on the other hand, will be identified by any subset consisting of edges and vertices whose combination results in explaining a cause-effect relationship (Section 3). Here the structural implications will be identified by the occurrence of verbs which require a preposition. Once the implication is identified, the agent will paint it with a certain color: yellow for local, green for the systemic, and blue for the structural.

The tool will be available both for students and teachers. Students may access it at any time to see how good the quality of their maps is. For example, if just yellow, showing only local implications, that suggests the student proceed to the next level. Once saved and finally sent to the teacher, the map will be temporarily unavailable for the student. Figure 5 illustrates the architecture resulting from the specification. However, it is in its preliminary version where the relationships between its elements are not yet well constituted.

B. The Functioning of the Tool

In the following, we describe all the activities and steps involved in the functioning of the architecture proposed in this paper.

1) Students deposit their maps of the domain previously created by the teacher.
2) The software agent searches the maps in the corresponding base. For a map, each link is analyzed according to the following actions: a) Stopwords are eliminated, since they are negligible for the retrieval of information, b) the agent checks if the verb of the connecting sentence matches some of the verbs of the base of significant implications.
3) The concepts are identified in the ontology by a recognizer. This recognizer is a dictionary automatically populated with concepts of the ontology. Words which are not concepts of the ontology are stemmed.
4) The map is then colored by the agent and deposited in the map and implication database. Figure 6 shows the expected result of the action of the tool.

Whenever the state of the maps with implications database changes, a message is sent to the teacher. He/She accesses the readings database and gives to each map the corresponding reading. The readings with their respective working groups are then stored in a groups with readings database. Messages are sent to the groups.

C. The Prototype

We created a prototypical version of our future tool only partially to illustrate the functionality we desire. The prototype takes as input a set of propositions extracted from concept maps constructed by our students. Figure 6 shows part of the code of the prototype with results. In the future, these propositions will be obtained through software agents. The output shows the implications to which propositions belong. The prototype was developed in Java. The experiment was conducted in a master degree class in computer science researching the question "What´s an Environment for ClickAçao, a chatterbot?".

The results obtained are just the same as the ones shown in Figure 7. However, the tool is presently in its first version and not yet able to identify the whole set of the significant implications. The final tool will be one of the results of a master thesis in computer science.

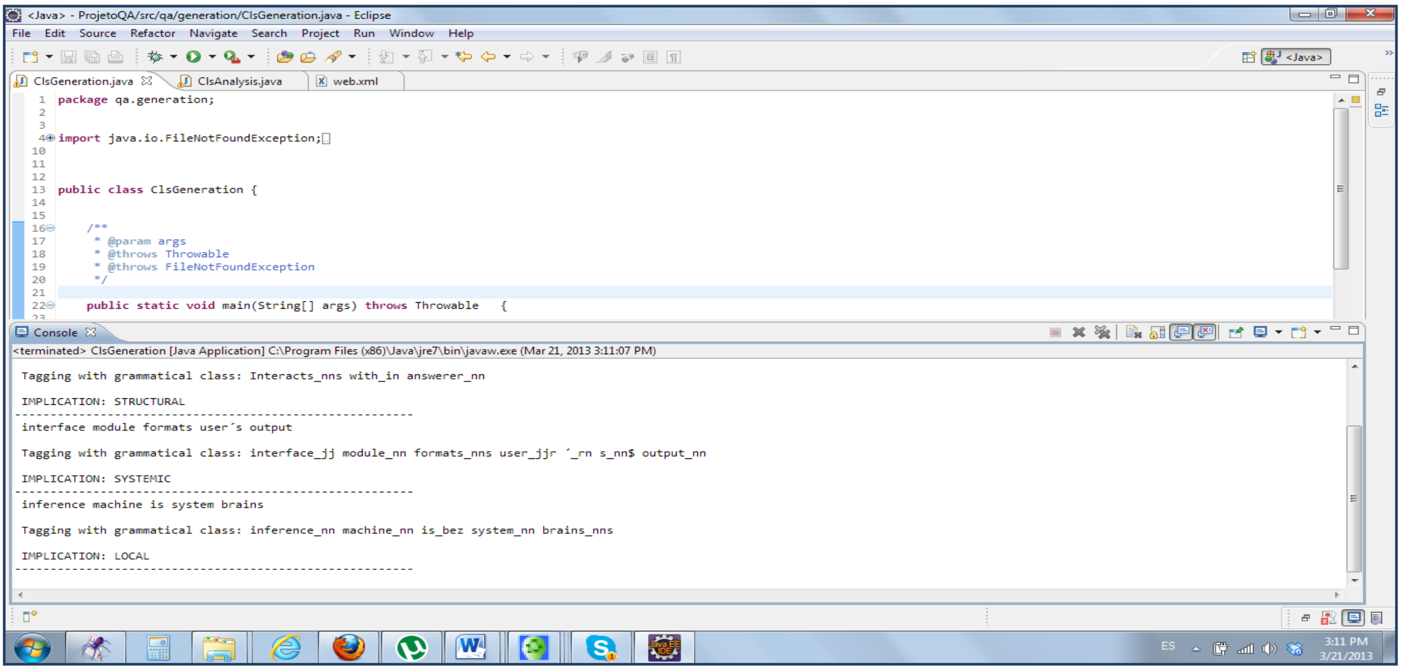

Figure 6 – The prototype partially implemented in Java.

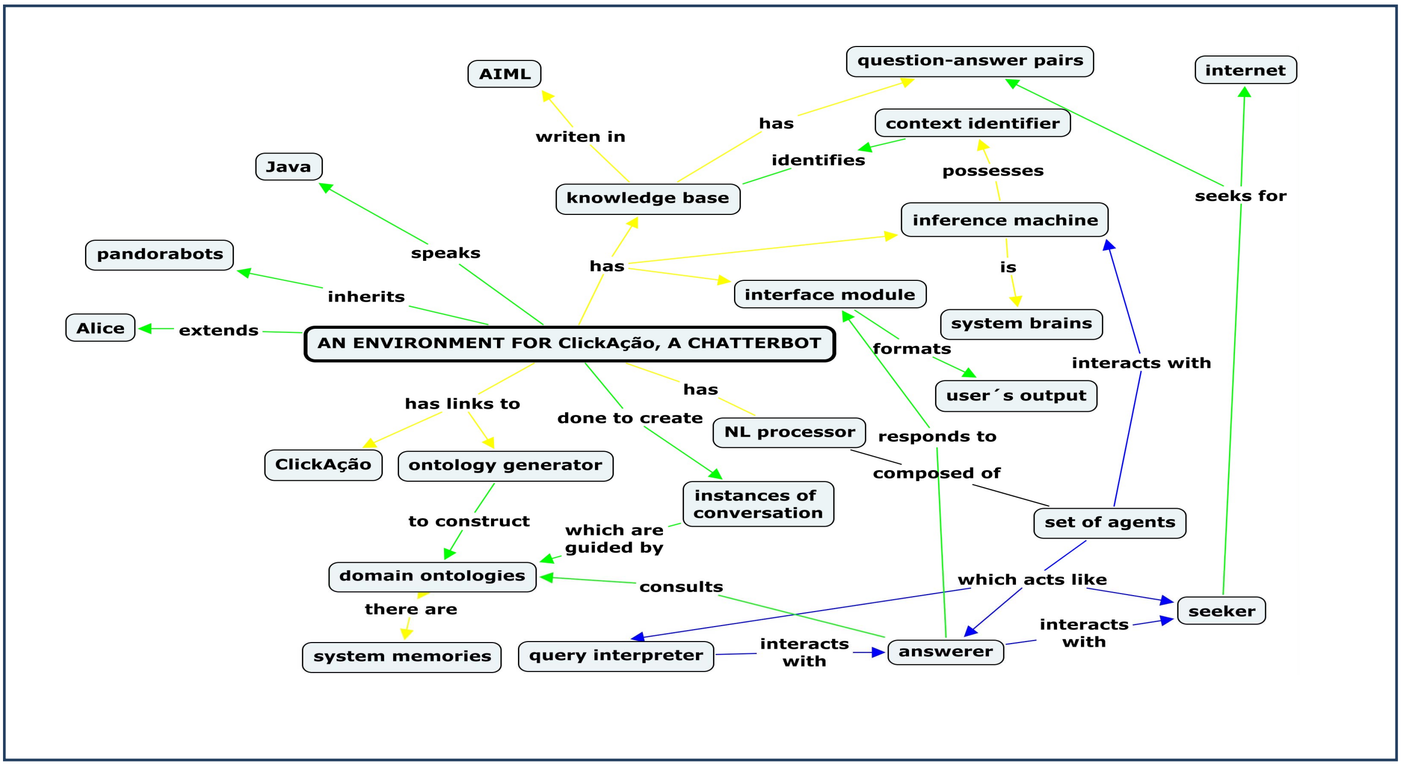

Figure 7 – Concept map colored by the tool.

I. PRELIMINARY CONCLUSIONS

The main idea is the use of concept maps as support to record students' understanding of a particular domain. The project proposes a form of automatic identification of the significant implications defined by Piaget in a map. This identification is made by using a family of software agents guided by an ontology of the relevant domain.

We are using concept maps for carrying several disciplines in computer science, where the analysis of maps based on Piagetian theory is being considered. Some related results are presented in this article. A prototype of the proposed environment is under development and will be used to support the analysis of the maps produced. This project is still in its first year, so the results are still preliminary. However, some experimental results have demonstrated its viability.

It is very well known that concept maps are good graphic representations for monitoring the learning process. Besides, they are a useful tool for knowledge construction. We dare to add that binding concept maps with piagetian implications creates a favorable context to learning. That becomes even more evident when the maps are automatically painted with the colors of the implications. This is valid not only for the teacher but also for the student. Like in a game, the implications establish the need of changing level, i.e., the need of going deeper into the domain. Immediately after seeing the map colored by the tool the teacher can see at which level the student is. Teaching becomes much easier than before, for the benefit of education.

So far, only a few computational tools have been developed to support constructivist teaching. We believe that the one presented here, which is based on Piaget´s learning theory, is an important step in facilitating the effective monitoring of the learning process.

Enhancing Student Motivation In Targeted Undergraduate Education

M.Kemal Bayrakceken, A.Ersan Oguz and Aydemir Arisoy
Turkish Air Force Academy
Electronics Engineering Department
Istanbul, Turkey
{kbayrakceken, aeoguz, aarisoy}@hho.edu.tr

***Abstract*— Future aims of an undergraduate student are likely to evolve during the education timeline. While new knowledge and experiences emerge into students mind, the way of thinking and decision making matures, hence builds up student's mental and academic perspective. This whole progress embodies a natural motivation as a result of ongoing "change". However, a targeted undergraduate education may suffer from the deficiency of this natural motivation where the students are partially aware of the future awaiting them. Military academies are good examples of targeted education, since the students have substantial amount of knowledge about their career alternatives. It is up to the instructor to overcome the negative effects of this situation. The instructor, being acquainted with the practical aspects of the courses, can build solid connections between conceptual knowledge and real-world applications where possible. For instance, it is natural that Air Force Academy students are best motivated with flight and related activities. Hence, using flying platforms, flight dynamics and similar content in experimental studies and in-class demonstrations will play a vital role in motivating students for academic study. In this sense, a four rotor aerial experimentation platform is designed, built and utilized for courses and laboratories. Here learning objectives/outcomes of in-class demonstrations are emphasized rather than technical details which are given in previously published articles. The method is evaluated by student surveys and instructor observations.**

Keywords—undergraduate education; control education; flight control; UAVs

I. INTRODUCTION

Future aims of an undergraduate student are likely to evolve during the education timeline. While new knowledge and experiences emerge into students mind, the way of thinking and decision making matures, hence builds up student's mental and academic perspective. This whole progress embodies a natural motivation as a result of ongoing "change". However, a targeted undergraduate education may suffer from the deficiency of this natural motivation where the students are partially aware of the future awaiting them.

Military academies are good examples of targeted education, since the students have substantial amount of knowledge about their career alternatives. This situation has both negative and positive effects on students. If the student is in a good mental state and has clear future aims, academic motivation might well exceed expectations. Student becomes eager to learn and is often willing to participate in additional social and scientific activities, which is a clear sign of motivation. However, if the student has below average grades and unclear future aims, he begins to question the necessity of the academic education and its direct/indirect relations to his future career. The chronic questions, though not always expressed in an audible way, "why am I learning all this theory" or "where am I going to use these information" are quite common among students. These contagious questions wipe the positive attitude and remaining motivation. However, the scene is still well recoverable. The instructor, being acquainted with the practical aspects of the courses, can build solid connections between conceptual knowledge and real-world applications.

Turkish Air Force Academy (TurAFA) offers four year undergraduate education. There are five departments which are aeronautical, civil, electronics, computer engineering and management sciences. Flight training and related activities continue concurrently with the four year undergraduate education. Upon graduation, students acquire a bachelor degree in one of the five departments. This paper focuses on education enhancement in electronics engineering department courses. Basic motivation of cadets is concentrated around flight and pilotage right from the first day at TurAFA, hence every educational activity in the TurAFA must have a rich sense of applied flight practices wherever possible. Innovative and insightful approaches are essential for the motivation of cadets for a targeted undergraduate education. The instructor, who is acquainted with the practical aspects of the courses, builds solid connections between conceptual knowledge and real-world applications wherever possible. Laboratory courses and in-class demonstrations play a vital role at this point. Electronics engineering department curriculum includes control related courses that are considered suitable for practical applications [1], which are directly related to the Air Force mission. In this sense the four rotor experimentation setup which is used in such practical applications fosters the flight and pilotage ambition by highlighting dynamics, modeling, and control of a quadrotor UAV.

Four rotor mini unmanned air vehicles are popular among researchers, academicians, and hobbyists [2-6]. The reasons

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

behind this popularity can be listed as reduced mechanical complexity compared to helicopters, ease of manufacturing and maintenance, as well as presenting a challenging control problem due to coupled and highly nonlinear dynamics [4]. Additionally, the widespread usage of quadrotor platforms led to a new benchmark system similar to acrobot, pendubot, and helicopter platforms. Comparison between control algorithms, tuned parameters, and mechanical structures might be made by means of metrics such as controller performance, robustness, and stability [5-7]. These key features answer the question of why a four rotor platform is chosen. Additionally, the platform is fixed on a universal joint for the safety issues while still maintaining the axial movement. The word "setup" is used throughout the paper to denote the educational platform..

Modern aircrafts are equipped with fly-by-wire systems where the aircraft is controlled by a flight computer rather than the direct operator manipulations. The flight computer receives data from sensors as well as pilot, calculates the best maneuver and activates control surfaces to achieve the required maneuver. This technology wrapped pilotage enables operation of sophisticated aircrafts, however it is not adequate for training of cadets. The real sensation of flight is achieved by a true understanding of the dynamics and how these dynamics are controlled. The setup is meant to help fulfill this requirement from an engineering point of view and prepare cadets for future practices. Engineering courses covering control related topics are adequate for this purpose. The setup is used to enhance learning in courses such as Automatic Control, Flight Control Systems, Control Systems Theory, and Control Systems Laboratory at the graduate level. This paper focuses on Automatic Control course.

The goal of the study is to present the motivation and learning enhancement in Automatic Control course with the aid of quadrotor setup. The learning objectives/outcomes of the in-class demonstrations are given in the second section. Third section addresses a summary of the procedure followed during in-class demonstrations. The success of the method is evaluated by student surveys and instructor observations in the fourth section. The conclusions are given in the fifth section.

II. The Learning Objectives/Outcomes Of In-class Demonstrations

In-class demonstrations are performed by the instructor within a single class hour (45 min) for maximum 15 students. If the number of students in a class is more than 15, two demonstration sessions are performed. Based on the subject and the learning objectives, the demonstrations are performed before or after the theoretical session. If it is aimed to put forward the question in advance, and arouse curiosity, demonstrations are performed right at the start of the class. Otherwise, they are performed after a theory or discussion to support learning by showing the practical aspect. In the latter case, the side benefits are eliciting an enjoyable discussion during the demonstration and helping students recover their concentration. The learning objectives/outcomes of the in-class demonstrations performed in Automatic Control course are summarized in Table **1**.

Table 1 The Learning Objectives/Outcomes of In-Class Demonstrations

Topic	**No**	**Objectives (It is aimed to learn …)**	**Before or after theory**	**Checklist of the desired outcomes (Can the students …)**
Feedback Control Basics	1	what feedback is.	before	define what is feedback?
				give examples of feedback?
	2	how feedback is applied to control systems.	after	give examples for open and closed loop control systems?
				design simple open and closed loop control systems?
Dynamic Modeling	3	what a dynamic model is.	before	see the physics behind the dynamic model?
				make an analogy between system behavior and its dynamic model?
	4	how parameters affect dynamic model.	after	identify the system parameters?

	10	what the differences between controllers are.	after	find an appropriate controller for given controller requirements?

III. The Procedure of In-class Demonstrations

The following paragraphs describe the procedure followed during in-class demonstrations.

A. Feedback Control Basics

Before the theory, a volunteer student is asked to help with the demonstration; and his eyes are covered. Then, he is asked to walk on a line without external support. After a few steps, he misses the line no matter how. It is emphasized that the eyes provide feedback to achieve walking precisely. Following this scene, the quadrotor setup is run; and it is emphasized that the inertial sensor mimics the eyes of the setup that provides feedback. Then, the inertial sensor is powered off; and it is shown that the setup can still be controlled; however, it is almost impossible to stabilize.

After the theory, the setup is run and the Simulink model of the controller are projected on the board. The closed and open loop control concept is shown on the model, and it is applied on the setup at the same time. A discussion about open and closed loop control systems in daily applications is elicited.

B. Dynamic Modeling

Before the theory, the setup is run, and the quadrotor coordinate system and dynamic equations are projected on the board. The symbols on the equations are briefly explained, and then the students are asked to brainstorm about the dynamic model while performing arbitrary maneuvers on the setup. Random questions are asked to students and they are couraged to make comments on the answers whether they are logical or not.

C. Stability

The stability demonstration aims to show what stability and instability are. Before the theory, the setup is run, and the quadrotor is held in a stabilized position. Then the controller coefficients are changed and it is seen that stability is lost and cannot be regained. After performing random maneuvers in unstable state, the controller coefficients are changed back to their optimized values and stability is regained. Following the scene, the students are asked to give examples of stability and instability from their daily lives. Additionally, a discussion is started about the practical applications of stable and unstable systems.

D. Time Domain Analysis

Before the theory, setup is run and arbitrary excitations on roll, pitch, and yaw axes are performed. The transient and the steady state responses for a unit step input are plotted and projected on the board. Maximum overshoot, rise time, settling time are emphasized on plots without giving formal definitions.

After the theory, the nonlinear causes of steady state error are demonstrated. The saturation and dead zones of actuators are simulated by artificially increasing and decreasing rotor speeds. The quantization error is simulated by decreasing the refresh rate of the inertial sensor. Following the demonstrations, the students are asked to give examples from daily life about systems suffering from steady state error and possible solutions to this problem.

E. Control System Design

Before the theory, the students are asked to think of maneuver envelopes and associated flight control systems of an airliner, a jet fighter, a UAV, and an air-to-air missile. Then, the setup is run and random maneuvers are performed with different controller coefficients. It is important to help students assign a coefficient profile to each air vehicle type. A simple table might be drawn on the board if necessary. Then a discussion is encouraged about flight controller characteristics of different types of flying machines.

The demonstrations of control system design aim to stress only the practical aspect and help students gain insights about the system behavior and the associated controller. This demonstration is last in the curriculum and the students should be monitored carefully not to go beyond the intended topics.

IV. Evaluation of the Method

A success criterion of in-class demonstrations is assessed by the survey results of spring 2012 in Figure 1. 68 students attended the survey anonymously. The average rating of each question is shown on top of the bar. Only 8 instances of “bad” ratings exist. However, “not good” ratings also address the issues that are awaiting improvement. The students are also asked whether having the setup fixed limited their interest or not. The majority of the students’ answers reveal that they are satisfied with the demonstrations and do not expect a flying setup in a room sized laboratory. However, it is thought that if the setup were located in a high ceiling laboratory where a quadrotor would safely fly, the students would well be expecting a flying setup. Consequently, a flying setup located in a furnished laboratory is considered a necessity for the future improvement of the in-class demonstrations.

In addition to survey analysis, instructor observations of years 2011 and 2012 are considered as a valuable metric. Since the number of students attending the demonstration sessions is below 15, the instructor can maintain eye contact and monitor individual involvements. It is up to the instructor to tune the level of the demonstration to the perception of the audience, and maximize learning as well as motivation. Students reveal their mental state by asking questions, making comments, joining discussions and all forms of body language. Based on two years’ observation of in-class demonstrations using the setup, it is fair to express that a notable enhancement of learning and motivation in “Automatic Control” course is achieved.

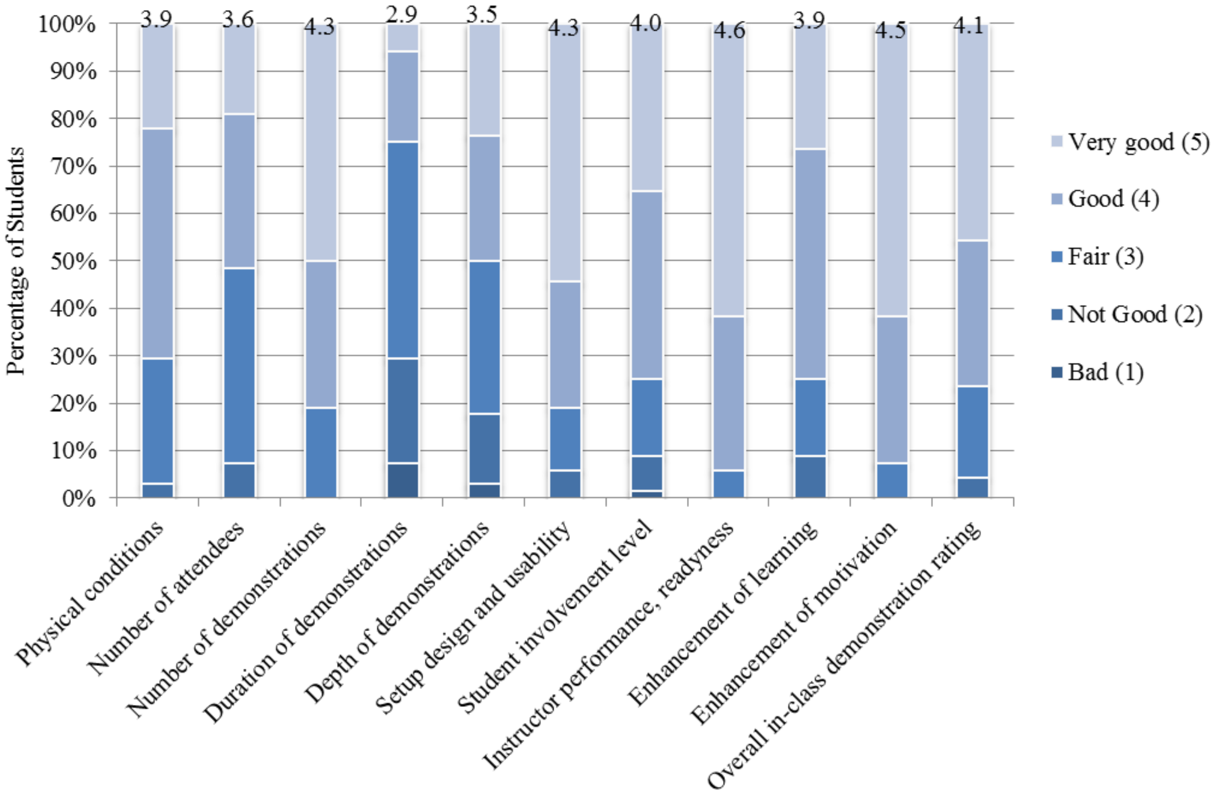

Figure 1 Student Feedback Analysis Graph

V. CONCLUSION

The presented quadrotor setup is a useful tool for control education. The setup meets the main objective which is an enhancement of motivation and learning in Automatic Control course. Additionally, the setup satisfies the academic requirements of undergraduate students, who are involved in pilotage or flight related activities. The success of the setup is deduced from the student survey analysis and instructor observations of years from 2011 to 2013.

A Semi-Autonomous Embedded Systems Course

John Oliver, Lynne A. Slivovksy, Bridget Benson, Jim Harris

Cal Polytechnic State University
San Luis Obispo, USA
{jyoliver, lslivovs, bbenson, jharris}@calpoly.edu

***Abstract*— Educational research has shown that students learn with deeper understanding and retain that understanding for a greater duration when they learn in an environment of inquiry. In order to foster an environment of inquiry in an embedded systems course, we have redesigned the course to give students more and more autonomy with course material as the course progresses. In this paper, we describe the design and preliminary assessment of a semi-autonomous embedded systems course in the computer engineering program at Cal Poly, San Luis Obispo. Preliminary assessment data indicate that the course appears to provide an environment of inquiry for students, but further assessment is required to determine if the semi-autonomous nature of the course increased student understanding and retention of course material.**

Keywords—embedded systems; learner autonomy; scaffolding; self-directed learning

I. Introduction

Evidence shows that when students learn out of curiosity, they learn with deeper understanding and retain that understanding for greater duration [1,2]. Providing for students' needs of autonomy, relatedness and competence positively affects their intrinsic motivation, academic performance, and healthy psychological growth [3,4]. Opportunities for self-regulated learning may help learners attain a sense of competence [5]. High self-efficacy has a positive effect on motivation and learning performance [6]. Additionally, positive correlations exist between motivational components such as perceived competance, value and interest, and cognitive components such as engagement and self-regulation [7]. In order to foster an environment of inquiry and to support student autonomy, this paper describes the ongoing transformation of a microcontroller embedded systems course at California Polytechnic State Univeriesty, San Luis Obispo (Cal Poly) that is designed to support learner autonomy. We present a preliminary summative assessment of the course based on the Learning Climate Questionnaire (LCQ) [8] and the Motivated Strategies for Learning Questionnaire (MSLQ) [9]. The objective of this work-in-progress paper is to reach out to the engineering educational community for suggestions and feedback on how to improve both the embedded systems course and our assessment methodology.

II. Designing a Semi-Autonomous Embedded Systems Course

The embedded systems course (CPE 329) that is the topic of this paper is a required course for electrical engineering students and computer engineering students. Students typically take this 10-week course in the student's junior year. In this course, students work in pairs in what we call a "studio format", where students are in a lab for a total of six hours per week. This was a change from the previous format of three hours of lecture and three hours of lab per week.

While the disciplines of electrical engineering and computer engineering share significant overlap, we have found that the students in this course have wide and varying technical interests and enter our class with varying technical capabilities. We have developed a semi-autonomous pedagogy to accommodate students with these diverse backgrounds. Students with more experience in circuit design can tailor their course to incorporate more circuit design into their embedded systems, while students with a stronger background in programming can develop more software intensive projects. Students can progress at their own rate through much of the course material. This can keep the course challenging for those students who enter the course with embedded systems experience and, more importantly, relaxes the pace for students who require greater time to construct a solid foundation of embedded systems. To facilitate the semi-autonomous nature of CPE 329, there are four different mechanisms in place: 1. written tutorials, 2. instructional videos, 3. course projects, and 4. lab access.

Written Tutorials

The first mechanism is a set of tutorials. These tutorials are designed to be short, are typically two pages of written text and include a hands-on exercise that most students can complete in an hour. Tutorials cover topics such as C-programming, bit-twiddling, timers, interrupts, and common I/O interfaces. The tutorials are available at the start of the course and grouped into required or optional categories. The required tutorials are ordered at the start of the course to provide scaffolding for the first two course projects, which will be discussed later. As the course progresses, students choose tutorials from a selection, allowing them to customize the course to explore their strengths or develop technical competency in areas they are less comfortable.

Instructional Videos

The second mechanism that makes CPE 329 semi-autonomous is a series of instructional videos with associated self-assessments. Videos typically cover one interface of the microcontroller, or other related issue to embedded systems. Videos are designed to last about 10 minutes, can be watched

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

at any time during the quarter, and are accessible anywhere via an internet connection. Suggested due dates for watching videos are included as the videos can serve as scaffolding for the course projects as well. Students can watch the videos in any order, thereby allowing students with more experience with microcontrollers to proceed to working on the course design projects sooner than their peers.

A majority of the videos cover required topics to fulfill the learning objectives of the course. However, there is also a set of videos that may be optionally viewed by students. Finally, some videos have been developed by students for their peers. Students receive credit for these videos through a "course improvement" assignment.

The self-assessments that accompany the instructional videos may be taken by students at any time and are administered online through our learning-management software (Moodle). There is at least one self-assessment per video. The self-assessments are typically 4-5 multiple choice or numeric questions. There are several goals of the self-assessments. The first goal is to highlight the most important aspects of the course. Another goal is to provide a low-pressure method for students to test their understanding of some of the basics of the course. Finally, the completion rates of the self-assessments provide the instructor feedback on the progress of the students in the course.

Course Projects

A third mechanism for facilitating autonomy is the use of course projects. In this course, there are four course projects, each of which have increasing amounts of autonomy. In the first project, students learn to write and compile C code and use software delays with general-purpose IO to display messages on an LCD display. Students design a function generator by using timers, interrupts and a digital-to-analog converter in the second project. These first two projects are highly scaffolded and cover the majority of the required learning objectives of the course. For the third project, students begin to have more autonomy while developing a sensor project. Students select a particular sensor from a list, or get one approved by the instructor. The goal of the project is to integrate the sensor with the microcontroller and test the sensor system for accuracy. Since both the sensor and its application are up to the student, there is considerable autonomy in the third project. For the final course project, students propose a microcontroller system of their choosing, allowing for significant autonomy.

Lab Access

Finally, at a lab-intensive school such as Cal Poly, it is sometimes difficult for students to access laboratories outside of class time. To mitigate this, we strive to provide lab access to students in the evenings and during weekends. For students with their own computers, the software development tools for the ATMega microcontroller used in the course are freely available. Low-cost lab measurement tools are promoted to the students, such as Salae's Logic 16 and Digilent's Analog Discovery tools. The cost of these tools is offset by providing all course resources in free electronic format. These tools, in conjunction with tutorials, videos and self-defined projects allow students to work remotely on their own schedule.

III. ASSESSMENT OF CPE 329

Assessing how autonomy contributes to learning is the primary concern we have for CPE 329. We have adapted the Learning Climate Questionnaire (LCQ) [8] to assess if the course is conducive to learning autonomy. The Motivated Strategies for Learning Questionnaire (MSLQ) [9] has also been distributed to students in CPE 329. We distributed the MSLQ survey to students before and after the course but the LCQ only at the end of the course. The new format has only existed for one quarter, for a total of N=42 students and the results collected are currently not statistically significant. However using the results of these surveys, we hope to draw a few broad generalizations to further inform out assessment strategy.

Fig. 1 shows the average results for the MSLQ pre and post surveys, broken down by different value components typically). We can see that Cal Poly students scored high on "task value" (measures perception of material interest, importance and utility), extrinsic motivation and their ability to control their academic performance. Likewise, students reported low metacognitive self-regulation, and do not seek help from others nor use many techniques for deep learning such as critical thinking, organization and rehearsal. For a student group with these characteristics, we believe that more autonomy is well suited but the challenge will be to influence deeper understanding of embedded systems issues.

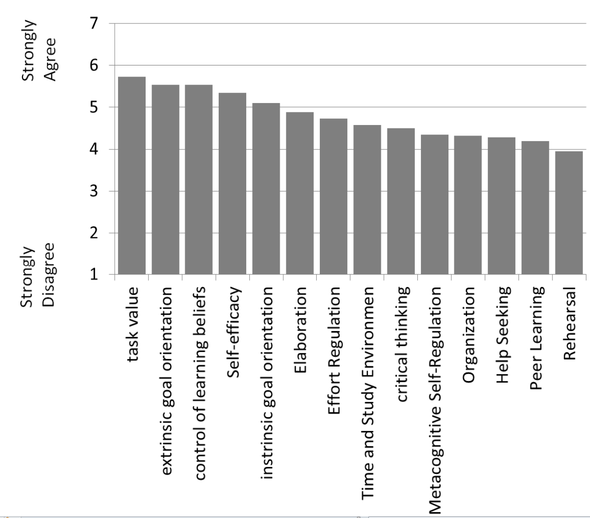

Figure 1. Average MSLQ results broken down by value component.

Fig. 2 shows results on the MSLQ with the largest difference between the pre-course survey and the post-course survey. For Fig.2, the number of responses to the pre-survey was 42 and the number of responses for the post survey was 34. Generally, students agree that the course material as taught in CPE 329 is both useful and interesting, meaning they have high motivation due to interest. This is encouraging as the context of the course material is being conveyed despite the semi-autonomous nature of the course. However, student motivation due to expectancy has fallen during the course of CPE 329. Possible reasons could be due to the semi-autonomous nature of the course, students feel disconnected from the assessment strategy of the course, possibly feel unsure if they are attaining the learning outcomes of the course, or in the worst case do not feel that the assessments fairly measure the course learning objectives.

Other questions with the largest differential between pre-course survey and post-course survey fall into two different categories. Survey questions relating to the understanding of written course materials fell by 1.25 ranks (on a Likert scale of 1 to 7). This is not particularly alarming as video is the primary method for delivering learning objectives in this course. However, since reading comprehension is an irreplaceable skill, this is something to be cognizant of for the future. Similarly, survey questions relating to note taking and summarization of course content also see a negative trend from pre to post course surveys.

The results of the LCQ were generally positive but uninteresting. Students found the learning environment comfortable and that their instructor would listen to them. Participation in the LCQ was very low (N=13) as the survey was given after the end of the class.

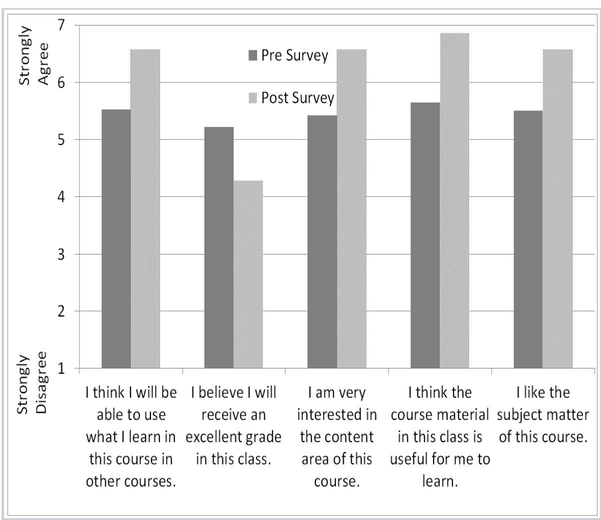

Figure 2. MSLQ questions with a high pre-to-post differential

Several confounding factors in our assessment strategy have been identified. First is that the data was gathered across different instructors. While lecturing in these courses is kept minimal, the instructor has a significant role in helping students in the classroom with the course material. Instructor personal interaction style could influence the data. The problems in schools questionnaire [10] could be used to help differentiate instructor differences.

Correlating learning outcomes with student motivation is difficult and due to the anonymity of the surveys we are unable to correlate final course grades with the different survey questions.

Outside of assessment, future work may include requiring students to complete some meta-cognitive exercises such as a reflective journal [11] and including exercises that will help students identify learning strategies that work well for them. Also including more assigned readings and group problem solving could address issues in reading comprehension as well as help seeking.

IV. NEXT STEPS & DISCUSSION

It was our hope that our assessment strategy would show growth in student self-efficacy in CPE 329. Instead, preliminary results indicate that students' confidence in getting a good grade in the course eroded over the course of the class. While results indicate that task value may have increased, we attribute these gains more to the subject material and its application to course projects rather than due to the semi-autonomous nature of the course. We are searching for alternative assessment strategies to better determine the contribution of autonomy in learning objective attainment. Also, rather than using a summative assessment, perhaps a formative assessment approach would yield more interesting results.

Can utilizing social media and visual programming increase retention of minorities in programming classes?

Khallai Taylor
Computer Information Systems Department
Triton College
River Grove, USA

***Abstract*— This paper discusses how Social Digital Literacy is being used in CS1 to teach critical and computational thinking by delivering content to students through the use of social media. Social Digital Literacy (SDL) is the way in which people use social media to enhance their social network, effectively increase their knowledge base, while communicating clearly and professionally through the use of social media. The increased popularity of social media amongst college students makes it an opportune time to consider a new form of literacy based on how technology is used by students, the devices that students interact with on a daily bases and the mainstream acceptance of social media in daily life. In order to retain students in computing classes, students are taught in an efficacious manner how to capitalize on the technology that they use on a daily basis. By increasing their SDL proficiency to become a more informed student, a well versed employee and consciously aware of what they post to social media. The expectation is that the approach being used can be implemented in any introductory programming course.**

Keywords—social media; visual programming; engineering education; diversity

I. INTRODUCTION

At the community college level it can be a challenge to retain women and underrepresented minorities in programming classes, mainly due to misconceptions of what programmers do, what a programmer looks like, and the misconception amongst Triton students that high level math is required before a programming class can be taken. This paper discusses how Social Digital Literacy is being used at Triton College to teach critical and computational thinking by delivering content to students through the use of social media and visual programming. Social Digital Literacy (SDL) is the way in which people use social media to enhance their social network, effectively increase their knowledge base, while communicating clearly and professionally through the use of social media

The increased popularity of social media amongst college students makes it a opportune time to consider a new form of literacy based on how technology is used by students, the devices that students interact with on a daily bases and the mainstream acceptance of social media in daily life. SDL addresses this by creatively teaching students how to maximize technology through the use of social media.

We use technology which students are most familiar to introduce them to the principles of programming. Students are required to read, watch and comment on technology postings made to the class Facebook page. They are able to learn about engineering and computing jobs through social media, which they can access from their smartphones or any web enabled device. As for students who do not have a facebook account, or who prefer not to have a social media account as part of thier daily life. Are given the option of creating an alias facebook account that is connected to an email that they create just for the semester to link to facebook. These students who number less then three per class are able to learn SDL skills by having an alias facebook account. Thereby allowing for all students to participate in the facebook questions each week.

Programming fundamentals are taught in conjunction with visual programming using Scratch. Scratch enables students the ability to fully understand abstract concepts such as objects, making it possible for them to have a clearer understanding of computer programming [1]. This paper discusses how (1)SDL is being used for undergraduate college students to increase student engagement in introductory programming classes (CS1) and (2) how SDL is being used as a retention strategy for women and under-represented minorities.

Currently 94% of freshmen students entering Triton College have test into developmental math and do not have the desired level of math achievement for a traditional programming course. Triton College has chosen to eliminate the math pre-requisite for CS1 programming courses, which consists of CIS 191 Programming for Engineers, CIS 121 Introduction to Programming and CIS 163 Introduction to Java, thereby allowing students who would traditionally not be qualified to take a freshmen level programming course to be exposed to the world of engineering in the early stages of their academic journey within a community college classroom [4][2]. Research supports the utilization of social media and visual programming as successful learning tools for the 21st century student [1][3][4][5]. Literature also supports the need for faculty to be cognizant of the unique needs of women and underrepresented minorities in programming classes when teaching fundamental programming concepts to students [6]. While removing the math requirement is not a new concept its absence at the community college level is significant because it opens up the possibility for a new pool of qualified candidates for engineering and computing professions that would otherwise be overlooked.

II. SOCIAL MEDIA

The use of social media as a tool to teach students has been shown to enhance engagement and interest of students while increasing digital literacy [4][3]. Due to familiarity with Facebook and the nonjudgmental environment, students currently ask questions that require critical thought processes via this format more often then they do in class. Types of posts include articles and videos to watch such as the video from code.org entitled "What most schools don't teach," which features computing pioneers, women, and underrepresented minorities who advocate teaching kids to code. Students where asked to respond to the following question based on the content in the video [7].

Question: Why should kids learn to code?

Student Responses:

"I agree that computer programming can seem a bit intimidating but its a learned language if you give the kids opportunity to learn something new they have a feel for it and it can even drive them into the computer field like the video said everything is dependent of technology. Since taking this class I catch myself at work a little fascinated by how a program is constructed. What codes where required to build the software being used. " *Hispanic Female*

"Coding should be taught to children because coding involves problem-solving…The biggest justification for learning a valuable skill is not economic but moral. If our educational system doesn't act now, children will be short-changed, if they don't have a deeper understanding of technology they will effectively be intellectually crippled. They will grow up as passive consumers of closed devices and services …" *African-American Female*

Exposing students to how different programmers are in respect to age, gender, and race conveys to students positive impressions of programming as a career. Removing 'unspoken' barriers that would otherwise hold students back from entertaining a career or major in engineering. An example of what programmers look like was shown to students via a video by Google in Education focusing on women in technology [8].

Question: What excites these women about Technology?

Student Responses:

"I liked this video because it shows that girls can be creative and make a difference in the technology world too. Most people think of guys when they think of technology and this video proves that stereotype wrong. I also liked this video because it shows me that there are girls working on the technology I will be using in my career". *Caucasion Female*

"The ladies in the video are excited about what they do because they love the interaction they get to do with other people and touching other fields because mostly every field requires a computer. They want to contribute to the technology business as much as they can and show it is not just a male dominate world anymore. Just like men get a kick out of the things they create also the women in the video love the new ideas and creations they make." *Hispanic Male*

The concept of SDL is explained to students prior to completing a Facebook question. With a brief in class discussion on the topic posted on Facebook. All students are given up to twenty minutes of class time, once a week, to complete the facebook question. Completing Facebook as a class allows for videos to be watched as a group, clarification of the question, if needed, to be explained and access to a web enabled computer for question completion. Giving students the resources needed in class has proven to be successful for students who do not own smartphones or have internet access at home. Allowing all students the opportunity to develop SDL skills.

Using social media in class requires students to think critically about the particular question before responding; while educating students about the diverse nature of computing. Such as the Facebook post of a Technology, Entertainment, Design (TED) talk video that focused on how technology is being used to find jobs in England[9].

Question: After viewing the TED talk do you think jobs and workers are being impacted by technology? Why?

Student Responses:

"It would appear that there is a tremendous untapped market for immediate hands on workers whom themselves are out of traditional work (myself included). Providing such a system would have immediate beneficial effects on workers and companies; companies get the bodies they need to get the job done and workers get to earn some money in the little free time they have to spare. One could argue that with such a system in place some people would have the option of working only when they needed to thus relieving the strain of life with having to work but also having other obligations that one simply cannot ignore such as higher education and child care.." *African-American Male*

Students are learning how coding is fundamentally connected to programming and are taught in CS1 courses how the two become one, instead of experiencing them as seperate entities as it was taught in the 20th century[10]. Students are empowered by the intricacies and diversity of programming.

Scratch enables students to understand abstract concepts in programming such as objects, variables and looping through the use of programming blocks. Scratch was designed for grade school children but can be used at the CS1 level to teach programming concepts [1][5]. At the beginning of the semester Scratch is introduced to help students understand the fundamentals of programming. This exposure has proven effective for students who have limited math skills and minimal computational thought process. By effectively letting the student see an abstract object, such as a variable that is used for taking score or the use of random numbers working immediately. "*Scratch helps users stay engaged in testing, debugging, and improving their projects*"[1]. By using Scratch in conjunction with traditional teaching strategies and social media, students are more enthusiastic and eager to create a Java or C++ program. A Hispanic Female student pointed out that she saw the similarities between arithmetic operators and variables used in C++ to that used in visual programming blocks in Scratch

III. Retention Strategies

Research has shown that "understanding digital communication tools and putting them to work effectively- achieving digital literacy- is essential for success in the 21st Century"[4]. The use of social media as a tool for student retention and engagement in college classrooms is in its infancy, yet students have fully embraced every aspect of social media, and are comfortable using it for educational purposes[3].

Emphasizing digital literacy through social media and visual programming has increased the retention of students in CS1 courses at Triton College. Approximately 30% of Students who have taken CS1 went on to register for advanced Programming courses. Compared to 2% the previous year. There were a total of 38 students enrolled in two CS1 courses for Spring 2013 semester; 32 students remained enrolled beyond week 6 of the semester, 26 males and 6 females of that 11 Hispanic males, 3 Hispanic females, 3 African-American males, and 0 African-American females.

CS1 taught with social media, visual programming and traditional methods retained 84% of students in the course after the official drop date compared to only 55% of students after the official drop date for Fall 2012 semester. At the end of the semester students share via an online survey upon course completion what they learned form the course; how they feel about the use of Facebook in the class and any recommendations they have to improve the course. 89% of the students said that they liked using Facebook in the course. 90% said they learned how to use social media for educational purposes and 10% disliked using Facebook for educational use.

The primary question posed in this paper - Can utilizing social media and visual programming increase retention of minorities in programming classes? Yes, it has been successfully implemented at Triton College with students enrolling in advance programming courses after completion of CS1, with the belief that CS1 nurtured a sustainable interest with students who want to major in Computer Science or Engineering. The expectation is that the approach being used can be implemented in any introductory programming course to attract, retain, and graduate a more diverse group of qualified engineering and computing professionals for the 21st century workforce. Therefore the question that Academia should consider would be how to incorporate social media into the curriculum and not if social media is relevant to education.

***Abstract*— The recent sensing capabilities of mobile devices along with their interactivity and popularity in the student community can be used to create a unique learning environment in engineering education. Android Java-DSP (AJDSP) is a mobile educational application that interfaces with sensors and enables simulation and visualization of signal processing concepts. In this paper, we present the work done towards building non-invasive physiological signal monitoring tools in AJDSP through hardware interfaces to both external sensors and on-board device sensors. Examples of laboratory exercises that can be introduced in classes are presented. The proposed software tools can be used to provide intuitive understanding in wireless sensing and feature extraction to demonstrate the application of DSP to health monitoring systems. The effectiveness of the software modules in enhancing student understanding is demonstrated with the help of preliminary assessments.**

Keywords—Android, DSP, Mobile Health Monitoring, Wireless Sensors, Physiological Signals

I. Introduction

Over the last decade computer based tools have created a great impact in engineering education. This has led to the development of several tools used in digital signal processing (DSP) courses that enable students to apply concepts in a variety of contexts. One such important tool is Java-DSP [1,2], a web-based visual programming environment consisting of various functions built to perform DSP simulations. Recently, mobile devices are being used to progressively engage students through their ability to provide enhanced visual representations of content with interactive user interfaces. This, in turn, brings a need to develop mobile applications (apps) that can augment a course curriculum in STEM education. Instead of using these devices as an alternative platform for content delivery, exploiting their interactivity can create a personalized learning environment that continues to move outside the classroom [3]. Wireless and mobile technologies can provide learning in multiple contexts [4] by connecting students with their peers and teachers, and introducing instant feedback in the learning process. Studies suggest that students feel more confident, develop critical reasoning and are able to retain their learning for longer when working in such an environment [5].

Current Android devices comprise sufficient memory, processing power and a rich set of on-board peripherals such as accelerometers, digital magnetometers, gyroscopes, GPS receivers, microphones, and cameras [6]. Together, these sensors enable the development of a diverse set of applications, many of which can be used for research in mobile healthcare (m-Health). For instance, parameters such as pulse rate, blood pressure, oxygen saturation, and skin conductance, shown to vary based on physical activity and stress can be measured using mobile devices and sensors.

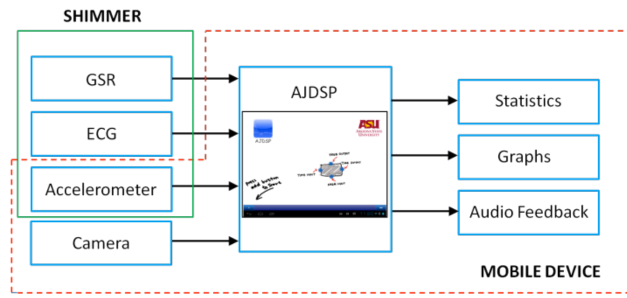

Fig. 1. Overview of the proposed mobile health monitoring system using android mobile devices.

In this paper, we explore the trend of mobile sensing and adapt it towards improving digital signal processing (DSP) instruction by building interfaces to external and on-board sensors (Fig. 1), thereby providing a new scientific paradigm for teaching. Some of the popular Android apps available for learning DSP principles include MATLAB Mobile [7], WolframAlpha [8], and Octave [9]. Several of these apps typically have a command-line interface and require Internet connectivity to interface with the cloud. In addition, MATLAB Mobile and WolframAlpha also require an active license. Although these and other applications available in the market today are compelling, most do not provide a way to design and configure simulations and visualize results. To address these drawbacks, we have developed iOS and Android graphical programming apps (iJDSP and AJDSP) that can be used to complement instruction in graduate and undergraduate DSP courses [10-13]. The iJDSP app is available for free download on the iTunes App Store [14]. The AJDSP app will be available for download on the Google Play store by late summer 2013, and it can be run on all Android smartphones and tablets [15]. The apps support several DSP functions pertaining to topics such as filter design, convolution, multirate signal processing and the FFT. They also comprise an easy-to-use interactive design, numerous visualization tools, and a provision to create simulations of DSP systems.

The primary focus of this paper is to present AJDSP interfaces to wearable wireless sensors, developed by

Shimmer Research Inc. The new sensing features are used to link concepts in DSP and wireless networks to applications in health monitoring. The proposed interfaces will enable students from the STEM program to perform laboratories that associate basic parameters estimated from bio-signals with bio-physical conditions. As part of this work, we have developed software modules in AJDSP to: (a) acquire data from on-board and SHIMMER sensors; (b) extract relevant features from the sensor measurements; and (c) compute and visualize bio-signal parameters. In addition, data acquired from these sensors can be processed using other AJDSP functions. Laboratory exercises and tutorials to be deployed in an undergraduate level DSP course (EEE 407) and a graduate level biosensors (EEE 598) course at Arizona State University (ASU) are being developed. The AJDSP app with its unique combination of sophisticated DSP functionalities, the proposed sensing features, and interactive workspace for performing block-based simulations make it a novel and valuable educational tool.

This rest of this paper is organized in the following manner. Section II provides a brief background on mobile apps for education and healthcare, and the SHIMMER sensor platform. Section III gives an overview of the AJDSP app. Section IV describes the proposed interfaces and the various physiological signals that can be monitored using AJDSP. In addition, it presents an overview of the learning opportunity using such interfaces. Section V presents a few sample laboratory exercises. Section VI discusses the assessment results, and concluding remarks are presented in Section VII.

II. MOBILE APPLICATIONS AND SENSORS

In this section, a brief overview of existing apps used in education and health monitoring are presented. Furthermore, a background on the SHIMMER sensor platform that is interfaced with the AJDSP app is also provided.

A. *Apps in Education and Healthcare*

A plethora of apps exist in the market today, many of which are geared towards assisting teachers and students in various tasks related to coursework. Some examples are Blackboard Mobile [16], Class Dojo [17], Calculus Tools [18], and Cram [19].

In addition, there exist several apps providing health related information based on measurements acquired using on-board device sensors. At times these can also connect to remote databases containing patient health records. A few examples are: (a) Endomondo which monitors users engaged in activities such as running, walking, and cycling [20]; (b) Instant Heart Rate Pro is an app that measures heart rate and allows sharing information via internet; (c) The Stress Check app measures stress levels of a person using their heart rate [21]; (d) Blood Pressure Journal that measures blood pressure, heart rate, custom medication doses, weight, and body mass index (BMI) [22]; and (e) FitBit, which automatically and wirelessly records data such as steps, distances, and calories burned, obtained from a FitBit tracker. It enables daily monitoring of food, activity, weight, water, and sleep [23]. However, these apps do not have the facility to allow users to perform tasks and analyses using DSP tools, and therefore have no scope to be used for DSP education and research.

B. *SHIMMER Sensor Platform*

Sensing Health with Intelligence, Modularity, Mobility and Experimental Reusability (SHIMMER) is a small wireless low-power sensor platform that can record and transmit physiological and kinematic data in real-time. This sensing platform has been adopted to increase the applications of sensor technology in healthcare, using open standards to achieve this goal. The platform focuses on integrating hardware and software components to allow for rapid prototyping of research in biomedical applications [24]. The SHIMMER baseboard forms the core component of this platform and comprises a microcontroller, a Texas Instruments™ MSP430 MCU, the advantage of which is that it consumes low power when inactive and is effective in medical sensing applications. The baseboard also consists of a Bluetooth or 802.15.4 low power radio transceiver, an accelerometer for activity monitoring, data storage using a micro SD card, and connection capabilities to different kinds of daughterboards (biosensors). The daughterboards extend the abilities of this platform by providing various kinematic, ambient and physiological sensing functionalities:

1) *Kinematic sensing:* Accelerometers, gyroscopes and magnetometers are included and utilized for inertial measurement applications.
2) *Physiological sensing:* Incorporates Galvanic Skin Response (GSR), Electrocardiogram (ECG), and Electromyography (EMG) sensors.
3) *Ambient sensing:* Comprises of temperature and light sensors.

In the recent past, several m-Health applications have used the SHIMMER sensor platform to reliably obtain sensing measurements in real-time for signal monitoring and diagnosis. BioMOBIUS is an example where SHIMMER is used as part of a medical research platform [24]. Accelerometers have been used to study energy expenditure estimation in patients with Rheumatoid Arthritis [25]. ECG sensors have enabled a wavelet-based real-time delineation and compressed sensing-based compression of ECG signals [26,27]. Motion analysis of patients with Parkinson's disease, stroke, and epilepsy, using a wearable wireless sensor platform called Mercury has been developed in [28]. A combination of physiological sensors has been used to perform activity aware stress detection [29].

In the proposed interface, we employ the SHIMMER platform for real-time sensing, as it includes libraries for app development on Android devices. Moreover, the compact size, extensive sensing capabilities, wearability and light weight nature, make the SHIMMER ideal for creating mobile and nonintrusive physiological signal monitoring systems. The purpose of building this platform has primarily been for use in various biomedical and activity aware applications; however, it has not been used for demonstrative purposes in an undergraduate DSP course.

Fig. 2. SHIMMER interface to stream data in real-time. As an example, the accelerometer is chosen as shown in the options menu.

III. AJDSP OVERVIEW

In this section, we provide a brief background on the AJDSP app and its functionalities.

AJDSP is a standalone mobile graphical programming app designed to be used to aid in signal processing education. The app comprises of a block-based interface consisting of inputs and outputs that allow presentation of DSP concepts in an easily understandable manner. Using AJDSP, students can establish and run DSP algorithms with various configurations on their Android devices and can also perform undergraduate signal processing laboratories.

Signal processing functions, including signal generation, signal processing and signal display units are incorporated into the application. AJDSP has capabilities to generate deterministic and random signals, as well as MIDI and DTMF waveforms. Along with a rich suite of time and frequency domain signal processing functions, algorithms such as the fast Fourier transform, filter design and *z*-domain operations have been implemented. Furthermore, interactive demonstrations to teach concepts of continous-time and discrete-time convolution and relationships between the *z*-domain and the frequency-domain using the pole-zero placement method are provided.

IV. DEVELOPMENT OF AJDSP HEALTH MONITORING LABS

In this section, we describe the proposed sensing interfaces for AJDSP and highlight the concepts about which intuition can be provided by introducing health monitoring laboratories in DSP courses.

The proposed sensor interfaces allow access to both external SHIMMER sensors and on-board mobile device sensors. Data can be streamed in real-time from the SHIMMER-based electrocardiogram (ECG) sensor, galvanic skin response (GSR) sensor, and the accelerometer using the *Shimmer Signal Generator* block. It establishes a Bluetooth connection between the SHIMMER baseboard and the

Fig. 3. FFT processing of SHIMMER sensor data.

Android device and data is acquired by configuring the required sensor to be turned on. Fig. 2 shows streaming data from a 3-axis accelerometer and Fig. 3 shows the FFT of the data. Changes in readings indicate movement of the sensor along each of the 3 axes. A brief description of the various sensor signals and the corresponding features that can be extracted using AJDSP is presented below. In addition, concepts that are intended to be taught using the proposed interfaces of AJDSP for in-class demonstrations and purposes of performing laboratory exercises are mentioned.

A. *Accelerometer*

The accelerometer can be used to measure instantaneous acceleration due to forces acting on the sensor. Analysis of accelerometer data requires extraction of features such as mean, standard deviation, and energy for each axis, and correlations between axes. Students can be provided with an insight on how physiological responses tend to be affected by physical activity. Examples inlude, displaying readings and waveforms of sensor measurements obtained while a person is at rest, in comparison to while a person is walking. Therefore, a need to incorporate accelerometer measurements in context-aware applications such as stress detection can be demonstrated. Furthermore, the appropriate placement and positioning of sensors for different appplications can be presented. For example, it can be shown that placing the accelerometer on the hip helps in classifying physical activity [30].

B. *Electrocardiogram (ECG)*

The ECG sensor detects small changes in electrical activity of the skin at every heart beat. The measurement is used to analyze the functionality of the heart based on the regularity of the heartbeats. An important processing step in ECG signal analysis is the extraction of the QRS-complex and detection of the R-wave peaks [31]. A few other features that can be extracted include the mean and standard deviation of heart rate and R-R interval, root mean square (RMS) value of the differences between successive R-R intervals, and percentage of heat beat intervals with a successive R-R difference in interval greater than 50ms (pNN50) [32].

Using these functions, demonstrations on the different configurations of electrode placement used to acquire the ECG measurements can be provided. Typical characteristics of ECG waveforms (Fig. 4) like the QRS-complex, P-wave and T-wave segments and their corresponding range of time intervals for normal and abnormal recordings can be understood. ECG signal artifacts such as low frequency baseline wandering and high frequency power line interferences that occur during signal acquisition can be observed.

Fig. 4. The ECG Signal Generator function block.

Concepts of signal denoising operations and the challenges faced can be highlighted. In addition, the time-domain and the frequency-domain visualization of extracted feature vectors such as, R-R interval and heart rate variability (HRV) can be associated with corresponding health conditions.

C. *Galvanic Skin Response (GSR)*

The GSR sensor measures the electrical resistance of skin based on the amount of moisture content present in it. This conductance varies based on skin and muscle tissue responses to stimuli. It is used to detect stress, fear or anxiety, all of which make sweat glands more active and cause a decrease in the skin resistance. Two signal characteristics that can be visualized from the GSR signal are: (a) Skin Conductance Level (SCL) – a slowly varying signal; and (b) Skin Conductance Response (SCR) – a fast varying signal. Important features extracted from this signal are the amplitude and latency of SCR and the mean and standard deviation of SCL. The distribution of the SCL peak and the SCR peak rate can be shown to carry information regarding the stress level of a person [29]. Using these features, classification of skin conductance into Tonic conductance and Phasic conductance can be demonstrated. The former is observed as a sharp transition in the signal values due to a stimulus and the latter is observed 1-2 seconds after the stimulus. Tonic conductance can further be shown to increase with stress levels or demanding mental activities. In addition to this, concepts of a startle response, which is the physiological response of the body due to a sudden stimulus, can be presented. The total number of startle responses in a windowed segment of GSR, the sum of the response magnitude and the sum of the response duration can be shown to characterize the startle response.

D. *Photoplethysmogram (PPG):*

In addition to acquiring physiological signals from SHIMMER sensors, the on-board device camera can be used to extract a Photoplethysmogram (PPG). The PPG signal is obtained by recording a video with the finger tip placed on the camera lens.

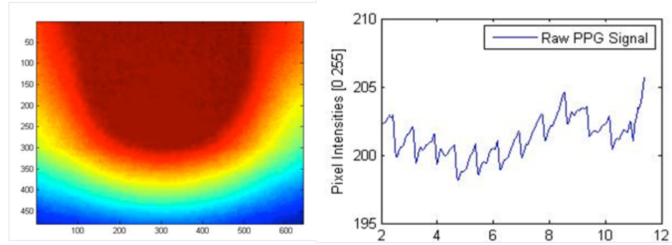

Fig. 5. The pixel intensities present in a single video frame (left) and the extracted PPG signal (right).

It provides a volumetric measurement of organs, such as the heart and the lungs. The PPG typically measures changes in light absorption by the skin. It can be used to monitor heart-rate and cardiac cycle, respiration, and hypovolemia and hypervolemia. The algorithm used to extract the PPG signal from the video was derived from [33] and an example signal is shown in Fig. 5.

V. SAMPLE LABORATORY EXERCISES

In this section, a few sample laboratory exercises designed for undergraduate students belonging to the STEM program is described.

A. *Undertanding QRS detection and Denoising of ECG*

Most physiological signals are non-stationary (frequency varies with time) and need to be observed in real-time to provide students a better perspective of its content. However, acquiring ECG signals from each student individually to work on an exercise can be cumbersome. Therefore, a few sample ECG recordings are provided internally within the *ECG Signal Generator* block. Fig. 4 shows the ECG signal generator interface with a normal sinus rhythm loaded into the block. It also shows the buttons provided to enable frame-by-frame processing of the non-stationary signal. The objective of this exercise is to provide hands-on experiences with AJDSP and a basic understanding of ECG signal characteristics, parameter estimation, and filtering.

The first part of the exercise provides an overview of various signal characteristics in relation to the corresponding health conditions diagnosed from the patient data. Students are asked to use the *ECG Signal Generator* block to load the sample synthetic waveform obtained from Physionet's ECGSYN toolkit [34]. They observe the P-wave, the QRS-complex and the T-wave of this artificially synthesized normal ECG and understand concepts of atrioventricular (AV) ratio, and the required ordering of the wave segments for a normal heart. The sampling rate of this signal and number of samples comprising the R-R time interval are provided to enable students to estimate the heart rate.

Next, real ECG recordings, normal sinus rhythm, arterial fibrillation (AFB) and ventricular tachycardia (VT), and the corresponding waveforms are observed for these abnormalities. Furthermore, signals obtained using a lead VI configuration with and without baseline wandering (noise) are also provided and visualized [35].

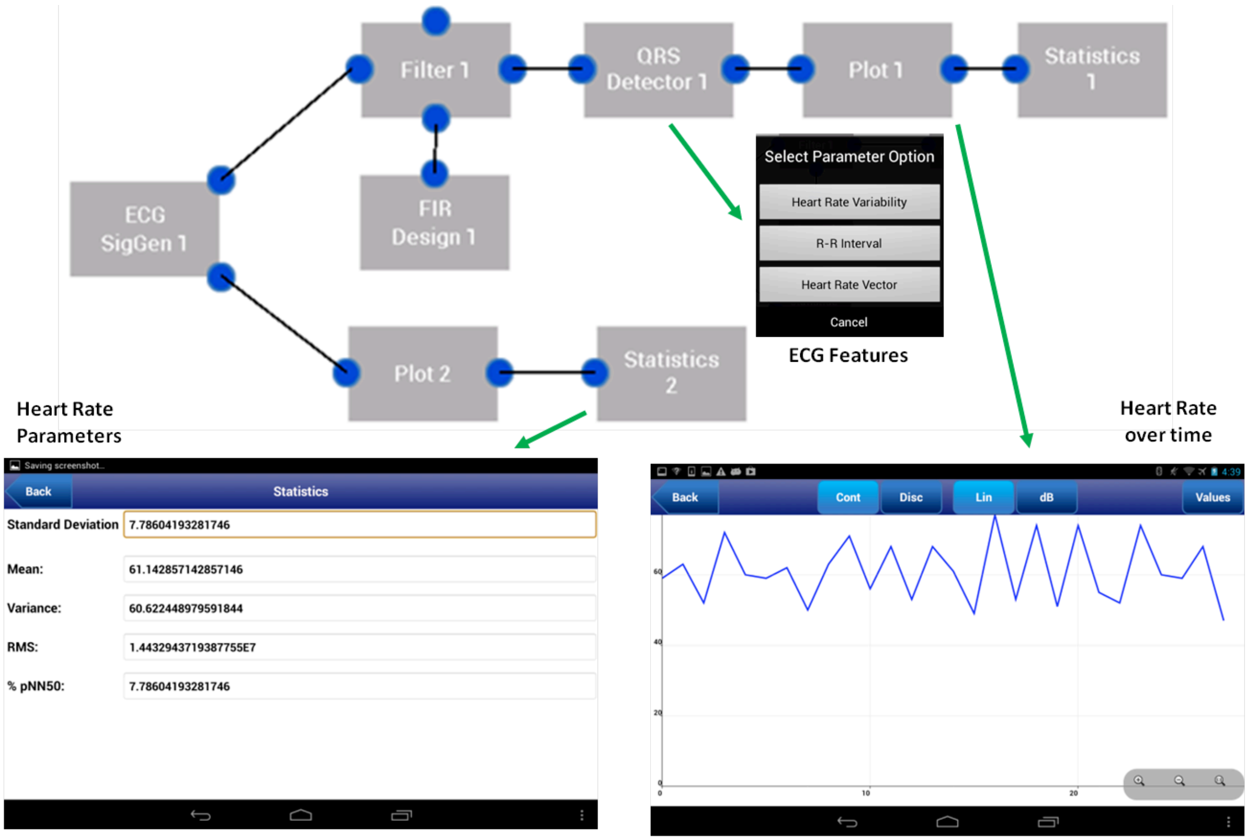

Fig. 6. Sample laboratory simulation exercise using ECG signals.

In the second part of the exercise, the baseline wandering artifact is removed by designing filters using the *FIR Design* block. The R-wave peaks are detected and relevant features are extracted using the *QRS Detector* block. The algorithm to detect these R-R peaks and extract features is based on multiresolution wavelet transform as described in [36]. The simulation diagram and expected outputs for this part of the exercise are shown in Fig. 6. Students can also visualize the frequency spectra of both the noisy and the de-noised ECG signals using the *FFT* block. Heart rate variability (HRV) analysis is conducted and feature vectors such as difference in successive R-R interval, mean and standard deviation of heart rate and R-R interval are calculated in the time-domain using the *Statistics* block.

B. Accelerometer Data Acquisition for a Step Counter Application

The objective of this exercise is to demonstrate a wireless DSP sensor system, to understand remote data acquisition, and to learn simple concepts about accelerometers and their role in context aware applications.

In the first part of this exercise students are asked to use the *Accelerometer* block and select the option to connect to Shimmer sensors. The sensors are either held in their hand or strapped around their waist/ankle. They then establish a Bluetooth connection between the mobile device and the sensor through the app user interface. Data is streamed from the accelerometer and the signal from each of the 3 axes is observed. The change in the axis experiencing the gravitational-force and the corresponding signal transitions based on different orientations of the sensor and activity of the subject is noted. In the second part of the exercise, students stream data from the accelerometer built-in-to the mobile device. They are asked to simultaneously stream data and calibrate the step counter by performing a predetermined activity, such as walking for five steps. Once calibrated, they then perform one of three activities: standing, walking and running. On stopping the data streaming, the total number of steps taken and the duration of each of the listed activities are displayed. By observing the frames of the signal, students learn that each step corresponds to a peak in the accelerometer magnitude and sharp signal transitions mark a change in activity.

C. PPG Extraction and Bio-parameter Estimation using a Camera

The objective of this exercise is to demonstrate a non-invasive health monitoring system by using the camera to extract a physiological signal.

In the first part of this exercise students record a video of their finger tip using the *Health Meter* block. A preview of the video is observed during the recording to understand the optical principle behind the PPG signal. A pulsating light ring within the preview can be visualized with care to understand the physiological property of the signal obtained as every pulsing ring corresponds to a heartbeat [33]. After about 15 seconds, the recording stops and a meter displays the estimated heart rate. The extracted PPG waveform can be observed along with parameters such as oxygen saturation and respiratory rate. In the second part of the exercise students learn about extracting the frequency band that corresponds to the respiratory information in the PPG signal using the *Wavelet Transform* and *Inverse Wavelet Transform* blocks. The different bands can be observed by selecting the low frequency detail coefficients to be preserved during reconstruction of the transformed signal. Concepts on the relationship between scale, wavelet width and frequency can be understood using the wavelet blocks. The significance of approximation and detail coefficients and their relationship to signal energy can also be understood. In addition, a brief idea on the different family of wavelets that exist and choosing the right one in relevance to the application is provided.

Performing laboratories using these sensors provides an overview of the procedure of collecting sensor measurements from the different sensors, and the abilities of mobile devices to act as computational signal analysis platforms. Additionally, the AJDSP block functionality of processing signals in a frame-by-frame manner gives a better intuition of the processing operation that takes place, and a way to closely observe important signal characteristics. The interface between sensors and mobile apps can be used to present students with the diverse applications of DSP.

VI. ASSESSMENTS AND OUTREACH

Preliminary assessments were conducted for AJDSP in general DSP and how students receive it in class. Two workshops were held, one comprising graduate students and the other, undergraduate students. A detailed evaluation methodology was designed to test various aspects of the AJDSP app such as educational value, robustness, and improvement in conceptual understanding.

The goal for the graduate student workshop was to assess the robustness and the accuracy of the software while the undergraduate student workshop was conducted to assess the ability of the application to foster understanding of signal processing concepts. The concepts tested in the workshop with the help of exercises consisted of filter design, FFT, *z*-transforms and convolution. A total of thirty-three students participated in the assessment workshops. Fig. 7 shows the results obtained. Most students were satisfied with the robustness and speed of the AJDSP app. Based on this exercise, an overall improvement in understanding was observed to be about 11 percent (Fig. 8). From these results, we can substantiate that mobile learning introduced into the curriculum improves conceptual learning. Detailed assessments on using the proposed functions for m-health applications will be provided at the conference.

As part of outreach, the AJDSP app was displayed at the Engineering Open House event conducted at ASU. The event was designed to showcase engineering and technology, in a creative and interactive fashion to students from K through 8th Grade.

VII. CONCLUSIONS

The ability to experience how sensors measurements are acquired and signals are processed will help students relate textbook knowledge to applications and creatively conceptualize their understanding. By depicting the challenges faced in the healthcare domain, students can be guided to innovate in these areas. In particular, the role of DSP in tackling problems in such real-world contexts can be presented along with its diverse applications. Furthermore, the AJDSP app helps to serve as a platform to visualize physiological signals such as PPG, ECG and GSR. In addition, function blocks to extract features and compute parameters such as heart rate, oxygen saturation and step count were developed. These functions were used to create laboratory exercises, samples of which were provided. Preliminary assessments show promise in improving students' understanding of DSP concepts when using the AJDSP app as part of the curriculum. Detailed assessments will be conducted and the results will be presented at the conference.

ACKNOWLEDGEMENTS

The authors were supported in part by the NSF TUES Award No. 0817596 and by the SenSIP Center, School of ECEE, Arizona State University. The authors also wish to thank Dr. J.J. Thiagarajan and Dr. K.N. Ramamurthy for stimulating discussions that led to several improvements in the paper.

***Abstract*—The primary goals of the iCollaborate Materials Science and Engineering (MSE) project are to improve student learning outcomes, engagement, and completion rates in introductory materials engineering courses. This extensive research project is multidimensional and includes several interrelated components, all of which are founded upon best practices from STEM education research. There are several individual elements within the project that operate simultaneously or sequentially and unite to form a novel teaching and learning system. The first element of the project was the transformation of the structure in our basic MSE course from primarily deductive practice to an Information Communication Technology (ICT) enabled, student centered, inductive teaching and learning environment. Collaborative learning, active/inquiry learning, concept learning, peer learning, problem/case-based learning, low stakes quizzing, mini-lectures with just-in-time reading, collaborative research writing, and constructive alignment are all important components of our multi-dimensional approach. Also completed as part of this research program were: detailed explorations to understand the students' pre-course knowledge and misperceptions, an investigation of student preparation and how that preparation influenced pre-course concept knowledge and overall course outcomes, and an analysis of Felder's Index of Learning Styles (ILS) assessment by student and course section. The detailed analysis of pre-course knowledge and misperceptions showed a surprising lack of pre-conceptual knowledge and revealed several important student misperceptions.**

This paper focuses on components of the iCollaborate project that were researched, analyzed, or developed during the Fall 2011 through Winter 2013 timeframe. First, a summary of the pre-course assessment findings is given in this paper. Second, an overview of the suite of MSE iPod applications and newly developed web applications for iCollaborate is presented. Finally, an overview of the supporting web site for the project, which is currently under development, is described. The paper concludes with a description of the remaining objectives for the iCollaborate project and future research directions.

Keywords—inductive practice; Information Communication Technology (ICT); distributed cognition; collaborative learning; iLearning

I. Introduction

The primary goals of the iCollaborate MSE project are to improve specific, targeted student learning outcomes, student engagement opportunities, and completion rates in introductory materials science and engineering courses. The iCollaborate project combines best practices from STEM education research and targeted, outcome based ICT support in novel ways to create a student centered teaching and learning system. The other project elements include: detailed research to understand students' pre-course knowledge and misperceptions, an investigation of student preparation and how that preparation influences pre-course concept knowledge and overall course outcomes, an analysis of ILS assessments by student and course section, inductive teaching practices which include collaborative learning, active learning modules, concept/peer learning opportunities, collaborative writing of research papers, low stakes quizzing, the development of targeted iPod applications that promote enhanced student understanding in MSE, and the development of a web site with web apps. Individual elements within the project operate simultaneously or sequentially. The justification of the STEM education research base for this project has been described in detail elsewhere [1]-[2]. Educational theory based on cognitive and social constructivism support the effectiveness of our project elements [3]-[4]. There is an additional research base that supports connections between ICT enhanced collaborative learning, distributed cognition, and enhanced student outcomes [5]. "Between 1924 and 1997, over 168 studies were conducted comparing the relative efficacy of cooperative learning. These studies indicate that cooperative learning promotes higher individual achievement than do competitive approaches … "[6].

II. Analysis of Pre-course Information

As part of the iCollaborate MSE project, the students completed a pre-course evaluation instrument consisting of 26 questions, in three broad conceptual areas (chemistry, basic physics/science knowledge, and hands-on/project learning) and Felder's ILS assessment. An outside evaluator and assessment specialist (Dr. Phil Buly) completed the analysis of all pre-course information. For this element of the research, we placed the students into four categories: engineering technology (ET) majors, industrial technology (IT) majors, science majors, and non-science or technology majors. For the pre-course evaluation materials, we examined overall GPA, GPA in the Chemistry pre-requisite, GPA in the Mathematics pre-requisite, and the ILS data for each student

The National Science Foundation is supporting this research project (NSF CCLI/TUES #941012).

978-1-4673-5261-1/13/$31.00

for each question. A one-way ANOVA test with $p<0.05$ was used to evaluate statistically significant differences, except where IT and ET students only were compared. In those cases, a T-test with $p<0.05$ was used. The overall sample size was 180 students.

When we aggregated the pre-course assessment, we found that overall the students answered only about half (54%) of our very basic questions correctly. This result was alarming in that we had always assumed the students had a basic level of knowledge about materials. We were surprised to learn that the students could not always name an example of a metal, ceramic, or polymer, or the three basic bond types, and that their fundamental understanding of the term "elastic constant" was fundmentally flawed. The students performed the worst on the basic chemistry questions (44% correct), while they only did only somewhat better on the questions reflecting on hands-on learning (55% correct). As disappointing as the overall results were, chemistry pre-requisite GPA did, for certain questions, predict understanding. For the question covering metallic bonding, GPA in the introductory chemistry class resulted in different outcomes, with 2.0 GPA students scoring the lowest (34% correct), as compared to 3.0 and 4.0 GPA students (48%, 44% correct). Interestingly, Intuitive (INT) learners scored higher (50%) than Sensing (SEN) students (39%). A science (SCI) student, with a high GPA in chemistry, who is an INT learner, had the overall best outcome. And, an ET student, with a low GPA in chemistry, who is a SEN learner, needs the most support during conceptual change activities. Chemistry GPA also correlated to the ability of the students to name a ceramic material. Seventy-four percent of Chemistry GPA 4.0 students were able to name one ceramic material, while only 51% of the GPA 2.0 students answered correctly. Overall GPA also was significant for this question, with students in the top quartile answering correctly 75% of the time, while the students in the lowest quartile answered correctly only 54% of the time. Overall GPA also was linked to the ability of students to correctly identify a polymer, but in a more complex manner.

For the pre-course assessment, major type did predict the overall outcomes, even though all the students have completed the same course pre-requisites in Chemistry, Mathematics, and Physics. The SCI students scored the best, with 60% correct overall and IT students scored slightly higher than ET students (55% versus 53%). And, VIS students outscored VER students 55% versus 48.5%. Finally, INT learners scored 56.7% versus 52.7% for SEN students. Obviously, we are not claming learning style correlates to outcome. But, these results certainly do reinforce what has been found in STEM education research about students, student learning, and the complexities of instructional design. We do know that students come to our classrooms with different levels of preparation and that scores in pre-requisite courses do matter, but are not always perfect indicators that key information has been retained. Students enter our courses with a wide range of learning styles, and some pre-requisite information is retained or learned differently based on student learning style and many, many other factors.

III. iPod and Web Applications

MSE content based apps were developed with the Apple iOS SDK for our research project: iCollaborate Vocabulary (Vocab), iCollaborate Basic Knowledge building (BasicK), iCollaborate Concept Questions (ConQuest), skill tune-up (Tune-Up), a graphical Materials Properties application with list features (MatProps), a unit conversion tool specific to only those units encountered in a basic MSE course (MSEConvert), and a tool to calculate the Elastic Constant of two component, unidirectional fiber composites (MSEComposites). The MSEKnowledge Tools app has been built, but we are still developing the content for the topic-by-topic study guides. In order to facilitate our dissemination plan, web app versions for the iCollaborate website are under development for key MSE apps. The web apps are designed to run from any PC or Apple computer and mobile devices that support browsers. Thus far, the Materials Properties web app and the MSE Vocabulary web app have been built and are undergoing testing.

Screen captures of the MSE Vocabulary apps are shown in Figs. 1 and 2. Fig. 1 shows the conceptual topic titles that are common to the apps for the iPods, while Fig. 2 compares the Vocabulary mobile and web app interfaces. The topics are those specific to introductory materials engineering courses, but are generic in nature and are not tied to any one particular text. Similarly, vocabulary terms are common to materials science and engineering topics, but are not focused on any particular text and, in general, go well beyond the content of any one text and basic content. In these mobile apps, the students flip the card to see if they have the correct answer. If their answer is incorrect, another screen shows up with a more detailed explanation, a web link, and an audio explanation. In these apps, the students can work in either practice mode or test mode since these apps are designed to facilitate collaborative knowledge building. The concept question app (MSEConQuest) was built with the same type of help for the user, but in a multiple choice format so that we could display known misperceptions as multiple choice answers or have the students select different material choices, also based upon discovered, common student misperceptions. In this application, the students select an answer, and the correct answer displays as green (other answers display as red). Currently, students rate this MSEConquest app as the most helpful in building their own knowledge.

However, other apps have helped improve student outcomes in totally different ways. For example, even though there are commercially available unit conversion tool apps, we found that they contained too many different types of units, and none had the exact suite of tools needed for basic MSE courses. Thus, we built a unit conversion program that was limited to only those unit conversations commonly encountered in basic materials engineering courses. The units conversion areas are: mass, force, stress, density, temperature, length, area, volume, SI Prefixes, fracture toughness, specific heat, and thermal conductivity. The MSEConvert app allows students with poor mathematics skills to check their own work and rarely do we see simple unit conversion errors now on design problems as the term progresses. Similarly, the

MatProp app (see Figs. 3 and 4) helps students develop a sense of the range of material property values for different classifications of materials. MatProp shows conceptually contained lists of material properties because students can select from different basic material decks that are predefined by the instructor. The app helps the students compare a material property of up to six different materials or, later in the course, they can create scatter plots of two different material properties for six different materials. The bar graph view is more useful at the beginning of the term, but the scatter plot is more useful as the students begin their design work. As a result, the students infrequently select inappropriate materials for various applications by the end of the term. We also built an elastic constant, density, and volume fraction of fiber calculator app for a unidirectional composite composed of a matrix and unidirectional fibers. We have found this app useful to help the students understand the implication of fiber to matrix ratio and, the students do not neglect the influence of the matrix material on overall composite materials properties now in their research papers. On the other hand, we found it was unnecessary to keep building our Basic Knowledge app because robust support for both basic Mathematics and basic Chemistry are widely available. Additionally, robust periodic chart apps are also commercially available. Thus, we chose to invest development time into novel application of those existing periodic tables and made the support apps in both Chemistry and Mathematics available on the iPods.

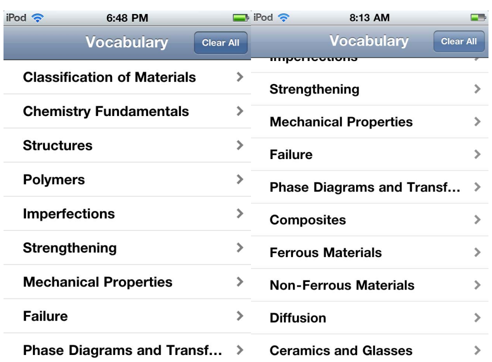

Figure 1. Topics Areas for MSE iOS Apps.

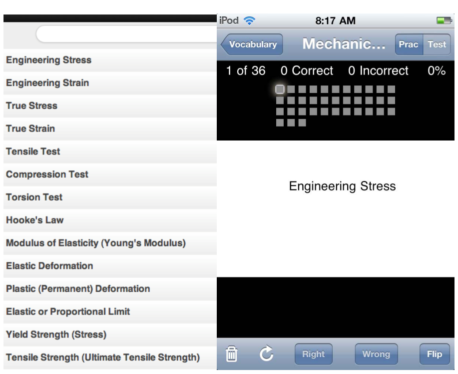

Figure 2. Card Interface for Web App Versus Mobile App.

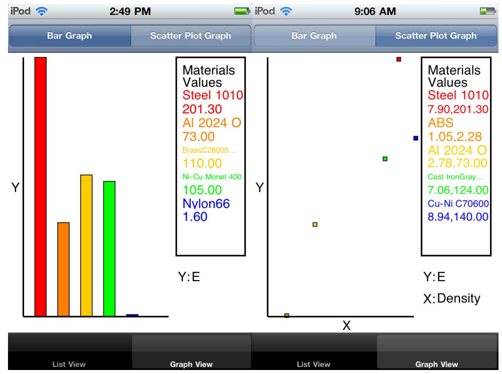

Figure 3. Mobile iOS Interface for Materials Properties App.

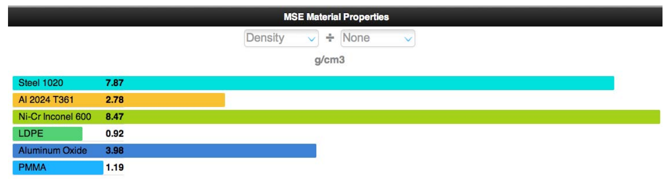

Figure 4. Web App Interface for Materials Properties App.

IV. FUTURE TASKS

The final assessment task is to examine standard test scores by individual question by individual student by individual section. And, we then need to aggregate those results. The few remaining anomalies need to be removed from the apps and the web apps completed. And, we must find a way to move the apps to the Apple Store for free distribution rather than keeping them on development devices. The content for the Knowledge app will be added next summer. The concept map web site to accompany the project needs additional content. An additional future project would be to revise our app code to understand how the students use the iPods in their own learning.

The effectiveness of brief, spaced practice on student difficulties with basic and essential engineering skills

Brendon D. Mikula, Andrew F. Heckler
Department of Physics
The Ohio State University
Columbus, OH, 43210
mikula.20@osu.edu, heckler.6@osu.edu

***Abstract*—Through extensive testing and interviews of sophomore, junior, and senior engineering students in a Materials Science Engineering course at The Ohio State University, we found that these students struggle with many skills necessary for their coursework. Often these "essential skills" were prerequisite to the course and little to no instruction time was spent on them. Online training was developed to attempt to improve these skills. Students participated in the training several times over the term, with each assignment taking 10-20 minutes and consisting of 10 questions. Students were allowed unlimited attempts on each assignment and were required to achieve mastery (80% or better) for full credit. Training covered a wide range of topics: interpreting log plots and log scales, using metric prefixes for various conversions, estimating typical values of common material properties, employing dimensional analysis, and operating equations when given variables in mixed units. Unlike the success achieved by the log plots training, most of the topics saw little and insufficient improvement as a result of training, despite the basic nature of the skills. Future improvements to the training will focus on determining which factors will help to convince students of the importance of mastering these prerequisite skills.**

Keywords—engineering, computer training, online homework, mastery learning, student understanding, essential skills

I. Introduction and Theoretical Background

Many engineering students at The Ohio State University are required to take an introductory course in Materials Science Engineering. Students are expected to leave the course with mastery of certain categories of knowledge which are utilized frequently during coursework, some of which are considered prerequisite to the course. An example of this knowledge is the ability to read and interpret log plots, training on which has been successful across multiple terms [1]. Through interviews with instructors and exploratory pilot testing, we found that students have significant difficulties with a number of other basic skills essential to a functional understanding of materials science engineering and engineering in general.

The "essential skills" studied here consist both of prerequisite skills to the course—e.g., metric prefixes and conversions, dimensional analysis, and operating equations when given variables with mixed units—as well as skills the instructor expects to impart to the students—e.g., order of magnitude estimates and patterns of common material properties.

One critical aspect of the essential skills is that they are necessary for solving the types of problems posed in exams—even the simpler ones. Therefore, it is expected that students are near 100% accuracy with these skills. Even if students are 80% accurate with these essential skills, this lack of mastery is a critical bottleneck for successful performance. Here we demonstrate that a worrisome 20-50% of students performed poorly in many of these categories. Despite this, instructional time was typically not dedicated to the prerequisite skills. In this study, we developed a series of computer-based training tasks, assigned as homework, to attempt to address these issues. The training employs the method of mastery learning, in which time on task is allowed to vary to allow each student to obtain a required level of mastery.

The two most influential versions of mastery learning are Bloom's Learning For Mastery [2] and Keller's Personalized System of Instruction [3]. Though these strategies vary in many ways, Block and Burns describe their similarities in [4]: (1) they prespecify a set of course objectives that students will be expected to master at some high level, (2) they break the course into a number of smaller learning units so as to teach only a few of the course's objectives at one time, (3) they teach each unit for mastery--all students are first exposed to a unit's material in a standard fashion; then they are tested for their mastery of the unit's objectives, and those whose test performance is below mastery are provided with additional instruction, (4) they evaluate each student's mastery over the course as a whole, on the basis of what the student has and has not achieved rather than on how well he has achieved relative to his classmates.

In a meta-analysis of courses utilizing mastery criterion for learning, Kulik showed in [5] that mastery learning is effective in improving student performance on exams at all levels of learning. This improvement is greater for students with weaker content knowledge, making mastery learning a useful remediation tool.

Another successful, and more recent, approach to learning is to use computer training as part of coursework. This has been successful in many forms: Multimedia learning modules

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

viewed before lecture improved performance on immediate and delayed post-tests when compared to reading static text and figures alone [6]; deficiencies in math are largely remediated by the adaptive ALEKS tutor program [7]; and integration of physics simulations, such as circuit building, into lab have been successful in improving content knowledge as well as proficiency at actual lab tasks [8]; to name a few.

The prerequisite nature of many of the knowledge gaps we observed in Materials Science Engineering students suggests that computer-based training graded for mastery may be able to provide successful remediation of these difficulties.

This paper aims to investigate and describe student difficulties with engineering essential skills. A more complete understanding of the knowledge state of the current student population is invaluable to future steps in correcting these difficulties. Also presented are the results of mastery-based training, which can be used as a model or starting place for future corrective measures.

II. Methods

Exploratory data taken during Autumn quarter 2011 showed poor performance at the essential skills described in this paper. During Autumn semester 2012, computer-based training was given to N = 271 students in an introductory Materials Science Engineering course at The Ohio State University. Most of the students in this class are sophomore and junior engineering majors. For 6 weeks during the term, beginning in week 6, students completed the "Essential Skills Quizzes", each worth approximately the same amount of credit as one homework assignment. There were 6 quizzes, each remaining open to the students for one week. Students all followed the same training pattern; they were allowed unlimited attempts on each quiz and were required to achieve mastery--80% or better--to obtain full credit. Content in the six Essential Skills Quizzes was divided approximately evenly between interpreting log scales and the "essential skills" mentioned above. Time spent on each week's quiz varied due to the mastery grading criterion, but averaged around 15 minutes per quiz. The "essential skills" comprised the entirety of Essential Skills Quizzes 2 and 4, and half of Essential Skills Quiz 6. The remainder of the six Essential Skills Quizzes covered log scales; these results are not considered here.

In addition to the Essential Skills Quizzes, students were again awarded approximately one homework's worth of points to attend a "FLEX homework" session, where the students completed the essential skills assessment, which took about 30 minutes; cumulative time spent during the term on essential skills training and assessment averaged around 70 minutes per student. In order to better assess the impact of both the essential skills quizzes and instruction, the population was randomly split into two conditions: 127 pre-Essential Skills Quiz (week 4) participants and 144 post-Essential Skills Quiz (week 13) participants. Twenty students per condition were selected for interview data; these students were video recorded while taking the essential skills assessment and were asked to think out loud and respond to prompts from the proctor. An overview of the experimental design can be seen in Fig. 1.

Condition	Week 4	Weeks 6-12	Week 13
Pretest	**FLEX Homework** Essential Skills Assessment (≈30 minutes)	**Computer Training** Essential Skills Quizzes (≈40 minutes total)	None
Posttest	None	**Computer Training** Essential Skills Quizzes (≈40 minutes total)	**FLEX Homework** Essential Skills Assessment (≈30 minutes)

Fig. 1. Experimental conditions used in this study. Students in both conditions took the same assessment but at different times; all students completed the Essential Skills Quizzes concurrently.

Training with the Essential Skills Quizzes was administered on Carmen, a course management website used by The Ohio State University and developed by Desire2Learn. Each quiz draws randomly from a categorized question bank, so that the content each student sees is the same for a given quiz, but the specific questions may not be. This also means that consecutive attempts at a single quiz by a single student will not yield the same 10 questions, but rather a new set of 10 on the same topics. This pseudo-randomization was included to attempt to reduce the number of students simply copying down solutions from earlier attempts or from other students.

Training was consistent with the four common traits of mastery learning described by Block as follows: (1) the "essential skills" to be learned and their importance to the students were specified to the students prior to training, (2) he topics covered by the Essential Skills Quizzes were divided into 6 separate quizzes, with one quiz given per week, (3) each Essential Skills Quizzes was mastery graded and all students were given quizzes over the same content. Upon completing an attempt, Carmen provided the correct answers to all questions on the quiz, allowing the students the opportunity to learn from their errors, (4) As the entire course was not taught in mastery learning style--just the Essential Skills Quizzes--student mastery over the course as a whole could not be evaluated. However, students were awarded more points for mastering more of the quizzes. In this sense, students were rewarded by their mastery alone, not by the time it took to achieve.

Thus, the computer-based Essential Skills Quizzes fit within the standard framework of mastery learning, as described above.

III. Results

All comparisons were between-student. Correctness between pretest and posttest was compared using a Chi-squared test and numerical values were compared using appropriate t tests. Effect sizes are reported using Cohen's d such that a positive d means improvement, not merely an increase in proportion. Results are presented by category:

A. Metric Conversions

Engineering students are expected to be proficient in converting between metric units (micrograms to kilograms, centimeters to nanometers, megapascals to gigapascals, etc.). Pretest students averaged only 74.8% correct on simple metric conversion problems--surprisingly far from ceiling, given the simplicity of the skill and its constant use in the engineering

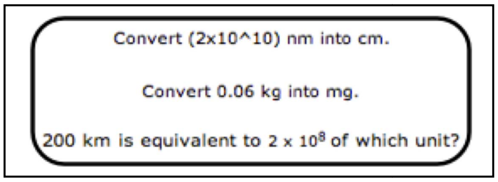

Fig. 2. Metric conversion training questions came in three types: scientific notation questions (top); decimal form questions (middle); and "find the unit" questions (bottom), which were given with multiple choice options.

courses the student had already taken. Training on metric conversions comprised 6 of the 10 questions in Essential Skills Quiz #2 plus 2 of the 10 questions in Essential Skills Quiz #6, and involved three problem types (Fig. 2).

Despite the fact that students had to achieve mastery during the Essential Skills Quizzes, we found that training on metric conversions resulted in no significant change in student performance. One of the three metric conversion questions on the essential skills assessment asked students to make a volumetric conversion from cubic centimeters to cubic meters. There was no significant difference in scores from pretest (73%) to posttest (71%). The most common error was to treat the problem as a length conversion (centimeters to meters), ignoring the volumetric nature of the problem (Fig. 3). It should be noted, however, that volumetric problems were not included in the training, thus students failed to utilize any skills they may have acquired from this quiz.

The remaining two metric conversion questions involved only linear conversions and gave conflicting results. One question asked students to convert from micrograms to megagrams, working in scientific notation; this question significantly improved from 62% to 74% ($\chi^2(1)$^2 = 4.053, p = 0.044, d = 0.25). The other question asked students to convert from kilometers to centimeters in decimal form; this question showed a marginal decrease from 89% to 82% ($\chi^2(1)$^2 = 2.652, p = 0.103, d = -0.20).

Overall, student performance on metric conversions yielded rather limited and inconsistent results. Given the importance and relative simplicity of the task, student performance is unacceptable low. On average, students scored just 74.8% correct on the three metric conversion questions before training and 75.5% after (t = 0.193, p = 0.847).

B. Dimensional Analysis

Students in engineering are expected to understand units, meaning they need to be able to analyze the dimensional relationships between variables in an equation with minimal

Response	Pretest	Posttest
Correct	73.2%	70.8%
Treat as length conversion	11.8%	15.3%

Fig 3. Common answer patterns on an example metric conversion problem. Students were asked to convert from cubic meters to cubic centimeters. The most common error was to treat the problem as a length conversion, as though converting from meters to centimeters. Neither of these changes were statistically significant.

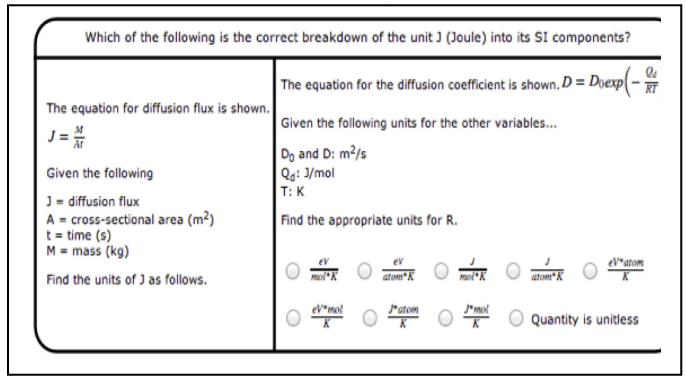

Fig 4. Dimensional analysis training questions came in three categories: unit breakdown questions (top); find the missing unit questions (left), where students were given an equation and units for all but one of the variables, then asked to solve for the units of the remaining variable; and specialized find the missing unit questions (right) dealing with the difference between the gas constant, R, and the Boltzmann constant, k. Each category consisted of both multiple choice questions and directed fill-in-the-blank questions where the student indicated the powers of respective units. An example of multiple choice responses is shown (right).

effort. For example, students should be able to determine the units of a given quantity in an equation based on the other variables involved (e.g., Fig. 4). Students would also be expected to know whether to use the gas constant or the Boltzmann constant—identical constants in different units—depending on the units of the other variables. Training on dimensional analysis involved three problem types and consisted of 7 of the 10 questions in Essential Skills Quiz #4, plus 3 of the 10 questions in Essential Skills Quiz #6.

In contrast to other essential skills categories, training on dimensional analysis resulted in significant gains in student performance for the category as a whole, improving average scores on the dimensional analysis portion of the assessment from 43% to 57% (t = 3.922, p = 0.0001, d = 0.48); it is worth noting that this is still far from ceiling, despite a relatively large effect size. Significant gains were also seen on many individual questions. One item on the assessment gave the students the equation for the theoretical density of a crystalline metallic solid as well as appropriate units for all but one of the variables. The students were then tasked with finding the units for the remaining variable. Significant improvement was shown after training (χ^2 (1)^2 = 6.781, p = 0.009, d = 0.32), with correctness increasing from 71% to 84%.

Another similar question involved determining the units of a variable in the exponent of the equation for the equilibrium number of vacancies in a material. Through interviews, it became apparent that some students were merely balancing the sides of the equation, ignorant to the fact that the exponent itself must be unitless. Part of the way through the pretest, this question was updated to the form shown in Fig. 5. This updated question showed significant improvement in terms of correctness ($\chi^2(1)$ = 7.500, p = 0.006, d = 0.49) from 33% to 56%, while the most common error--the belief that more information was needed to answer the question--decreased significantly ($\chi^2(1)$^2 = 4.545, p = 0.033, d = 0.38) from 42% to 25%. Most students claiming to need more information indicated that the rest of the equation was required.

A certain quantity changes in proportion to $e^{\frac{Q_V}{RT}}$, where
Q_V = energy required for vacancy (eV/mol)
T = temperature (K)

Find the appropriate units for the gas constant R.
If you cannot determine this without more information, what more information is required?

Response	Pretest	Posttest	
Correct	32.6%	56.4%	*
Need more info	41.9%	25.0%	*
Inverse Error	4.7%	7.1%	

Fig. 5. An example dimensional analysis question from the essential skills assessment and patterns of right and wrong answers. Asterisks indicate statistical significance at the $p < 0.05$ level. Student committing an inverse error submitted an answer that was the reciprocal of the correct answer.

Interestingly, students who believed that the problem could be solved with the given information showed an improvement in correctness from 56% to 72%, though this result fell just outside the range of significance ($\chi^2(1)$^2 = 3.670, p = 0.055, d = 0.43). The lack of statistical significance--despite a respectable effect size--is likely due to small pretest sample sizes, a deficiency owed to the change in pretest versions of the problem and the larger proportion of students believing more information was needed in the pretest condition.

C. Mixed Unit Equations

Engineers in the field use equations to calculate values from measurements, and the instruments providing these measurements don't always do so in consistent units. As such, it is essential that engineering students be able to operate equations--to find the value of the dependent variable--when presented with independent variables in mixed units.

The equation for the diffusion flux is shown.

$$J = \frac{M}{At}$$, where

A = cross-sectional area
M = mass (or number of atoms)
t = elapsed time.

Given M = 1.0 mols of a gas passing through an area of 1 cm^2 over a time of 40 ms, what is the diffusion flux in atoms/(m^2s)?

Response	Pretest	Posttest	
Correct	39.7%	46.2%	
Wrong Units	15.1%	6.3%	*
Forgot only mole to atoms conversion	10.3%	11.9%	
Off only by some power of 10	23.0%	20.3%	
Forgot mole to atoms AND off by some power of 10	19.0%	13.3%	

Fig 6. An example of a mixed unit equation train question is shown. All questions in this category had the same form, but many dealt with different equations.

The equation for the theoretical density of a crystalline metallic solid is $\rho = \frac{nA}{V_C N_A}$, where

n = number of atoms associated with each unit cell
A = atomic weight
V_C = the volume of the unit cell
N_A = Avogadro's number

Given n = 4 atoms/unit cell of aluminum (A = 27 g/mol) with V_C = 4.42*10^-23 cm^3/unit cell, find the theoretical density in kg/m^3

Fig. 7. An example mixed unit equations question from the assessment and patters of right and wrong answers. Asterisks indicate statistical significance at p< 0.05 level.

As a part of training, students were presented with an equation as well as values for the independent variables involved, which were purposefully given in mixed units (Fig. 6). Students were then asked to calculate the dependent variable in specified "target units." Training on mixed unit equation consisted of 3 of 10 questions in Essential Skills Quiz 4. Training was somewhat successful in improving average assessment scores on mixed unit equation questions from 36% to 48% (t = 2.765, p= 0.006, d=0.34), leaving posttest scores still below 50%.

While overall scores in the mixed unit equations category showed significant improvement in student performance, two of the three individual questions in the essential skills assessment failed to do so. Scores on the diffusion flux question, increased from 40% to 46%, but this improvement was not statistically significant ($\chi^2(1)$^2 = 1.144, p = 0.285, d = 0.13). The question statement and common errors--explicitly converting to incorrect target units, forgetting the mole to atoms conversion, and erring exactly by some power of 10--are shown in Fig. 7. For this item, the only error significantly affected by training was students giving an answer in different target units than specified in the problem statement.

A similar question involving a conversion from psi to gigapascals using Hooke's law also showed no significant change in student performance ($\chi^2(1)$^2 = 2.279, p = 0.131, d = 0.18) from pre (35%) to post (44%).

The simplest question provided students with a force in newtons and an area in square millimeters, then asked for a force in kilopascals; this was the only mixed unit equation question to show significant improvement ($\chi^2(1)$^2 = 8.992, p = 0.003, d = 0.37), with correctness increasing from 35% to 53%. It is worth emphasis that this was the simplest of the three questions of this type presented in the essential skills assessment, and 47% of students are still submitting incorrect answers after training.

D. Typical Values of Material Properties

Engineers are expected to know approximate values for various material properties and other physical constants. For example, an engineer should know that melting points and Young's moduli are usually higher for metals than polymers. They should also be able to provide a rough value for a specific material that is within a reasonable range. Training on typical values contained two problem types (Fig. 8) and consisted of 4 of the 10 questions in Essential Skills Quiz #2.

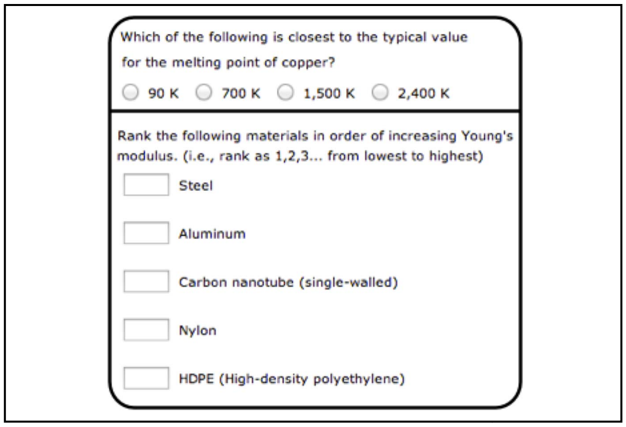

Fig 8. Typical values training questions had two categories: multiple choice (top); and ranking questions (bottom), which contained 2-5 materials to be appropriately ranked by some material property.

Training on estimates of typical values of material properties produced a range of results from significant gains to marginal losses. Cumulative student performance on questions in this category showed a nonsignificant change (t = 1.461, p = 0.145, d = 0.18) from pre (35%) to post (40%).

A series of three questions asked students to estimate the Young's modulus of three materials: copper, aluminum, and high-density polyethylene (HDPE). Since student responses to these questions spanned such a broad range, we analyze the results a number of ways. One metric was to use an "acceptable range" for the numerical answers, which was set by a course instructor (see Fig. 9). By this metric, student responses to the question on copper showed significant improvement ($\chi^2(1)$^2 = 5.377, p = 0.020, d = 0.30), with the percentage of students in the acceptable range increasing from 34% to 49%. Student estimates of the Young's modulus of aluminum showed no significant improvement ($\chi^2(1)$^2 = 0.805, p = 0.370, d = 0.11) from pre (40%) to post (45%). HDPE started and remained at 25% within the acceptable range, showing no change at all. Note that none of the posttest values are higher than 50%, despite the fact that training contained problems dealing with Young's modulus.

A second metric was to determine whether student responses were in any of four increasingly large "ballparks": within 20% of the correct answer, within 2x the correct answer, within 5x the correct answer, and within 10x the correct answer. This metric revealed a slightly more detailed picture which can be seen Fig. 10. While student performance on the copper question showed some improvement across the board, most of this came from significant increases in the larger ranges--students in the "within 10x" range increased from 48% to 75% ($\chi^2(1)$^2 = 18.531, p < 0.0001, d = 0.57). Conversely, students in the "within 20%" range did not significantly change ($\chi^2(1)$^2 = 1.988, p = 0.159, d = 0.18) from pre (9%) to post (15%). Student responses for aluminum displayed strange behavior; students in the "within 10x" range significantly increased ($\chi^2(1)$^2 = 10.349, p = 0.001, d = 0.41) from 55% to 74%, while those in the "within 20%" range actually saw a significant decrease ($\chi^2(1)$^2 = 5.395, p = 0.020, d = -0.30) from 21% to 10%. In essence, student responses settled into something resembling orbit around the correct answer. This approach yielded no significant change in student responses for the question about HDPE for all ranges.

The final metric attempts to focus more on the relative values of student responses, rather than the magnitude of the value itself. Through discussions with the course instructor, it was expected of the students that they at least give higher Young's modulus values for the metals than for the polymer. Students giving a higher value for HDPE than for aluminum decreased significantly ($\chi^2(1)$^2 = 9.280, p = 0.002, d = 0.40) from 55% to 36%; students giving a higher value for HDPE than for copper decreased significantly ($\chi^2(1)$^2 = 6.250, p = 0.012, d = 0.32) from 59% to 43%. The percentage of students incorrectly giving a higher Young's modulus for HDPE than for both aluminum and copper fell significantly ($\chi^2(1)$^2 =4.314, p = 0.038, d = 0.27) as well, from 49% to 36%. These values can be seen in Fig. 11. Despite statistical significance, it is again worth noting that posttest students still make at least one of these errors about 40% of the time.

Students were also asked to rate their confidence in their answers. Student confidence increased significantly for copper (t = 2.477, p = 0.014, d = 0.43) and HDPE (t = 2.410, p = 0.017, d = 0.43), but decreased non-significantly for aluminum (t = -1.159, p = 0.248, d = -0.20). Neither pretest nor posttest confidence rankings exceeded 2.2 out of 5 for any of

Material	Actual Value	Accepted Range
Copper	117 GPa	50 - 300 GPa
Aluminum	69 GPa	25 - 200 GPa
HDPE	800 MPa	500 MPa - 10 GPa

Fig 9. "Acceptable ranges" for the Young's modulus of materials used on the essential skills assessment, specified by the instructor.

Material & Range	Pretest	Posttest	
Copper (within 20%)	8.9%	14.8%	
Copper (within 2x)	27.7%	39.3%	
Copper (within 5x)	40.2%	68.1%	*
Copper (within 10x)	48.2%	74.8%	*
Aluminum (within 20%)	20.7%	10.2%	*
Aluminum (within 2x)	33.6%	31.4%	
Aluminum (within 5x)	43.1%	59.9%	*
Aluminum (within 10x)	55.2%	74.5%	*
HDPE (within 20%)	1.8%	0.7%	
HDPE (within 2x)	6.2%	5.9%	
HDPE (within 5x)	15.9%	17.0%	
HDPE (within 10x)	28.3%	25.9%	

Fig 10. Classification of student estimates of the Young's modulus of copper, aluminum, and high-density polyethylene (HDPE) in relation to the actual value. Asterisks indicate significant change at the p < 0.05 level, though not all of these changes were improvements.

Error	Pretest	Posttest	
HDPE > Aluminum	55.4%	36.0%	*
HDPE > Copper	59.3%	43.4%	*
HDPE > Both	49.1%	36.0%	*

Fig 11. Relative value error frequencies for typical value problems asking student to estimate Young's modulus of aluminum, copper and HDPE. As these are errors, a decrease in percentage corresponds to increasing correctness.

the three materials involved, and changes in student confidence did not match student improvement in terms of correctness.

Finally, posttest students were asked to give approximate melting points for metals, polymers, and ceramics—this question was not included in the pretest. Student responses were judged based on the correct relative order of melting points; 71% of students ordered the melting points correctly. This leaves almost 30% of posttest students unable to correctly rank typical melting points of three distinct material classes.

E. *Interview Data*

Twenty students each from pretest posttest conditions were subjected to "think-aloud" interviews as they completed the FLEX assessment. The most striking feature of these interviews was that many students not only admitted that they lacked certain knowledge and skills, but seemed content with that fact. Some excerpts from interviews are shown below:

- "Usually I look [the metric prefixes/conversions] up."
- "[Metric prefixes are] readily available on the internet and textbook."
- When asked if they felt it was important to memorize: "I feel like there's always a table for it."
- Some students described their lack of memorization of these topics as a conscious choice: "I've always been able to look them up. So, as of now, I haven't *decided* to memorize them." (Emphasis is author's)

The prevailing view for certain knowledge components seems to be something along the lines of "Why memorize it when I can always look it up?" Perhaps the whole experience is best described by one student in particular. When this student struggled on metric conversions, the proctor stated "I can answer any questions you have [about metric prefixes and conversions] once you're done." to which the student replied "Or I can just go on Wikipedia."

IV. Discussion

Computer-based, mastery-graded training on engineering "essential skills" has been effective for some knowledge, while failing to be effective other knowledge. 20-30% of students were unable to perform simple metric conversions, and neither instruction nor training was able to alter these numbers. Almost 30% of posttest students were unable to correctly rank the typical melting points of polymers, metals, and ceramics. More than 50% of students were unable to correctly operate

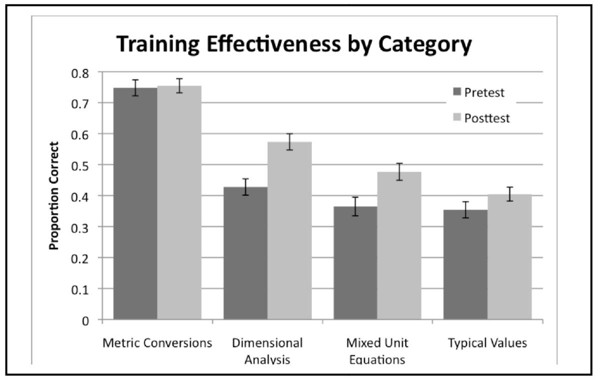

Fig 12. Training effectiveness as measured performance on the essential skills assessment, averaged by category. Only dimensional analysis and mixed unit equations showed statistically significant improvement at the $p<0.05$ level.

equations when given variables in mixed units; once again, instruction and training did little to alter these numbers. While some limited success was seen in student estimates of common material properties, 50% of posttest students were unable to estimate the Young's moduli of two metals within an instructor-specified acceptable range; a similar question involving a polymer saw 75% of students outside the acceptable range. Not only were the values incorrect, about 40% of students gave a higher Young's modulus for the polymer than for the metals.

An overview of student performance as a result of training in the four categories considered in this study can be seen in Fig. 12. Even where training was effective, as in dimensional analysis, posttest scores are still far from ceiling. The highest-performing question still saw 16% of posttest students unable to solve for the units of a given variable when given an equation and units for all other variables. As many as 25% of students leave the course not knowing that an exponential is unitless and, of the ones that do, still 25% cannot correctly solve for the units of the variable in question. Further more, 50% of student could not successfully convert a force in Newtons and an area in mm^2 to a stress in kilopascals.

Though training was more effective for some categories than for others, it was not as effective overall as necessary for such essential and fundamental skills, i.e. a posttest performance of greater than 90% correct. There are a number of possible explanations for these observations. These include:

- The training was too short (≈20 minutes for each topic).
- Posttest scores were already approaching ceiling (71% for the unit conversion).
- The students did not exert their full efforts in answering the post test questions.
- The students did not learn some of the categories because they believe that the knowledge and skills are not relevant to them.
- The students did not learn the some of the categories because they perceive the information as something not to be learned, but looked up online or in a text.

It is likely that some combination of these explanations are relevant, but as stated earlier, we have evidence from interviews that the last bullet is important for at least some of the topics. The interview data hint at an explanation for this lack of consistent success. “Or I can just go on Wikipedia.” Unlike training on log plots, the answers to which questions cannot be easily “googled,” many of the essential skills can be performed with the aide of computer tools and text references—unit conversions can be typed into the Google search bar, the metric prefixes are inside the front cover of the text, Wolfram Alpha will operate equations and perform conversions for you. Because these references are so readily available, many students do not see committing these essential skills to memory as a task worthy of their time. In the process of maximizing points earned per time spent, these tasks simply fall by the wayside. The relative success of dimensional analysis training is in line with this explanation; you can’t “google” dimensional analysis very easily, so knowledge in this category was better retained in training.

As far as students not exerting a full effort in the posttest, this is likely to play a factor, but from a number of years of experience with tests in this context, we have found that students *do* answer these questions with a reasonable amount of effort.

Note that one threat to the external validity of this study is that pre to post training gains on the test were in fact not due to the training but rather from the instruction in the course. That is, all effects reported here may be the result of a combination of training *and* course instruction, and it is not clear which (if not both) caused the gains. Therefore further research in this area would benefit from a more controlled design in order to isolate the effects of training and instruction. In any case, it is clear that, from an instructional point of view, significantly higher gains are desired.

V. INSTRUCTIONAL IMPLICATIONS AND NEXT STEPS

The results of this study offer invaluable insights into the knowledge state of undergraduate engineering students. Instructors should be aware of these fundamental deficiencies in their classrooms and should take measures to ensure students are made aware of their shortcomings as well. Simple mastery-based training has been shown to be effective with some skills; future training can use this study as a starting point or a model upon which to build. At the very least, some form of intervention—instructional or otherwise—seems necessary to prevent allowing students with such critical deficiencies to slip through the academic cracks.

The continued poor performance of students suggests that it may be useful to focus on determining with factors might help convince them of the importance of mastering these essential skills, thus motivating the students to achieve mastery. In this study, the essential skills were somewhat separate from the activities of the lecture and recitations. One way to mitigate this effect is to increase the direct involvement of the instructors, helping to create a dialogue with students as to why mastery of these skills is important.

Another possible approach to further improving mastery and fluency is to progressively limit the time allowed for the Essential Skills Quizzes, particularly those containing knowledge that can easily be looked up online. This will help compel students to internalize and automate the essential skills and related knowledge.

Finally, this study suggests that instructors should consider two practical categories of essential skills and knowledge. The first is the category of skills and knowledge that lend themselves well to short, spaced training. The second category is comprised of simple knowledge or skills that one can quickly access via other resources such as the internet. This study suggests that the latter category seems to be resistant to brief training, as students often recognize easier methods for success in place of committing the skills to memory. In this second case, the relevant instructional goal would be to improve students’ mastery in efficiently accessing this information.

***Abstract*— Through extensive student testing and interviews, we found that the majority of university sophomore, junior, and senior engineering students in a standard introductory materials science engineering course have a variety of difficulties reading correct values from simple logarithmic graphs. For example, students often unknowingly interpreted the log scale as linear and were confused about the order of magnitude of a value in the negative exponent region. To address these issues, we used the results of our findings to develop and implement a set of online "essential skills" tasks to help students achieve a core level of mastery and fluency in reading log plots, a basic and critical skill for engineers. The online tasks were administered as for-credit homework assigned several times throughout the semester, and students spent 10-20 minutes on each assignment. Results of post-tests indicate that with this minimal practice, students were able to dramatically improve their accuracy in reading log plots compared to a control group with no log plot practice. Furthermore, testing one month after training demonstrated that student continued to retain the learned skill. Future development will focus on making these essentials skills task broadly available online and further improving effectiveness and usability.**

Keywords—logarithmic graphs; problem solving skills ; graph interpretation; online homework

I. INTRODUCTION

While complex problem solving skills are critical for engineers to learn and are thus the focus of considerable research and instructional efforts, it is also the case that more simple, elementary skills, are also necessary for solving problems. These simple yet "essential skills" may be fairly straightforward to learn through deliberate practice, but, often to the surprise or chagrin of the instructor, students typically do not have these skills or they are far from fluent in their use. In this study, we investigate the essential skill of reading logarithmic plots. We demonstrate and describe the significant difficulties that most junior and senior level students have with reading simple log plots, and we demonstrate a method to help students achieve and retain significant gains in mastery with a relatively small commitment of time.

II. PARTICIPANTS AND METHODS

The participants in this study were enrolled in an introductory materials science course for engineers, which is a required core course for many of the engineering major programs at Ohio State University, a large public research university. The students ranged from 2nd to 5th-year engineering students. About 10-15% of the students intended on becoming materials science engineering majors, and about 35% of the students were mechanical engineering majors, the most common major in the course.

Data was collected over a period of 5 quarters, for a total of approximately 600 participants. The data was collected in three ways. First, we administered free response and multiple choice tests. In addition to the standard homework, students were given a "flexible homework" assignment with credit for participation as part of the course grade. The flexible homework assignment consisted of participation in a one-hour session where students completed some combination of testing and interviewing. Throughout the quarter, students were randomly selected to participate in the flexible homework. Typically, about 95% of all enrolled students participated in the flexible homework. The tests items were in either multiple-choice, free-response, or a multiple-choice-with-explanation format. Students completed the material at their own pace at individual stations in a quiet room. Afterwards we would informally ask students to explain their answers and they were also asked whether they had any questions. We observed during these sessions that students made a good faith effort to answer the questions to the best of their ability.

Second, we conducted individual or group interviews with over 50 students. These interviews consisted of asking students to verbally answer questions and provide their reasoning on simple log plot questions. Several dozen interviews were videotaped, and the rest were recorded via interview notes. The interviews were used to gain more insight into student difficulties that were discovered in the written tests. Most interviews were conducted individually, but some were given in groups of 3 or 4.

Finally, the third method for collecting data was via the official online homework assignments administered as part of the course.

Tests and interviews were administered either before or after relevant instruction. Different conditions were constructed in order to obtain pre-post test data needed to assess the effectiveness of the instructional intervention.

This work has been supported in part by the Center for Emergent Materials at The Ohio State University, an NSF MRSEC (Award Number DMR – 0820414).

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

The difficulties reported here were found in both written tests and interviews. Thus incorrect answers to the questions should not be viewed as uninteresting artifacts of the particular questions, but rather indicative of authentic student difficulties with understanding and interpreting logarithmic plots.

III. STUDENT DIFFICULTIES WITH LOG PLOTS

Perhaps surprisingly, we could find no research documenting student difficulties with reading log plots, though there are studies documenting student difficulties with understanding logarithm functions [1], and logarithmic functions in the context of pH [2,3].

In the course of testing and interviews we identified a number of specific difficulties, described below. Note that for results reported in this section, testing was administered near the end of the course, and as such the reported student difficulties should be considered post traditional instruction.

A. *Determining Values when Minor Tick Marks are Absent*

When minor tick marks between orders of magnitude are absent on a graph, most students interpret the scale between the orders of magnitude as linear. To demonstrate this, we randomly assigned students into one of two conditions. In the first condition, 107 students were given a numerical value and asked to provide a mark were this value is represented on a line that has orders of ten (major tick marks) indicated on a logarithmic scale. In the second condition, a mark was provided on the scale, and 106 students were asked to determine the value. For example, as seen in Figures 1 and 2, students were either asked to determine the value of the position approximately half-way between 10^8 and 10^9, or they were given the value of 3.0×10^8 and asked to mark that value on the graph.

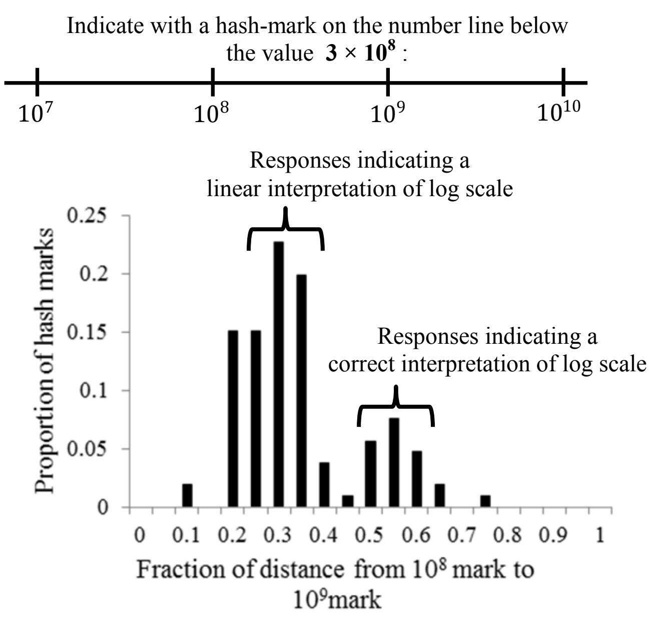

Fig.1 Provide-mark question with minor tick marks absent. Majority of student responses indicated a linear interpretation of log scale.

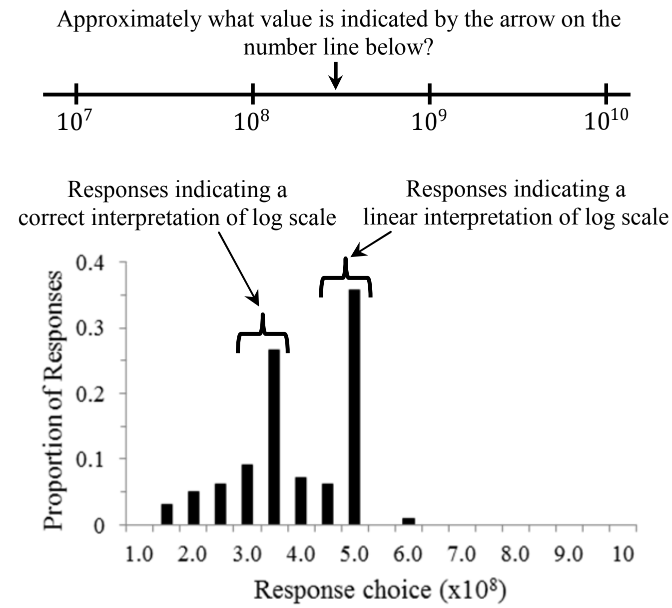

Fig 2. Determine-the-value question with minor tick marks absent. Almost half of student responses indicated a linear interpretation of log scale.

The results indicate that in both conditions, the majority of students interpreted the scale between the major tick marks as linear. For example, in the provide-mark condition in Figure 1, 57% of students indicated that 3.0×10^8 was one-third of the way between 10^8 and 10^9, clearly a linear interpretation. In the determine-value condition in Figure 2, 49% of students indicated that the arrow (placed at the 3.0×10^8 position, which is a little less than halfway between 10^8 and 10^9 on the graph), indicated a value between 4.0×10^8 and 5.0×10^8. This is also a clear indication of a linear interpretation, and post- interviews with students verified this interpretation for both conditions.

B. *Confusion of Values of Minor Tick Marks*

When minor tick marks are provided between the order of magnitude major tick marks, many students misinterpret the value to the hash marks, counting the first mark as "1" instead of "2" and so on. Also, to our surprise, even with minor tick marks present, some students still interpret the logarithmic scale as linear. To demonstrate this, we randomly assigned students to either a minor tick-mark present condition or a minor tick marks absent condition. As shown in Figure 3, students were provided with a graph with mark at the same position for both conditions, the only difference being that one graph had minor tick marks provided and the other did not.

The results indicate that student perform poorly in both conditions, but more students answer correctly when tick marks are provided (41%) compared to when they are not (21%) ($\chi(1)= 6.3$, $p = 0.01$) . The majority of the errors for the tick mark present condition are in misinterpreting the values of the tick marks (15%), and surprisingly interpreting the scale as linear, apparently ignoring the minor tick marks (20%). Note also, that a small number of students made an error on the order of magnitude, this error will appear more frequently in another context discussed in the next subsection. For the tick mark absent condition, the majority of errors resulted from

interpreting the scale as linear, which is a replication of results from the experiment in the previous subsection.

C. Determining Values in the Negative Exponent Region

When logarithmic graphs represent regions of negative exponents, additional difficulties of determining the correct order of magnitude, and determining the correct direction of the scale are introduced, further decreasing student performance. This was demonstrated by assigning students to either a tick mark present or absent condition, similar to the previous experiment, only in this experiment, the graphs represent negative exponent regions. For example, students where shown graphs with a mark between 10^{-5} and 10^{-4} indicating the value of 2.3×10^{-5}, and student were asked to determine this value from the graph (see Figure 4).

The results shown in Figure 4 suggest that the performance on this task is even worse than the performance on positive exponent graphs with only 30% of students answering correctly in the tick mark present condition, and only 13% of students in the tick mark absent condition answering correctly. The low scores are a result of an additional error in the interpretation of the order of magnitude. Students were often confused, for example which side of the 10^{-4} major tick mark (i.e., to the right or left side) represents the order of magnitude of 10^{-4}. In addition, student often made what we labeled in Figure 4 as the "reverse scale error", meaning that students would "count down" (leftward) from the higher order of magnitude and use the fraction of distance as the value. For example in figure 4, students would note that the arrow is about 3/4 away from (to the left of) the 10^{-4} mark toward 10^{-5}, so they would reason that the value should be 7.5×10^{-4}. Post interviews with students verified our interpretations of the errors and correct responses.

D. Determining Values on 2-d Graphs

Up to this point, we have only discussed student interpretations of one dimensional logarithmic plots. However, in practice we are more interested in student performance on two dimensional logarithmic plots (i.e. log-log or log-linear plots), which are commonly found in materials science text books. For two dimensional plots, we found that student performance is still poor, and the mistakes they make are the same as those found in one dimensional plots. To demonstrate this, we provided 206 students with a log-log plot with a line on it, gave them the value on one axis and asked them to read off the value on the other axis. For example in figure 5, we present a stress vs. creep rate log-log graph, and ask the students to determine the creep rate for a given stress.

The results, shown in Figure 5, indicate that 41% of students answered within the accepted range, however, some of these responses may be false positives, since the accepted range includes one of the possible tick mark errors. The Figure also indicates that many students make the order of magnitude error and the minor tick mark error, though interestingly there was no evidence of the linear interpretation error, though this could be due to the specific values, which in this case do not lend themselves to a clear signal of a linear interpretation error because the values are not near the middle of the scale.

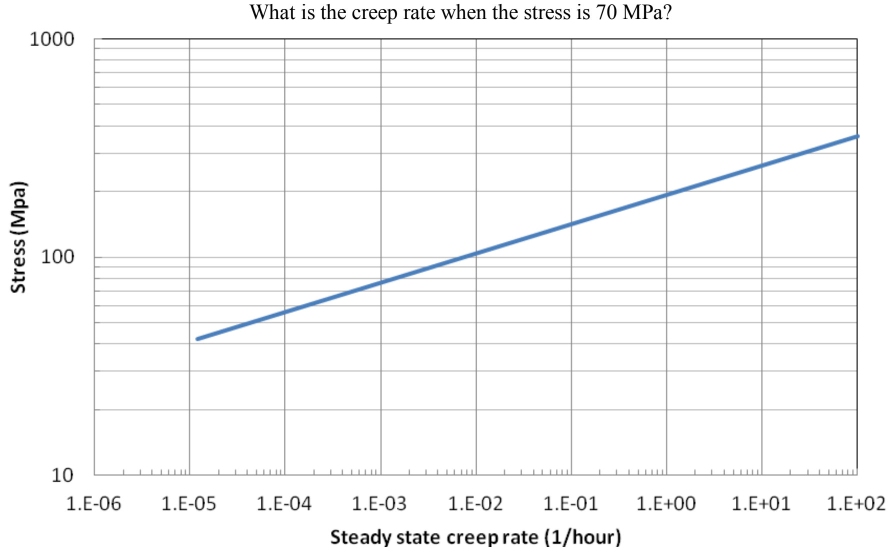
IV. ADDRESSING STUDENT DIFFICULTIES: ESSENTIAL SKILLS PRACTICE ASSIGNMENTS

The results of the last section not only clearly demonstrate that even junior and senior level engineering students have difficulty reading values off of simple logarithmic plots, but the details of the difficulties allow us to design practice tasks to help them improve on specific common errors and become proficient in the essential skill of reading logarithmic plots.

To this end, we designed a set of training tasks to improve student performance on reading logarithmic plots. The rationale is based on the general finding that experts have mastered a set of basic skills and knowledge to the extent that they are fluent or automatic in their use [4]. The central idea is that if necessary and frequently called processes are automated, this will place less demand on attention and other cognitive processes, allowing for efficient and effective problem solving (e.g., reference [5]). In this case, we are interested in improving fluency in reading logarithmic plots so that student may devote resources to solving more important engineering problems.

The strategy used in this proposal to improve mastery and fluency is based on numerous studies demonstrating that testing with feedback can be an effective method for learning [6,7]. In order to further improve the learning and retention, the practice will also be spaced on the order of weeks, following the evidence of the advantages of spaced practice (e.g., reference [8]).

The figure below presents a stress vs. steady state creep rate graph for a steel alloy at 925°C.
What is the creep rate when the stress is 70 MPa?



Responses (N=206)					
< 1.0×10^{-4}	1.0-3.5 $\times10^{-4}$	4.0-8.0 $\times10^{-4}$	1.0-1.5 $\times10^{-3}$	4.0-8.0 $\times10^{-3}$	Other
3%	15%	**41%**	12%	21%	7%
Order of mag error	Order of mag error + tick mark error	**Correct (potential tick mark error)**	Tick mark error	Order of mag error	

Fig 5. Example of 2-dimensional graph question, including table of student responses.

We employed practical logistical constraints on the training, namely that the training would be administered via an automated online system as for-credit homework, and the training, integrated over the course, would require only a relatively small time commitment by the student, on the order of one hour, since this is an additional task assigned in the course.

The training consisted of four assignments spaced throughout the semester, and each assignment took 15 minutes to complete on average. The assignments consisted of sets of ten questions drawn randomly from a pool of questions, taking care to ensure that each set receives a diversity of question types. To receive credit for the assignment, students were required to continue to complete sets until they correctly answered at least 80% of the questions in a set. If they did not reach this level on a given set, they were provided with the answers to the set they failed, then given another set of ten questions This follows a "mastery" model of training, namely that students must practice until they have reached some minimum level of proficiency.

The training consisted of a combination of questions that were aimed at improving the common student errors, including linear interpretation of a log plot, minor tick mark error, order of magnitude error and the reverse scale error. Log plots in one and two dimensions were given, as well as plots with positive or negative exponent regions. This included typical plots that one would find in the text book. These the training items were very similar to the questions presented in Figures 1-5, with variations in numbers, scales etc.

V. Assessment and Results

In order to assess the effectiveness of the essential skills practice tasks, we randomly assigned students to one of three conditions: 47 students to control (no practice), 44 to train and delayed test (practice for 4 weeks early in the quarter), and 53 to train and no-delay test (practice for 4 weeks late in the quarter). Afterwards, all conditions were given a 10 item log plot test, which consisted of a combination of one and two dimension graphs, graphs with positive and negative exponents, and graphs in which minor tick mark values are critical. The items were similar in content to the training questions given in the homework assignment. During the construction of the log plot test, we conducted think-aloud and post student interviews for each items and made adjustments to the items as necessary in order to improve the validity of each item. Two training conditions were used in order to compare student performance shortly after the training (~ few days) vs. 4 weeks after the training. That is, the second condition had a delay of 4 weeks between the last practice and the test, and the third condition had "no-delay" (i.e. only a few days) between the last practice and the test. Note that, to be fair to all students, log plot training was given to the control group after the log plot test and before the final course exam.

The results, shown in Figure 6, indicate that both the log plot training resulted in significant gains in student performance on log plot questions. Specifically, the averages for the train and delay and train and no-delay test were approximately 75% correct on a post test, compared to control, which had an average score of 39% correct ($t(142)=7.1$, $p<0.001$). This gain in score was relatively uniform across all

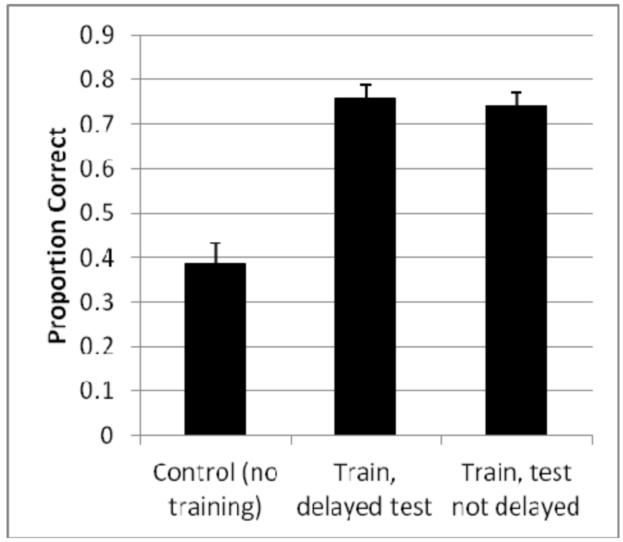


Fig 6. Average scores on log plot test for the control and two training conditions. Results indicate a significant gain (d=1.4) from training.

question types in the assessment, though the poorest performance remained in reading plots with negative exponents (about 70% after training).

In terms of effect size, either training resulted in a large increase in score of approximately d = 1.4 standard deviations. Furthermore, the final score for both the delay and no-delay testing training conditions was the same, thus there was no loss of performance even 4 weeks after the assignment, indicating that the students retained what they learned for at least one month after training.

VI. Conclusion

We found that sophomore, junior, and senior level engineering students had significant difficulties reading off values from simple log plots. Their poor performance (around 30-40% correct) resulted from a number of difficulties including interpreting log scales as linear, confusion on how to interpret negative exponent regions, and confusion of the values of minor tick marks.

Based on these findings we constructed brief practice assignments for the students, and found that with less than an hour of practice, spaced in several sessions over the semester, students could dramatically increase their performance, and they retained this knowledge even one month after training. However, it should be noted that the average post-training performance was still only at the 80% level, and since this is such a basic skill, we would like to continue with further improvement of the practice tasks in order to increase this to above 90% accuracy.

Nonetheless, since the skill of reading log plots is both a critical skill and a skill assumed to be mastered, it would appear that assigning students this automated online "essential skill" homework task is a useful and effective course of action requiring a relatively small amount of effort on the part of the student and the instructor.

ACKNOWLEDGMENT

The authors would like to thank Katharine Flores and Alison Polasik for their comments and generous cooperation with us in implementing the assignments in their courses.

***Abstract*—The present study aims to discuss the development of a collaborative inquiry-based learning environment with the support of an intelligent tutoring system for general education. Following an inquiry-based learning approach, the learner-centered activities involve students making questions about a given theme based on a subject proposed by teachers. Here the collaborative nature of interaction is seen as a fertile space for learning since it enables the mobilization, interpretation and coordination of contributions to achieve a common goal. Students may require instruction and feedback to help them exploit the learning environment to its full potential. To provide the necessary assistance, an intelligent tutoring system is proposed. Intelligent tutoring systems are computer programs capable of providing immediate and customized instruction or feedback to students, without the need of human intervention. In our proposal, a text mining tool provides key concepts about the interaction of the student within the environment. This information can be used by a recommender system, which searches for related material in the Internet and in other specific learning repositories. The relevance of the learning environment proposed here lies on its capacity to give assistance through a recommender system, promoting a richer interactive learning.**

I. Introduction

Reports from PISA (Program for International Student Assessment) have been indicating the deficiency of students in many countries regarding language and digital literacy. Despite the fact that a lot of investments have been made in computer laboratories in schools and other educational settings, technology's full potential as a collaborative learning tool tends to be undermined by traditional teacher-centered approaches.

Current studies indicate the importance of promoting creative, reflective and autonomous use of technology and language, by proposing tasks that challenge students to adapt and transform knowledge towards their learning goals [1], [2], [3]. As Benson [4] claims, autonomy is the ability of individuals to control their own learning. The author adds that such capability is the result of a constant process of construction and redevelopment of knowledge based on the evaluation of previous decision-making in problem solving.

An active positioning of students towards their learning process derives from their own interests [5]. Therefore, critical thinking, autonomy and collaborative skills can be promoted by learning that emerges from students' questioning, which is supported by social interaction [6]. According to Kim et. al. [7], further research is needed in order to establish a relationship between intersubjectivity, collaborative interaction, media choice as an expression of meaning, critical thinking and problem-solving strategies.

Based on this educational scenario, this paper aims to present a collaborative inquiry-based learning environment with the support of a tutoring system for general education to improve students' language and digital literacy proficiency. This interactive virtual environment is intended to foster autonomy, critical thinking and collaborative skills.

II. The project

This section describes the main features of the environment and the theory used to support it. In Section II-A is described *inquiry-based learning*, the learning theory in which we support our environment. Section II-B describes *intelligent tutoring system*, which, alongside with *text mining* (Section II-C), produce the means for the environment to interact with the users (both teachers and students).

A. Inquiry-based learning environment

Inquiry-based learning is defined as a learning approach guided by the process of making questions by learners themselves [8]. The research presented here focuses on the expansion of the SMILE Project (Stanford Mobile Inquiry Based Learning Environment), whose goal is to allow students to create and share questions and answers related to a given subject [7]. In our project, students are requested to make questions about a given theme based on a triggering text proposed by teachers, as a way to lead them to develop their own investigations about a given topic.

After reading the triggering text, the students are asked to create their own questions. These questions are shared among students who are challenged to reflect about the topics proposed by interacting with their classmates. To help students create more elaborate questions, this web-based environment is integrated to a recommender system that suggests additional material according to the main concepts extracted from the triggering text. When a student posts a question, the system uses a text mining tool to extract relevant terms from the student's writings and the triggering text, as a way to identify keywords. Then, these keywords are sent to a web search engine that returns different contents such as texts, documents,

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

images and videos. These contents are subsequently filtered and presented to the students as recommendations that may assist them in broadening or deepening their investigations.

B. Intelligent Tutoring System

The learning environment proposed uses an intelligent tutoring system in the form of a pedagogical agent, who assists students based on their performance on the quiz, indicating complimentary learning materials and correcting syntactic and semantic mistakes. Pedagogical agents are human-like virtual characters used in interactive learning systems that can search and interpret information to support learners' activities through a more natural interaction. The pedagogical agent can adapt its interventions to provide appropriate feedback, based on the analysis of the students' actions [9], [10], [11]. It can promote learning by modeling, scaffolding and guiding students' actions, facilitating students' use of multimedia content, motivating learners to participate in a virtual learning community. Gulz [12] emphasizes that pedagogical agents may increase students' motivation and improve their perception of ease and comfort in using a learning environment.

Research on pedagogical agents in educational applications has demonstrated that, by simulating social interaction, these animated characters may improve student's engagement and learning experience [13]. Here, we consider the pedagogical agent's role as a tutor [14] that helps students to notice and correct errors by suggesting complimentary study material. Thus, high order thinking processes are fostered through the interaction of the agent with the student in cognitive and social spaces [6], [15], [16]. Besides language literacy, this new learning environment promotes digital fluency skills since it requires a creative and active use of technology to produce and transform knowledge [1]. The system's main contribution to education lies on its capacity to provide relevant assistance through a pedagogical agent who can promote knowledge construction through a more interactive learning environment.

C. Text mining

Text mining is a research area that has as a main goal to retrieve relevant information from texts. Such information can be retrieved through the identification of patterns in non-structured data [17], thus separating text mining from data mining, which is mostly based on the search for patterns in structured data bases. The recommender system and pedagogical agent's actions rely on the use of a text mining tool to identify concepts the students use in their writings. In this project, a text mining tool called Sobek [18] is employed.

The mining process starts with a statistical approach that identifies the most frequent concepts. A concept may be one or several words, if the combining words represent a single concept (e.g. "global warming" or "United States"). After this, the connection between those concepts is set using the proximity between them and the frequency with which they are related. The final result is a collection of concepts and relationships that is represented internally in the form of a graph. The process is similar to the one proposed by Schenker [19].

This mining tool has already been used in the development of a system to assist teachers to evaluate students' contributions in discussion forums [20]. Another recent application has discussed the use of a pedagogical agent to mediate collaborative chats in English as a foreign language [21]. Here we propose the integration of the mining tool with the collaborative inquiry-based learning environment to inform the recommender system and the pedagogical agent with the concepts extracted from the students' writings and the texts provided by the teacher. The agent uses these concepts to help students focus on their writings. By keeping track of students' activity in the learning environment, the agent also recommends students with peers that have obtained a high score in the activities developed in the course.

III. THE TUTOR-USER INTERACTION

The agent-student interaction occurs in different moments in the learning environment. Initially, the agent introduces itself to the student, presenting the ways they may interact and how it can help him. After that, the system (through the use of text mining) provides the agent with information regarding the main concepts in the questions being introduced by the student. This information is used to search for complementary material that may help the student to find appropriate answers. Besides, the agent may help the students to improve their writing skills by answering questions regarding vocabulary, and by instigating them to reflect and write about relevant topics they still have not considered in their texts.

At the end of an interactive session with the agent, the system sends a feedback message to the teacher reporting problems faced by the student: spelling mistakes, difficulty in answering his/her own questions or in focusing on the topics proposed.

IV. IMPLEMENTATION

The virtual learning environment proposed here is under implementation to be distributed in the future as open source code. In order to use the system, one must install it on a server, which can be later accessed by users through the web. This server presents features to include all necessary components and classes, making it easy to create new classes and tasks, as well as serving as a database for all questions created. In that way, all the work done by one group of students may be viewed and used by other students, fostering the creation of a collaborative community.

Explaining Semiconductor Device Physics with a Fusion of Lectures and Videos

Kathleen Meehan
Bradley Department of Electrical and Computer Engineering
Virginia Tech, Blacksburg, VA 24061
kameehan@vt.edu

Abstract - **Concepts that describe the operation of semiconductor devices tend to be some of the most difficult for students to grasp. Hands-on experimentation can be used to demonstrate the concepts discussed in lectures or course readings and to stimulate student interest through visual applications of the concepts. However, such activities can be impractical to integrate into the classroom. Thus, multimedia tutorials have been developed on some of the concepts to support student learning and to address why a solid foundation in semiconductor device physics is critical to their development as electrical or computer engineers. Each tutorial includes a review of the theory that is demonstrated in the experiment, which is then presented. Reinforcement of their learning occurs immediately in the form of a brief video from an expert (not necessarily the course instructor) with his or her explanation. Assessment on student learning has been initiated using an assessment tool developed to evaluate hands-on learning at Georgia Tech.**

Index Terms – Semiconductors, Device physics, Video tutorials.

INTRODUCTION

Concepts that describe the operation of semiconductor devices tend to be some of the most difficult for students to grasp. The idea that a hole moves through the semiconductor can stump some of the best abstract thinkers in the classroom. The equations to calculate the intrinsic carrier concentration and the contribution of drift and diffusion currents to the total current are some of most complex that the second semester electrical and computer engineering (ECE) sophomores have had to apply by that point in their academic careers. There are additional barriers to learning this material. First issue is that many ECE students question why they need to know the material. Semiconductor device physics has not be presented as an ECE discipline when they visited campus as high school students or during their exposure to ECE during freshman year. At Virginia Tech, the multidisciplinary nature of the field is no longer supported by a year-long chemistry sequence and a one-semester material science course; both were eliminated during a curriculum revision more than a decade ago. Unfortunately, engaging students in hands-on activities that demonstrate the concepts discussed in lectures or course readings and that stimulate their interest through visual applications of the concepts has proven to be impractical, even for some of the simplest experiments, because of resource limitations. Educators have developed Java applets [1] and MATLAB programs [2-5] to provide visual demonstration of semiconductor concepts to promote student learning. However, many of these learning materials do not include a link between the concept and the physical devices and circuits. Thus, video tutorials have been created that show students the operation of real devices and circuits, and describe how the equations from semiconductor device physics influence specific behavior, and how students can calculate the physical constants from measurements collected from the devices and circuits.

PEDAGOGICAL APPROACH

The video tutorials combine PowerPoint slides, still images, and videos that have been recorded with the assistance of Virginia Tech Video Broadcast Services (VBS). A formal process, guided by Gagne's hierarchical theory of instruction [6], has been used to organize the presentation of learning materials for each topic. The PowerPoint slides are used to introduce the students to the learning objectives of the multimedia tutorial and provide guided learning by presenting or reviewing the abstract concepts that will be applied when the students are asked to explain the reasons for the behavior observed during the experiments. Audio tracks for the multimedia presentations are recorded using Audacity and Adobe Presenter. The video content are recorded experiments as well as clips on how the materials and devices used in the experiments were fabricated in the Virginia Tech cleanroom and how the experimental setups were assembled. Some of the tutorials are viewed during class with open discussions afterwards to connect the conclusions about the experiment to theory. When the tutorials are assigned, brief quizzes have been designed to encourage students to view the tutorials and to prompt students for their explanations and conclusions drawn from the multimedia material. Reinforcement of their learning occurs immediately in the form of a brief video from an expert (not necessarily the course instructor) with his or her explanation. The topics covered in the videos that have been developed thus far are listed in Table I as well as the ones

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

that will be addressed in videos that will be made during the fall semester.

Table 1. Topics of Videos

Topic	Status
Parameter extraction from diode I-V characteristic	Completed
Half-wave rectifier	Completed
Full-wave rectifier with transformer	Completed
Full-wave rectifier bridge	Completed
Diode logic circuits (AND and OR gates)	Completed
Parameter extraction from MOSFET I-V characteristic	Planned
Parameter extraction from BJT I-V characteristic	Planned
NMOS, PMOS, and CMOS inverter	Planned
TTL inverter	Planned

While it would be preferable to have the students perform the experiments in class, the surface area and flatness of student desks and the number and distribution of power outlets available in several classrooms do not support in-class hands-on activities. Whenever possible, the circuits are constructed from components that are available in the parts kits that are distributed to all electrical and computer engineering students in the department. Most of the measurements are performed using the same model digital multimeter and the USB powered oscilloscopes that the students purchase during their first semester circuits laboratory course. Thus, the students are able to repeat the experiments shown in the video tutorials.

CONCEPTS FROM SEMICONDUCTOR DEVICE PHYSICS

It is important for students to have a good grasp of the ideal diode equation to understand the operation of diodes and bipolar junction transistors, as explained using the Eber-Moll equations, and the origin of certain leakage currents in these devices as well as in field-effect transistors. The relationship between the concentration of acceptors and donors on the drift current across a p-n junction influences the magnitude of the reverse saturation current. The intrinsic carrier concentration of the semiconductor also affects the magnitude of the reverse saturation current. The basis for the piecewise model of a diode is also critical to understand. The donor, acceptor, and intrinsic carrier concentrations influence the built-in voltage and the series resistance of the diode, which determine the values of the parameters in piecewise model of the forward-biased model.

.

EXAMPLE TUTORIALS

Several tutorials have been developed on the ideal diode equation, the piecewise model of the diode, and that describe the operation of the diode in a full-wave bridge rectifier. As part of the first two tutorials, the current-voltage (I-V) characteristic of a light-emitting diode is plotted after measurements of the resistance of resistor R (nominally, 10 kΩ) and the measurement of the voltage drops across the resistor and diode as the input voltage is swept from 0 V to 5 V are made on circuit shown schematically in Fig.1.

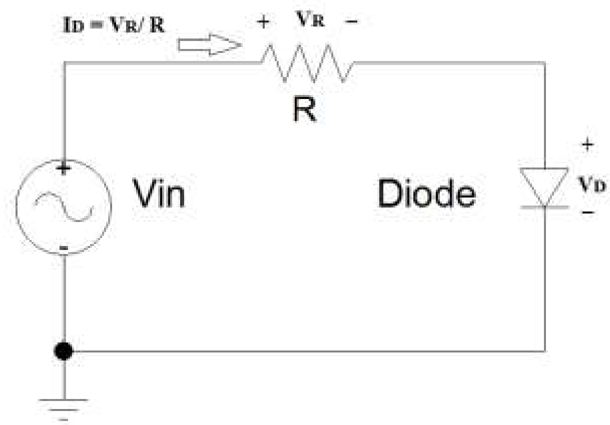

Fig. 1. Schematic diagram of the circuit used to measure the diode voltage and diode current as Vin is swept from 0 V to 5 V.

In the tutorial on the ideal diode equation, the PowerPoint slides that precede the video of the measurements on the circuit describe the drift and diffusion currents that flow across a p-n junction as a function of diode voltage. Following the video of the measurement, the analysis of the data to determine the reverse saturation current, I_S, and the ideality factor, n, is presented (see Fig. 2). In the second tutorial, an explanation about the turn-on voltage and the series resistance of the diode is given with a discussion on why the internal resistance of the diode causes the I-V characteristic to deviate from the ideal diode equation. The same I-V plots that were generated for the tutorial on the ideal diode equation are used to calculate the turn-on voltage, V_J, and series resistance of the diode, R_S

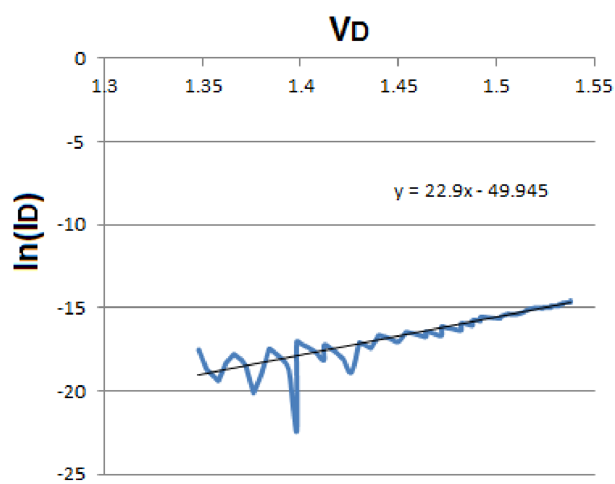

Fig. 2. Plot of the natural log of the diode current vs. diode voltage where the slope of the line is equal to q/(nkT) and the y-intercept is equal to the reverse saturation current I_S.

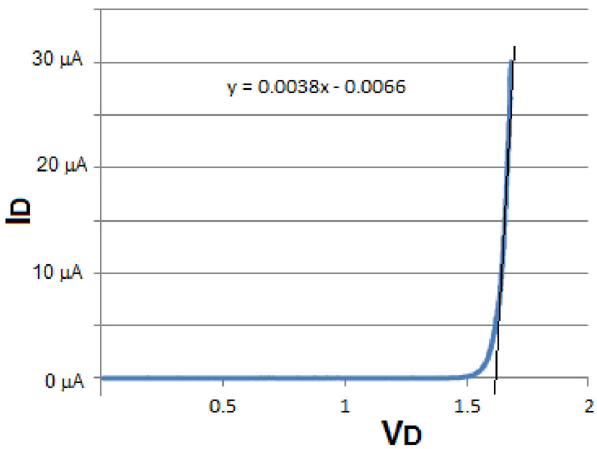

Fig. 3. Plot of the diode current vs. diode voltage. The slope is equal to $1/R_S$ and the x-intercept is equal to V_J.

(see Fig. 3) and a piecewise model using these parameters is constructed for the diode, demonstrating the connection between the ideal diode equation and the piecewise model of the diode. In addition to the tutorials, an Excel spreadsheet containing the data used to calculate the diode parameters is made available to the students. Students are asked to consider how changes in the acceptor and donor concentration and in the material used to fabricate the diode will affect the I-V characteristics and diode parameters.

Typically, full-wave bridge rectifiers are analyzed using the piecewise models of a diode. However, as the magnitude of the load resistor is increased, the operation of the diode is more appropriately modeled using a combination of the piecewise models and the ideal diode equation. In Fig. 4a, the load resistor is small, 270 Ω; while in Fig. 4b, the load resistor is 270 kΩ. The ranges of diode voltages where the ideal diode and the piecewise models should be applied can be determined by a review of the range of voltages used to determine the parameters in the ideal diode equation and the diode voltages used to calculate the turn-on voltage and series resistance.

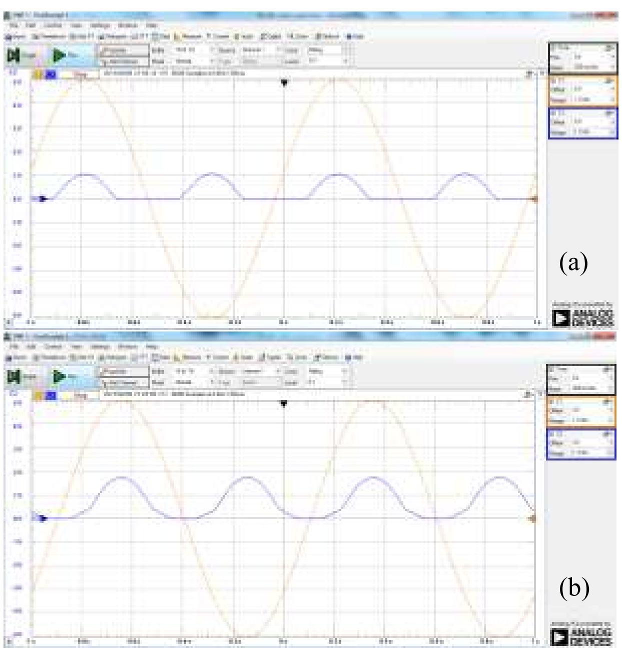

Fig. 4. Plot of the voltage across the load resistor in a full-wave bridge rectifier where the value of the load resistor is (a) 270 Ω and (b) 270 kΩ..

The explanation about the regions where the ideal diode equation and the piecewise model of the diode should be applied is reinforced by overlaying the measured voltage on top of the voltages across the load resistor as calculated using the ideal diode equation and the piecewise model. The measurements are imported into MATLAB using the Data Acquisition Toolbox Support Package, which is integrated as an application in MATLAB R2013 [7]. The students can then see how well each of the approximations predicts the performance of the diode in the circuit.

CONCLUSION

The video tutorials were introduced in the Spring 2013 academic year to support the instruction on semiconductor device physics. The analysis of the initial assessment results is on-going. A longitudinal study on the students' retention of the fundamental concepts in semiconductor device physics that are reinforced by the video tutorials as compared to those concepts that are not presented in one of the video tutorial are planned.

Development of a Concept Inventory for Microelectronics Courses

David H. K. Hoe
The University of Texas at Tyler
Department of Electrical Engineering
Tyler, TX 75799
dhoe@uttyler.edu

***Abstract*—This paper describes our initial attempts at developing a concept inventory for a microelectronics course. The methodology for selecting the core concepts to be tested and the development of the questions are described. Results of the assessment data indicate some areas where student conceptual understanding is weak. The proposed method to improve the concept inventory is also detailed.**

***Keywords*—Concept inventory, microelectronics, nanotechnology**

I. Introduction

Rapid advances in the microelectronics industry, including the scaling of electronic devices to nanometer-scale geometries and the development of radical new nanotechnology-based devices, mandate that curriculum revisions be continually made in electronics and integrated circuit (IC) design courses. These revisions, encompassing the enhancement of existing courses in IC design and the development of new ones in nanoelectronics, are necessary to ensure that graduates from electrical engineering programs are well-prepared to design and innovate in an increasingly nanotechnology-based world. As new material and pedagogies are introduced into microelectronics courses, it is essential to have an accurate assessment of student understanding of the core concepts in this discipline. This paper describes the initial development of a concept inventory (CI) targeted at microelectronics courses with introductory nanoelectronics content. A CI allows an assessment of the conceptual understanding of the students with regard to a specified body of knowledge, typically the core content for a targeted course. Hence, a CI is an invaluable diagnostic instrument for uncovering student misconceptions about the course material and for planning improvements in the curriculum to remove these misconceptions. An effective means of curriculum assessment will combine the results of a CI test with other assessment data obtained from student interviews, self-assessment surveys, and faculty observations [1].

The Force Concept Inventory (FCI), developed by David Hestenes and his colleagues to assess student conceptual understanding in a freshman physics course, was the first prominent use of CIs in the STEM fields [2]. The results provided the motivation for curriculum innovations involving interactive engagement activities in the classroom [3]. In the past decade, CIs have been developed for several disciplines, including biology, chemistry, and geosciences [1]. Some CIs have been introduced recently for core courses in the electrical engineering curriculum, including electronics, digital systems, and signal processing courses [4-6]. However, most CIs target lower-level courses, with few developed for upper-division courses. Our CI targets a senior-level course in microelectronics, with two main objectives in mind:

1. Assess the conceptual understanding of students of the core concepts for a course with nanoelectronics content
2. Determine the impact of new pedagogical methods of interactive engagement used to introduce nanotechnology principles into the course

Our initial set of CI tests was administered in an IC design course called VLSI (Very Large Scale Integration) Design in Fall 2012 in which nanoelectronics concepts were introduced. The development of the CI for this course is motivated by our overall goal of integrating nanoelectronics material into an existing integrated circuits (IC) design course. The expectation is that a stimulating introduction to nanotechnology will motivate our students to take more advanced courses in this area either as senior technical electives or in graduate school. The details of the actual course implementation were reported elsewhere [7].

II. Development of the Concept Inventory

For the initial development of our CI, twenty-five questions were created that were distributed over three separate tests. Our methodology followed the standard approaches reported in the literature. The first step is critical: identifying the core concepts for the course. For this initial attempt, the author surveyed several popular textbooks on VLSI design [8-10]. Future work, discussed below, will look to ensuring a recognized standard of core concepts is included. Second is the creation of the questions. Generally, multiple choice questions are preferred since appropriate distractors can be included to probe for common student misconceptions. The questions do not require any use of formulas and aim to contain language that is comprehensible to all students. The use of any special terms should be widely recognized. Three to five choices for the answers are usually optimum [1]. Most questions prompted the student to provide a brief written explanation for their answer in order to gain further insight into their conceptual understanding.

The first CI test consisted of nine questions. This test was given on the first day of class to fulfill objective one – providing a basis for assessing student understanding of some core concepts upon entering the course. Courses such as Digital Systems and Electronic Circuits are important prerequisites for this course. As such, we used existing concept inventories that have been developed for these courses for our source of questions [4-5]. The instructor selected questions that are important for VLSI design from three key areas: digital logic, device operation, and circuit analysis.

For the second objective, the student conceptual understanding of material taught in the course was assessed by the second and third CI tests, each consisting of eight questions. The second one covered some of the core concepts of the course such as device scaling, physical layout of devices, and transistor-level logic gate design. The third CI test covered advanced logic gate design and low power design methods.

III. DISCUSSION OF RESULTS

On the initial CI test to assess objective one, several areas that presented difficulties to the students were evident. This included basic device concepts such as identifying the different regions of operation and circuit analysis which depends on an understanding of device characteristics. For example, the question that caused the students the most difficulty is depicted in Figure 1. Only two students out of twenty correctly identified (a) as the answer. The question probes for an understanding of body effect and its impact on the threshold voltage. (The answers were equally split between (b) and (c)).

In the n-channel MOS circuit shown, $V_{in1}=V_{in2}=V_{DD} > V_{T0}$, where V_{T0} is threshold voltage of an nMOS device with zero bias. Let V_{T1} and V_{T2} be the threshold voltages of FETs M1 and M2, respectively. Select the best answer.

(a) $V_{T1} > V_{T2}$
(b) $V_{T1} < V_{T2}$
(c) $V_{T1} = V_{T2}$

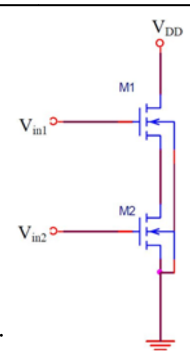

Figure 1. CI question on body effect [4].

Their written answers reveal a lack of conceptual understanding as well. This type of question is likely difficult for the students because it requires the ability to analyze the circuit at the transistor level and to recall a device-level concept (i.e., the body effect). This is a good example where the instructor used the results to plan an appropriate intervention: in this case, a review of threshold voltage and body effect and circuit analysis in a class lecture. An interesting contrast was between a question on a logic gate with a resistive pull-up and a standard CMOS logic gate. Only 4 out of 20 students could correctly identify a NOR gate in the first case, but most could identify the operation of the standard CMOS logic gate (14 of 20). The difference is that the first question requires some circuit analysis, while the second can be analyzed with a simple switch-level FET model (the transistor is either on or off) that is covered in their electronics courses. On the tests given later in the semester, several other important areas of student struggles were identified. One area that stood out was the confusion of related concepts. For example, a pair of questions probing for a conceptual understanding of the importance of the dielectric material in the scaling of IC processes indicated most students confused the need for a high dielectric constant under the gate of a device with the need for a low dielectric constant between the interconnect. This could be due to the need for more time to review and reflect on the material. Some correlation between student difficulties with nanoscale concepts and their work on the course project was evident. For the course project, the students were asked to select a circuit from a CMOS logic family discussed in class and simulate it at a nanoscale technology node as well as provide some analysis of the impact of scaling on the circuit's performance. Overall, this component of the project was rated at an average of 7.53/10. On the second CI test, four of the eight questions were related to issues with scaling transistor geometries to the very deep submicron (VDSM) regime. On those four questions, the students selected the correct answer an average of 58.5% of the time, indicating on average their struggles to grasp scaling issues. Detailed results will be presented at the conference.

A focus group discussion was conducted with four students to obtain additional feedback. The aim was to assess communication validity from the test-taker's perspective, i.e., whether the students understood the questions in the way they were intended. Some useful feedback was obtained, especially in regards to confusing terminology. A CI test should use language which is familiar and considered standard terminology and should not be confusing or ambiguous to the students. For example, on the discussion of the MOS pass-transistor, some students did not understand the reference to a "weak" logic level (i.e., a threshold voltage drop). Our suspicions regarding the trouble with the body-effect question mentioned above were also confirmed from these interviews.

IV. SUMMARY AND FUTURE WORK

This paper has summarized our initial attempts at developing a CI for a microelectronics course. The results from this assessment have given some indications of the conceptual areas that students find difficult to grasp and the impact of our attempts to introduce nanoelectronics concepts through active learning exercises reported in [7]. Further development of this microelectronics CI is planned. This will include a more rigorous determination of the core concepts for the course by getting expert feedback through the Delphi process, a structured multi-step process designed to obtain consensus on a subject [11]. More questions will be added so concepts are covered more than once in order to measure the reliability of the test. To ascertain the validity of the test, three things are planned. First, feedback from instructors of VLSI design courses on the suitability of the questions will be obtained by circulating an alpha version of the test. Second, we plan to have a beta version administered at several other institutions to obtain further data. And third, semi-structured interviews and focus groups will be planned with students to assess the communication validity of the questions.

***Abstract*— On-line laboratories (virtual or remote) are widely used in experimental engineering subjects as part of the learning process. In order to develop these laboratories, a development framework called RELATED (Remote Laboratories exTendED) is used by the Communications and Control System Department of the Spanish University for Distance Education of Spain (UNED). This framework defines a structured and methodological development procedure, allowing the students the generation of their own laboratories. Once the laboratory is developed (based in its components), students have to configure their own computing resources in order to make their labs available. However, several problems must be faced by students in the "deployment" of their labs: network configuration, hardware availability, and so on. So, in order to solve these problems, an automatic system based on cloud providers is defined to allow students having their own cloud network/resources for their developed labs. This system simplifies the lab deployment and avoids common errors/mistakes in the development of laboratories with RELATED.**

Keywords—remote/virtual laboratories, development, cloud service model, laboratory deployment

I. INTRODUCTION

On-line laboratories (virtual or remote) [1], [2], [3] are widely used in experimental engineering subjects as part of the learning process [4]. In order to develop these laboratories, a development framework called RELATED (Remote Laboratories exTendED) [5] is used by the Communications and Control System Department of the National Distance Education University of Spain (UNED). This framework defines a structured and methodological development procedure, allowing the students the generation of their own laboratories. Also, students can integrate different elements included in other laboratories provided by the department due to the modular approach in the development. These student's laboratories are considered as part of the evaluation process in several subjects offered by the department in the EHEA (European Higher Education Area).

In the development and laboratory deployment steps, some resources are required in order to use the framework's tools (configuration validation and deployment process application). These resources are based on the availability of a java virtual machine and a correct network configuration (needed for laboratory access). The first software requirement is easy to meet (java versions could be another problem, but it is resolved updating the java distribution) but not the network configuration. Most of students usually use their own hardware (pc, laptops, etc.) with a fixed network configuration (ADSL modems routing ports not available, private ips, etc). So, in order to get a solution for students to resolve the before requirements, a cloud service model [6], [7] can be used to provide software/hardware/network resources. This means that a private/public cloud be used in order to provide these resources, and students could have a cloud panel to have control over their "cloud" deployments.

The "cloud" deployment of remote/virtual laboratories developed using RELATED uses the same elements as the "standalone" deployment, i.e., using the local deployment tool provided by RELATED. These elements are: 1) a configuration file with the lab structure which is XML based; 2) code implementations for "run-able" entities defined in the laboratory (modules and views, in RELATED terminology). With this new deployment option, student gets a full laboratory with an automatic network configuration ready to be used. Thus, lecturers can test the performance of student's labs, in order to evaluate them without running them in their own limited computing resources. It will also prevent the local execution of labs in lecturer's computers as usually it's done in the evaluation process (this simplifies the evaluation process and saves time for lecturers/students).

The paper shows the differences between deployment process using the cloud and standalone approaches, using the same development methodology defined in RELATED. In section II, a brief introduction of development process for remote/virtual labs is presented. The fundamentals of RELATED framework will be presented. In section III the "standalone" deployment process for a virtual/remote lab is reviewed. In section IV, details about cloud configuration and service model will be shown, and how it is managed. Finally, statistical information about lab cloud service used by students will be presented, focusing in two subjects, which are part of Computer Science Degree of the UNED: Distributed systems and Distributed Applications.

II. Methodological Development of Virtual/Remote Labs

In order to use the RELATED framework facilities, an RLAB (Remote LABoratory) system must be defined. This can be done using a formal specification which is named LEDML (Laboratory Experimentation Description Markup Language). LEDML is based on XML language, and it is used to define structured components for the laboratory. The laboratory description, LEDML based, is really a lab configuration, and it is used in the same way as other configuration files in other software tools (for example, the server.xml configuration file in Tomcat). Every component in a RLAB XML file is represented by its corresponding XML fragment. These fragments are text based, so they can be reused in a simple way including them in the configuration files of RELATED laboratories.

The main component is an experiment, so lecturers/students can run these experiments using RELATED facilities as, painting data from the laboratory, change any relevant variable or have a look to the laboratory structure. In order to integrate the laboratory as an RLAB system, researchers/lecturers/students only have to develop local access to equipment using Java technology. The element responsible for carrying out this function is called a module.

A module is a run-able entity, executed into the RELATED server facilities. The module is responsible to get/set data from/to the equipment. They can be seen like a "black box" used to describe a component as a set of input/output variables. Considering modules are "black boxes", and using the RELATED modular architecture, it is possible to flow data between modules. Developers must provide read/write functions to get/set data for these variables. Java programming language is used to develop these read/write functions and XML tags are used to set-up a laboratory and to specify the module configuration.

There are also other main components in a RLAB LABORATORY, the views. Views are responsible of human interaction with the lab and provide the lab GUI. As it can be seen in figure 1, modules and views are the main components of an experiment. One or several experiments compose a laboratory (RLAB). One of the most interesting features in RELATED is that RELATED uses the "module paradigm" and, this way, modules and views can be reused in several experiments, even in several laboratories distributed on different Internet locations (for example, laboratories developed by students that can have modules running in the own student's equipment).

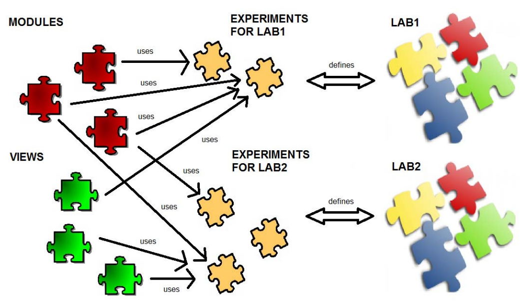

Fig. 1. RELATED modular structure.

As mentioned above, views provide the visual information to the final user (students, teachers, etc.). So, graphical interfaces (GUI, Graphical User Interface) can be included in these views in order to get a better user experience. These views use data from modules to update the experiments state, and it is possible to change and send values from the GUI to the modules.

Experiments define the behavior expected from the lab, so one or more experiments can be defined on the lab. Basically, it is possible to define an experiment by stating the set of modules and views that will be used in the experiment. Any convenient combination of modules and views can be used as an experiment.

III. Standalone Deployment for the Student's Lab

Once the lab definition and components are available, the next step is to deploy/run the lab. In this study case for Distributed Systems and Distributed Applications subjects, the student has to develop a virtual lab [8] representing a simple signal generator with three signal types (Sine, square and triangle) which will be connected (the module component) to a real equipment (magnetic levitator). First, student develops the module representing the behavior of signal generator (module named "SG_MODULE" in figure 2) and a view to get a visual representation of the module. Both of them are developed following the RELATED guidelines. In order to test the generated lab, an experiment is defined in the lab specification file (experiment "Generate signals" in figure 2). Once the specification file is ready (and also the components), students have to deploy their labs using the RELATED tools.

```

Fig. 2. Signal generator's lab definition using LEDML.

To do the lab's deployment, student has to configure a properties file which defines several hardware/software/network parameters (See figure 3):

- Local path of lab's definition.
- Local path of logs generated by the RLAB server which is responsible of the laboratory's execution.
- Network configuration for the RLAB server (the lab) which will be run on the local host of student.

The network configuration parameters are especially important due to the laboratory will listen client connections on the defined ports. So, if these ports are not available to external clients, there will no opportunity to run experiments from the experimentation client. Usually, students use their own personal computers to develop the laboratories, and these personal computers have private ip's. This is a big problem to lecturers and students in order to check the online laboratory, due to lack of visibility of private ip's on the internet network.

```
# Properties file for initiating values for server

# XMl file with LEDM Specification
xmlfile=../examples/signal_generator_gui/LEDML_Specification/signal_generator_gui.xml
#Show GUI (values --> yes, no )
show=yes
#Debug (values --> yes, no). If yes, output will be redirected to log/rlab.log
debug=yes
#log_file
log_file=./log/signal_generator_gui/rlab_signalgeneratorGUI.log
# Publish (values --> yes, no). If yes, rlab system is publish as public from
# rlab website, once the LEDML file is parsed
publish=no
# Rmi port, port for start rmi registry
rmiport=1099
#RMI Service port. RMI service port for an RLAB system --> It is different of rmiport
(assigned to naming service)
rlabserviceport=1095
#UDP port. Port for data communication
udpport=10003
# REST Server port assigned. Jetty needs a port to listen REST request
restport = 9996
```

Fig. 3. Properties file needed for run a RELATED laboratory.

Once the properties file is configured, then the student has to run the publish application tool provided by RELATED. This application checks the xml definition and creates the laboratory using the parameters defined before. Now, students can carry out the experiments defined in the lab specification from the related web server, showing the experimentation client like in the figure 4.

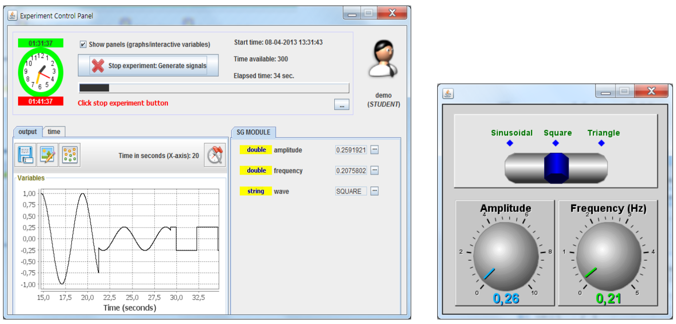

Fig. 4. Experiment client running the experiment defined in the student's laboratory.

Students claim that they waste so much time in a correct configuration for the parameters for their computing nodes (their personal computers). This hide the main objective of the evaluation task: the development of their own laboratories. So, the first problem to face is the simplifying of lab's configuration process. Also, another big problem consists in to get a public availability of the lab, avoiding the use of private ip's. This availability must consists not only in terms of public access across Internet, but using computing resources (computing nodes) to get a "full time" availability of lab. This feature allows to lecturers and students the testing of their lab, and in the lecture's case the evaluation of the tasks associated to the developed lab by students.

IV. USING CLOUD PROVIDERS TO DEPLOY RELATED BASED LABS

In order to solve the problems detected in the above section, it's mandatory to get computing resources using public/private available resources. For this objective, the well-defined cloud service model [9], [10] (see figure 5) can be used. The idea is to use the public/private resources defined in several cloud providers to get "computing nodes" which will run the student's labs [11]. Nowadays, RELATED was using the cloud model for the management services [12] but not for the lab's execution. To move the lab's execution to the cloud, the PaaS (Platform as a Service) layer of cloud computing model is used to develop a new "deployment" application for RELATED laboratories named "RELATED Cloud Labs". The PaaS layer focus on applications and the "RELATED Cloud Labs" application provides the lab's deployment services for users, as it is required in this case.

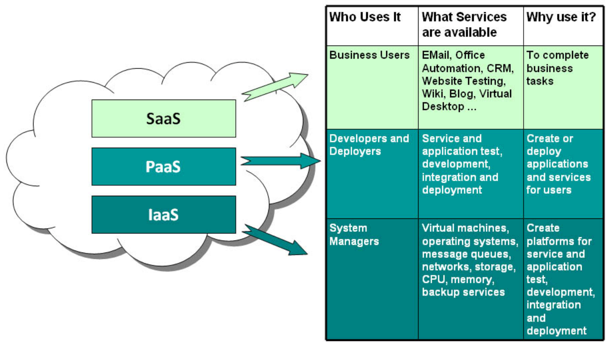

Fig. 5. Cloud service model. Referenced from http://info.apps.gov/content/what-are-services.

This application represents a computing node, and it will take care of the student's laboratories, running them inside the "computing node". The computing node will be represented as a Java Web Application running inside a Java EE 6 container. Thus, any compliant PaaS provider can be used to create "computing nodes". There are several options for public PaaS providers which offer this kind of environment, hosted in the cloud. Actually, three nodes are available for students in order to be used:

- http://cloudlabs.rpastorvargas-uned.cloudbees.net. Running in the public PaaS provider name "Cloud Bees" [13].
- http://cloudlabs-rpastor.rhcloud.com/. Running in the public PaaS provider name "Openshift" [14].
- http://lab-app.scc.uned.es:8080/CloudLabsDeployer/. Running in a private node owned by RELATED project.

The process of adding "computing nodes" is quite simple: installation of the "RELATED Cloud Labs" application in a cloud provider with PaaS/J2EE support. Thus, to get more computer nodes is easy and other PaaS providers like CloudFoundry [13] or AWS Elastic Beanstalk [14] will be added as computing nodes providers in the future.

Students can select the "computing node" to deploy their labs from the RELATED web server. Even, they can deploy and run the same laboratory in several nodes (up to three now) to test the performance of the computing node.

V. DETAILS ABOUT THE DEPLOYMENT PROCESS IN THE CLOUD

Once the student selects the computing node, he/she has access to the web application (RELATED Cloud Labs). This application allows to student the uploading of their xml definitions for labs, and also the components which compose the labs (basically the implementing jar files of views/modules). In figure 6 is represented the main window for the web application (with the student "demo" logged in the system) running in the computing node provided by Cloud Bees. From this window (a web page in a browser), the student can view their cloud labs deployments and upload new laboratories using the corresponding options.

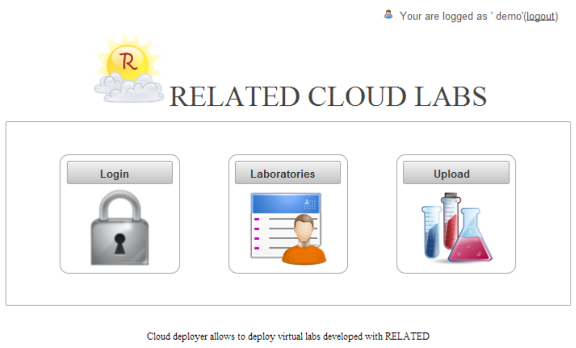

Fig. 6. Main form for the computing node hosted by CloudBees.

In order to upload a new laboratory, students simply click the "Upload icon" (see figure 6) and a new form will be presented to upload the lab's definition. This form is presented in figure 7. The first step is the uploading of the xml file and its validation. The validation is used to detect components and definitions errors in the laboratory specification.

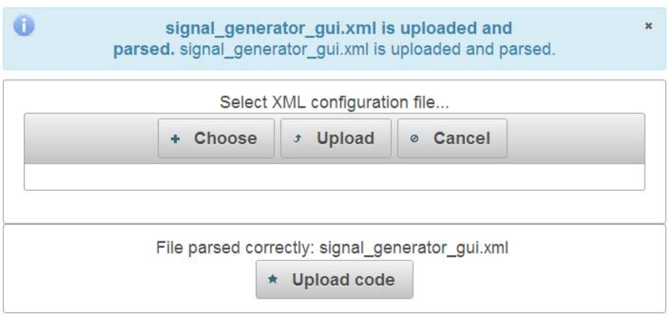

Fig. 7. Uploading and verifying of laboratory specification.

If the laboratory's definition is ok, the "Upload code" button is enabled in order to allow to students to upload components defined in the lab, as it seen in figure 8. In this case, the student's lab is composed by one module representing the signal generator and a view to interact with the lab. As mentioned before, these components are developed using the RELATED methodology. Every component must have at least one main jar (implementing the behavior of component) and optionally, one or more "helper" jar files. These helper files allow including third part libraries in an easy way.

In order to upload lab components, the "Choose" button must be clicked to upload all the implementing jar files. Students can upload all the files in one step, using the multiples items capability of the upload component (see figure 9). Once all the files are uploaded, the lab is ready to be added to the student's cloud labs using the corresponding button (enabled when all files are uploaded and checked) in figure 10.

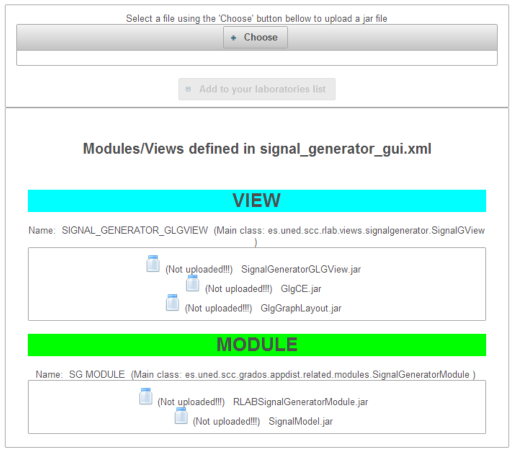

Fig. 8. Uploading laboratories components: modules and views.

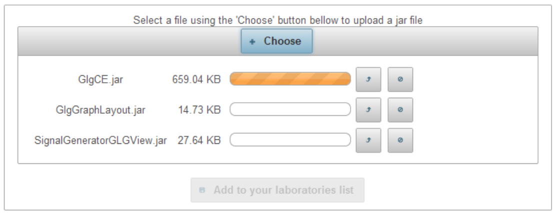

Fig. 9. Uploading multiple laboratories components at the same time.

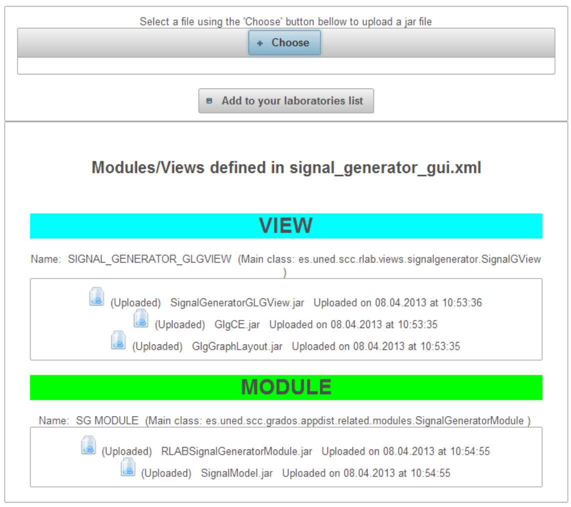

Fig. 10. Laboratory components uploaded and ready to be deploy/run in the cloud.

Finally, once the laboratory is ready, it will be available in the laboratory list (see figure 6). Now, students can get details about their clouds labs, like it is shown in figure 11. In this case, the student's lab being deployed is shown in figure 11 (marked with a red box). From every cloud lab defined, the name and description are presented and also, the deployment options and management options.

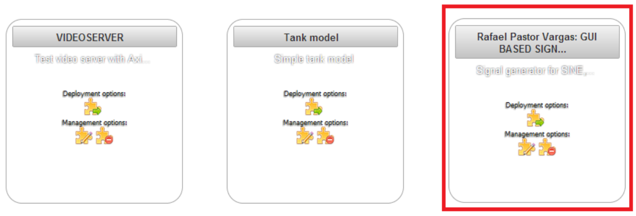

Fig. 11. Laboratories deployed on a computing node.

The last step to get the public availability of lab consists in changing the state of cloud lab. This is done using the icon. Clicking this icon, it starts the running of the laboratory in the computing node, making available from the laboratory list in the related web server. At the start of lab running, the computing node assign automatically the parameters for the configuration of a RELATED laboratory (see figure 3), based on the availability of resources in the computing node (network ports and paths to logs for laboratory). This feature allows students and lecturers forget all about the configuration file and focus on the testing of the laboratory.

In figure 12, the running laboratory list in related web server [17] is presented. In this figure, two laboratories with the same name are showed, one running using the "standalone" deployment process and the same running on the cloud.

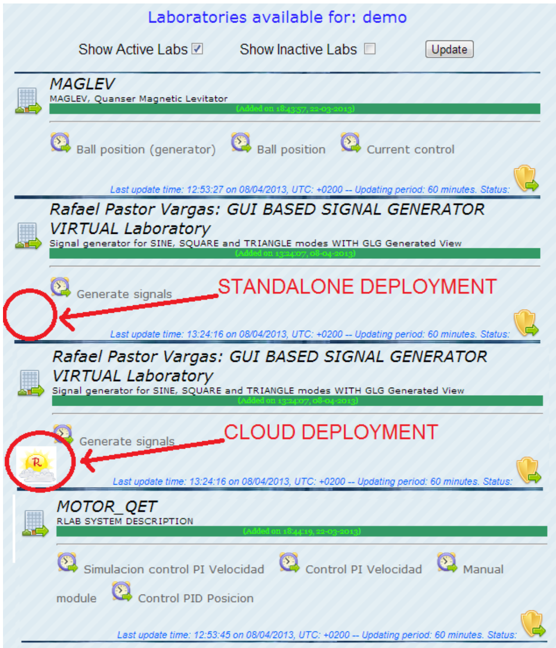

Fig. 12. Laboratories list available from the related web server.

Students can manage their cloud labs from the details panel of lab. They can delete (undeploy) the laboratory using the icon or edit the components in order to upload new versions of the components (using the icon).

VI. STUDENT'S CLOUD LABORATORIES AND SURVEYS

Once the practical experience with virtual/remote laboratory is over, students must perform a survey used to get development/services satisfaction information. This survey is mandatory and it has 20 questions, classified in 5 main areas (questions/ratings are shown in Table 1 only for the main interest area of this paper, focused on deployment options). The survey was performed by 45 students from 151 enrollment students in the two subjects considered. Due to the university's regulations, students can deliver the practical homework in two dates (February 2013 and September 2013), so only the first date surveys are included in this paper.

TABLE I. QUESTIONS AND RATING

Question (scored 1-5)	Code	Average rating
Deployment options (A4)		
Consider the two deployment options for your labs; do you consider that cloud options have a lot of advantages over the standalone deployment?	Q17	*4.9*
Consider the cloud deployment option; do you think is easy?	Q18	*4.8*
Consider the standalone deployment option; do you think is easy?	Q19	*2.7*
In the standalone deployment process, have you had a lot of problems with the network parameters?	Q20	*3.2*

All students have to do both deployments: "standalone" deployment in order to debug the code associated to the laboratory's component. Once the laboratory is fully tested and debugged, they have to deploy their labs to the cloud in order to be evaluated with no need of sending to lecturers their solutions.

In table I, it can be seen as all the students prefer the cloud deployment, due to the easy procedure defined for the uploading of laboratories and their execution without the use of their own resources. Also, they complain about configuration process in the "standalone" deployment process, but in general they are satisfied with both deployment options.

VII. CONCLUSIONS

Components of a laboratory in RELATED are defined by XML fragments and its corresponding implementing files, so the "deployment process" must deal with these components in an easy way. In the "standalone" deployment process, a previous configuration step is needed in order to run the laboratory, complicating the testing of laboratories for students and lecturers. Also, the testing of a RELATED laboratory implies the use of own hosted hardware/software/network services.

To solve these problems, and to get an automatic configured laboratory and computing resources related, it is introduced the concept of "computing node". This computing node represents an application running in the cloud, using the PaaS layer of the cloud service model. Using this concept, it is possible to use public PaaS providers like Cloud Bees to have computing nodes running RELATED laboratories in a simple way.

The use of options like the automatic configuration and cloud deployment, allows students to run their own laboratories using external computing resources. Also, lecturers avoid testing their student's laboratories in their own personal computers, getting a better experience in the evaluation of the tasks associated to the laboratories' development.

ACKNOWLEDGMENT

The Authors would like to acknowledge the support of the following European Union projects: RIPLECS (517836-LLP-1-2011-1-ES-ERASMUS-ESMO), PAC (517742-LLP-1-2011- 1-BG-ERASMUS-ECUE), EMTM (2011-1-PL1-LEO05- 19883), MUREE (530332-TEMPUS-1-2012-1-JO-TEMPUSJPCR), and Go-Lab (FP7-ICT-2011-8/317601). Furthermore, we thank Spanish Ministry of Science and Innovation for the Project TIN2008-06083-C03/TSI and the Region of Madrid for the support of E-Madrid Network of Excellence (S2009/TIC-1650).

Real-time FM Radio for Teaching DSP and Communication Systems

Joseph P. Hoffbeck

Portland, Oregon, USA
hoffbeck@up.edu

***Abstract*—In digital signal processing (DSP) and communication systems courses much of the material is theoretical. There are some students who are more motivated to learn if they can see a connection to the real world, but unfortunately many real-world communication and DSP systems are very complex, and including them as part of a course is difficult or impossible. The FM radio, however, is a relatively simple system that is in some ways ideal as a real-world example because it includes both analog and digital signals. The analog signals transmit the audio and the digital Radio Data System (RDS) signal transmits auxiliary information such as the name of the artist, song, current time, etc. This paper describes an FM radio with RDS decoder based on an inexpensive FM module and an affordable DSP board. The system runs in real-time, demodulates FM radio, plays the music through speakers, displays the name of the song and artist, and allows access to the internal signals. This real-time receiver can be used in demonstrations in a lecture course or as the basis for a series of laboratory experiments.**

Keywords—Digital Signal Processing, Communication Systems, Real-time, FM Radio, Radio Data System, Receiver

I. Introduction

One of the toughest challenges in teaching is finding effective ways to motivate students to learn the material. Some students are more motivated to learn the material if they can see how the material is used in the real world. One way to provide students this connection to the real world is through in-class demonstrations. Various commercial communication systems provide excellent examples of how digital signal processing techniques are used in practice, but unfortunately it is difficult to use these systems in classroom demonstrations because they are complex and do not allow access to the internal signals. Another way that real systems can be incorporated into a course is to have students build a working system in the laboratory. This provides context for the theoretical material, however many communication systems are just too complex to be built as part of a course.

There have been several approaches to teaching communication systems that attempt to bridge the gap between real systems and the theoretical material. A popular approach is to use simulations to demonstrate various concepts [1,2,3,4]. Simulations have the advantage that they can be very effective and are inexpensive regardless of the number of students, but some students do not find them compelling since they do not interact with real systems. Another approach is to capture the RF signals from real communication systems and demodulate them offline [5,6,7]. This approach has the benefit of having a direct tie to real systems and allowing the use of a high level computer language such as MATLAB. The disadvantage of this approach is that the programs do not run in real-time. Others have used hardware that was specifically designed to demonstrate communication system operations [8,9]. These systems come closer to real-world hardware but can be expensive and some cannot process signals from real RF systems since they do not operate at RF frequencies. Some others have used DSP's to demonstrate and teach communication systems [10,11], which has the advantage of using a more real-world hardware platform. The disadvantage of this approach is that DSP boards are not usually designed to process RF signals. And finally some courses use software defined radio to implement real systems in software that can operate on RF signals, but the hardware is complex and expensive [12,13,14,15]. The method described in this paper is to use an FM module and a DSP platform to implement an FM radio with an RDS decoder. Some advantages of this approach include: the hardware is inexpensive (less than $100), the system operates in real-time, most of the processing is performed in software, and the system allows access to the internal signals. Through lecture demonstrations or laboratory experiments, this platform can be used to help motivate students in a communication systems or DSP course by providing real-world context for the course material.

II. BACKGROUND

FM radio is in many ways an ideal system to provide the context and real-world connection for many concepts in communication systems and DSP. FM radio employs both analog and digital signals, is available in most populated areas, is a familiar system for students, is simple enough for use in an undergraduate course, and does something useful and interesting when it is completed.

FM radio stations transmit several signals in the stereo multiplex signal including analog mono (L+R), pilot carrier, analog stereo (L-R), and the digital RDS signal (see Fig. 1).

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

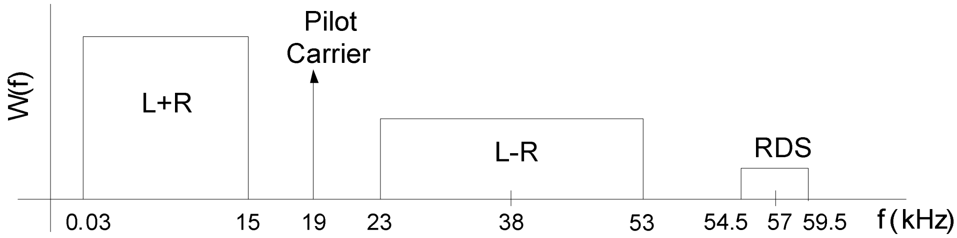

Fig. 1. Spectrum of the FM Stereo Multiplex Signal

The RDS signal, which in the United States is also called Radio Broadcast Data System (RBDS), is a digital signal that encodes auxiliary information such as the name of the artist and song, current time, etc. It has a fairly low bit rate of 1187.5 bits/sec and uses bi-phase (or Manchester) encoding and a raised cosine pulse shape [16,17].

III. HARDWARE

The hardware used to implement the FM radio with RDS decoder was selected to be a low cost and flexible solution that provides access to internal signals for instructional and debugging purposes. The hardware consists of a simple antenna, a very low cost FM module, DSP board, and a computer (see Fig. 2).

The FM module demodulates the RF signal from the antenna to produce the stereo multiplex signal called MPXO in Fig. 2. The module used in this project is based on the TEA5767HN module since it is very inexpensive (about $2) and is one of the few such modules that produces the full multiplex signal instead of just the left and right audio signals [18]. This module appears to be an obsolete part, but it is still readily available. Power for the module is supplied by the DSP board.

The DSP board converts the stereo multiplex signal to a digital signal. Since the highest frequency in the stereo multiplex signal is about 60 kHz, the DSP board must support a sampling rate of at least 120 kHz. The DSP board used in this project is the inexpensive TMS320C5515 eZdsp USB Stick from Spectrum Digital which supports sampling rates up to 192 kHz [19]. It contains a low cost fixed-point DSP (TMS320C5515) and comes with a copy of the compiler Code Composer Studio from Texas Instruments. A tutorial for this board is available from Texas Instruments [20]. The DSP board is connected to the FM module through an I2C port, which is used to initialize the FM module and tune to the desired radio station.

A computer is used to program the DSP board and to plot signals for debugging and instructional purposes.

IV. SOFTWARE

Most of the processing is performed in software which allows the students to learn about the algorithms by building them themselves and allows access to the internal signals so that they can see the signals from a real system. The software initializes the FM module through an I2C port using the TMS320C55x Chip Support Libraries [21]. It also uses an example program from Texas Instruments to transfer data to and from the codec using a double buffering scheme with direct memory access (DMA) [22]. The example program was modified to increase the sampling rate from 48 kHz to the maximum possible sampling rate of 192 kHz. When one of the buffers is full, an interrupt is generated which sets a flag. A program monitors the flag, and when it is set, calls a function to process the data in the buffer.

The FM mono receiver takes the stereo multiplex signal and passes it through a lowpass de-emphasis filter to undo the emphasis that is performed at the transmitter, and then the output is written to one of the output buffers and sent to the codec so that the students can listen to the mono signal through speakers or headphones (see Fig. 3).

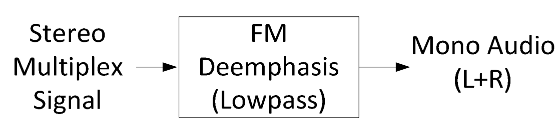

Fig. 3. Mono Receiver Block Diagram

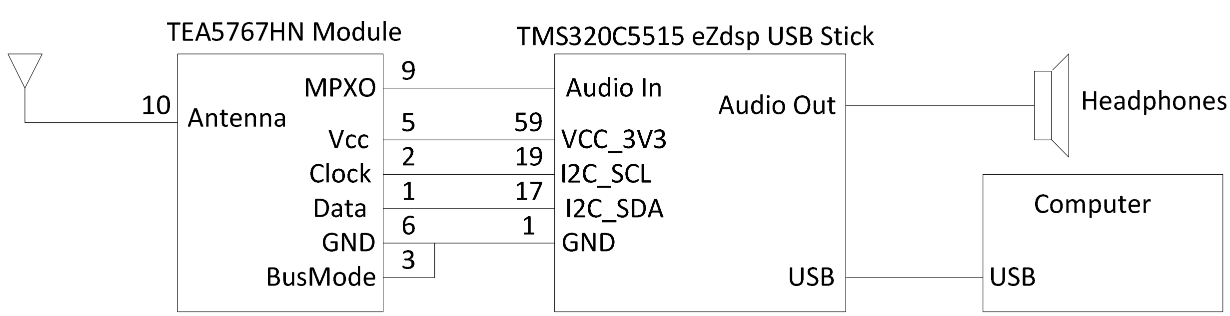

Fig. 2. Hardware Diagram

The RDS demodulator is more complex (and interesting) than the mono receiver for the analog signal. As shown in Fig. 4, the RDS demodulator includes a Costas Loop to estimate the carrier signal frequency and phase and to shift the RDS signal back to baseband [23]. The pilot carrier signal could be used in place of the Costas Loop to demodulate the RDS signal, but the authors chose not to use this method since most wireless systems do not send a carrier signal and some radio stations do not transmit a stereo signal, in which case the pilot carrier will not be present. The Costas Loop is followed by a matched filter that reduces noise, completes the pulse shaping, and decimates the signal to lower the sampling rate. The DSPLIB library [24] was used to implement the sine function and the filters required in the Costas Loop and the matched filter.

The matched filter is followed by the timing recovery algorithm [4] that estimates the best time to sample the signal. This algorithm is similar to the one that maximizes the average power of the samples but has been modified for use with the RDS pulse shape. The samples are quantized by the slicer which outputs 1 if the input is positive and 0 if the input is negative.

The output of the slicer is processed by a differential decoder to remove the differential encoding that is performed at the transmitter. This process allows the receiver to recover the correct bits even if the signal is inverted, which would otherwise complement the bits (change the 0's to 1's and vice versa).

The bits from the differential decoder are buffered up until a full 26-bit block is received and then the CRC checksum is computed. If the checksum shows that one or more bit errors occurred, the program advances one bit and checks again in order to discover the correct word alignment. If the checksum shows no bit errors, the decoder checks to see if the block is part of a radioText group that carries the text that shows the name of the song, artist, and program. If so, the characters are extracted and, after the entire radioText message has been received, it is displayed on the screen on the DSP board.

The program can also route internal signals to the codec so that they can be viewed on an oscilloscope, spectrum analyzer, or sent to speakers for listening.

Possible future enhancements for the project include designing a printed circuit board for the FM module, fixing a software issue that causes a short beep in the audio each time the processor updates the display because updating the display takes too long, adding the ability for the user to control the radio using the pushbuttons on the DSP board, adding support for displaying other RDS data such as the station, current time, traffic information, etc., and adding a stereo receiver for the audio signals.

V. USE IN THE CLASSROOM

This project has two main uses in a communication systems or DSP course. The project can be used as a demonstration tool to show students how a typical receiver works by allowing them to see the internal signals, or it can be the basis of laboratory experiments.

The advantage of this project over a commercial receiver as a demonstration tool is that it allows access to the internal signals, which would be very difficult to access in a commercial radio. Students may find course material more interesting if they are able to watch the signals on an oscilloscope and spectrum analyzer while listening to the audio signal. It is also very easy to demonstrate the noise, distortion, and interference that occur in real communication systems. This project can also be used in a series of laboratory experiments. The software is simple enough that it could be written by students and would culminate in a working analog and digital receiver.

The project could also be used to motivate the study of any single part of the receiver such as the filters, Costas Loop, timing recovery algorithm, or the CRC check. Students could write the software to implement any of these algorithms and then test their code by inserting it into the rest of the software to see if it works in the whole system. Thus the system could provide a more compelling way to test any of these parts than just a simulation.

In the fall of 2014, one of the authors plans to teach a new course on real-time digital signal processing where the students will develop and test most of the FM radio with RDS decoder in a series of projects. Since the hardware is inexpensive, it should be possible to supply each student with an FM module and DSP board so that they can work on the project outside of the laboratory.

VI. ASSESSMENT

Currently, the FM radio with RDS decoder is used as a demonstration in an undergraduate course on communication systems. In this course, the students use a real-time spectrum analyzer to record the RF signal from a radio station and write software (in MATLAB) to demodulate both the analog mono audio signal and the digital RDS signal off-line. The demonstration is used to show the internal signals of a receiver running in real-time and to hopefully increase interest in the material. The demonstration was first used in the spring 2013 semester. A survey was given the day before the demonstration and after the demonstration to try to assess the effectiveness of the demonstration. The following questions were on the survey:

1. How would you rate your current knowledge about communication systems?
2. How would you rate your current level of motivation to learn more about communication systems?
3. How interesting do you currently find communication

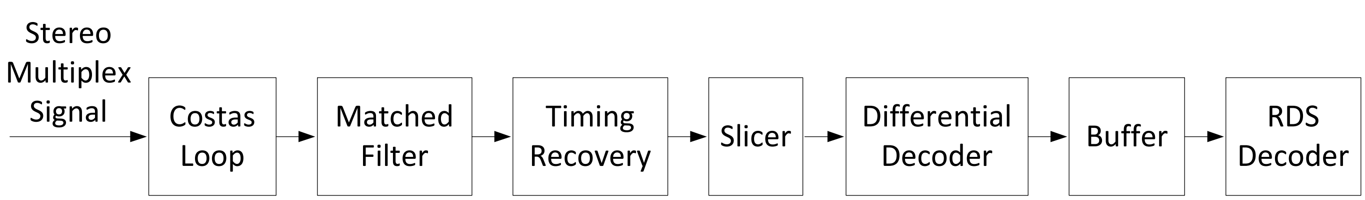

Fig. 4. RDS demodulator block diagram

systems?

4. List the major parts of a receiver in a digital communication system.

The first three questions were self-scored on a scale of 1 to 5, with a score of 5 indicating very knowledgeable, motivated, or interested, and a score of 1 being not at all knowledgeable, motivated, or interested. The answer to Question 4 was graded by the instructor on a scale of 0 to 5, with 0 indicating no answer or no correct answer, and 5 being a complete list of the major parts of a digital receiver (demodulator, matched filter, timing recovery, quantizer, and decoder). The results of the survey are summarized in Table 1.

TABLE I. TABLE 1. SURVEY RESULTS

Before Demo (N=10 students)	Mean	STD
1. Knowledge	3.30	0.48
2. Motivation	3.20	0.92
3. Interest	3.90	1.20
4. Major Parts	2.90	1.73

After Demo (N=12 students)	Mean	STD
1. Knowledge	3.50	0.67
2. Motivation	3.67	0.78
3. Interest	4.00	0.95
4. Major Parts	3.58	2.07

Table 1 shows that the average score on all of the questions increased after the demonstration, which is encouraging. With the small sample size, however, none of the differences was large enough to be considered statistically significant at the 5% significance level using the two-tailed t-test for differences in population means assuming identical but unknown variances.

VII. CONCLUSION

This paper described a real-time FM radio with RDS decoder that can be used in teaching communication systems and DSP courses to give the students exposure to a real system and to increase students' interest and motivation. It uses a hardware platform that is much less expensive than most DSP boards, software defined radio systems, or specially design hardware. Furthermore the proposed radio is a real-time system that operates on real RF signals. The software is available for free from the authors for educational use.

***Abstract*—This paper highlights the successes of contestants enrolled in an Introduction to Engineering class that took on the task of designing and building a robot to solve a problem with little or no background in electronics or programming. The semester long project started with developing a problem statement and from there timeline followed the Digilent Design Contest. Students had deadlines and formats for design documentation required by Digilent for the contest. While some students were attracted to the challenge of creating and implementing a design of their very own, other students are excited to compare their design against projects from students at other institutions. These competitions are designed to feed the excitement of the students and also fuel creativity.**

Keywords—Robotics; Introduction to Engineering; Student Contests; Assessment

I. INTRODUCTION

Digital systems are ubiquitous. College students carry a computer, smart-phone, tablet and/or music player everywhere they go. Growing up with so much technology means they are not easily impressed with flashing lights or even fairly complex graphics. It takes something a little more physical to motivate interest in digital systems. In a first year course this might mean connecting the digital system to an autonomous robot.

Early engagement of students in hands-on activities in the lab is a widely known technique to get and keep students interested in engineering [1] [2]. For electrical engineering and mechanical engineering students these activities are often within the field of robotics. Kits are available for a wide range of ability levels and range such as kits that can be used in elementary or middle school from LEGO® MINDSTORMS® to large manufacturing robots used in industry. Finding a kit or individual parts to provide an appropriate challenge for students in engineering can be difficult if budgets are tight. Often, materials that are suitable for juniors or seniors are too complex for first year students. However, the advent of single board microcontroller systems such as the Arduino [3], have made interfacing and programming robotics systems very accessible to first year students. Some introduction to the fundamental concepts such as analog-to-digital conversion, timing issues, and electrical power is needed. However, in-depth knowledge of the implementation of each individual component is not necessary to apply the technology to a small project.

Electrical engineering and mechanical engineering projects require access to laboratories and tools to build and test mechanical and electrical systems. It is these hands-on activities that are critical to student learning [1]. Keeping labs and shops open for student use can be expensive. Costly and sometimes dangerous equipment needs to be monitored and students need training in handling the equipment. A lower cost, safer alternative is needed. An engineering design contest sponsored by Digilent Inc. and Xilinx Inc. allows students to get the electronics hardware they need without cost to the students or their institution. Students must provide a well thought out design proposal upon entering the contest. Digilent then provides the FPGA or microcontroller-based hardware and interface circuits for controlling motors and sensing physical quantities such as light and distance.

Contests are a popular method to engage students in learning [3] [4]. But, most contests are designed for upper classmen who have extensive background in either electrical or mechanical engineering. We describe a contest where first year engineering students were able to dive in and create something with little or no knowledge of microcontrollers.

II. THE DESIGN CONTEST

The Digilent Design Contest has been held at Technical University of Cluj-Napoca, Romania since 2005 [4],with the first US contest at Rose-Hulman Institute of Technology, Terre Haute, Indiana in 2007 [5]. Initially, the contests were only open to students from the host institutions. In 2011 and 2012 the contest expanded to four separate regional or "continental" contests. A "World Finals" event was held each year to bring the top projects from all areas together to share their projects and compete. While most of the students are juniors and seniors with multiple courses in digital systems design there are now opportunities for students with little or no experience. The Digilent Design Contest has proven to be a strong motivator for first year and upper class students as evidenced by the number of students who enter the contest from a small college in the Midwest.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

At the 2012 Digilent Design Contest held in Indianapolis, the backgrounds of the students ranged widely as did the variety of institutions represented. Backgrounds ranged from first year engineering students through graduate students working toward a Ph.D. in majors such as computer engineering, nuclear science and engineering and computer sciences. Institutions represented ranged from a small liberal arts college to average-sized technical schools to medium-sized research universities

This paper highlights the successes of students in an Introduction to Engineering class that took on the task of designing and building a robot to solve a problem. The semester long project started with developing a problem statement and from there followed the timeline of the Digilent Design Contest. Students had deadlines forced upon them from Digilent and formats for design documentation that were required for the contest. Informal reflections with students indicated that many students were attracted to creating and implementing a design of their very own. Other students were more excited to compare their design to projects from students at other institutions, that competition was inspiring for them. In such a contest, participation is not just about competing; it is also about seeing what others have been able to do and learning from the successes and failures of others. These competitions feed the excitement of the students and also fuel their creativity.

III. First Year Engineering Course

Most engineering programs require a one or two semester introduction to engineering course(s) during the first year of study. The courses are designed to orient the student to engineering problem solving, engineering communication methods (including CAD), and the engineering design process. At schools where there are multiple engineering programs the first year courses often provide a glimpse of the different types of engineering to help students decide upon an initial career path.

Loras College offers a single general engineering program that emphasizes electromechanical systems. The first semester of the two course introductory sequence concentrates on the use of CAD to model parts and communicate designs. Students work as individuals or in teams on one or two small design projects, such as a business card holder and a fan powered car with a light sensor. CAD drawings are part of the project and a heavy component of the first semester. In the second semester the course includes a larger design project of an electromechanical system. The instructor has enough freedom to shift emphasis to/from electrical systems and mechanical systems given his or her interests. The instructor assigned for the spring semesters of 2012 and 2013 has a background in electrical and computer engineering and so the course was centered on a microcontroller based robot design and implementation.

A. Course Outcomes

Defining a set of measureable outcomes is a critical first step in designing a course. The following outcomes were set based on the needs in the curriculum and the lab projects designed for the course. Students will demonstrate the ability to:

1. Employ the engineering design process to design and create a prototype.
2. Organize a project with a timeline and appropriate documentation.
3. Present a design with proper written and graphical documentation.
4. Present a design with an oral presentation.
5. Write a simple computer program.
6. Reflect upon a project to practice skills of critical thinking, decision making, self-learning, and teamwork.

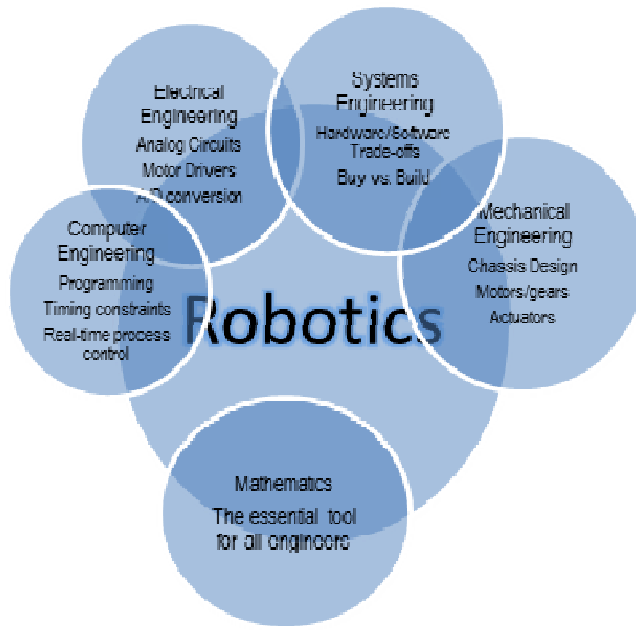

Fig. 1: The many disciplines within Robotics.

B. The Case for Robotics

A robotics project can meet the needs of introducing students to electromechanical systems as well as providing practice with the engineering design process on a project that lasts most of the semester. The project is complex enough to require some redesign and rework when the original design does not meet the design specifications. Thus students can demonstrate the iterative nature of the design process. Even if the project comes off without a hitch (highly unlikely), students are able to reflect at the end of the semester see how to improve their design.

The field of robotics spans several disciplines as shown in Fig. 1. Students are not expected to master all of the subjects within one course or even with one entire program. The goal for the instructor is to present enough knowledge for student success without overwhelming the students. For example students need not know how to design an H-bridge circuit in order to use on as a motor driver circuit. However, presenting the H-bridge as a “black box” can make the students overconfident and lead to motivational issues later on. The Digilent Pmod™ devices that are designed to be plugged into the microcontroller board provide a way to get students started on robotics projects without having extensive knowledge of analog circuit design.

In the course described here, the students are limited to chipKIT™ Uno32™ with the I/O interfacing provided by the Digilent Pmod™ devices. A sample set of hardware is shown in Fig. 2.

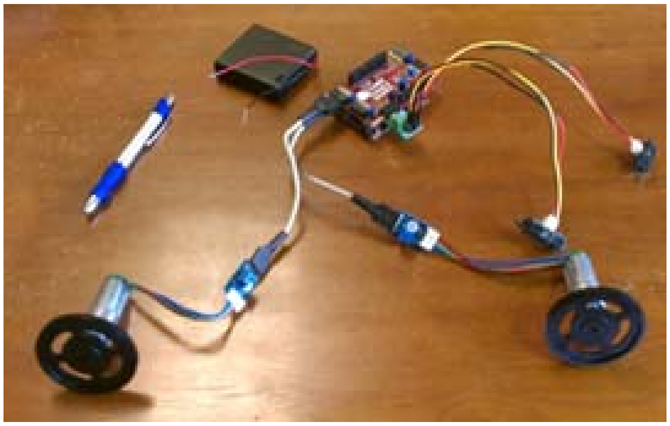

Fig. 2: ChipKIT, H-bridges, gear motors and IR Range sensors

C. Integrating Lab Work, Assignments, and the Contest

Given the course outcomes a sequence of lab projects was designed to lead the students through the material enough to complete their robots in time. The sequence of labs is shown in Table 1.

TABLE 1: ORDER OF LABS AND GENERAL SECHEDULE FOR THE SEMESTER.

Lab	Title	Topics/Activity
Lab 1	Introduction to the Design Process [8]	Build-a-boat contest using modeling clay
Lab 2	Electrical circuit analysis and construction	Ohm's Law, Resistor networks, V-I characteristics of a diode
Lab 3	Circuit Design (H-Bridge with discrete components)	Transistors as switches, Logic Design, h-bridge construction
Lab 4	Analog and digital input/output with the chipKIT™	Analog and Digital I/O
Lab 5A	Programming Fundamentals	Loops and selection structures (if-else-if)
Lab 5B	Project Planning	Project Management, Gantt charts
Project Work time		
Lab 6	Project Update	
Project Work time		
Other topics	Ethics, spreadsheets, etc.	
Final Presentation		

D. Example Projects

In 2012, the majority of projects were Sumobots. Other students looked for something different from the rest and chose projects such as a Lego™ collection device, a line following robot that could be used in factory automation and a maze traversal robot. Fig. 3 shows the maze traversal robot early in the build and test phase of the project.

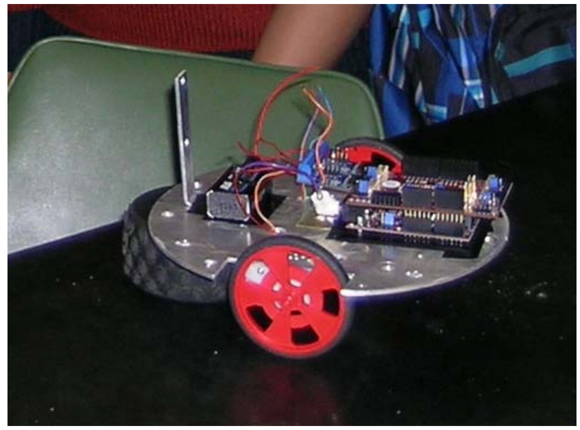

Fig. 3: Maze traversal robot.

IV. ASSESSMENT DATA

Assessment of course outcomes is done via embedded assessment. Performance on outcomes is measured against a predetermined expected score on a specific assignment, lab, or exam problem, or a combination of two or more items. After the course is complete the instructor writes a Course Assessment Report (CAR). The data and analysis from the CAR is used to improve individual courses as well as for continuous improvement of the program. As a side note, the Course Outcomes from each course are mapped to the ABET a through k Student Outcomes from criterion 3. Results from the CAR are shown below for each Student Outcome.

TABLE 2: ASSESSMENT MATRIX SHOWING MATERIALLS USED TO ASSESS COURSE OUTCOMES.

ASSIGNMENT	COURSE OUTCOMES					
	1	2	3	4	5	6
Specific Lab Projects	x				x	
Course Project	x	x	x			
Project Oral Presentation				x		
Final Exam and quizzes	x					x
Reflection Paper						x

A. Course Outcome assessment data.

The following is taken from the Course Assessment report. These data are taken to determine if the course outcomes are being met and where changes may be needed to improve student learning.

*1) **Outcome 1**: Employ the engineering design process to design and create a prototype.*

Lab 1 required the students to design and build a boat made of modeling clay to float as many pennies as possible. The average score on lab 1 was 89.7%. This is probably due to the simplicity of the design project. All thirteen students achieved better than 70% on this assessment. The course project also provides a measure of this design outcome. The project requires some knowledge electrical and mechanical systems as well as programming and microprocessor interfacing. The scores on the final design documentation for the course project averaged 78.8% with 11 of the 13 students receiving a grade of 70% or higher. One problem on the final exam also measured the students' knowledge of the design process. The average on that exam problem was 88.1%. 12 of 13 students scored above 70%. Outcome 1 was met.

*2) **Outcome 2**: Organize a project with a timeline and appropriate documentation.*

Lab 5B required the students to develop a project timeline and plan out the rest of the semester. No measurement was taken to determine if their plan failed or was even followed. Students were graded on the detail level of the plan. The average on lab 5B was 71.2%. Two students did not turn in the assignment, but the remainder of the students scored above 70%. Overall outcome 2 was met.

*3) **Outcome 3**: Present a design with proper written and graphical documentation.*

All students were required to present to the class their final product. Grading was done with the Oral Presentation Rubric also used in the Senior Capstone. The average score on the presentation was 77.3%. One student missed class on the day of the presentations. The remainder of the students scored above 70%. Overall outcome 3 was met.

*4) **Outcome 4**: Present a design with an oral presentation.*

All students were required to present to the class their final product. Grading was done with the Oral Presentation Rubric also used in the Senior Capstone. The average score on the presentation was 77.3%. One student missed class on the day of the presentations. The remainder of the students scored above 70%. Overall outcome 4 was met.

*5) **Outcome 5**: Write a simple computer program.*

Labs 4, 5A, and 6 all required a significant component of programming and are thus used to measure Outcome 5. The average score on these labs was 84%. 11 of the 13 the students scored 70% or above. Overall outcome 5 was met. The two students who scored below 70% did not complete some of the lab assignments.

*6) **Outcome 6**: Reflect upon a project and practice skills of critical thinking, decision making, self-learning, and teamwork.*

One homework assignment required the students to analyze one of two ethical scenarios. The average on this homework assignment was 72%. 9 of 13 students scored above 70%. Three students failed to turn in the assignment. The outcome was also measured with multiple choice questions on the final exam. 6 of 13 students attained a level of 70% on this portion of the exam. This outcome was not met due to the lack of participation of some students and poor performance on the final exam.

B. Student Survey Data

Students were surveyed at the end of the semester to determine their view of the course material and the project itself. Student survey data must be reviewed with some skepticism as with all survey data. Students are just as prone to bias any human and perhaps more so. Survey data often shows how students felt about the course in general and is not a direct measure of their learning. In particular, the last survey question might be considered inappropriate since first year students do not yet know what is required for engineering practice. This is a measure of customer satisfaction. The data show that students felt they were learning some of the skills and techniques they will need as engineers. Perceived relevance can be a strong motivator for students.

TABLE 3: STUDENT SURVEY DATA, SA=STRONGLY AGREE, A=AGREE, N=NUETRAL, D=DISAGREE, SD=STRONGLY DISAGREE

	SA	A	N	D	SD
*This course is a good introduction to the field of Engineering.	10	2			
*The robot design project was a valuable tool for learning engineering design.	10	2			
*I am better able to design a system to meet desired needs after taking this course.	8	4			
*I am better able to function on a team as a result of taking this course.	3	6	3		
*I am better able to communicate effectively as a result of taking this course.	7	2	2	1	
*I have learned important techniques and skills necessary for engineering practice.	8	4			

The data in Table 3 shows that most students feel their intro to engineering course gave them a good feel for what engineering and engineering design are all about. The one exception might be in how students felt about their ability to communicate. Even in this area, the majority students feel their ability to communicate has increased as a result of taking the course. This survey coupled with data from scores on labs, the project, and the final exam show that students did learn the engineering design process. Of course, the depth of that knowledge is only appropriate for first year students and not graduates of an engineering program.

V. JUDGING

Judges were instructed to evaluate the projects primarily on five criteria: technical complexity, conceptual innovation, a written report, a formal presentation and product marketability. Each area is equally important in the evaluation. The detailed evaluation criteria are shown below.

I. Technical/Software/Hardware
   a. Is the project complex?
   b. Was the hardware used to its capacity?
   c. Was the software original and fully functional?
II. Concept
   a. Is the core, underlying idea understandable, believable, innovative, creative, feasible, path-breaking, etc.?
   b. Was there feedback from the community? Did the feedback influence the project?
III. Written Report
   a. Is the written report thorough, clear, compelling, logical, elegant, and professional? (see Sample Written Report outline attached)
IV. Presentation
   a. Are presenters professional, confident, comfortable and enthusiastic?
   b. Is the presentation thorough, well structured, clear, compelling, logical, informative, and professionally delivered?
V. Market
   a. Does the project solve a problem? Could the idea be commercialized? Did the presenter make a good sales pitch?
   b. Was the video compelling?
   c. Was there any feedback from community members on the feasibility of the idea?

VI. CONCLUSIONS:

Survey data shows that students' are of the opinion that they have learned the basics of engineering design and something of the tools used in engineering. Data from embedded assessments within the course agree with the survey data. Although the initial experiment with the design contest has been a success further experimentation is needed. The course and contest were repeated in the spring of 2013. Improvements in assessments can be made by further student surveys to get information about the specific course outcomes.

For the 2012-2013 academic year the contest began in Fall semester before registration for the spring semester was complete. This made it difficult to get first year students engaged when they were not yet signed up for classes for the spring semester. The design contests are also held in Europe and China in in 2013. These contests have appealed well to upper-class students and graduate students who are capable of developing sophisticated FPGA-based designs. With the introduction of the chipKIT, an Arduino compatible system, it is now possible for the Digilent Design Contest to appeal to first year students in Engineering and Computer Science.

Motivating and Preparing First-Year Students in Computer and Engineering Science

Håkan Jonsson
Department of Computer Science, Electrical and Space Engineering
Luleå University of Technology
Luleå, Sweden

***Abstract*—During recent years the interest in Engineering Studies has declined at universities both in the United States and in many Western European countries including Sweden. In addition, among those students that do enroll, an increasing number drop-out. This paper presents an attempt to mitigate these worrying problems in the form of a new kind of introductory course for first-year engineering students studying on a 5-year long Master of Science program in Computer Science and Engineering. The course is novel in that it takes a holistic approach to motivate and prepare students for their further studies. Core subjects and useful tools are mixed together into an intense 10-week course with 12 separate course modules on different topics, often running in parallel. The course has a total of 21 individual examinations to take, tasks to carry out, and deadlines to meet. The examinations and tasks are chosen among those common in our School of Engineering. Evaluations show that, although demanding for the students, the course works well and fulfills its goals.**

***Index Terms*—Engineering education, Computer science education, motivation, preparation, first-year student, freshman education, retention.**

I. Introduction

During recent years the interest in Engineering Studies has declined at universities both in the United States and in many Western European countries including Sweden [3], [15], [20], [24], [34]. In addition, among those students that do enroll, an increasing number fail their first theory courses in Mathematics and Physics and even drop out of their educational programs at an early stage. At our university, we have had a similar situation. Since the 90:s, and in particular after the IT-boom around the Millennium, the number of applicants to our 5-year long Master of Science[1] in Computer Science and Engineering (CSE) program had decreased quite substantially. First-year students had (increasingly) trouble coping with the first math courses and, in general, weak motivation, which is why many performed poorly and dropped out.

One natural approach is to address these problems as early as possible on a national, or even international, level and long before potential engineering students get to the point that they could actually apply to university [15], [19]. Examples involve information campaigns and the reformation of public schools. Also, universities carry out various activities to attract and keep engineering students [11], [12], [22]. Still, despite these efforts, many students do not go through with their studies. Becker [3] puts focus on an important reason for this, namely that university degree programs are poorly adopted. While engineering is fascinating and exciting to learn, many educational programs in engineering start with a lot of theory and hardly no practical content, which puts-off potential students who then instead go on to other advanced educations. From an industrial point of view, it would also be desirable to loosen up the traditionally very theoretical education in favor of a more holistic engineering education [28]. There is today indeed a trend among universities to develop courses in this direction [7], [17], [18], [33].

A. Contribution

To address these worrying problems, we have developed a new kind of introductory course designed for first-year engineering students in our 5-year long Master of Science program in CSE. Like many other introductory courses that seek to motivate by addressing core Computer Science topics without going into depth – Brookshear [6] give an example on what can typically by covered – this new course takes a holistic approach providing students with an overview and understanding of the vast area of CSE, its role and importance in the modern Information Society, its relation to Engineering Science as well as how it relates to and is used in business and academia. Integral parts focus in on technical problem solving and engineering while others teach students skills and tools that support them during the remainder of their studies. The course is independent of, but runs in parallel with, a first course on computer programming, and the two complement each other quite well.

The novelty, however, of this new course lies in how the topics covered are varied and combined during the course, and in how the course is setup and given by the instructor. In 10 weeks the students complete 12 separate course modules, all on different topics and activating the students in different ways. In total the students pass 21 examinations of different kinds chosen among those common in our School of Engineering.

To give some examples of activities, students interview research groups at the department and give presentations in conference-like settings. They learn about the professional engineer hands-on during study visits to companies. They program embedded systems using Arduino boards [2], create

[1] Students in Sweden enroll in these engineering programs for 5 years and go directly for a MSc degree without getting a BSc on the way. However, it is also possible to stop after 3 years with a BSc degree.

Q1	Q2	Q3	Q4
D0009E Introduction to Programming	M0009M Discrete Mathematics	D0010E Object-oriented Programming and Design	D0011E Digital Design
D0015E Computer and Engineering Science	F0004T Physics 1	M0029M Calculus	M0030M Linear Algebra and Calculus

Fig. 1. Courses in year 1 and the order in which they are given. Q1, the first quarter of study, starts in September, while Q4 ends in June. (D0015E is the course we present in this paper.)

3D-worlds and animate them in Alice [8], learn to typeset documents with LaTeX [26] (which they use later on in the course to write reports) and use UNIX [29] commands to go beyond what can be done in window-based operating systems. They study the historic developments that lie behind the engineering discipline, as we know it today, and read about scientists' views on what the future might bring.

The result is very pleasing. In questionnaire-based evaluations many students testify to the effectiveness of this course, how it brings them up to speed, and makes them interested. Even elder students, who took the course some years ago, still remember it and point out how it motivated and prepared them. Moreover, students, also those that do not show any clear signs of such abilities at the beginning, become more diligent, timely, accurate with details, and good at planning as the course progresses – all signs of a successful student and a good engineer.

B. Outline

Below we will go into detail about the course, its contents, design, and realization. Then follows an attempt to explain how the course works, and that it indeed works as intended. But first a few words on the local context in which the new course resides.

II. Background

The decline in interest among potential applicants, the difficulty first-year students had with their courses in Mathematics, and the ever falling retention rates had not gone undetected. In particular, the long trend of ever worse results in Mathematics troubled not only the faculty at our department but also the Department of Mathematics and the faculty board. So, in 2008, a decision was taken to redo the curriculum. Essentially, two changes were made in an attempt to give the first-year students a better start.

The first was that the start of the standard block of three consecutive courses of Engineering Mathematics traditionally given at the beginning of the first year – in the form of the three courses Calculus, Linear Algebra, and Differential Equations – was pushed forward half-a-year from Quarter 1 to Quarter 3. Instead an early CSE start was created (Fig. 1). The first semester was remade into containing courses on programming, an introduction, Discrete Mathematics, and Physics. Since students increasingly had such trouble with the Engineering Mathematics the idea was also to have the physics course, in essence classical mechanics, act like a warm-up mathematics course before reaching the Engineering Mathematics. Discrete Mathematics is – of course – a mathematics course, but one of more interest and direct use for CSE students.

The second change was that among the courses in this new CSE-early sequence, a new introductory course – the main subject of this paper – was added to give students an overview of the field of Computer and Engineering Science, motivate them, and prepare them technically, theoretically, and practically for the years to come and ultimately their carriers afterwards. It is beyond the scope of this paper to go into detail about the changes in the curriculum, how courses were re-arranged, and the reasons thereof. This paper is mainly concerned with the new course.

III. Course description

The course, known as *D0015E Computer and Engineering Science* [9], earns the student 7.5 ECTS[2] credits once completed. The course is given in Quarter 1, a roughly 10 week long period that starts in September, and designed so that the intended student spends a total of 200 hours studying in class and at home[3] (Fig. 1).

The course is part of our MSc degree program in Computer Science and Engineering, which is officially accredited under public Swedish law [32] and highly inspired by the ACM/IEEE Curricula Recommendations [1]. In the Fall of 2012, 62 students enrolled, which is a typical class size in the School of Engineering at our university.

A. Entry requirements

Apart from general requirements regarding on what level an applicant must master Swedish, English, and Mathematics to at all enroll at a Swedish university, engineering students are required to have a substantially stronger background in Mathematics and Natural Sciences. In practice, the largest obstacle for students interested in applying is the Mathematics requirement.

Being a first-year course, D0015E naturally has the same requirements. One should, however, note that although many students do also have a background in programming and other engineering related subjects, no such background is formally required. The youngest, and typical, applicant is 18 years old, and have been schooled for 12 years prior to applying.

B. Course aim

The course aims to provide an understanding of the vast area of CSE and its role in the modern Information Society. This is done in several dimensions. For instance, its relation to Engineering Science and how it relates to and is used in

[2]The *European Credit Transfer and Accumulation System* [13] aims to harmonize higher educations in Europe.

[3]One week of full-time study amounts to 40 hours and grants the successful student 1.5 ECTS credit. Students normally take two courses in parallel, studying 20 hours per week in each course.

business and academia. Integral parts of the course also focus in on practical problem solving and small engineering tasks where solutions are built using a combination of computers, electronics, and software. To be precise, after the course, the successful student

- can define the area of CSE, in particular with relation to other engineering disciplines but also Engineering Science in general by demonstrating an ability to integrate knowledge critically and systematically;
- is able to solve small technical problems using computers, and do so based on proven experience rather than theory and formal analysis;
- can identify and handle computer components, programs, and common computer equipment, in order to change the performance and function of a computer;
- knows about the main history of the area of CSE and can discuss the consequence the area has on the development of modern technology, sustainability, integrity, the equality of opportunity between women and men, and internationalization (globalization) by demonstrating an ability to make assessments informed by relevant disciplinary, social and ethical aspects;
- can account for how engineers with a degree in the area of CSE work, what their typical work tasks are and what methods they use in research, development, and administration, and show insight into current research and development work;
- is familiar with and can make use of modern computer-based technology for both spoken and written communication and collaboration over computer networks, and demonstrate a capacity for teamwork and collaboration with various constellations;
- is able to independently find scientific information, and use such information correctly and objectively,
- can plan and use appropriate methods to complete his/her own studies as well as advanced tasks within predetermined parameters for a successful academic career within the broad area of CSE.

C. Contents

The course consists of a multifaceted study of CSE as a subject area of its own, its history, distinctive character, and artifacts. These are theoretical artifacts like (formal) languages, models, computational problems, instances, and solutions as well as physical artifacts like computer programs, digital media, and electronics. In broad terms, the area is contrasted with Engineering Science in general, that is areas directly concerned with matter and physical building materials rather than instructions and computational devices.

The modules introduce to the students a number of problems and questions. Some of these are investigative in nature while others involve problem solving with computers or pen and paper. Computers and various software are used throughout the course. All problems or questions more or less highlight various aspects of the area of CSE as well as Engineering Science in general, and are carried out in connection with ongoing research projects at the department.

The students are also introduced to some useful tools, both technical and non-technical, handy not only during their years at the university but also as graduated engineers. They are taught, for instance, how to work in teams, give presentations, and perform interviews. Moreover, they get useful advise on techniques that improve their own studies, how they can get information from various sources and report scientific work.

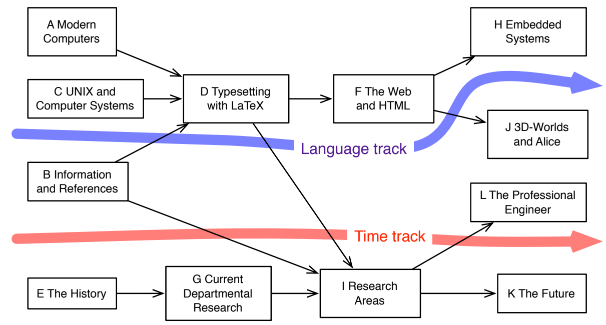

Fig. 2. Dependencies among the course modules and the two major tracks *(Formal) Languages* and *Time*.

D. Structure

The content of the course is divided into 12 separate *modules* labeled A-L. Each module is centered around a topic of its own, and is examined separately. These modules form two, although only loosey connected, parallel tracks (Fig. 2).

The first has as its theme *languages*, as in “formal languages for instructions”. It consists of the modules C, D, F, H, and J and introduce UNIX, LaTeX, HTML [23], Alice, and C [25] (which is used to program Arduino boards).

The second track is structured around *time* - the past, now, and the future. This track starts with a module on history (E), goes on to current research performed at the department (G) and vital areas of research (I), and ends with the future (K), as well as it can be predicted right now, and a glimpse of the life of the professional engineer (L) - the future of the majority of the students.

Below we list and describe each module. One should keep in mind, while reading the list, that the course is shallow in the sense that we do not go deep into theory and analysis in the modules. There is simply no room to squeeze in what would take several years of study into the course. On the other hand, this works fine and is sufficient because our goal is (merely) to motivate and prepare for future studies.

1) Module A – Modern Computers: In this module students learn about the major components that can be found in modern computers like the CPU, the mother board, cards (graphics and network), primary memory, external storage units (hard disks, DVD-readers, SSD devices, USB memory sticks etc), power units, common connectors, cords etc. In a theory part, they learn their function and are questioned orally. Then, in a practical part, they work in groups and disassemble a computer into its parts and open up components. (For this purpose, we keep a stash of old and broken hard disks and media readers through-out the year, and let the students break them before they are trashed.)

2) Module B - Information and References: This takes place in the university library and under the guidance of experienced librarians. Students are taught how to search for and retrieve trustworthy and peer-reviewed information – not just google for it as so many do – and use such information in a honest way in their own work. They are also informed about the rules concerning Academic Honesty. The module contains a test that is taken on-line in an LMS [16].

3) Module C – UNIX and Computer Systems: While all students are very tech-savvy, this module introduces something new to many: The operating system UNIX and low-level control of a computer via a command line interface. We cover commands for handling files, navigating file systems, and controlling processes but leave out more advanced topics like shell programming and system configuration. For most part of the course, although UNIX (or, in practice, Linux [30]) might run "under the hood", students use computers via one of the well-known window-based graphical user interfaces.

To pass, students first must write up experiences of their first week of study in a short document, convert it to pdf, and email it in from their university email account. Then they must complete a set of command tasks and document them with the UNIX command `script`.

4) Module D – Typesetting with LaTeX: Here students learn the basics about how to typeset documents with LaTeX. We go through the most common commands and environments ranging from overall document structure to details in mathematical formulas. The idea is to give the students the same academic typesetting tool as their professors, as well as to expose them to a formal (artificial) language with rigorous syntactic rules and semantics that resembles a programming language[4].

The examination has two parts. First, students are to produce a LaTeX-document identical to a master provided by their instructor. Then, their task is to complete and typeset a given (hand-written) solution to a high school mathematics problem.

5) Module E – The History: As the name suggests, this module covers – in a very broad sense – the history behind the IT revolution and modern engineering. Starting with prehistoric inventions like writing and alphabets we leap through the centuries while relating new technologies to human need and the development of society. At the end, we reach the age of electricity, mass production, computers, nuclear war, space explorations, the internet, gene technology, mobile phones, and much more. The module ends with a written test.

6) Module F – The Web and HTML: Here, the students are introduced to another formal language: Hyper-Text Markup Language (HTML). They are also taught the basics about the Web. Using a given set of tags, the task is here to produce a detailed webpage describing the organization and function of our university.

[4]TeX, and (of course) also LaTeX, is known to be Turing complete(!)

7) Module G – Current Departmental Research: In this module students interview research groups at the department about their research projects, and present their findings to the class in a conference-like setting. To do so they are taught how to prepare an interview, carry it out, documenting the result, and presenting it to the class.

8) Module H - Embedded Systems: Most computers are embedded and this module introduces the concept of embedded systems in the form of Arduino units that the students get to experiment with. This experimentation entails both hands-on wiring of electronic components on a board and programming different functionalities (using a simple subset of the programming language C). This is known as *physical programming*, as the system normally causes some noticeable effect. To pass, the students must complete a set of lab assignments.

9) Module I – Research Areas: In an attempt to give further insight into our research, and bring the students closer to the department, three professors give talks about their research areas. After each talk, the students write a short, but proper, report on a topic given by the professors. They must do so using LaTeX and on their own over a period of two weeks.

10) Module J - 3D-Worlds and Alice : Alice is a graphical programming system where programs are constructed to a large degree without typing. Alice is known for rapidly introducing someone to the ideas behind programming without having to go through the hassle of learning an old-fashioned programming language (which these students, of course, also eventually get to do).

Here students get the task to make up a 3D-world of their liking, and write instructions that describe what should happen in these worlds.

11) Module K – The Future: This is a group activity in which students investigate some given sources in the literature on likely future developments in the field of Computer and Engineering Science. Findings are reported back to the class in a presentation.

12) Module L – The Professional Engineer: Here, finally, the students go on study visits to companies and meet with professional engineers. Based on these visits, the students write up their observations in the form of a short report.

E. Realization

Although modules are separate as far as their contents is concerned, at any given instance of time, two, and often even three, of them are simultaneously going on (Fig. 3). This is intentional in order to have students plan their work on the various tasks and problems themselves in a diligent manner.

The course is taught via lectures using AV-equipment (not writing on blackboards), educational study visits and field trips, lab assignments, writing assignments, and project work. Students also take active part in presentation, feedback, performing interviews, and interacting in (and between) groups they have been assigned to.

The teaching is based on *Constructivism* (see, for instance, Biggs [4]), where the idea is that students construct their

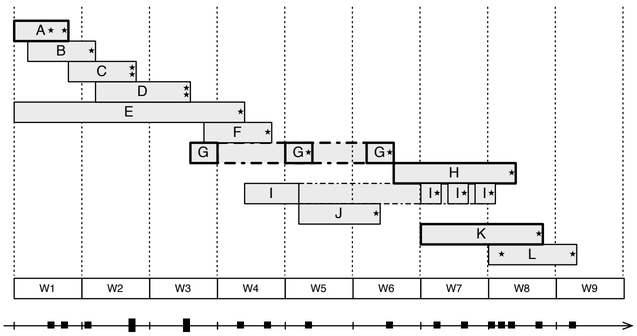

Fig. 3. A sketch of the timetable from W1 to W9, week 1 of study to week 9. Rectangles stand for modules, labeled A-L as listed in Section III-D. Stars indicate deadlines of examinations. Stars have also been projected down to black squares on the time-axis below the diagram in order to more clearly show the continuous nature of the examination that takes place during the course. Thick frames denote modules in which students work in groups.

Examination	A Modern Computers	B Information and References	C UNIX and Computer Systems	D Typesetting with LaTeX	E The History	F The Web and HTML	G Current Departmental Research	H Embedded Systems	I Research Areas	J 3D-Worlds and Alice	K The Future	L The Professional Engineer

TABLE I
KINDS OF EXAMINATIONS AND WAYS OF GRADING.

own understanding and knowledge of the world, through experiencing things and reflecting on those experiences, *Active Learning* [5] but with (passive) guidance first and (active) practice after that, and *Inductive Learning* [27]. The actual instruction is inspired by *Visible Learning* [21] in that the instructor, for instance, a) defines clear goals and criteria for achieving these goals, b) is clear about organization, explanations, examples, procedures, and assessments, and c) builds honest and trustful relations to the students by respecting their different backgrounds, listening to them, showing empathy and attention. The idea is that the student's confidence in the instructor creates a feeling of security, and that this leads to better results.

Each module starts with one lecture in which the instructor introduces the topic of the module. Then, students start working on the tasks, module E on the history being the exception in that it instead contains some additional lectures. In module H on Embedded Systems, for example, there are a number of lab assignments to carry out. For this purpose, students are divided up into groups of three people and lent a box containing an Arduino board together with some electronic components. It is then up to the groups to organize their work with the assignments either on their own at home or on certain scheduled lab sessions, when an instructor is also present (most do the latter). During lab sessions, students build small electronic circuits that they program, and have them checked. Guided by feedback from the instructor, they improve their circuits, in case they do not meet expectation, until they have gotten everything right. There is also an assignment in which it is up to the group to also come up with what to do (within reason) and then do that. Students build technical solutions in this manner also in modules C, D, F, and J. In contrast, G, I, K, and L are similar in that students are asked to gather information on their own and synthesize it. However, while students give presentations in G and K they write reports in I and L.

To aid the students in their work, and their planning, a publicly available course webpage [10] is maintained by the instructor. This page serves as a connection point and information central for the students. It contains slides, instructions, deadlines, extra material, and various links to useful resources. This web page, together with a book on history [31] and some unpublished material written by the instructor, makes up the course literature.

F. Examination

The examination is continuous throughout the course. Fig. 3 shows the distribution of the deadlines of examinations over time in a “Gantt chart”. In this chart, a rectangle corresponds to a module (identified by the letter). Rectangles are laid out horizontally in time-order going from left to right starting with modules A and E in Week 1 of study (W1), and ending with module L in Week 9 (W9). While module A starts and ends in the first week, module E goes on into Week 4. Each star denotes a deadline. The downward projections of stars onto small black boxes on the time-axis below the Gantt chart is provided to more clearly visualize the continuous nature of the examinations.

The methods of examination are deliberately chosen among those that are common within our School of Engineering such as written tests, reports, lab work and demonstrations, and conference-like oral presentations of findings to the class (Table I). The methods of examination varies throughout the course to prepare students for courses to come. In addition, participation on presentations, field trips, visits and other joint activities is mandatory.

G. Grading

Each module has one or more examinations each of which is graded. Although some problems require students to work together in groups, and be collectively examined as a

Year:	2008	2009	2011	2012	
Number of students filling out the questionnaire:	20	24	16	45	Average
"My overall impression is that this was a good course."	80,0%	82,0%	85,0%	75,0%	80,5%
"The workload is appropriate for the credits given."	78,0%	72,0%	81,7%	71,7%	75,8%
"The aims of the course are clear."	-	-	86,7%	71,7%	79,2%
"The examination was in accordance with the learning objectives."	-	-	81,7%	78,3%	80,0%
"I spent at most 20h/week (the intended amount) on the course."	-	-	93,6%	91,1%	92,4%

group (shaded in Table I), all grades are set individually. Some examinations only give as result passed or failed while some individual examinations earn the student that pass a numerical score ranging from 1 (lowest) to 3 (highest, best). Table I also summarizes the two forms of grading done. Here, "P/F" means "Pass or Fail", and "1–3" means the grading results in a score. The final grade on the course is calculated from the scores obtained on the individual examinations only. To pass the course, however, a student must pass all examinations, not only those that give numerical scores.

IV. EVALUATION

To evaluate the course we have looked at three dimensions: The course itself, effects on the educational program it belongs to, and other effects. Regarding the course itself we have used a) summaries of feedback given on questionnaire-based evaluations all students fill out directly after the course (Table II), b) protocols from meetings with the educational board at the department, and c) official statistics over the number of students that pass the course and when they do so (Table III).

The questionnaires contain many questions and we choose here to only include results on five general ones, listed in Table II, that relate to the overall function of the course. As they are based on answers not only from students that have passed, but also all that had failed or were not yet done at the time the questionnaire-based survey was conducted, the numbers are very high compared to many other courses. Despite the high workload experienced by almost 25% of the students, still 92.4% of them spend no more time studying than what is expected. These are signs of a course functioning well.

In the protocols of the board, in which also higher-year students take part, the course is, in somewhat loose but still distinctive terms, deemed intense and demanding but in general good. We choose not to include them here since they only state summarized testimonies of those that are members of the board. The protocols are available from the university webpage [14].

The official statistics in Table III has been extracted out of the university database containing student records. These numbers are also very high compared to other courses. Directly after the course (after Semester 1), 62.7% of the students have passed; after the first year of study (Semesters 1 and 2), in practice just a couple of extra months, 81.1% have passed. If we would disregard the first, rather turbulent, year the course was given (2008), the number of students immediately passing the course would increase to 72.5%. The reason $10\% - 15\%$ never pass could depend on drop-outs. Furthermore, from student feedback given on other questions in the questionnaires than those listed in Table II, it is clear that the average student studied a bit differently in 2011. In 2011, the average level of attendance was for instance 4% lower than in 2012, and the amount of preparation/reading ahead before class was 9% lower. This difference might (perhaps) explain the sudden drop in Table III down to 70.2% that year. However, the course was given in the same way 2011 as in other years, so the reason why students studied somewhat differently in 2011 remains unclear. Anyhow, the overall results show that the course works well and fulfills its goals of motivating and preparing students in line with the aims of the course. Moreover, introductory courses, modelled and designed after the course we have described, have today also been created and included in the program in *Applied Physics and Electrical Engineering* as well as the program in *Space Engineering*, two other engineering programs at our department.

V. CONCLUSION AND DISCUSSION

We have presented a kind of introductory course designed for first-year engineering students in our 5-year long Master of Science program in Computer Science and Engineering. Like many other introductory courses it takes a holistic approach providing students with an overview and understanding of the vast area of Computer Science and Engineering. As we have

[5]Data from 2010 is unfortunately missing. The reason data is missing in 2008 and 2009 is because in these years the questionnaires were shorter and did not contain the same questions as they do now.

described, the course is novel in how it is divided into 12 separate modules with a total of 21 examinations in roughly 10 weeks. Despite being tough and demanding, the course works well and manages to motivate and prepare students for further studies in line with the aims of the course.

The first batch of students in the re-made educational program (see Section II), to which the new introductory course belongs, are soon about to graduate. This makes it possible to determine what effect, if any, the course might have on the retention rate through-out the engineering program, for instance via a study of student records. Here, a challenge is how to isolate effects caused by the course from those caused by the re-arrangement of the order in which courses are taught and other changes in the curricula.

ACKNOWLEDGMENT

The authors would like to thank Jenny Niemi, Marie-Therese Tricot, and Jonny Johansson for kindly assisting in the process of digging out statistics over student performance. We thank Laurynas Riliskis for introducing us to inductive learning. We also thank him and Jingsen Chen for much appreciated feedback on an earlier draft. Finally, we are grateful to three anonymous referees whose insightful comments really improved the paper.

Evolution of a First Year Project Based Design Course

Allen H. Hoffman
Mechanical Engineering Department
Worcester Polytechnic Institute
Worcester, MA 01609

***Abstract*—First year project based design courses may face several obstacles. The students have very limited experience in design, construction and realization of prototypes, and in testing and evaluation of their designs. Most first year introduction to engineering courses cover a wide variety of important topics, but lack a strong emphasis on design. Originally our Introduction to Engineering course was similar to those offered at other institutions. In 2004 the format and focus of this course was transformed into a project based design course for first year students. This paper discusses the changes that have been implemented over the past nine years, to the point where this first year course now contains most of the elements of more advanced design courses at our institution.**

Keywords—first year courses, design courses, project based education, prototyping, realization and evaluation of designs

I. INTRODUCTION

Many students choose to study engineering because they have a strong interest in design and the realization of their designs. Precollege programs and competitions, such as the FIRST Robotics competition [1], have capitalized on this interest and attracted large numbers of participants who later go on to study engineering. However, even in these programs, it is unlikely that a participant will be immersed in the complete design process from identification of need through to testing and evaluation of a prototype. For example, the FIRST competition defines the need for the robot as well as many of its critical design specifications.

Most engineering programs have a course directed toward first year students that introduces engineering. The goals of these types of courses are to introduce students to the engineering profession, provide advice on studying to become an engineer, introduce basic analytical, graphical and project management tools used by engineers, and develop communication skills. These courses may also include short sections on design methodology. There are many excellent textbooks available for use in these courses [2-4]. These courses and textbooks fulfill a well-defined need and have been very successful. Prior to 2004 WPI offered a similar course, Introduction to Engineering (ES 1020), that is offered every fall during the first 7 week term of the academic year. The course meets for one hour, four times per week. This course provided a general introduction to engineering and included topics such as explanations of different engineering majors, presentations from practicing engineers, computer programing and use of spreadsheets, problem solving techniques, project management tools and communication skills. At the end of the course there was a brief project where teams of students undertook a common project such as construction of a mousetrap powered vehicle or an egg drop container. The class usually culminated in a competition between teams. This course was very successful in fulfilling its objectives. However, the course project did not focus on using a structured process to achieve the final design nor did it require a realistic process for the realization of that design. While valuable elements were included in this course, it was felt that first year students would be better served by a course that focused exclusively on the design process. Thus, in 2004, ES 1020 was revamped into a project based design course directed towards entering first year students. Details of the initial offering of this new format have been previously published [5] and are briefly described in the following section. This paper reviews the evolution of this course over the past 9 years into its present format where it now contains most of the basic elements of more advanced design courses at our institution.

II. INITIAL COURSE FORMAT (2004)

It was anticipated that a first year, project based, design course would face three major obstacles. First, students would be relying almost exclusively upon their high school background. Second, most students would have little or no prior design experience and very limited hands-on realization experience by which to construct and evaluate a prototype device. Third, selection of appropriate project topics might prove to be difficult since the topics must be interesting and exciting as well as be able to be successfully completed within our 7 week term. Briefly, the students' design experience was rapidly built through the use of a design text that emphasizes case studies [6]. Early lectures focused on design methodology and the process of developing and weighting design specifications. Weekly quizzes and homework were used to insure that students kept pace with the material presented in the lectures and readings in the book. A reverse engineering laboratory was used to develop hands-on experience as well as an understanding of the role of components in achieving design objectives. In the initial offering, eight teams of 4-5 students worked on the same design project for a period of 4 weeks. Three weekly written progress reports were required. Each team was responsible for constructing a working prototype device and reporting their results in both oral and written form.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

In summarizing the outcomes of the initial offering of the course under the new format, we emphasized that proper selection of the project topic was the most critical component of implementing a project based, first year design course [5].

III. EVOLUTUTION OF THE COURSE

Successful elements of the course have been maintained, including the goals, format, textbook and general subject matter. Coverage of professional ethics, product liability, and failure analysis has been considerably enhanced. Weekly quizzes are still used to insure that students keep pace with the course. Several significant changes have occurred in the project based portion of the course. These changes include the method of forming student teams, the length of the project, the number and types of design projects available to the students, introduction of library research training, budgeting, increased focus on written and oral reporting and the use of peer and self-evaluation within the project teams.

Formation of student teams: Initially the students were responsible for self-assembling into project teams of four or five. Hence teams were randomly assembled to include newly made friends or simply from students sitting near each other in the classroom. The project topics were announced after the teams had been formed. This method often resulted in the formation of teams that lacked the full range of skills to develop a design, create a prototype and evaluate its performance. To partially alleviate this problem, a previously developed method for forming design teams based upon a company officer model was introduced to the class [7]. This method was already used in our upper level design courses and requires each student to interview before the entire class for one of four company officer positions on the project team (Chief Executive Officer, Chief Technical Officer, Chief Information Officer and Chief Manufacturing/Financial Officer). In addition to contributing to the overall project, each officer is responsible for managing/overseeing the specific tasks associated with his/her position. Student teams are then self-assembled based upon these interviews. The fact that ES 1020 enrolls 45-50 students ruled out conducting individual interviews in the classroom. Instead, the company model was introduced during the 4th class period and the students were instructed to consider its implications prior to forming project teams in the next class.

Length of the project: The project topics are now introduced in the 6th class period. This allows the teams to work on the project for 5 ½ weeks.

Project topics: Initially there was considerable concern about selecting appropriate project topics for the course. In the first offering, all teams worked on the same project. This approach had two significant disadvantages. Since the problem was not that sophisticated some of the designs were quite similar. In addition, unstructured design teams of five students seemed to result in unequal distributions of effort. In subsequent offerings, the instructor supplied 2-3 project topics and restricted teams sized to a maximum of 4 students. Meanwhile, our upper level project based design courses began to allow students to select either a structured (instructor defined) project or an unstructured (student defined) project [8]. In an unstructured project the student team has to develop the need for the project. Based upon the successes achieved in the upper level courses, student defined projects were introduced into ES 1020 beginning in 2011.

Library research training: Design projects require that students locate appropriate references for several aspects of the project including background research, benchmarking, patents, and sourcing materials for construction of prototypes. The majority of first year students lack the skills and/or knowledge of how to conduct proper literature searches in the areas related to design projects. Originally the instructor attempted to cover this material in lectures and encouraged the students to seek further help from the library staff. This type of approach proved to be unsuccessful. The instructor's coverage of the material tended to lack sufficient detail and the students usually did not follow up with the library staff. In 2011 the instructor asked a university librarian to help in present this material with the goal of improving the students' information literacy skills. The librarian now presents formal instruction to the class and directly encourages students to follow up if they encounter any difficulties. Additional details and results from directly involving a librarian in this first year project based design course appear in a companion paper [9].

Budgeting: Initially, the student teams were given an upper dollar limit that they could spend for supplies for building their prototype. With instructor approval and a good design, the project team could ask for addition funds. This process was later changed to better reflect the realities of the real world. The teams are now required to submit a budget application and have it approved by the instructor prior to ordering or purchasing any materials. The budget application must include a drawing of the design and a bill of materials related to the parts shown on that drawing. It is clearly indicated that better designs will receive higher levels of funding. There is a deadline after which budgets will not be accepted.

Peer and self-evaluation: Each student receives a small amount of credit (~1.5% of the total grade) for submitting a peer and self-evaluation form at the end of the course. The form asks the students to assess their own and other team members overall effort, their most significant contribution to the project and their overall opinion of working on the design team.

IV. PRESENT COURSE FORMAT (2012)

In the fall of 2012, 46 students enrolled in ES 1020. Twelve design teams, each comprised of 3-4 students, were formed during the fourth class period and the project lasted approximately 5 1/2 weeks. Four project topics could be selected from an instructor supplied list. Two projects were well defined and were oriented towards designing devices for persons with stroke. One of the structured projects was "to create a device to allow a person with one arm to dispense toothpaste onto a tooth brush" (Fig. 1). The second project was "to develop a device to enable a person to insert and remove a contact lens with one hand" (Fig. 2). In order to maintain diversity in the final designs, each of these topics was restricted to a maximum of 4 teams. Seven project teams chose one of these two topics. The two additional topics only defined broad areas in which the teams could develop their own project. These broad topic areas were “to develop an assistive device for a person(s) with a disability” and “to develop a toy for a young child with a disability”. Five project teams chose to develop their own projects within these two areas. These project descriptions are very general and were used in both 2011 and 2012. Fig. 3 shows an attendant pushed curb climbing wheelchair attachment that was developed in 2011. This device allows the attendant to sequentially first lift the front wheels of the wheelchair over the curb as shown in Fig. 3. Then the wheelchair is pushed forward so that the rear wheels touch the curb. The attendant then stands on the rear of the platform to raise the rear wheels of the wheelchair. In 2012 a student team developed a 3 dimensional cube puzzle for children who are blind or have low vision. Each cube has braille and a tactile raised figure on each of the six sides. Each face of the cube is also color coded to categorize similar objects such as clothing and body parts. This feature makes the puzzle attractive to both sighted children and those with low vision. Another 2012 project was to design a drawing board for a child with cerebral palsy. The writing/drawing instrument was attached to the board by a mechanism that provided damping for unintended motions. Another project developed an alarm clock for a deaf person based upon bright flashing lights. Weekly quizzes and homework were used to evaluate understanding of the course material developed in the text and lectures. A librarian created a website specifically designed for this course and appeared before the class to explain how to utilize it. Contents of the website include benchmarking against existing products, patent searching, utilizing design handbooks, sourcing components for constructing a prototype and referencing sources in written reports [9]. The design project constituted about 1/3 of the overall course grade and was based upon the 3 progress reports, the budget submission, the prototype and the final oral and written reports. For the oral reports, the student teams are required to submit their presentation slides to the instructor and teaching assistant on the day before the presentation.

V. DISCUSSION

Many high school students are motivated to choose engineering due to a strong creative interest in design. Often, introduction to engineering courses focus on a variety of significant topics, while only giving limited attention to design and realization. Many engineering programs delay introducing true design courses until the second year or beyond, preferring instead to first build the students' backgrounds in mathematics, physics and engineering fundamentals. For creative students, this 1-2 year delay before they can express their creative talents may have a chilling effect on their overall interest in engineering. Others have noted that underclassmen tend to be more creative than their older peers but at this earlier level there is a need to focus this creativity into a more structured process [10]. First year project based design courses fulfill a significant alternative by allowing entering students to become immersed in real life engineering activities at the very beginning of their college careers.

The transformation of ES 1020 into a true project based design course occurred through a series of well-defined steps with each succeeding step based upon the success of the preceding ones. The initial step was to transform the academic content of the lectures through the use of a design textbook [6] and to introduce a 4 week design project into the course. It was felt that project topics had to be very carefully selected [5]. In the initial offering only a single project topic was offered to the class. In succeeding years, the time devoted to the project was increased as were the number of project topics offered to the student teams. The method of selecting teams was altered to encourage forethought as to the set of skills the group would need in order to successfully complete the project. As the course evolved some instructor supplied topics became less well defined and in 2011 students were allowed to define their own projects within broad guidelines.

The three required progress reports define general milestones that should have been reached within each preceding time interval. The progress reports allow the instructor to intercede with groups that are falling substantially behind the expected timeline for successful project completion. Students tend to chronically underestimate the amount of time that must be allocated to obtaining materials and constructing the prototype. Introduction of a formal budgeting process better modeled engineering experiences in the real world and created a firm milestone for developing a final design.

Historically, the overall quality of the final written reports had been a continuing problem due to the lack student understanding of how to access and utilize a wide variety of sources. Relatively few references were cited and most of those were websites of widely varying quality. Directly collaborating with a librarian has greatly improved this situation and is an ongoing effort [9].

First year students are generally not experienced in evaluating others, particularly peers. Peer and self-evaluation within project teams was originally introduced as an exercise, since it was a topic covered in the textbook [6]. The students are promised that their remarks will be confidential. When coupled with the company officer model of forming teams [7], peer and self-evaluation creates a situation where each student can objectively evaluate each team member's contributions including themselves with respect to their expected roles. The students' evaluations are generally very insightful and fair and reveal how groups of students with limited prior design team experience adjust and overcome difficulties in working with others. This information would not otherwise be available and has enabled the instructor to better understand and manage student project groups at this educational level.

Since most students lack prior design experience, the instructor has to balance the presentation of subject matter concerning design methodologies with the development of realization and construction skills for the project. Course evaluations reveal that the project based format of the course is very well received. Most students are enthusiastic about the project experience. The major student criticism is the "large amount" of work required by the course. However, these same evaluation forms show that most students report spending approximately 12 hours per week (including class time) on the course which is somewhat below the general expectations of our institution. It is important to note that most of our entering students graduated from high school near the top of their class and may not have been challenged to the same extent as they now are at the college level. The other significant student criticism is the number of required written reports. In addition to the progress reports and final report, the weekly homework assignments often include short written reports. It is clear that the value of developing written communication skills is not yet fully appreciated by this segment of the class.

In summary, project based design courses can play an important role in the first year engineering curriculum. These courses allow entering students to express their creative talents and engage in significant design activities that yield useful outcomes. Contrary to our initial concerns, it has been relatively easy for the instructor or even the students themselves to develop design projects that are suitable for this first year course. While projects and content in our upper level design courses are more sophisticated, our first year course now contains most of the elements found in these upper level courses.

ACKNOWLEDGMENT

Librarian Laura R. Hanlan is acknowledged for her contributions towards improving the information literacy skills of the students in this course.

***Abstract*—Engaging students early in meaningful STEM experiences will help them maintain a level of interest in STEM fields later in life. However, the key is developing meaningful courses in STEM for K-12 students. These students not only need to have a "fun" experience, but a meaningful one, where they connect with, and develop deep understanding of the material being presented.**

STEM Explore, Discover, Apply (STEM EDA) is being created by the Cyber Innovation Center, a 501c not-for-profit as a middle school elective course. STEM EDA is designed as a three course progression through topics that foster excitement for STEM. The curriculum is designed to enhance the core science and math classes taken in middle school. STEM EDA begins by exploring STEM concepts (STEM Explore, 6th grade) then transition to discovering fundamental concepts (STEM Discover, 7th grade), followed by the application of the concepts (STEM Apply, 8th grade).

This work in progress will outline the framework for STEM EDA, including the various modules of the courses. Additionally, this paper will discuss how the engineering design process is integrated into the modules, how other disciplines are highlighted, and showcase a specific module in this innovative middle school elective curriculum.

Keywords*— *Middle School; Engineering Design Process; curriculum

I. Introduction

Research has shown that engaging students with valuable STEM experiences early can help students maintain their interest in STEM later in life [1]. Introducing middle school students to STEM topics in a meaningful manner can increase their likelihood of staying engage with STEM in high school and college [1]. Thus, there is a need for creating worthwhile STEM experiences for middle school students. This is evident by the national common core initiative. The common core standards for mathematics include incorporating lessons learned from previous classes to build on the students' knowledge [2]. Additionally, the Next Generation Science Standards (NGSS) outline the need for engineering to be included in K-12 classrooms [3]. Incorporating engineering principles early can build the students' problem solving and critical thinking skills as well as provide real applications to problems that students normally see as abstract [1]. Additionally, NGSS discusses the need for incorporating multiple disciples in classrooms [3]. By learning through a multi-disciplinary lens, students can make connections throughout their classes and the world around them, rather than looking at each course as a discrete subject [4]. Incorporating these aspects in the middle school classroom can provide the meaningful experience needed to maintain student interest in STEM later in life.

A difficulty, though, is creating that meaningful STEM experience; this is no easy task. Project-based learning, a popular pedagogical style, is typically employed in order to engage students. This pedagogy has been shown to be beneficial [5]. However, in many cases that pedagogy is abused; and so often, the intent of "project-based" is lost. Rather than using the projects to enhance the course and drive to the fundamental topics, the projects become the main focus and the fundamentals are neglected. This is not to say that the project-based learning should no longer be used in classrooms, but it should be used in that manner by which it is intended. A more "project-driven" approach should be employed, where the fundamental topics are the main focus and the projects are used to enhance the curriculum, engage the students, and most importantly "drive" to the fundamental concepts.

In order to address this issue on the middle school level, the Cyber Innovation Center was asked to create elective STEM courses for 6th, 7th, and 8th grades. In order to develop these courses, the curriculum designers decided to use "classic" science projects, while leveraging the engineering design the process to provide continuity, depth, and meaning to curriculum. Additionally, liberal arts context for each project will be included to provide deeper meaning to the projects as well help students make connections to the world around them, physically, culturally, and ethically. Thus the curriculum designers are developing STEM Explore,

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Discover, Apply (6th, 7th, 8th, respectively) using these characteristics.

II. Framework of Courses

The curriculum is being designed using a modular approach to each of the courses. STEM Explore, Discover, and Apply (STEM EDA) will capitalize on the "classic" science projects (e.g. the egg drop, volcano, catapult, bottle rockets) to drive to fundamental STEM topics as well as cultural and society applications. In order to provide continuity, depth, and meaning, within the various modules the curricula will leverage the engineering design process. The modules will incorporate a social studies, historical, and/or societal context to provide intellectual applications to the projects. Each level of the course will use the same themed project (e.g., module 1 is an egg drop for all grades), but will have different context and parameters, such that students will being doing completely different projects in each course. Additionally, the level of the fundamental concepts will increase gradually with each grade of the curriculum. Table I outlines the projected modules for each course in STEM EDA.

TABLE I. Outline of Course Modules

Weeks	Module
1 – 3	Egg Drop (Engineering Design Process)
4 – 6	Volcanoes
7 – 9	Musical Instruments
10 – 12	Catapults/Trebuchets
13 – 15	Electricity
16 – 18	Solar Ovens
19 – 21	Trusses
22 – 24	Boats
25 – 27	Bottle Rockets
28 – 30	Earthquakes
31 – 33	Racecars
34 – 36	Roller Coasters

Each module will span approximately three weeks. The students will follow the steps in Figure 1 throughout each three-week module. Students will be guided through each step by the instructor, while building their own inclination for the process.

In Step 1, students will learn how to interpret information and write a concise, but informative problem statement. In Step 2, student will learn to interpret information from articles. Step 2 will be a large focus of the modules, allotting for many of days in the three week module. Students will be given, and when appropriate find for themselves, applicable articles. Students will be challenged to read the articles and extract pertinent information. Students will have open discussions and sharing opportunities which will drive the learning of the fundamental content. During Step 3, students will learn to plan ahead. They will think of various solutions to the problem and organize their ideas accordingly. For Step 4, students will use their critical thinking skills and the information they learned in Step 2 to choose the best solution to the problem. After they have chosen the solution, they will begin to build the prototype of their design in Step 5. This will put their construction skills to the test as well as help them realize how something they design on paper and in their minds can be built in the physical world. Once the prototype is built, the students will move to Step 6 Test and Evaluate the Prototype. This is an essential step; students will see if what they built performs in the manner they intended. Finally, after testing and evaluating the prototype the student will reflect on the design and determine ways they can improve upon their design, Step 7.

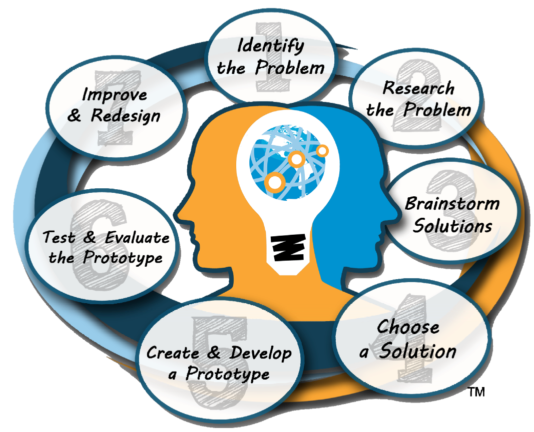

Fig. 1. Engineering Design Process

In addition to the engineering design process steps, the students will learn the overarching themes of the process: iteration, communication, imagination, and creativity. Students will learn that design is never completed and the process is based on iteration so that improvements can be made. Throughout the modules, students will be challenged to maintain communication with not only their teammate, but the instructor and other classmates as well. Heavy emphasis will be placed on imagination and creativity such that students are able to express themselves through the projects.

With each module, students are tasked with developing a creative story element related to the context and their design. Including the creative writing assignments will help the students develop their writing skills, while also helping them think through the context of the module and how their design applies to the context. Additionally, the creative writing assignment adds another layer of depth to the curriculum such that students are applying elements from other classes, like English, to a STEM course.

III. Example Module

The egg drop module will be first for each level of the curriculum. This project is based on the classic, "create a vessel to protect an egg from breaking as it falls from a specified height." Typically this project is completed over a two day time span, with one day for building a vessel. The next day, students drop the vessel hoping that the egg will not break. When done in this manner, often the fundamentals are over looked, and the activity itself takes the main focus. However, in STEM EDA, because of the engineering design process, time will be allotted to the research component. Therefore, the fundamentals concepts will be at the forefront. Additionally, since the egg drop is the first module of the curriculum, it will serve as the vehicle to frame the importance of the engineering design process. In STEM EDA, students will complete the egg drop module in the typical manner first, where they will build a vessel with little to no research or discussion on the fundamentals. The following day the students will drop the vessels. Many students will fail; this is okay because now the teacher has an opening to discuss why the vessel may not have performed as planned. This will be a natural lead into the engineering design process, where students will redo the project; this time, however, using the engineering design process as a guide. In each course, heavy emphasis will be placed on open discussion, where students will be asked to share their thoughts and designs with the class throughout the engineering design process.

A. Explore (6th grade)

The context for the Explore egg drop module is based on a stuntman jumping from a building. Students will be required to use only a select amount of materials such as cotton balls, Styrofoam cup, Styrofoam bowl, straws, limited amount of tape, and twine to build their vessel. Through the research process students will learn the concepts of gravity, force, velocity, acceleration, Newton's second law of motion, center of gravity, and mass versus weight. Prior to dropping the vessels students will have to calculate the force at which the vessel will hit the ground, and during the drop, students will determine the average velocity of their falling vessels. After constructing the prototype vessel, students will have to write a creative story on why the stuntman is jumping and how their vessel will keep a stunt man safe as he jumps out of a building.

B. Discover (7th grade)

The context for the Discover egg drop module is based on a skydivers jumping from a plane. Students will only be given straws, tape and a garbage bag to construct their vessels. Through the research component, students will learn about gravity, velocity, acceleration, law of conservation of energy, kinetic energy, potential energy, air resistance, and parachutes. Students will have to calculate the potential energy for their vessel. During the drop they will have to find the velocity of their falling vessels to determine the kinetic energy. Knowing the law of conservation, students will make the connection that energy was dissipated elsewhere since the kinetic and potential energy will not equal each other due to the parachute. They will then determine the amount of energy dissipated due to air resistance. Also, students will be tasked with writing a story about the skydiver and how their design will keep him/her safe.

C. Apply (8th grade)

The context for the Apply egg drop module is based on a dropping supplies to refugees in a foreign country. Students will be able to use various items like straws, tape, garbage bags, cotton balls, Styrofoam cups, Styrofoam bowls, and twine to construct their vessels. However an added element to the Apply lesson is the consideration of cost efficiency. Students will be given a budget, and must purchase the items for their vessels within the budget. The size of the vessel will also have a cost associated with it. The larger the vessel the more money the students will have to spend. Students will have to research the same concepts as Discover, as well as calculate potential/kinetic energy and drag. However, in addition to these concepts, the students will have to find articles of supplies being dropped to refugees in a foreign country. They will then use this information to write their creative story on the vessel design. Students will have to choose refugees from one of their articles, and incorporate factual information about them as they write their story from the view point from the pilot dropping the supplies.

IV. Conclusion

Currently two modules, the egg drop and volcanoes, have been created for all three levels of the curriculum, Explore, Discover, and Apply. The egg drop, which is used as the vehicle to demonstrate the necessity of the engineering design process, is being piloted at a local middle school. For the Fall 2013 school year, three to four middle schools will be piloting the curriculum. The designers intend to have five to six modules fully developed for the beginning of the school year. As the first semester concludes, the designers aim to have the remaining six to seven modules completed.

Sparking Creativity in Computer Science for Interdisciplinary Students

Renita Murimi
Paul Dickinson College of Business
Oklahoma Baptist University
Shawnee, OK
renita.murimi@okbu.edu

Abstract— **A class on Technologies for Creative Learning was designed to investigate the answers to a well-researched question: "What learning mechanisms spark creativity?" The class was offered for the first time at Oklahoma Baptist University during the Winter 2013 semester, and was structured to introduce computer science concepts to an interdisciplinary group of students. A key enabler of most learning mechanisms today is technology, and this class explored the use of various platforms in the design and functionality of learning through technology, using computer science as the learning objective. This work addresses the implications of programming and robotics to foster creativity in computer science and discusses the outcomes of the class.**

Keywords—computer science; interdisciplinary; robots

I. INTRODUCTION

"What learning mechanisms spark creativity?' was the question we sought to answer as we designed a new course in Computer Science at Oklahoma Baptist University (OBU). OBU is a liberal arts school, and students majoring in a wide spectrum of disciplines could be sought to understand the learning mechanisms that encouraged creativity. We designed a class on Technologies for Creative Learning to encourage creativity in Computer Science through the design platform of robots. We were inspired by similar classes at Massachusetts Institute of Technology [1] and at University of California, Berkeley [2] and at, where the classes were designed to study the impact of educational technologies. Our class, however, was designed to introduce computer science to interdisciplinary students through robotics [3]. To accomplish this, students were first introduced to various learning theories and programming environments [4]. These lessons were then applied to design creative projects using robots to form a culmination of computer science, creativity and learning by discovery in student-created projects.

II. CURRICULUM DESIGN

The curriculum was divided into three modules: Introduction to the Theory of Learning, Learning Computer Science Concepts and Creativity and Collaboration. Each module comprised of a learning phase and a testing phase. Information about each of these modules and associated activities are as follows.

A. Introduction to the Theory of Learning

The first week of class introduced students to the theories of learning [5] and innovation [6]. Students were encouraged to approach the class with the mindset of a kindergarten student whose learning mechanism can be represented by a spiral [5]. Since learning is a lifelong activity, it was chosen to be the key element of investigation and it was explored through the medium of computer science. As part of the design phase of this module, students were introduced to Scratch [7] through a two-fold assignment where they were asked to familiarize themselves with Scratch and build a simple project to introduce themselves to the class through a Scratch project. In the second part, students built a gallery of projects around a theme. For both of these assignments, students noted that while Scratch was intuitive to learn, the most challenging part of the assignments was figuring out the theme of the individual project and the gallery of projects. This simple experiment demonstrated the utility of programming platforms that could be explored by students of various backgrounds. Through Scratch, students were introduced to computer science concepts such as decision structures, loops, I/O, synchronization, functions, algorithms and OOP.

The second half of the design phase introduced students to multi-agent modeling using Netlogo[8]. Students were encouraged to explore the library of models available in Netlogo and modify the simulation parameters of the models and observe the varying outcomes. Through this assignment, the class was introduced to concepts in randomness, swarm intelligence and simulation mechanisms. Scratch and Netlogo formed the cornerstones of learning about computer science in this class.

B. Learning Computer Science Concepts

The second module on Learning CS concepts expanded on the knowledge of Scratch that the students gained in the first modules. Using the software environment supported by Alice [9], students used the design platform of the Finch robot [8]. This module focused on learning by discovery, where they explored Alice based on their knowledge of Scratch and programmed a Finch robot. Robotics was chosen as the design platform in the design phase, since robotics is an important tool in cultivating an interest in computer science. Since robots are a cultural construct in our world, robotics can inspire cross-

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

disciplinary interest in students and foster creativity and collaboration. The individual projects were judged by a panel of judges for their novelty and execution. The projects that were built consisted of robots that danced, moved around a maze, a robot that hid from light, a robot that avoided obstacles and a name-tracing robot. The programming of these robots required students to understand the functionality of the various sensors in the robot, and use their knowledge of programming concepts introduced in the first module.

C. Creativity and Collaboration

This final module on Creativity and Collaboration was designed to tie in computer science concepts, learning theories, collaboration and creativity. The final module was a group project whose theme was 'The Social Life of Robots'. The interpretation and implementation of this theme was left open to students. The students decided to program the robots around a pursuit-evasion game called Zombie tag. The rules of the game were designed as follows:

1. The game starts with one robot being the Zombie, and the rest of the robots are Humans. Zombies move slower, and only in straight lines, while Humans (who can launch into panic at the sight of a zombie) can move around in any direction and faster than Zombies. A Zombie's LED (the beak of the Finch robot) is green, and that of the Human is purple.
2. The Zombie's aim is to tag (pursue) a Human, while the Human seeks to evade the Zombie(s). The tag is accomplished by touch between the robots. As soon as a Zombie tags a Human, the Human Finch's beak turns green to signal that it is now turned into a Zombie and adopts all the characteristics of a Zombie. The game continues with two Zombies pursuing to tag the remaining Humans. This process continues till there is one Human left, who now becomes the initial Zombie for the next round of Zombie tag.

The design of this game is interesting for two reasons: first, a group of interdisciplinary students designed a game around a classic game-theory concept, and second, it involved distributed programming. The Zombie that started the game could be any robot, and all the robots seamlessly switched from Human mode to Zombie mode upon being tagged. The initial computer science concepts and multi-agent modeling were implemented through robots at the interface of computer science and game theory. Considering that there was no requirement for previous programming experience, in the true spirit of interdisciplinary learning, this class touched on educational research in the areas of cognition, psychology, education, computer science and programming.

III. Class Outcomes

Surveys were conducted to assess the outcomes [11] of this pilot offering. At the start of the first module, students were asked to note their most challenging experience out of the following three choices: learning to program, learning to share and learning to ride a bike. This question was adopted from [5], and the responses were typical. The non-computer science majors unanimously chose 'learning to program'. At the end of this class, this response changed, with 75% of the non-computer science students choosing an option different from 'learning to program'. Additional questions on the survey asked students to reflect on the kindergarten model of learning: (Imagine, Create, Play, Reflect, Imagine) and to note their most interesting and challenging parts of this spiral in learning about computer science. 'Imagine' and 'Create' emerged as the top two answers for the entire class. The entire class picked 'Programming the Finch' as the most fun task out of a list of options that included reading assignments, maintaining a blog, programming in Scratch and exploring Netlogo. However, the cost of the robots was a limiting factor in the breadth of robotics assignments that could be made possible for the design of this curriculum, and was stated by students as an element that needed to be addressed for future versions of this class.

IV. Results and Future Work

The pilot offering of this class generated a huge amount of interest on and off campus. We are planning to offer this class every Winter term, and expand the offerings available to students in terms of robotics projects that students can work on. Plans are underway to establish a robotics lab, and we are investigating various modes of curriculum design to continue sparking creativity in computer science in a liberal arts environment.

Abstract—**This paper will explore a project associated with the National Science Foundation STEM GK-12 Program at Drexel University titled "Catalyzing STEM Education via the NAE Grand Challenges" (http://www.engineeringchallenges.org) that serves to address the need for more STEM educated workers. Specifically, the Drexel NSF STEM GK-12 program pairs ten College of Engineering graduate students (Fellows) with ten School District of Philadelphia high school teachers to help introduce engineering concepts to high school students through the context of the National Academy of Engineering (NAE) Grand Challenges. This work in progress explores a high school vehicle design project as part of the Kensington Kinetic Sculpture Derby (KKSD) facilitated by a fellow/teacher partnership at Central High School, an urban school in Philadelphia comprised of 40% underrepresented groups in the STEM fields. A unique feature of the project is that students from the IB Design Technology course were grouped in an interdisciplinary team with other students from World History and Sculpture classes to develop a vehicle based on the structure of a bicycle.**

Keywords— STEM; K-12; Engineering Design

I. Introduction

The Kensington Kinetic Sculpture Derby (KKSD) (http://kinetickensington.org) is a design competition featuring human powered kinetic sculptures on display in a parade. It was started in 2007 and has since grown to have dozens of entries and thousands of spectators. For this project, twenty-three juniors from the IB Design Technology class, twenty-five juniors from the Sculpture class, and sixty-six freshmen from the World History class at Central High School in Philadelphia were split into eight groups of fourteen to sixteen students with about three IB Design Technology, three Sculpture, and eight World History students per group. World History class students led the project team in researching the culture and historical time period of the vehicle design and acted as clients presenting a product idea/request to the IB Design Technology students. IB Design Technology students were then tasked to incorporate what they had learned about product design, mechanical design, system design, as well as other topics from the course to design a vehicle. The World History students were tasked with building the kinetic sculpture, while IB Design Technology students designed and built three kinetic devices to affix to the sculpture that would satisfy the kinetic requirement of the derby; these devices had to move due to human power. The Sculpture students were the aesthetic design leads of the project.

The goal of the project is to not only improve interest in STEM career paths for the IB Design Technology students but also to increase aptitude for STEM fields in the liberal arts students.

II. Methodology

To measure the students' abilities and interest in STEM fields, a survey was given to all of the students at the beginning of the project. It asked three questions of the students: 1) Rate your ability in math and science; 2) Rate your interest in STEM fields; and 3) Rate your likelihood of majoring in a STEM field. These questions were all answered on a scale of 1 to 4 with 1 being not interested at all or not very likely, 2 being somewhat interested or somewhat likely, 3 being interested or likely, and 4 being very interested or very likely.

In order to determine the effectiveness of this project, an after project survey will be given to the students to determine the impact the project had on the students perception of STEM fields. This survey will have the same questions as the first survey but will have additional questions in order to more accurately quantify the impact this project had on the students as well as gather feedback from the students to use in improving future implementations of the project. These additional questions will be: 1) Would you recommend this project to your peers; 2) What did you like about this project, what did you not like about this project; and 3) What would you change about this project.

III. Preliminary Findings

About 80% of all the students (82% of the IB Design Technology students, 72% of the sculpture students, and 83% of the world history class) said they had above average ability in math and science. However, there was a marked difference between the classes in the responses to the other two questions.

In the IB Design Technology class, 68% of the students were very interested in STEM fields, but only 8% of the Sculpture students felt the same about STEM fields. Fifty-nine

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

percent of those same IB Design Technology students said they would be very likely to major in a STEM field in college (Figure 1), but compare that to the Sculpture class where 12% said they would be very likely to major in a STEM field in college (Figure 2). This is to be expected somewhat because these students are juniors who are in specialized elective classes that interest them. They already are in the process of thinking about what they want to do after high school and have been evaluating what interests them leading to a marked difference in the survey results about which students are interested in STEM fields.

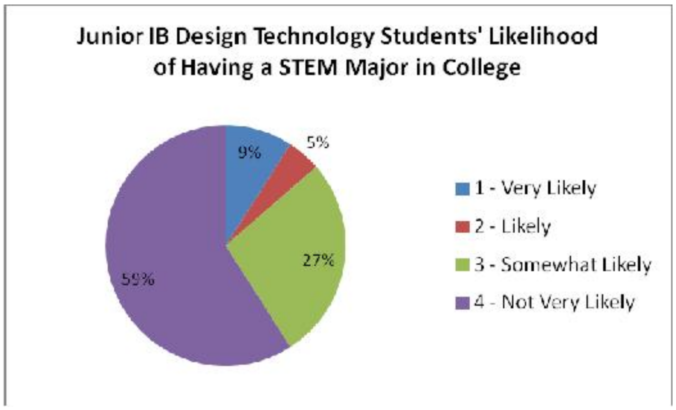

Fig. 1. Pie Chart of Junior IB Design Technology Students' Likelihood of Having a STEM Major in College

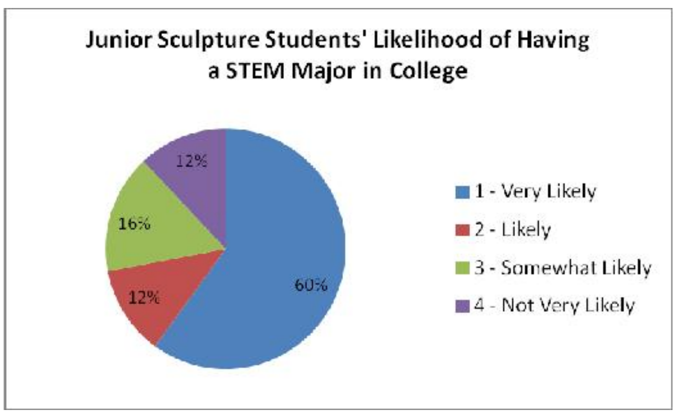

Fig. 2. Pie Chart of Junior Sculpture Students' Likelihood of Having a STEM Major in College

Looking at the freshman World History students shows that 32% are interested and 37% are somewhat interested in STEM fields. The students split the last question pretty evenly with each response receiving about 25% of the selection from students on whether they would likely major in a STEM field in college (Figure 3). These freshmen have the most variation in the survey responses out of all the classes, which makes sense since they are the youngest students involved in the project. This is also the group of students with the most potential for change because they are only freshmen and have not had much experience with STEM fields before, so this project will hopefully increase their interest in these fields.

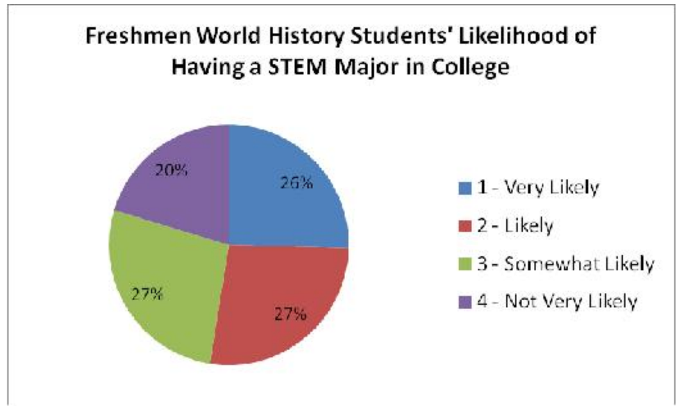

Fig. 3. Pie Chart of Freshmen World History Students' Likelihood of Having a STEM Major in College

IV. Conclusion

Using the survey to broadly characterize the students, it can be said that the IB Design Technology students are the most interested in STEM fields, the Sculpture students are the least interested in STEM fields, and the World History students have no clear consensus among them. However, students from all classes learned through inquiry what aspects of STEM related fields do or do not interest them. Student interest in STEM fields is evaluated by a pre and post project survey that asks students to rate their interest in STEM fields and their likelihood of majoring in a STEM field in college. The post project survey has not yet been given, but will given once the KKSD has finished. These survey results will be compared with the pre project survey results at the conference.

Additionally as a result of the project, the IB Design Technology students discovered a way to practically apply the engineering concepts they have learned in a meaningful project as well as explored the nature of customer relations by translating customer desires into a manageable reality by working with their clients, who in this case were the World History students.

V. Future Work

As previously stated, in order to determine the impact this project had on students, an after project survey will be given to the students. The results of the final survey will be compared with the pre project survey and used to help improve the project for future iterations.

Curriculum Integration for the ECE Undergraduate Core Courses in Electronics

Qing Zheng, Pengtao Lin, Fong Mak, Ramakrishnan Sundaram, Lin Zhao
Department of Electrical and Computer Engineering, Gannon University,
zheng003, lin003, mak001, sundaram001, zhao001@gannon.edu

Abstract - **This paper discusses the work in progress to restructure the Electronics curriculum in the Department of Electrical and Computer Engineering (ECE) in order to improve the system integration learning experience gained by the undergraduate students. The goals of restructuring the ECE Electronics curriculum are as follows: a) train and prepare students to design and analyze complex electronic systems first at the subsystem and system level before teaching and learning electronics at the component level; and b) strengthen the infrastructure for the system integration learning experience with other courses such as power electronics through the use of integrated projects developed for the Electronics curriculum. To realize these goals, the curriculum of Electronics I and Electronics II are redesigned. Electronics I is designed to focus on the design and analysis of electronic circuits, devices, and processes at the system and subsystem level. Electronics II is designed to focus on the study, operation, and analysis of electronic circuits, devices, and processes at the component level. Centralized projects are selected as platforms to allow students to develop the skills in designing and analyzing electronic systems. The students' performance and survey show that the Electronics curriculum restructure has a positive impact on students' learning.**

Keywords - Curriculum Integration; Electronics; Restructuring.

I. Introduction

Curriculum integration is getting more and more attention [1-3]. The subject matter of *Electronics* constitutes one or more core courses taught to electrical engineering students. In the ECE Department at our University, both Electronics I and Electronics II are offered. Traditionally, the focus of Electronics I has been the study, operation, and analysis of electronic circuits, devices, and processes at the component level. Topics include the "I-V" characteristics, the DC load line and operating point, the AC load line, large signal and small signal analysis of electronic circuits comprising diodes, transistors, and operational amplifiers. Electronics II focuses on the design and analysis of electronic circuits, devices, and processes at the system and subsystem level. In our ECE Department, students can focus on one of the two tracks: *Electrical and Electronics* track and *Computer Engineering* track. Students in the *Electrical and Electronics* track are required to take Electronics I and Electronics II. Students in the *Computer Engineering* track only need to take Electronics I. As a result, students in the *Computer Engineering* track miss the opportunity to learn electronics at the system or subsystem level or know how to integrate the learning at the component level with electronic system and subsystem design. In addition, we learn from our past experience that students in general have difficulty to integrate what they learn in electronics with advanced subject matter such as Power Electronics. The Electronics curriculum is restructured to better prepare students' system integration skills in both tracks first so that at the minimum students will know how to integrate what they learn to other courses.

In the new infrastructure, Electronics I is designed to focus on the design and analysis of electronic circuits, devices, and processes at the system and subsystem level. Electronic circuits and processes are explained through the integration of subsystems comprising electronic devices such as oscillators, voltage regulators, and switching circuits. The electronic devices and operational amplifiers are studied from a cause-effect standpoint. Centralized projects are selected as platforms to allow students to develop the skills necessary to design and analyze electronic systems. The laboratory activities are redesigned to deliver the required training to students in system design and integration skills and needed for related subjects such as Power Electronics. Electronics II is designed instead to focus on the study, operation, and analysis of electronic circuits, devices, and processes at the component level.

With the new infrastructure, *Electronics I* prepares students with knowledge of electronics at the system and subsystem level. By successfully completing this course, students will have the ability to analyze and design complex electronic systems. Students can apply software skills learned in the course to the analysis and design of electronic systems.

Electronics II provides the students with an understanding of the characterization and operation of electronic components. The students will acquire skills with contemporary software tools to analyze the characteristics and performance of basic and advanced electronic components.

This paper is organized as follows. The course outcomes are discussed in Section II. The development of centralized projects is described in Section III. The assessment of the effectiveness of the electronics curriculum restructuring is shown in Section IV. Finally, concluding remarks are given in Section V.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

II. Course Outcomes

The course outcomes for *Electronics I* and *Electronics II* are listed below. Each course outcome maps to a specific ABET-approved student learning outcome.

A. Electronics I Course Outcomes:

1. Comprehend the electronic design process at the system and sub-system level
2. Demonstrate skills to analyze and design electronic circuits, devices, and processes at the system and sub-system level
3. Demonstrate skills to analyze and design complex electrical and electronic systems

B. Electronics II Course Outcomes:

1. Demonstrate skills to analyze electronic circuit at the component level
2. Demonstrate the ability to characterize electronic components
3. Demonstrate skills to use contemporary software tools for electronic circuit analysis

The primary aspect of the redesign is to deliver the content in modules which focus on a *central electrical engineering project* that uses the drive board design of a DC motor for an electric GOLF cart [4] as platform.

III. Development of Centralized Projects

To develop the centralized platform, the drive board for the DC motor of the electric golf cart is designed. The schematic design for the drive board of the DC motor is shown in Figure 1. The printed circuit board (PCB) design is shown in Figure 2. This system includes the following subsystems: 1) controller system; 2) power supply; 3) programming status indicator; 4) temperature test circuit; 5) PWM signal connector and MOSFET driver. The drive board system and the related subsystems are used as the centralized platform projects for the redesigned courses. Students use Printed Circuit Board (PCB) design software (Cadence Layout Plus) to design PCB and PCB maker (LPKF ProtoMat) to produce PCB. The projects are done progressively throughout the semester. A set of similar large system projects will be developed and rotated through each semester.

IV. Assessment

The students completed an online survey to rate the effectiveness of the courses through an online Outcomes Assessment system: EvalTools® [5]. The feedback from the students has demonstrated the effectiveness of the courses in delivering critical system and subsystem level skills and competencies. The following are samples of student comments in the course survey.

- *I feel that the material we covered in class was very efficient with what we were doing in lab.*
- *I liked that after having Electronics I, things in Electronics II made a lot more sense and we were able to build upon what we already knew.*
- *I liked that we were able to put into practice with what we were learning in the class.*

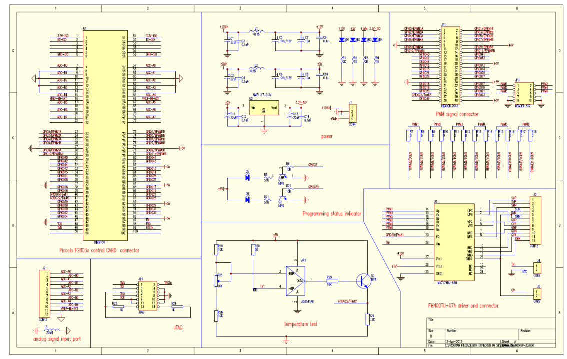

Figure 1. The schematic design for the drive board of the DC motor.

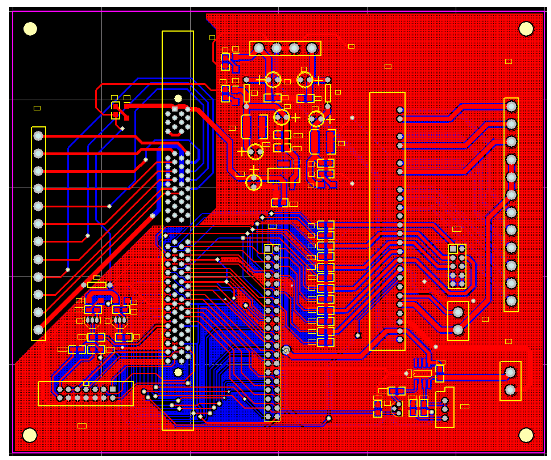

Figure 2. The printed circuit design for the drive board of the DC motor.

The students' performance and survey indicate that teaching with the restructured Electronics Curriculum helps students understand electronics concepts better and improves their system integration skills.

V. Concluding Remarks

The redesigned courses strengthen the understanding and skills required for electronic system design & integration and improve the preparation of students for industrial projects. The centralized projects provide a platform for restructuring the undergraduate electronics curriculum to incorporate the teaching pedagogy. The students' performance and survey demonstrates that the restructure of the electronics curriculum has a positive impact on student's learning. A rubric for assessment of the course outcomes is being developed and will be employed for measuring the effectiveness of system, subsystem, and component level teaching and learning with this curriculum integration.

Daytona Beach, Florida, USA
phant2e9@my.erau.edu and allamy@erau.edu

***Abstract*— The College of Engineering at Embry-Riddle Aeronautical University requires its students to take a semester long engineering profession and project-based design course as first-year students and a capstone project-based design course over the span of two semesters as seniors. There is a desire to ascertain the actual and normalized time, process progression, and traffic patterns of engineering student design project teams navigating a design process and gauge these metrics across engineering majors and against faculty impressions and expectations, with an eventual goal of gauging against professional practice as well. Once student design activity application is analyzed with respect to faculty and professional expectations, pedagogical and curricular content adjustments can be made as necessary to align these project-based, experiential learning activities with perceived practice. The analysis of student progress compared to faculty and professional perspectives will provide an opportunity to dissect and reinforce the foundation of engineering design education at the University.**

Keywords—engineering design education; design process; senior design; capstone; first-year engineering; freshman engineering; cornerstone; project-based learning

I. Introduction

Properly designed cornerstone design projects can potentially address most, possibly all, of the ABET 2000 Criteria to varying extents throughout the project. Cornerstone design coursework supports constructionist pedagogical theory and incorporates instructional strategies that are student-centered and promote active learning while addressing a variety of learning styles [1]. When compared to the traditional lecture environment, the enhanced environmental similarity of cornerstone (and capstone) experiences to the engineering workplace fosters more transferability and provides the student with importance and reason for that which they are learning through simultaneously applying content in the instructor-provided context as they learn it, as shown by several studies reviewed by Prince and Felder [2]. The importance of design in engineering education curricula is emphasized by Dym [3].

Freshman and senior level student application of and transitions within the design process are studied using short design scenarios [4, 5] where it is shown through verbal protocol analysis that senior level students showed greater numbers of transitions throughout information processing phases, possibly correlating to greater process efficiency, and a higher quality paper design. These studies of freshman versus senior engineering student applications of the design process through short, open-ended scenarios are somewhat analogous at the micro level to the ongoing study discussed here of engineering student applications of the design process through existing term-length and mini design project-based learning curriculae at the macro level in a full-term project experience.

Teaching in a student-centered manner allows students to incur educational experiences that straddle many learning styles to satisfy the needs of the heterogeneous student body. Project-based learning by its nature incorporates much of the spectrum of learning styles. Project-based learning also invokes many pedagogical approaches and theories throughout its application. This work in progress presents preliminary results from an ongoing study [6-7] on engineering student design activity with the eventual goal of comparing student activities against the practices and prescriptions of design experts in academia and industry.

II. Purpose

This study investigates student application of design process scaffolding provided to students in first-year and senior year engineering design project experiences by measuring student activities as students navigate various phases of the design process and manage their projects.

Questions considered in this ongoing study include:

- Is the design process and project management scaffolding provided to first-year engineering students in cornerstone experiences appropriate?
    - How much time do students spend on each phase of the design process and project management phases of the cornerstone design project?
    - What is the frequency of and what design activities comprise iterations in the phases of the design process and project management?

Embry-Riddle Aeronautical University 2012-13 Faculty Internal Research Grant #13294.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

- How do student weekly activities compare to desired (expert) practices?
- How do these metrics vary, if at all, across different design projects?

III. Methods / Procedure

In current efforts to address research questions, students' application of the engineering design process is monitored via biweekly surveys throughout their design project experiences. The student team data collection is currently ongoing and uses the information provided by the senior design courses of the Mechanical Engineering Department and the Freshman Engineering Department's EGR 101: Introduction to Engineering project data. The data is collected through an anonymous survey instrument that has a list of potential activities visited during a design effort. The current version of the survey was informed by a pilot study, a literature review, and faculty survey. In this latest version of the survey, students provide section and team identifiers, the time spent on each design activity, the number of group members who participated in each activity, the number of visits to each activity, the two-week time period during which the activities occurred, and the design activity visited prior to each activity being addressed. The Design Process Weekly Survey is shown in Fig. 1.

NUMBER ORDER NOT IMPORTANT; JUST A LABEL	ACTIVITY WITH EXAMPLES / DESCRIPTION	TIME TOTAL HRS:MIN SPENT HERE SINCE LAST SURVEY	PARTICIPANTS NUMBER OF PEOPLE WORKING ON THIS	VISITS TOTAL NUMBER OF VISITS SINCE LAST SURVEY	VISITED FROM LIST PRECEDING STEP NUMBER PRIOR TO EACH VISIT HERE

Fig. 1. Design Process Weekly Survey.

This survey was changed from the pilot version from the previous academic year after querying for the students' opinions on ease of survey comprehension and the procedure for populating it. The most significant difference between survey versions is previously each activity was called a step and each step featured only one definition. The current survey has multiple definitions of each activity to better accommodate each professor's choice of terminology and explanation of the design process. Another difference is that the previous survey did not query the students on the originating activity that immediately preceded the current activity for which students are providing visit time and instance quantity data.

A. Data Collection

The surveys were given to observe how student teams work through a design cycle during a project. The design survey was given to two specific groups, the Mechanical Engineering (ME) senior design students and the freshman EGR 101 students. EGR 101 is Embry-Riddle's introductory engineering course. This class takes up 2.5 to 3 hours a week and the projects are mostly done outside of the classroom with a few classes working in a lab. Senior design students work on one project over two semesters and have class for 3 hours per week, but most students work many hours outside of class as well. The students were asked to separate into their project teams to complete the survey. Also, a majority of first-year students complete several mini projects throughout the semester rather than one large project for the entire semester. The EGR 101 surveys collected for this study addressed one mini-project.

B. Frequency and Schedule

The design surveys were given out biweekly throughout two semesters for the senior design students and two to three times in one semester for the first year students. The first year students were given the surveys once after the first week that the project was assigned, one to two times during the middle of the project and once again at the end of the project. The senior design students had a graduate student familiar with the design survey proctor each biweekly meeting. Due to the great number of sections, the first year students were proctored by their professors who received a briefing on the design survey.

C. Faculty Surveys

Engineering design faculty were also surveyed. Faculty were asked to indicate design process scaffolding provided to their students, how students are expected to apply the design process, student levels of preparedness and relative weaknesses before, during, and after project experiences, and how student design application related to their own professional experiences.

IV. Results

The seniors had a classroom size of 8 to 14 students whereas the first year students had a classroom size ranging 28 to 32 students. The largest senior design subgroups consisted of 3-4 students while the largest first year teams consisted of 6-7 students. In the 2012-13 academic year, 47 first-year student teams have provided 1762 design process activity data records and 17 senior design teams have provided 2284 process activity data records. The results of the student team surveys are compared to the faculty survey feedback. Normalized, aggregated student time spent on design activities is graphically displayed and can be seen on Fig. 2 and 3. Design process raw (non-normalized) traffic patterns are also graphically displayed and are shown in Fig. 4 and 5. Table 1 is lists the data from which those figures were derived.

8	0	1	0	0	7	1	3	6	4
PM	2	1	3	3	0	5	10	12	4

V. DISCUSSION

It is noteworthy that the senior design students generally completed the survey more correctly than the first-year students. It was common to see that the first-year students did not properly indicate which activity was last visited before moving on. The senior design students completed the surveys more willingly and carefully with an instructor present. In some cases, the instructions were given several times and confusion in survey response was resolved through conversation with the students. Survey completion was requested as a team effort, but sometimes only one team member would complete a survey for an entire team.

The pie charts depict a proportion of time student teams spent on the various design activities. As seen from the data in Table 1 and Fig. 4 and 5, the first-year students spent much of their visits in the first third of the design process and visits generally involved less skipping of neighboring steps. The ME senior design students spent more of their normalized time working on Brainstorming / Design Concepts (step 3), Detailed Design / Communication (7), and Production (8), but relatively less time on Research / Testing / Analysis (4), Modeling / Prototyping (5), and Model / Protype Evaluation (6).

Differences in freshman versus senior application of the design process are likely the result of differences in project scope and student experience and advancement.

VI. FUTURE WORK AND CONCLUSION

Aerospace and Civil engineering senior capstone design data collection is planned during the 2013-14 academic year, as is a faculty Delphi study derived from existing faculty survey data to further refine faculty input. The Delphi study will address faculty impressions of student design activities and faculty expertise regarding the most important areas of student focus within the design process and the key process iteration loops to emphasize. This information will be gauged against actual student design activity. Although the survey was changed once and the input and opinions of the students are different every semester, it is important that the survey be adopted on a semester-to-semester basis to better suit varying groups of students. The data collected support programmatic monitoring, improvement, and comparisons across engineering departments of experiential learning via application of the design process by engineering students. The findings were also included in relevant ABET accreditation materials.

ACKNOWLEDGMENT

The authors would like to thank the faculty of the Mechanical and Freshman Engineering Departments and faculty teaching the first-year design topics in EGR 101 for continuing to allow the authors to use their classrooms, survey their students, and survey the faculty themselves as well.

***Abstract*—Advances in technology have made possible the development of low-cost portable electronic instrumentation. Such instrumentation opens the door to new possibilities for hands-on pedagogy related to analog circuits and physics education. This workshop will introduce attendees to the Digilent Analog Discovery platform and pedagogies that have been developed for it. Attendees will see examples of and have opportunities to try activities that have been developed for undergraduate electrical engineering and high-school physics courses. All attendees will be given a memory stick that contains pedagogical materials and an opportunity to receive an Analog Discovery system free of charge.**

Keywords—active learning; hands-on activities; STEM; analog circuits; nonmajors; K-12 outreach

Goals of the Workshop

There are three primary goals for this workshop: 1) to demonstrate how active learning modules using portable compact electronic instrumentation can be integrated into undergraduate circuits and electronics courses for majors and nonmajors as well as into outreach programs for high-school students, 2) to discuss approaches to include active learning modules in lecture in the classroom or as hands-on homework assignments/projects, and 3) to provide supporting instructional materials that will enable participants to rapidly incorporate hands-on activities into their existing courses. Research on active hands-on pedagogy has shown that students are more engaged in learning, develop an intuitive understanding of key concepts instead of just memorizing facts, and gain self-confidence about their knowledge of the subject. The proposed mini-workshop falls under the FIE 2013 topic of research-proven classroom materials or processes for engineering, technology, and physical science education. The active learning modules will include examples that can be integrated into courses on energy engineering.

Description of Workshop Topics

Active hands-on learning pedagogy in electrical engineering, electrical engineering technology, and physics has been facilitated by the recent availability of inexpensive portable compact electronic instrumentation. This instructional approach has been shown to stimulate student interest in engineering, technology, and physical sciences and promote greater understanding of circuits and electronics, particularly in students who struggle when presented with abstract and highly mathematical concepts. Drs. Simoni and Meehan will present an introduction to the pedagogical approach that has been adopted at Rose-Hulman, Virginia Tech, and at high schools and other institutions of higher learning. They will describe the results from assessment of the impact of the active hands-on pedagogy on student learning that they and others have found that demonstrate the benefits of this educational approach. Drs. Simoni and Meehan will discuss several implementation models that have been used to integrate hands-on learning modules into various courses. Participants will engage in several activities from learning modules that have been developed for high school outreach to circuits and electronics courses for ECE majors and nonmajors. The design of hands-on activities, the value of supporting instructional materials, and methods to incorporate these activities into the curriculum will be illustrated through these activities. The instructional and learning materials that are available for free for educators and students will be described. Specific instructional scenarios, suggested by the participants, and techniques to address common barriers to adoption will be discussed.

Workshop Agenda

- Overview of Pedagogy **(10 minutes)**
- Example Learning Modules **(60 minutes)**
  - High School Physics
  - Circuits for Nonmajors
  - Electronics for ECE majors
  - Design Projects Integrated with PSpice and MATLAB
- Discussion on Integration of Hands-On Activities in Curriculum **(20 minutes)**
  - Available Instructional Materials
  - Supplemental Tutorials

Take-Away Skills, Knowledge, and Material

Participants will learn about the active hands-on learning pedagogy, see how others have integrated hands-on learning modules into the engineering, engineering technology, and physics courses, and suggestions on ways in which the participants can adapt the pedagogical approach for their use. Flash drives will be distributed that will include the workshop presentation, files with links to online learning materials that include textbooks, procedures for hands-on activities and design projects, tutorial videos, and other materials geared towards circuits and electronics. Participants will receive a

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

card that can be returned at the Digilent booth at FIE 2013 to receive a free Analog Discovery portable analog circuit design kit. Participants may elect to join the online community on active hands-on learning hosted by the Center for Mobile Hands-On STEM, which will be launched in Summer 2013.

THE ANTICIPATED AUDIENCE

The anticipated audience includes faculty members, instructors, and laboratory staff in Electrical and Computer Engineering and Engineering Technology, Mechanical Engineering and Engineering Technology, First Year Engineering Education, Engineering Physics, Physics, and middle and high school teachers in the physical sciences. The maximum number of attendees is 25.

QUALIFICATIONS OF THE PRESENTERS

Kathleen Meehan, PhD, is an Associate Professor in the Bradley Department of Electrical and Computer Engineering at Virginia Tech. Kathleen earned her BS in Electrical Engineering from Manhattan College and her MS and PhD from the University of Illinois. After working in industry, she moved into academia full-time in 1997. She is involved in curriculum development and educational research as well as the growth, fabrication, and packaging of nanoscale and microscale optoelectronic devices. Since 2003, she has collaborated with Dr. Robert W. Hendricks to develop an instructional platform known as Lab-in-a-Box with the assistance of more than 50 ECE students[1].

Mario Simoni, PhD, is an Assistant Professor in the Electrical and Computer Engineering Department at Rose Hulman Institute of Technology (RHIT). Mario earned his BS in Electrical Engineering from Park's College of St. Louis University and his MS and PhD from Georgia Institute of Technology. At RHIT, Mario has taught a range of classes ranging from introductory level to advanced graduate level. His research interests include improving learning in introductory linear systems courses, analog and RF integrated circuit design, and outreach activities for high-school physics education. He has presented papers at ASEE and FIE and published papers in various IEEE Transactions journals[1][3].

***Abstract*—Women of all colors are underrepresented in most technical disciplines. For example, electrical engineering college graduates have comprised only about ten percent women for many years, and computing graduates only about eighteen percent women, down from about thirty-five percent in the mid-1980s. Gender stereotypes and stereotypes about creators of technology contribute to this underrepresentation. Nevertheless, these prevailing conditions can be overcome to a substantial degree by actively recruiting diverse female students. This panel session will provide an introduction to the reasons for active recruiting, methods for successful active recruiting, examples of effective applications of the recommended methods, and resources to help participants as they attempt to actively recruit underrepresented students to their courses. The panel's focus will be on computing disciplines, but the information applies to other technical disciplines as well.**

Keywords—recruit; diversity; computing; Tapestry

I. Goals of the Workshop

The goal of this workshop is to motivate and explain active recruiting of female students into technical classes. The presenters will explain why it is important to recruit actively from underrepresented groups, and they will give examples of successsful recruiting into computer science at the high school and college levels. Sufficient information will be provided for participants to increase the number and diversity of students in their technical classes.

II. Description of Topics & Agenda

A. *Why actively recruit females*

This topic will cover data showing the lack of diversity in computing and how high school and college contribute to this problem. The presenter will explain how active recruiting can help alleviate the problem and provide the key research-informed ingredients.

B. *A spectacular example of effective recruiting*

A charismatic high school CS teacher will describe how he went from an award-winning teacher with 35 students, 12% girls in AP CS to more than 300 students, 40% girls by creatively applying research-informed recruiting advice.

C. *A modest example of successful recruiting*

Recruiting is more than signing up students. In this session, a high school teacher will describe the broad changes he made to attract more diverse students.

D. *Recruiting through the intro course*

This topic will describe the key ingredients for converting students to CS majors through the introductory course.

E. *Summary and Discussion of main points*

The final five minutes of this session will be dedicated to answering remaining questions and considering any necessary adaptations for different disciplines and institutions.

Questions and discussion will follow each presentation.

III. Knowledgeable Presenters

J. McGrath Cohoon is a Senior Research Scientist at the National Center for Women & IT (NCWIT), and Associate Professor of Science, Technology, and Society at the University of Virginia. Cohoon conducts nationwide empirical studies of gender and computing. Her results are reported in scholarly journals and an award-winning book, co-edited with William Aspray – Women and Information Technology, Research on Underrepresentation. Cohoon's work at NCWIT involves conducting, translating, applying, disseminating, and evaluating research. She also serves on the CRA-W Board, offers professional development to computing high school teachers, trains and supervises consultants, and collaborates on increasing women's participation in volunteer computing. Cohoon presents twice at every Tapestry Workshop conveying information about the why and how of active recruiting. She also offers a resource designed for use when informing others about the importance of a computing education.

Jim Cohoon is a Computer Science professor at the University of Virginia. He is a co-founder and organizer of the Tapestry Workshop initiative. He has received IEEE Computer Science highest education award in recognition of his sustained efforts in Computer Science diversity. He is the author of several award-winning introductory textbooks. He has designed and implemented his Department's three-pronged approach to introductory computing so that it maximizes the interest and abilities of all students. He is a strong proponent of active and group learning. His other research interests include swarm robotics, VLSI physical design, routing, and free flight. His interdisciplinary approach there applies and extends nontraditional techniques such as computational geometry, probabilistic search, genetics, and parallel computing.

Seth Reichelson is a Computer Science an award-winning high school teacher in Lake Brantley, Florida. He has achieved national recognition for his approach to high school computing

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

courses in general and AP Computer Science in particular. His efforts in the recruitment, retention, and teaching of a diverse student body currently attract about 1/10th of all the students at his school. About 39% of his students are female. His numbers along with the pass rate of his students makes him one of the USA's most successful AP instructors. Seth is a frequent presenter at Tapestry Workshops. Attendees consider his talks a very important part of the workshops.

After attending the Tapestry Workshop in last summer, Selwyn made a number of changes, including more welcoming room décor, keeping girls together for group project, more hands-on engaging lessons, explaining the opportunities available with a computing career. All of his changes made instruction and learning better for all students. His enrollments increased modestly for female, African-American, and Hispanic students, despite a new school requirement that diverted many of his potential students for one year.

IV. Anticipated Audience

Anyone interested in diversity in technical disciplines, but especially high school and college educators, will be interested in this workshop.

V. Materials Provided

Each participant will recieve multiple copies of materials from the National Center for Women & Information Technology. These high-quality materials are professionally designed for visual appeal and written for research-based and field-tested practical advice by scholars of gender and computing. The materials include Talking Points cards in English and Spanish for explaining to young women why they should learn computer science; a workbook for planning coordinated recruiting efforts; data about the current gender imbalance in computing and the predicted shortfall of skilled professionals, for example.

Pastoral Care and Student Support: Developing a Method of Retention

Craig A. Watterson, Dale A. Carnegie
School of Engineering and Computer Science
Victoria University of Wellington
Wellington, New Zealand
craig.watterson@vuw.ac.nz

Abstract—**The transition from High School to first year Engineering at University can be very difficult for many students. Victoria University of Wellington, New Zealand (VUW), developed an early warning system for student grade performance: Big Sister, and a system of Pastoral Care within the School of Engineering and Computer Science. This paper will discuss how Big Sister supports the identification of at risk students and how this system is integrated into the delivery of effective Pastoral Care. Importantly, this paper will also discuss the information gained from student interviews by the Pastoral Care staff member. In particular, we discuss the findings in relation to student self-efficacy and success and how this is being used to improve the first year teaching and learning environment.**

Keywords- engineering retention, pastoral care, student support, teaching and learning

I. INTRODUCTION

The Bachelor of Engineering (BE) at Victoria University of Wellington (VUW), New Zealand, is a relatively new degree which recently received full Washington Accord accreditation in 2012. This BE has specializations in Electronic and Computer Systems Engineering (ECEN), Network Engineering (NWEN) and Software Engineering (SWEN). The BE programme is the outcome of support from the New Zealand Government which has targeted funding for tertiary engineering programmes to increase the number of tertiary qualified engineers to meet industry demand.

The majority of students gain entry to the BE having passed through the National Certificate of Educational Achievement (NCEA) system which operates throughout New Zealand High Schools. Potential engineering students are required to have moderate final year grades in High School calculus and physics.

Students are required to obtain an above average B grade (65% or above) over their core first year engineering subjects in order to progress further with the BE. Since its introduction in 2007, the BE programme has had a 60-70% failure rate of students not achieving this B average in their first attempt.

In 2009, the New Zealand Government funded a project at VUW to investigate the barriers to success and retention for first year university engineering students. The project conducted grade analyses of High School results, VUW course marks, student focus groups, surveys and curriculum analyses. This project uncovered that much of the failure could be attributed to poor academic preparation by students entering the BE directly from High School. The project also identified a disturbingly poor level of engagement by students with the numerous available support services, and poor engagement with first year courses.

To reduce the high attrition rates and improve student engagement, the School of Engineering and Computer Science (SECS), developed several key initiatives.

A significant development was collaboration with the Te Rōpū Āwhina whānau (Āwhina) programme in the creation of "Big Sister", an at risk student early warning and progress system. The paper will explain how Big Sister fits into the overall student academic performance analysis at VUW and how it allows our pastoral care staff member (a position created in 2012) to identify at risk students through poor grade performance across their first year courses. Pastoral care in our context refers to the efforts made by our staff member to directly contact students and meet with them to discuss any difficulties they may be facing and offer guidance and support. These interviews often lead to follow up meetings throughout the study year.

Crucially, this paper will then detail the findings and solutions developed as a result of the information gathered by the pastoral care interviews with students identified through Big Sister. Importantly, these interviews have some limitations as research data since they have produced what amounts to field notes resulting from the 50 minute intervention interviews, with the primary task of the interview to assist the student rather than gather research data. The interviews notes are taken by hand and shown to the participants during the interview but are not audio recorded and transcribed and then coded for emergent themes as is the case in many qualitative studies, such as the commonly used grounded theory [1]. That said, the interview notes were examined for comparative and consistent themes.

Despite these limitations the interviews have revealed many possible factors affecting student progress, for example, student and teacher teaching and learning behavior in High School

NCEA, coupled with generational factors makes the university's reliance on NCEA as a method of entry assessment criteria for engineering students problematic. Student self-efficacy, or belief in their own ability to succeed, a crucial factor in continued success, can be falsely high as a result of the NCEA assessment criteria and actually form a barrier to student success when they are faced with difficult first year courses.

These findings have been a major contributor to the review of the first year BE programme and have influenced a significant redesign of first year mathematics and engineering courses.

II. Context

To explain Big Sister it is important to understand the context in which it functions as part of the overall work undertaken at VUW to investigate and resolve factors affecting student academic performance. The overall aim of conducting Student academic performance analyses and associated pastoral care at VUW is to:

- Further our understanding of barriers to students in achieving the B average required in first year core courses
- Accumulation of student performance data and trends
- Offer course advice and assistance to students experiencing difficulty in achieving the mandatory B average across core papers first year
- Activate student engagement with support services

Student performance analyses of students during their first year of study at VUW has two main aspects: Immediate analysis and On-going analysis. The first, Immediate analysis takes place within the first two weeks of a student beginning the BE. In the students' first week of classes we conduct Mathematics and Physics Diagnostic Testing. This takes the form of a one hour test. Currently this is only for ECEN students and is primarily used to give students Math and Physics course advice as soon as possible and redirect students into courses more appropriate for their ability.

The diagnostic also functions as a 'wake-up call' activating student engagement with the reality of course demands in the first week of study. The main issues with the diagnostic test is that no comparable test exists for the NWEN or SWEN students whose pathway does not automatically include the stringent physics or mathematics of the ECEN major, but rather includes a large amount of programming courses which the students have no preparation for at Secondary School.

In addition to the diagnostic test, by the end of week two, we obtain a full grade and performance report that details all engineering students' NCEA final year results. A student's final year NCEA results are the main university measure for student entry to the degree. From our earlier analysis these have no 'real' predictive value [2]. However, they do often form a background of a student's 'potential' ability in first year tertiary papers and when combined with an ECEN student's diagnostic test result does form a partial predictor of student success in Part I. Yet, as already reported, this is statistically too small to be used as a stand-alone method [2]. NCEA remains the only form of student academic background available for SWEN and NWEN students.

Students who received marginal to low marks in the diagnostic and those who appear to be lacking in NCEA physics and mathematics at level three are invited to attend a Pastoral Care interview and a study plan is discussed and the student is made aware of suitable help available at VUW.

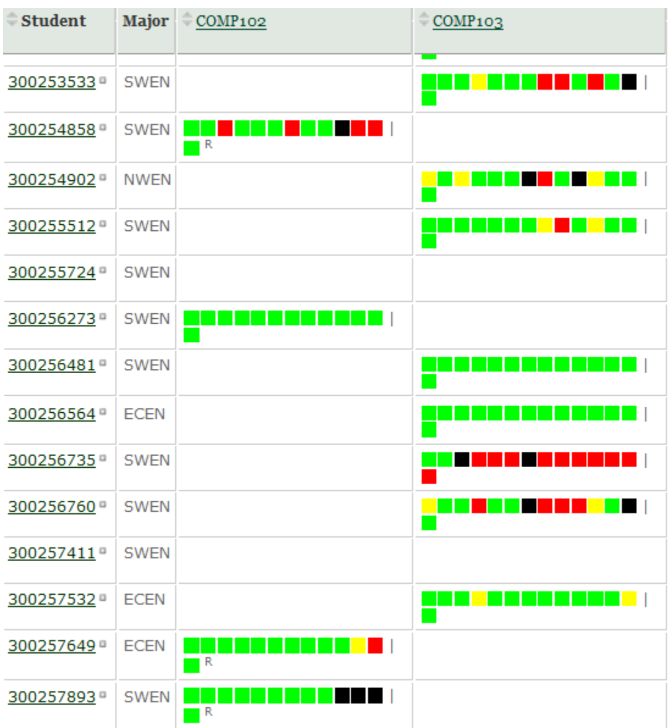
After conducting the Immediate analysis and as students begin to get immersed into trimester one, we begin On-going analysis. On-going analysis has several key aspects:

- Student surveys of first year engineering students conducted at the start and end of the study year
- Collection of Big Sister grade data, identification and contact made with at risk students
- Analysis of at risk student interviews
- Follow up interviews with students who have been seen and results incorporated into analysis
- Continuation of the grade data comparison between NCEA and performance in first year courses

III. Big Sister

Big Sister forms a major component of the On-going analysis and is a means of identifying students who perform poorly. It is a database reporting system which gathers student assignment and test grade data from all course coordinators in the first year of the BE in near real-time.

Picture I. Snapshot of Big Sister



On the screen the student's results run across all of their first year courses (not shown here). For each student, results are displayed to the right of the student ID number. In this instance some students are shown doing COMP102 and COMP103, two first year programming courses. The boxes represent individual assignments, tests or labs results and are color coded. Green is a good pass, yellow a marginal pass, red is a fail and black is where a student has not submitted the work. These can be read in this format or in a grade weighted format. This system also allows subcategories such as individual courses to be examined and also allows for a comparison at a glance of the class performance.

During the creation of Big Sister one of the main challenges we faced was obtaining permission to access the grade data from course coordinators. The first year of the BE is taught across several departments such as Engineering and Computer Science, Mathematics and Physics. Despite gaining ethical approval from the University Human Ethics Committee many course coordinators were of the opinion that the student data still had confidentiality issues and remained the 'property' of the relevant course coordinator and department.

After two years of negotiation this issue was resolved in 2012 and Big Sister could begin across all courses relevant to the BE in first year.

A second major challenge in setting up Big Sister was obtaining the data in a timely manner. The university system does not dictate the manner in which course coordinators store course grades until all grades are finally transferred to the VUW grading database. For example, we encountered lecturers who stored grades in excel spread-sheets, moodle grade books, and on the Blackboard grade system. As such, a staff member must import the results into a common format for uploading to Big Sister. This slows the availability of timely grade data.

In addition, the assignments and tests have to be marked within a short timeframe in order to enable the pastoral care staff member to contact the student and begin assistance. In practice some course coordinators are better than others at providing speedy data. A major outcome of this knowledge has been a new SECS policy from the Dean and Head of School for marking to be conducted at the latest within a two week turn-around.

The Big Sister data report now gives us relatively (within one-two weeks after a grade has been given) up-to-date information enabling us to identify at risk students by examining grade performance across all the courses an engineering student is doing.

After a student is identified as being at risk, the Pastoral Care staff member contacts the student with an offer of assistance and an interview. This is done via email or by phone, and if necessary severely at risk students can be contacted at labs or tutorials.

Students attending the (up to 50min) interview are asked to sign an ethics form allowing the Pastoral Care staff member to record, in note form, the details of the interview. The notes are written in full view of the student and the student is asked to read the notes at several stages throughout the interview and make any changes they feel comfortable with. If a student does not sign the form the interview goes ahead without notation.

The outcome of this interview usually results in students being given advice and appropriate support service and encouraged to use it. Some of these support services include, Āwhina, Student Learning Support Service, Peer Assisted Study Support (PASS) Scheme, Tutorials, the Lecturer, Course Coordinator or Dean of Students. In some cases student counseling, disability support and student health may be contacted.

IV. Interviews

Throughout trimester one, 2012, the pastoral care staff member interviewed over 80 students deemed 'at risk', with 60 agreeing to have information recorded in note form, of 152 first year BE students. An 'at risk' student in this case was a student who showed continued poor performance or who suddenly declined in performance in one or more courses. These interviews produced information on student attitudes and abilities. These themes were grouped together and a selection of common themes, those that occurred in over 80 percent of the participants interviews, identified. Common student interview themes were:

- A belief they are academically prepared by High School for Tertiary study
- A belief that NCEA assessment at High School was easy
- A huge workload increase from High School
- A disconnect with Math, Physics and Engineering lectures, both in content and style
- A lack of understanding about what engineering at VUW is and what subjects are required to study it
- Teaching (lecturing) style very different to School across all of university
- Assessment is completely different from NCEA
- A new realisation that they are not prepared but lacking the motivation to remedy
- A lack of desire to put the work in if it does not interest them
- Computer Science first year courses perceived as hard but more interesting and gets more study attention
- "Game-playing" course work to achieve a pass
- Students perceive of themselves as lazy – but justify this by claiming boredom with courses-material and lecture style
- Students are not comfortable (fear) accessing support help - its help designed for 'our' system
- They are stressed with non-academic issues which compete on an equal footing for their attention with course work

Conclusions gained from the pastoral care interviews point to 'huge' differences between the expectations we have of students and those they have of us, academically, environmentally and behaviorally. It must be emphasized that we can only indicate conclusions for this particular group of students based on their self-reported perceptions and viewpoints.

Students believe the NCEA teaching and assessment system they have experienced prior to university is the norm and for many of these the lack of motivation and transition difficulties could be attributed to patterns learnt while studying NCEA.

A recent study of NCEA noted:

- Teachers and parents were positive about the overall impact of NCEA on many students, particularly those who were low achieving.
- Teachers and parents felt that high achieving students would work hard no matter what.
- Teachers and parents had concerns that some aspects of credit accumulation and assessments could motivate students to "do just enough" rather than do their best.
- Teachers and students were concerned about the possibility that assessment could drive teaching and learning rather than the curriculum.
- There was some concern by teachers that assessment could fragment subject understandings in some areas where integration, synthesis and/or evaluation across standards were seen as critical [2].

While it is clear that not all students struggle in the transition to university, our poor pass rates indicate a widespread problem and it is possible that the NCEA system is not adequately preparing potential tertiary students for the level of motivation for academic success or independent learning style, presumed by the manner of teaching at VUW.

University engineering, mathematics and physics (all core first year BE) courses at VUW predominantly revolve around students attending lectures taking notes and then attending labs or tutorials where the emphasis is often on completing assignments and going over lecture material. The teaching component of these classes as it relates to personalizing the learning environment is low and in many cases non-existent. Motivation is also generally left to the student with the assumption similar to that mentioned above: '…high achieving students would work hard no matter what' [3].

Our 'teaching' and learning environment/culture does not always help. It is designed for our perception of teaching that fits into one of Ramsden's pervasive tertiary teaching myths that: '[teaching] consists in presenting or transmitting information from teacher to student, or demonstrating the application of a skill in practice; and that students in higher education must not be too closely supervised, lest the bad habits of dependent learning they are supposed to have acquired at school are reinforced' [4]. Ramsden makes the further salient point that: 'It is said in support of this myth that able students understand and apply the skills and information they have been exposed to. If the rest don't learn, they have a difficulty that the teaching cannot be blamed for; after all, they are in higher education now' [4]. Statements of similar content can be heard throughout meetings of academic staff at VUW.

Zepke's research into student perceptions revealed that out of the three factors affecting students' success; 'teaching, motivation and external influences, teaching is the most important'[5]. Yet Zepke, argues that while teaching was the most significant factor, that understanding student engagement was not that simple and was always a complex interplay between teaching, motivation and external influences and as such it is difficult to point to only one factor as the pre-eminent causation of poor student academic performance. Zepke describes the findings of the research in an interesting manner:

- 'Student engagement is complex. It comprises nodes (e.g. teaching, motivation, external influences) clustered into larger nodes (e.g. student engagement) clustered yet into larger nodes (e.g. research orientations). Each node is understood as a network in its own right linked to other node networks. This means that teaching, motivation and external influences each form a complex network connected with every other node in the system. Simultaneous connection and distinction is a feature of this network.
- Since teaching, motivation and external circumstances are distinct, these nodes can be investigated separately and compared. But researchers need to be aware that by doing so, they are not taking into account the simultaneous connections between these nodes and therefore they are oversimplifying the results.
- The finding that teaching is more important than motivation, then, cannot be taken at face value. While useful, it neglects the complexity that underpins the relationships between these terms' [5].

Importantly this leads to the conclusion by Zepke that there are many nodes or node networks beyond those listed above affecting student engagement. The pastoral care interviews point to NCEA as a node potentially affecting student performance. Another significant node was a lack of understanding about what it was they were going to study in engineering at VUW. This confirmed much of the work done by the Engineering Pathways Project at VUW [6].

The more we investigated retention issues the more it became apparent that the complex interplay of factors, or as Zepke describes it nodes, makes any single solution problematic in terms of effectiveness across the whole student cohort, which in turn increased the importance of targeted individual pastoral care. For example, an interesting finding of the interviews was the unwillingness to access help or support services when students found themselves in a difficulty node. This node then has a network of related causes. Students expressed a general reluctance to access help stating comments such as, 'I thought I could catch up', or 'I didn't think I needed any help'. Other student comments included a general acknowledgement of fear in accessing help. This was related to a general perception of help indicating that they were academically inferior to their peers and also fear of being part of a ‘help group’, preferring anonymity. Awhina support was largely rejected by our predominantly male students of European descent who felt put off by the Maori and Pasifika face presented by Awhina.

The interviews and the intervention of the pastoral care provides access to the complex node networks allowing for immediate connection with the individual student regarding their difficulties and also allows for some broader understanding of common barriers across the main student cohort.

V. OUTCOMES

While it is difficult to directly attribute the pastoral care interviews with student improvement we believe these interviews resulted in some positive outcomes for student engagement in the core engineering paper Engineering Fundamentals (ENGR101). Feedback was given to the course coordinator throughout the process of the interviews and subsequent changes were made in the structure and teaching of the course [7]. Many students who had attended interviews showed a grade improvement in the weeks following the interviews. Overall, the results were that the pass rates significantly improved from 52% of the students gaining a B or greater in 2011 to 63% in 2012.

At least 20 students changed their major or degree as a result of the pastoral care interviews to better suited educational pathways.

In addition, there was a significant increase in the uptake on accessing ‘help’ in the Peer Assisted Student Support (PASS) Scheme. PASS groups are study groups run by a good student who did the course the previous trimester. These have been run successfully by the Student Learning Support Service at VUW for many years in several faculties. In 2011 Engineering set up a PASS group for Math 151 (an introduction to linear algebra) and had a poor uptake, with only 2 students out of the 58 enrolled in MATH151 attending PASS. This suggested that students were poor at accessing help and reluctant to take independent responsibility for their own learning.

With the advent of a Pastoral Care staff member in 2012 we saw an increase in the uptake of students attending PASS groups for MATH151, with 28 students out of 64 attending. The academic results of PASS were however disappointing with only 6 out of 28 students (21%) receiving a B or better grade for Math151.

Feedback from students attending the PASS group indicated that it was not assisting in developing increased mathematical ability in the attendees and focused on solving tutorial or assignment questions. PASS groups are led by a student who has done the course within the previous couple of years. As such, we had great difficulty in obtaining PASS leaders who had sufficient knowledge of math to answer difficult questions of the material and who also understood good teaching practice. PASS group leaders do undergo training and also have access to mentoring but we feel that a more experienced tutor would yield better results.

The 2012 end of year grades have been received and the results have improved. Table I below details the data collected on first year students’ progress with Part One of the BE over its first six years. The numbers represent actual first year students in calendar years so all students starting in trimester two will show up as an earlier student when they complete. In 2012 the number of new entrants completing Part One in their first year is up 46% on the best previous year and a corresponding increase in grade average performance with 40 students achieving an A- average. There is also a substantial trend of students now completing in their second year.

Table I. Student Performance in Part One of the BE
2007-2012

	2007	2008	2009	2010	2011	2012
Students completing at least one Part One course	104	92	111	120	108	172
Students completing all required courses for their Part One major.	40	40	54	48	42	72
Students passing all required courses for their Part One major	23	22	31	36	26	54
Students achieving a GPA ≥ 4.5 in their Part One courses	38	46	46	54	42	77
Students achieving a GPA ≥ 6.5 in their Part One courses	18	20	18	33	13	40
Students passing Part One	22	21	31	35	25	51
Earlier students completing Part One.		9	18	14	21	23
Total students completing Part One	22	30	49	49	46	74

In addition, we have made steps to disseminate our findings and actively involve lecturers and support staff in the challenges we face. This has led to a gradual interest across the faculty. The interview findings have also been the subject of several seminars at VUW.

One of the major outcomes of the Pastoral care interviews and Big Sister programme has been an informed motivation to revamp first year engineering, mathematics and physics papers to meet student expectations and academic ability. Suggested changes include the complete overhaul of the core mathematics courses currently taught by the mathematics department. The proposed change aims to introduce three papers that have as their principal concept the belief that the course must be interesting and show engineering relevance to students through project based learning.

Alongside the proposed changes to first year papers already mentioned, the School of Engineering and Computer Science has recently (at the time of writing) received approval to appoint an additional academic staff member to assist directly in the teaching of first year papers and a tutor to assist in developing 'new' tutorials in support of difficult first year courses. It is also planned that this tutor will run one-on-one and group sessions for students identified through the pastoral care. Discussion has been active on whether these tutorials should or could be compulsory.

While we are confident in the success of the intervention of Pastoral Care and analysis provided by Big Sister we realize that we have a long way to go. Many questions remain:

- How do we educate the students in what is required at university in first year without using the sink or swim approach?
- How do we increase the pass rate without decreasing the quality of students progressing?
- How do we 'more' get students to attend currently available help?
- How do we get students to take responsibility for their own learning?
- How do we get 'all' lecturers and courses engaged in pedagogy and improving the teaching and learning experience?

It is hoped that in the future we will have the answers to some of these questions and be able to report further on developments made. We also look forward to any feedback from the conference participants on how we might continue to improve our support.

Student Perceptions of Cheating in Online and Traditional Classes

Stephen W. Turner and Suleyman Uludag
Department of Computer Science, Engineering & Physics
University of Michigan - Flint, Flint, MI 48502, {swturner, uludag}@umich.edu

***Abstract*—With classroom instruction undergoing a massive transformation to incorporate online learning techniques at unprecedented levels, technological advances have facilitated a range of mechanisms that improve teaching and learning. At the same time, these technological advances have also facilitated different forms of cheating in classes.**

Although the impact and implications of cheating have often been studied, we feel that this problem experiences constant evolution, and the dynamics of cheating, especially in online courses, needs more examination to be fully grasped. The study presented here surveyed computer science, computer information systems, and engineering college students, with the goal of gaining a greater understanding of their perceptions, beliefs, and attitudes about the many dimensions of academic integrity violations. Results of this survey, coupled with statistical analysis and some conclusions, are presented.

The impact of our popular Virtual Lab (VLAB) facility is also examined in this context, and it is found to make a positive difference in student attitudes about cheating in classes.

I. Introduction

Technological advances open up many new directions, opportunities and paradigms to augment and improve the learning experience. In particular, classroom instruction is now undergoing a massive transformation, with the increased adoption of research-driven instruction methods, experiential learning, and online learning. With a bona fide approach by both instructors and students, there is no doubt that all will benefit. At the same time, many of the technological advances that help to improve pedagogy have also facilitated different forms of cheating in classes. Like never before, cheating has become easier and ubiquitous. In this Internet age, it has become almost too tempting for students to examine and experience behavior that can easily fall under the category of academic integrity policy violations.

Educators, university administrators, parents, and the general public are getting more concerned about the impact and implications of students cheating while earning college degrees. In this study, we have surveyed college students with the goal of gaining greater understanding of the many different dimensions of academic integrity violations. Another goal is to reveal some preliminary delineation of gray and white zones from among generally agreed-upon clear academic integrity violations. As part of the study, we have sought students' anonymous and candid responses related to the acceptability of cheating in different life and social settings, as well as in the classroom, together with their awareness and perception of such behavior. We believe that our study is a contribution toward understanding the extent of today's students' exposure, awareness, and perception of academic integrity violations.

We surveyed students who had participated in a variety of different computer science and engineering classes on our campus, with a secondary goal of examining the impact of our popular Virtual Lab (VLAB) environment's effects on our students' tendency toward cheating. We present VLAB as a concrete example to examine possible correlations between technological change in delivery (or online teaching in general) and any manifestations of integrity violations by students.

The rest of the paper is organized as follows: Section II presents background and related work. The details of the survey with question categories are provided in Section III. An assessment and analysis of the the survey results are given in Section IV. Section V contains a summary of the conclusions and future work.

II. Related Work, Background

The definition of cheating in online or traditional (in-person) classes may be interpreted imprecisely by students and instructors. Instructors will have different definitions/interpretations of what constitutes cheating, and in the absence of a clear definition, students are free to draw their own conclusions. In this age of instant Internet access, many have grown accustomed to various types of dishonesty without considering their moral or legal ramifications. For example, consider the situation of a person who is otherwise honest but who downloads copyrighted content from the Internet without paying for it. It seems reasonable to imagine that, due to the lack of a clear framework or definition of "right and wrong" on the Internet, such a person might make a relatively short moral leap into cheating in online classes.

In society, there are various potential definitions of cheating: in most sports, cheating is considered to be part of the game and acceptable behavior - as long as the player is not caught. For example, one might consider stealing a base in baseball to be a form of cheating, except that it is allowable within the rules. A better example might be that of committing a minor violation, such as holding, in American rules football, without getting caught by the referee. Most sports typically write off instances such as this; the game moves on and the incident is usually forgotten. Additionally, penalties for such behavior (when caught) are swift and well-defined, but they are also relatively minor in most cases.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Other forms of cheating also have varying levels of punishment and societal views on how bad they are. It may be informative to consider whether it is acceptable to cheat on taxes, on a spouse, or in an online video game. In fact, a quick survey of literature finds considerable work examining cheating in online video games, for example [1], [2], [3]. The precise definition of cheating is often contextual. Even in academic activities, its definition may depend completely on an explicit agreement between student and instructor. Other work also supports the notion that the context of cheating is related to how it is perceived in society. Bowyer [4] argues that in war, politics, and espionage, cheating is pervasive and expected.

There have been numerous studies related to the concept of academic cheating, whether online or not. We primarily focus here on work related to cheating in online mode classes, in terms of the approaches to take to deal with it in prevention and/or detection. These can be roughly classified into several different approaches: cultural/social/attitudinal; embedding structural mechanisms into courses; educational approaches; and technical approaches. Additionally, there is considerable literature studying the precise forms of cheating and student motivations to cheat.

A comprehensive set of definitions of cheating behavior, for traditional classes, is presented in [5]. This presents various forms, in which students cheat on homework assignments, as well as in online, in-person and take-home exams. Other definitions include *e-cheating* techniques, such as accessing websites, instant messaging, email, seeding test computers with answers, and using non-exam disks containing exam answers [6]. Ramim [7] provides an overview of the common aspects of academic misconduct and proposes a standard definition based on the findings of a study, for online learning environments.

Motivations for cheating are explored by several authors [8], [9], [10]. In particular, Harding et al. [9] present a fairly comprehensive survey of past research on student motivations. The work of Carpenter et al. [10] also identifies implementations of student-suggested techniques to deal with it. In general, the research shows that extrinsic motivations, such as pressure to succeed academically from various sources, are among the more commonly cited reasons for cheating. The research highlighted by Novotney in [8] also shows that students who cheat tend to adjust their morality to fit their circumstances. In other words, behaviors that may have formerly been incorrect are later justified, once they have been done.

Cultural mechanisms are also presented by Novotney in [8]. These include facilitating community feelings of disgust at cheating behavior, greater education in the classroom about academic integrity, and more student engagement. Other means of improving culture are studied by Broeckelman-Post in [11], in which it is reported that effective engagement with students, as well as more in-depth discussion of cheating behaviors and expectations, can have a significant effect on deterring cheating. An approach to defining cheating that also uses cultural/attitudinal factors is presented by Stepp and Simon in [12]. The authors asked students to define the act of cheating as it related to their own course assignments. Having the students take ownership in this fashion helped to facilitate a culture against cheating. Another study [13] presents an argument for education of faculty members, as it discusses approaches to educate new faculty members on establishing cultures discouraging cheating.

Other studies [14], [15] examined student and instructor beliefs on cheating and explored techniques to curtail it. Some effective techniques cited include improved learning objectives, group work, review sessions before exams, and building a good rapport with students.

There are many studies examining technical approaches. Webley [16] presents a discussion of the potential for cheating in Massively Open Online Courses (MOOCs), discussing approaches to deal with it, including the use of honor codes, high-tech remote proctoring, and giving unique exams, with a focus on the exams themselves as potential solutions. The study focused on the use of the course's exams, coupled with anti-cheating measures, to determine whether a student receives credit. Various authors present technical approaches that focus on exams themselves, whether they are online or in-person [17], [18], [19], [20]. These may include problem randomization, encryption of questions/answers, imposing time limits, the use of laptop-installable exam software such as Secure Exam Environment (SEE) [19], and even mobile technologies for smart phones [20]. Others [21], [22] present work on remote proctoring mechanisms (aka remote invigilation), in which networks of computers connected via web cam are used, as well as the possibility of image processing. Frank [23] also presents a framework and a risk analysis of *dependable distributed testing* with a classification of seven types of risks encountered in taking exams in online classes.

Some other technical mechanisms, such as identity verification, IP address verification, and pedagogical methods (e.g. video interactions with the instructor) are highlighted by Lepi in [24]. Others include anti-cheating software, such as Moss, TurnItIn, WCopyfind [25], [26], NetSupport [6], and Quenlig [27], which is a generic questionnaire assessment tool with built-in cheating detection mechanisms. Some solutions simply involve denial of access to the Internet [28], although this solution primarily applies to in-person and not online classes. Burlak et al. [29] proposed the use of data mining techniques for detection of cheating in online student assessment.

Other approaches include mechanisms for automated assignment individualization [30], with the goal of encouraging peer teaching rather than cheating behavior. The use of steganography has also been proposed [31], in which voice samples are embedded into an exam paper at regular intervals, to ensure safe and correct authentication of exam participants.

Structural mechanisms can also be effective deterrents to cheating. For example, McCloud [25] describes a class in which, aside from a mid-term exam administered in a monitored situation (i.e., proctored), cheating was essentially impossible because there were no other summative assessments, and all students had access to the same online files. Other mechanisms, such as centralized testing locations, strict timing of online exams, and using course management software to set up password-protected areas for each student, are cited as not working well [26]. For example, requiring online students to take exams at centralized locations is difficult to implement for all online students. In contrast, Richardson and North [32] argue in favor of exam proctoring, citing it as an effective means for improving trust in online courses. They also argue that some technical mechanisms may be easily circumvented by simply having other students login for the ones supposed to be doing the work.

To examine the issue of trust further, many researchers argue that less technological solutions are the only effective means to deal with the issue of cheating in online courses. Trust and honor codes are one approach [26], [32], [33]. Simply making the courses more interesting and engaging has also been found to be an effective mechanism to reduce, if not completely eliminate, online cheating. Harding et al. [34] also highlight honor codes, as well as pressure to succeed, as strong factors influencing cheating behavior.

Other structural mechanisms appear to be enacted not specifically to discourage cheating, but the effect worked this way. In a paper on student peer reviews in an online class [35], Wolfe cites the student community as an effective countermeasure against cheating. Collaboration was acceptable, as long as the students gave due credit to the source. Wolfe observed that instances of outright plagiarism were detected and reported by the online student community, partly due to the structure of the assignments requiring students to examine each others' work.

Hanfer et al [36] argue that a systems approach, in which many different techniques are employed to create a unified "system against cheating" may be the most effective means of combating cheating. This may be the ultimate point of the ongoing research into countermeasures against cheating. Ultimately, the best deterrents involve using multiple approaches, ideally using all of the categories highlighted earlier.

We consider our approach to be a combination of several mechanisms: technical, structural, and cultural. Its technical aspects involve the use of our *Virtual Laboratory (VLAB)* facility to accomplish laboratory exercises in systems and networking-oriented courses in a fully online fashion. These are performed by using virtual machines provided on a server that is accessible over the Internet. Further details of this approach are provided in [37], [38], [39]. The structural and cultural aspects of our approach involve our attempts to make our exercises highly engaging and interesting for the students, in such a way as to discourage cheating and to foster a culture of collaborative learning without cheating.

III. SURVEY

The survey was distributed online to a total of 756 graduate and undergraduate students in computer science (CS), computer information systems (CIS), and engineering. The total number of completed surveys was 88, including 66 from CS/CIS and 22 from engineering. Graduate students who responded to the survey attend a hybrid in-person/online Master's program in computer science and information systems, and they represented 34% of the respondents. Seniors represented 33% of the respondents, with the remainder of the responses evenly distributed among freshmen and sophomores. The number of female respondents was 20, with a similar distribution (freshman through graduate) as that of the overall population. Racial demographic information was not collected.

A. Categorization of Questions

We attempted to probe student views on a number of different categories of information with some embedded control questions at various points in the survey. The categories of questions asked included:

1) Notion of cheating in "every day life" situations: students were asked whether they felt cheating was acceptable in various "real-life" and academic situations; the questions attempted to probe their awareness of cheating by asking whether it was ever acceptable, as well as how often they felt it occurred.
2) Awareness and perception of cheating: students were asked a series of questions gaging their awareness of the university's academic integrity policy, as well as awareness/identification of cheating websites.
3) Definition of cheating in classes: students were asked whether various actions (e.g. copying work, getting information online, etc.) conformed to their definition of cheating. They were also asked whether and how they differentiated between cheating in traditional and online classes.
4) External motivations toward cheating: students were asked whether outside influences might affect their likelihood of cheating. These included the level of commitment to a class (whether it cost money, whether it meant something in terms of a degree or professional certification), as well as more commonly cited influences, such as lack of interest in the class, pressure to succeed, etc.
5) Instances of cheating: students were asked whether they had cheated, and how often. This was followed-up with similar questions specifically oriented toward the cheating in various categories of instruction: online classes, traditional classes, online exams/quizzes, and take-home exams/quizzes. In all cases, students were given the option of selecting "I haven't cheated" as an exclusive answer.
6) Motivations for cheating: as a follow-up to the prior categories of questions, students were asked why they had cheated in various situations, with the option of selecting "I haven't cheated" as an exclusive answer.
7) Moral views on cheating: students were asked a series of questions on how to deal with those caught cheating. Additionally, they were asked whether certain extrinsic factors would make them less likely to cheat.
8) Questions related to classes at the university: students were asked whether they had taken courses that use our virtual laboratory (VLAB) facility, including whether they felt the VLAB had been a factor in behavior that has been found by other researchers to discourage cheating activity.

9) Additional thoughts: students were invited to share any additional thoughts in an open-ended format.

The survey was implemented online, and many of the questions were dependent on others. For example, we only asked questions regarding online cheating if the students verified that they had completed online classes. This is similar for taking online exams, taking take-home exams, and the use of our VLAB facility. Consequently, the value of N varies in different categories of questions. The total number of survey respondents was 88, with varying response rates.

IV. Assessment of Survey Results

A. Survey Results

Figure 1 presents the results of the question in which students were asked whether the listed behavior constituted cheating, showing the percentage of students who agree. Several control questions were included to validate the data - i.e. to ensure the students were not confused about the definitions. The "non-cheating" activities primarily related to solution strategies or other activities that were not restricted in a class. Although all of the categories that represent cheating in some form had a large majority of students in agreement, there were some behaviors in which significant numbers of students did not perceive the activity as cheating, including: posting questions at web sites, reading instructor's manuals, watching videos that show answers, and sharing of answers with fellow students.

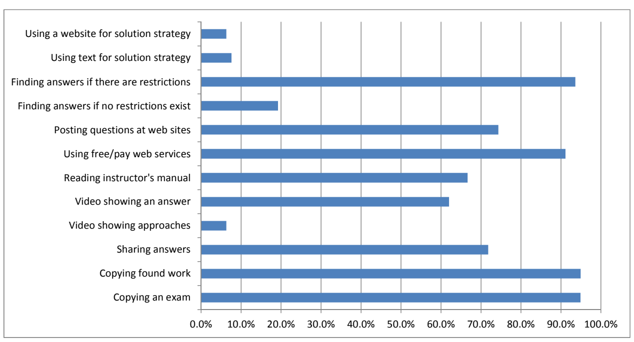

Fig. 1. Percentage of students who would consider cheating, given these factors.

Figure 2 shows the results of one question in which the students were asked whether cheating is acceptable in various social and academic situations (for $N = 64$). In all cases, the majority of students believe none of these are acceptable activities, but a significant minority responded in the affirmative as it concerns cheating in sports. That is, the question of whether some form of skirting the rules is acceptable. It is also notable that a relatively large percentage (24%) felt that downloading of copyrighted material off the Internet is also acceptable, at least occasionally.

As for comparison with student responses on their likelihood of actually cheating in an online class, we found no correlation for $r(60) = 0.211$, $p < 0.05$ (one-tailed). That is, although a significant percentage of the students felt that downloading copyrighted Internet content was acceptable, there was no correlation with attitudes on acceptable online cheating (responses illustrated in Figure 4). This lack of correlation does not apparently support the contention that students who do something viewed as illegal in one context will be more likely to cheat in class.

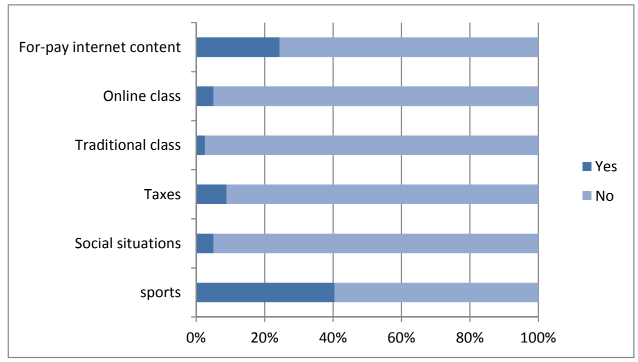

Fig. 2. Percentage of respondents believe cheating is OK in various situations.

Students were asked about their perceptions of the prevalence of cheating using a 5-point Likert scale (never, rarely, sometimes, often, always). Figure 3 shows the percentage of students who believed cheating occurs at least some of the time (i.e. rarely or higher on the response scale). The primary conclusion drawn here is that there appears to be a common belief among students that cheating is prevalent in many aspects of life and learning.

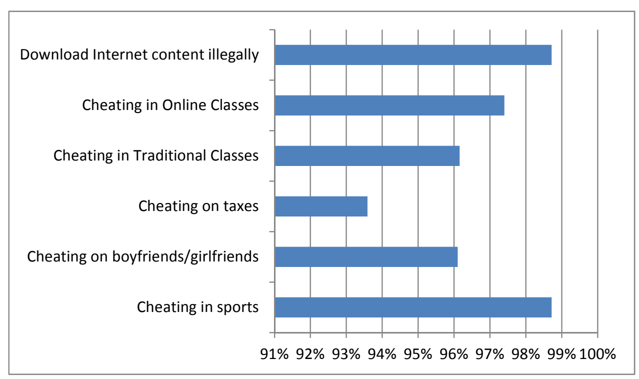

Fig. 3. Percentage of students who believe cheating occurs, at least sometimes.

As it concerns external factors that might lead them to cheat, we asked the students two categories of questions: whether the level of financial or professional commitment made them more likely to cheat, and whether various external factors made them more likely to cheat. In the case of professional commitment, the levels of commitment were defined to include free classes, inexpensive classes, typical college classes (costing hundreds of dollars to more than a thousand dollars), free professional certification classes, and paid-for professional certification classes. The level of commitment seems to present unremarkable information; between 43% and 54% of respondents felt that varying monetary and/or professional commitments would make them more likely to cheat.

Of more interest were the responses to the questions that asked them about external factors. Students were asked to rate their likelihood of cheating on a 5-point Likert scale (not at all, occasionally, sometimes, much of the time, always) based on various external motivating factors. Figure 4 shows the percentage of students who responded with a rating of at least occasionally, indicating they would be influenced to cheat at least some of the time, given these factors.

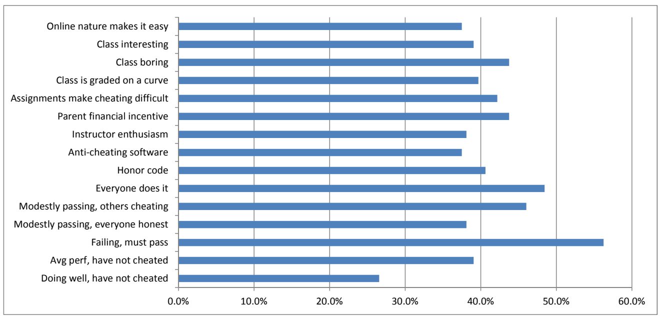

Fig. 4. Percentage of students who would consider cheating, given the listed factors.

The student responses to this question agree with results reported in prior research, which have found that certain external factors tend to encourage or facilitate cheating behaviors [26], [32], [33], [34] As they pertain to our survey, these especially include non-engaging (boring) subject matter, external pressures such as curved grading, pressure to succeed, and the idea that "everyone else is doing it". Additionally, the responses agree with assertions about the opposing behaviors, which contend that students are less likely to cheat with interesting class material, good instructor interaction, a social/cultural feeling that everyone is honest, and the simple possibility that the student is already doing well without having cheated.

Figure 5 presents results from a question in which we asked students about various cheating activities they had participated in, without having differentiated among class type (online or traditional) or course activity type (homework and exams). This question also was phrased using a 5-point Likert scale (not at all, occasionally, sometimes, much of the time, always), and the figure shows the percentage of students (for $N = 64$) who admitted to having done these activities at least occasionally. Most of the activities shown in the graph conform to the definition of cheating, although "watching videos - strategies" was included as a control question in the survey (we do not view it as cheating). It was included to verify that students recognize that watching of solution strategies is not cheating. The figure illustrates that certain activities are practiced by students in significant numbers. In particular, finding solutions via web search and sharing of solutions were both reported to be practiced by more than 50% of respondents. Additionally, 37.5% of students reported having downloaded/used instructor's manuals.

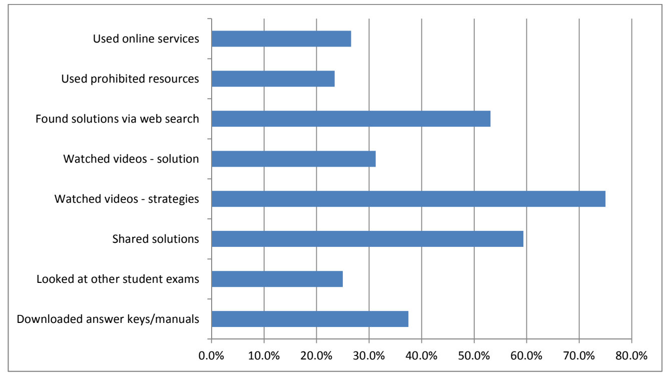

Fig. 5. Percentage of students reporting "cheating" activities.

We also found some correlation ($r(60) = 0.211$, $p < 0.05$ one-tailed) in students who admit to having cheated (i.e. participated in some of the activities listed in Figure 5) and those who felt likely to cheat, given various external motivating factors, as illustrated in Figure 4. This is not surprising, and it agrees with earlier conclusions indicating that if the factors are removed, the students will be less likely to cheat.

Student response rates to questions related to motivations for cheating are shown in Figure 6. The figure shows the underlying reasons that students cheated, when they did. Responses were not mutually exclusive, and the figure shows that typically, a lack of information on how to approach problems, as well as external factors that included stress, outside commitments, etc., were among the most commonly-cited reasons for cheating.

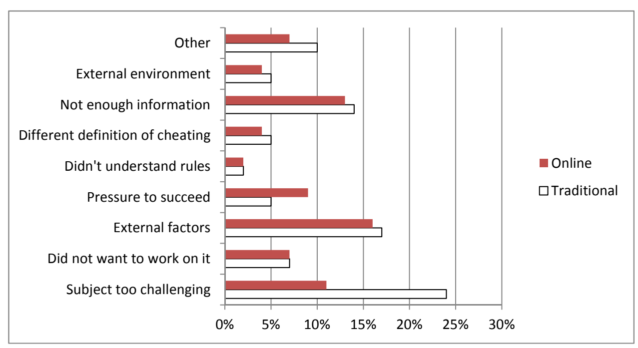

Fig. 6. Self reporting: why they cheated in classes.

The numbers here are mostly highly correlated, indicating support for the contention that the motivating factors for cheating in online and traditional classes are not significantly different, except possibly in one category. When presented with the option concerning the difficulty of the class ("subject too challenging"), student reporting of their experiences in traditional classes cited this much more often as a reason for having cheated (24% of the time vs. 11%). We believe this may be due to two possible factors: first, students working in online classes are already online and material relevant to the class is already at their fingertips through web search; second, the more traditional classes may indeed simply be more challenging to the students.

Figure 7 presents survey responses as they relate to the VLAB facility. Here, 30 respondents had experience with classes using our VLAB facility. In most cases, the student responses indicated the majority of them agreed with the statements posed in the questions. We are especially encouraged by the responses related to student completion of the activities by themselves. Students generally reported believing that the level of detail and ease of completion encouraged them to complete the assignments on their own. They also felt the assignments were engaging and interesting.

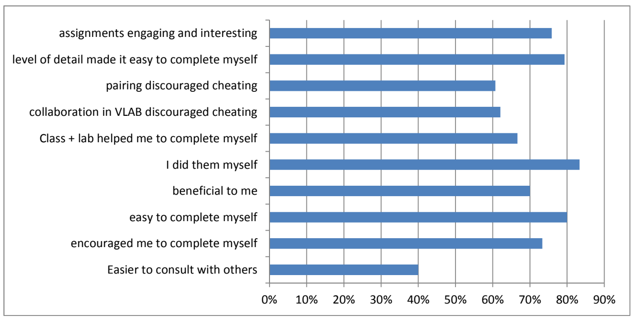

Fig. 7. Student Perceptions of VLAB Benefits.

These results agree with prior research, which concluded that engaging and interesting class activities make students more likely to work on the assignments themselves [8], [11]. Results shown in Figure 8 also appear to support this. The figure presents the results of a question in which students were asked what factors would make them less likely to cheat. The largest factor was reported to be a high interest in the assignments. Categories that also had high ratings included having their identity verified and the use of anti-cheating software.

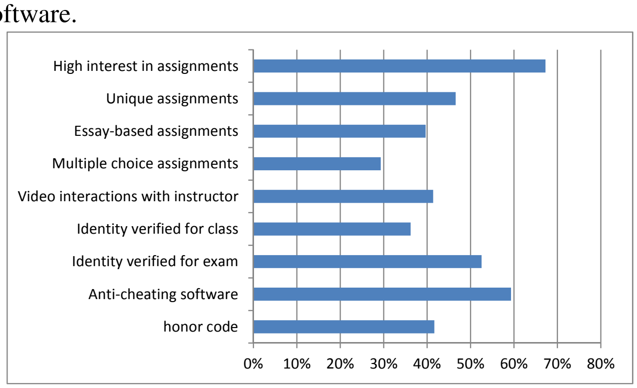

Fig. 8. Factors making students less likely to cheat

B. Student Comments

The last question in the survey requested comments, inviting students to share any thoughts they had related to the issue of cheating, whether they happened to be inspired by the survey, or otherwise. We feel that these responses were very valuable, in terms of pointing us toward further investigations. Although there is no statistical correlation to be found within, many of the responses showed considerable insight.

Some of the comments focused on the precise definition of cheating and/or the teaching itself. For example, one student stated "I think the teacher of any class has a responsibility to clearly state their policy about what is and isn't cheating. After that, they can leave it to the student's integrity. But if they haven't even done that much then what can they expect from their students?"

Some evidence of a lack of understanding of the precise nature of cheating is illustrated by another student comment: "My only instances of 'cheating' have been the sharing of answers as a group in an attempt to collaborate and better understand homework. I have never given or received answers just to get the points. Whether this is truly 'cheating' is up for debate".

It is also interesting to note that some of the comments echoed what has been revealed in the literature, specifically that teacher interaction can improve student learning and also help to curb cheating: "Teacher interaction is key to students learning. Just assigning due dates and exams does nothing to teach."

V. Conclusions, Recommendations, and Future Work

This paper presented results of a survey examining current student attitudes, knowledge, and practice related to cheating. The reported results agree with some of the prior results related to student attitudes about cheating, and they also found a positive effect from student use of our VLAB facility.

The study also represents the beginning step of a longer-term, and wider in scope, study of the same topic. As part of our future work, we will try to examine in greater detail the above VLAB approach, and we intend to expand this study to other colleges across the US, as well as in international universities.

We have also found that results of this study will allow us to refine the studies we conduct in the future. Additional studies will delve into greater detail on precise methods of cheating employed by the students, as well as an examination of more questions related to societal/cultural issues, which we did not consider in great detail within this survey.

Some of the student comments in the end-of-survey question also indicated that there is a disconnect between the instructor definition of cheating and that perceived by the student. Thus, another thrust of future work will be to delve into the definition of cheating, to differentiate among student perceptions of what is acceptable and what the instructor considers to be cheating. We also intend to examine alternative class instruction methodologies that accommodate a broader definition of what may be acceptable in the class setting. These may include employment of additional mechanisms to make the course both more interesting and engaging, as well as structurally less possible to engage in academic misconduct. We feel that going too far into technological solutions may be missing the point.

Ultimately, we feel that the results we observed point to the implementation of an overall systemic approach to improve teaching and learning, while simultaneously addressing the cheating problem. Several actions, including developing more engaging classes and assignments, fostering a culture against cheating, being absolutely clear with students about the definition of cheating, and implementing some effective deterrents, are all supported.

***Abstract*—In the 2012-2013 academic year, a survey to investigate why engineering and computer science students persist in their major was conducted at Michigan Technological University. This paper discusses the results of the survey and ties the findings to the literature. It focuses on: (1) who influenced students' decisions on picking a major or on changing a major (for example, friends, family, academic advisors, faculty, upper-division or graduate students, co-workers, and supervisors), and how did they affect students' persistence and (2) what is the impact of role models on student persistence. The analysis compares students who reported not having considered changing majors to students who considered switching to another major. The findings show that the students who did not consider changing majors reported having a stronger support system including faculty, academic advisors, and engineers who serve as role models. The data suggest that university faculty and staff need to reach out to the students who are deliberating about their initial choice of major and support the decision making process.**

Keywords—Engineering education; computer science education; persistence; retention; attrition; survey; role models

I. Introduction

The US as well as the global economy is increasingly relying on a highly educated workforce in engineering and computer science. Careers in these disciplines usually promise a job well-respected by society and one with a good salary. However, approximately 55% of the students across the US who enter engineering and computer science programs leave these fields within 6 years, either switching to a non-STEM field or leaving higher education altogether [1]. Therefore, a detailed investigation of persistence of students in engineering and computer science disciplines is of widespread interest to educators.

Student persistence in any university discipline is a complex issue. Starting in grades K-12, the decisions of students are affected by a multitude of individuals, groups, and communities, i.e., stakeholders. All of these stakeholders strive to help students so that they can make career decisions that are best for them, and consequently complete their degree. While the role of stakeholders is important, it is hard to determine how students perceive the degree of their influence.

Studies pertaining to influencers of student persistence are commonly organized with respect to two stages that correspond to well-defined transition points. During high school years, the major stakeholders are family members, high school teachers, counselors, university outreach staff, and role models who share the goal of helping with the transition to college. During college, family members, university faculty and staff, support groups, and mentors help students with the goal of having the student graduate and transition to being a professional. However, there is an additional phase where a student considers if their current major is right for him or her, and deliberates about whether to change majors. This is a critical but not well-studied phase, which may include a transition from one major to another.

The purpose of this study is to analyze the influence of stakeholders in students' decisions about whether to change majors. This approach aligns with recent research that shifts away from viewing persistence as an issue of prior knowledge or personal traits. Instead, persistence is viewed as an issue of being integrated into the culture of a discipline, or ``identity,'' and is seen as being affected by the communities surrounding the students [2]. In this study, communities of stakeholders are divided into two as internal to the institution, such as university faculty, staff, and peers; and external to the institution, such as family and external role models.

The analysis relies on survey data collected in the 2012-2013 academic year at Michigan Technological University (Michigan Tech). This analysis focused on students who were at some point engineering or computer science majors, dividing their responses in two groups. The first group is the students who reported not having considered changing majors (*resolute* about continuing in their current major). The second group is the students who considered changing their current major (*deliberated* about changing their major) regardless of whether they switched as a result of their deliberation.

In the remainder of this paper, a brief overview of the literature on influencers who affect student persistence is presented. Next, the methodology is explained, followed by a discussion of the findings. The paper concludes with a summary and recommendations.

II. Background

The behavioral choices made by individuals are driven by self perceptions related to skills, characteristics, competencies, personal values, and goals [3]. During the pre-college years, these perceptions are potentially influenced by the individuals

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

that students interact with [2], namely teachers, counselors, family, peers, and other significant adults.

In 2010, Aschbacher et al. looked at how relationships and interactions with family, teachers and other important socializers in students' different communities of practice influence identity in SEM (Science, Engineering, Medicine) fields [4]. This was a longitudinal study of 33 students with diverse ethnic and economic backgrounds. Overall, family encouragement was reported as the reason for the initial interest in science. However, less than half of the high school students reported that family members were still encouraging. Most of the students who expressed continued interest in SEM majors described family members in SEM fields who served as role models. There were gender and ethnic differences where fewer girls felt parental encouragement towards ambitious careers, while parents of minority boys strongly advised them to go to college.

Another 2010 article described a gender-based study of the predictors of high schools students' choice of physics as a career [5]. They found that both female and male high school teachers can positively affect physics identity by focusing on conceptual understanding, making real-world connections, and countering stereotypes, and by exhibiting care, engagement, and passion.

A survey of 280 secondary school students was conducted in 2004 [6]. The response to "my science teachers make me more interested in science" was very positive for 49% of the 11 year old students but dropped significantly to 31% for 14-16 year old students. The responses to questions about science as presented in the media were not very positive, with up to two-thirds of students declaring that they would not watch a TV program about science or did not read news items about science.

Media, in particular television programming, is known to widely affect career perceptions of students. In 2008, 86 women in the United Kingdom who had earned degrees in science, engineering and technology were interviewed to determine the impact of media on their career choices, along with their perceptions about how the media portrays women in technical careers [7]. In general, these women felt that the media did a poor job overall portraying women in technical fields in programming targeting both children and adults. However, science fiction programming for movies and television, along with books, did provide women with positive role models. Many women stated that news events such as the launch of the space shuttle had a significant impact on their career decision. On television programs, the women stated that the female characters who were technically oriented were portrayed negatively as incompetent, victims, de-feminized, or supporting a strong, male character. When discussing the negative impact of the media, many women stated that they received positive support from other sources such as family members, teachers, and other mentors in their decision to pursue a technical degree.

Studies show that there are many students who are not aware of the career options in engineering and computer science. In a survey of 431 New Jersey junior and senior high school students, participants responded with "I don't know" or "No Opinion" to a surprisingly high number of items regarding technical fields [8]. For example, 41% of the students did not know whether they would have a problem finding a job if they had an engineering degree; 44% did not know whether engineers get involved in business decisions; and 50% did not know whether engineers spend most of their time working in laboratories. These results showed that these students would benefit highly from outreach programs.

Many people look to others to see how they handle different situations and then "model" that behavior. The phrase "role model" is based on "the concept of role and the tendency of individuals to identify with other people occupying important social roles" and "the psychological matching of cognitive skills and patterns of behavior between a person and the observing individual" [9].

The efficacy of computer science (CS) role models was studied with respect to gender in 2011. The study participants were women non-CS students. They interacted with role models who were either stereotypical or non-stereotypical CS undergraduates. Stereotypical CS students were ones who wore unfashionable clothes and/or glasses, played video games or programmed in their free time and other characteristics associated with this group. The non-stereotypical CS undergraduates wore "cool" clothing, played sports or hung out with friends and did other "fun" activities. Prior to the meeting, the participants were asked if they thought they could succeed in CS. The participants were asked the same question at the end of the meetings. It was found that participants who interacted with a non-stereotypical CS student reported that they had similar beliefs in CS success as prior to the interaction. The opposite occurred for those participants who interacted with stereotypical CS undergraduates where the success belief of the participants was much lower than the baseline [10].

Faculty take a key role in not only teaching the discipline but also shaping students' attitudes toward careers in STEM fields. An interesting study looked at the attributes of faculty role models in medical schools [11]. The attending physicians who were identified as role models differed from their colleagues in a multitude of ways. In particular, they spent additional time with students beyond their teaching responsibilities, had formal training in teaching, and demonstrated a comprehensive approach to patient care. This led to the conclusion that excellence in role modeling is a skill that can be acquired through training and advice. Other literature pertaining to the role of faculty in student persistence exhibits similar findings. Barker et al.'s study shows that when faculty incorporate peer interaction as a mainstream activity in their courses, students' intention to persist increases [12]. Lewis et al.'s research compares the attitudes and beliefs of students in the introductory CS courses and senior students to the expectations of faculty. Their findings suggest that faculty can develop more effective curricula by closely studying attitude shifts of students as they progress in their studies [13]. A report by Brown et al. includes several strategies for faculty to support student retention [14]. One recommendation is to explain to students how the course content develops the skills required for careers in the field. A recent article in the Chronicle of Higher Education explores student motivation as a predictor of retention, and suggests that faculty, rather than the institution as a whole, are the key players [15].

III. SURVEY METHODS

In Spring 2013, a survey was completed at Michigan Tech. The survey was anonymous and conducted online. The survey questions were designed by extending questions developed for a previous survey completed in Spring 2011 [16, 17] and using additional questions from other related projects [5, 18]. The prototype survey was given to five students outside of Michigan Tech for review, and the questions were modified according to their feedback. Upon completion, an e-mail message containing the objectives of the survey along with the web link was sent to all program advisors who in turn sent it to the students in their program. All undergraduate students were invited to participate in the survey. Follow-up e-mails and reminders were forwarded by faculty in the departments and student organizations, e.g., Society of Women Engineers (SWE), Women in Computing Sciences (WiCS).

This analysis concerns only those students who have reported working towards degrees in engineering or computer science at some time in their university career; referred to as ENG&CS students for this analysis. The survey response rate was 12%. The current major reported by the ENG&CS students and the university enrollment figures (preliminary numbers for Spring 2013) are shown in Table I. Majors were grouped into a single item when the underlying departments incorporate multiple majors. The "Other Engr." category includes general engineering, engineering undeclared, geological engineering, material science and engineering, and those who have changed to current majors outside of ENG&CS. Within the ENG&CS population, the proportion of female students responding to the survey was greater then the university enrollment (see Table II) with a response rate of 24% among female students and 9% among male students. The higher response rate is expected from the directed invitations to participate sent to members of student organizations.

The ENG&CS population had less than one percent of respondents identifying themselves as Hispanic or Latino/a (*n*=8). The race of the respondents was predominantly Caucasian (*n*=374), with students also reporting American Indian or Alaskan Native (*n*=3), African American (*n*=4), and Asian (*n*=48); students were asked to select all that apply.

TABLE I. SURVEY PARTICIPANTS & ENROLLMENT BY MAJOR

	Survey Participants		University Enrollment	
Major	**Num.**	**Perc.**	**Num.**	**Perc.**
Biomed. Engr.	15	3.8	246	7.4
Chem. Engr.	46	11.6	405	12.2
Civil & Env. Engr.	85	21.5	511	15.4
Comp. Sci.	37	9.4	294	8.9
Elec. & Comp. Engr.	62	15.7	505	15.2
Mech. Engr.	103	26.1	1041	31.4
Other Engr.	47	11.9	313	9.4
ENG&CS	395	100.0	3315	100.0

TABLE II. SURVEY PARTICIPANTS & ENROLLMENT BY GENDER

	Survey Participants		University Enrollment	
Factor	**Num.**	**Perc.**	**Num.**	**Perc.**
Female	149	37.7	627	18.9
Male	246	62.3	2688	81.1
Total	395		3315	

The overall structure of the survey is depicted in Fig. 1 (the full survey structure is available at [19]). All survey participants completed the first two sections about pre-college experiences and who was an inspiration. Then students were asked if they had thought about switching majors or had switched majors. The students who had not thought about switching were grouped as *resolute*, while the students who had thought about switching or switched were in the *deliberated* group. Both groups were asked similar questions regarding who influences their decisions and whether or not these people or groups were supportive. The students in the *deliberated* group were asked about their decision on switching. The last section of the survey involved questions regarding the student's career plans and demographics. The following sections describe the survey components that were analyzed in greater detail.

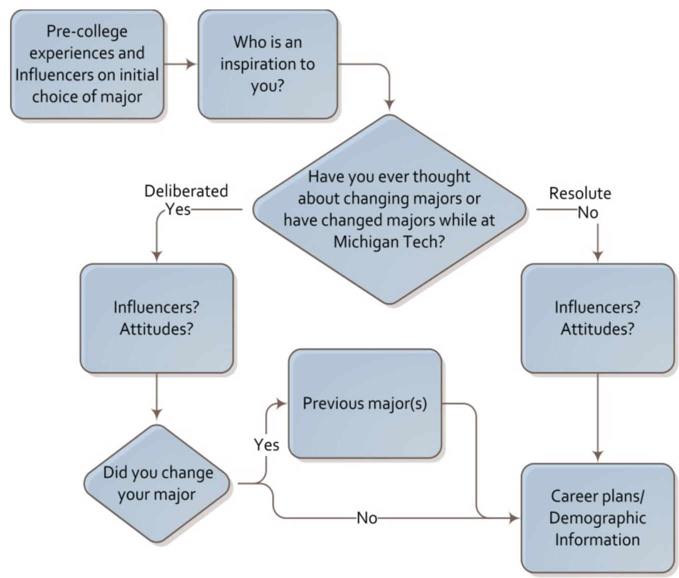

Fig. 1. Survey Structure.

A factor of particular interest within the survey is respondents' answer to the question, "have you ever thought of changing majors or have changed majors?" Students who responded negatively to this question are labeled *resolute*, that is, they are convinced about continuing in their current major. Students who responded positively to the query are labeled *deliberated*, that is, they are or have at some point considered switching majors. Of the ENG&CS respondents, 50.6% (*n*=200) are *resolute* while 49.4% (*n*=195) *deliberated*.

The survey respondents were asked about the interactions they had with others regarding their majors. The *deliberated* students, those who thought about or did change their major, were asked a series of questions regarding the role others had in their deliberations. The population of *resolute* students, those who had not thought about changing, were asked a parallel series of questions regarding the role the same set of people had in their continuing in their major. The structure of the survey (Fig. 1) shows where the split occurred in the survey questions.

IV. RESULTS

The results focus on four questions, with whom do students discuss their progress, who influences a student's decision to persist or change majors, what were these peoples' attitudes (positive/negative), and who were the students' role models.

A. With Whom do Students Discuss their Scholastic Progress

The students were asked with whom and how often they discussed progress in their major. The people or groups of people they were asked about included their family, friends, and significant others. From within their peer or near-peer groups, they were asked about their roommates and hallmates, resident assistants, more senior students, teaching assistants and learning center coaches, and fellow members of student organizations. They were asked about faculty, academic advisors, career services, and counseling services as well as work colleagues and supervisors. The respondents were given the choice of "NA", "never", "one time", "once a semester", once a month", "every week", and "every day".

There was no statistically significant difference between the *resolute* and the *deliberated* students in their answers to questions about with whom and how often they discussed progress in their major. The groups students talked about progress in their major most often with were "Family", "Friends", "Roommates, Hallmates", "Significant Other", and "Academic Advisors", in that order. Over 48% of the students talked to their families about their progress at least once a week. They talked to their friends and roommates at about the same frequency. Approximately 44% of the students talked to them at least once a week. The question regarding "Significant Other" had the highest response for discussing progress every day at 22%, with 42% of the students saying they discussed progress with their significant other at least once a week. An additional 42% of the students marked the "Significant Other" questions as not applicable. Students typically discussed progress in their major with "Academic Advisors" once a semester (61%). A small number reported these discussions once a month (14%), one time (11%), and never (8%).

B. Who Influences Decision of Persisting or Changing Major

This portion of the analysis focused on several different groups of people to determine who impacted student decisions regarding remaining within their chosen field and contemplating changing to a different major. The people or groups considered were the student themselves, plus those considered in the previous section on discussions about progress in the major.

TABLE III. WHO INFLUENCED DELIBERATION ON STAYING / SWITCHING MAJOR: SURVEY RESPONSES ON DEGREE OF INFLUENCE FOR RESOLUTE AND DELIBERATED STUDENTS

		% (*n*)								
		NA/no		small/some		large/v. large		Mean		
Statement	**Choice**	**1-2**		**3-4**		**5-6**		**Choice**	**Total**	***p*-value†**
Self	resolute	2.0	(4)	2.5	(5)	95.5	(190)	5.73	5.71	0.948
	deliberated	1.6	(3)	2.6	(5)	95.8	(182)	5.68

Members of Student Organizations	resolute	71.1	(140)	22.8	(45)	6.1	(12)	2.37	2.23	0.009
that you are Affiliated With	deliberated	84.0	(158)	12.2	(23)	3.7	(7)	2.08		

† *p*-values were calculated using a chi-squared test, with a null hypothesis of independence of choice

The question asked students who had a role in their deliberation on changing majors or continuing in a major. For each group, students had a choice of six answers, "NA", "no role", "small role", "some role", "large role" and "very large role". The results are shown in Table III with the students' responses condensed into three categories.

There are many similarities. Looking at who had the largest role, as measured by the largest percentage of responses in the "large/very large" category, the top six are very similar for *resolute* and *deliberated* students. For both groups of students (*resolute* and *deliberated*), "Self" had the largest role, followed by "Family". Both student groups ranked "Faculty" fourth and "Friends" the fifth highest. The third and sixth highest items are switched for the two groups. "Significant Other" is the third highest among *resolute* students and sixth amongst *deliberated* students. "Academic Advisors" is the third highest among *deliberated* students and sixth among *resolute* students.

It is noteworthy that there are only two groups of people which more than 1 in 5 students weigh as having a "large" or "very large" role in continuing their major or in deliberation of changing, "Self" and "Family". Also, for *deliberated* students, over 50% say that "Academic Advisors" and "Faculty" have no role in the deliberations. Over 85% of students reported that "Career Services" had no role, although career services offers an on-line career planning tool that many of the students have completed.

Eight of the questions have responses that are statistically significantly different with respect to whether the student is *deliberated* or *resolute*. Chi-square tests, with the null hypothesis that *deliberated* and *resolute* groups were independent, were performed on the data in Table III. From these tests, the p-values are reported. The statistical tests were also run on the original data without condensing the categories. The same eight people or groups are statistically significantly different in either case. The groups where differences exist are "Family", "Significant Other", "Friends", "Roommates, Hallmates", "Faculty", "More Senior Students", "TAs, Learning Center Coaches", and "Work Colleagues and Supervisors". Each of these items had a larger role in the *resolute* students than in the *deliberated* students. This can be seen by comparing the means for the two groups of students and by looking at the percentage of the responses in the "large/very large" category.

C. *Attitude of Influencers of Deliberation*

The students were asked about the attitude each of the people/groups took toward their possible change in major or their continuing in a major. The choices were "NA", "Negative", or "Positive". These results are shown in Table IV. For all items, the response was overwhelmingly more positive than negative. The primary differences were between positive and not applicable (NA). Both the *resolute* and *deliberated* students reported that very few people had negative attitudes toward what they wanted to do. Note,

TABLE IV. ORIENTATION OF INFLUENCERS' ATTITUDE ON DELIBERATION: SURVEY RESPONSES FOR RESOLUTE AND DELIBERATED STUDENTS

		% (*n*)						
Statement	**Choice**	**NA**		**Negative**		**Positive**		***p*-value†**
Self	resolute	1.5	(3)	2.0	(4)	96.5	(192)	0.000
	deliberated	10.6	(20)	13.8	(26)	75.7	(143)

† *p*-values were calculated using a chi-squared test, with a null hypothesis of independence of choice

student's perceptions of others' attitudes are subjective and not independent of their own attitudes and interactions.

For both groups of students, the first five questions with the largest percentage with a positive attitude are the same. In order they are "Self", "Family", "Friends", "Academic Advisors", and "Roommates, Hallmates".

It is notable that all of the questions have responses that are statistically significantly different with respect to whether the student is *deliberated* or *resolute*. Chi-square tests, with the null hypothesis that *deliberated* and *resolute* groups were independent, were performed on the data in Table IV. From these tests, the p-values are reported and they all were very small (p-value<0.000). For each question the positive attitude percentages are higher for *resolute* students than for *deliberated* students. In fact, the average of the difference between the two percentages is almost 30%.

There is also a marked difference in the proportion of each question that was marked not applicable (NA). The *deliberated* students had on average a little over 25% greater marked NA than *resolute* students. This may indicate that the *deliberated* students' support system was not as strong as those who were continuing their major. Their consideration of changing majors, instead of being a result of negative attitudes from the people around them, could be a result of not having strong influencers that are either positive or negative.

D. Role Models (Inspirations)

The survey had a series of questions where the students focused on "one person who inspired you in what you want to be." The intent of this series of questions was to explore the people who were an inspiration to students, in other words, role models. Approximately 10% of each student group did not answer these questions, meaning they did not have a "role model" or could not select one to be the focus of their responses.

The first question asked "how do you know this person," or what is their relationship to you? Fig. 2 shows the responses of the two groups of students to this question. No statistical significant differences between the two groups were found (p-value 0.447).

Next, the respondents reported the career or profession of the person who inspired them. The categories were drawn from occupations tracked by the Bureau of Labor Statistics. The 7 most frequently reported occupations are shown in Fig. 3 with the remaining selections grouped into STEM and non-STEM related fields. There is a statistically significant difference between the responses of *resolute* and *deliberated* students (p-value 0.022). Those who are convinced of their major are more likely to have an engineer as an inspiration than those debating their major.

Another aspect of this person of interest is how long the person selected had been an inspiration to the student. The distribution of responses is illustrated in Fig. 4. There is not a statistically significant difference between the responses of the two groups (p-value 0.274).

Finally, the ways in which students interact with the person

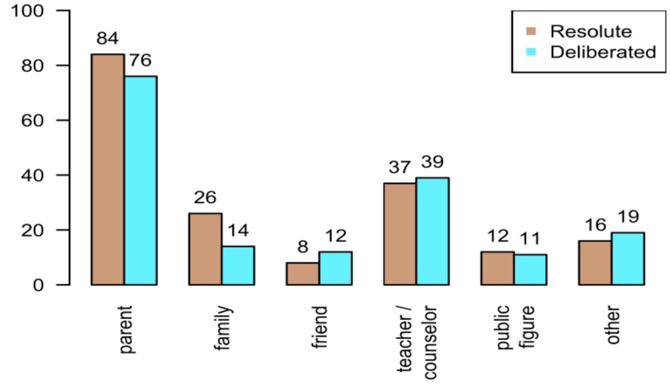

Fig. 2. Responses to "Who is an inspiration to you?"

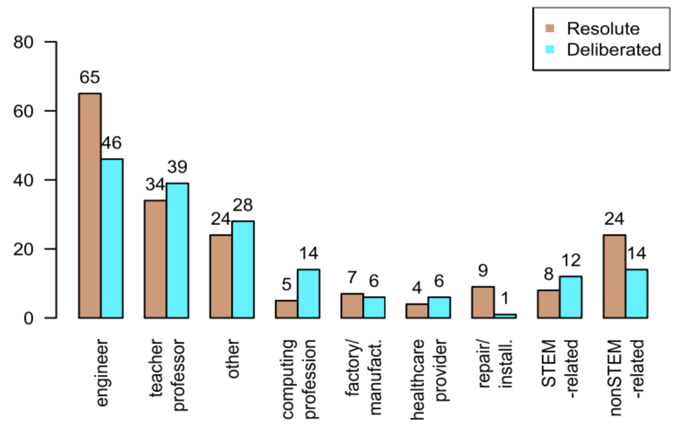

Fig. 3. Responses to "Career or profession of who is an inspiration to you?"

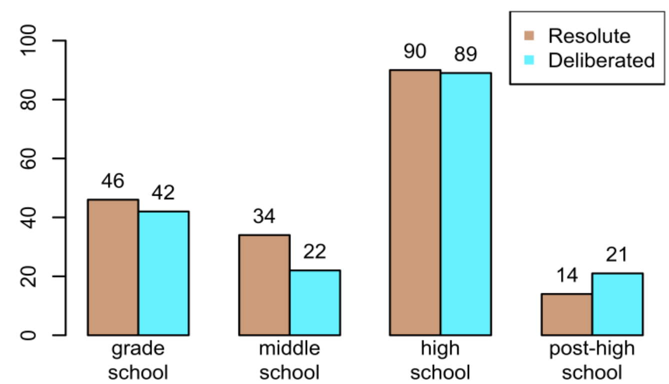

Fig. 4. Responses to "When did this person become an inspiration to you?"

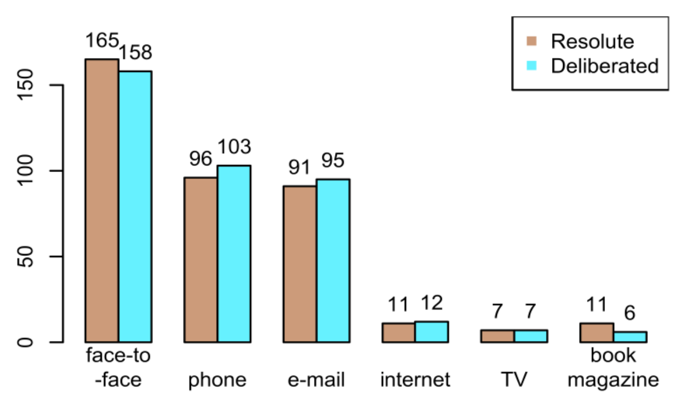

Fig. 5. Responses to "How have you interacted with this person?"

who inspires them are reported in Fig. 5. The interaction method was not restricted to one response. There is no statistically different response based on whether the student is *resolute* or *deliberated* (p-value =0.849).

V. Conclusion

As students progress through their degree program, there are times when many of them debate their choice of major, while others are resolute in their decision. All students had a group of supporters. The people who had the greatest influence on the students' decisions were similar between the *resolute* and *deliberated* groups. On the other hand, these people had higher influence on the *resolute* students versus the *deliberated* students. The findings show that the students who did not consider changing majors reported having a stronger support system including faculty, academic advisors, and engineers who serve as role models. These data suggest that university faculty and staff need to make a larger effort to reach out to all students, so that students, especially those deliberating, will view faculty and staff as resources in their decision making process.

Of the students who indicated they had a role model, there were few differences between the two groups. One difference was that many more of the *resolute* engineering and computer science students reported that an engineer was inspirational to them than the other group. For the students reporting a role model, the person most frequently became an inspiration during high school. Most students reported having personal interaction with their role model. These results confirm other research with respect to role models. Therefore, efforts should be made at the high school level for students to have meaningful contact with engineering and computer science professionals. In addition, faculty need to be aware that a student's personal interaction with role models is still very important during college. Faculty serve as role models themselves and should also facilitate role model connections between students and engineering and computer science professionals.

In future analyses, differences between female and male students, STEM and non-STEM majors, and various STEM majors will be explored. Questions related to future career plans, perseverance, perceptions of gender composition within majors, and anecdotal evidence of the persistence of other students will be examined. Additionally, it will be interesting to compare the data from this survey to other national surveys, such as PACE and NSSE [18, 20]. One of the future goals of this research is to have focus groups to explore some of the more qualitative differences between deliberated and resolute groups that quantitative (survey) data cannot address.

VI. Acknowledgements

The authors would like to thank the students who prototyped the survey and the Michigan Tech students who participated in the survey. Their feedback is very valuable.

The Dynamic Image of the Engineer

John W. Pritchard and Mani Mina
Iowa State University, USA, johnp@iastate.edu, mmina@iastate.edu

Abstract **– In this work, engineering students are asked what engineering is and what it means to be an engineer. Their responses suggest that there may be an inconsistent development of the image of an engineer as the student progresses within their engineering program, and a lack of philosophical discussion that leads to a deeper understanding of their field. Additionally, non-engineering students are given the same questions, providing an interesting perspective. The survey questions are presented and an analysis of the results is provided with suggested approaches to improve the observed issues.**

Keywords – Engineering Education, Engineering Identity, Engineering Society, Engineering Culture

I. Introduction

More than ten years ago, common perceptions of engineering and its stereotypes had been based on years of development of the fields and the culture, their academic tracks, professional and amateur accomplishments, average salaries, etc. Through the many facts and fictions provided by books and media engineering was a well-developed image in the minds of the public. There are numerous studies about the effect of new media and communication possibilities that have been creating and transforming the image of professionals and, in particular, engineers [1-2].

There may be no unique or generally acceptable image for what an engineer is, but the fact that this image has the ability to transform more rapidly now than ever before cannot be ignored. Research shows that the freshman engineering classes are among the most transformational experience of most students [3-4]. There have also been several studies on the mutual effects, expectations, and communication venues that separate or unify the student's and instructor's perspective in these first year courses [5-6]. What may be a most probing issue is the difference in expectations and interdependencies between teacher and student beliefs of what engineering and the image of the engineer is.

It is safe to assume that an engineering instructor has a matured expectation of what an engineer is and what they expect students to become. Students in engineering, on the other hand, have very malleable definitions of their engineering degree. In many cases, students' defining image of a professional in their field does not mature until late in their academic career. Additionally, the engineering curriculum has great influence in how this image matures, and may or may not be helping. A consequence of this delayed image maturity may lead to fulfillment (because students have found that their chosen field is what they thought it was), dissatisfaction or depression (because they have found that it is opposite, but it is too late to switch or quit), or switching fields (which takes more time and money).

In this work we analyze the image of the engineer from the perspective of freshman and senior students in electrical and computer engineering as well as non-engineering students taking engineering studies courses. The goal is to help engineering students develop their unique identity, gain a better understanding of student image progression, and possibly capture a glimpse of the current and future trends that could be transforming the engineering field.

II. Experimental Setup

In this experiment, 32 engineering students from a freshman class in electrical engineering (EE), 71 from a senior class in electrical and computer engineering (ECpE), and 33 non-engineering students from a sophomore class in engineering studies (EngSt) at Iowa State University were asked the following:

> *"Imagine that you are at a party, and a person with no particular background in engineering asks you, "What is engineering, and what does it mean to be an engineer?" In your own words, please describe your reply. What is your belief of what engineering is and what it means to be an engineer?"*

From the replies, 11 characteristics or descriptive phrases were extracted that may or may not have been common among each answer. The number of times a criterion had been made reference was then tabulated, and a ratio (in percent) of the number of references to the respective population was reported. Finally, the top five referenced criteria were chosen to represent the image of the engineer.

In the tabulation process, each characteristic could only be tabulated once per respondent, however multiple characteristics could be tabulated from one description. The 11 criteria are the following:

1. Technical problem solving, design, and innovation
2. Ethical behavior
3. Advance society
4. Develop products
5. Apply use of math, science, and physics
6. Apply leadership and communication
7. Apply critical thinking and creativity
8. Make the world a better place
9. Gain and apply knowledge
10. Lifelong learning
11. Lack social and communication skills

III. Results and Discussion

The tabulated results are provided (Table I). Common among all groups is the characteristic of engineering being a field that practices technical problem solving, design, and innovation.

TABLE II. DEFINITIONS OF AN ENGINEER

Source	First Definition of "Engineer" or "Engineering"
Oxford English Dictionary	Engineer: A person who makes engines, structures or systems.
Merriam-Webster Dictionary	Engineer: A member of a military group devoted to engineering work.
Encyclopedia Britannica	Engineering: the application of science to the optimum conversion of the resources of nature to the uses of humankind.
Dictionary.com	Engineer: A person trained and skilled in the design, construction, and use of engines or machines, or in any of various branches of engineering.
Wikipedia	Engineer: An engineer is a professional practitioner of engineering, concerned with applying scientific knowledge, mathematics, and ingenuity to develop solutions for technical problems.

Maybe the most noticeable difference in perspective between freshman students and seniors is the placement of criterion #8: "Make the world a better place." These results suggest that as one learns and grows in the program, students lose sight of the purpose and mission of engineering, which is to benefit humanity. This difference also may suggest a dilution of the essence of engineering ideals.

Another interesting point to note is the close alignment between the image of an engineer in the eyes of senior engineers in ECpE and sophomore non-engineers in EngSt. Only one criterion is different, not considering order of importance, between the two: #7 for the engineers and #11 for the non-engineers. Additionally, criterion #11 was not mentioned at all by the engineering students (for an understandable reason). It seems that in the eyes of non-engineers, engineering students lack social skills and abilities to communicate well. Terms and phrases were used to describe engineers such as "geek," "nerd," "know-it-alls," and "superiority complex." Although these are purely subjective opinions which may have derived from single, defining events, the fact that there may be merit to this on a broadened scale cannot be ignored [7].

Finally, one should notice the qualities of engineers that did not make it to the top 5 in any of the student sample sets: Criterion #2, #3, #6, and #10. It appears that although some agree these are important, the collective student sample population does not. The application of leadership and communication can directly affect social skills. This may be a reason why non-engineering students feel criterion #11 was worth mentioning. Lifelong learning was within the bottom three criteria of all sample sets, if mentioned at all. This suggests a lack of inspiration to pursue higher education or other academic endeavors.

To serve as a reference, first definitions from the Oxford English Dictionary, Merriam-Webster Dictionary, Encyclopedia Britannica, Dictionary.com, and Wikipedia are stated (Table II). It is arguable that the definition of an engineer from these five external sources fit criteria #1, #5, and #9 posed by students. In addition, these criteria are all in the top five mentioned for each of the three student groups. Thus, one may conclude that the majority of the respondents have a relatively accurate technical definition of what an engineer is.

Overall, it seems that as students progress throughout their education program they begin to place more emphasis on technical-oriented activities and understandings and less emphasis on the philosophical questions that define how they fit in the world and what their contribution to society is (other than technical problem-solving). Based on these results, it is possible that increasing efforts to include more activities that practice ethical behavior, leadership, communication, and lifelong learning in the engineering curriculum may broaden students' understanding of engineering and its cultural bearing. Much effort has been taken by educators to help with this and similar issues [8]. However, it is clear that further efforts may be needed.

This study posed one question from a single perspective to draw conclusions about the image of an engineer. In addition, the respondents represent less than 3% of the total enrolled engineering students at Iowa State University. The authors plan to expand this study using a similar methodology but involving more questions, students, and external sources to enhance and refine the results. Therefore, this study serves as a work in progress.

IV. CONCLUSION

In this work, it has been found that the image of an engineer has the ability to change drastically throughout an engineering education curriculum. Analysis shows that students and external sources agree that an engineer practices technical problem solving, design, and innovation. However, there appears to be inconsistencies on the philosophy of engineering and its non-technical role in the world as students progress in their program. To improve this, it is suggested that topics relating to the philosophy of engineering be brought to the curriculum, in addition to activities that practice ethical behavior, leadership and communication, and lifelong learning.

Comparing the Attitudes towards Engineering of Honors Students and Engineering Students at a Liberal Arts University

Rick T. Olson, Truc T. Ngo, and Susan M. Lord
Department of Engineering
University of San Diego
San Diego, CA
r_olson@sandiego.edu; tngo@sandiego.edu; slord@sandiego.edu

***Abstract*—In Fall 2012, 53 honors students and 53 engineering students (including seven students in both honors and engineering) completed a survey designed to examine their attitudes towards engineering and their ability to succeed in engineering. Preliminary analysis of five factors shows that the attitudes of engineers and honors students were similar in many respects. The main areas of difference were that honors liberal arts students had lower confidence in their ability to succeed in science and math and all non-engineers showed lower aptitude for engineering. Non-engineering women showed slightly less affinity for solving open-ended problems. All students expressed similar attitudes about the creativity of engineers and their contributions to solving society's problems.**

Keywords— Attitudes; Factor Analysis; First-year; PFEAS

I. INTRODUCTION

In this work, the attitudes towards engineering of 99 University of San Diego (USD) students who were studying engineering and/or participating in the Honors Program are analyzed to identify differences and commonalities. Understanding these attitudes may help engineering programs to identify students who have the potential to succeed as engineers, but who might need encouragement, or who might have impressions of engineering that can be changed through intervention prior to, or shortly after arrival on campus.

The next section presents a brief survey of the literature related to student attitudes towards engineering, followed by a description of USD's engineering and honors programs. In Section III, the survey is described. Section IV presents preliminary analysis of the survey results.

II. BACKGROUND

A. *Prior Research on Engineering Attitudes*

Several studies have assessed how student attitudes or motivations affect their pursuit of engineering degrees. The Pittsburgh Freshman Engineering Attitude Survey (PFEAS) [1, 2, 3] identified 13 distinct attitudes of students towards engineering, and was used to explain persistence and differences in attitudes across gender and race. Discriminant analysis was applied to PFEAS results to predict persistence in engineering [4]. The Persistence in Engineering survey was used [5] to assess 20 factors related to student attitudes towards engineering among 8,000 students at 29 schools. Factor analysis has been used to compare the attitudes of engineering and non-engineering students [6, 7].

Overall, the prior work showed that confidence in the ability to perform college-level math and science, and a belief that engineering degrees improve job security were important predictors of persistence in engineering. Women generally conveyed less confidence in the basic engineering skills and abilities, and a lower perception of how engineers contribute to society than the men. Engineering students' opinions of engineering's contribution to society was significantly higher than the opinions of non-engineers.

B. *Engineering and Honors Students at USD*

USD is a private, faith-based, national liberal arts university. Students applying for admission do not apply to specific majors, and there are no enrollment caps on any major. The engineering programs require 4.5 years to complete and students receive a dual B.S./B.A. in their engineering field, electrical, industrial and systems, or mechanical engineering. Because of the core requirements, it is believed that USD tends to attract fewer engineering students who have narrow, technical interests, and more students who are interested in a broad, liberal arts education. Thus, the attitudes of these engineering students may not reflect those of students at large public universities, or institutions with an emphasis on engineering or science.

Incoming students who have demonstrated unusual accomplishments in leadership, community involvement and academic excellence may be invited to participate in the Honors Program. Selection is based on admission scores used to award scholarships and a separate application to the Honors Program. Students in the Honors Program typically take one honors class each semester towards fulfilling USD's core curriculum and complete an Honors Thesis. Each year approximately 120 first-year students out of an incoming class of 1100 are invited to join the Honors Program.

During their first semester at USD, incoming first-time in college (FTIC) students are placed in one *preceptorial* class

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

according to their expressed academic interests. Honors students are placed in honors preceptorial classes. In Fall 2012, there was one honors section of ENGR 101, the introductory class taken by all engineering students. Because there were not enough engineering students to fill a complete honors section, some high achieving engineers who were not in the Honors Program were added to this section. All other students expressing interest in studying engineering were enrolled in regular sections of ENGR 101.

III. USD Attitude Study

In Fall 2012, FTIC students were surveyed to assess their attitudes towards engineering. The purpose of the survey was to explore differences in the attitudes of students across many disciplines at a predominantly liberal arts university. The 30-question survey was based on the PFEAS and a revised version of the PFEAS [7]. Each question was phrased so that students could state the degree of agreement or disagreement with a statement such as, "*I have strong problem solving skills.*" A 5-level Likert scale was used ranging from *Strongly Disagree* to *Strongly Agree.* The complete survey appears in [8].

The survey was completed by 272 students in 28 classes. Factor analysis was performed on the results, and five significant factors based on 16 questions were identified [8]. The remaining questions were not used. These factors were: APP (mechanical, technical, and computer aptitude), CONF (confidence and enjoyment of Science, Technology, Engineering and Math), CREATE (creativity of engineers), PROB (student affinity for solving open-ended problems), and SOC (engineering contributions to society). Factor loadings were between 0.44 and 0.92 and no questions were associated with more than one factor. Oblimin rotation was applied to account for correlation between factors.

In this work, a subset of the survey responses is examined more closely. The attitudes of engineering students are compared to the attitudes of honors students. Because honors students have demonstrated high levels of academic success, it is hypothesized that many of them may be able to succeed in engineering, but have chosen different fields because of different attitudes towards engineering.

The survey was completed by 99 students who were in ENGR 101, a course in the Honors Program, or the honors section of ENGR 101. Table I gives a summary of the respondents. Science, math and computer science students are identified as SMCS, and all other students are considered liberal arts students. SAT scores were not available for all students. The averages of the available scores are presented. High school grade point averages were available for all students.

Table I contains some evidence that most honors students are academically qualified to pursue engineering. Their SAT-Math scores were on par with those of the engineers and their critical reading scores and GPAs were much higher.

TABLE I. Characteristics of Students Who Completed Attitude Survey in Fall 2012

		# of Students	**SAT-CR**	**SAT-M**	**HSGPA**
ENGR Non-Honors	Men	34	598	668	3.81
	Women	12	578	668	3.98
Honors ENGR	Men	5	660	668	4.06
	Women	2	N/A	N/A	4.31
Honors Liberal Arts	Men	10	640	652	4.25
	Women	10	705	672	4.28
Honors SMCS	Men	8	658	688	4.37
	Women	18	649	688	4.37

IV. Preliminary Analysis of Survey Results

The Likert responses' values for each question are summarized here. Questions were reverse coded where necessary so that a "positive attitude" to engineering would be scored as a five regardless of the wording of the original question. All questions related to a factor were averaged to yield an overall response from the student. (A more comprehensive analysis that considers the factor scores is beyond the scope of this preliminary investigation).

Figures 1-4 present box plots of the most interesting results. In each plot, the thick horizontal line represents the median response, and the box represents the limits of the first (Q1) and third quartile (Q3) of the responses. The dashed whiskers denote observed responses within 1.5*(Q3-Q1) of the box. Circles represent outliers.

Figs. 1-3 all reflect a student's perception of their ability to succeed in STEM (science, technology, math and engineering) classes, or affinity for solving the types of open-ended problems that engineers encounter. Although rigorous statistical tests have not been conducted, Fig. 1 suggests that all STEM majors felt confident in their science and math capabilities, and are much more confident than liberal arts students are. The relatively narrow height of the boxes suggests uniformity in these attitudes. On the other hand, Fig. 2 shows that students' perception of their mechanical, technical, and computer aptitude is much less consistent, that men are more confident than women, and that SMCS students are more similar to liberal arts students than to engineers despite their strong math and science confidence. Fig. 3 suggests that, regardless of the discipline, women generally enjoy open-ended problems less than men do, or have less confidence in their problem solving skills, even though they enjoy, or are confident in their math and science abilities.

Fig. 4 shows that all USD students had similar attitudes towards the ability of engineers to address societal problems. These results do not reflect the gender differences that were observed in other published studies [3]. The results for attitudes regarding the creativity of engineers were similar to the SOC responses.

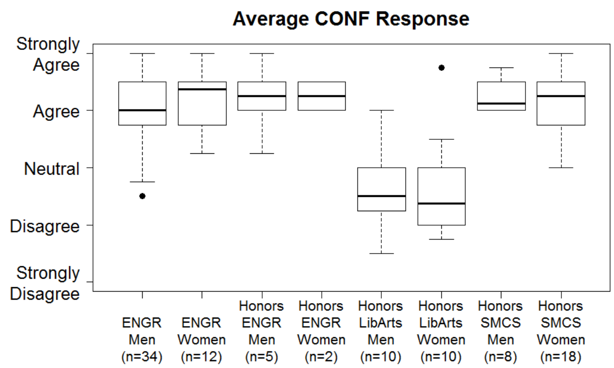

Fig. 1. Average response to questions probing subject's confidence and enjoyment of STEM classes.

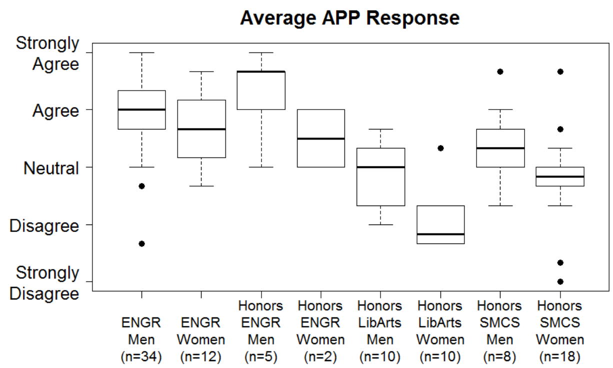

Fig. 2. Average response to questions probing subject's mechanical, technical and computer aptitude.

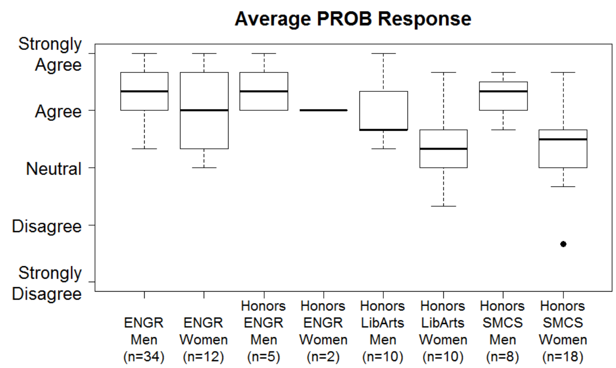

Fig. 3. Average response to questions probing subject's affinity for working on open-ended problems.

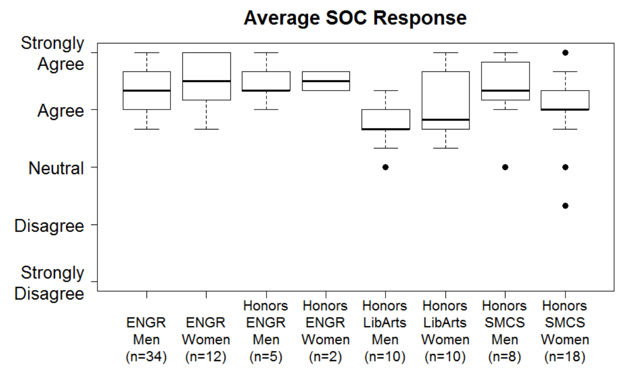

Fig. 4. Average response to questions probing subject's perception of engineering contributions to society.

V. Conclusions

These preliminary results support earlier work that shows that students who pursue engineering have strongly positive attitudes towards factors related to engineering success. However, they also show that many SMCS students have similar attitudes to many of the factors with the most notable exception being mechanical, technical, or computer aptitude. This observation suggests that these students may be more attracted to engineering if they can be encouraged to believe in their abilities, or if they can be made aware of a broader understanding of engineering including that many fields of engineering solve important problems that are not "mechanical" in nature and that their math and science skill will help them succeed in engineering.

Acknowledgment

The authors gratefully acknowledge the assistance of the 28 USD preceptorial professors who administered the survey in their classes. This work was supported in part by the National Science Foundation (NSF), award DUE-0817332: National Model for Engineering Mathematics Education.

Carry-on Effect in Extreme Apprenticeship

***Abstract*—We argue that the first undergraduate courses are the most important ones on the student's path towards becoming a computer scientist. Therefore, during 2010-2012, we have exercised extensive effort in order to improve the first-semester Computer Science (CS) courses. We have been able to use a learning-by-doing approach called the Extreme Apprenticeship (XA) method accompanied by personal advising even for courses with hundreds of students. We claim that when high demands are met with sufficient support, students learn valuable programming skills that become a foundation that carries them in their further CS courses. In this paper, we analyze how the effects of a three-year effort of renovating our introductory programming courses propagate to further studies. Compared to the control cohorts of 2007-2009, we observe a carry-on-effect caused by the XA method in student success that is visible in the per-student average accumulation of credits after 7 and 13 months after the start of studies. In addition, we can see the effect propagating to mandatory subsequent courses, even without the XA method.**

I. Introduction

It is well known that learning to program is hard [1]. As computer science is typically not taught in high schools, first-year Computer Science (CS) students experience difficulties that are manifested in high failure and drop-out rates in the first programming courses (often referred to as CS1). Improving the operation of the first programming course has been a popular topic for years in the CS education community.

A challenge in examining the improvements in education is that the examination is oftentimes either too broad or too narrow. The administrative view to teaching development emphasizes the student throughput and number of degrees, cost-effectiveness [2], faculty readiness to adopt new teaching methods (see e.g. [3], [4]) but does not elicit the true effect of the improvements in the learning within the CS1 course. On the other hand, a teacher's view and reports thereof emphasize the uniqueness of the course without inspecting the effect on the subsequent courses [5], [6]. Extending the view from a single course is important as the expertise accumulates throughout the degree.

At our department, we have exercised extensive effort on improving the first-semester Computer Science courses that our university students encounter. Due to the teaching improvements and efforts, our department has been awarded various national teaching prizes during the last decade. During the last three years, we have made effort to investigate and apply a learning-by-doing approach accompanied by personal advising even for courses with hundreds of students. The application of the method to our introductory programming courses has both increased students success rates as well as actual learning. The results are significant, as the improvements have been made in a context, where the teaching has already been praised both by the students and the nation.

We purposefully and openly press our students to immerse themselves into a mode of building a strong programming routine by deliberate practise from day one of their studies. Contrary to many other approaches, we do not seek a silver bullet that would allow our students to spend fewer hours on learning. Instead, we want our students to really put the effort into purposefully guided learning-oriented activities. We claim that when high demands are met with sufficient support, students learn valuable hidden skills that become a foundation that carries them during their further studies.

Now, after three years of applying the method to our first semester, we are ready to examine the long-term effect of the *learning* in the students' first CS1 course. It is known that "teacher-induced learning has low persistence, with three-quarters or more fading out within one year" [7]. However, we have observed a rise in the skills of the students that suggests there is a carry-on effect from the first course to subsequent courses.

In this paper, we present the data that shows that the increase in programming skills in the first course enables more students to continue on a path to become a computer scientist. We observe an effect on the success of the studies 7 and 13 months after the initial programming course, as well as the courses immediately after the first programming course.

II. Background and Context

In Finland, there are no tuition fees for anyone in studies in higher education. There are more study positions in STEM (science, technology, engineering, and mathematics) subjects in higher education than there are high school students with a suitable high school course selection, and naturally, every institution wants to recruit good students. Unfortunately Computer Science is not among the most desirable study subjects, therefore, it is not very difficult to secure a study right in CS. The entrance exam for CS studies is based on logical and analytical skills and does not require programming knowledge. The studies start with no expectation of previous knowledge on the subject.

The Department of Computer Science at the University of Helsinki has been selected as a national Centre of Excellence (CoE) in higher education twice in a row, 3 years at a time. This is a remarkable achievement for the department, since in the last round of CoE, the status was awarded only to 10 units in the whole country. The CoE status was received based on ten years of well-documented department-wide teaching improvements, such as formalized study circles, detailed and explicit

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

learning outcome rubrics for all mandatory and steadily recurring courses, and arranging the study environment according to the so-called *constructive alignment* [8]. Thus, it is safe to say that the education and teaching provided by the department has been highly valued and in a solid form already before the advent of the latest development that is in the focus of this paper.

Contrary to the common attitude, where faculty draws away from undergraduate education in order to teach graduate courses and fulfill research demands [9], we have exercised extensive effort to improve the undergraduate education starting from the very first courses. The most recent work in this area has been an improvement to both teaching arrangements and the content of our software engineering-related courses [10].

During the improvement, we have created and started applying a pedagogical method that we call the Extreme Apprenticeship (XA) method. As the first undergraduate courses are important on a student's path towards becoming an expert computer scientist, meaningful support activities must be organized for early courses. Approaching the early student population with too much distance can be detrimental to the learning community, students and teachers alike. Therefore, one important aspect of XA is to reduce the distance between the students and the teachers. In practice, this means constant emphasis on two-way feedback (interaction) between the teachers and the students.

A. The Extreme Apprenticeship method

Extreme Apprenticeship (XA) [11] is a method of organizing programming instruction in an effective and scalable manner [12]. It is not only about *learning about expertise* but *becoming an expert* in the practiced skill, e.g. programming. XA is influenced by Extreme Programming [13], where software development best practices such as code reviews are taken to the extreme, and Cognitive Apprenticeship [14], where emphasis is put on making tacit processes visible for the students via modeling, after which the students are scaffolded as they work on the task at hand themselves.

Exercises play a crucial role in XA education. Our courses are carefully structured around collaboratively produced learning objectives and assessment criteria that are visible to the students and teachers alike. Each learning objective is covered using several of exercises, that build on top of each other in a stepwise fashion. The stepwise increment is an adaptation of test-driven development [15] and the Spiral approach in education, where students deepen their knowledge on the topic step-by-step validating their work during each step.

Exercises are designed to help students start easy and deepen their knowledge in an iterative manner. An easy start provides feelings of success and helps students achieve their comfort level. Feelings of success feed the motivation that is known to be fluctuating strongly even within a course [16]. As the students work through the easier exercises, they practice skills that have been relevant in the earlier parts in the course, as well as are introduced to new topics in a gentle fashion. As students proceed within a course, the learning objectives of the exercises start overlapping each other, and more focus is put on facilitating deliberate practise [17].

As students start their work on a task, they first build a mental model of the problem at hand e.g. via well-structured exercise design, process recordings, or during lectures. Once the modeling phase has been continued to a state, where the student feels that she is confident about working on the task, she works on the task under guidance of a more experienced instructor, e.g. a teaching assistant. The teaching assistant scaffolds the student if she needs support, and even in such cases the student is only nudged towards a direction, where she can again proceed on her own.

In our context, the students are constantly helped in computer labs by course instructors, who actively engage the students that work on the exercises; students typically receive help within minutes, depending on the time of day, and the amount of students in the labs. Scaffolding provided by the instructors and learning material are designed to help the students to reach their zone of proximal development [18]. There are tens of weekly exercises, some of which provide step-by-step guidance for completing them, mimicking the solution process that a master can utilize while solving them, while other exercises are open-ended and allow students a larger degree of freedom for designing and programming a solution for them. While the students receive support and guidance in the labs, we also provide (semi-)weekly code reviews for some of the open-ended exercises.

Although there is no limit on the amount of guidance that a student can receive, or on the amount of times that the exercises can be returned, it is of utmost importance that as soon as the student does not require scaffolding and can proceed on their own, the scaffolding is faded, i.e. the support is reduced. The cycle of modeling, scaffolding, and fading takes place several times each week as each week typically contains several learning objectives and tens of exercises; the exercise sets for each week also have a strict deadline, after which they cannot be returned. Even if a solution that the student ends up with is correct, it may still require refinement. Depending on the quality of the solution, the student may be directed to further improve her work in the lab and apply practices such as clean code [19].

In practice, the most significant differences between XA and the traditional operation from the organizational perspective are: 1) there are no lectures in XA (or if there is, the lectures serve the exercises); 2) students are encouraged and expected to use as much time as needed to master the skills (thereby different students use very varying amounts of time in the XA lab during the week). Students are free to come and go as they wish to the XA labs. With careful allocation of resources, XA does not cost more than the traditional way of organizing lecture-based education [12].

So far the results in our XA-based programming education within the programming courses have been impressive. The change from traditional (lecture-based with take-home assignments) has resulted in a statistically significant change in acceptance rates of our programming courses; the average rates of our introductory programming course and advanced programming course have increased by 32% and 37% respectively (see [20] for further details). This is a noteworthy improvement as a lot of effort was already put into the improvement for the introductory programming course.

B. Students as voluntary TAs

In XA-based programming courses, most of the work is typically done in computer labs, where the teaching personnel scaffolds the students that work on the exercises. Since starting to apply XA, we have observed a substantial increase in students that are willing to help others in the labs, even on a voluntary basis. As a response to the increase, we have welcomed the student teaching assistants; many of them are in a very early phase of their studies, and are participating in the teaching community even as early as during their second semester [21].

The students that participate as teachers become legitimate peripheral participants [22] of the teaching community. Having young student members as part of the teaching community is beneficial for all parties, as it may increase the retention rate [23] and create a more enjoyable learning context [24]. Between fall 2010 and spring 2013, in addition to the course faculty, we have had 93 junior teaching assistants participating in making the XA experience as positive as possible to the students in the classes. Contrary to some other laudable efforts in using students as agents of educational reform [25], we aim to have some 20% of our students involved in XA labs as TAs.

III. Study Setting

The carry-on-effect of XA-based education is studied using three different measures: (1) grade distribution in the first mandatory programming course; (2) credit accumulation per average student 7 and 13 months after the start of their studies, and (3) success in the expected study path during the first semester by examining the success in two of the subsequent courses right after the first programming course. In all of these examinations, the point of introduction of XA-based education is the year 2010.

The data used in this study is extracted from the official study records of the University of Helsinki, and contains records for students that have enrolled at the university with CS as their major subject since 2007. In total, the database extract has information on 895 students. The yearly intake of students has been aimed at 130 (except 2007 when it was 150). In practice, there is year-by-year fluctuation since a part of the accepted students do not register for CS (as they probably have succeeded in landing a more preferable study place somewhere else). "Overbooking" in the student intake is typically something around 35% but fairly difficult to predict. This is the reason for normalizing the numbers year-by-year so that we can compare the relative, not absolute changes in the results.

The application of Extreme Apprenticeship method for the first courses was started in 2010. Hence, years 2010-2012 are post-XA years, and 2007-2009 are pre-XA years in the data. Pre-XA years means a more traditional way of organizing education around a fixed number of weekly lectures, exercise sessions, and study groups. The teacher responsible for the courses Introduction to Programming and Advanced Programming has been the same during 2007-2011, while a different teacher was assigned to the courses during 2012.

A. Grade Distribution

Even though the first programming course has been completely revamped with the advent of XA, the paper-based final exam has been deliberately kept mandatory and as closely corresponding to the exams during the pre-XA era as possible. Therefore, the grade distribution of the course Introduction to Programming is comparable on a yearly basis. It is important to note that the grade distribution at our university is completely decidable by the teacher responsible for the course. In other words, the grades do not need to be forced into a bell curve. Changes in grade distribution can therefore truthfully reflect the changes in student skills and knowledge.

We acknowledge the fact that since XA is about heavy practice, students are likely to accumulate a stronger programming routine and other desirable qualities that are not captured by the traditional final exam. In order to emphasize the thinking and not just the doing – as Allendoerfer et al. [26] aptly put it – a paper-based final exam that requires higher-order thinking skills is a valid addition to the educational arrangements, even when XA is employed.

B. Credit Accumulation

Possible differences in credit accumulation were analyzed by extracting the number of computer science credits that each student had gathered in 7 and 13 months since the start of their studies. As there is always a handful of students that do not start their studies during the same year they enroll, we removed the students that had not attempted to take any courses from the analysis.

As the number of students starting their studies each year differs, the credit accumulations have been normalized based on the number of active students, i.e. students, that have at least attempted a single course. After normalization, the results are directly comparable. As the students start their studies on August 1st, the 13 month accumulation for year 2012 is not available during the time of writing this article.

C. Early Study Path Success

In addition to the credit accumulation for each student group, we analyze if there is any difference in study path success between students. The student cohorts are built based on the year when they took their first introductory programming course, which is considered as the first step in computer science studies, as it is mandatory for every student.

We analyze two different course pairs for each student cohort: (1) Introduction to Programming and Advanced Programming (both changed to XA after 2010), and (2) Introduction to Programming and Software Modeling (the latter has not been changed to XA). The courses are organized right after the course on Introduction to Programming in the same semester.

The method employed here resembles the research conducted by Carrell and West [27]. However, as the organization of courses and allocation of teachers is not so structured at our department and administratively collected student feedback infrequent, we cannot examine the effects of XA in such a comprehensive fashion.

IV. Data and Results

In this section, we show the data and the results extracted from the study registry. First, we discuss how the grade distribution has changed within our introductory programming course. Then, we focus on the overall credit accumulation between students that have started during different years, and finally, we consider students' early study path success.

It should be noted that there have not been other significant organizational arrangements that can interfere with the results. The required study path for BSc students has been the same from 2007 to 2012. The number of teachers has remained the same, and no differences in student intake can be evoked. However, as the yearly intake in 2007 was 150 and only 130 from 2008 to 2012, we use the year 2008 as a baseline, as one could argue that the student cohort of the year 2007 was somehow inferior to the subsequent years.

Another worthy detail is that all teachers responsible for these courses are tenured teachers, not adjunct or contingent. All of the courses have had several students as paid TAs; the number and the "quality" of TAs is comparable year-by-year.

A. Grade Distribution

The grade distribution in the introductory programming courses from 2007 to 2012 is visible in Figure 1. The areas in dark color, i.e. grade 0, depict the number of students that have failed the course, while the areas in brighter color indicate students that have passed the course. In the XA-based courses, 38.5% of the students have received the highest grade available, i.e. 5, which is indicated by the brightest color. The grade 5 has been awarded to 22.6% of the students in traditional courses. During 2007-2009, 42.3% of the students failed the course Introduction to Programming on the first try, while during 2010-2012, 28.2% of the students failed the course on the first try.

It is clearly visible that the grade distribution and pass rate has been improving. However, as we do not employ tests similar to ACT/SAT, we are not able to directly compare e.g. grade inflation [28], as is possible in several other countries. However, in our context, there are no direct or hidden incentives tied to the grade distribution, and the teacher responsible for every course instance has been a tenured teacher who also teaches many of the subsequent courses to the very same students; "letting the students off easy" would be harmful for the teacher herself.

Successful start on the study path is a valuable first step, as it is a clear signal for a student that she is doing a good job and is appropriately rewarded. A successful first step can start a virtuous cycle for the student but only if the student truly has learned the required skills. Grade inflation would be counterproductive in XA-based education.

B. Credit Accumulation

Credit accumulation describes the number of credits that students have received during an observed interval. The students are grouped based on the year when they enroll at the university and start their studies. The number of credits has been aggregated from the student groups. Table I shows number of students, sum of credits after 7 months of studying

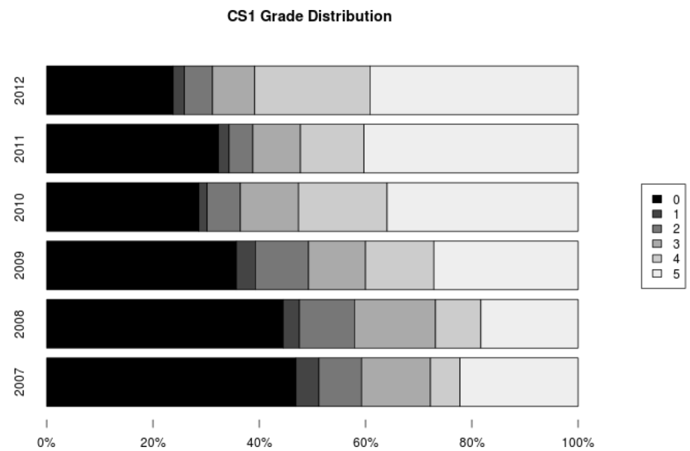

Fig. 1. Grade distribution for the course Introduction to Programming between 2007 and 2012

and credits after 13 months of studying for each student group. In addition to the sum of credits, normalized credit counts and comparison to year 2008 are also shown. The normalization is done based on the student population size, and year 2008 was chosen as a baseline as the student intake was decreased from 2007 by 20 students. Note that the data only contains students that have started their studies, i.e. at least attempted a single course.

TABLE I. Credit accumulation for student groups from different yearly intakes

Year	Students	Credits 7 (norm, scaled %)	Credits 13 (norm, scaled %)
2007	136	1681 (2237, **91.6**)	2558 (3404, **95.2**)
2008	119	1605 (2441, **100**)	2352 (3577, **100**)
2009	120	1616 (2437, **99.9**)	2686 (4051, **113.3**)
2010	136	2030 (2701, **110.7**)	3418 (4549, **127.2**)
2011	140	2287 (2957, **121.1**)	3352 (4334, **121.1**)
2012	168	3042 (3277, **134.3**)	n/a

When looking at the years 2010-2012, we observe a clear increase in the number of credits that students gain during their early studies when compared to the years 2007-2009. The higher number of freshmen in 2012 is explained by an experiment, where we utilized a massive open online course (MOOC) in programming as an entrance exam to CS studies [29]. The number of students that received a study place through "the normal way" was not influenced by the experiment.

To compare whether there is a difference between the 2007-2009 and 2010-2012 cohorts, analysis of variance (ANOVA) was conducted on the credit gains after 7 and 13 months. With three samples in both groups, there is a statistically significant difference between the groups ($p < 0.05$). In the 13 month groups, where the numbers from 2012 is missing, there is no statistically significant difference ($p = 0.062$).

This may be partially explained by the number of samples, and partially by the introduction of XA. XA was introduced during spring 2010, and some of the students that failed first programming courses during fall 2009 retook their programming courses during spring 2010. Typically, spring versions of the programming courses are populated by CS minor students, whereas fall versions are for CS major students.

In addition, we analyze the credit gains of students that attempted their studies, i.e. enrolled to at least a single class, and students that passed courses.

When analyzing the students that attempted their studies, the students in the pre-XA group gained 13.1 credits during the first 7 months (n=375, σ=11.6), while the students in the post-XA group gained 16.6 credits (n=444, σ=11.1). The two groups were also compared using an ANOVA test, which indicated that there is a statistically significant difference for the pre-XA and post-XA groups after 7 months of studies ($p < 0.01$).

When considering the credit gains after 13 months, where year 2012 has been excluded due to currently unavailable data, the pre-XA group gained 20.3 credits on average (n=375, σ=18.6), while the post-XA group gained 24.5 credits on average (n=276, σ=19.0). A statistically significant difference was observed using an ANOVA test ($p < 0.01$).

When considering students that passed courses, i.e. they have passed at least a single course, the students in the pre-XA group gained 17.0 credits during the first 7 months (n=289, σ=10.4), while the students in the post-XA group gained 19.6 credits (n=376, σ=9.3). An ANOVA test indicated that there is a statistically significant difference for the pre-XA and post-XA groups after 7 months of studies ($p < 0.01$).

When considering the credit gains after 13 months, where year 2012 has been excluded due to currently unavailable data, the pre-XA group gained 25.6 credits on average (n=297, σ=17.4), while the post-XA group gained 29.3 credits on average (n=231, σ=17.1). A statistically significant difference was observed using an ANOVA test ($p < 0.05$).

C. Early Study Path Success

In order to validate the effect of XA, we want to examine the mandatory first course (Introduction to Programming) and see whether the success in two mandatory subsequent courses (Advanced Programming and Software Modeling) benefits from the fact that the first course is based on XA or not. To validate the effect even further, one of the subsequent courses (Advanced Programming) is also XA-based, but the other one (Software Modeling) is not. All of these three courses are mandatory courses for every BSc student in CS, and all of the three courses are scheduled to be taken during the first semester.

In the following examination, study path success describes the student percentage that has succeeded in a specific course pair on the first attempt. The percentage for yearly course pairs is shown in Table II.

TABLE II. STUDY PATH SUCCESS WHEN MOVING FROM INTRODUCTION TO PROGRAMMING TO ADVANCED PROGRAMMING AND INTRODUCTION TO PROGRAMMING TO SOFTWARE MODELING

Year	Intr. Prg. & Adv. Prg	Intr. Prg. & SW. Modeling
2007	45.1	41.5
2008	39.2	48.8
2009	50	54.2
2010	68.5	63
2011	71.1	74.4
2012	70.3	72.2

Before XA, the year with the best success was 2009, where 50% of the students that enrolled in both Introduction to Programming and Advanced Programming passed both courses on their first attempt. A similar result is visible in the course pair Introduction to Programming and Software Modeling; 54.2% of the students that started both courses passed both on their first attempt.

The lowest scores after the introduction of XA are from the year 2010. Here 68.5% of the students passed both programming courses on their first attempt, and 63% of the students passed both Introduction to Programming and Software Modeling. However, a clear difference can be observed between the pre-XA and post-XA courses. An interesting issue is that the effect of the first course using XA appears to carry over to the subsequent course, irrespective of the use of XA in the subsequent course.

When conducting an ANOVA test for the course pair Introduction to Programming and Advanced Programming, there is a statistically significant difference ($p < 0.01$) between the pre-XA and post-XA groups. Statistically significant difference is observed also for the course pair Introduction to Programming and Software Modeling ($p < 0.05$).

V. DISCUSSION

We have described results from a long-term study of student performance before and after applying a method called XA in our early programming courses. Our results indicate that the grade distribution, pass-rate, overall credit accumulation, and student success in staying on the desired study path have all improved after applying XA, when looking at students' performance after 7 months and 13 months of studying.

At our university, the teachers are not rewarded for performing well, nor are they punished for performing poorly. As a matter of fact, it is very difficult for a teacher to even know how they are performing, as there are no formal measures other than student grades that the teacher herself decides. The administration oversees the study progress on a larger scale but has no measures to evaluate *learning*. Many times even the formal course feedback received from the students has little impact as the teacher herself is the main actor in processing the feedback. Fortunately, in our context where teaching is valued and teachers want to be good teachers rather than bad teachers, our introductory programming courses have always received excellent feedback and been held in high esteem. Therefore, the improvements described in this paper are valuable, as they extend beyond a single course and improve an already well-functional educational arrangement.

The results and XA that are described in this paper are a part of a larger change, which was started in late 2009. Every change requires people willing to change; we have been lucky to have teachers eager to deliberately practice and hone both their skills and knowledge, and apply their knowledge fully into teaching. Communication and bi-directional feedback valued by XA requires that the teachers are on the same level as the students, as students work on their exercises: both receive feedback on what they are doing well, and what could be improved, which allows a cycle, where the courses can be aligned to match the needs of individual learners.

Acknowledgements

We gratefully acknowledge Matti Luukkainen and Arto Wikla, who have both done great work in improving the programming education at our department. We also gratefully acknowledge the grant from the Dean of Faculty of Science for this project. Part of the research is funded by the Centennial Foundation of the Finnish Technology Industries.

***Abstract*—Modern web-based services increasingly have a cloud-based component, which only in recent years has been studied in an academic manner. Many cloud-computing courses focus on fundamental concepts that, while universal to cloud computing understanding, may not provide students with enough background to actually deploy an application to the cloud. To that end we present a cloud computing class that through the use of labs, presentations, and research projects, integrates practical hands-on experiences with academic research. The labs not only deploy to multiple public cloud environments, but also walk students through the process of creating, configuring, and maintaining their own private clouds. We maintain that this juxtaposition of practice and theory leads to not only better learning outcomes in the classroom in the form of refereed publications and further study, but also leads to practical skills which better prepare students for joining the workforce.**

Keywords – cloud computing; graduate teaching; hands-on laboratories.

I. INTRODUCTION

The rising use of cloud computing in industry has led to a shift in the way modern web services are architected and deployed. With the previous paradigm of purchasing and racking servers to create a website slowly going away, the new generation of programmers is faced with a unique dilemma.

Traditional development assumes a dedicated server farm in a well-maintained data center with an army of system administrators available 24 hours a day. Each server is reliable, closely monitored, and treated as a business critical asset. With cloud computing this paradigm is no longer valid. A server is now a virtual entity competing for resources with other entities on shared hardware in a common network. Depending on what applications are being run on neighboring computing instances, this can result in wildly different performance and usage patterns for the cloud as whole.

In the current computing landscape it is possible to create a fully functional, virtual computing environment with scaling, configuration, and redundancy built in. Replacing the traditional model of dedicated hardware in a private data center for a shared computing environment in a public cloud however requires a different way of thinking about how to create and maintain a modern online web-based service.

Much like the shift from declarative to object-oriented programming, cloud-based programming requires a new way of thinking. While a virtual machine (VM) in a cloud environment is generally abstracted as a fully functional (albeit amorphous) computer on the Internet, it is in actuality an entity that is fundamentally different when compared to a similar physical server housed in a dedicated data center. Differences in performance and reliability must be accounted for in a cloud-based architecture, as they can make the difference between a successful deployment or a complete failure. It is this difference that makes the study of cloud computing of paramount importance in a modern engineering curriculum.

This paper describes a graduate level cloud-computing course that was first taught at San José State University in San José, California, USA in the fall semester of 2012. Because of the proximity of San José to Silicon Valley, it was decided to incorporate a variety of cutting-edge cloud computing technologies with the traditional curriculum to better prepare students for local positions in industry as well as for further Ph. D. study. The success of this teaching method is the focus of the remainder of this paper.

The paper is organized as follows: the second section describes the course content in-depth. The third section focuses on the hands-on lab assignments, including lessons learned designing the labs. The fourth section presents the results of the course in the form of student feedback, success stories, and the results of one particular project. The fifth section details goals for future classes, and finally the last section concludes the paper.

II. COURSE DESCRIPTION

A. Overview

The course used a traditional curriculum including lectures, student presentations, and group research projects, supplemented with eight hands-on labs intended to introduce various aspects of cloud computing. The overarching goal of the labs was to provide the students with practical experience building and deploying a cloud infrastructure from the ground up.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

B. Student Background

Most of the students in the class had graduate standing either in Computer Science or Electrical Engineering with several additional non-regular students who were working professionals. Roughly half of the students attended school part-time while working full-time in some capacity in the IT field. Several of the students were also in the process of pursuing their second (and in one case third) graduate degree. For the majority of the students, this class was their first exposure to cloud computing.

C. Lectures

For the first part of the semester traditional lectures from the primary textbook were presented which introduced cloud computing from an academic perspective [1]. The focus of the lectures was on fundamental concepts common to cloud computing including: distributed system models, virtual machines (VM), virtualization, cloud platforms and architectures, service-oriented architectures, cloud programming and software environments.

In addition at the beginning of each class session students took turns presenting a chapter from a secondary textbook on cloud computing [2]. Unlike the primary textbook, which approached cloud computing from an academic viewpoint, this textbook was written primarily for professionals currently employed in industry with a desire to learn more about cloud computing. As a result, the emphasis was more on real world examples that focused less on theory and more on practice.

This was the first student activity that required demonstrable mastery of the practical application of cloud theory and its importance in industry. The second was the use of the hands-on labs that students worked on for the duration of the class.

D. Laboratories

The labs were divided into three general groups, each of which emphasized a different student-learning outcome. The labs start with a description of the VM as the fundamental unit of the cloud with each subsequent section showcasing its use in both the private and public cloud.

1) Introduction to VM – The first group of labs describes the VM as the fundamental unit of a cloud and leads the student through the automated creation and configuration of a VM through the use of specialized software tools.

2) Private IaaS (Infrastructure-as-a-Service) - The next group introduces the concept of a private cloud infrastructure and walks the student through the steps required to programmatically create, configure, and use a private cloud using the OpenStack IaaS open-source software application [5].

3) Group 3: Public Clouds – The next group introduces public clouds which are used to repeat the application deployment done previously in the private cloud. In this way students gain an appreciation for the benefits (and drawbacks) of using a public versus a public cloud computing environment.

4) Group 4: Advanced Topics - The final group introduced advanced cloud computing concepts deemed to be topical to the class. In our class students were introduced to advanced configuration management using heterogeneous public clouds by having the students create a cloud based configuration server on one public cloud and use it to manage cloud instances on a different public cloud provider. This allowed students to see how subtle differences in public cloud providers can result in additional effort on the part of the programmer to ensure cloud interoperability.

Additionally students also configured a private Storage-as-a-Service cloud using the OpenStack cloud created previously. This allowed the students the ability to see how a cloud-based storage system could be implemented using open source software in a private cloud.

E. Research Projects

After gaining hands-on experiences from the labs, the students then worked on two advanced cloud computing research projects. The first focused on research survey while the second required programming and a project demonstration.

1) Project 1

The first project is a literature review whereby each student team selects an advanced research topic relevant to cloud computing. One such topic was *"Workflow algorithms for scheduling in cloud computing"*. Each team then researches their topic by reading available journal articles and conference proceedings related to the selected topic. Once their research is done, the student team writes a paper summarizing their findings, which is presented in class. Completion of this project segues into the second project. The list of project topics for this term is given in Section IV.

2) Project 2

In the second project the student teams come up with an original idea based on their work on the previous project. Student teams are given wide latitude for their topics and are encouraged to find something they are interested in learning more about. If necessary, the student will confer with the instructor for ideas, but the students are ultimately responsible for the final proposal, which must be novel, quantifiable, and practical to test and/or implement. As an example for Fall 2012 the group that chose the following topic for Project 1: *"Workflow algorithms for scheduling in cloud computing"*, worked on the following topic for Project 2: *"A tunable Workflow Scheduling Algorithm Based on Particle Swarm Optimization for Cloud Computing"*.

Once the ideas have been formally approved the student teams will then begin work immediately. The project involves original work with regular check-ins with the instructor for the remainder of the semester and culminates at the end of the term when every team presents their work to the class, submits a paper, and does a live demonstration of their work. The students are then evaluated by their peers, who provide feedback to the instructor who assigns the final grades.

III. HANDS-ON LABORATORIES

In the following section we first present the eight lab sessions, followed by a discussion of these labs. Finally, we discuss the lessons learned from designing these labs.

A. The Laboratories

There are a total of eight labs, organized into four groups. Each of the lab assignments focuses on a specific aspect of cloud computing and are meant to build on the work and ideas introduced in prior assignments. They are deliberately broad in scope so that students may become familiar with major cloud computing paradigms.

1) Lab 1: Introduction to VM

The first lab in the series walks the students through the installation and configuration of VirtualBox, the Virtual Machine Manager (VMM) software application used for the remainder of the semester [3]. The student is evaluated on whether they are able to successfully create and use a VM.

2) Lab 2: VM Configuration

This lab introduces the concept of the programmatic configuration of a VM using Puppet, a widely used automated configuration tool [4]. The student is evaluated on their successful creation of multiple customized VMs programmatically via configuration files.

3) Lab 3: Private IaaS configuration

In this lab the student creates a private IaaS cloud using the VMM they installed and used in the previous two labs. The student is evaluated on the successful creation of a standard VM running OpenStack that is functionally equivalent to the Amazon EC2 service [6].

4) Lab 4: Advanced IaaS

This lab introduces the configuration of external cloud images as well as the creation and use of virtual storage. The student is evaluated on the successful import of third-party disk images and their ability to successfully use virtualized storage with virtual instances created using the aforementioned images.

For the next three labs, students used cloud-computing resources available on the Internet, which they programmatically controlled and configured. In the interest of minimizing the cost, only cloud entities that had a free tier of computing service that was deemed sufficient for successful completion of the remainder of the labs were used.

5) Lab 5 – Public IaaS

This lab walks the students through creating and customizing a VM using the Amazon EC2 platform. It additionally introduces the students to the programmatic creation of a public cloud infrastructure via application program interface (API) calls [7]. Students were evaluated on their ability to successfully write software to programmatically create and configure VMs in a public cloud.

6) Lab 6 – Platform-as-a-Service (PaaS)

An alternative PaaS cloud is introduced using the Google App Engine (GAE) platform [8]. Students were evaluated on their ability to create a website using the GAE Java software development kit (SDK) [9].

7) Lab 7: Inter-Cloud Configuration Management

With a sponsorship provided by GoGrid, students worked to integrate two different public clouds, Amazon EC2 and GoGrid [10]. The students built a VM with the Puppet configuration server using GoGrid which they used to create and provision a cloud web service in the Amazon EC2 cloud. Students were evaluated on their ability to manage multiple VMs in heterogeneous clouds.

8) Lab 8: Storage-as-a-Service

Originally, only seven labs were designed. As students asked for extra credit opportunities, one extra lab was then added. This lab may be seen as an extension to Lab 4 (advanced IaaS). It details the addition and use of the Storage-as-a-Service functionality to the installation of OpenStack in Lab 3 and to the generation and use of virtual storage in Lab 4. Students were evaluated on their ability to create a functional equivalent of the Amazon Simple Storage Service (S3).

B. Lab Discussions

In this section we discuss some major decisions made while designing these labs.

1) Private Cloud vs. Public Cloud

It may be easier (and sometimes more economical) to do everything in the public cloud over the Internet. However we decided to include both private and public clouds in these lab sessions since both are vital and have their own advantages.

Working to build and configure private clouds forces students to learn a great deal of technical details of cloud computing. One thing that the cloud purposefully does is obfuscate the myriad of details that go into creating a fully functional VM. These are details that, while deploying to the cloud (which is essentially a third party), an engineer should carefully consider. Below are some examples:

- What happens behind the scenes when a new image is imported?
- When a VM instance is launched but there are not enough resources, what does that look like from the VM perspective? What about from the hardware perspective?
- If I run x number of VM instances on a dedicated hardware, what is an optimal load on the host operating system (OS)?

In an ideal world a developer not only has experience using the cloud, but also running it. By having students build their own cloud they are able to use and evaluate the cloud as both consumers and producers.

2) OpenStack vs. Eucalyptus

The original version of the class was planned using the Eucalyptus IaaS platform [12]. One attractive feature of Eucalyptus is that it offers API compatability with Amazon's EC2, thus enabling the creation of AWS-compatible private and hybrid clouds. Its steep hardware requirements however, led us to look for other alternatives.

After careful evaluation of competing IaaS platforms, we decided to use OpenStack [5] instead. OpenStack is another open-source project that is also API-compatible with Amazon EC2, S3, etc. It offers another advantage in that it has been adopted by several major Linux distributions (Ubuntu, Red Hat) and companies (Hewlett Packard). It also boasted a community-supported, VM-based install which allowed students to create their own self-contained cloud-computing environment.

3) Amazon EC2 vs. GoGrid

Initially the labs were designed to use only the cloud-computing resources freely available in the Internet (in addition to students' own computers). Thus, all but the last lab sessions were based on Amazon EC2, Google GAE, etc.

GoGrid is a local company based in San Francisco, CA, USA [10]. It reached out to us shortly after the class began and generously offered cloud computing resources for our students. The availability of GoGrid offered a unique teaching opportunity for students to create multi-vendor cloud-based web services (Lab 7).

4) Online Documentation

To help students quickly and confidently master the labs, a detailed lab menu was created. Most of the documentation for the labs was adapted from online sources. This is especially true in the labs using the public clouds, which by and large referred students to the vendor's "Getting Started" guides.

5) Teaching Assistant

There is usually no teaching assistant (TA) available for graduate courses at San Jose State University. The first author, then a graduate student at SJSU and having many years as a system administrator and program manager, volunteered himself as the TA for the course. The TA helped create, administer, and grade the lab assignments. He was familiar with cloud computing concepts and had hands-on experience creating and deploying private clouds using both Eucalyptus and OpenStack. Furthermore, the TA had held regular office hours specific to the labs in addition to the professor's normal office hours.

C. Lessons Learned

1) Assumptions about students' Linux background

As this class was focused on cloud computing in general, we tried as much as possible to be platform-agnostic. This however did become an issue as there were a small number of students who had no previous experience working in a Unix command-line environment, which presented a problem when using VMs based on Linux.

A detailed lab menu and documentation were created partly to deal with this issue and to help these students. This is essential especially for the first three labs, so that students' lack of Unix experience did not become a negative factor for their success. Additionally, the TA had held extra office hours for students who needed more help in the first several weeks. In practice we found that students who made it past the second week did not have problems completing the remainder of the labs regardless of their experience using Unix.

2) Open-Source Software

One informal goal was to teach cloud computing in a way that was as platform-agnostic as possible. To that end it was decided to use open-source software as much as possible that was not tied in to a particular OS or hardware platform. This goal was achieved as students successfully completed the labs using recent versions of Windows, Linux, and Macintosh operating systems. However it was decided to have a standard platform that would be supported for the class. We went with the 64-bit version of Microsoft Windows running on a recent (within the last two years) PC to minimize potential pitfalls involved in running multi-platform software.

3) Software Versions

To avoid additional problems regarding incompatible versions the software was "frozen" during the class session so that the software versions available on the first day of class were the only versions that were guaranteed to work.

This decision became important later in the course as the version of the OpenStack IaaS platform used by the class is a development version that is continuously updated. With this in mind the TA would do a fresh installation of OpenStack once a day to ensure that the latest version used by the students was functional.

4) Liability

Another concern when using the public cloud was the possibility of the student being charged for using up the "free" tier of computing service and being charged. This was not a problem with GAE. Amazon however, did require a valid credit card prior to allowing the use of their free tier. As a precaution a warning was placed in every lab that utilized the public cloud reminding students that they are responsible for any and all charges.

D. Overall Feedback

The feedback from the students after the end of the lab sessions was overall very positive. Students especially enjoyed the "hands on" nature and in particular said they enjoyed the opportunity to create their own private clouds. For the students who had some exposure to cloud computing all of them said that they learned something new while doing the labs that they had not known was possible previously.

IV. Research Results

In this section we focus on the results of research projects (Projects 2 and 3). The list of research projects is first presented. Next, one particular research result is described. This is followed by an overview of student feedback.

A. Research Projects

Among 17 students, seven teams were formed. These student teams chose their project topics based on their own interest and their assessment of importance/usefulness of various topics. The following is the list of projects:

1. Workflow scheduling algorithms for cloud computing
2. The issue of energy efficiency on mobile cloud computing
3. Water-marking for Hadoop security

4. Quantitative and analytical comparison of cluster and cloud computing
5. Parallel Java for cloud computing
6. Improving cloud computing privacy using smart phones
7. Two-party auditing for cloud computing privacy

B. Example: Workflow Algorithm for Cloud Computing

In this section, we present a particularly successful example, in which the research project led to a refereed publication [13]. In this project, the team of four members started a literature survey, and decided to work on workflow scheduling for cloud computing. Its major results are described below.

1) Introduction

Cloud computing uses a great amount of heterogeneous resources to deliver countless different services to users of distinctive quality of services (QoS) requirements. Numerous diverse tasks need to be carried out to meet the vastly different QoS and budget requirements. Workflow scheduling is therefore critical for the success of large-scale cloud computing.

A workflow is formed by a logical sequence of interdependent tasks decomposed from applications. The scheduler decides which resources will be used, as well as which tasks will be executed on each of these resources while satisfying the QoS constraints set by users, such as execution time and cost. The workflow scheduling problem, like general scheduling problems, is NP-complete. Workflow scheduling algorithms therefore often utilize heuristics to obtain approximated solutions.

This research project adopts a workflow scheduling strategy using Particle Swarm Optimization (PSO). PSO, developed by Kennedy and Eberhart [14], is one of the latest evolutionary algorithms inspired by nature. PSO approximates an optimal solution by iteratively improving a swarm of candidate solutions, called particles. Each particle is modified iteratively by the best information from both the individual and the entire swarm. PSO works well on most global optimal problems.

Makespan and cost are two main performance measurement criteria specified by cloud users and considered by workflow schedulers. Makespan is the time from the beginning till the completion of the sequence of tasks in a workflow. Some algorithms are designed to achieve minimum cost [15][16]while others strives for minimum makespan [17] or for load balance [16].

In this project, a workflow scheduling strategy to attain a combined minimal cost and minimal makespan is introduced. The main contributions are:

1. *A model for a mapping between tasks and resources is formulated, achieving a tunable objective between cost and makespan.*
2. *A PSO-based heuristics is presented to realize the optimal mapping for the tunable objective.*
3. *The heuristics is further improved by addressing bottleneck tasks and thus reduces the makespan even more.*
4. *While most PSO papers simply use a fixed particle number in their experiments, the effect of the number of particles in the PSO performance is studied.*

2) Scheduling Problem Formulation

Several optimization objectives are formulated as follows. Let $Makespan_{total}(M)$ denote the makespan of the workflow with respect to the mapping M:

$$Makespan_{total}(M) = finish\ time\ of\ the\ last\ task - start\ time\ of\ the\ first\ task\ . \quad (1)$$

The makespan of a workflow is the time duration from the beginning of the first task till the end of the last task. Since a workflow consists of interdependent tasks, both execution time and transfer time need to be considered.

Next, let $Cost_{exec}(R_i)$ and $Cost_{trans}(R_i)$ be the execution and transfer costs of resource R_i, respectively. $Cost_{total}(R_i)$ denotes the total cost of resource R_i:

$$Cost_{total}(R_i) = Cost_{exec}(R_i) + Cost_{trans}(R_i)\ \ 1 \le i \le m\ . \quad (2)$$

Let $Cost_{total}(M)$ be the total cost of the workflow *w.r.t* the mapping M:

$$Cost_{total}(M) = \sum_{i=1}^{m} Cost_{total}(R_i)\ . \quad (3)$$

For the objective of minimizing the cost while balancing the load [16], the fitness function is given as:

$$Fitnessfunction_1 = Max(Cost_{total}(R_i)),\ 1 \le i \le m\ . \quad (4)$$

The objective is to minimize $Fitness\ function_1$. The reason for not using the total cost of all the resources is to prevent from mapping all the tasks to a single, least-cost resource.

For the objective of optimizing makespan (such as the work by Zhang et al [17]), the fitness function can be defined as:

$$Fitnessfunction_2 = Makespan_{total}(M)\ . \quad (5)$$

The objective is to minimize $Fitness\ function_2$.

In this paper we propose an objective of minimizing the *weighted* sum of total cost and makespan; the fitness function can then be defined as:

$$Fitness function_3 = \alpha\, Cost_{total}(M) + (1-\alpha)\, Makespan_{total}(M), \quad 0 \le \alpha \le 1, \quad (6)$$

where α is the weight given to the total cost and $1-\alpha$ is the weight given to makespan. This fitness function can be easily tuned by changing the value α to satisfy the various QoS requirements including budget constraints. Again the objective is to minimize $Fitness\ function_3$.

3) The PSO Algorithm

The evaluation of each particle is performed by the fitness function, defined according to the optimization objective, as described above. The high-level structure of a PSO algorithm is given in Table I

.

TABLE I. The PSO Algorithm

1: Initialize particles' position and velocity randomly.
2: ***While*** *stopping criterion is not satisfied* ***do***
3: ***For*** *each particle* ***do***
4: Calculate its fitness value using the fitness function.
5: Update its local best position.
6: ***End For***
7: Update the global best position.
8: ***For*** *each particle* ***do***
9: Update its velocity and position.
10: ***End For***
11: ***End While***
12: Return the global best position.

Next, we present a heuristics to further reduce the makespan, as illustrated in Table II. Since all the ready tasks assigned to a specific resource are independent, it will speed up the workflow by scheduling first the "bottleneck" task; i.e., the task having most descendants.

TABLE II. Improvement: Bottleneck Reduction Algorithm

1: ***For*** *each resource* ***do***
2: ***For*** *all the ready tasks in the resource* ***do***
3: Sort tasks in descending order of the number of descendants.
4: ***For*** *ready tasks having the same number of descendants* ***do***
5: Sort tasks in ascending order of execution time.

4) Performance Evaluation

In this section, we first describe the four PSO algorithms and the cloud experiment setup. Next, a subset of performance results are presented.

a) PSO Algorithms

The JSwarm package is extended for conducting the PSO experiments [18]. The number of iterations in the PSO algorithm is set to be 100. Four algorithms are evaluated, as summarized in Table III.

TABLE III. Four PSO Algorithms

Algorithm	Objective	Fitness Function	Strength
1 [20]	Minimize the maximal cost	(4)	Load balance
2	Minimize the makespan	(5)	Low makespan
3 (Proposed)	Minimize the weighted sum of total cost and makespan	(6)	*Tunable*
4 (Proposed)	Minimize the weighted sum of total cost and makespan, with *bottleneck reduction*	(6)	*Tunable*, with Bottleneck-reduction, minimal cost & min. makespan

b) Cloud Experiment Setup and Results

CloudSim 3.0 is used to configure cloud environment and simulate the execution of workflow [19]. A data center consisting of one switch and four hosts each having two VM (Virtual Machines) is configured in CloudSim. The millions of instructions per second (MIPS) and execution cost of each VM, and the data transfer cost between different VMs are set as the experiment input. The prices are by referring to the pricing policy of Amazon EC2's pricing policy.

We vary the tasks' MI (Millios of Instruction) by multiplying different proportion values. Fig. 1 shows the total cost of the four algorithms. The cost of Algorithms 3 and 4 are lower than Algorithms 1 and 2, while the cost of Algorithm 2 is the highest. This is reasonable since Algorithm 1 minimizes the maximal of the individual costs rather than the total cost (to prevent all the tasks executing on a single resource), while Algorithm 2 minimizes the makespan. Algorithms 3 and 4 aim to minimize the sum of total cost and makespan, both achieves the lowest cost.

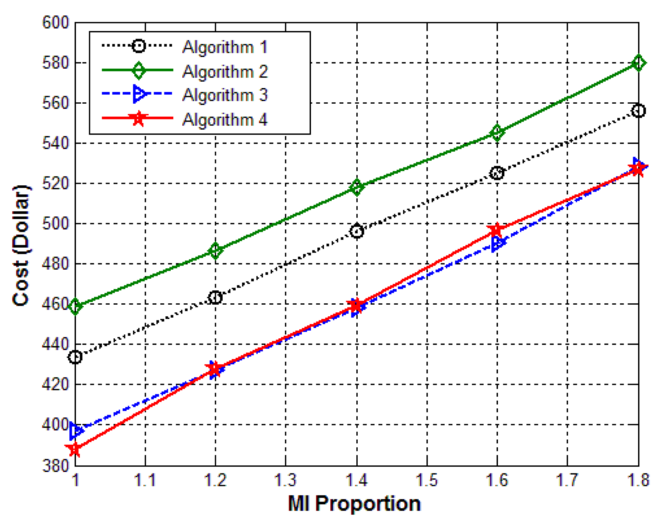

Fig. 1. Cost vs. MI (Millions of Instructions).

The makespan of the four algorithms is shown in Fig. 2. It is clear, and with obvious reason, that Algorithms 1 and 2 have the highest and the lowest makespan, respectively. Note that Algorithm 4 attains a makespan that is very close to Algorithm 2, and is even lower than Algorithm 2 with MI proportion = 1.8. *This demonstrates that Algorithm 4 has achieved concurrently both minimal total cost and minimal makespan.*

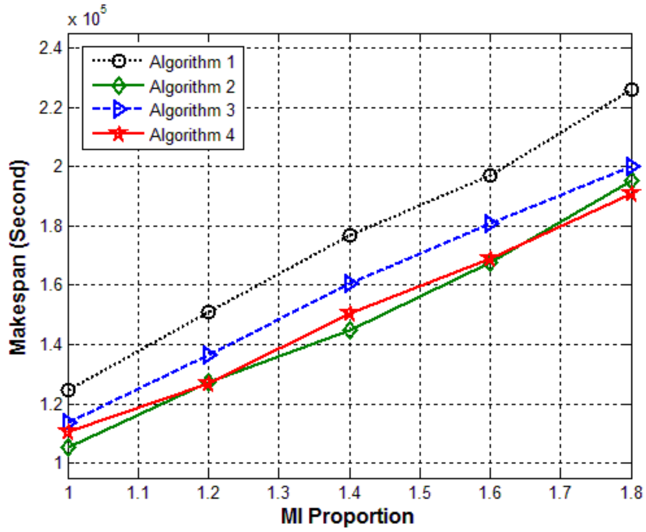

Fig. 2. Makespan vs. MI (Millions of Instructions).

C. *The Next Step: Master Thesis*

In our experience a large number of these research projects have led to Masters thesis as well as publications in various conferences and academic journals [21].

V. FUTURE COURSES

Based on the success of the first course as of Fall 2013 the class is now a part of the San José State Computer Science curriculum. There will be a newer updated set of labs provided by the instructor and TA that we hope will continue to explore new and novel uses of the cloud.

Some ideas include having one student group build a private cloud while another group uses their cloud for deployment. After which they would then evaluate each other and present their findings to the class detailing why their peers are (or are not) a good cloud provider. This would be interesting in that it would allow students to see what makes an optimal cloud user as well as provider.

With the rise of big data processing the automated on-demand creation of a virtual Hadoop cluster within a private OpenStack cloud would also be an interesting project as the same processes and methodology could be applied to a public cloud.

VI. SUMMARY

This paper has presented our experiences integrating practical hands-on lab assignments with a traditional classroom setting. Cloud computing is a broad topic that is constantly evolving. To that end we feel this class does an excellent job introducing key cloud concepts such as VM configuration and maintenance while also exposing the students to real world cloud environments that they are most likely to be using in their careers after college. In addition, students are also involved with advanced research survey and projects. The results include refereed publications, advancement to master theses and advanced Ph. D. studies.

ACKNOWLEDGMENT

Special thanks to GoGrid for their generous gift of cloud computing resources in support of the course. The second author would also like to thank Dr. Melody Moh, Dr. Sami Khuri, Dr. Chris Pollett, and the San José State Department of Computer Science for their tireless commitment to making better engineers.

Abstract**—***Learning languages can be hard. As the yearly results of the course "Introduction to structured and object-based programming" at our university show, learning the first programming language might be even harder. Many students complain about the difficulty of the course and fail in the exam. With the desire to support the students and enhance the learning outcomes we initiated the project "Brain-based Programming". The basic question is: "How can learning to program be made easier?" The answer may come from the interdisciplinary field of neurodidactics that offers many general suggestions for improving teaching and designing teaching material. But concrete examples for computer science education are scarce, and empirical research is still missing. This was the impetus for the project "Brain-based Programming" that aims at (1) creating and evaluating a brain-based script for beginners in Java programming and at (2) implementing and evaluating brain-based teaching methods in the programming course. In the pilot phase we conducted a didactic experiment in one of seven parallel groups and combined brain-based teaching methods and exercises. The results demonstrate the success of the experiment and support the hypothesis that learning is more effective when it considers how the brain learns and follows neurodidactical principles.*

Keywords—brain-based learning; neurodidactics; cooperative learning; programming;

I. Introduction

Learning languages can be hard. As the yearly results at the University show, learning the first programming language might be even harder. Many students taking the course "Introduction to structured and object-based programming", shortly "ESOP", complain about the difficulty of the course. But more important and alarming, many students fail at completing the course. With the desire to support the students and enhance the learning outcomes of this course, the idea for the project "Brain-based Programming" was born.

The basic question is: "How can learning a programming language be made easier?" Answers may come from two directions: Firstly, in the literature about introductory programming learning different approaches can be found, e.g. the use of a three dimensional animation software [1] or interactive learning objects [2]. Furthermore, all attempts to increase motivation may be helpful as described e.g. in [3].

Other answers can be found in the field of neurodidactics and educational neuroscience that offers mainly general suggestions for improving teaching and designing teaching material by considering the functioning of the brain [4], [5]. But concrete examples for the field of computer science education are scarce [6], [7] and empirical research is still missing. This was the impetus for the project "Brain-based Programming" that wants to build a first bridge between theory and practice - between neurodidactical research and its application in computer science education.

The aims of the project are:

(1) Developing, testing and evaluating a "brain-based" self-learning script for beginners in Java programming and

(2) Implementing and evaluating brain-based teaching methods in an university course for beginners in Java programming.

This paper first describes the basis of the project "Brain-based Programming", the neurodidactical principles behind the concept, and reports on the pilot test: a didactic experiment in the programming course, its evaluation by the students and the learning results in comparison with the other parallel courses. These results demonstrate the success of the experiment and moreover the principles behind it. The paper will close with the discussion of the results and an outlook on future work in this field.

II. Neurodidactics – The Basis of Brain-based Programming

A. The Basis: Neurodidactics – A New Way for Teaching?

Neurodidactics is an interdisciplinary research field that combines findings of brain and memory research, psychology, pedagogy and didactics that shall help to improve teaching and learning. The term neurodidactics, a combination of neuroscience and didactics, was proposed by a German mathematician in order to emphasize the interdisciplinarity of the field. In the English-speaking world two other terms for similar research have become widespread: Educational Neuroscience and Brain-based Learning. All three have the same goal: the improvement of teaching and learning by considering how the brain works. The contributions come from three directions:

1. *Neuroscientists* inform about structure and functions of the brain that might be useful for teachers. They also give suggestions for the improvement of pedagogy and didactics, but sometimes without considering that the everyday life in schools and university courses often deviate from the experimental settings of their research. [8]

2. Contributions from authors of different disciplines (not neuroscience), criticize the current pedagogy and offer more or less useful guidebooks for brain-based learning. Unfortunately, in the booming business of brain-based learning some neuro-

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

myths like the left brain/right brain oversimplification or the use of only 10 % of our brains persist. [8], [9]

3. Educators and didactics experts who work out neuropedagogical or neurodidactical concepts based on brain and memory research offer the third approach. Their point of view can be important when they consider the real conditions in the classroom. But often the suggestions are too vague and general like "Learning should be fun". [8]

Neuroscience can do much for education but only when neuroscientists work together with didactic experts and teachers and when neurodidactical concepts are investigated empirically [8]. The project "Brain-based Programming" and the planned follow-up project "Teaching informatics with the brain in mind" shall be a step in this direction.

B. Neurodidactical Principles for Brain-based Programming

The most important principles that were considered in the project "Brain-based Programming" are the following:

1. Knowledge cannot be transferred. It has to be generated in each student's brain [10].

Learning contents can be provided to students in different ways; but storage in the long-term memory is only possible when the input is actively processed in the brain of each student. Students should be active instead of only listening to a lecture and they should be supported to discover structures and rules themselves. This works best in open lessons where they can follow their own learning rhythm. [11]

2. Learning through imitating

Mirror neurons enable us to understand, interpret and imitate observed actions and to predict their results. They are responsible for learning through mirroring respectively imitating [4]. Students need models that they can imitate (e.g. role models, step-by-step instructions, solution-based learning). This activates also the brain mechanism of pattern recognition.

3. The brain recognizes and produces patterns, categories and rules itself [12].

Pattern recognition or patterning is a basic function of the brain. It helps us to extract rules and structures from available examples. So students do not need declarations and rules, but good and meaningful examples (e.g. correct program code, role models, step-by-step instructions, etc.) to understand the structure and extract the essential rules [12]. Using the function of patterning e.g. in discovery learning leads to a more active and therefore deeper processing and retention of information whereas lecture usually results in the lowest degree of retention (see fig. 1). [4]

4. New content is always built on existing knowledge and learning occurs through associating.

In this context knowledge is not only subject-specific but means also experience as well as knowledge from all living areas and from the world of the students. The physiological basis for this principle is that learning occurs through creating new or strengthening existing synapses (connections between neurons). This previous knowledge is individually different, which means that students should have the possibility and time to ask their individual questions to the teacher and/or peers respectively peer-tutors. [4, 12]

5. Learning is more effective when it makes sense and has meaning [4].

This criterion should be considered where possible in the selection of topics, tasks and products to be developed by the learners. The students should have the possibility of choice between different competence-oriented exercises and different topics. This increases motivation and, hence, may increase the learning outcomes, too. [4]

6. The brain needs time for consolidation.

The brain needs time (short breaks) to consolidate new information. Only then it can be permanently stored in the long-term memory. This should be considered in the structure and organization of the lessons. If the brain does not get time for consolidation (e.g. in usual lectures of 90 minutes) new information can overlay earlier content and/or information heard before can inhibit the processing and memorizing of new input. [4, 11]

7. The instruction method has impact on the retention of new information [4].

Besides practice by doing cooperative learning settings like group discussion and peer tutoring (teaching others) seem to be the most effective methods concerning retention as shown in fig. 1.

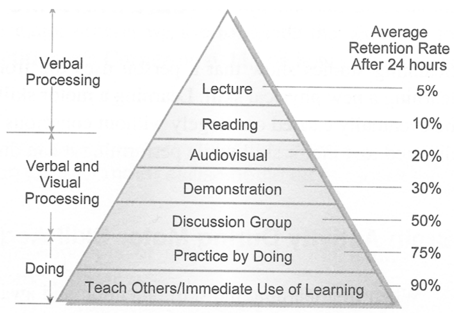

Fig. 1. Average percentage of retention of material after 24 hours [4]

An evaluation of more than 800 meta-analyses considering millions of students confirms the effectiveness of cooperative learning environment and shows an overall effect size of d= 0.41 [13]. The success of cooperative learning can be explained by the fact that it supports the memory process: cooperation and communication always require a recall from the memory and each recall or retrieval always causes a restart of the whole memory process. It leads to new processing, new storing and also new and stronger anchoring of the information in the long-term memory. Cooperative methods can therefore support the learning and memory process and are an essential part of the new brain-based programming concept. [4, 11]

III. The Project "Brain-based Programming"

A. About the Project

"Brain-based Programming" is the pilot project for a larger empirical study about "Teaching Informatics with the brain in mind". It is based on the hypothesis that teaching and learning can be more effective when neurodidactical principles are considered in the design of tasks and exercises as well as in the lesson structure and the teaching methods. The phases of the project are the following:

1. The development of tasks and worksheets under consideration of neurodidactical principles as well as their first evaluation in the university course "Introduction to structured and object-based programming" (2012).

2. A didactic experiment: Application and evaluation of "brain-based" teaching methods of the developed worksheets in one of seven parallel practical courses "Introduction to structured and object-based Programming" (winter term 2012/13).

3. Evaluation and adaptation of the worksheets, aiming to develop a self-learning script for beginners in Java programming based on neurodidactical principles (2013).

The project is currently in phase three, where the results of the brain-based course are taken into account and the student feedback is used to redesign the worksheets for the following self-learning script.

Before describing the didactical experiment the following section gives a detailed description of the developed worksheets and the different types of "brain-based" tasks, always referring to the related neurodidactical principles. After that we present the course organization in the experimental group, the applied teaching methods and the form of assessment.

B. Brain-based Tasks

Usually, all students of the parallel courses get the same worksheets. The experimental group got them, too, but only for voluntary work and in order to provide a broader variety of exercises. Additionally, they got the new "brain-based" worksheets because one reason for the difficulties in the course may lie in complex contents (e.g. mathematical problems) or too complicated instructions of the existing worksheets that are often incomprehensible for beginners.

Every worksheet is divided into three parts and contains the following types of exercises:

1. Reading exercises

The first part of the worksheet shall foster discovery learning and take advantage of the automatic brain function of patterning. It contains the following types of tasks:

- Reading corners with a simple and small, but complete piece of Java program code, which is accompanied by some questions that should lead the learners and help them to discover the structures and rules behind.
- Puzzles of jumbled program code or cloze-tests where small parts of the code are missing.
- Step-by-step instructions including also the whole sample solution, which help to comprehend and reproduce a task by taking one step after another.
- Mini exercises or short tasks including a sample solution that the students can use immediately in the sense of discovery learning or after having resolved the task for verifying their own solutions.

2. Competence-oriented tasks

This part provides short and rather easy competence-oriented tasks covering different contents and topics that may have sense and meaning for the students, e.g. programming a course schedule or a vocabulary trainer. Following the principle "practice makes perfect", the students get a big variety of tasks that they can choose according to their individual interests, competences and needs. This may increase motivation, occupy all students with useful tasks and may therefore support the memory process and enhance the learning outcomes, too.

3. Programming tasks

The last part of the worksheet provides different tasks for small, complete programs or some subprograms as parts of a complex semester topic that have to be assembled to complex Java project at the end of the course. This considers a neurodidactical principle already postulated by Aristotle "The whole is more than the sum of its parts" or, as defined in neurodidactical literature, "Learning is more effective when it considers the whole AND the details" [14]

C. Brain-based Lessons: A Didactic Experiment

Usually in the practical programming courses only two settings are used in turns – *laboratory* in one week, where the students had to do a part of the exercises that they continue at home, and *presentation* in the following week, where one student presents his/her solution and the others are passive. In the experimental group we tried to offer more possibilities and to keep all students active according to their individual capabilities. This satisfies the neurodidactical principle that learning has to be active.

In the very first lesson of the experimental group the students had to do a self-evaluation of their programming skills by means of a competence grid that should help them categorize their capabilities and competencies. Based on this self-evaluation, three groups were formed:

1. Professionals: students with solid knowledge about the topics in the course and the ability to help their colleagues as peer-tutors or peer-teachers.

2. Amateurs: students with some experience in programming, but who did not feel able to assist their colleagues.

3. Beginners: students without any programming experiences.

These groups were formed because we tried to take into account, as much as possible, the individual experiences, talents and needs of each student. The neurodidactical principles "New content is always built on previous knowledge" and "Learning is more effective when it makes sense and has meaning" were considered, as the students could choose between different types of tasks, topics and collaboration in the course. Whereas the advanced students solved more complex projects and/or acted as peer-tutors and peer-teachers the beginners got more short competence-oriented exercises and could benefit from the peer-tutors.

The weekly lessons of 90 minutes each were characterized by an open learning setting considering the individual learning rhythm that allowed time and room for individual interests and needs. In general the lessons were divided into the following three phases and, when required, supplemented by a short lecture of the teacher or a peer-teacher: Asking questions, discovering and laboratory with pair programming.

1. Asking Questions

In the first phase (ten to fifteen minutes) the students worked together in small groups with one peer-teacher or peer-tutor (one "professional" or "amateur" student). In this time, the students got the chance to ask any question they had in mind. The idea behind was to encourage them to ask also questions that they would have never asked in the whole group, perhaps because they considered them too trivial or too stupid. But sometimes these questions and certainly the corresponding answers can help to understand a concept because they build up on the previous knowledge of the students…

2. Discovering

In the second phase (ten to twenty minutes) the students worked in small groups, too, each of them guided by a peer-tutor. On the base of the different reading exercises, already described in section A *Worksheets and Tasks*, as well as short video clips they tried to discover new topics or re-discover topics they had already learned before. This active way of processing input takes advantage of the brain's automatic pattern recognition and rule extraction, which may lead to a better and stronger storage in the long-term memory [12]. The video clips of some minutes offer a further advantage: the multimedia or modality effect, investigated by [15]. When information is double coded, e.g. text combined with corresponding pictures or animations, it can be remembered better.

3. Laboratory: Pair Programming

The third and last phase in the course was the laboratory. The students were ought to solve the tasks of the given worksheets by collaborating in pairs according to a well known and effective software engineering method: pair programming. This setting allows cooperation and communication, which may enhance learning because, as mentioned above, each recall from the memory (which is necessary when discussing the problem of the task and the way to solve it) restarts the whole memory process.

Depending on the topic and the needs of the students, these three phases could differ from time to time. Worth to mention is that all students were active in all phases. Due to the open learning setting the lecturer had enough time to visit the small groups, one after another, to ask questions for checking participation and comprehension as well as to help them with upcoming difficulties. At the second half of the lesson, a student tutor of a master course assisted the teacher in answering questions and helping the students solving the exercises.

The open learning setting allowed the students to follow their own learning rhythm, and hence consider the individual consolidation phase of the brain. Sometimes a supplementary phase of lecture was necessary where the lecturer or a peer-teacher explained a topic or concept for all students in a maximum of twenty minutes. More is not useful because we know from neurodidactics that the attention decreases approximately after this period. The following "down-time" with a low attention level shall be used for consolidation and revision. Fig. 2 visualizes a possible segmentation of a learning episode. After presenting new information in the first prime-time and some practice in the following down-time a phase of closure or summary of the new information is offered.

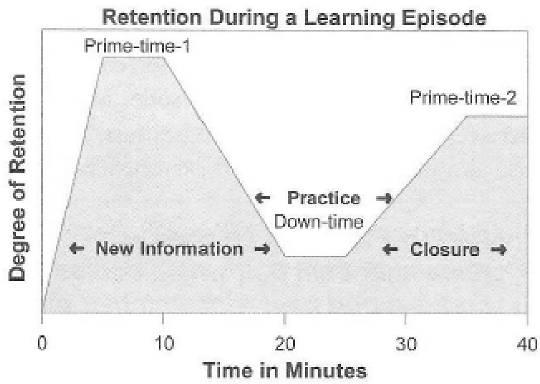

Fig. 2. Retention during a learning episode [4]

D. *The assessment*

The standard assessment criteria of all parallel courses of the "Introduction to structured and object-based programming" were valid for the experimental group, too, but were slightly adapted as follows:

- The course grade consists of 50% written exams a mid term and a final exam, each graded with max. 25 points and 50% participation in the course (number of correctly solved exercises, presentations, active participation in the lessons).

To get a positive grade, the students had to fulfill the following requirements:

- Compulsory attendance is required in at least 85% of the lessons.
- At least 50% of the tasks of each worksheet must be completed and the program code must be executable. As the students in the experimental group got the double number of worksheets and tasks, they had more choice. To offer a fair grading method, each task of the worksheets (the regular ones for all students as well as the "brain-based" tasks for the experimental group) was evaluated with points. Whereas usually only completely executable solutions are counted, the experimental group had a graduated assessment. The number of points depended on the percentage of the available correct program code. To give fair points, four categories were introduced: (1) complete and executable, (2) complete, but not executable (with slight errors), (3) program code mostly complete and (4) less than 50%. This concept of evaluation was introduced to motivate the students to do their own work, to avoid copying and to value mistakes, as we learn from them.
- A minimum of 50% of the written exams the same for all parallel groups must be achieved, that means 12.5 points for each, in total at least 25 points. Students who

don´ t reach half of the points in the mid term exam usually have to terminate the course. This was slightly adapted in the experimental group. The students had to achieve the total minimum of 25 points, too. But if one reached less than 12.5 points in the mid term exam s/he could compensate that in the final exam. This opportunity should motivate the students to remain in the course, to work more and to catch up on the missed topics. Whereas many students of the parallel courses had to terminate after their negative mid term exam two of three students in the experimental group actually could benefit from this criterion and terminate the course with a positive grade.

IV. Evaluation and Results

Brain-based programming was implemented as a didactical experiment in one of seven parallel groups with 21 of 126 students. Due to this small group and a certain teacher bias the positive results of this pilot project are not statistically relevant, but seem to support the hypothesis that learning can be more effective when brain and memory functions are considered in lesson and task design. This will be verified in a larger follow-up study at university and secondary school level.

To measure the acceptance and benefit of the brain-based methods and tasks, the students of the experimental group were given surveys at the beginning, the middle and the end of the semester. Furthermore, the university's official student feedback, completed by 15 of 21 students, has been considered.

Taking a closer look at this official feedback with grades from on a scale from 1 (best) to 5 (worst), it can be said that the experiment was successful. The "brain-based" course was graded with 1.1, whereas the average grading of all equivalent courses in the last three years lies at 2.1. Moreover, the students were very satisfied with the concepts used in this course. According to the students' verbal feedback, most notably and helpful are the concepts of peer-tutoring and peer-teaching, reading exercises discovery learning, mini exercises including solutions, step-by-step instructions, and the revision worksheet at the end of the course.

This confirmed the mid term feedback where 19 of 21 students graded the methods and tasks from 1 = very useful to 4 = not so useful (fig. 3).

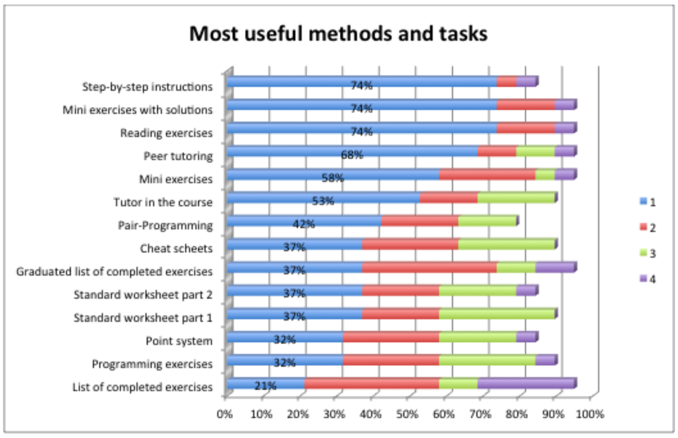

Fig. 3 Mid term evaluation of methods and tasks

Step-by-step instructions, mini exercises with solutions and reading exercises were considered as most useful tasks by 74% of the students. Concerning the teaching methods mainly peer tutoring (68%), the tutor from a master course (53%) and pair programming (42%) were considered very useful. Compared to the standard worksheets part 1 and 2 distributed in all parallel courses all new "brain-based" tasks (except programming exercises) and methods scored better.

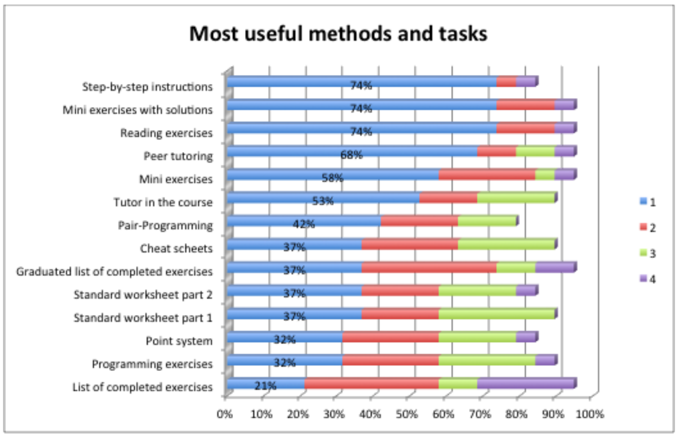

Fig. 4 Mid term evaluation of methods and tasks

The evaluation of the last survey (fig. 4), completed after the course only by 11 of 21 students, shows similar results.

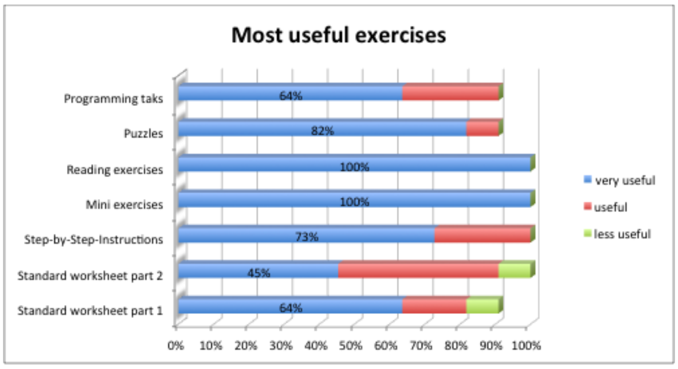

Fig. 5: Evaluation of the different exercise types

The students appreciated all forms of material for discovery learning, mainly the mini exercises including solutions and reading exercises (100% considered them very useful). They are followed by puzzles (82%) and step-by-step instructions (73%), which are other types of reading exercises. This shows that learning from worked-out examples, and benefiting from the automatic brain function of pattern recognition can be very useful.

The final evaluation of the methods shows the following results: All students found that the sample exams offered in the unit before the mid term and the final exam were very useful. Peer tutoring and pair programming where the most helpful methods (both indicated by 91% of the students) followed by the tutor (82%), discovery learning (73%) and asking questions (64%). the methods used in the parallel courses – laboratory programming and presentation of one student's solution – were considered very useful only by 45% of the students.

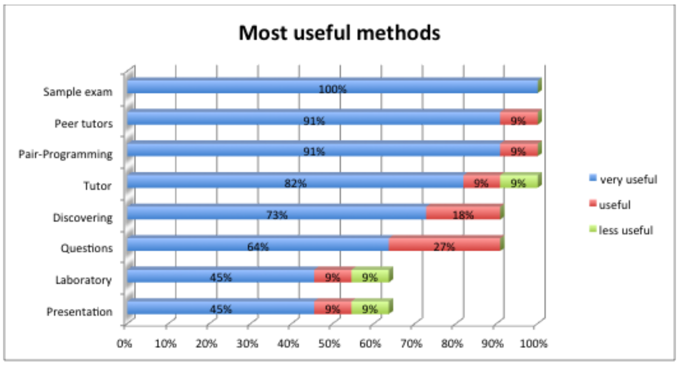

Fig. 6 Most useful methods, results of the final survey

In order to verify if brain-based methods and tasks can enhance the learning outcomes the results of two courses shall be compared: the practical courses as well as the corresponding lecture on “Introduction to structured and object-oriented programming”. Unfortunately, the results of the lecture exams are still not available, hence we can only describe the outcomes of the practical courses.

As all students of the parallel practical courses got the same exams, a mid term and a final exam, that are evaluated using the Austrian grading system from 1 = excellent to 5 = failed. It has to be mentioned that there is still a teacher bias in this evaluation although all lecturers tried to assess the exams in the same way. The results of the lecture will be more relevant. The average of the grades in the experimental group was 2.19 whereas the average of the seven parallel courses was 2.94. Fig. 5 shows the average grades for all groups. The numbers in brackets indicate the final number of students in the respective courses.

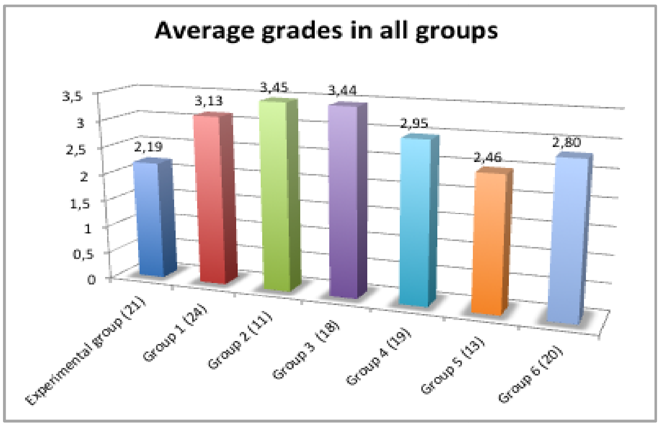

Fig. 7 Average grades in all parallel courses

This clearly shows a tendency of enhancement, although comparing the grading is, of course, only a week indicator. There are many factors involved in learning that can influence the outcomes. So the better score of the students in the experimental group could have different reasons; perhaps it is due to single methods, but the combination of different methods and exercise types. Maybe it is simply a consequence of higher motivation and more practice. This is to be verified in the larger follow-up study next year that will focus on the effects of cooperative learning (peer tutoring and pair programming) as well as on discovery learning (reading exercises and step-by-step instructions), which benefits from the functions of pattern recognition and rule extraction.

V. CONCLUSION AND OUTLOOK

The evaluation of the didactical experiment shows, that tasks and concepts based on neurodidactical principles are positively mentioned and preferred by the students. All in all the results of the pilot test "Brain-based Programming" are satisfying and show an overall improvement for the students as well as an above-average evaluation of the course. This supports the hypothesis that learning is more effective when the functioning of brain and memory is considered. As learning is a very complex process it cannot be said that the success of the pilot project is due to certain methods or the appropriate material. We suppose that the combination of both “brain-based” teaching material and “brain-based” methods, above all cooperative and discovery learning was the key to success. Should there really be single neurodidactical factors that lead to better learning, this has to be verified in further studies.

Therefore the concept of “Brain-based Programming” will be continued in a larger follow-up project “Teaching Informatics with the brain in mind”. It is now extended to other courses of our department (Introduction to Computer Science and Software Engineering) and will be then adapted for testing and evaluation at schools, too.

***Abstract*— In order to contribute to the improvement of Computer Science 1 (CS1) course's results we designed a set of activities based on competencies and multiple intelligence approach. Hypothetically, we propose that including this kind of activities helps to obtain better results in the course. A preliminary experimentation was done in 2012. This year, the course included a low number of freshmen students. The initial results show a positive difference in student's results, particularly in freshmen students and no differences in students who are taking the course for the second or third time.**

Keywords— competencies; computer science 1; multiple intelligences.

I. Introduction

Introductory programming courses usually have high drop out rates and failure [1,2,3,4]. Our goal is to contribute to the improvement of Computer Science 1 (CS1) course's results by the incorporation of activities based on multiple intelligences and generic competencies. In this paper we include definitions of "competence" and possible classifications. We include also concepts related to multiple intelligences. After that, we detail our CS1 course, the activities proposed; the experimentation, results, conclusions and future work.

II. Competencies

Competencies represent a dynamic combination of knowledge, understanding, skills and abilities [5]. A competence is defined as the capacity of a person to use knowledge and skills in different situations either personal or professional [6]. Tovar [7] defines competence as the ability shown by the use of knowledge, technical, personal, social and methodological skills that can lead to success in professional and academic environments.

Competencies are distinguished in subject specific and generic ones. The generic competencies are also distinguished in three types: instrumental, interpersonal and systemic [5]. Transversal or generic competencies have acquired a special relevance in last years [7]. Generic competencies play a key role in the teaching and learning process [8]. Higher education must provide advance knowledge, skills and competencies that students need for their professional life [9]. The development of competencies in educational programs can significantly contribute to join reflection and work at university level [5].

Tovar and Soto found that reading, analytical comprehension and mathematical skills are part of the core competencies required to succeed in computer engineering studies, also suggests that universities must decide whether to take a comprehensive set of skills (such as the Tuning or extended version of it) [7,10].

Tuning Latin America Project [11] refers to 27 generic competencies. From this list, we select those that apply in the context of our CS1 course: capacity for abstraction, analysis, and synthesis (C1), ability to apply knowledge in practice (C2), ability to organize and plan time (C3), capacity for oral and written communication (C4), ability to use information and communication technology (C5), ability to learn and update learning (C6), ability to identify, pose, and solve problems (C7), ability to work as part of a team (C8), interpersonal skills (C9) and ethical commitment (C10). Most of these competencies are skills that software engineering graduates must possess [9].

III. Multiple intelligences

The theory of multiple intelligences (MI) was proposed by Gardner [12,13,14,15]. Gardner [16] argues that traditional ideas about intelligence must be reformed, so he proposes a new approach. Gardner defined intelligence as: "the ability to solve problems or to create products that are valued within one or more cultural settings". In this context, enumerates the intelligences: linguistic (MI1), logical mathematical (MI2), spatial (MI3), bodily-kinesthetic (MI4), musical (MI5), interpersonal (MI6), intrapersonal (MI7) and naturalist (MI8). Armstrong [17] refers two key points of MI: each person possesses all eight intelligences and most people can develop each intelligence to an adequate level of competency.

According to Gardner [16], the purpose of education should be to develop intelligence and to help people reach vocational and avocational goals that are appropriate to their particular spectrum of intelligence. In this context, Gardner [15] argues that MI theory is certainly relevant, to education, but not in itself an educational rationale or goal. Gardner 's notion of multiple intelligences shows that competencies are neither innate nor predetermined. People, with their intelligence are capable of preparing constructions based on the demands from their surroundings and they can develop specific capacities [18]. Research studies related to multiple intelligences in engineering education [19,20] suggest that students benefit from learning materials adapted to suit their intelligences.

IV. CS1 COURSE

Introductory programming courses have generally high failure and high drop out rates [1,2,3,4]. Research studies have been proposed to face the problem with different approaches: for example: games [21,22], robots [23], pair programming [24].

The course of CS1 at Universidad ORT Uruguay makes emphasis on teaching using problem-solving methodology and enables the student to analyze, design and implement simple object oriented language applications. It involves programming assignments, problem sets and a project. The duration is 15 weeks, 4 hours of lectures and 2 hours for lab session per week. The programming language used is Java for all this assignments. The main topics are: pseudo code, variables and control structures (weeks 1-3), objects and classes (week 4), association (weeks 5-7), inheritance (week 8), aggregation and collections (weeks 9-10), enumeration (week 11), sorting and searching (week 12) and advanced use of collections (weeks 13-15). Our teaching strategy is based on design activities that motivate and engage students in order to achieve lower dropout rates.

V. ACTIVITIES PROPOSED

In order to improve the results of the course, we present a set of activities designed using MI1-MI7 and C1-C10 approach:

1) Scratch (week 1): The use of Scratch in CS1 course promoted a high level of motivation, thus a positive perception of learning programming [25]. Students solve practical programming games that include sound and images.

2) Infographics (week 4): This is a graphic visual representation of information combined with words to help students explore and conceptualize Java. In this activity each student creates an infographic of Java technology (i.e. What is Java? , Who developed it?).

3) Kinesthetic (week 4): To become familiar with the concept of identifying objects, aliasing and message passing we propose a kinesthetic learning activity modeling clay [26] promoting comprehension of object oriented concepts.

4) Minute Test (week 4): Student reflects on what the main concepts of objects shown in the lecture are, answering in one minute several questions: for instance: "What do you want to find out about the theme?", "Which concepts are important?".

5) Wordle (week 5): Wordle [27] generates "word clouds" from a provided Java source. Students generate a cloud of words and analyze the most frequent reserved words of the language (public, private, int, …).

6) UML Modeling Game (week 6): We bring to class some child games. This activity aims to develop a simple design model of those games. Students use top down criteria identifying attributes and represent the model in UML.

7) Rubric (week 7): To improve students own learning and communication expectations, we propose and discuss a rubric and students must evaluate sample works using it.

8) Pair Programming videos (week 8): The activity is oriented to discuss the benefits of using pair programming methods analyzing some related videos.

9) Inheritance (week 8): Group of students read in class material related to a new topic (inheritance). They read chapters of several books of the course and complete a questionnaire.

10) Concept Test (week 10): Peer Instruction (PI) [28] engages students during class through activities that require each student to apply the core concepts being presented, and then to explain those concepts to their fellow students. A class taught with PI is divided into a series of short presentations, each focused on a central point and followed by a related conceptual question. We apply this activity to introduce foundational topics of arrays.

Each activity refers to some competences and intelligences (Table I and Table II).

TABLE I
ACTIVITIES - COMPETENCIES

C1	C2	C3	C4	C5	C6	C7	C8	C9	C10
1,2,3 4,5,6 7,8,9 10	2,5,6 7,8 10	2,5	2,4,5 7,10	2,9,5	4,9 10	1,4	6,8,7 10	5,6,7 8,9	7,8

TABLE II
ACTIVITIES – MULTIPLE INTELLIGENCE APPROACH

MI1	MI2	MI3	MI4	MI5	MI6	MI7
2,5,9	1,10	1,2,5,8	3,6,8,9 10	1	1,5,6,7,8,9 10	1,2,3,4,5 10

VI. EXPERIMENTATION

One random group of 20 students was selected to participate in the activities and 16 were in the control group. None of the students had already been exposed to MI techniques nor the activities proposed. Both groups included a high number of students who are not really "freshmen": they were taking the course for the second or third time. The repeat students had the same course contents in their previous attempts. Hypothetically, we propose that including this kind of activities helps to obtain better results in the course. An initial experimentation was done in 2012. Considering only the students who take the course for first time, in the selected group, 44% (4/9) of them had successful results and in the control group, 22% (2/9) gained the course. For students who took the course a second or third time, there were no significant differences in the results.

VII. CONCLUSION AND FUTURE WORK

The inclusion of activities to promote skills and multiple intelligences seem to provide better results in the case of students taking the course for the first time. The use of these activities in the case of students who were enrolled and did not pass the course previously showed no significant difference in the results. These differences appear in the case of new students. In 2013 we will replicate the experience, with some improvements, in order to validate or not the results.

Integrating highly-capable corobots into a computing curriculum

Zack Butler, Rajendra K. Raj and Minseok Kwon
Department of Computer Science
Rochester Institute of Technology
Rochester, New York 14623, USA
Email: {zjb, rkr, jmk}@cs.rit.edu

***Abstract*—Robots are typically used at the college level either as a pedagogic platform for introductory programming or for more advanced courses in robotics. With robots becoming cheaper and more plentiful, personal interactions with them will become more commonplace. This project therefore takes the position that undergraduate computing students need the opportunity to explore core computing concepts in a robotics context. Specifically, we will give students the ability to work alongside teams of highly capable and easily programmable corobots, a term used to identify robots that work side by side with humans, rather than being completely autonomous and isolated. A modular approach is used to incorporate corobotics into various computer science (CS) courses such as first-year computing, networking, and data management, thus permitting the students to see these corobots in multiple contexts. This work-in-progress paper describes the corobotics infrastructure that has been developed, and outlines how this infrastructure can be used to support diverse courses in the CS curriculum.**

Keywords—robotics, corobotics, computer science coursework.

I. Introduction

Robots have been used in many universities as a teaching platform, primarily for introductory programming and robotics courses. Student motivation and real-world applicability are continued concerns within CS education [1], and robotics has promise to deliver on both counts. Pedagogic robots however tend to be either simple and inexpensive (for novice programming support and affordability, e.g. [2]) or complex and expensive (supporting more interesting algorithms, but requiring much more background knowledge). In our project, we are taking a different approach and are developing a team of highly capable but easily programmable corobots. The term “corobots” is used to identify systems that work side by side with humans, rather than being completely autonomous and isolated. These corobots will “live” in our department, roaming the (large) floor of our building that houses the Computer Science labs, classrooms and faculty offices, exposing all students to a functional robot system. With the corobots in place and available for coursework, computing or engineering students without robotics expertise will be able to write high-level programs that direct the robot to different locations, take pictures, interact with people in their vicinity, and report back in real time via a web interface.

We are developing the underlying infrastructure to allow our corobots to navigate our building and interact nearly autonomously. Students will make use of a simple API, currently in development in Python and in Java, to direct the corobots. Our past experience has shown us that students are intrigued by using robots to develop course and term projects, but learning and dealing with all of the needed robotics knowledge and/or maintaining the robotics hardware is overly burdensome [3]. The corobotics infrastructure will enable students to ignore details of robot navigation and the like, allowing them to develop meaningful software for many different types of tasks that also has a physical presence in their environment.

With this corobotics infrastructure in advanced development, we are creating course modules for a variety of computer science courses. For example, a course module in a networking course would have students use the infrastructure to develop and use ad-hoc networking protocols, thus ensuring corobots and humans can share information on an as-needed basis. A module in a data management course would have students use the infrastructure to develop a database application that will allow both corobots and humans can contribute to, query from, and analyze a shared database of information (e.g., photos of the building). In the long run, our goal is that the presence of this team of corobots will inspire students to develop novel applications to help drive the progress of the field as robotics becomes even more prevalent in everyday life.

In this WIP paper, we describe our corobotics infrastructure and discuss how it can be leveraged in diverse computer science courses such as first-year computing, networking, and data management.

II. The Corobotics Infrastructure

The corobotics infrastructure consists of two main components: the robots themselves (both the hardware and software), and the server and API as seen by the students. The robots are based on the iRobot Create platform, augmented with a Microsoft Kinect, two cameras, and a Linux-based laptop that runs the navigation and control code. This hardware is similar to the popular Turtlebot developed by Willow Garage [4], but with two important differences: first, the presence of the extra cameras allows the robots to detect QR codes to aid in localization; and second, the laptop is mounted in such a way that it is visible to and usable by humans in the vicinity. In this way, the robots become part of the community of the department, as they can more effectively interact with passers-by, such as to offer tours or request assistance. This type of system is also similar in spirit to the Cobot system developed

```
# Take control of a robot
robot = corobot.acquire_robot()
# Store the current pose for later
pose = robot.get_pose()
# Go to the break room, program pauses here
robot.navigate_to("BreakRoom1",wait=True)
# Ask for coffee
robot.display_message("Please make some coffee!")
# Wait for someone to make the coffee (5 mins)
robot.wait_for_confirm(300)
# Return to the original location
robot.nav_xy(pose.x, pose.y, wait=False)
```

Fig. 1. Sample code to control a corobot

at CMU [5], but our focus is on integrating the corobots with an API that allows students to program them as part of general coursework.

The most critical piece of the system, however, is our development of fully-functional robot control along with a closed API. The goal of the control and the API is to free the programmer from any direct involvement with the robotics (obstacle avoidance, navigation, etc.) unless they specifically desire it, while still allowing the programmer to integrate robot commands with any other code they desire. In addition, a small API allows us to more easily predict and control the performance of the robots when directed by those who are not robotics experts.

On the control side, the robots use standard techniques to perform localization and navigation, aided by the fact that they will work only in our building. Local navigation is simply standard obstacle avoidance, using the 3D Kinect data to avoid any objects in the robot's intended path. The localization uses an Extended Kalman Filter (EKF) approach to incorporate Kinect data, wheel odometry, and QR detection to determine the robot's position. The QR detection, based on the ZBar barcode detection library [6], not only uses the identity of the barcode, but also its location within the image, and as such is currently able to determine an absolute robot position within the building with 2-10 cm error when one code is visible. The other sensors are then used by the EKF to maintain position understanding during travel. We have put bar codes beside each office and classroom door, and we have chosen to use QR codes so that they will not only be useful for robot navigation, but also link to appropriate web pages for people using smartphones with barcode-reading apps. For long-distance path planning and navigation, we have hard-coded a high-level roadmap within the building so that the robots can easily search for paths to a specified location, and so that points can be named in a student program (such as `"GraphicsLab"` or `"Office3451"` rather than an X, Y location in some arbitrary coordinate system). The control code then uses a standard A* search over this roadmap, and the map is created such that at least one waypoint is visible from anywhere that the robot is intended to travel.

With the navigation capability built into our corobots, our API can then enable students to write simple code such as shown in Fig. 1. This small example just shows a sequence of a few robot commands, written in Python, but would invoke a non-trivial amount of planning, motion and obstacle avoidance. Additionally, it can be seen how such code could easily be interleaved with any other Python code as demanded by the

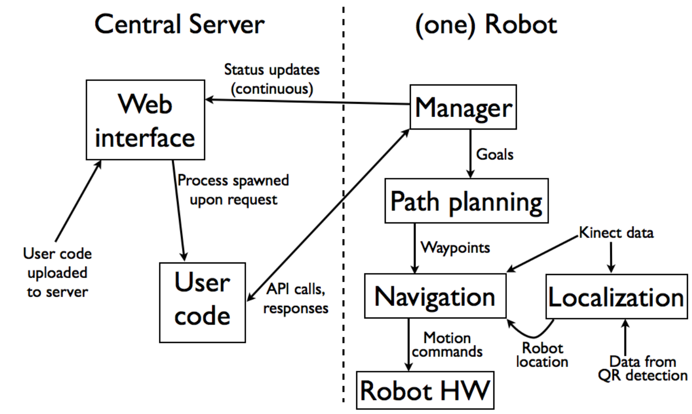

Fig. 2. Schematic of corobot software/hardware architecture, showing processes running on the server and one of (potentially) many robots.

student's task. We have also written a simple simulator that implements the API in a primitive way to serve as a simple verification process before submitting code to the physical robots. Students are able to log in using a web interface to submit code to the corobot and monitor its progress. Our current infrastructure does not as yet provide full authentication, but this will be incorporated shortly. The web interface also presents the current status of all robots, visible to anyone. Once logged in, a student can upload code, review previously uploaded code, and request code deployment either on a specific robot or on the first robot available. Student code is then run in a sandboxed process that communicate with the corobot over WiFi. In addition to real-time feedback, a log is also created and returned to the student. Figure 2 gives an overview of how the server and robot components work together.

III. Corobotics in the CS Curriculum

Once the infrastructure is ready and the team of corobots operational, we plan to develop and deliver course modules at least three different courses, as detailed below. Each target course covers standard topics in the CS curriculum, i.e., these modules may be adoptable at other colleges and universities.

A. *First-year Computing*

The first year of computing usually consists of an introductory course in computer science (often called CS1) that introduces students to the basic concepts of compuer science using a problem-centered approach. Specific topics covered include the expression of algorithms in pseudo code and a programming language; problem solving; basic searching and sorting; and elementary data structures such as lists, trees, and graphs. The second course (CS2) delves further into problem solving by expanding the coverage of data structures including tree and graph structures and nested data structures.

The first course module focuses on making graphs and simple graph traversals in CS2 more relevant to first year students. Our corobot system is equipped with a roadmap with named locations, and these locations include neighbor relationships, forming a graph. This provides a natural basis for a breadth-first search. The sample course module being developed is centered around a problem where a corobot is summoned to a particular location on the floor to then interactively lead a human to a desired destination. The student's program is provided with the locations and neighbors of the named waypoints in the roadmap as input data, along with a particular start and goal point. The student code then generates the shortest path connecting several waypoints. For slightly more advanced students, the actual physical locations of the waypoints can be used to create weighted edges (where the weight is equal to the actual distance) and Dijkstra's algorithm used over this weighted graph to determine the fastest route between the given locations. In either case, this programming assignment can be set up like any other CS2 assignment, as the robotics aspect will be a small amount of additional coding relative to a fairly traditional graph algorithm implementation.

B. Networking

A typical introductory computer computer science course in Computer Networking covers concepts and principles of computer networks. Standard topics include transport, network, and data link protocols and algorithms. The course may also include an introduction to local area networks, data transmission fundamentals, and network security. Students typically design and implement projects using application protocols, but the relevance of networking in the modern interconnected world of computing is often not brought into the course.

For such a course, we plan to develop a course module that covers an *ad-hoc routing protocol* using the corobots. As the robots move around the building, they may join or leave the network. The module will allow students to build a scalable, efficient, self-organizing, and fault-tolerant routing protocol, thus addressing two main challenges in networking: (a) lack of a fixed infrastructure for routing and (b) appropriate handling of mobility. Given these challenges, it is a meaningful task to build a scalable, efficient, self-organizing, and fault-tolerant routing protocol that runs among mobile entities.

C. Data Management

A traditional introductory Data Management course in computer science typically provides a broad introduction to the principles and practice of modern data management, with an emphasis on the relational database model. Topics include data modeling and the relational model; relational algebra; Structured Query Language (SQL); and data quality, transactions, integrity and security. Students also learn how to build database application programs.

Such a course lends itself well to the world of corobots where humans and robots will need to share data consistently and reliably to achieve a common goal. To support this course, our infrastructure will provide suitable APIs between the corobots, and their local and remote databases. Our planned corobotics module for this course covers the management of data consistency when data is partitioned across multiple databases. The course module will permit students to examine issues underlying consistent data sharing when parts of the data are stored within the robots and in remote databases, with both corobots and humans dynamically accessing and changing this data. The challenge is that the data might become stale and inconsistent, and students need to learn techniques to prevent or minimize such data inconsistencies. The use of corobots thus immediately brings a real-world focus to these issues of data quality, integrity and security, and the need for transactions, which is often lacking in a tradtional client-server database setting.

IV. Current Status and Ongoing Work

At present, we have implemented the core robot functionality and are in the testing phase for the hardware. The server is essentially functional and we are working on its usability and visual appeal for the general student population. We are starting to develop sample applications as mentioned, expanding the student API as the planned course modules require. The current plan is to produce a full team of corobots during summer 2013. Throughout the course of the project, our software infrastructure and design documents will continue to be open source and publicly available through GitHub so that once mature it can be adopted by other schools.

The course modules mentioned in this paper will be developed over the course of the summer of 2013, and the course modules will be offered as part of a trial section of each of the three courses over the next academic year. As each course is required in our curriculum, and thus typically offered in multiple sections per term, we plan to use these parallel offerings to assess whether the use of the corobots results in improved student learning as compared with existing versions of these courses. As the project continues, we plan to investigate the use of corobots in other courses, as well as a project platform for independent studies and MS capstone projects, so that students can have multiple different interactions with the corobots in different guises. Our hope is that this will lead students to investigate the possibilities that such a system provides and drive further development of the robots, the API, and the possible applications of such systems.

Acknowledgments
